

Blackout: What Really Happened

Jamie Butler and Kris Kendall

Outline

- Code Injection Basics
- User Mode Injection Techniques
- Example Malware Implementations
- Kernel Mode Injection Techniques
- Advanced Code Injection Detection via Raw Memory Analysis

Code Injection Basics

- “Code Injection” refers to techniques used to run code in the context of an existing process
- Motivation:
 - Evasion: Hiding from automated or human detection of malicious code
 - IR personnel hunt for malicious processes
 - Impersonation: Bypassing restrictions enforced on a process level
 - Windows Firewall, etc
 - Pwdump, Sam Juicer

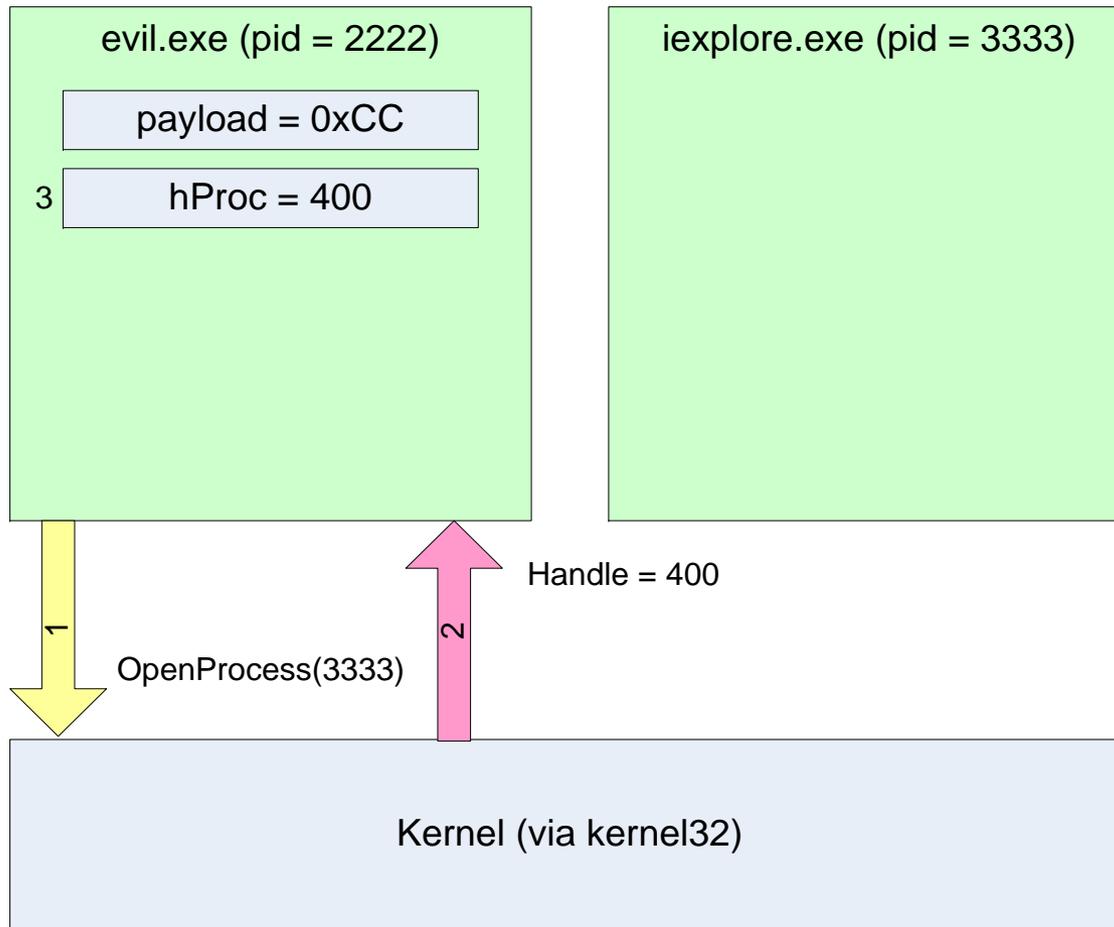

User Mode Injection Techniques

- Techniques
 - Windows API
 - AppInit_Dll
 - Detours

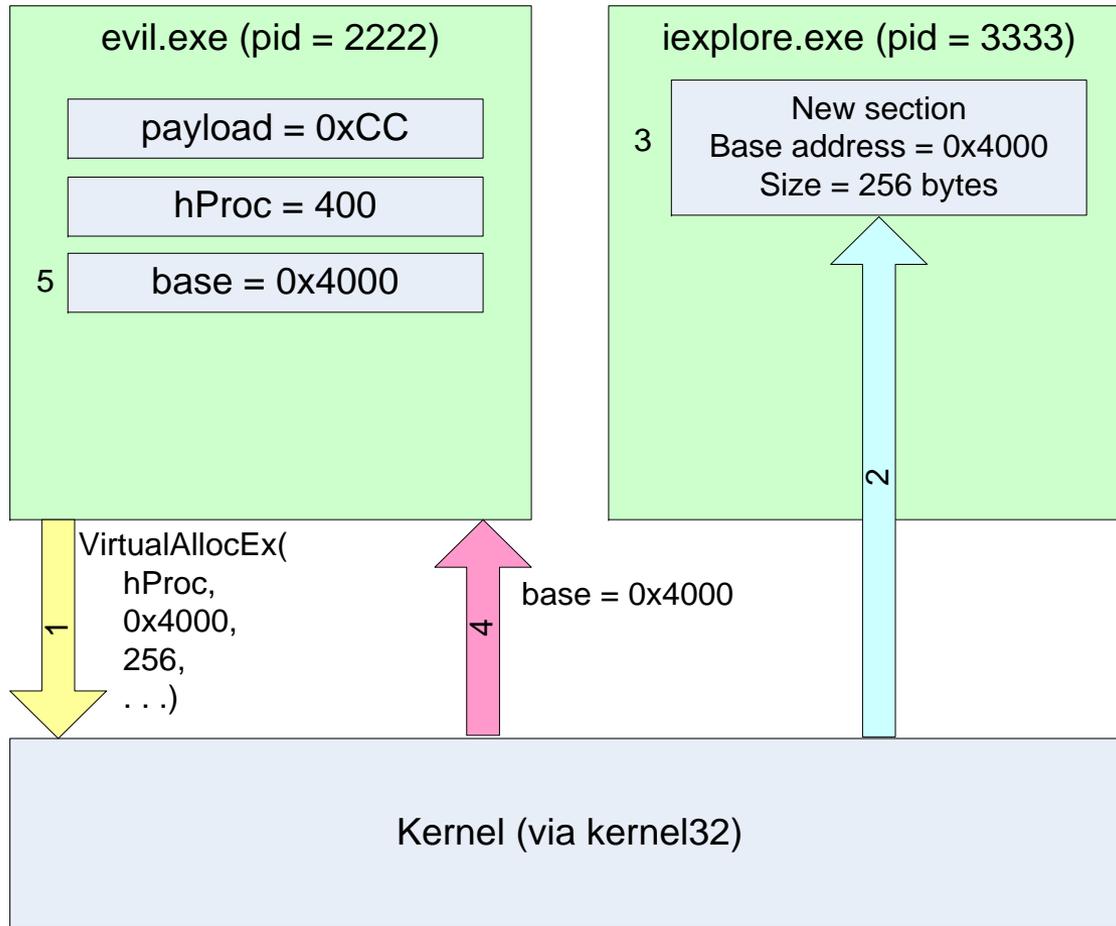

Injecting code via the Windows API

- Somewhat surprisingly, the Windows API provides everything you need for process injection
- Functions:
 - `VirtualAllocEx()`
 - `WriteProcessMemory()`
 - `CreateRemoteThread()`
 - `GetThreadContext()` / `SetThreadContext()`
 - `SetWindowsHookEx()`

