The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if an error occurs so that applications can distinguish “failure to find a utility” from “invoked utility exited with an error indication”. The value 127 was chosen because it is not commonly used for other meanings; most utilities use small values for “normal error conditions” and the values above 128 can be confused with termination due to receipt of a signal. The value 126 was chosen in a similar manner to indicate that the utility could be found, but not invoked. Some scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for any other reason.

**EXAMPLES**

It is frequently desirable to apply *time* to pipelines or lists of commands. This can be done by placing pipelines and command lists in a single file; this file can then be invoked as a utility, and the *time* applies to everything in the file.

Alternatively, the following command can be used to apply *time* to a complex command:

```
time sh -c 'complex-command-line'
```

**RATIONALE**

When the *time* utility was originally proposed to be included in the ISO POSIX-2: 1993 standard, questions were raised about its suitability for inclusion on the grounds that it was not useful for conforming applications, specifically:

- The underlying CPU definitions from the System Interfaces volume of POSIX.1-2008 are vague, so the numeric output could not be compared accurately between systems or even between invocations.
- The creation of portable benchmark programs was outside the scope this volume of POSIX.1-2008.

However, *time* does fit in the scope of user portability. Human judgement can be applied to the analysis of the output, and it could be very useful in hands-on debugging of applications or in providing subjective measures of system performance. Hence it has been included in this volume of POSIX.1-2008.

The default output format has been left unspecified because historical implementations differ greatly in their style of depicting this numeric output. The *-p* option was invented to provide scripts with a common means of obtaining this information.

In the KornShell, *time* is a shell reserved word that can be used to time an entire pipeline, rather than just a simple command. The POSIX definition has been worded to allow this implementation. Consideration was given to invalidating this approach because of the historical model from the C shell and System V shell. However, since the System V *time* utility historically has not produced accurate results in pipeline timing (because the constituent processes are not all owned by the same parent process, as allowed by POSIX), it did not seem worthwhile to break historical KornShell usage.

The term *utility* is used, rather than *command*, to highlight the fact that shell compound commands, pipelines, special built-ins, and so on, cannot be used directly. However, *utility* includes user application programs and shell scripts, not just the standard utilities.

109437 **FUTURE DIRECTIONS**

109438 None.

109439 **SEE ALSO**109440 [Chapter 2](#) (on page 2319), *sh*109441 XBD [Chapter 8](#) (on page 173), [Section 12.2](#) (on page 215)109442 XSH *times()*109443 **CHANGE HISTORY**

109444 First released in Issue 2.

109445 **Issue 6**

109446 This utility is marked as part of the User Portability Utilities option.

109447 **Issue 7**109448 The *time* utility is moved from the User Portability Utilities option to the Base. User Portability  
109449 Utilities is now an option for interactive utilities.

109450 SD5-XCU-ERN-115 is applied, updating the example in the DESCRIPTION.

109451 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0144 [266] is applied.

+

109452 **NAME**

109453 touch — change file access and modification times

109454 **SYNOPSIS**109455 touch [-acm] [-r *ref\_file*|-t *time*|-d *date\_time*] *file*...109456 **DESCRIPTION**109457 The *touch* utility shall change the last data modification timestamps, the last data access  
109458 timestamps, or both.109459 The time used can be specified by the -t *time* option-argument, the corresponding *time* fields of  
109460 the file referenced by the -r *ref\_file* option-argument, or the -d *date\_time* option-argument, as  
109461 specified in the following sections. If none of these are specified, *touch* shall use the current time.109462 For each *file* operand, *touch* shall perform actions equivalent to the following functions defined  
109463 in the System Interfaces volume of POSIX.1-2008:

- 109464 1. If *file* does not exist:
  - 109465 a. The *creat*() function is called with the following arguments:
    - 109466 — The *file* operand is used as the *path* argument.
    - 109467 — The value of the bitwise-inclusive OR of S\_IRUSR, S\_IWUSR, S\_IRGRP,  
109468 S\_IWGRP, S\_IROTH, and S\_IWOTH is used as the *mode* argument.
  - 109469 b. The *futimens*() function is called with the following arguments:
    - 109470 — The file descriptor opened in step 1a.
    - 109471 — The access time and the modification time, set as described in the OPTIONS  
109472 section, are used as the first and second elements of the *times* array argument,  
109473 respectively.
- 109474 2. If *file* exists, the *utimensat*() function is called with the following arguments:
  - 109475 a. The AT\_FDCWD special value is used as the *fd* argument.
  - 109476 b. The *file* operand is used as the *path* argument.
  - 109477 c. The access time and the modification time, set as described in the OPTIONS  
109478 section, are used as the first and second elements of the *times* array argument,  
109479 respectively.
  - 109480 d. The *flag* argument is set to zero.

109481 **OPTIONS**109482 The *touch* utility shall conform to XBD [Section 12.2](#) (on page 215).

109483 The following options shall be supported:

- 109484 -a Change the access time of *file*. Do not change the modification time unless -m is  
109485 also specified.
- 109486 -c Do not create a specified *file* if it does not exist. Do not write any diagnostic  
109487 messages concerning this condition.
- 109488 -d *date\_time* Use the specified *date\_time* instead of the current time. The option-argument shall  
109489 be a string of the form:  
109490 YYYY-MM-DDThh:mm:ss[.frac][tz]  
109491 or:

109492 `YYYY-MM-DDThh:mm:ss[,frac][tz]`

109493 where:

- 109494 • YYYY are at least four decimal digits giving the year.
- 109495 • MM, DD, hh, mm, and SS are as with `-t time`.
- 109496 • T is the time designator, and can be replaced by a single <space>.
- 109497 • [,frac] and [,frac] are either empty, or a <period> ('.') or a <comma>
- 109498 (' , ') respectively, followed by one or more decimal digits, specifying a
- 109499 fractional second.
- 109500 • [tz] is either empty, signifying local time, or the letter 'Z', signifying UTC.
- 109501 If [tz] is empty, the resulting time shall be affected by the value of the TZ
- 109502 environment variable.

109503 If the resulting time precedes the Epoch, the behavior is implementation-defined. If

109504 the time cannot be represented as the file's timestamp, *touch* shall exit immediately

109505 with an error status.

109506 **-m** Change the modification time of *file*. Do not change the access time unless **-a** is

109507 also specified.

109508 **-r ref\_file** Use the corresponding time of the file named by the pathname *ref\_file* instead of

109509 the current time.

109510 **-t time** Use the specified *time* instead of the current time. The option-argument shall be a

109511 decimal number of the form:

109512 `[[CC]YY]MMDDhhmm[.SS]`

109513 where each two digits represents the following:

|        |    |                                                 |
|--------|----|-------------------------------------------------|
| 109514 | MM | The month of the year [01,12].                  |
| 109515 | DD | The day of the month [01,31].                   |
| 109516 | hh | The hour of the day [00,23].                    |
| 109517 | mm | The minute of the hour [00,59].                 |
| 109518 | CC | The first two digits of the year (the century). |
| 109519 | YY | The second two digits of the year.              |
| 109520 | SS | The second of the minute [00,60].               |

109521 Both CC and YY shall be optional. If neither is given, the current year shall be

109522 assumed. If YY is specified, but CC is not, CC shall be derived as follows:

| If YY is: | CC becomes: |
|-----------|-------------|
| [69,99]   | 19          |
| [00,68]   | 20          |

109526 **Note:** It is expected that in a future version of this standard the default century inferred

109527 from a 2-digit year will change. (This would apply to all commands accepting a

109528 2-digit year as input.)

109529 The resulting time shall be affected by the value of the TZ environment variable. If

109530 the resulting time value precedes the Epoch, the behavior is implementation-

109531 defined. If the time is out of range for the file's timestamp, *touch* shall exit

109532 immediately with an error status. The range of valid times past the Epoch is  
 109533 implementation-defined, but it shall extend to at least the time 0 hours, 0 minutes,  
 109534 0 seconds, January 1, 2038, Coordinated Universal Time. Some implementations  
 109535 may not be able to represent dates beyond January 18, 2038, because they use  
 109536 **signed int** as a time holder.

109537 The range for *SS* is [00,60] rather than [00,59] because of leap seconds. If *SS* is 60,  
 109538 and the resulting time, as affected by the *TZ* environment variable, does not refer  
 109539 to a leap second, the resulting time shall be one second after a time where *SS* is 59.  
 109540 If *SS* is not given a value, it is assumed to be zero.

109541 If neither the **-a** nor **-m** options were specified, *touch* shall behave as if both the **-a** and **-m**  
 109542 options were specified.

#### 109543 OPERANDS

109544 The following operands shall be supported:

109545 *file* A pathname of a file whose times shall be modified.

#### 109546 STDIN

109547 Not used.

#### 109548 INPUT FILES

109549 None.

#### 109550 ENVIRONMENT VARIABLES

109551 The following environment variables shall affect the execution of *touch*:

109552 *LANG* Provide a default value for the internationalization variables that are unset or null.  
 109553 (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 109554 variables used to determine the values of locale categories.)

109555 *LC\_ALL* If set to a non-empty string value, override the values of all the other  
 109556 internationalization variables.

109557 *LC\_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as  
 109558 characters (for example, single-byte as opposed to multi-byte characters in  
 109559 arguments).

109560 *LC\_MESSAGES*

109561 Determine the locale that should be used to affect the format and contents of  
 109562 diagnostic messages written to standard error.

109563 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

109564 *TZ* Determine the timezone to be used for interpreting the *time* option-argument. If *TZ*  
 109565 is unset or null, an unspecified default timezone shall be used.

#### 109566 ASYNCHRONOUS EVENTS

109567 Default.

#### 109568 STDOUT

109569 Not used.

#### 109570 STDERR

109571 The standard error shall be used only for diagnostic messages.

109572 **OUTPUT FILES**

109573       None.

109574 **EXTENDED DESCRIPTION**

109575       None.

109576 **EXIT STATUS**

109577       The following exit values shall be returned:

109578       0   The utility executed successfully and all requested changes were made.

109579       &gt;0   An error occurred.

109580 **CONSEQUENCES OF ERRORS**

109581       Default.

109582 **APPLICATION USAGE**

109583       The interpretation of time is taken to be *seconds since the Epoch* (see XBD [Section 4.15](#), on page 113). It should be noted that implementations conforming to the System Interfaces volume of POSIX.1-2008 do not take leap seconds into account when computing seconds since the Epoch. When *SS=60* is used, the resulting time always refers to 1 plus *seconds since the Epoch* for a time when *SS=59*.

109588       Although the `-t time` option-argument specifies values in 1969, the access time and modification time fields are defined in terms of seconds since the Epoch (00:00:00 on 1 January 1970 UTC). Therefore, depending on the value of *TZ* when *touch* is run, there is never more than a few valid hours in 1969 and there need not be any valid times in 1969.

109592       One ambiguous situation occurs if `-t time` is not specified, `-r ref_file` is not specified, and the first operand is an eight or ten-digit decimal number. A portable script can avoid this problem by using:

109595       touch -- file

109596       or:

109597       touch ./file

109598       in this case.

109599       If the *T* time designator is replaced by a <space> for the `-d date_time` option-argument, the <space> must be quoted to prevent the shell from splitting the argument.

109601 **EXAMPLES**

109602       Create or update a file called **dwc**; the resulting file has both the last data modification and last data access timestamps set to November 12, 2007 at 10:15:30 local time:

109604       touch -d 2007-11-12T10:15:30 dwc

109605       Create or update a file called **nick**; the resulting file has both the last data modification and last data access timestamps set to November 12, 2007 at 10:15:30 UTC:

109607       touch -d 2007-11-12T10:15:30Z nick

109608       Create or update a file called **gwc**; the resulting file has both the last data modification and last data access timestamps set to November 12, 2007 at 10:15:30 local time with a fractional second timestamp of .002 seconds:

109611       touch -d 2007-11-12T10:15:30.002 gwc

109612       Create or update a file called **ajosey**; the resulting file has both the last data modification and last data access timestamps set to November 12, 2007 at 10:15:30 UTC with a fractional second

109614 timestamp of .002 seconds:

109615 `touch -d "2007-11-12 10:15:30.002Z" ajosey`

109616 Create or update a file called **cathy**; the resulting file has both the last data modification and last  
109617 data access timestamps set to November 12, 2007 at 10:15:00 local time:

109618 `touch -t 200711121015 cathy`

109619 Create or update a file called **drepper**; the resulting file has both the last data modification and  
109620 last data access timestamps set to November 12, 2007 at 10:15:30 local time:

109621 `touch -t 200711121015.30 drepper`

109622 Create or update a file called **ebb9**; the resulting file has both the last data modification and last  
109623 data access timestamps set to November 12, 2007 at 10:15:30 local time:

109624 `touch -t 0711121015.30 ebb9`

109625 Create or update a file called **eggert**; the resulting file has the last data access timestamp set to  
109626 the corresponding time of the file named **mark** instead of the current time. If the file exists, the  
109627 last data modification time is not changed:

109628 `touch -a -r mark eggert`

## 109629 RATIONALE

109630 The functionality of *touch* is described almost entirely through references to functions in the  
109631 System Interfaces volume of POSIX.1-2008. In this way, there is no duplication of effort required  
109632 for describing such side-effects as the relationship of user IDs to the user database, permissions,  
109633 and so on.

109634 There are some significant differences between the *touch* utility in this volume of POSIX.1-2008  
109635 and those in System V and BSD systems. They are upwards-compatible for historical  
109636 applications from both implementations:

- 109637 1. In System V, an ambiguity exists when a pathname that is a decimal number leads the  
109638 operands; it is treated as a time value. In BSD, no *time* value is allowed; files may only be  
109639 *touched* to the current time. The `-t time` construct solves these problems for future  
109640 conforming applications (note that the `-t` option is not historical practice).
- 109641 2. The inclusion of the century digits, *CC*, is also new. Note that a ten-digit *time* value is  
109642 treated as if *YY*, and not *CC*, were specified. The caveat about the range of dates  
109643 following the Epoch was included as recognition that some implementations are not able  
109644 to represent dates beyond 18 January 2038 because they use **signed int** as a time holder.

109645 The `-r` option was added because several comments requested this capability. This option was  
109646 named `-f` in an early proposal, but was changed because the `-f` option is used in the BSD  
109647 version of *touch* with a different meaning.

109648 At least one historical implementation of *touch* incremented the exit code if `-c` was specified and  
109649 the file did not exist. This volume of POSIX.1-2008 requires exit status zero if no errors occur.

109650 In previous version of the standard, if at least two operands are specified, and the first operand  
109651 is an eight or ten-digit decimal integer, the first operand was assumed to be a *date\_time* operand.  
109652 This usage was removed in this version of the standard since it had been marked obsolescent  
109653 previously.

109654 The `-d date_time` format is an ISO 8601:2004 standard complete representation of date and time  
109655 extended format with an optional decimal point or <comma> followed by a string of digits  
109656 following the seconds portion to specify fractions of a second. It is not necessary to recognize

109657 " [+/-] hh:mm" and " [+/-] hh" to specify timezones other than local time and UTC. The *T*  
109658 time designator in the ISO 8601:2004 standard extended format may be replaced by <space>.

109659 **FUTURE DIRECTIONS**

109660 None.

109661 **SEE ALSO**

109662 *date*

109663 XBD [Section 4.15](#) (on page 113), [Chapter 8](#) (on page 173), [Section 12.2](#) (on page 215), [<sys/stat.h>](#)

109664 XSH [creat\(\)](#), [futimens\(\)](#), [time\(\)](#), [utime\(\)](#)

109665 **CHANGE HISTORY**

109666 First released in Issue 2.

109667 **Issue 6**

109668 The obsolescent *date\_time* operand is removed.

109669 The Open Group Corrigendum U027/1 is applied. This extends the range of valid time past the  
109670 Epoch to at least the time 0 hours, 0 minutes, 0 seconds, January 1, 2038, Coordinated Universal  
109671 Time. This is a new requirement on POSIX implementations.

109672 The range for seconds is changed from [00,61] to [00,60] to align with the ISO/IEC 9899:1999  
109673 standard, and to allow for positive leap seconds.

109674 **Issue 7**

109675 Austin Group Interpretation 1003.1-2001 #118 is applied.

109676 Austin Group Interpretation 1003.1-2001 #193 is applied, adding support for subsecond  
109677 timestamps.

109678 SD5-XCU-ERN-45 is applied, adding a new paragraph to the RATIONALE.

109679 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

109680 SD5-XCU-ERN-110 is applied, updating the OPTIONS section.

109681 Changes are made related to support for finegrained timestamps.

109682 **NAME**

109683       tput — change terminal characteristics

109684 **SYNOPSIS**109685       tput [-T *type*] *operand...*109686 **DESCRIPTION**

109687       The *tput* utility shall display terminal-dependent information. The manner in which this  
 109688       information is retrieved is unspecified. The information displayed shall clear the terminal  
 109689       screen, initialize the user's terminal, or reset the user's terminal, depending on the operand  
 109690       given. The exact consequences of displaying this information are unspecified.

109691 **OPTIONS**109692       The *tput* utility shall conform to XBD [Section 12.2](#) (on page 215).

109693       The following option shall be supported:

109694       -T *type*       Indicate the type of terminal. If this option is not supplied and the *TERM* variable  
 109695       is unset or null, an unspecified default terminal type shall be used. The setting of  
 109696       *type* shall take precedence over the value in *TERM*.

109697 **OPERANDS**

109698       The following strings shall be supported as operands by the implementation in the POSIX locale:

109699       **clear**       Display the clear-screen sequence.

109700       **init**        Display the sequence that initializes the user's terminal in an implementation-  
 109701       defined manner.

109702       **reset**       Display the sequence that resets the user's terminal in an implementation-defined  
 109703       manner.

109704       If a terminal does not support any of the operations described by these operands, this shall not  
 109705       be considered an error condition.

109706 **STDIN**

109707       Not used.

109708 **INPUT FILES**

109709       None.

109710 **ENVIRONMENT VARIABLES**109711       The following environment variables shall affect the execution of *tput*:

109712       LANG        Provide a default value for the internationalization variables that are unset or null.  
 109713       (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 109714       variables used to determine the values of locale categories.)

109715       LC\_ALL       If set to a non-empty string value, override the values of all the other  
 109716       internationalization variables.

109717       LC\_CTYPE     Determine the locale for the interpretation of sequences of bytes of text data as  
 109718       characters (for example, single-byte as opposed to multi-byte characters in  
 109719       arguments).

109720       LC\_MESSAGES

109721       Determine the locale that should be used to affect the format and contents of  
 109722       diagnostic messages written to standard error.

109723 XSI **NLSPATH** Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

109724 **TERM** Determine the terminal type. If this variable is unset or null, and if the **-T** option is  
109725 not specified, an unspecified default terminal type shall be used.

109726 **ASYNCHRONOUS EVENTS**

109727 Default.

109728 **STDOUT**

109729 If standard output is a terminal device, it may be used for writing the appropriate sequence to  
109730 clear the screen or reset or initialize the terminal. If standard output is not a terminal device,  
109731 undefined results occur.

109732 **STDERR**

109733 The standard error shall be used only for diagnostic messages.

109734 **OUTPUT FILES**

109735 None.

109736 **EXTENDED DESCRIPTION**

109737 None.

109738 **EXIT STATUS**

109739 The following exit values shall be returned:

109740 0 The requested string was written successfully.

109741 1 Unspecified.

109742 2 Usage error.

109743 3 No information is available about the specified terminal type.

109744 4 The specified operand is invalid.

109745 >4 An error occurred.

109746 **CONSEQUENCES OF ERRORS**

109747 If one of the operands is not available for the terminal, *tput* continues processing the remaining  
109748 operands.

109749 **APPLICATION USAGE**

109750 The difference between resetting and initializing a terminal is left unspecified, as they vary  
109751 greatly based on hardware types. In general, resetting is a more severe action.

109752 Some terminals use control characters to perform the stated functions, and on such terminals it  
109753 might make sense to use *tput* to store the initialization strings in a file or environment variable  
109754 for later use. However, because other terminals might rely on system calls to do this work, the  
109755 standard output cannot be used in a portable manner, such as the following non-portable  
109756 constructs:

109757 ClearVar='tput clear'  
109758 tput reset | mailx -s "Wake Up" ddg

109759 **EXAMPLES**

109760 1. Initialize the terminal according to the type of terminal in the environmental variable  
109761 *TERM*. This command can be included in a **.profile** file.

109762 tput init

109763           2.   Reset a 450 terminal.  
109764           tput -T 450 reset

109765 **RATIONALE**

109766           The list of operands was reduced to a minimum for the following reasons:

- 109767           • The only features chosen were those that were likely to be used by human users interacting  
109768           with a terminal.
- 109769           • Specifying the full *terminfo* set was not considered desirable, but the standard developers  
109770           did not want to select among operands.
- 109771           • This volume of POSIX.1-2008 does not attempt to provide applications with sophisticated  
109772           terminal handling capabilities, as that falls outside of its assigned scope and intersects with  
109773           the responsibilities of other standards bodies.