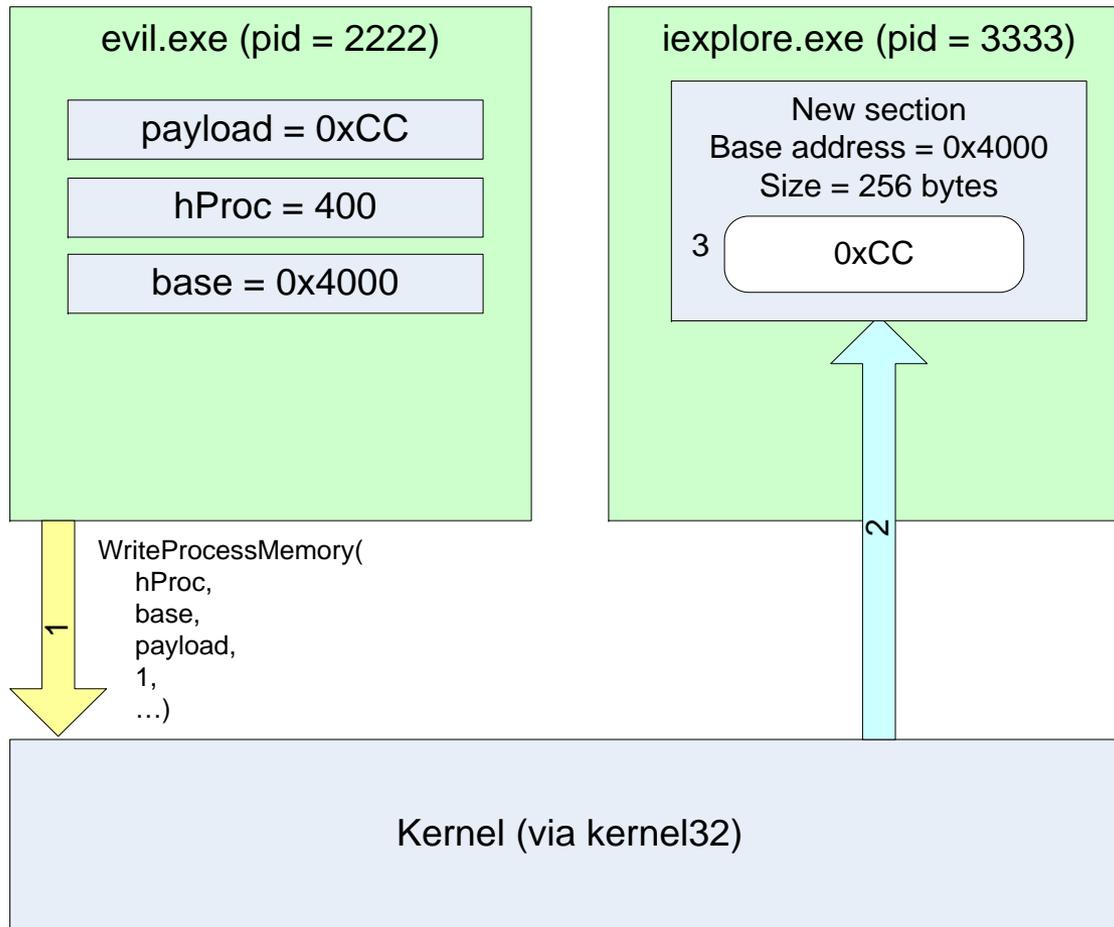

1. OpenProcess

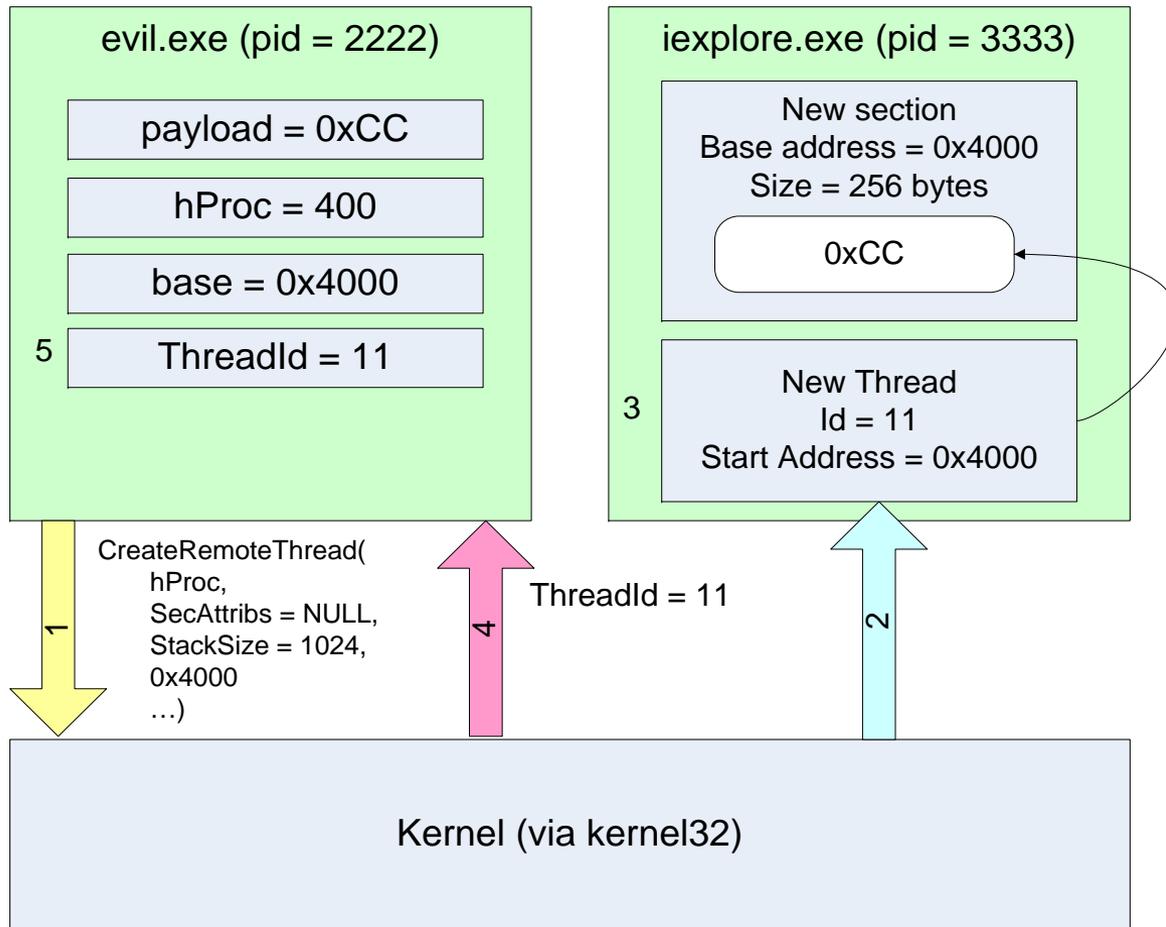

2. VirtualAllocEx

3. WriteProcessMemory

4. CreateRemoteThread

#Inject an infinite loop into a running process

```
import pydbg
```

```
k32 = pydbg.kernel32
```

```
payload = '\xEB\xFE'
```

```
pid = int(args[0])
```

```
...
```

```
h = k32.OpenProcess(PROCESS_ALL_ACCESS, \
                    False, pid)
```

```
m = k32.VirtualAllocEx(h, None, 1024, \
                        MEM_COMMIT, \
                        PAGE_EXECUTE_READWRITE)
```

```
k32.WriteProcessMemory(h, m, payload, \
                        len(payload), None)
```

```
k32.CreateRemoteThread(h, None, 1024000, \
                        m, None, 0, None)
```

Better Payloads

- Breakpoints and Loops are fun, but what about real payloads?
- If we directly inject code it must be “position independent”
- Any addresses that were pre-calculated at compile time would be wrong in the context of a new process

Better Payloads

- Building large position independent payloads is possible, but not trivial
- However, DLL injection is much simpler
- DLLs are designed to be loaded in a variety of processes, addresses are automatically fixed up when the DLL is loaded

DLL Injection

- Use the basic process we just described
- DLLs are loaded using `kernel32!LoadLibrary`
- `kernel32` is at the same address in every process → we know its address in the remote process (ignoring ASLR)
- Allocate space for the name of the DLL to be loaded, then create a thread with a start address that points to `LoadLibrary`

#DLL Injection Excerpt

```
import pydbg
k32 = pydbg.kernel32
pid = int(args[0])
dllname = args[1]
...
h = k32.OpenProcess(PROCESS_ALL_ACCESS, \
                    False, pid)
m = k32.VirtualAllocEx(h, None, 1024, \
                       MEM_COMMIT, \
                       PAGE_EXECUTE_READWRITE)
k32.WriteProcessMemory(h, m, dllname, \
                       len(dllname), None)
k32.CreateRemoteThread(h, None, 1024,
                       k32.LoadLibrary, m, 0,
                       None)
```

User Mode API Variants

- Rather than create a new remote thread, we can hijack an existing thread using `GetThreadContext`, `SetThreadContext`
- `SetWindowsHookEx` can also be used to inject a DLL into a single remote process, or every process running on the current Desktop