109774           The difference between resetting and initializing a terminal is left unspecified as this varies  
109775           greatly based on hardware types. In general, resetting is a more severe action.

109776           The exit status of 1 is historically reserved for finding out if a Boolean operand is not set.  
109777           Although the operands were reduced to a minimum, the exit status of 1 should still be reserved  
109778           for the Boolean operands, for those sites that wish to support them.

109779 **FUTURE DIRECTIONS**

109780           None.

109781 **SEE ALSO**

109784 **CHANGE HISTORY**

109785           First released in Issue 4.

109786 **Issue 6**

109787           This utility is marked as part of the User Portability Utilities option.

109788 **Issue 7**

109789           The *tput* utility is moved from the User Portability Utilities option to the Base. User Portability  
109790           Utilities is now an option for interactive utilities.

109791 **NAME**

109792 tr — translate characters

109793 **SYNOPSIS**109794 tr [-c|-C] [-s] *string1 string2*109795 tr -s [-c|-C] *string1*109796 tr -d [-c|-C] *string1*109797 tr -ds [-c|-C] *string1 string2*109798 **DESCRIPTION**

109799 The *tr* utility shall copy the standard input to the standard output with substitution or deletion  
 109800 of selected characters. The options specified and the *string1* and *string2* operands shall control  
 109801 translations that occur while copying characters and single-character collating elements.

109802 **OPTIONS**109803 The *tr* utility shall conform to XBD [Section 12.2](#) (on page 215).

109804 The following options shall be supported:

109805 **-c** Complement the set of values specified by *string1*. See the EXTENDED  
 109806 DESCRIPTION section.

109807 **-C** Complement the set of characters specified by *string1*. See the EXTENDED  
 109808 DESCRIPTION section.

109809 **-d** Delete all occurrences of input characters that are specified by *string1*.

109810 **-s** Replace instances of repeated characters with a single character, as described in the  
 109811 EXTENDED DESCRIPTION section.

109812 **OPERANDS**

109813 The following operands shall be supported:

109814 *string1, string2*

109815 Translation control strings. Each string shall represent a set of characters to be  
 109816 converted into an array of characters used for the translation. For a detailed  
 109817 description of how the strings are interpreted, see the EXTENDED DESCRIPTION  
 109818 section.

109819 **STDIN**

109820 The standard input can be any type of file.

109821 **INPUT FILES**

109822 None.

109823 **ENVIRONMENT VARIABLES**109824 The following environment variables shall affect the execution of *tr*:

109825 **LANG** Provide a default value for the internationalization variables that are unset or null.  
 109826 (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 109827 variables used to determine the values of locale categories.)

109828 **LC\_ALL** If set to a non-empty string value, override the values of all the other  
 109829 internationalization variables.

109830 **LC\_COLLATE**

109831 Determine the locale for the behavior of range expressions and equivalence classes.

| 109848 | The operands <i>string1</i> and <i>string2</i> (if specified) define two arrays of characters. The constructs in the following list can be used to specify characters or single-character collating elements. If any of the constructs result in multi-character collating elements, <i>tr</i> shall exclude, without a diagnostic, those multi-character elements from the resulting array. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 109852 | <i>character</i>                                                                                                                                                                                                                                                                                                                                                                             | Any character not described by one of the conventions below shall represent itself.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 109853 | <i>\octal</i>                                                                                                                                                                                                                                                                                                                                                                                | Octal sequences can be used to represent characters with specific coded values. An octal sequence shall consist of a <backslash> followed by the longest sequence of one, two, or three-octal-digit characters (01234567). The sequence shall cause the value whose encoding is represented by the one, two, or three-digit octal integer to be placed into the array. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading <backslash> for each byte.                                                                                                                                    |

The characters or collating elements in the range shall be placed in the array in ascending collation sequence. If the second endpoint precedes the starting endpoint in the collation sequence, it is unspecified whether the range of collating elements is empty, or this construct is treated as invalid. In locales other than the POSIX locale, this construct has unspecified behavior. |

| 109883 |                                      | When both the -d and -s options are specified, any of the character class names shall be accepted in string2. Otherwise, only character class names lower or upper are valid in string2 and then only if the corresponding character class (upper and lower, respectively) is specified in the same relative position in string1. Such a specification shall be interpreted as a request for case conversion. When [:lower:] appears in string1 and [:upper:] appears in string2, the arrays shall contain the characters from the toupper mapping in the LC_CTYPE category of the current locale. When [:upper:] appears in string1 and [:lower:] appears in string2, the arrays shall contain the characters from the tolower mapping in the LC_CTYPE category of the current locale. The first character from each mapping pair shall be in the array for string1 and the second character from each mapping pair shall be in the array for string2 in the same relative position. |

| 109899 | [=equiv=]                            | Represents all characters or collating elements belonging to the same equivalence class as equiv, as defined by the current setting of the LC_COLLATE locale category. An equivalence class expression shall be allowed only in string1, or in string2 when it is being used by the combined -d and -s options. The characters belonging to the equivalence class shall be placed in the array in an unspecified order.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| 109904 | [x*n]                                | Represents n repeated occurrences of the character x. Because this expression is used to map multiple characters to one, it is only valid when it occurs in string2. If n is omitted or is zero, it shall be interpreted as large enough to extend the string2-based sequence to the length of the string1-based sequence. If n has a leading zero, it shall be interpreted as an octal value. Otherwise, it shall be interpreted as a decimal value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| 109916 |                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 109917 |                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 109918 |                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

- If string2 is present, each input character found in the array specified by string1 shall be replaced by the character in the same relative position in the array specified by string2. If the array specified by string2 is shorter than the one specified by string1, or if a character occurs more than once in string1, the results are unspecified.
- If the -C option is specified, the complements of the characters specified by string1 (the set of all characters in the current character set, as defined by the current setting of LC\_CTYPE, except for those actually specified in the string1 operand) shall be placed in the array in ascending collation sequence, as defined by the current setting of LC\_COLLATE.

- If the **-c** option is specified, the complement of the values specified by *string1* shall be placed in the array in ascending order by binary value.
- Because the order in which characters specified by character class expressions or equivalence class expressions is undefined, such expressions should only be used if the intent is to map several characters into one. An exception is case conversion, as described previously.

When the **-d** option is specified:

- Input characters found in the array specified by *string1* shall be deleted.
- When the **-C** option is specified with **-d**, all characters except those specified by *string1* shall be deleted. The contents of *string2* are ignored, unless the **-s** option is also specified.
- When the **-c** option is specified with **-d**, all values except those specified by *string1* shall be deleted. The contents of *string2* shall be ignored, unless the **-s** option is also specified.
- The same string cannot be used for both the **-d** and the **-s** option; when both options are specified, both *string1* (used for deletion) and *string2* (used for squeezing) shall be required.

When the **-s** option is specified, after any deletions or translations have taken place, repeated sequences of the same character shall be replaced by one occurrence of the same character, if the character is found in the array specified by the last operand. If the last operand contains a character class, such as the following example:

```
tr -s '[:space:]'
```

the last operand's array shall contain all of the characters in that character class. However, in a case conversion, as described previously, such as:

```
tr -s '[:upper:]' '[:lower:]'
```

the last operand's array shall contain only those characters defined as the second characters in each of the **toupper** or **tolower** character pairs, as appropriate.

An empty string used for *string1* or *string2* produces undefined results.

## EXIT STATUS

The following exit values shall be returned:

- 0 All input was processed successfully.
- >0 An error occurred.

## CONSEQUENCES OF ERRORS

Default.

## APPLICATION USAGE

If necessary, *string1* and *string2* can be quoted to avoid pattern matching by the shell.

If an ordinary digit (representing itself) is to follow an octal sequence, the octal sequence must use the full three digits to avoid ambiguity.

When *string2* is shorter than *string1*, a difference results between historical System V and BSD systems. A BSD system pads *string2* with the last character found in *string2*. Thus, it is possible to do the following:

```
tr 0123456789 d
```

which would translate all digits to the letter 'd'. Since this area is specifically unspecified in

this volume of POSIX.1-2008, both the BSD and System V behaviors are allowed, but a conforming application cannot rely on the BSD behavior. It would have to code the example in the following way:

```
tr 0123456789 '[d*]'
```

It should be noted that, despite similarities in appearance, the string operands used by *tr* are not regular expressions.

Unlike some historical implementations, this definition of the *tr* utility correctly processes NUL characters in its input stream. NUL characters can be stripped by using:

```
tr -d '\000'
```

## EXAMPLES

1. The following example creates a list of all words in **file1** one per line in **file2**, where a word is taken to be a maximal string of letters.

```
tr -cs "[:alpha:]" "[\n*]" <file1 >file2
```

2. The next example translates all lowercase characters in **file1** to uppercase and writes the results to standard output.

```
tr "[:lower:]" "[:upper:]" <file1
```

3. This example uses an equivalence class to identify accented variants of the base character 'e' in **file1**, which are stripped of diacritical marks and written to **file2**.

```
tr "[=e=]" "[e*]" <file1 >file2
```

## RATIONALE

In some early proposals, an explicit option **-n** was added to disable the historical behavior of stripping NUL characters from the input. It was considered that automatically stripping NUL characters from the input was not correct functionality. However, the removal of **-n** in a later proposal does not remove the requirement that *tr* correctly process NUL characters in its input stream. NUL characters can be stripped by using *tr -d '\000'*.

Historical implementations of *tr* differ widely in syntax and behavior. For example, the BSD version has not needed the bracket characters for the repetition sequence. The *tr* utility syntax is based more closely on the System V and XPG3 model while attempting to accommodate historical BSD implementations. In the case of the short *string2* padding, the decision was to unspecify the behavior and preserve System V and XPG3 scripts, which might find difficulty with the BSD method. The assumption was made that BSD users of *tr* have to make accommodations to meet the syntax defined here. Since it is possible to use the repetition sequence to duplicate the desired behavior, whereas there is no simple way to achieve the System V method, this was the correct, if not desirable, approach.

The use of octal values to specify control characters, while having historical precedents, is not portable. The introduction of escape sequences for control characters should provide the necessary portability. It is recognized that this may cause some historical scripts to break.

An early proposal included support for multi-character collating elements. It was pointed out that, while *tr* does employ some syntactical elements from REs, the aim of *tr* is quite different; ranges, for example, do not have a similar meaning ("any of the chars in the range matches", *versus* "translate each character in the range to the output counterpart"). As a result, the previously included support for multi-character collating elements has been removed. What remains are ranges in current collation order (to support, for example, accented characters), character classes, and equivalence classes.

110004 In XPG3 the `[class:]` and `[equiv=]` conventions are shown with double brackets, as in RE syntax.  
 110005 However, *tr* does not implement RE principles; it just borrows part of the syntax. Consequently,  
 110006 `[class:]` and `[equiv=]` should be regarded as syntactical elements on a par with `[x*n]`, which is  
 110007 not an RE bracket expression.

110008 The standard developers will consider changes to *tr* that allow it to translate characters between  
 110009 different character encodings, or they will consider providing a new utility to accomplish this.

110010 On historical System V systems, a range expression requires enclosing square-brackets, such as:

110011 `tr '[a-z]' '[A-Z]'`

110012 However, BSD-based systems did not require the brackets, and this convention is used here to  
 110013 avoid breaking large numbers of BSD scripts:

110014 `tr a-z A-Z`

110015 The preceding System V script will continue to work because the brackets, treated as regular  
 110016 characters, are translated to themselves. However, any System V script that relied on "a-z"  
 110017 representing the three characters 'a', '-', and 'z' have to be rewritten as "az-".

110018 The ISO POSIX-2: 1993 standard had a `-c` option that behaved similarly to the `-C` option, but did  
 110019 not supply functionality equivalent to the `-c` option specified in POSIX.1-2008. This meant that  
 110020 historical practice of being able to specify `tr -cd\000-\177` (which would delete all bytes with  
 110021 the top bit set) would have no effect because, in the C locale, bytes with the values octal 200 to  
 110022 octal 377 are not characters.

110023 The earlier version also said that octal sequences referred to collating elements and could be  
 110024 placed adjacent to each other to specify multi-byte characters. However, it was noted that this  
 110025 caused ambiguities because *tr* would not be able to tell whether adjacent octal sequences were  
 110026 intending to specify multi-byte characters or multiple single byte characters. POSIX.1-2008  
 110027 specifies that octal sequences always refer to single byte binary values when used to specify an  
 110028 endpoint of a range of collating elements.

110029 Earlier versions of this standard allowed for implementations with bytes other than eight bits,  
 110030 but this has been modified in this version.

#### 110031 FUTURE DIRECTIONS

110032 None.

#### 110033 SEE ALSO

110034 *sed*

#### 110036 CHANGE HISTORY

110037 First released in Issue 2.

#### 110038 Issue 6

110039 The `-C` operand is added, and the description of the `-c` operand is changed to align with the  
 110040 IEEE P1003.2b draft standard.

110041 The normative text is reworded to avoid use of the term "must" for application requirements.

110042 IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/31 is applied, removing text describing  
 110043 behavior on systems with bytes consisting of more than eight bits.

110044 IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/32 is applied, updating an example in the  
 110045 EXAMPLES section to avoid using unspecified behavior.

110046 IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/33 is applied, making a correction to the

110054 **NAME**

110055           true — return true value

110056 **SYNOPSIS**

110057           true

110058 **DESCRIPTION**110059           The *true* utility shall return with exit code zero.110060 **OPTIONS**

110061           None.

110062 **OPERANDS**

110063           None.

110064 **STDIN**

110065           Not used.

110066 **INPUT FILES**

110067           None.

110068 **ENVIRONMENT VARIABLES**

110069           None.

110070 **ASYNCHRONOUS EVENTS**

110071           Default.

110072 **STDOUT**

110073           Not used.

110074 **STDERR**

110075           Not used.

110076 **OUTPUT FILES**

110077           None.

110078 **EXTENDED DESCRIPTION**

110079           None.

110080 **EXIT STATUS**

110081           Zero.

110082 **CONSEQUENCES OF ERRORS**

110083           None.

110084 **APPLICATION USAGE**

110085           This utility is typically used in shell scripts, as shown in the EXAMPLES section. The special  
110086           built-in utility `:` is sometimes more efficient than *true*.

110087 **EXAMPLES**

110088           This command is executed forever:

```
110089 while true
110090 do
110091 command
110092 done
```

110093 **RATIONALE**

110094 The *true* utility has been retained in this volume of POSIX.1-2008, even though the shell special  
110095 built-in : provides similar functionality, because *true* is widely used in historical scripts and is  
110096 less cryptic to novice script readers.

110097 **FUTURE DIRECTIONS**

110098 None.

110099 **SEE ALSO**

110100 [Section 2.9](#) (on page 2338), *false*

110101 **CHANGE HISTORY**

110102 First released in Issue 2.

110103 **Issue 6**

110104 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/39 is applied, replacing the terms “None”  
110105 and “Default” from the STDERR and EXIT STATUS sections, respectively, with terms as defined  
110106 in [Section 1.4](#) (on page 2310).

110107 **NAME**

110108           tsort — topological sort

110109 **SYNOPSIS**110110           tsort [*file*]110111 **DESCRIPTION**110112           The *tsort* utility shall write to standard output a totally ordered list of items consistent with a  
110113           partial ordering of items contained in the input.110114           The application shall ensure that the input consists of pairs of items (non-empty strings)  
110115           separated by <blank> characters. Pairs of different items indicate ordering. Pairs of identical  
110116           items indicate presence, but not ordering.110117 **OPTIONS**

110118           None.

110119 **OPERANDS**

110120           The following operand shall be supported:

110121           *file*           A pathname of a text file to order. If no *file* operand is given, the standard input  
110122           shall be used.110123 **STDIN**110124           The standard input shall be used if no *file* operand is specified, and shall be used if the *file*  
110125           operand is '-' and the implementation treats the '-' as meaning standard input. Otherwise,  
110126           the standard input shall not be used. See the INPUT FILES section.110127 **INPUT FILES**

110128           The input file shall be a text file.

110129 **ENVIRONMENT VARIABLES**110130           The following environment variables shall affect the execution of *tsort*:110131           *LANG*           Provide a default value for the internationalization variables that are unset or null.  
110132                           (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
110133                           variables used to determine the values of locale categories.)110134           *LC\_ALL*          If set to a non-empty string value, override the values of all the other  
110135           internationalization variables.110136           *LC\_CTYPE*       Determine the locale for the interpretation of sequences of bytes of text data as  
110137           characters (for example, single-byte as opposed to multi-byte characters in  
110138           arguments and input files).110139           *LC\_MESSAGES*110140                           Determine the locale that should be used to affect the format and contents of  
110141           diagnostic messages written to standard error.110142 XSI           *NLSPATH*   Determine the location of message catalogs for the processing of *LC\_MESSAGES*.110143 **ASYNCHRONOUS EVENTS**

110144           Default.

110145 **STDOUT**110146           The standard output shall be a text file consisting of the order list produced from the partially  
110147           ordered input.

**110148 STDERR**

110149       The standard error shall be used only for diagnostic messages.

**110150 OUTPUT FILES**

110151       None.

**110152 EXTENDED DESCRIPTION**

110153       None.

**110154 EXIT STATUS**

110155       The following exit values shall be returned:

110156       0   Successful completion.

110157       >0  An error occurred.

**110158 CONSEQUENCES OF ERRORS**

110159       Default.

**110160 APPLICATION USAGE**

110161       The *LC\_COLLATE* variable need not affect the actions of *tsort*. The output ordering is not  
110162       lexicographic, but depends on the pairs of items given as input.

**110163 EXAMPLES**

110164       The command:

```
110165 tsort <<EOF
110166 a b c c d e
110167 g g
110168 f g e f
110169 h h
110170 EOF
```

110171       produces the output:

```
110172 a
110173 b
110174 c
110175 d
110176 e
110177 f
110178 g
110179 h
```

**110180 RATIONALE**

110181       None.

**110182 FUTURE DIRECTIONS**

110183       None.

**110184 SEE ALSO**

110185       XBD [Chapter 8](#) (on page 173)

**110186 CHANGE HISTORY**

110187       First released in Issue 2.

110188 **Issue 6**

110189 The normative text is reworded to avoid use of the term “must” for application requirements.

110190 **Issue 7**

110191 Austin Group Interpretation 1003.1-2001 #092 is applied.

110192 The *tsort* utility is moved from the XSI option to the Base.

110193 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0146 [241] is applied.

+

110194 **NAME**110195        `tty` — return user's terminal name110196 **SYNOPSIS**110197        `tty`110198 **DESCRIPTION**

110199        The `tty` utility shall write to the standard output the name of the terminal that is open as  
 110200        standard input. The name that is used shall be equivalent to the string that would be returned by  
 110201        the `ttyname()` function defined in the System Interfaces volume of POSIX.1-2008.

110202 **OPTIONS**110203        The `tty` utility shall conform to XBD [Section 12.2](#) (on page 215).110204 **OPERANDS**

110205        None.

110206 **STDIN**

110207        While no input is read from standard input, standard input shall be examined to determine  
 110208        whether or not it is a terminal, and, if so, to determine the name of the terminal.

110209 **INPUT FILES**

110210        None.

110211 **ENVIRONMENT VARIABLES**110212        The following environment variables shall affect the execution of `tty`:

110213        `LANG`        Provide a default value for the internationalization variables that are unset or null.  
 110214                      (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 110215                      variables used to determine the values of locale categories.)

110216        `LC_ALL`      If set to a non-empty string value, override the values of all the other  
 110217                      internationalization variables.

110218        `LC_CTYPE`   Determine the locale for the interpretation of sequences of bytes of text data as  
 110219                      characters (for example, single-byte as opposed to multi-byte characters in  
 110220                      arguments).

110221        `LC_MESSAGES`  
 110222                      Determine the locale that should be used to affect the format and contents of  
 110223                      diagnostic messages written to standard error and informative messages written to  
 110224                      standard output.

110225 `XSI`        `NLSPATH`   Determine the location of message catalogs for the processing of `LC_MESSAGES`.

110226 **ASYNCHRONOUS EVENTS**

110227        Default.

110228 **STDOUT**

110229        If standard input is a terminal device, a pathname of the terminal as specified by the `ttyname()`  
 110230        function defined in the System Interfaces volume of POSIX.1-2008 shall be written in the  
 110231        following format:

110232        `"%s\n", <terminal name>`

110233        Otherwise, a message shall be written indicating that standard input is not connected to a  
 110234        terminal. In the POSIX locale, the `tty` utility shall use the format:

110235        `"not a tty\n"`

**110236 STDERR**

110237 The standard error shall be used only for diagnostic messages.

**110238 OUTPUT FILES**

110239 None.

**110240 EXTENDED DESCRIPTION**

110241 None.

**110242 EXIT STATUS**

110243 The following exit values shall be returned:

110244 0 Standard input is a terminal.

110245 1 Standard input is not a terminal.

110246 >1 An error occurred.

**110247 CONSEQUENCES OF ERRORS**

110248 Default.

**110249 APPLICATION USAGE**

110250 This utility checks the status of the file open as standard input against that of an  
110251 implementation-defined set of files. It is possible that no match can be found, or that the match  
110252 found need not be the same file as that which was opened for standard input (although they are  
110253 the same device).

**110254 EXAMPLES**

110255 None.

**110256 RATIONALE**

110257 None.

**110258 FUTURE DIRECTIONS**

110259 None.

**110260 SEE ALSO**

110261 XBD [Chapter 8](#) (on page 173), [Section 12.2](#) (on page 215)

110262 XSH [isatty\(\)](#), [ttyname\(\)](#)

**110263 CHANGE HISTORY**

110264 First released in Issue 2.

**110265 Issue 5**

110266 The SYNOPSIS is changed to indicate two forms of the command, with the second form marked  
110267 as obsolete. This is a clarification and does not change the functionality published in previous  
110268 issues.

**110269 Issue 6**

110270 The obsolescent `-s` option is removed.

110271 **NAME**

110272           type — write a description of command type

110273 **SYNOPSIS**110274 XSI       type *name*...110275 **DESCRIPTION**110276           The *type* utility shall indicate how each argument would be interpreted if used as a command  
110277           name.110278 **OPTIONS**

110279           None.

110280 **OPERANDS**

110281           The following operand shall be supported:

110282           *name*           A name to be interpreted.110283 **STDIN**

110284           Not used.

110285 **INPUT FILES**

110286           None.

110287 **ENVIRONMENT VARIABLES**110288           The following environment variables shall affect the execution of *type*:110289           *LANG*           Provide a default value for the internationalization variables that are unset or null.  
110290                           (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
110291                           variables used to determine the values of locale categories.)110292           *LC\_ALL*       If set to a non-empty string value, override the values of all the other  
110293                           internationalization variables.110294           *LC\_CTYPE*   Determine the locale for the interpretation of sequences of bytes of text data as  
110295                           characters (for example, single-byte as opposed to multi-byte characters in  
110296                           arguments).110297           *LC\_MESSAGES*  
110298                           Determine the locale that should be used to affect the format and contents of  
110299                           diagnostic messages written to standard error.110300           *NLSPATH*   Determine the location of message catalogs for the processing of *LC\_MESSAGES*.110301           *PATH*       Determine the location of *name*, as described in XBD [Chapter 8](#) (on page 173).110302 **ASYNCHRONOUS EVENTS**

110303           Default.

110304 **STDOUT**110305           The standard output of *type* contains information about each operand in an unspecified format.110306           The information provided typically identifies the operand as a shell built-in, function, alias, or  
110307           keyword, and where applicable, may display the operand's pathname.110308 **STDERR**

110309           The standard error shall be used only for diagnostic messages.

**110310 OUTPUT FILES**

110311 None.

**110312 EXTENDED DESCRIPTION**

110313 None.

**110314 EXIT STATUS**

110315 The following exit values shall be returned:

110316 0 Successful completion.

110317 >0 An error occurred.

**110318 CONSEQUENCES OF ERRORS**

110319 Default.

**110320 APPLICATION USAGE**

110321 Since *type* must be aware of the contents of the current shell execution environment (such as the  
110322 lists of commands, functions, and built-ins processed by *hash*), it is always provided as a shell  
110323 regular built-in. If it is called in a separate utility execution environment, such as one of the  
110324 following:

110325 `nohup type writer`

110326 `find . -type f | xargs type`

110327 it might not produce accurate results.

**110328 EXAMPLES**

110329 None.

**110330 RATIONALE**

110331 None.

**110332 FUTURE DIRECTIONS**

110333 None.

**110334 SEE ALSO**

110335 *command*, *hash*

110336 XBD [Chapter 8](#) (on page 173)

**110337 CHANGE HISTORY**

110338 First released in Issue 2.

110339 **NAME**

110340           ulimit — set or report file size limit

110341 **SYNOPSIS**110342 XSI        ulimit [-f] [*blocks*]110343 **DESCRIPTION**

110344       The *ulimit* utility shall set or report the file-size writing limit imposed on files written by the  
 110345       shell and its child processes (files of any size may be read). Only a process with appropriate  
 110346       privileges can increase the limit.

110347 **OPTIONS**110348       The *ulimit* utility shall conform to XBD [Section 12.2](#) (on page 215).

110349       The following option shall be supported:

110350       -f           Set (or report, if no *blocks* operand is present), the file size limit in blocks. The -f  
 110351       option shall also be the default case.

110352 **OPERANDS**

110353       The following operand shall be supported:

110354       *blocks*       The number of 512-byte blocks to use as the new file size limit.110355 **STDIN**

110356       Not used.

110357 **INPUT FILES**

110358       None.

110359 **ENVIRONMENT VARIABLES**110360       The following environment variables shall affect the execution of *ulimit*:

110361       LANG        Provide a default value for the internationalization variables that are unset or null.  
 110362                   (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 110363                   variables used to determine the values of locale categories.)

110364       LC\_ALL      If set to a non-empty string value, override the values of all the other  
 110365                   internationalization variables.

110366       LC\_CTYPE    Determine the locale for the interpretation of sequences of bytes of text data as  
 110367                   characters (for example, single-byte as opposed to multi-byte characters in  
 110368                   arguments).

110369       LC\_MESSAGES

110370                   Determine the locale that should be used to affect the format and contents of  
 110371                   diagnostic messages written to standard error.

110372       NLSPATH     Determine the location of message catalogs for the processing of *LC\_MESSAGES*.110373 **ASYNCHRONOUS EVENTS**

110374       Default.

110375 **STDOUT**

110376       The standard output shall be used when no *blocks* operand is present. If the current number of  
 110377       blocks is limited, the number of blocks in the current limit shall be written in the following  
 110378       format:

110379       "%d\n", &lt;number of 512-byte blocks&gt;

110380       If there is no current limit on the number of blocks, in the POSIX locale the following format

110381 shall be used:

110382 "unlimited\n"

### 110383 **STDERR**

110384 The standard error shall be used only for diagnostic messages.

### 110385 **OUTPUT FILES**

110386 None.

### 110387 **EXTENDED DESCRIPTION**

110388 None.

### 110389 **EXIT STATUS**

110390 The following exit values shall be returned:

110391 0 Successful completion.

110392 >0 A request for a higher limit was rejected or an error occurred.

### 110393 **CONSEQUENCES OF ERRORS**

110394 Default.

### 110395 **APPLICATION USAGE**

110396 Since *ulimit* affects the current shell execution environment, it is always provided as a shell  
110397 regular built-in. If it is called in a separate utility execution environment, such as one of the  
110398 following:

110399 `nohup ulimit -f 10000`

110400 `env ulimit 10000`

110401 it does not affect the file size limit of the caller's environment.

110402 Once a limit has been decreased by a process, it cannot be increased (unless appropriate  
110403 privileges are involved), even back to the original system limit.

### 110404 **EXAMPLES**

110405 Set the file size limit to 51 200 bytes:

110406 `ulimit -f 100`

### 110407 **RATIONALE**

110408 None.

### 110409 **FUTURE DIRECTIONS**

110410 None.

### 110411 **SEE ALSO**

110412 XBD [Chapter 8](#) (on page 173), [Section 12.2](#) (on page 215)

110413 XSH [ulimit\(\)](#)

### 110414 **CHANGE HISTORY**

110415 First released in Issue 2.

### 110416 **Issue 7**

110417 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

110418 **NAME**

110419       umask — get or set the file mode creation mask

110420 **SYNOPSIS**110421       umask [-S] [*mask*]110422 **DESCRIPTION**

110423       The *umask* utility shall set the file mode creation mask of the current shell execution environment (see [Section 2.12](#), on page 2353) to the value specified by the *mask* operand. This mask shall affect the initial value of the file permission bits of subsequently created files. If *umask* is called in a subshell or separate utility execution environment, such as one of the following:

```
110427 (umask 002)
110428 nohup umask ...
110429 find . -exec umask ... \;
```

110430       it shall not affect the file mode creation mask of the caller's environment.

110431       If the *mask* operand is not specified, the *umask* utility shall write to standard output the value of the file mode creation mask of the invoking process.

110433 **OPTIONS**110434       The *umask* utility shall conform to XBD [Section 12.2](#) (on page 215).

110435       The following option shall be supported:

110436       -S       Produce symbolic output.

110437       The default output style is unspecified, but shall be recognized on a subsequent invocation of *umask* on the same system as a *mask* operand to restore the previous file mode creation mask.

110439 **OPERANDS**

110440       The following operand shall be supported:

110441       *mask*       A string specifying the new file mode creation mask. The string is treated in the same way as the *mode* operand described in the EXTENDED DESCRIPTION section for *chmod*.

110444       For a *symbolic\_mode* value, the new value of the file mode creation mask shall be the logical complement of the file permission bits portion of the file mode specified by the *symbolic\_mode* string.

110447       In a *symbolic\_mode* value, the permissions *op* characters '+' and '-' shall be interpreted relative to the current file mode creation mask; '+' shall cause the bits for the indicated permissions to be cleared in the mask; '-' shall cause the bits for the indicated permissions to be set in the mask.

110451       The interpretation of *mode* values that specify file mode bits other than the file permission bits is unspecified.

110453       In the octal integer form of *mode*, the specified bits are set in the file mode creation mask.

110455       The file mode creation mask shall be set to the resulting numeric value.

110456       The default output of a prior invocation of *umask* on the same system with no operand also shall be recognized as a *mask* operand.

110458 **STDIN**

110459 Not used.

110460 **INPUT FILES**

110461 None.

110462 **ENVIRONMENT VARIABLES**110463 The following environment variables shall affect the execution of *umask*:

110464 *LANG* Provide a default value for the internationalization variables that are unset or null.  
 110465 (See XBD Section 8.2 (on page 174) for the precedence of internationalization  
 110466 variables used to determine the values of locale categories.)

110467 *LC\_ALL* If set to a non-empty string value, override the values of all the other  
 110468 internationalization variables.

110469 *LC\_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as  
 110470 characters (for example, single-byte as opposed to multi-byte characters in  
 110471 arguments).

110472 *LC\_MESSAGES*

110473 Determine the locale that should be used to affect the format and contents of  
 110474 diagnostic messages written to standard error.

110475 *XSI NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

110476 **ASYNCHRONOUS EVENTS**

110477 Default.

110478 **STDOUT**

110479 When the *mask* operand is not specified, the *umask* utility shall write a message to standard  
 110480 output that can later be used as a *umask mask* operand.

110481 If *-S* is specified, the message shall be in the following format:

110482 "u=%s,g=%s,o=%s\n", <owner permissions>, <group permissions>,  
 110483 <other permissions>

110484 where the three values shall be combinations of letters from the set {*r*, *w*, *x*}; the presence of a  
 110485 letter shall indicate that the corresponding bit is clear in the file mode creation mask.

110486 If a *mask* operand is specified, there shall be no output written to standard output.110487 **STDERR**

110488 The standard error shall be used only for diagnostic messages.

110489 **OUTPUT FILES**

110490 None.

110491 **EXTENDED DESCRIPTION**

110492 None.

110493 **EXIT STATUS**

110494 The following exit values shall be returned:

110495 0 The file mode creation mask was successfully changed, or no *mask* operand was supplied.

110496 &gt;0 An error occurred.

## 110497 CONSEQUENCES OF ERRORS

110498 Default.

## 110499 APPLICATION USAGE

110500 Since *umask* affects the current shell execution environment, it is generally provided as a shell  
 110501 regular built-in.

110502 In contrast to the negative permission logic provided by the file mode creation mask and the  
 110503 octal number form of the *mask* argument, the symbolic form of the *mask* argument specifies those  
 110504 permissions that are left alone.

## 110505 EXAMPLES

110506 Either of the commands:

110507 `umask a=rx,ug+w`110508 `umask 002`

110509 sets the mode mask so that subsequently created files have their S\_IWOTH bit cleared.

110510 After setting the mode mask with either of the above commands, the *umask* command can be  
 110511 used to write out the current value of the mode mask:

110512 `$ umask`110513 `0002`

110514 (The output format is unspecified, but historical implementations use the octal integer mode  
 110515 format.)

110516 `$ umask -S`110517 `u=rwx,g=rwx,o=rx`

110518 Either of these outputs can be used as the mask operand to a subsequent invocation of the *umask*  
 110519 utility.

110520 Assuming the mode mask is set as above, the command:

110521 `umask g-w`

110522 sets the mode mask so that subsequently created files have their S\_IWGRP and S\_IWOTH bits  
 110523 cleared.

110524 The command:

110525 `umask -- -w`

110526 sets the mode mask so that subsequently created files have all their write bits cleared. Note that  
 110527 *mask* operands `-r`, `-w`, `-x` or anything beginning with a <hyphen>, must be preceded by `--` to  
 110528 keep it from being interpreted as an option.

## 110529 RATIONALE

110530 Since *umask* affects the current shell execution environment, it is generally provided as a shell  
 110531 regular built-in. If it is called in a subshell or separate utility execution environment, such as one  
 110532 of the following:

110533 `(umask 002)`110534 `nohup umask ...`110535 `find . -exec umask ... \;`

110536 it does not affect the file mode creation mask of the environment of the caller.

110537 The description of the historical utility was modified to allow it to use the symbolic modes of

110538 *chmod*. The **-s** option used in early proposals was changed to **-S** because **-s** could be confused  
110539 with a *symbolic\_mode* form of mask referring to the **S\_ISUID** and **S\_ISGID** bits.

110540 The default output style is unspecified to permit implementors to provide migration to the new  
110541 symbolic style at the time most appropriate to their users. A **-o** flag to force octal mode output  
110542 was omitted because the octal mode may not be sufficient to specify all of the information that  
110543 may be present in the file mode creation mask when more secure file access permission checks  
110544 are implemented.

110545 It has been suggested that trusted systems developers might appreciate ameliorating the  
110546 requirement that the mode mask “affects” the file access permissions, since it seems access  
110547 control lists might replace the mode mask to some degree. The wording has been changed to say  
110548 that it affects the file permission bits, and it leaves the details of the behavior of how they affect  
110549 the file access permissions to the description in the System Interfaces volume of POSIX.1-2008.

#### 110550 FUTURE DIRECTIONS

110551 None.

#### 110556 CHANGE HISTORY

110557 First released in Issue 2.

#### 110558 Issue 6

110559 The following new requirements on POSIX implementations derive from alignment with the  
110560 Single UNIX Specification:

- 110561 • The octal mode is supported.

110562 IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/34 is applied, making a correction to the  
110563 RATIONALE.

#### 110564 Issue 7

110565 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

110566 **NAME**

110567 unalias — remove alias definitions

110568 **SYNOPSIS**

110569 unalias *alias-name*...

110570 unalias -a

110571 **DESCRIPTION**

110572 The *unalias* utility shall remove the definition for each alias name specified. See [Section 2.3.1](#) (on  
110573 page 2322). The aliases shall be removed from the current shell execution environment; see  
110574 [Section 2.12](#) (on page 2353).

110575 **OPTIONS**

110576 The *unalias* utility shall conform to XBD [Section 12.2](#) (on page 215).

110577 The following option shall be supported:

110578 -a Remove all alias definitions from the current shell execution environment.

110579 **OPERANDS**

110580 The following operand shall be supported:

110581 *alias-name* The name of an alias to be removed.

110582 **STDIN**

110583 Not used.

110584 **INPUT FILES**

110585 None.

110586 **ENVIRONMENT VARIABLES**

110587 The following environment variables shall affect the execution of *unalias*:

110588 *LANG* Provide a default value for the internationalization variables that are unset or null.  
110589 (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
110590 variables used to determine the values of locale categories.)

110591 *LC\_ALL* If set to a non-empty string value, override the values of all the other  
110592 internationalization variables.

110593 *LC\_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as  
110594 characters (for example, single-byte as opposed to multi-byte characters in  
110595 arguments).

110596 *LC\_MESSAGES*

110597 Determine the locale that should be used to affect the format and contents of  
110598 diagnostic messages written to standard error.

110599 *XSI NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

110600 **ASYNCHRONOUS EVENTS**

110601 Default.

110602 **STDOUT**

110603 Not used.

110604 **STDERR**

110605 The standard error shall be used only for diagnostic messages.

**110606 OUTPUT FILES**

110607 None.

**110608 EXTENDED DESCRIPTION**

110609 None.

**110610 EXIT STATUS**

110611 The following exit values shall be returned:

110612 0 Successful completion.

110613 >0 One of the *alias-name* operands specified did not represent a valid alias definition, or an  
110614 error occurred.

**110615 CONSEQUENCES OF ERRORS**

110616 Default.

**110617 APPLICATION USAGE**

110618 Since *unalias* affects the current shell execution environment, it is generally provided as a shell  
110619 regular built-in.

**110620 EXAMPLES**

110621 None.

**110622 RATIONALE**

110623 The *unalias* description is based on that from historical KornShell implementations. Known  
110624 differences exist between that and the C shell. The KornShell version was adopted to be  
110625 consistent with all the other KornShell features in this volume of POSIX.1-2008, such as  
110626 command line editing.

110627 The *-a* option is the equivalent of the *unalias \** form of the C shell and is provided to address  
110628 security concerns about unknown aliases entering the environment of a user (or application)  
110629 through the allowable implementation-defined predefined alias route or as a result of an *ENV*  
110630 file. (Although *unalias* could be used to simplify the “secure” shell script shown in the *command*  
110631 rationale, it does not obviate the need to quote all command names. An initial call to *unalias -a*  
110632 would have to be quoted in case there was an alias for *unalias*.)

**110633 FUTURE DIRECTIONS**

110634 None.

**110635 SEE ALSO**

110636 [Chapter 2](#) (on page 2319), *alias*

110637 XBD [Chapter 8](#) (on page 173), [Section 12.2](#) (on page 215)

**110638 CHANGE HISTORY**

110639 First released in Issue 4.

**110640 Issue 6**

110641 This utility is marked as part of the User Portability Utilities option.

**110642 Issue 7**

110643 The *unalias* utility is moved from the User Portability Utilities option to the Base. User  
110644 Portability Utilities is now an option for interactive utilities.

110645 **NAME**110646        `uname` — return system name110647 **SYNOPSIS**110648        `uname [-amnrsv]`110649 **DESCRIPTION**

110650        By default, the *uname* utility shall write the operating system name to standard output. When  
 110651        options are specified, symbols representing one or more system characteristics shall be written to  
 110652        the standard output. The format and contents of the symbols are implementation-defined. On  
 110653        systems conforming to the System Interfaces volume of POSIX.1-2008, the symbols written shall  
 110654        be those supported by the *uname()* function as defined in the System Interfaces volume of  
 110655        POSIX.1-2008.

110656 **OPTIONS**110657        The *uname* utility shall conform to XBD [Section 12.2](#) (on page 215).

110658        The following options shall be supported:

- 110659        **-a**            Behave as though all of the options **-mnrsv** were specified.
- 110660        **-m**            Write the name of the hardware type on which the system is running to standard  
 110661                        output.
- 110662        **-n**            Write the name of this node within an implementation-defined communications  
 110663                        network.
- 110664        **-r**            Write the current release level of the operating system implementation.
- 110665        **-s**            Write the name of the implementation of the operating system.
- 110666        **-v**            Write the current version level of this release of the operating system  
 110667                        implementation.

110668        If no options are specified, the *uname* utility shall write the operating system name, as if the **-s**  
 110669        option had been specified.

110670 **OPERANDS**

110671        None.

110672 **STDIN**

110673        Not used.

110674 **INPUT FILES**

110675        None.

110676 **ENVIRONMENT VARIABLES**110677        The following environment variables shall affect the execution of *uname*:

- 110678        **LANG**        Provide a default value for the internationalization variables that are unset or null.  
 110679                        (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 110680                        variables used to determine the values of locale categories.)
- 110681        **LC\_ALL**        If set to a non-empty string value, override the values of all the other  
 110682                        internationalization variables.
- 110683        **LC\_CTYPE**     Determine the locale for the interpretation of sequences of bytes of text data as  
 110684                        characters (for example, single-byte as opposed to multi-byte characters in  
 110685                        arguments).

110686 **LC\_MESSAGES**  
 110687 Determine the locale that should be used to affect the format and contents of  
 110688 diagnostic messages written to standard error.

110689 XSI **NLSPATH** Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

110690 **ASYNCHRONOUS EVENTS**  
 110691 Default.

110692 **STDOUT**  
 110693 By default, the output shall be a single line of the following form:  
 110694 "%s\n", <sysname>  
 110695 If the **-a** option is specified, the output shall be a single line of the following form:  
 110696 "%s %s %s %s %s\n", <sysname>, <nodename>, <release>,  
 110697 <version>, <machine>  
 110698 Additional implementation-defined symbols may be written; all such symbols shall be written at  
 110699 the end of the line of output before the <newline>.  
 110700 If options are specified to select different combinations of the symbols, only those symbols shall  
 110701 be written, in the order shown above for the **-a** option. If a symbol is not selected for writing, its  
 110702 corresponding trailing <blank> characters also shall not be written.