SetWindowsHookEx

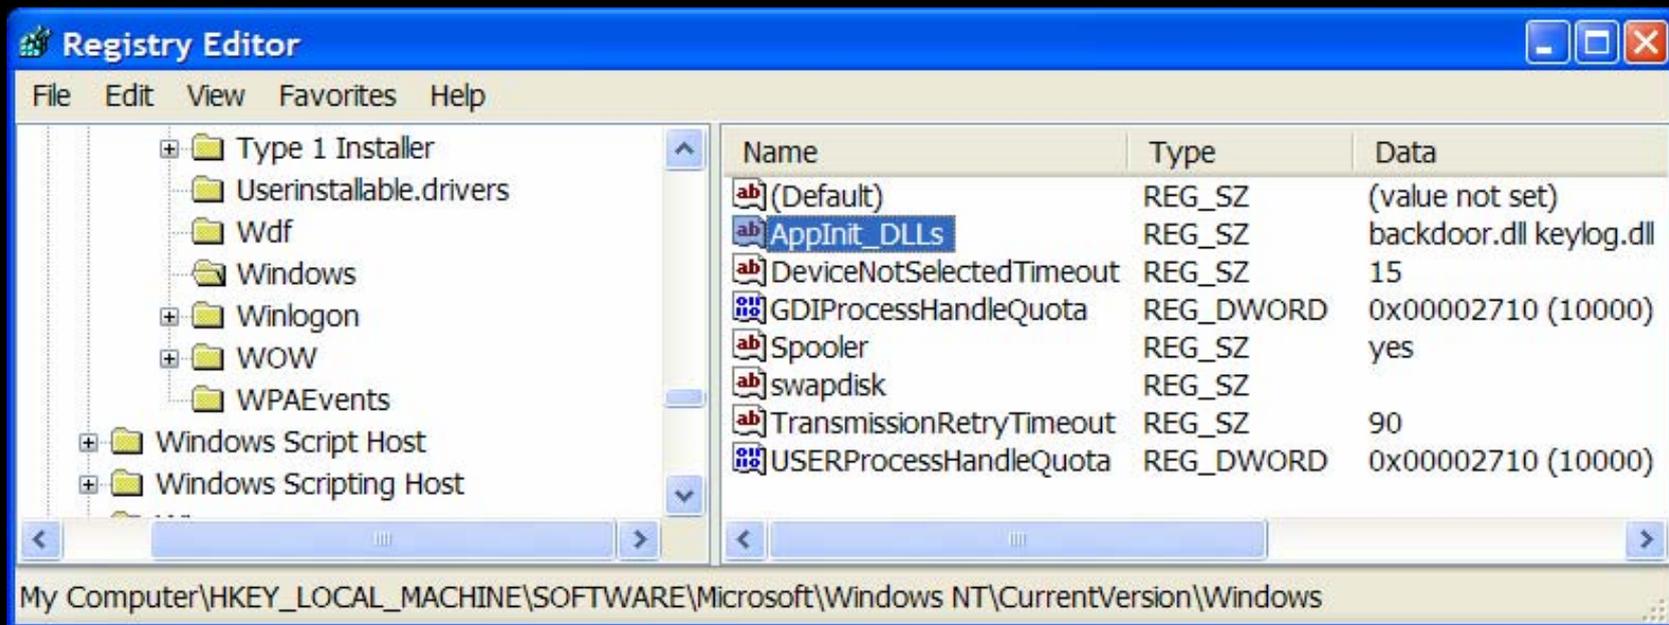

- SetWindowsHookEx defines a hook procedure within a DLL that will be called in response to specific events
- Example events: WH_KEYBOARD, WH_MOUSE, WH_CALLWNDPROC, WH_CBT
- Whenever the hooked event is first fired in a hooked thread, the specified DLL is be loaded

Permissions and Security

- To open a process opened by another user (including SYSTEM), you must hold the SE_DEBUG privilege
- Normally SE_DEBUG is only granted to member of the Administrator group
- However, even if you are running as a normal user, malware can still inject into another process that you own

Injecting code via AppInit_DLLs

- The AppInit_DLLs registry value provides another convenient method of DLL injection

Injecting code via Detours

- Detours is a library developed by Microsoft Research in 1999
- The library uses the same techniques already described, wrapped up in slick package

Detours Features

- Function hooking in running processes
- Import table modification
- Attaching a DLL to an existing program file
- Detours comes with great sample programs:
 - Withdll
 - Injdll
 - Setdll
 - Traceapi

Setdll

- Detours can add a new DLL to an existing binary on disk. How?
- Detours creates a section named “.detours” between the export table and debug symbols
- The .detours section contains the original PE header, and a new IAT
- Detours modifies the PE header to point at the new IAT (reversible)

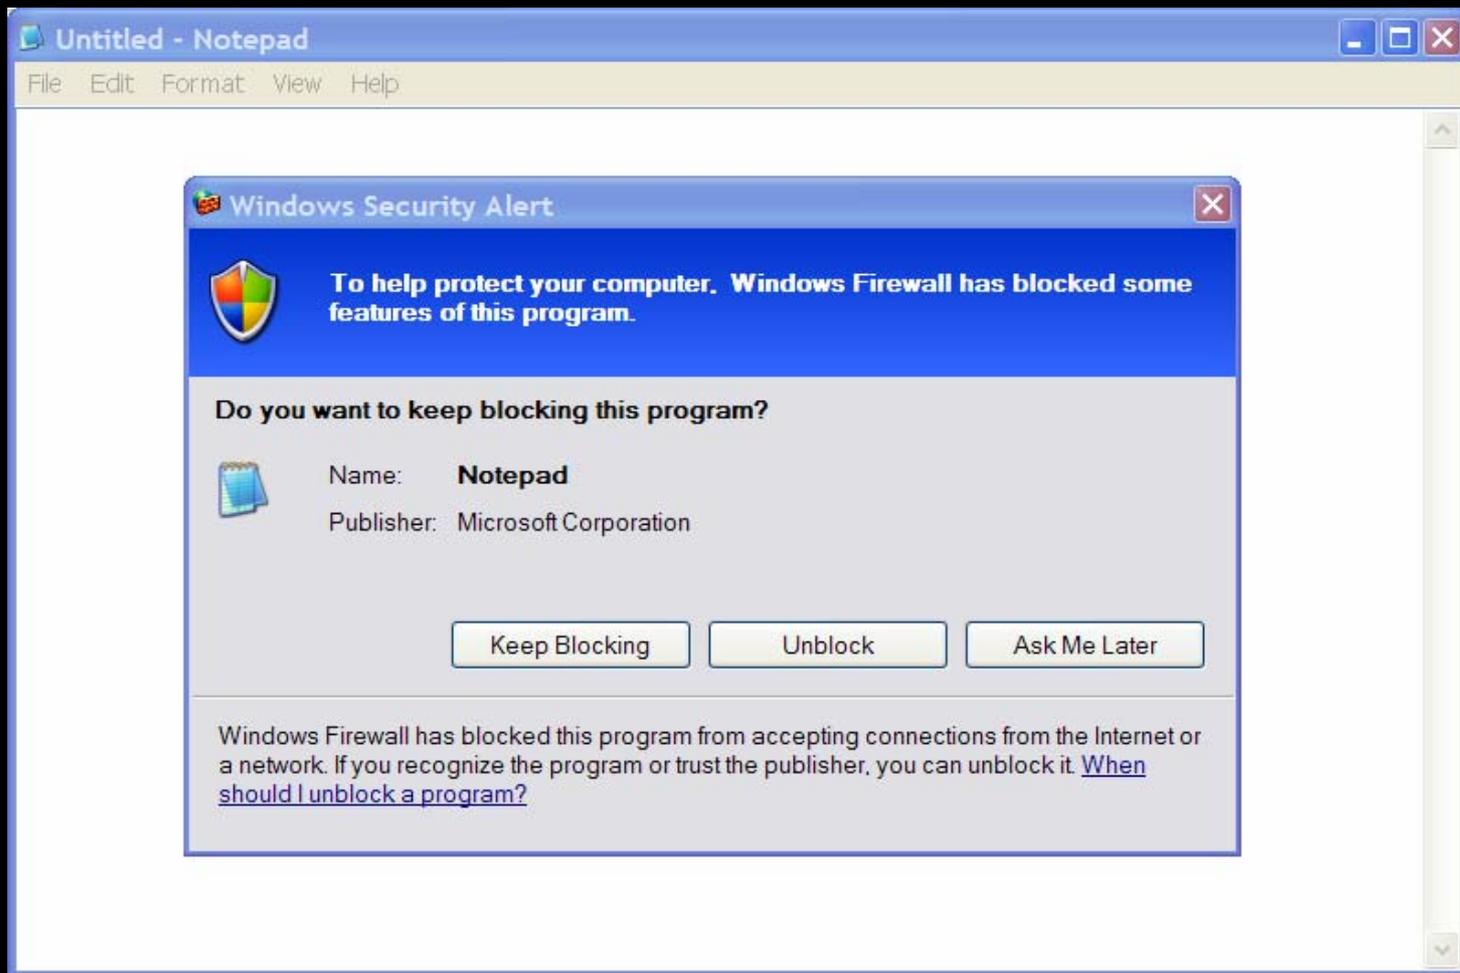

Setdll Demo

The screenshot shows the PEView application window titled "PEView - C:\temp\notepad.exe". The interface includes a menu bar (File, View, Go, Help) and a toolbar with various icons. On the left, a tree view shows the file structure of notepad.exe, with the "IMPORT Name Table" under the "SECTION .detour" folder selected. The main pane displays a table of import entries.

Viewing IMPORT Name Table

Setdll Demo

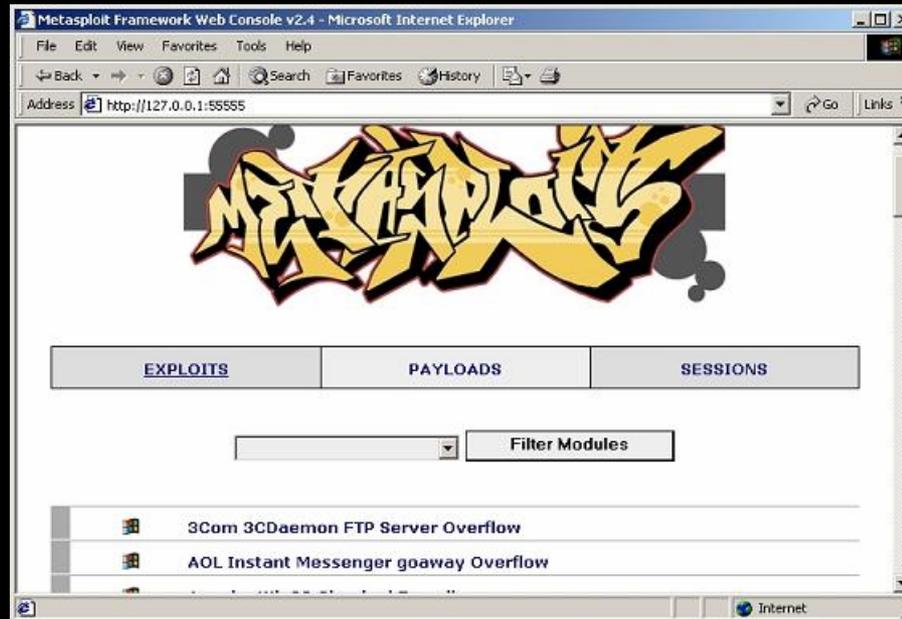

Avoiding the Disk

- When we perform DLL injection, `LoadLibrary` expects the DLL to be on the disk (or at least an SMB share)
- The Metasploit project eliminates this requirement using a clever hooking strategy
- By hooking functions that are involved in reading the file from disk, they fool Windows into thinking the DLL is on disk