110703 **STDERR**  
 110704 The standard error shall be used only for diagnostic messages.

110705 **OUTPUT FILES**  
 110706 None.

110707 **EXTENDED DESCRIPTION**  
 110708 None.

110709 **EXIT STATUS**  
 110710 The following exit values shall be returned:  
 110711 0 The requested information was successfully written.  
 110712 >0 An error occurred.

110713 **CONSEQUENCES OF ERRORS**  
 110714 Default.

110715 **APPLICATION USAGE**  
 110716 Note that any of the symbols could include embedded <space> characters, which may affect  
 110717 parsing algorithms if multiple options are selected for output.  
 110718 The node name is typically a name that the system uses to identify itself for inter-system  
 110719 communication addressing.

110720 **EXAMPLES**  
 110721 The following command:  
 110722 `uname -sr`  
 110723 writes the operating system name and release level, separated by one or more <blank>  
 110724 characters.

110725 **RATIONALE**

110726 It was suggested that this utility cannot be used portably since the format of the symbols is  
110727 implementation-defined. The POSIX.1 working group could not achieve consensus on defining  
110728 these formats in the underlying *uname()* function, and there was no expectation that this volume  
110729 of POSIX.1-2008 would be any more successful. Some applications may still find this historical  
110730 utility of value. For example, the symbols could be used for system log entries or for comparison  
110731 with operator or user input.

110732 **FUTURE DIRECTIONS**

110733 None.

110734 **SEE ALSO**

110735 XBD [Chapter 8](#) (on page 173), [Section 12.2](#) (on page 215)

110736 XSH [uname\(\)](#)

110737 **CHANGE HISTORY**

110738 First released in Issue 2.

110739 **NAME**

110740 uncompress — expand compressed data

110741 **SYNOPSIS**110742 XSI `uncompress [-cfv] [file...]`110743 **DESCRIPTION**

110744 The *uncompress* utility shall restore files to their original state after they have been compressed  
 110745 using the *compress* utility. If no files are specified, the standard input shall be uncompressed to  
 110746 the standard output. If the invoking process has appropriate privileges, the ownership, modes,  
 110747 access time, and modification time of the original file shall be preserved.

110748 This utility shall support the uncompressing of any files produced by the *compress* utility on the  
 110749 same implementation. For files produced by *compress* on other systems, *uncompress* supports 9 to  
 110750 14-bit compression (see *compress*, **-b**); it is implementation-defined whether values of **-b** greater  
 110751 than 14 are supported.

110752 **OPTIONS**

110753 The *uncompress* utility shall conform to XBD [Section 12.2](#) (on page 215), except that Guideline 1  
 110754 does apply since the utility name has ten letters.

110755 The following options shall be supported:

- 110756 **-c** Write to standard output; no files are changed.
- 110757 **-f** Do not prompt for overwriting files. Except when run in the background, if **-f** is  
 110758 not given the user shall be prompted as to whether an existing file should be  
 110759 overwritten. If the standard input is not a terminal and **-f** is not given, *uncompress*  
 110760 shall write a diagnostic message to standard error and exit with a status greater  
 110761 than zero.
- 110762 **-v** Write messages to standard error concerning the expansion of each file.

110763 **OPERANDS**

110764 The following operand shall be supported:

- 110765 *file* A pathname of a file. If *file* already has the **.Z** suffix specified, it shall be used as the  
 110766 input file and the output file shall be named **file** with the **.Z** suffix removed.  
 110767 Otherwise, *file* shall be used as the name of the output file and **file** with the **.Z**  
 110768 suffix appended shall be used as the input file.

110769 **STDIN**

110770 The standard input shall be used only if no *file* operands are specified, or if a *file* operand is **'-'**.

110771 **INPUT FILES**

110772 Input files shall be in the format produced by the *compress* utility.

110773 **ENVIRONMENT VARIABLES**

110774 The following environment variables shall affect the execution of *uncompress*:

- 110775 **LANG** Provide a default value for the internationalization variables that are unset or null.  
 110776 (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 110777 variables used to determine the values of locale categories.)
- 110778 **LC\_ALL** If set to a non-empty string value, override the values of all the other  
 110779 internationalization variables.

110780 *LC\_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as  
110781 characters (for example, single-byte as opposed to multi-byte characters in  
110782 arguments).

110783 *LC\_MESSAGES*  
110784 Determine the locale that should be used to affect the format and contents of  
110785 diagnostic messages written to standard error.

110786 *NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

110787 **ASYNCHRONOUS EVENTS**  
110788 Default.

110789 **STDOUT**  
110790 When there are no *file* operands or the *-c* option is specified, the uncompressed output is written  
110791 to standard output.

110792 **STDERR**  
110793 Prompts shall be written to the standard error output under the conditions specified in the  
110794 DESCRIPTION and OPTIONS sections. The prompts shall contain the *file* pathname, but their  
110795 format is otherwise unspecified. Otherwise, the standard error output shall be used only for  
110796 diagnostic messages.

110797 **OUTPUT FILES**  
110798 Output files are the same as the respective input files to *compress*.

110799 **EXTENDED DESCRIPTION**  
110800 None.

110801 **EXIT STATUS**  
110802 The following exit values shall be returned:  
110803 0 Successful completion.  
110804 >0 An error occurred.

110805 **CONSEQUENCES OF ERRORS**  
110806 The input file remains unmodified.

110807 **APPLICATION USAGE**  
110808 The limit of 14 on the *compress -b bits* argument is to achieve portability to all systems (within  
110809 the restrictions imposed by the lack of an explicit published file format). Some implementations  
110810 based on 16-bit architectures cannot support 15 or 16-bit uncompression.

110811 **EXAMPLES**  
110812 None.

110813 **RATIONALE**  
110814 None.

110815 **FUTURE DIRECTIONS**  
110816 None.

110817 **SEE ALSO**  
110818 *compress*, *zcat*  
110819 XBD Chapter 8 (on page 173), Section 12.2 (on page 215)

**110820 CHANGE HISTORY**

110821 First released in Issue 4.

**110822 Issue 6**

110823 The normative text is reworded to avoid use of the term “must” for application requirements.

**110824 Issue 7**

110825 SD5-XCU-ERN-26 is applied, clarifying that this utility is allowed to break the Utility Syntax Guidelines by having ten letters in its name.

110826 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

110828 **NAME**

110829 unexpand — convert spaces to tabs

110830 **SYNOPSIS**110831 unexpand [-a|-t *tablist*] [*file...*]110832 **DESCRIPTION**

110833 The *unexpand* utility shall copy files or standard input to standard output, converting <blank>  
 110834 characters at the beginning of each line into the maximum number of <tab> characters followed  
 110835 by the minimum number of <space> characters needed to fill the same column positions  
 110836 originally filled by the translated <blank> characters. By default, tabstops shall be set at every  
 110837 eighth column position. Each <backspace> shall be copied to the output, and shall cause the  
 110838 column position count for tab calculations to be decremented; the count shall never be  
 110839 decremented to a value less than one.

110840 **OPTIONS**110841 The *unexpand* utility shall conform to XBD [Section 12.2](#) (on page 215).

110842 The following options shall be supported:

110843 **-a** In addition to translating <blank> characters at the beginning of each line,  
 110844 translate all sequences of two or more <blank> characters immediately preceding a  
 110845 tab stop to the maximum number of <tab> characters followed by the minimum  
 110846 number of <space> characters needed to fill the same column positions originally  
 110847 filled by the translated <blank> characters.

110848 **-t *tablist*** Specify the tab stops. The application shall ensure that the *tablist* option-argument  
 110849 is a single argument consisting of a single positive decimal integer or multiple  
 110850 positive decimal integers, separated by <blank> or <comma> characters, in  
 110851 ascending order. If a single number is given, tabs shall be set *tablist* column  
 110852 positions apart instead of the default 8. If multiple numbers are given, the tabs  
 110853 shall be set at those specific column positions.

110854 The application shall ensure that each tab-stop position *N* is an integer value  
 110855 greater than zero, and the list shall be in strictly ascending order. This is taken to  
 110856 mean that, from the start of a line of output, tabbing to position *N* shall cause the  
 110857 next character output to be in the (*N*+1)th column position on that line. When the  
 110858 **-t** option is not specified, the default shall be the equivalent of specifying **-t 8**  
 110859 (except for the interaction with **-a**, described below).

110860 No <space>-to-<tab> conversions shall occur for characters at positions beyond  
 110861 the last of those specified in a multiple tab-stop list.

110862 When **-t** is specified, the presence or absence of the **-a** option shall be ignored;  
 110863 conversion shall not be limited to the processing of leading <blank> characters.

110864 **OPERANDS**

110865 The following operand shall be supported:

110866 *file* A pathname of a text file to be used as input.

110867 **STDIN**

110868 See the INPUT FILES section.

110869 **INPUT FILES**

110870 The input files shall be text files.

110871 **ENVIRONMENT VARIABLES**

110872 The following environment variables shall affect the execution of *unexpand*:

110873 *LANG* Provide a default value for the internationalization variables that are unset or null.  
 110874 (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 110875 variables used to determine the values of locale categories.)

110876 *LC\_ALL* If set to a non-empty string value, override the values of all the other  
 110877 internationalization variables.

110878 *LC\_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as  
 110879 characters (for example, single-byte as opposed to multi-byte characters in  
 110880 arguments and input files), the processing of <tab> and <space> characters, and  
 110881 for the determination of the width in column positions each character would  
 110882 occupy on an output device.

110883 *LC\_MESSAGES*

110884 Determine the locale that should be used to affect the format and contents of  
 110885 diagnostic messages written to standard error.

110886 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

110887 **ASYNCHRONOUS EVENTS**

110888 Default.

110889 **STDOUT**

110890 The standard output shall be equivalent to the input files with the specified <space>-to-<tab>  
 110891 conversions.

110892 **STDERR**

110893 The standard error shall be used only for diagnostic messages.

110894 **OUTPUT FILES**

110895 None.

110896 **EXTENDED DESCRIPTION**

110897 None.

110898 **EXIT STATUS**

110899 The following exit values shall be returned:

110900 0 Successful completion.

110901 >0 An error occurred.

110902 **CONSEQUENCES OF ERRORS**

110903 Default.

110904 **APPLICATION USAGE**

110905 One non-intuitive aspect of *unexpand* is its restriction to leading <space> characters when neither  
 110906 *-a* nor *-t* is specified. Users who always want to convert all <space> characters in a file can  
 110907 easily alias *unexpand* to use the *-a* or *-t 8* option.

110908 **EXAMPLES**

110909 None.

110910 **RATIONALE**

110911 On several occasions, consideration was given to adding a *-t* option to the *unexpand* utility to  
 110912 complement the *-t* in *expand* (see [expand](#)). The historical intent of *unexpand* was to translate  
 110913 multiple <blank> characters into tab stops, where tab stops were a multiple of eight column

110914 positions on most UNIX systems. An early proposal omitted `-t` because it seemed outside the  
110915 scope of the User Portability Utilities option; it was not described in any of the base documents.  
110916 However, hard-coding tab stops every eight columns was not suitable for the international  
110917 community and broke historical precedents for some vendors in the FORTRAN community, so  
110918 `-t` was restored in conjunction with the list of valid extension categories considered by the  
110919 standard developers. Thus, *unexpand* is now the logical converse of *expand*.

#### 110920 FUTURE DIRECTIONS

110921 None.

#### 110922 SEE ALSO

110923 *expand*, *tabs*

110924 XBD [Chapter 8](#) (on page 173), [Section 12.2](#) (on page 215)

#### 110925 CHANGE HISTORY

110926 First released in Issue 4.

#### 110927 Issue 6

110928 This utility is marked as part of the User Portability Utilities option.

110929 The definition of the `LC_CTYPE` environment variable is changed to align with the  
110930 IEEE P1003.2b draft standard.

110931 The normative text is reworded to avoid use of the term “must” for application requirements.

#### 110932 Issue 7

110933 The *unexpand* utility is moved from the User Portability Utilities option to the Base. User  
110934 Portability Utilities is now an option for interactive utilities.

110935 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

110936 **NAME**110937 unget — undo a previous get of an SCCS file (**DEVELOPMENT**)110938 **SYNOPSIS**110939 XSI unget [-ns] [-r *SID*] *file...*110940 **DESCRIPTION**110941 The *unget* utility shall reverse the effect of a *get -e* done prior to creating the intended new delta.110942 **OPTIONS**110943 The *unget* utility shall conform to XBD [Section 12.2](#) (on page 215).

110944 The following options shall be supported:

110945 **-r** *SID* Uniquely identify which delta is no longer intended. (This would have been  
 110946 specified by *get* as the new delta.) The use of this option is necessary only if two or  
 110947 more outstanding *get* commands for editing on the same SCCS file were done by  
 110948 the same person (login name).

110949 **-s** Suppress the writing to standard output of the intended delta's *SID*.

110950 **-n** Retain the file that was obtained by *get*, which would normally be removed from  
 110951 the current directory.

110952 **OPERANDS**

110953 The following operands shall be supported:

110954 *file* A pathname of an existing SCCS file or a directory. If *file* is a directory, the *unget*  
 110955 utility shall behave as though each file in the directory were specified as a named  
 110956 file, except that non-SCCS files (last component of the pathname does not begin  
 110957 with **s**.) and unreadable files shall be silently ignored.

110958 If exactly one *file* operand appears, and it is **'-'**, the standard input shall be read;  
 110959 each line of the standard input shall be taken to be the name of an SCCS file to be  
 110960 processed. Non-SCCS files and unreadable files shall be silently ignored.

110961 **STDIN**

110962 The standard input shall be a text file used only when the *file* operand is specified as **'-'**. Each  
 110963 line of the text file shall be interpreted as an SCCS pathname.

110964 **INPUT FILES**

110965 Any SCCS files processed shall be files of an unspecified format.

110966 **ENVIRONMENT VARIABLES**110967 The following environment variables shall affect the execution of *unget*:

110968 **LANG** Provide a default value for the internationalization variables that are unset or null.  
 110969 (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 110970 variables used to determine the values of locale categories.)

110971 **LC\_ALL** If set to a non-empty string value, override the values of all the other  
 110972 internationalization variables.

110973 **LC\_CTYPE** Determine the locale for the interpretation of sequences of bytes of text data as  
 110974 characters (for example, single-byte as opposed to multi-byte characters in  
 110975 arguments and input files).

110976 **LC\_MESSAGES**

110977 Determine the locale that should be used to affect the format and contents of  
 110978 diagnostic messages written to standard error.

110979 *NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

110980 **ASYNCHRONOUS EVENTS**

110981 Default.

110982 **STDOUT**

110983 The standard output shall consist of a line for each file, in the following format:

110984 "%s\n", <*SID removed from file*>

110985 If there is more than one named file or if a directory or standard input is named, each pathname

110986 shall be written before each of the preceding lines:

110987 "\n%s:\n", <*pathname*>

110988 **STDERR**

110989 The standard error shall be used only for diagnostic messages.

110990 **OUTPUT FILES**

110991 Any SCCS files updated shall be files of an unspecified format. During processing of a *file*, a

110992 locking *z-file*, as described in *get*, and a *q-file* (a working copy of the *p-file*), may be created and

110993 deleted. The *p-file* and *g-file*, as described in *get*, shall be deleted.

110994 **EXTENDED DESCRIPTION**

110995 None.

110996 **EXIT STATUS**

110997 The following exit values shall be returned:

110998 0 Successful completion.

110999 >0 An error occurred.

111000 **CONSEQUENCES OF ERRORS**

111001 Default.

111002 **APPLICATION USAGE**

111003 None.

111004 **EXAMPLES**

111005 None.

111006 **RATIONALE**

111007 None.

111008 **FUTURE DIRECTIONS**

111013 **CHANGE HISTORY**

111014 First released in Issue 2.

111015 **Issue 6**

111016 The normative text is reworded to avoid use of the term “must” for application requirements.

111017 **Issue 7**  
111018

SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

111019 **NAME**

111020        **uniq** — report or filter out repeated lines in a file

111021 **SYNOPSIS**

111022        **uniq** [**-c|-d|-u**] [**-f** *fields*] [**-s** *char*] [*input\_file* [*output\_file*]]

111023 **DESCRIPTION**

111024        The *uniq* utility shall read an input file comparing adjacent lines, and write one copy of each  
111025        input line on the output. The second and succeeding copies of repeated adjacent input lines shall  
111026        not be written. The trailing <newline> of each line in the input shall be ignored when doing  
111027        comparisons.

111028        Repeated lines in the input shall not be detected if they are not adjacent.

111029 **OPTIONS**

111030        The *uniq* utility shall conform to XBD [Section 12.2](#) (on page 215), except that '+' may be  
111031        recognized as an option delimiter as well as '-'.  
111032        The following options shall be supported:

111033        **-c**            Precede each output line with a count of the number of times the line occurred in  
111034                      the input.

111035        **-d**            Suppress the writing of lines that are not repeated in the input.

111036        **-f** *fields*    Ignore the first *fields* fields on each input line when doing comparisons, where  
111037                      *fields* is a positive decimal integer. A field is the maximal string matched by the  
111038                      basic regular expression:

111039                      `[[:blank:]]*([[:blank:]]*)`

111040                      If the *fields* option-argument specifies more fields than appear on an input line, a  
111041                      null string shall be used for comparison.

111042        **-s** *chars*    Ignore the first *chars* characters when doing comparisons, where *chars* shall be a  
111043                      positive decimal integer. If specified in conjunction with the **-f** option, the first  
111044                      *chars* characters after the first *fields* fields shall be ignored. If the *chars* option-  
111045                      argument specifies more characters than remain on an input line, a null string shall  
111046                      be used for comparison.

111047        **-u**            Suppress the writing of lines that are repeated in the input.

111048 **OPERANDS**

111049        The following operands shall be supported:

111050        *input\_file*    A pathname of the input file. If the *input\_file* operand is not specified, or if the  
111051                      *input\_file* is '-', the standard input shall be used.

111052        *output\_file*   A pathname of the output file. If the *output\_file* operand is not specified, the  
111053                      standard output shall be used. The results are unspecified if the file named by  
111054                      *output\_file* is the file named by *input\_file*.

111055 **STDIN**

111056        The standard input shall be used only if no *input\_file* operand is specified or if *input\_file* is '-'.  
111057        See the INPUT FILES section.

111058 **INPUT FILES**

111059        The input file shall be a text file.

111060 **ENVIRONMENT VARIABLES**

111061 The following environment variables shall affect the execution of *uniq*:

111062 *LANG* Provide a default value for the internationalization variables that are unset or null.  
 111063 (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 111064 variables used to determine the values of locale categories.)

111065 *LC\_ALL* If set to a non-empty string value, override the values of all the other  
 111066 internationalization variables.

111067 *LC\_COLLATE*  
 111068 Determine the locale for ordering rules.

111069 *LC\_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as  
 111070 characters (for example, single-byte as opposed to multi-byte characters in  
 111071 arguments and input files) and which characters constitute a <blank> in the  
 111072 current locale.

111073 *LC\_MESSAGES*  
 111074 Determine the locale that should be used to affect the format and contents of  
 111075 diagnostic messages written to standard error.

111076 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

111077 **ASYNCHRONOUS EVENTS**

111078 Default.

111079 **STDOUT**

111080 The standard output shall be used if no *output\_file* operand is specified, and shall be used if the  
 111081 *output\_file* operand is '-' and the implementation treats the '-' as meaning standard output.  
 111082 Otherwise, the standard output shall not be used. See the OUTPUT FILES section.

111083 **STDERR**

111084 The standard error shall be used only for diagnostic messages.

111085 **OUTPUT FILES**

111086 If the *-c* option is specified, the output file shall be empty or each line shall be of the form:

111087 "%d %s", <number of duplicates>, <line>

111088 otherwise, the output file shall be empty or each line shall be of the form:

111089 "%s", <line>

111090 **EXTENDED DESCRIPTION**

111091 None.

111092 **EXIT STATUS**

111093 The following exit values shall be returned:

111094 0 The utility executed successfully.

111095 >0 An error occurred.

111096 **CONSEQUENCES OF ERRORS**

111097 Default.

## 111098 APPLICATION USAGE

111099 The *sort* utility can be used to cause repeated lines to be adjacent in the input file.

## 111100 EXAMPLES

111101 The following input file data (but flushed left) was used for a test series on *uniq*:

```
111102 #01 foo0 bar0 fool bar1
111103 #02 bar0 fool bar1 fool
111104 #03 foo0 bar0 fool bar1
111105 #04
111106 #05 foo0 bar0 fool bar1
111107 #06 foo0 bar0 fool bar1
111108 #07 bar0 fool bar1 foo0
```

111109 What follows is a series of test invocations of the *uniq* utility that use a mixture of *uniq* options  
 111110 against the input file data. These tests verify the meaning of *adjacent*. The *uniq* utility views the  
 111111 input data as a sequence of strings delimited by '*\n*'. Accordingly, for the *fields*th member of  
 111112 the sequence, *uniq* interprets unique or repeated adjacent lines strictly relative to the *fields*+1th  
 111113 member.