Meterpreter

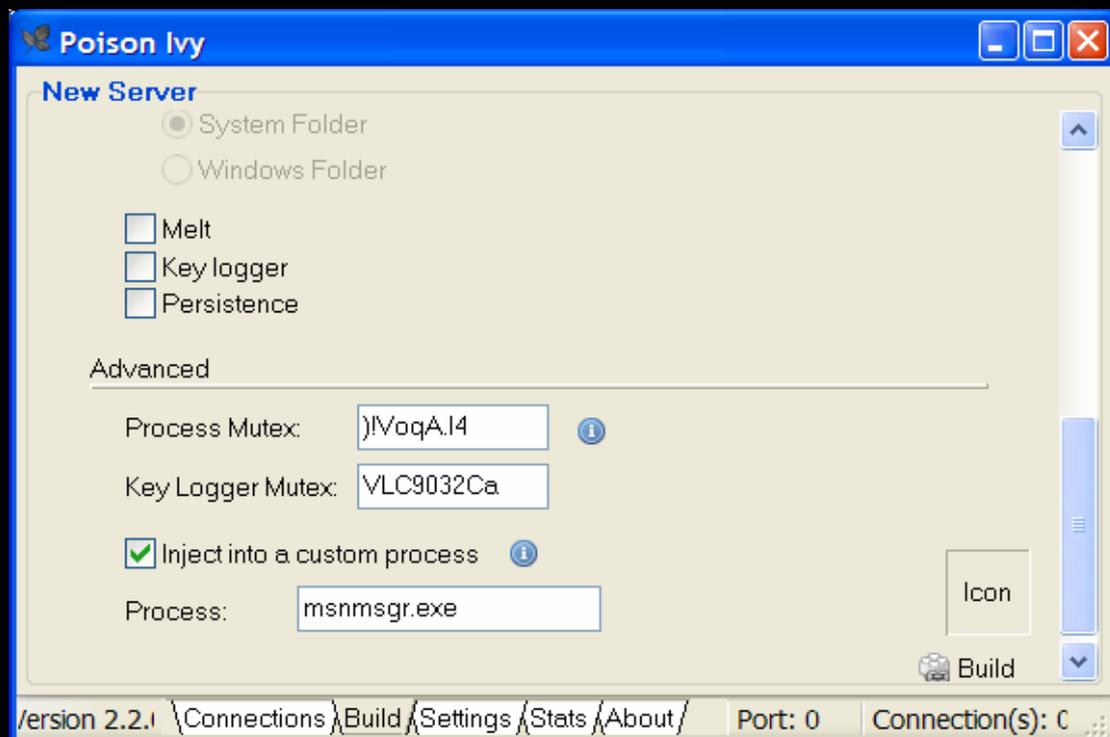

- Hook → Call LoadLibrary → Unhook
- Hooked functions:
 - NtMapViewOfSection
 - NtQueryAttributesFile
 - NtOpenFile
 - NtCreateSection
 - NtOpenSection
- See remote_dispatch.c and libloader.c in MSF 3.0

Meterpreter Demo

Poison Ivy RAT

- Tons of malware uses Code Injection
- We'll quickly dig into the details of one example

Poison Ivy Capabilities

bh_vm [192.168.61.130] - Poison Ivy

Kernel Process Injection

Two Halves of the Process

- User land processes are comprised of two parts
 - Kernel Portion
 - EPROCESS and KPROCESS
 - ETHREAD and KTHREAD
 - Token
 - Handle Table
 - Page Tables
 - Etc.

Two Halves of the Process

- User land Portion
 - Process Environment Block (PEB)
 - Thread Environment Block (TEB)
 - Windows subsystem (CSRSS.EXE)
 - Etc.

Kernel Process Injection Steps

- Must find suitable target
 - Has a user land portion
 - Has kernel32.dll and/or ntdll.dll loaded in its address space
 - Has an alterable thread (unless hijacking an existing thread)
- Allocate memory in target process
- Write the equivalent of “shellcode” that calls LoadLibrary
- Cause a thread in the parent to execute newly allocated code
 - Hijack an existing thread
 - Create an APC

Allocate memory in parent process

- Change virtual memory context to that of the target
 - KeAttachProcess/KeStackAttachProcess
 - ZwAllocateVirtualMemory
 - (HANDLE) -1 means current process
 - MEM_COMMIT
 - PAGE_EXECUTE_READWRITE

Creating the Shellcode

- “shellcode” that calls LoadLibrary
 - Copy function parameters into address space
 - Pass the address of function parameters to calls
 - Can use the FS register
 - FS contains the address of the TEB
 - TEB has a pointer to the PEB
 - PEB has a pointer to the PEB_LDR_DATA
 - PEB_LDR_DATA contains all the loaded DLLs

Creating the Shellcode

- As an alternative to using the FS register
 - Find the address of ntdll.dll from the driver
 - Parse its exports section
 - Does not work with all DLLs
 - Only address of ntdll.dll returned by ZwQuerySystemInformation

Thread Hijacking

- Cause a thread in the parent to execute newly allocated code - Hijack an existing thread
 - Locate a thread within the parent process
 - Change its Context record
 - Change Context record back when done
- Problems:
 - Low priority threads
 - Blocked threads
 - Changing Context back

Thread Context Hijacking

- Hijack and Context records
- lkd> dt nt!_CONTEXT
- +0x000 ContextFlags : Uint4B
- +0x004 Dr0 : Uint4B
- +0x008 Dr1 : Uint4B

Alternative Method: APC

- Cause a thread in the parent to execute newly allocated code - Create an APC
 - Threads can be notified to run an Asynchronous Procedure Call (APC)
 - APC has a pointer to code to execute
 - To be notified, thread should be Alertable