- 111114 1. This first example tests the line counting option, comparing each line of the input file data  
 111115 starting from the second field:

```
111116 uniq -c -f 1 uniq_0I.t
111117 1 #01 foo0 bar0 fool bar1
111118 1 #02 bar0 fool bar1 fool
111119 1 #03 foo0 bar0 fool bar1
111120 1 #04
111121 2 #05 foo0 bar0 fool bar1
111122 1 #07 bar0 fool bar1 foo0
```

111123 The number '*2*', prefixing the fifth line of output, signifies that the *uniq* utility detected a  
 111124 pair of repeated lines. Given the input data, this can only be true when *uniq* is run using  
 111125 the *-f 1* option (which shall cause *uniq* to ignore the first field on each input line).

- 111126 2. The second example tests the option to suppress unique lines, comparing each line of the  
 111127 input file data starting from the second field:

```
111128 uniq -d -f 1 uniq_0I.t
111129 #05 foo0 bar0 fool bar1
```

- 111130 3. This test suppresses repeated lines, comparing each line of the input file data starting  
 111131 from the second field:

```
111132 uniq -u -f 1 uniq_0I.t
111133 #01 foo0 bar0 fool bar1
111134 #02 bar0 fool bar1 fool
111135 #03 foo0 bar0 fool bar1
111136 #04
111137 #07 bar0 fool bar1 foo0
```

- 111138 4. This suppresses unique lines, comparing each line of the input file data starting from the  
 111139 third character:

```
111140 uniq -d -s 2 uniq_0I.t
```

111141 In the last example, the *uniq* utility found no input matching the above criteria.

**111142 RATIONALE**

111143 Some historical implementations have limited lines to be 1 080 bytes in length, which does not  
111144 meet the implied {LINE\_MAX} limit.

111145 Earlier versions of this standard allowed the *-number* and *+number* options. These options are no  
111146 longer specified by POSIX.1-2008 but may be present in some implementations.

**111147 FUTURE DIRECTIONS**

111148 None.

**111149 SEE ALSO**

111151 XBD [Chapter 8](#) (on page 173), [Section 12.2](#) (on page 215)

**111152 CHANGE HISTORY**

111153 First released in Issue 2.

**111154 Issue 6**

111155 The obsolescent SYNOPSIS and associated text are removed.

111156 The normative text is reworded to avoid use of the term “must” for application requirements.

111157 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/40 is applied, adding *LC\_COLLATE* to the  
111158 ENVIRONMENT VARIABLES section, and changing “the application shall ensure that” in the  
111159 OUTPUT FILES section.

**111160 Issue 7**

111161 Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying that ‘+’ may be recognized  
111162 as an option delimiter in the OPTIONS section.

111163 Austin Group Interpretation 1003.1-2001 #092 is applied.

111164 Austin Group Interpretation 1003.1-2001 #133 is applied, clarifying the behavior of the trailing  
111165 <newline>.

111166 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

111167 SD5-XCU-ERN-141 is applied, updating the EXAMPLES section.

111168 **NAME**

111169 unlink — call the *unlink()* function

111170 **SYNOPSIS**

111171 XSI `unlink file`

111172 **DESCRIPTION**

111173 The *unlink* utility shall perform the function call:

111174 `unlink (file);`

111175 A user may need appropriate privileges to invoke the *unlink* utility.

111176 **OPTIONS**

111177 None.

111178 **OPERANDS**

111179 The following operands shall be supported:

111180 *file* The pathname of an existing file.

111181 **STDIN**

111182 Not used.

111183 **INPUT FILES**

111184 Not used.

111185 **ENVIRONMENT VARIABLES**

111186 The following environment variables shall affect the execution of *unlink*:

111187 *LANG* Provide a default value for the internationalization variables that are unset or null.  
111188 (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
111189 variables used to determine the values of locale categories.)

111190 *LC\_ALL* If set to a non-empty string value, override the values of all the other  
111191 internationalization variables.

111192 *LC\_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as  
111193 characters (for example, single-byte as opposed to multi-byte characters in  
111194 arguments).

111195 *LC\_MESSAGES*  
111196 Determine the locale that should be used to affect the format and contents of  
111197 diagnostic messages written to standard error.

111198 *NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

111199 **ASYNCHRONOUS EVENTS**

111200 Default.

111201 **STDOUT**

111202 None.

111203 **STDERR**

111204 The standard error shall be used only for diagnostic messages.

111205 **OUTPUT FILES**

111206 None.

111207 **EXTENDED DESCRIPTION**

111208 None.

111209 **EXIT STATUS**

111210 The following exit values shall be returned:

111211 0 Successful completion.

111212 &gt;0 An error occurred.

111213 **CONSEQUENCES OF ERRORS**

111214 Default.

111215 **APPLICATION USAGE**

111216 None.

111217 **EXAMPLES**

111218 None.

111219 **RATIONALE**

111220 None.

111222 None.

111223 **SEE ALSO**111224 *link, rm*111225 XBD [Chapter 8](#) (on page 173)111226 XSH *[unlink\(\)](#)*111227 **CHANGE HISTORY**

111228 First released in Issue 5.

111229 **NAME**

111230 uucp — system-to-system copy

111231 **SYNOPSIS**111232 UU `uucp [-cCdfjmr] [-n user] source-file... destination-file`111233 **DESCRIPTION**

111234 The *uucp* utility shall copy files named by the *source-file* argument to the *destination-file* argument.  
 111235 The files named can be on local or remote systems.

111236 The *uucp* utility cannot guarantee support for all character encodings in all circumstances. For  
 111237 example, transmission data may be restricted to 7 bits by the underlying network, 8-bit data and  
 111238 filenames need not be portable to non-internationalized systems, and so on. Under these  
 111239 circumstances, it is recommended that only characters defined in the ISO/IEC 646:1991  
 111240 standard International Reference Version (equivalent to ASCII) 7-bit range of characters be used,  
 111241 and that only characters defined in the portable filename character set be used for naming files.  
 111242 The protocol for transfer of files is unspecified by POSIX.1-2008.

111243 Typical implementations of this utility require a communications line configured to use XBD  
 111244 [Chapter 11](#) (on page 199), but other communications means may be used. On systems where  
 111245 there are no available communications means (either temporarily or permanently), this utility  
 111246 shall write an error message describing the problem and exit with a non-zero exit status.

111247 **OPTIONS**111248 The *uucp* utility shall conform to XBD [Section 12.2](#) (on page 215).

111249 The following options shall be supported:

- 111250 **-c** Do not copy local file to the spool directory for transfer to the remote machine  
 111251 (default).
- 111252 **-C** Force the copy of local files to the spool directory for transfer.
- 111253 **-d** Make all necessary directories for the file copy (default).
- 111254 **-f** Do not make intermediate directories for the file copy.
- 111255 **-j** Write the job identification string to standard output. This job identification can be  
 111256 used by *uustat* to obtain the status or terminate a job.
- 111257 **-m** Send mail to the requester when the copy is completed.
- 111258 **-n user** Notify *user* on the remote system that a file was sent.
- 111259 **-r** Do not start the file transfer; just queue the job.

111260 **OPERANDS**

111261 The following operands shall be supported:

111262 *destination-file, source-file*

111263 A pathname of a file to be copied to, or from, respectively. Either name can be a  
 111264 pathname on the local machine, or can have the form:

111265 *system-name!pathname*

111266 where *system-name* is taken from a list of system names that *uucp* knows about.  
 111267 The destination *system-name* can also be a list of names such as:

111268 *system-name!system-name!...!system-name!pathname*

111269 in which case, an attempt is made to send the file via the specified route to the

111270 destination. Care should be taken to ensure that intermediate nodes in the route  
111271 are willing to forward information.

111272 The shell pattern matching notation characters ' ? ' , ' \* ' , and " [ . . . ] " appearing  
111273 in *pathname* shall be expanded on the appropriate system.

111274 Pathnames can be one of:

- 111275 1. An absolute pathname.
- 111276 2. A pathname preceded by *~user* where *user* is a login name on the specified  
111277 system and is replaced by that user's login directory. Note that if an invalid  
111278 login is specified, the default is to the public directory (called *PUBDIR*; the  
111279 actual location of *PUBDIR* is implementation-defined).
- 111280 3. A pathname preceded by *~/destination* where *destination* is appended to  
111281 *PUBDIR*.

111282 **Note:** This destination is treated as a filename unless more than one file is being  
111283 transferred by this request or the destination is already a directory. To  
111284 ensure that it is a directory, follow the destination with a ' / ' . For  
111285 example, *~/dan/* as the destination makes the directory **PUBDIR/dan** if it  
111286 does not exist and puts the requested files in that directory.

- 111287 4. Anything else shall be prefixed by the current directory.

111288 If the result is an erroneous pathname for the remote system, the copy shall fail. If  
111289 the *destination-file* is a directory, the last part of the *source-file* name shall be used.

111290 The read, write, and execute permissions given by *uucp* are implementation-  
111291 defined.

## 111292 STDIN

111293 Not used.

## 111294 INPUT FILES

111295 The files to be copied are regular files.

## 111296 ENVIRONMENT VARIABLES

111297 The following environment variables shall affect the execution of *uucp*:

111298 *LANG* Provide a default value for the internationalization variables that are unset or null.  
111299 (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
111300 variables used to determine the values of locale categories.)

111301 *LC\_ALL* If set to a non-empty string value, override the values of all the other  
111302 internationalization variables.

111303 *LC\_COLLATE*  
111304 Determine the locale for the behavior of ranges, equivalence classes, and multi-  
111305 character collating elements within bracketed filename patterns.

111306 *LC\_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as  
111307 characters (for example, single-byte as opposed to multi-byte characters in  
111308 arguments and input files) and the behavior of character classes within bracketed  
111309 filename patterns (for example, " ' [ : lower : ] \* ' ").

111310 *LC\_MESSAGES*  
111311 Determine the locale that should be used to affect the format and contents of  
111312 diagnostic messages written to standard error, and informative messages written  
111313 to standard output.

- 111314 *NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.
- 111315 **ASYNCHRONOUS EVENTS**
- 111316 Default.
- 111317 **STDOUT**
- 111318 Not used.
- 111319 **STDERR**
- 111320 The standard error shall be used only for diagnostic messages.
- 111321 **OUTPUT FILES**
- 111322 The output files (which may be on other systems) are copies of the input files.
- 111323 If *-m* is used, mail files are modified.
- 111324 **EXTENDED DESCRIPTION**
- 111325 None.
- 111326 **EXIT STATUS**
- 111327 The following exit values shall be returned:
- 111328 0 Successful completion.
- 111329 >0 An error occurred.
- 111330 **CONSEQUENCES OF ERRORS**
- 111331 Default.
- 111332 **APPLICATION USAGE**
- 111333 This utility is part of the UUCP Utilities option and need not be supported by all implementations.
- 111334
- 111335 The domain of remotely accessible files can (and for obvious security reasons usually should) be severely restricted.
- 111336
- 111337 Note that the *'!'* character in addresses has to be escaped when using *cs**h* as a command interpreter because of its history substitution syntax. For *ksh* and *sh* the escape is not necessary, but may be used.
- 111338
- 111339
- 111340 As noted above, shell metacharacters appearing in pathnames are expanded on the appropriate system. On an internationalized system, this is done under the control of local settings of *LC\_COLLATE* and *LC\_CTYPE*. Thus, care should be taken when using bracketed filename patterns, as collation and typing rules may vary from one system to another. Also be aware that certain types of expression (that is, equivalence classes, character classes, and collating symbols) need not be supported on non-internationalized systems.
- 111341
- 111342
- 111343
- 111344
- 111345
- 111346 **EXAMPLES**
- 111347 None.
- 111348 **RATIONALE**
- 111349 None.
- 111350 **FUTURE DIRECTIONS**
- 111351 None.
- 111352 **SEE ALSO**
- 111353 *mailx*, *uuencode*, *uustat*, *uux*

111355 **CHANGE HISTORY**

111356 First released in Issue 2.

111357 **Issue 6**111358 The *LC\_TIME* and *TZ* entries are removed from the ENVIRONMENT VARIABLES section.111359 The UN margin codes and associated shading are removed from the *-C*, *-f*, *-j*, *-n*, and *-r*  
111360 options in response to The Open Group Base Resolution bwg2001-003.111361 **Issue 7**

111362 SD5-XCU-ERN-46 is applied, moving this utility to the UUCP Utilities Option Group.

111363 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

111364 **NAME**

111365       uudecode — decode a binary file

111366 **SYNOPSIS**111367       uudecode [-o *outfile*] [*file*]111368 **DESCRIPTION**

111369       The *uudecode* utility shall read a file, or standard input if no file is specified, that includes data  
 111370       created by the *uuencode* utility. The *uudecode* utility shall scan the input file, searching for data  
 111371       compatible with one of the formats specified in *uuencode*, and attempt to create or overwrite the  
 111372       file described by the data (or overridden by the **-o** option). The pathname shall be contained in  
 111373       the data or specified by the **-o** option. The file access permission bits and contents for the file to  
 111374       be produced shall be contained in that data. The mode bits of the created file (other than  
 111375       standard output) shall be set from the file access permission bits contained in the data; that is,  
 111376       other attributes of the mode, including the file mode creation mask (see *umask*), shall not affect  
 111377       the file being produced. If either of the *op* characters '+' and '-' (see *chmod*) are specified in  
 111378       symbolic mode, the initial mode on which those operations are based is unspecified.

111379       If the pathname of the file to be produced exists, and the user does not have write permission on  
 111380       that file, *uudecode* shall terminate with an error. If the pathname of the file to be produced exists,  
 111381       and the user has write permission on that file, the existing file shall be overwritten.

111382       If the input data was produced by *uuencode* on a system with a different number of bits per byte  
 111383       than on the target system, the results of *uudecode* are unspecified.

111384 **OPTIONS**111385       The *uudecode* utility shall conform to XBD [Section 12.2](#) (on page 215).

111386       The following option shall be supported by the implementation:

111387       **-o *outfile***    A pathname of a file that shall be used instead of any pathname contained in the  
 111388       input data. Specifying an *outfile* option-argument of **/dev/stdout** shall indicate  
 111389       standard output.

111390 **OPERANDS**

111391       The following operand shall be supported:

111392       *file*            The pathname of a file containing the output of *uuencode*.111393 **STDIN**

111394       See the INPUT FILES section.

111395 **INPUT FILES**111396       The input files shall be files containing the output of *uuencode*.111397 **ENVIRONMENT VARIABLES**111398       The following environment variables shall affect the execution of *uudecode*:

111399       **LANG**            Provide a default value for the internationalization variables that are unset or null.  
 111400       (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 111401       variables used to determine the values of locale categories.)

111402       **LC\_ALL**          If set to a non-empty string value, override the values of all the other  
 111403       internationalization variables.

111404       **LC\_CTYPE**       Determine the locale for the interpretation of sequences of bytes of text data as  
 111405       characters (for example, single-byte as opposed to multi-byte characters in  
 111406       arguments and input files).

111407 *LC\_MESSAGES*  
 111408 Determine the locale that should be used to affect the format and contents of  
 111409 diagnostic messages written to standard error.

111410 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

111411 **ASYNCHRONOUS EVENTS**  
 111412 Default.

111413 **STDOUT**  
 111414 If the file data header encoded by *uuencode* is `-` or `/dev/stdout`, or the `-o /dev/stdout` option  
 111415 overrides the file data, the standard output shall be in the same format as the file originally  
 111416 encoded by *uuencode*. Otherwise, the standard output shall not be used.

111417 **STDERR**  
 111418 The standard error shall be used only for diagnostic messages.

111419 **OUTPUT FILES**  
 111420 The output file shall be in the same format as the file originally encoded by *uuencode*.

111421 **EXTENDED DESCRIPTION**  
 111422 None.

111423 **EXIT STATUS**  
 111424 The following exit values shall be returned:  
 111425 0 Successful completion.  
 111426 >0 An error occurred.

111427 **CONSEQUENCES OF ERRORS**  
 111428 Default.

111429 **APPLICATION USAGE**  
 111430 The user who is invoking *uudecode* must have write permission on any file being created.

111431 The output of *uuencode* is essentially an encoded bit stream that is not cognizant of byte  
 111432 boundaries. It is possible that a 9-bit byte target machine can process input from an 8-bit source,  
 111433 if it is aware of the requirement, but the reverse is unlikely to be satisfying. Of course, the only  
 111434 data that is meaningful for such a transfer between architectures is generally character data.

111435 **EXAMPLES**  
 111436 None.

111437 **RATIONALE**  
 111438 Input files are not necessarily text files, as stated by an early proposal. Although the *uuencode*  
 111439 output is a text file, that output could have been wrapped within another file or mail message  
 111440 that is not a text file.

111441 The `-o` option is not historical practice, but was added at the request of WG15 so that the user  
 111442 could override the target pathname without having to edit the input data itself.

111443 In early drafts, the `[-o outfile]` option-argument allowed the use of `-` to mean standard output.  
 111444 The symbol `-` has only been used previously in POSIX.1-2008 as a standard input indicator. The  
 111445 standard developers did not wish to overload the meaning of `-` in this manner. The `/dev/stdout`  
 111446 concept exists on most modern systems. The `/dev/stdout` syntax does not refer to a new special  
 111447 file. It is just a magic cookie to specify standard output.

111448 **FUTURE DIRECTIONS**

111449 None.

111450 **SEE ALSO**111451 *chmod*, *umask*, *uuencode*111452 XBD [Chapter 8](#) (on page 173), [Section 12.2](#) (on page 215)111453 **CHANGE HISTORY**

111454 First released in Issue 4.

111455 **Issue 6**

111456 This utility is marked as part of the User Portability Utilities option.

111457 The **-o** *outfile* option is added, as specified in the IEEE P1003.2b draft standard.

111458 The normative text is reworded to avoid use of the term “must” for application requirements.

111459 IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/35 is applied, clarifying in the  
111460 DESCRIPTION that the initial mode used if either of the *op* characters is '+' or '-' is  
111461 unspecified.

111462 **Issue 7**

111463 The *uudecode* utility is moved from the User Portability Utilities option to the Base. User  
111464 Portability Utilities is now an option for interactive utilities.

111465 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

111466 **NAME**

111467 uuencode — encode a binary file

111468 **SYNOPSIS**111469 uuencode [-m] [*file*] *decode\_pathname*111470 **DESCRIPTION**

111471 The *uuencode* utility shall write an encoded version of the named input file, or standard input if  
 111472 no *file* is specified, to standard output. The output shall be encoded using one of the algorithms  
 111473 described in the STDOUT section and shall include the file access permission bits (in *chmod* octal  
 111474 or symbolic notation) of the input file and the *decode\_pathname*, for re-creation of the file on  
 111475 another system that conforms to this volume of POSIX.1-2008.

111476 **OPTIONS**111477 The *uuencode* utility shall conform to XBD [Section 12.2](#) (on page 215).

111478 The following option shall be supported by the implementation:

111479 **-m** Encode the output using the MIME Base64 algorithm described in STDOUT. If **-m**  
 111480 is not specified, the historical algorithm described in STDOUT shall be used.

111481 **OPERANDS**

111482 The following operands shall be supported:

111483 *decode\_pathname*

111484 The pathname of the file into which the *uudecode* utility shall place the decoded  
 111485 file. Specifying a *decode\_pathname* operand of **/dev/stdout** shall indicate that  
 111486 *uudecode* is to use standard output. If there are characters in *decode\_pathname* that  
 111487 are not in the portable filename character set the results are unspecified.

111488 *file* A pathname of the file to be encoded.

111489 **STDIN**

111490 See the INPUT FILES section.

111491 **INPUT FILES**

111492 Input files can be files of any type.

111493 **ENVIRONMENT VARIABLES**111494 The following environment variables shall affect the execution of *uuencode*:

111495 **LANG** Provide a default value for the internationalization variables that are unset or null.  
 111496 (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 111497 variables used to determine the values of locale categories.)

111498 **LC\_ALL** If set to a non-empty string value, override the values of all the other  
 111499 internationalization variables.

111500 **LC\_CTYPE** Determine the locale for the interpretation of sequences of bytes of text data as  
 111501 characters (for example, single-byte as opposed to multi-byte characters in  
 111502 arguments and input files).

111503 **LC\_MESSAGES**

111504 Determine the locale that should be used to affect the format and contents of  
 111505 diagnostic messages written to standard error.

111506 **XS** **NLSPATH** Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

111507 **ASYNCHRONOUS EVENTS**

111508 Default.

111509 **STDOUT**111510 **uuencode Base64 Algorithm**

111511 The standard output shall be a text file (encoded in the character set of the current locale) that  
 111512 begins with the line:

111513 "begin-base64Δ%sΔs\n", <mode>, <decode\_pathname>

111514 and ends with the line:

111515 "====\n"

111516 In both cases, the lines shall have no preceding or trailing <blank> characters.

111517 The encoding process represents 24-bit groups of input bits as output strings of four encoded  
 111518 characters. Proceeding from left to right, a 24-bit input group shall be formed by concatenating  
 111519 three 8-bit input groups. Each 24-bit input group then shall be treated as four concatenated 6-bit  
 111520 groups, each of which shall be translated into a single digit in the Base64 alphabet. When  
 111521 encoding a bit stream via the Base64 encoding, the bit stream shall be presumed to be ordered  
 111522 with the most-significant bit first. That is, the first bit in the stream shall be the high-order bit in  
 111523 the first byte, and the eighth bit shall be the low-order bit in the first byte, and so on. Each 6-bit  
 111524 group is used as an index into an array of 64 printable characters, as shown in [Table 4-22](#).

111525 **Table 4-22 uuencode Base64 Values**

| Value | Encoding | Value | Encoding | Value | Encoding | Value | Encoding |
|-------|----------|-------|----------|-------|----------|-------|----------|
| 0     | A        | 17    | R        | 34    | i        | 51    | z        |
| 1     | B        | 18    | S        | 35    | j        | 52    | 0        |
| 2     | C        | 19    | T        | 36    | k        | 53    | 1        |
| 3     | D        | 20    | U        | 37    | l        | 54    | 2        |
| 4     | E        | 21    | V        | 38    | m        | 55    | 3        |
| 5     | F        | 22    | W        | 39    | n        | 56    | 4        |
| 6     | G        | 23    | X        | 40    | o        | 57    | 5        |
| 7     | H        | 24    | Y        | 41    | p        | 58    | 6        |
| 8     | I        | 25    | Z        | 42    | q        | 59    | 7        |
| 9     | J        | 26    | a        | 43    | r        | 60    | 8        |
| 10    | K        | 27    | b        | 44    | s        | 61    | 9        |
| 11    | L        | 28    | c        | 45    | t        | 62    | +        |
| 12    | M        | 29    | d        | 46    | u        | 63    | /        |
| 13    | N        | 30    | e        | 47    | v        | (pad) | =        |
| 14    | O        | 31    | f        | 48    | w        |       |          |
| 15    | P        | 32    | g        | 49    | x        |       |          |
| 16    | Q        | 33    | h        | 50    | y        |       |          |

111544 The character referenced by the index shall be placed in the output string.

111545 The output stream (encoded bytes) shall be represented in lines of no more than 76 characters  
 111546 each. All line breaks or other characters not found in the table shall be ignored by decoding  
 111547 software (see [uudecode](#)).

111548 Special processing shall be performed if fewer than 24 bits are available at the end of a message  
 111549 or encapsulated part of a message. A full encoding quantum shall always be completed at the

end of a message. When fewer than 24 input bits are available in an input group, zero bits shall be added (on the right) to form an integral number of 6-bit groups. Output character positions that are not required to represent actual input data shall be set to the character '='. Since all Base64 input is an integral number of octets, only the following cases can arise:

1. The final quantum of encoding input is an integral multiple of 24 bits; here, the final unit of encoded output shall be an integral multiple of 4 characters with no '=' padding.
2. The final quantum of encoding input is exactly 16 bits; here, the final unit of encoded output shall be three characters followed by one '=' padding character.
3. The final quantum of encoding input is exactly 8 bits; here, the final unit of encoded output shall be two characters followed by two '=' padding characters.

A terminating "====" evaluates to nothing and denotes the end of the encoded data.

### uuencode Historical Algorithm

The standard output shall be a text file (encoded in the character set of the current locale) that begins with the line:

```
"beginΔ%sΔ%s\n" <mode>, <decode_pathname>
```

and ends with the line:

```
"end\n"
```

In both cases, the lines shall have no preceding or trailing <blank> characters.

The algorithm that shall be used for lines in between **begin** and **end** takes three octets as input and writes four characters of output by splitting the input at six-bit intervals into four octets, containing data in the lower six bits only. These octets shall be converted to characters by adding a value of 0x20 to each octet, so that each octet is in the range [0x20,0x5f], and then it shall be assumed to represent a printable character in the ISO/IEC 646:1991 standard encoded character set. It then shall be translated into the corresponding character codes for the codeset in use in the current locale. (For example, the octet 0x41, representing 'A', would be translated to 'A' in the current codeset, such as 0xc1 if it were EBCDIC.)

Where the bits of two octets are combined, the least significant bits of the first octet shall be shifted left and combined with the most significant bits of the second octet shifted right. Thus the three octets *A*, *B*, *C* shall be converted into the four octets:

```
0x20 + ((A >> 2) & 0x3F)
0x20 + (((A << 4) | ((B >> 4) & 0xF)) & 0x3F)
0x20 + (((B << 2) | ((C >> 6) & 0x3)) & 0x3F)
0x20 + ((C) & 0x3F)
```

These octets then shall be translated into the local character set.

Each encoded line contains a length character, equal to the number of characters to be decoded plus 0x20 translated to the local character set as described above, followed by the encoded characters. The maximum number of octets to be encoded on each line shall be 45.

### STDERR

The standard error shall be used only for diagnostic messages.

**111589 OUTPUT FILES**

111590       None.

**111591 EXTENDED DESCRIPTION**

111592       None.

**111593 EXIT STATUS**

111594       The following exit values shall be returned:

111595       0   Successful completion.

111596       >0  An error occurred.

**111597 CONSEQUENCES OF ERRORS**

111598       Default.

**111599 APPLICATION USAGE**

111600       The file is expanded by 35 percent (each three octets become four, plus control information) causing it to take longer to transmit.

111602       Since this utility is intended to create files to be used for data interchange between systems with possibly different codesets, and to represent binary data as a text file, the ISO/IEC 646:1991 standard was chosen for a midpoint in the algorithm as a known reference point. The output from *uuencode* is a text file on the local system. If the output were in the ISO/IEC 646:1991 standard codeset, it might not be a text file (at least because the <newline> characters might not match), and the goal of creating a text file would be defeated. If this text file was then carried to another machine with the same codeset, it would be perfectly compatible with that system's *uudecode*. If it was transmitted over a mail system or sent to a machine with a different codeset, it is assumed that, as for every other text file, some translation mechanism would convert it (by the time it reached a user on the other system) into an appropriate codeset. This translation only makes sense from the local codeset, not if the file has been put into a ISO/IEC 646:1991 standard representation first. Similarly, files processed by *uuencode* can be placed in *pax* archives, intermixed with other text files in the same codeset.

**111615 EXAMPLES**

111616       None.

**111617 RATIONALE**

111618       A new algorithm was added at the request of the international community to parallel work in RFC 2045 (MIME). As with the historical *uuencode* format, the Base64 Content-Transfer-Encoding is designed to represent arbitrary sequences of octets in a form that is not humanly readable. A 65-character subset of the ISO/IEC 646:1991 standard is used, enabling 6 bits to be represented per printable character. (The extra 65th character, '=', is used to signify a special processing function.)

111624       This subset has the important property that it is represented identically in all versions of the ISO/IEC 646:1991 standard, including US ASCII, and all characters in the subset are also represented identically in all versions of EBCDIC. The historical *uuencode* algorithm does not share this property, which is the reason that a second algorithm was added to the ISO POSIX-2 standard.

111629       The string "====" was used for the termination instead of the end used in the original format because the latter is a string that could be valid encoded input.

111631       In an early draft, the *-m* option was named *-b* (for Base64), but it was renamed to reflect its relationship to the RFC 2045. A *-u* was also present to invoke the default algorithm, but since this was not historical practice, it was omitted as being unnecessary.

111634 See the RATIONALE section in *uuencode* for the derivation of the **/dev/stdout** symbol.

111635 **FUTURE DIRECTIONS**

111636 None.

111637 **SEE ALSO**

111638 *chmod*, *mailx*, *uuencode*

111639 XBD [Chapter 8](#) (on page 173), [Section 12.2](#) (on page 215)

111640 **CHANGE HISTORY**

111641 First released in Issue 4.

111642 **Issue 6**

111643 This utility is marked as part of the User Portability Utilities option.

111644 The Base64 algorithm and the ability to output to **/dev/stdout** are added as specified in the  
111645 IEEE P1003.2b draft standard.

111646 **Issue 7**

111647 The *uuencode* utility is moved from the User Portability Utilities option to the Base. User  
111648 Portability Utilities is now an option for interactive utilities.

111649 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

111650 **NAME**

111651 uustat — uucp status enquiry and job control

111652 **SYNOPSIS**111653 UU uustat [-q|-k *jobid*|-r *jobid*]111654 uustat [-s *system*] [-u *user*]111655 **DESCRIPTION**

111656 The *uustat* utility shall display the status of, or cancel, previously specified *uucp* requests, or  
 111657 provide general status on *uucp* connections to other systems.

111658 When no options are given, *uustat* shall write to standard output the status of all *uucp* requests  
 111659 issued by the current user.

111660 Typical implementations of this utility require a communications line configured to use XBD  
 111661 [Chapter 11](#) (on page 199), but other communications means may be used. On systems where  
 111662 there are no available communications means (either temporarily or permanently), this utility  
 111663 shall write an error message describing the problem and exit with a non-zero exit status.

111664 **OPTIONS**111665 The *uustat* utility shall conform to XBD [Section 12.2](#) (on page 215).

111666 The following options shall be supported:

111667 -q Write the jobs queued for each machine.

111668 -k *jobid* Kill the *uucp* request whose job identification is *jobid*. The application shall ensure  
 111669 that the killed *uucp* request belongs to the person invoking *uustat* unless that user  
 111670 has appropriate privileges.

111671 -r *jobid* Rejuvenate *jobid*. The files associated with *jobid* are touched so that their  
 111672 modification time is set to the current time. This prevents the cleanup program  
 111673 from deleting the job until the jobs modification time reaches the limit imposed by  
 111674 the program.

111675 -s *system* Write the status of all *uucp* requests for remote system *system*.111676 -u *user* Write the status of all *uucp* requests issued by *user*.111677 **OPERANDS**

111678 None.

111679 **STDIN**

111680 Not used.

111681 **INPUT FILES**

111682 None.

111683 **ENVIRONMENT VARIABLES**111684 The following environment variables shall affect the execution of *uustat*:

111685 *LANG* Provide a default value for the internationalization variables that are unset or null.  
 111686 (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 111687 variables used to determine the values of locale categories.)

111688 *LC\_ALL* If set to a non-empty string value, override the values of all the other  
 111689 internationalization variables.

111690 *LC\_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as  
111691 characters (for example, single-byte as opposed to multi-byte characters in  
111692 arguments).

111693 *LC\_MESSAGES*  
111694 Determine the locale that should be used to affect the format and contents of  
111695 diagnostic messages written to standard error, and informative messages written  
111696 to standard output.

111697 *NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

111698 **ASYNCHRONOUS EVENTS**  
111699 Default.

111700 **STDOUT**  
111701 The standard output shall consist of information about each job selected, in an unspecified  
111702 format. The information shall include at least the job ID, the user ID or name, and the remote  
111703 system name.

111704 **STDERR**  
111705 The standard error shall be used only for diagnostic messages.

111706 **OUTPUT FILES**  
111707 None.

111708 **EXTENDED DESCRIPTION**  
111709 None.

111710 **EXIT STATUS**  
111711 The following exit values shall be returned:  
111712 0 Successful completion.  
111713 >0 An error occurred.

111714 **CONSEQUENCES OF ERRORS**  
111715 Default.

111716 **APPLICATION USAGE**  
111717 This utility is part of the UUCP Utilities option and need not be supported by all  
111718 implementations.

111719 **EXAMPLES**  
111720 None.

111721 **RATIONALE**  
111722 None.

111723 **FUTURE DIRECTIONS**  
111724 None.

111725 **SEE ALSO**  
111726 *uucp*  
111727 XBD [Chapter 8](#) (on page 173), [Chapter 11](#) (on page 199), [Section 12.2](#) (on page 215)

111728 **CHANGE HISTORY**  
111729 First released in Issue 2.

111730 **Issue 6**

111731 The normative text is reworded to avoid use of the term “must” for application requirements.

111732 The *LC\_TIME* and *TZ* entries are removed from the ENVIRONMENT VARIABLES section.

111733 The UN margin code and associated shading are removed from the *-q* option in response to The  
111734 Open Group Base Resolution bwg2001-003.

111735 **Issue 7**

111736 SD5-XCU-ERN-46 is applied, moving this utility to the UUCP Utilities Option Group.

111737 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

111738 **NAME**

111739       uux — remote command execution

111740 **SYNOPSIS**111741 UU       uux [-jnp] *command-string*111742 **DESCRIPTION**

111743       The *uux* utility shall gather zero or more files from various systems, execute a shell pipeline (see  
 111744       [Section 2.9](#), on page 2338) on a specified system, and then send the standard output of the  
 111745       command to a file on a specified system. Only the first command of a pipeline can have a *system-*  
 111746       *name!* prefix. All other commands in the pipeline shall be executed on the system of the first  
 111747       command.

111748       The following restrictions are applicable to the shell pipeline processed by *uux*:

- 111749       • In gathering files from different systems, pathname expansion shall not be performed by  
 111750       *uux*. Thus, a request such as:

111751       uux "c99 remsys!~/\*.c"

111752       would attempt to copy the file named literally \*.c to the local system.

- 111753       • The redirection operators ">>", "<<", ">|", and ">&" shall not be accepted. Any use of  
 111754       these redirection operators shall cause this utility to write an error message describing the  
 111755       problem and exit with a non-zero exit status.
- 111756       • The reserved word ! cannot be used at the head of the pipeline to modify the exit status.  
 111757       (See the *command-string* operand description below.)
- 111758       • Alias substitution shall not be performed.

111759       A filename can be specified as for *uucp*; it can be an absolute pathname, a pathname preceded by  
 111760       ~*name* (which is replaced by the corresponding login directory), a pathname specified as ~/*dest*  
 111761       (*dest* is prefixed by the public directory called *PUBDIR*; the actual location of *PUBDIR* is  
 111762       implementation-defined), or a simple filename (which is prefixed by *uux* with the current  
 111763       directory). See *uucp* for the details.

111764       The execution of commands on remote systems shall take place in an execution directory known  
 111765       to the *uucp* system. All files required for the execution shall be put into this directory unless they  
 111766       already reside on that machine. Therefore, the application shall ensure that non-local filenames  
 111767       (without path or machine reference) are unique within the *uux* request.

111768       The *uux* utility shall attempt to get all files to the execution system. For files that are output files,  
 111769       the application shall ensure that the filename is escaped using parentheses.

111770       The remote system shall notify the user by mail if the requested command on the remote system  
 111771       was disallowed or the files were not accessible. This notification can be turned off by the -n  
 111772       option.

111773       Typical implementations of this utility require a communications line configured to use XBD  
 111774       [Chapter 11](#) (on page 199), but other communications means may be used. On systems where  
 111775       there are no available communications means (either temporarily or permanently), this utility  
 111776       shall write an error message describing the problem and exit with a non-zero exit status.

111777       The *uux* utility cannot guarantee support for all character encodings in all circumstances. For  
 111778       example, transmission data may be restricted to 7 bits by the underlying network, 8-bit data and  
 111779       filenames need not be portable to non-internationalized systems, and so on. Under these  
 111780       circumstances, it is recommended that only characters defined in the ISO/IEC 646:1991  
 111781       standard International Reference Version (equivalent to ASCII) 7-bit range of characters be used

111782 and that only characters defined in the portable filename character set be used for naming files.

#### 111783 OPTIONS

111784 The *uux* utility shall conform to XBD [Section 12.2](#) (on page 215).

111785 The following options shall be supported:

111786 **-j** Write the job identification string to standard output. This job identification can be  
111787 used by *uustat* to obtain the status or terminate a job.

111788 **-n** Do not notify the user if the command fails.

111789 **-p** Make the standard input to *uux* the standard input to the *command-string*.

#### 111790 OPERANDS

111791 The following operand shall be supported:

111792 *command-string*

111793 A string made up of one or more arguments that are similar to normal command  
111794 arguments, except that the command and any filenames can be prefixed by *system-*  
111795 *name!*. A null *system-name* shall be interpreted as the local system.

#### 111796 STDIN

111797 The standard input shall not be used unless the **'-'** or **-p** option is specified; in those cases, the  
111798 standard input shall be made the standard input of the *command-string*.

#### 111799 INPUT FILES

111800 Input files shall be selected according to the contents of *command-string*.

#### 111801 ENVIRONMENT VARIABLES

111802 The following environment variables shall affect the execution of *uux*:

111803 **LANG** Provide a default value for the internationalization variables that are unset or null.  
111804 (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
111805 variables used to determine the values of locale categories.)

111806 **LC\_ALL** If set to a non-empty string value, override the values of all the other  
111807 internationalization variables.

111808 **LC\_CTYPE** Determine the locale for the interpretation of sequences of bytes of text data as  
111809 characters (for example, single-byte as opposed to multi-byte characters in  
111810 arguments).

111811 **LC\_MESSAGES**

111812 Determine the locale that should be used to affect the format and contents of  
111813 diagnostic messages written to standard error.

111814 **NLSPATH** Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

#### 111815 ASYNCHRONOUS EVENTS

111816 Default.

#### 111817 STDOUT

111818 The standard output shall not be used unless the **-j** option is specified; in that case, the job  
111819 identification string shall be written to standard output in the following format:

111820 "%s\n", <*jobid*>

111821 **STDERR**

111822       The standard error shall be used only for diagnostic messages.

111823 **OUTPUT FILES**

111824       Output files shall be created or written, or both, according to the contents of *command-string*.

111825       If **-n** is not used, mail files shall be modified following any command or file-access failures on  
111826       the remote system.

111827 **EXTENDED DESCRIPTION**

111828       None.

111829 **EXIT STATUS**

111830       The following exit values shall be returned:

111831       0   Successful completion.

111832       >0  An error occurred.

111833 **CONSEQUENCES OF ERRORS**

111834       Default.

111835 **APPLICATION USAGE**

111836       This utility is part of the UUCP Utilities option and need not be supported by all  
111837       implementations.

111838       Note that, for security reasons, many installations limit the list of commands executable on  
111839       behalf of an incoming request from *uux*. Many sites permit little more than the receipt of mail  
111840       via *uux*.

111841       Any characters special to the command interpreter should be quoted either by quoting the entire  
111842       *command-string* or quoting the special characters as individual arguments.

111843       As noted in *uucp*, shell pattern matching notation characters appearing in pathnames are  
111844       expanded on the appropriate local system. This is done under the control of local settings of  
111845       *LC\_COLLATE* and *LC\_CTYPE*. Thus, care should be taken when using bracketed filename  
111846       patterns, as collation and typing rules may vary from one system to another. Also be aware that  
111847       certain types of expression (that is, equivalence classes, character classes, and collating symbols)  
111848       need not be supported on non-internationalized systems.

111849 **EXAMPLES**

111850       1. The following command gets **file1** from system **a** and **file2** from system **b**, executes *diff* on  
111851       the local system, and puts the results in **file.diff** in the local *PUBDIR* directory. (*PUBDIR*  
111852       is the *uucp* public directory on the local system.)

111853       uux "!diff a!/usr/file1 b!/a4/file2 >!~/file.diff"

111854       2. The following command fails because *uux* places all files copied to a system in the same  
111855       working directory. Although the files **xyz** are from two different systems, their filenames  
111856       are the same and conflict.

111857       uux "!diff a!/usr1/xyz b!/usr2/xyz >!~/xyz.diff"

111858       3. The following command succeeds (assuming *diff* is permitted on system **a**) because the  
111859       file local to system **a** is not copied to the working directory, and hence does not conflict  
111860       with the file from system **c**.

111861       uux "a!diff a!/usr/xyz c!/usr/xyz >!~/xyz.diff"

111862 **RATIONALE**

111863 None.

111864 **FUTURE DIRECTIONS**

111865 None.

111866 **SEE ALSO**111867 [Chapter 2](#) (on page 2319), [uucp](#), [uuencode](#), [uustat](#)111868 XBD [Chapter 8](#) (on page 173), [Chapter 11](#) (on page 199), [Section 12.2](#) (on page 215)111869 **CHANGE HISTORY**

111870 First released in Issue 2.

111871 **Issue 6**

111872 The obsolescent SYNOPSIS is removed.

111873 The normative text is reworded to avoid use of the term “must” for application requirements.

111874 The UN margin code and associated shading are removed from the `-j` option in response to The  
111875 Open Group Base Resolution bwg2001-003.111876 **Issue 7**

111877 SD5-XCU-ERN-46 is applied, moving this utility to the UUCP Utilities Option Group.

111878 **NAME**111879       val — validate SCCS files (**DEVELOPMENT**)111880 **SYNOPSIS**

```
111881 XSI val -
111882 val [-s] [-m name] [-r SID] [-y type] file...
```

111883 **DESCRIPTION**

111884       The *val* utility shall determine whether the specified *file* is an SCCS file meeting the  
 111885       characteristics specified by the options.