Alertable Threads and APCs – MSDN

Parameter Settings of KeWaitForXXX Routines	Special Kernel-Mode APC		Normal Kernel-Mode APC		User-Mode APC		Alerts
	Wait Aborted?	APC Delivered and Executed?	Wait Aborted?	APC Delivered and Executed?	Wait Aborted?	APC Delivered and Executed?	Wait Aborted?
<i>Alertable</i> = TRUE <i>WaitMode</i> = User	No	If (A) then Yes	No	If (B) then Yes	Yes	Yes, after thread returns to user mode	Yes
<i>Alertable</i> = TRUE <i>WaitMode</i> = Kernel	No	If (A) then Yes	No	If (B) then Yes	No (since <i>WaitMode</i> = Kernel)	No	Yes
<i>Alertable</i> = FALSE <i>WaitMode</i> = User	No	If (A) then Yes	No	If (B) then Yes	No (since <i>Alertable</i> = FALSE)	No (with exceptions, EX, ^C to terminate)	No
<i>Alertable</i> = FALSE <i>WaitMode</i> = Kernel	No	If (A) then Yes	No	If (B) then Yes	No (since <i>Alertable</i> = FALSE and since <i>WaitMode</i> = Kernel)	No	No

A. $IRQL < APC_LEVEL$

B. $IRQL < APC_LEVEL$, thread not already in an APC, thread not in a critical section

Finding an Alertable Thread

```
PETHREAD FindAlertableThread(PEPROCESS eproc)
{
    PETHREAD start, walk;

    if (eproc == NULL)
        return NULL;
    start = *(PETHREAD *)((DWORD)eproc + THREADOFFSET);
    start = (PETHREAD)((DWORD)start - THREADFLINK);
    walk = start;

    do
    {
        DbgPrint("Looking at thread 0x%x\n", walk);

        if (*(PUCHAR)((DWORD)walk + ALERTOFFSET) == 0x01)
            return walk;
        walk = *(PETHREAD *)((DWORD)walk + THREADFLINK);
        walk = (PETHREAD)((DWORD)walk - THREADFLINK);
    }while (walk != start);

    return NULL;
}
```

Kernel Process Injection Demo

Memory Analysis

- Motivation
 - APIs lie. The operating system can be subverted.
 - Example: Unlink injected DLLs from the PEB_LDR_DATA in the PEB.
 - Example: Hooking the Virtual Memory Manager and diverting address translation.
 - APIs are not available to “classic” forensic investigations – offline analysis

Memory Analysis

- Requirements

- No use of APIs to gather data.
- Ability to use any analysis solution on both live memory and offline memory image dumps.
(Implies the ability to do all memory translation independently.)
- Do not require PDB symbols or any other operating specific information.

Steps to Memory Analysis

- Ability to access physical memory
- Derive the version of the OS – important to know how to interpret raw memory
- Find all Processes and/or Threads
- Enumerate File Handles, DLLs, Ports, etc.

Steps to Memory Analysis

- Virtual to Physical Address Translation
 - Determine if the host uses PAE or non-PAE
 - Find the Page Directory Table – process specific
 - Translate prototype PTEs
 - Use the paging file

Derive the version of the OS

- Find the System Process
 - Allows the derivation of:
 - The major operating system version in question
 - The System Page Directory Table Base
 - HandleTableListHead
 - Virtual address of PsInitialSystemProcess
 - PsActiveProcessHead
 - PsProcessType

Operating System Version

- Find the System image name
- Walk backwards to identify the Process Block
- The spatial difference between major versions of the OS is enough to begin to tell us about the operating system version

Operating System Version

- Drawback: Ghosts
 - There can be more than one System Process
 - Open a memory crash dump in Windbg
 - Run a Windows operating system in VMWare
 - Solution:
 - Non-paged kernel addresses are global
 - We know the virtual address of PsActiveProcessHead
 - PsActiveProcessHead and other kernel addresses should be valid and present (translatable) in both live or dead memory

Memory Translation

- PAE vs non-PAE
 - Different ways to interpret the address tables
 - The sixth bit in the CR4 CPU register determines if PAE is enabled
 - Problem: We do not have access to CPU registers in memory analysis
 - Solution?
 - Kernel Processor Control Region -> KPCRB -> KPROCESSOR_STATE -> KSPECIAL_REGISTERS -> CR4

Memory Translation

- CR4 Heuristic
 - Page Directory Table Base and the Page Directory Table Pointer Base look very different.
- CR3 is updated in the KPCR
 - This can be used to identify a valid Page Directory Table
 - The Page Directory can be used to validate the PsActiveProcessHead

Enumerating Injected DLLs

- Problem:
 - APIs lie.
 - Malware can unlink from the PEB_LDR_DATA lists of DLLs
- Solution:
 - Virtual Address Descriptors (VADs)

VADs

- Self balancing binary tree [1]
- Contains:
 - Virtual address range
 - Parent
 - Left Child and Right Child
 - Flags – is the memory executable
 - Control Area

1. Russinovich, Mark and Solomon, Dave, *Microsoft Windows Internals*, Microsoft Press 2005

A Memory Map to a Name

- VAD contains a CONTROL_AREA
- CONTROL_AREA contains a FILE_OBJECT
- A FILE_OBJECT contains a UNICODE_STRING with the filename
- We now have the DLL name

Demo

Conclusion