111886 **OPTIONS**

111887       The *val* utility shall conform to XBD [Section 12.2](#) (on page 215), except that the usage of the ‘-’  
 111888       operand is not strictly as intended by the guidelines (that is, reading options and operands from  
 111889       standard input).

111890       The following options shall be supported:

- 111891       **-m name**     Specify a *name*, which is compared with the SCCS %M% keyword in *file*; see [get](#).
- 111892       **-r SID**       Specify a *SID* (SCCS Identification String), an SCCS delta number. A check shall be  
 111893       made to determine whether the *SID* is ambiguous (for example, **-r 1** is ambiguous  
 111894       because it physically does not exist but implies 1.1, 1.2, and so on, which may exist)  
 111895       or invalid (for example, **-r 1.0** or **-r 1.1.0** are invalid because neither case can exist  
 111896       as a valid delta number). If the *SID* is valid and not ambiguous, a check shall be  
 111897       made to determine whether it actually exists.
- 111898       **-s**           Silence the diagnostic message normally written to standard output for any error  
 111899       that is detected while processing each named file on a given command line.
- 111900       **-y type**     Specify a *type*, which shall be compared with the SCCS %Y% keyword in *file*; see  
 111901       [get](#).

111902 **OPERANDS**

111903       The following operands shall be supported:

- 111904       *file*        A pathname of an existing SCCS file. If exactly one *file* operand appears, and it is  
 111905       ‘-’, the standard input shall be read: each line shall be independently processed  
 111906       as if it were a command line argument list. (However, the line is not subjected to  
 111907       any of the shell word expansions, such as parameter expansion or quote removal.)

111908 **STDIN**

111909       The standard input shall be a text file used only when the *file* operand is specified as ‘-’.

111910 **INPUT FILES**

111911       Any SCCS files processed shall be files of an unspecified format.

111912 **ENVIRONMENT VARIABLES**

111913       The following environment variables shall affect the execution of *val*:

- 111914       **LANG**       Provide a default value for the internationalization variables that are unset or null.  
 111915       (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 111916       variables used to determine the values of locale categories.)
- 111917       **LC\_ALL**     If set to a non-empty string value, override the values of all the other  
 111918       internationalization variables.

111919 **LC\_CTYPE** Determine the locale for the interpretation of sequences of bytes of text data as  
 111920 characters (for example, single-byte as opposed to multi-byte characters in  
 111921 arguments and input files).

111922 **LC\_MESSAGES**  
 111923 Determine the locale that should be used to affect the format and contents of  
 111924 diagnostic messages written to standard error, and informative messages written  
 111925 to standard output.

111926 **NLSPATH** Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

## 111927 **ASYNCHRONOUS EVENTS**

111928 Default.

## 111929 **STDOUT**

111930 The standard output shall consist of informative messages about either:

- 111931 1. Each file processed
- 111932 2. Each command line read from standard input

111933 If the standard input is not used, for each *file* operand yielding a discrepancy, the output line  
 111934 shall have the following format:

111935 "%s: %s\n", <pathname>, <unspecified string>

111936 If the standard input is used, for each input line yielding a discrepancy, the output shall have the  
 111937 following format:

111938 "%s\n\n %s: %s\n", <input>, <pathname>, <unspecified string>

111939 where <input> is the input line minus its terminating <newline>.

## 111940 **STDERR**

111941 Not used.

## 111942 **OUTPUT FILES**

111943 None.

## 111944 **EXTENDED DESCRIPTION**

111945 None.

## 111946 **EXIT STATUS**

111947 The 8-bit code returned by *val* shall be a disjunction of the possible errors; that is, it can be  
 111948 interpreted as a bit string where set bits are interpreted as follows:

|        |      |   |                                     |
|--------|------|---|-------------------------------------|
| 111949 | 0x80 | = | Missing file argument.              |
| 111950 | 0x40 | = | Unknown or duplicate option.        |
| 111951 | 0x20 | = | Corrupted SCCS file.                |
| 111952 | 0x10 | = | Cannot open file or file not SCCS.  |
| 111953 | 0x08 | = | <i>SID</i> is invalid or ambiguous. |
| 111954 | 0x04 | = | <i>SID</i> does not exist.          |
| 111955 | 0x02 | = | %Y%, -y mismatch.                   |
| 111956 | 0x01 | = | %M%, -m mismatch.                   |

111957 Note that *val* can process two or more files on a given command line and can process multiple  
 111958 command lines (when reading the standard input). In these cases an aggregate code shall be  
 111959 returned: a logical OR of the codes generated for each command line and file processed.

111960 **CONSEQUENCES OF ERRORS**

111961 Default.

111962 **APPLICATION USAGE**

111963 Since the *val* exit status sets the 0x80 bit, shell applications checking "\$?" cannot tell if it  
 111964 terminated due to a missing file argument or receipt of a signal.

111965 **EXAMPLES**

111966 In a directory with three SCCS files—*s.x* (of *t* type “text”), *s.y*, and *s.z* (a corrupted file)—the  
 111967 following command could produce the output shown:

```
111968 val - <<EOF
111969 -y source s.x
111970 -m y s.y
111971 s.z
111972 EOF
111973 -y source s.x
111974 s.x: %Y%, -y mismatch
111975 s.z
111976 s.z: corrupted SCCS file
```

111977 **RATIONALE**

111978 None.

111979 **FUTURE DIRECTIONS**

111980 None.

111981 **SEE ALSO**111982 *admin, delta, get, prs*111983 XBD [Chapter 8](#) (on page 173), [Section 12.2](#) (on page 215)111984 **CHANGE HISTORY**

111985 First released in Issue 2.

111986 **Issue 6**

111987 The Open Group Corrigendum U025/4 is applied, correcting a typographical error in the EXIT  
 111988 STATUS.

111989 **Issue 7**

111990 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

111991 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0147 [416] and XCU/TC1-2008/0148 +  
 111992 [416] are applied.

111993 **NAME**

111994 vi — screen-oriented (visual) display editor

111995 **SYNOPSIS**111996 UP `vi [-rR] [-c command] [-t tagstring] [-w size] [file...]`111997 **DESCRIPTION**111998 This utility shall be provided on systems that both support the User Portability Utilities option  
111999 and define the POSIX2\_CHAR\_TERM symbol. On other systems it is optional.112000 The *vi* (visual) utility is a screen-oriented text editor. Only the open and visual modes of the  
112001 editor are described in POSIX.1-2008; see the line editor *ex* for additional editing capabilities  
112002 used in *vi*. The user can switch back and forth between *vi* and *ex* and execute *ex* commands from  
112003 within *vi*.112004 This reference page uses the term *edit buffer* to describe the current working text. No specific  
112005 implementation is implied by this term. All editing changes are performed on the edit buffer,  
112006 and no changes to it shall affect any file until an editor command writes the file.112007 When using *vi*, the terminal screen acts as a window into the editing buffer. Changes made to  
112008 the editing buffer shall be reflected in the screen display; the position of the cursor on the screen  
112009 shall indicate the position within the editing buffer.112010 Certain terminals do not have all the capabilities necessary to support the complete *vi* definition.  
112011 When these commands cannot be supported on such terminals, this condition shall not produce  
112012 an error message such as “not an editor command” or report a syntax error. The implementation  
112013 may either accept the commands and produce results on the screen that are the result of an  
112014 unsuccessful attempt to meet the requirements of this volume of POSIX.1-2008 or report an error  
112015 describing the terminal-related deficiency.112016 **OPTIONS**112017 The *vi* utility shall conform to XBD [Section 12.2](#) (on page 215), except that ‘+’ may be  
112018 recognized as an option delimiter as well as ‘-’.

112019 The following options shall be supported:

112020 **-c *command*** See the *ex* command description of the **-c** option.112021 **-r** See the *ex* command description of the **-r** option.112022 **-R** See the *ex* command description of the **-R** option.112023 **-t *tagstring*** See the *ex* command description of the **-t** option.112024 **-w *size*** See the *ex* command description of the **-w** option.112025 **OPERANDS**112026 See the OPERANDS section of the *ex* command for a description of the operands supported by  
112027 the *vi* command.112028 **STDIN**112029 If standard input is not a terminal device, the results are undefined. The standard input consists  
112030 of a series of commands and input text, as described in the EXTENDED DESCRIPTION section.112031 If a read from the standard input returns an error, or if the editor detects an end-of-file condition  
112032 from the standard input, it shall be equivalent to a SIGHUP asynchronous event.

112033 **INPUT FILES**

112034 See the INPUT FILES section of the *ex* command for a description of the input files supported by  
 112035 the *vi* command.

112036 **ENVIRONMENT VARIABLES**

112037 See the ENVIRONMENT VARIABLES section of the *ex* command for the environment variables  
 112038 that affect the execution of the *vi* command.

112039 **ASYNCHRONOUS EVENTS**

112040 See the ASYNCHRONOUS EVENTS section of the *ex* for the asynchronous events that affect the  
 112041 execution of the *vi* command.

112042 **STDOUT**

112043 If standard output is not a terminal device, undefined results occur.

112044 Standard output may be used for writing prompts to the user, for informational messages, and  
 112045 for writing lines from the file.

112046 **STDERR**

112047 If standard output is not a terminal device, undefined results occur.

112048 The standard error shall be used only for diagnostic messages.

112049 **OUTPUT FILES**

112050 See the OUTPUT FILES section of the *ex* command for a description of the output files  
 112051 supported by the *vi* command.

112052 **EXTENDED DESCRIPTION**

112053 If the terminal does not have the capabilities necessary to support an unspecified portion of the  
 112054 *vi* definition, implementations shall start initially in *ex* mode or open mode. Otherwise, after  
 112055 initialization, *vi* shall be in command mode; text input mode can be entered by one of several  
 112056 commands used to insert or change text. In text input mode, <ESC> can be used to return to  
 112057 command mode; other uses of <ESC> are described later in this section; see [Terminate](#)  
 112058 [Command or Input Mode](#) (on page 3346).

112059 **Initialization in *ex* and *vi***

112060 See [Initialization in \*ex\* and \*vi\*](#) (on page 2666) for a description of *ex* and *vi* initialization for the *vi*  
 112061 utility.

112062 **Command Descriptions in *vi***

112063 The following symbols are used in this reference page to represent arguments to commands.

112064 *buffer* See the description of *buffer* in the EXTENDED DESCRIPTION section of the *ex* utility;  
 112065 see [Command Descriptions in \*ex\*](#) (on page 2675).

112066 In open and visual mode, when a command synopsis shows both [*buffer*] and [*count*]  
 112067 preceding the command name, they can be specified in either order.

112068 *count* A positive integer used as an optional argument to most commands, either to give a  
 112069 repeat count or as a size. This argument is optional and shall default to 1 unless  
 112070 otherwise specified.

112071 The Synopsis lines for the *vi* commands <control>-G, <control>-L, <control>-R,  
 112072 <control>-], %, &, ^, D, m, M, Q, u, U, and ZZ do not have *count* as an optional  
 112073 argument. Regardless, it shall not be an error to specify a *count* to these commands, and  
 112074 any specified *count* shall be ignored.

*motion* An optional trailing argument used by the **!**, **<**, **>**, **c**, **d**, and **y** commands, which is used to indicate the region of text that shall be affected by the command. The motion can be either one of the command characters repeated or one of several other *vi* commands (listed in the following table). Each of the applicable commands specifies the region of text matched by repeating the command; each command that can be used as a motion command specifies the region of text it affects.

Commands that take *motion* arguments operate on either lines or characters, depending on the circumstances. When operating on lines, all lines that fall partially or wholly within the text region specified for the command shall be affected. When operating on characters, only the exact characters in the specified text region shall be affected. Each motion command specifies this individually.

When commands that may be motion commands are not used as motion commands, they shall set the current position to the current line and column as specified.

The following commands shall be valid cursor motion commands:

|                   |   |    |   |   |
|-------------------|---|----|---|---|
| <apostrophe>      | ( | -  | j | H |
| <carriage-return> | ) | \$ | k | L |
| <comma>           | [ | %  | l | M |
| <control>-H       | ] | _  | n | N |
| <control>-N       | { | ;  | t | T |
| <control>-P       | } | ?  | w | W |
| <grave-accent>    | ^ | b  | B |   |
| <newline>         | + | e  | E |   |
| <space>           |   | f  | F |   |
| <zero>            | / | h  | G |   |

Any *count* that is specified to a command that has an associated motion command shall be applied to the motion command. If a *count* is applied to both the command and its associated motion command, the effect shall be multiplicative.

The following symbols are used in this section to specify locations in the edit buffer:

*current character*

The character that is currently indicated by the cursor.

*end of a line*

The point located between the last non-<newline> (if any) and the terminating <newline> of a line. For an empty line, this location coincides with the beginning of the line.

*end of the edit buffer*

The location corresponding to the end of the last line in the edit buffer.

The following symbols are used in this section to specify command actions:

*bigword* In the POSIX locale, *vi* shall recognize four kinds of *bigwords*:

1. A maximal sequence of non-<blank> characters preceded and followed by <blank> characters or the beginning or end of a line or the edit buffer
2. One or more sequential blank lines
3. The first character in the edit buffer

- 112117 4. The last non-<newline> in the edit buffer
- 112118 *word* In the POSIX locale, *vi* shall recognize five kinds of words:
- 112119 1. A maximal sequence of letters, digits, and underscores, delimited at both ends
- 112120 by:
- 112121 — Characters other than letters, digits, or underscores
- 112122 — The beginning or end of a line
- 112123 — The beginning or end of the edit buffer
- 112124 2. A maximal sequence of characters other than letters, digits, underscores, or
- 112125 <blank> characters, delimited at both ends by:
- 112126 — A letter, digit, underscore
- 112127 — <blank> characters
- 112128 — The beginning or end of a line
- 112129 — The beginning or end of the edit buffer
- 112130 3. One or more sequential blank lines
- 112131 4. The first character in the edit buffer
- 112132 5. The last non-<newline> in the edit buffer
- 112133 *section boundary*
- 112134 A *section boundary* is one of the following:
- 112135 1. A line whose first character is a <form-feed>
- 112136 2. A line whose first character is an open curly brace ( ' { ' )
- 112137 3. A line whose first character is a <period> and whose second and third characters
- 112138 match a two-character pair in the **sections** edit option (see *ed*)
- 112139 4. A line whose first character is a <period> and whose only other character
- 112140 matches the first character of a two-character pair in the **sections** edit option,
- 112141 where the second character of the two-character pair is a <space>
- 112142 5. The first line of the edit buffer
- 112143 6. The last line of the edit buffer if the last line of the edit buffer is empty or if it is a
- 112144 ]] or } command; otherwise, the last non-<newline> of the last line of the edit
- 112145 buffer
- 112146 *paragraph boundary*
- 112147 A *paragraph boundary* is one of the following:
- 112148 1. A section boundary
- 112149 2. A line whose first character is a <period> and whose second and third characters
- 112150 match a two-character pair in the **paragraphs** edit option (see *ed*)
- 112151 3. A line whose first character is a <period> and whose only other character
- 112152 matches the first character of a two-character pair in the *paragraphs* edit option,
- 112153 where the second character of the two-character pair is a <space>

#### 4. One or more sequential blank lines

*remembered search direction*

See the description of *remembered search direction* in *ed*.

*sentence boundary*

A *sentence boundary* is one of the following:

1. A paragraph boundary
2. The first non-`<blank>` that occurs after a paragraph boundary
3. The first non-`<blank>` that occurs after a `<period>` (`'.'`), `<exclamation-mark>` (`'!'`), or `<question-mark>` (`'?'`), followed by two `<space>` characters or the end of a line; any number of closing parenthesis (`' ) '`), closing brackets (`' ] '`), double-quote (`' "'`), or single-quote (`<apostrophe>`) characters can appear between the punctuation mark and the two `<space>` characters or end-of-line

In the remainder of the description of the *vi* utility, the term “buffer line” refers to a line in the edit buffer and the term “display line” refers to the line or lines on the display screen used to display one buffer line. The term “current line” refers to a specific “buffer line”.

If there are display lines on the screen for which there are no corresponding buffer lines because they correspond to lines that would be after the end of the file, they shall be displayed as a single `<tilde>` (`'~'`) character, plus the terminating `<newline>`.

The last line of the screen shall be used to report errors or display informational messages. It shall also be used to display the input for “line-oriented commands” (`/`, `?`, `:`, and `!`). When a line-oriented command is executed, the editor shall enter text input mode on the last line on the screen, using the respective command characters as prompt characters. (In the case of the `!` command, the associated motion shall be entered by the user before the editor enters text input mode.) The line entered by the user shall be terminated by a `<newline>`, a non-`<control>`-V-escaped `<carriage-return>`, or unescaped `<ESC>`. It is unspecified if more characters than require a display width minus one column number of screen columns can be entered.

If any command is executed that overwrites a portion of the screen other than the last line of the screen (for example, the *ex* **suspend** or `!` commands), other than the *ex* **shell** command, the user shall be prompted for a character before the screen is refreshed and the edit session continued.

`<tab>` characters shall take up the number of columns on the screen set by the **tabstop** edit option (see *ed*), unless there are less than that number of columns before the display margin that will cause the displayed line to be folded; in this case, they shall only take up the number of columns up to that boundary.

The cursor shall be placed on the current line and relative to the current column as specified by each command described in the following sections.

In open mode, if the current line is not already displayed, then it shall be displayed.

In visual mode, if the current line is not displayed, then the lines that are displayed shall be expanded, scrolled, or redrawn to cause an unspecified portion of the current line to be displayed. If the screen is redrawn, no more than the number of display lines specified by the value of the **window** edit option shall be displayed (unless the current line cannot be completely displayed in the number of display lines specified by the **window** edit option) and the current line shall be positioned as close to the center of the displayed lines as possible (within the constraints imposed by the distance of the line from the beginning or end of the edit buffer). If the current line is before the first line in the display and the screen is scrolled, an unspecified

112199 portion of the current line shall be placed on the first line of the display. If the current line is after  
 112200 the last line in the display and the screen is scrolled, an unspecified portion of the current line  
 112201 shall be placed on the last line of the display.

112202 In visual mode, if a line from the edit buffer (other than the current line) does not entirely fit into  
 112203 the lines at the bottom of the display that are available for its presentation, the editor may choose  
 112204 not to display any portion of the line. The lines of the display that do not contain text from the  
 112205 edit buffer for this reason shall each consist of a single ' @ ' character.

112206 In visual mode, the editor may choose for unspecified reasons to not update lines in the display  
 112207 to correspond to the underlying edit buffer text. The lines of the display that do not correctly  
 112208 correspond to text from the edit buffer for this reason shall consist of a single ' @ ' character (plus  
 112209 the terminating <newline>), and the <control>-R command shall cause the editor to update the  
 112210 screen to correctly represent the edit buffer.

112211 Open and visual mode commands that set the current column set it to a column position in the  
 112212 display, and not a character position in the line. In this case, however, the column position in the  
 112213 display shall be calculated for an infinite width display; for example, the column related to a  
 112214 character that is part of a line that has been folded onto additional screen lines will be offset from  
 112215 the display line column where the buffer line begins, not from the beginning of a particular  
 112216 display line.

112217 The display cursor column in the display is based on the value of the current column, as follows,  
 112218 with each rule applied in turn:

- 112219 1. If the current column is after the last display line column used by the displayed line, the  
 112220 display cursor column shall be set to the last display line column occupied by the last  
 112221 non-<newline> in the current line; otherwise, the display cursor column shall be set to the  
 112222 current column.
- 112223 2. If the character of which some portion is displayed in the display line column specified by  
 112224 the display cursor column requires more than a single display line column:
  - 112225 a. If in text input mode, the display cursor column shall be adjusted to the first  
 112226 display line column in which any portion of that character is displayed.
  - 112227 b. Otherwise, the display cursor column shall be adjusted to the last display line  
 112228 column in which any portion of that character is displayed.

112229 The current column shall not be changed by these adjustments to the display cursor column.

112230 If an error occurs during the parsing or execution of a *vi* command:

- 112231 • The terminal shall be alerted. Execution of the *vi* command shall stop, and the cursor (for  
 112232 example, the current line and column) shall not be further modified.
- 112233 • Unless otherwise specified by the following command sections, it is unspecified whether  
 112234 an informational message shall be displayed.
- 112235 • Any partially entered *vi* command shall be discarded.
- 112236 • If the *vi* command resulted from a **map** expansion, all characters from that **map** expansion  
 112237 shall be discarded, except as otherwise specified by the **map** command (see *ed*).
- 112238 • If the *vi* command resulted from the execution of a buffer, no further commands caused by  
 112239 the execution of the buffer shall be executed.

## Page Backwards

**Synopsis:**     [*count*] <control>-B

If in open mode, the <control>-B command shall behave identically to the **z** command. Otherwise, if the current line is the first line of the edit buffer, it shall be an error.

If the **window** edit option is less than 3, display a screen where the last line of the display shall be some portion of:

(*current first line*) -1

otherwise, display a screen where the first line of the display shall be some portion of:

(*current first line*) - *count* x ((*window edit option*) -2)

If this calculation would result in a line that is before the first line of the edit buffer, the first line of the display shall display some portion of the first line of the edit buffer.

*Current line:* If no lines from the previous display remain on the screen, set to the last line of the display; otherwise, set to (*line* - the number of new lines displayed on this screen).

*Current column:* Set to non-<blank>.

## Scroll Forward

**Synopsis:**     [*count*] <control>-D

If the current line is the last line of the edit buffer, it shall be an error.

If no *count* is specified, *count* shall default to the *count* associated with the previous <control>-D or <control>-U command. If there was no previous <control>-D or <control>-U command, *count* shall default to the value of the **scroll** edit option.

If in open mode, write lines starting with the line after the current line, until *count* lines or the last line of the file have been written.

*Current line:* If the current line + *count* is past the last line of the edit buffer, set to the last line of the edit buffer; otherwise, set to the current line + *count*.

*Current column:* Set to non-<blank>.

## Scroll Forward by Line

**Synopsis:**     [*count*] <control>-E

Display the line *count* lines after the last line currently displayed.

If the last line of the edit buffer is displayed, it shall be an error. If there is no line *count* lines after the last line currently displayed, the last line of the display shall display some portion of the last line of the edit buffer.

*Current line:* Unchanged if the previous current character is displayed; otherwise, set to the first line displayed.

*Current column:* Unchanged.

**Page Forward**

*Synopsis:*     [*count*] <control>-F

If in open mode, the <control>-F command shall behave identically to the **z** command. Otherwise, if the current line is the last line of the edit buffer, it shall be an error.

If the **window** edit option is less than 3, display a screen where the first line of the display shall be some portion of:

*(current last line) +1*

otherwise, display a screen where the first line of the display shall be some portion of:

*(current first line) + count x ((window edit option) -2)*

If this calculation would result in a line that is after the last line of the edit buffer, the last line of the display shall display some portion of the last line of the edit buffer.

*Current line:* If no lines from the previous display remain on the screen, set to the first line of the display; otherwise, set to (*line* + the number of new lines displayed on this screen).

*Current column:* Set to non-<blank>.

**Display Information**

*Synopsis:*     <control>-G

This command shall be equivalent to the **ex file** command.

**Move Cursor Backwards**

*Synopsis:*     [*count*] <control>-H

[*count*] h

the current erase character (see **stty**)

If there are no characters before the current character on the current line, it shall be an error. If there are less than *count* previous characters on the current line, *count* shall be adjusted to the number of previous characters on the line.

If used as a motion command:

1. The text region shall be from the character before the starting cursor up to and including the *count*th character before the starting cursor.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

*Current line:* Unchanged.

*Current column:* Set to (*column* – the number of columns occupied by *count* characters ending with the previous current column).

**Move Down**

*Synopsis:*     [*count*] <newline>  
                  [*count*] <control>-J  
                  [*count*] <control>-M  
                  [*count*] <control>-N  
                  [*count*] j  
                  [*count*] <carriage-return>  
                  [*count*] +

If there are less than *count* lines after the current line in the edit buffer, it shall be an error.

If used as a motion command:

1. The text region shall include the starting line and the next *count* – 1 lines.
2. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

*Current line:* Set to *current line* + *count*.

*Current column:* Set to non-<blank> for the <carriage-return>, <control>-M, and + commands; otherwise, unchanged.

**Clear and Redisplay**

*Synopsis:*     <control>-L

If in open mode, clear the screen and redisplay the current line. Otherwise, clear and redisplay the screen.

*Current line:* Unchanged.

*Current column:* Unchanged.

**Move Up**

*Synopsis:*     [*count*] <control>-P  
                  [*count*] k  
                  [*count*] –

If there are less than *count* lines before the current line in the edit buffer, it shall be an error.

If used as a motion command:

1. The text region shall include the starting line and the previous *count* lines.
2. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

*Current line:* Set to *current line* – *count*.

*Current column:* Set to non-<blank> for the – command; otherwise, unchanged.

## 112339 **Redraw Screen**

112340 *Synopsis:*      <control>-R

112341 If any lines have been deleted from the display screen and flagged as deleted on the terminal  
112342 using the @ convention (see the beginning of the EXTENDED DESCRIPTION section), they shall  
112343 be redisplayed to match the contents of the edit buffer.

112344 It is unspecified whether lines flagged with @ because they do not fit on the terminal display  
112345 shall be affected.

112346 *Current line:* Unchanged.

112347 *Current column:* Unchanged.

## 112348 **Scroll Backward**

112349 *Synopsis:*      [*count*] <control>-U

112350 If the current line is the first line of the edit buffer, it shall be an error.

112351 If no *count* is specified, *count* shall default to the *count* associated with the previous <control>-D  
112352 or <control>-U command. If there was no previous <control>-D or <control>-U command, *count*  
112353 shall default to the value of the **scroll** edit option.

112354 *Current line:* If *count* is greater than the current line, set to 1; otherwise, set to the current line –  
112355 *count*.

112356 *Current column:* Set to non-<blank>.

## 112357 **Scroll Backward by Line**

112358 *Synopsis:*      [*count*] <control>-Y

112359 Display the line *count* lines before the first line currently displayed.

112360 If the current line is the first line of the edit buffer, it shall be an error. If this calculation would  
112361 result in a line that is before the first line of the edit buffer, the first line of the display shall  
112362 display some portion of the first line of the edit buffer.

112363 *Current line:* Unchanged if the previous current character is displayed; otherwise, set to the first  
112364 line displayed.

112365 *Current column:* Unchanged.

## 112366 **Edit the Alternate File**

112367 *Synopsis:*      <control>-^

112368 This command shall be equivalent to the *ex* **edit** command, with the alternate pathname as its  
112369 argument.

**Terminate Command or Input Mode**

*Synopsis:*      <ESC>

If a partial *vi* command (as defined by at least one, non-*count* character) has been entered, discard the *count* and the command character(s).

Otherwise, if no command characters have been entered, and the <ESC> was the result of a map expansion, the terminal shall be alerted and the <ESC> character shall be discarded, but it shall not be an error.

Otherwise, it shall be an error.

*Current line:* Unchanged.

*Current column:* Unchanged.

**Search for tagstring**

*Synopsis:*      <control>-]

If the current character is not a word or <blank>, it shall be an error.

This command shall be equivalent to the *ex tag* command, with the argument to that command defined as follows.

If the current character is a <blank>:

1. Skip all <blank> characters after the cursor up to the end of the line.
2. If the end of the line is reached, it shall be an error.

Then, the argument to the *ex tag* command shall be the current character and all subsequent characters, up to the first non-word character or the end of the line.

**Move Cursor Forward**

*Synopsis:*      [*count*] <space>  
                 [*count*] 1 (ell)

If there are less than *count* non-<newline> characters after the cursor on the current line, *count* shall be adjusted to the number of non-<newline> characters after the cursor on the line.

If used as a motion command:

1. If the current or *count*th character after the cursor is the last non-<newline> in the line, the text region shall be comprised of the current character up to and including the last non-<newline> in the line. Otherwise, the text region shall be from the current character up to, but not including, the *count*th character after the cursor.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

If there are no non-<newline> characters after the current character on the current line, it shall be an error.

*Current line:* Unchanged.

*Current column:* Set to the last column that displays any portion of the *count*th character after the current character.

**Replace Text with Results from Shell Command**

*Synopsis:*     [*count*] ! *motion shell-commands* <newline>

If the motion command is the ! command repeated:

1. If the edit buffer is empty and no *count* was supplied, the command shall be the equivalent of the *ex :read !* command, with the text input, and no text shall be copied to any buffer.
2. Otherwise:
  - a. If there are less than *count* -1 lines after the current line in the edit buffer, it shall be an error.
  - b. The text region shall be from the current line up to and including the next *count* -1 lines.

Otherwise, the text region shall be the lines in which any character of the text region specified by the motion command appear.

Any text copied to a buffer shall be in line mode.

This command shall be equivalent to the *ex !* command for the specified lines.

**Move Cursor to End-of-Line**

*Synopsis:*     [*count*] \$

It shall be an error if there are less than (*count* -1) lines after the current line in the edit buffer.

If used as a motion command:

1. If *count* is 1:
  - a. It shall be an error if the line is empty.
  - b. Otherwise, the text region shall consist of all characters from the starting cursor to the last non-<newline> in the line, inclusive, and any text copied to a buffer shall be in character mode.
2. Otherwise, if the starting cursor position is at or before the first non-<blank> in the line, the text region shall consist of the current and the next *count* -1 lines, and any text saved to a buffer shall be in line mode.
3. Otherwise, the text region shall consist of all characters from the starting cursor to the last non-<newline> in the line that is *count* -1 lines forward from the current line, and any text copied to a buffer shall be in character mode.

If not used as a motion command:

*Current line:* Set to the *current line* + *count* -1.

*Current column:* The current column is set to the last display line column of the last non-<newline> in the line, or column position 1 if the line is empty.

The current column shall be adjusted to be on the last display line column of the last non-<newline> of the current line as subsequent commands change the current line, until a command changes the current column.

**Move to Matching Character***Synopsis:*     %

If the character at the current position is not a parenthesis, bracket, or curly brace, search forward in the line to the first one of those characters. If no such character is found, it shall be an error.

The matching character shall be the parenthesis, bracket, or curly brace matching the parenthesis, bracket, or curly brace, respectively, that was at the current position or that was found on the current line.

Matching shall be determined as follows, for an open parenthesis:

1. Set a counter to 1.
2. Search forwards until a parenthesis is found or the end of the edit buffer is reached.
3. If the end of the edit buffer is reached, it shall be an error.
4. If an open parenthesis is found, increment the counter by 1.
5. If a close parenthesis is found, decrement the counter by 1.
6. If the counter is zero, the current character is the matching character.

Matching for a close parenthesis shall be equivalent, except that the search shall be backwards, from the starting character to the beginning of the buffer, a close parenthesis shall increment the counter by 1, and an open parenthesis shall decrement the counter by 1.

Matching for brackets and curly braces shall be equivalent, except that searching shall be done for open and close brackets or open and close curly braces. It is implementation-defined whether other characters are searched for and matched as well.

If used as a motion command:

1. If the matching cursor was after the starting cursor in the edit buffer, and the starting cursor position was at or before the first non-`<blank>` non-`<newline>` in the starting line, and the matching cursor position was at or after the last non-`<blank>` non-`<newline>` in the matching line, the text region shall consist of the current line to the matching line, inclusive, and any text copied to a buffer shall be in line mode.
2. If the matching cursor was before the starting cursor in the edit buffer, and the starting cursor position was at or after the last non-`<blank>` non-`<newline>` in the starting line, and the matching cursor position was at or before the first non-`<blank>` non-`<newline>` in the matching line, the text region shall consist of the current line to the matching line, inclusive, and any text copied to a buffer shall be in line mode.
3. Otherwise, the text region shall consist of the starting character to the matching character, inclusive, and any text copied to a buffer shall be in character mode.

If not used as a motion command:

*Current line:* Set to the line where the matching character is located.

*Current column:* Set to the last column where any portion of the matching character is displayed.

**Repeat Substitution**

*Synopsis:*     &

Repeat the previous substitution command. This command shall be equivalent to the *ex &* command with the current line as its addresses, and without *options, count, or flags*.

**Return to Previous Context at Beginning of Line**

*Synopsis:*     ' *character*

It shall be an error if there is no line in the edit buffer marked by *character*.

If used as a motion command:

1. If the starting cursor is after the marked cursor, then the locations of the starting cursor and the marked cursor in the edit buffer shall be logically swapped.
2. The text region shall consist of the starting line up to and including the marked line, and any text copied to a buffer shall be in line mode.

If not used as a motion command:

*Current line:* Set to the line referenced by the mark.

*Current column:* Set to non-<blank>.

**Return to Previous Context**

*Synopsis:*     ` *character*

It shall be an error if the marked line is no longer in the edit buffer. If the marked line no longer contains a character in the saved numbered character position, it shall be as if the marked position is the first non-<blank>.

If used as a motion command:

1. It shall be an error if the marked cursor references the same character in the edit buffer as the starting cursor.
2. If the starting cursor is after the marked cursor, then the locations of the starting cursor and the marked cursor in the edit buffer shall be logically swapped.
3. If the starting line is empty or the starting cursor is at or before the first non-<blank> non-<newline> of the starting line, and the marked cursor line is empty or the marked cursor references the first character of the marked cursor line, the text region shall consist of all lines containing characters from the starting cursor to the line before the marked cursor line, inclusive, and any text copied to a buffer shall be in line mode.
4. Otherwise, if the marked cursor line is empty or the marked cursor references a character at or before the first non-<blank> non-<newline> of the marked cursor line, the region of text shall be from the starting cursor to the last non-<newline> of the line before the marked cursor line, inclusive, and any text copied to a buffer shall be in character mode.
5. Otherwise, the region of text shall be from the starting cursor (inclusive), to the marked cursor (exclusive), and any text copied to a buffer shall be in character mode.

If not used as a motion command:

*Current line:* Set to the line referenced by the mark.

*Current column:* Set to the last column in which any portion of the character referenced by the

112520 mark is displayed.

## 112521 **Return to Previous Section**

112522 *Synopsis:*     [*count*]   [ [

112523 Move the cursor backward through the edit buffer to the first character of the previous section  
112524 boundary, *count* times.

112525 If used as a motion command:

- 112526     1. If the starting cursor was at the first character of the starting line or the starting line was  
112527       empty, and the first character of the boundary was the first character of the boundary line,  
112528       the text region shall consist of the current line up to and including the line where the  
112529       *countth* next boundary starts, and any text copied to a buffer shall be in line mode.
- 112530     2. If the boundary was the last line of the edit buffer or the last non-<newline> of the last  
112531       line of the edit buffer, the text region shall consist of the last character in the edit buffer up  
112532       to and including the starting character, and any text saved to a buffer shall be in character  
112533       mode.
- 112534     3. Otherwise, the text region shall consist of the starting character up to but not including  
112535       the first character in the *countth* next boundary, and any text copied to a buffer shall be in  
112536       character mode.

112537 If not used as a motion command:

112538 *Current line:* Set to the line where the *countth* next boundary in the edit buffer starts.

112539 *Current column:* Set to the last column in which any portion of the first character of the *countth*  
112540 next boundary is displayed, or column position 1 if the line is empty.

## 112541 **Move to Next Section**

112542 *Synopsis:*     [*count*]   ] ]

112543 Move the cursor forward through the edit buffer to the first character of the next section  
112544 boundary, *count* times.

112545 If used as a motion command:

- 112546     1. If the starting cursor was at the first character of the starting line or the starting line was  
112547       empty, and the first character of the boundary was the first character of the boundary line,  
112548       the text region shall consist of the current line up to and including the line where the  
112549       *countth* previous boundary starts, and any text copied to a buffer shall be in line mode.
- 112550     2. If the boundary was the first line of the edit buffer, the text region shall consist of the first  
112551       character in the edit buffer up to but not including the starting character, and any text  
112552       copied to a buffer shall be in character mode.
- 112553     3. Otherwise, the text region shall consist of the first character in the *countth* previous  
112554       section boundary up to but not including the starting character, and any text copied to a  
112555       buffer shall be in character mode.

112556 If not used as a motion command:

112557 *Current line:* Set to the line where the *countth* previous boundary in the edit buffer starts.

112558 *Current column:* Set to the last column in which any portion of the first character of the *countth*  
112559 previous boundary is displayed, or column position 1 if the line is empty.

**Move to First Non-<blank> Position on Current Line***Synopsis:*     `^`

If used as a motion command:

1. If the line has no non-<blank> non-<newline> characters, or if the cursor is at the first non-<blank> non-<newline> of the line, it shall be an error.
2. If the cursor is before the first non-<blank> non-<newline> of the line, the text region shall be comprised of the current character, up to, but not including, the first non-<blank> non-<newline> of the line.
3. If the cursor is after the first non-<blank> non-<newline> of the line, the text region shall be from the character before the starting cursor up to and including the first non-<blank> non-<newline> of the line.
4. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

*Current line:* Unchanged.*Current column:* Set to non-<blank>.**Current and Line Above***Synopsis:*     `[count] _`If there are less than *count* -1 lines after the current line in the edit buffer, it shall be an error.

If used as a motion command:

1. If *count* is less than 2, the text region shall be the current line.
2. Otherwise, the text region shall include the starting line and the next *count* -1 lines.
3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

*Current line:* Set to current line + *count* -1.*Current column:* Set to non-<blank>.**Move Back to Beginning of Sentence***Synopsis:*     `[count] (`

Move backward to the beginning of a sentence. This command shall be equivalent to the `[]` command, with the exception that sentence boundaries shall be used instead of section boundaries.

**Move Forward to Beginning of Sentence***Synopsis:*     `[count] )`

Move forward to the beginning of a sentence. This command shall be equivalent to the `]` command, with the exception that sentence boundaries shall be used instead of section boundaries.

**Move Back to Preceding Paragraph**

*Synopsis:*     [*count*] {

Move back to the beginning of the preceding paragraph. This command shall be equivalent to the `[[` command, with the exception that paragraph boundaries shall be used instead of section boundaries.

**Move Forward to Next Paragraph**

*Synopsis:*     [*count*] }

Move forward to the beginning of the next paragraph. This command shall be equivalent to the `]]` command, with the exception that paragraph boundaries shall be used instead of section boundaries.

**Move to Specific Column Position**

*Synopsis:*     [*count*] |

For the purposes of this command, lines that are too long for the current display and that have been folded shall be treated as having a single, 1-based, number of columns.

If there are less than *count* columns in which characters from the current line are displayed on the screen, *count* shall be adjusted to be the last column in which any portion of the line is displayed on the screen.

If used as a motion command:

1. If the line is empty, or the cursor character is the same as the character on the *count*th column of the line, it shall be an error.
2. If the cursor is before the *count*th column of the line, the text region shall be comprised of the current character, up to but not including the character on the *count*th column of the line.
3. If the cursor is after the *count*th column of the line, the text region shall be from the character before the starting cursor up to and including the character on the *count*th column of the line.
4. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

*Current line:* Unchanged.

*Current column:* Set to the last column in which any portion of the character that is displayed in the *count* column of the line is displayed.

**Reverse Find Character**

*Synopsis:*     [*count*] ,

If the last **F**, **f**, **T**, or **t** command was **F**, **f**, **T**, or **t**, this command shall be equivalent to an **f**, **F**, **t**, or **T** command, respectively, with the specified *count* and the same search character.

If there was no previous **F**, **f**, **T**, or **t** command, it shall be an error.

**Repeat**

*Synopsis:*      [*count*] .

Repeat the last **!**, **<**, **>**, **A**, **C**, **D**, **I**, **J**, **O**, **P**, **R**, **S**, **X**, **Y**, **a**, **c**, **d**, **i**, **o**, **p**, **r**, **s**, **x**, **y**, or **~** command. It shall be an error if none of these commands have been executed. Commands (other than commands that enter text input mode) executed as a result of map expansions, shall not change the value of the last repeatable command.

Repeated commands with associated motion commands shall repeat the motion command as well; however, any specified *count* shall replace the *count*(s) that were originally specified to the repeated command or its associated motion command.

If the motion component of the repeated command is **f**, **F**, **t**, or **T**, the repeated command shall not set the remembered search character for the **;** and **,** commands.

If the repeated command is **p** or **P**, and the buffer associated with that command was a numeric buffer named with a number less than 9, the buffer associated with the repeated command shall be set to be the buffer named by the name of the previous buffer logically incremented by 1.

If the repeated character is a text input command, the input text associated with that command is repeated literally:

- Input characters are neither macro or abbreviation-expanded.
- Input characters are not interpreted in any special way with the exception that <newline>, <carriage-return>, and <control>-T behave as described in [Input Mode Commands in vi](#) (on page 3371).

*Current line:* Set as described for the repeated command.

*Current column:* Set as described for the repeated command.

**Find Regular Expression**

*Synopsis:*      /

If the input line contains no non-<newline> characters, it shall be equivalent to a line containing only the last regular expression encountered. The enhanced regular expressions supported by *vi* are described in [Regular Expressions in ex](#) (on page 2699).

Otherwise, the line shall be interpreted as one or more regular expressions, optionally followed by an address offset or a *vi* **z** command.

If the regular expression is not the last regular expression on the line, or if a line offset or **z** command is specified, the regular expression shall be terminated by an unescaped **'/'** character, which shall not be used as part of the regular expression. If the regular expression is not the first regular expression on the line, it shall be preceded by zero or more <blank> characters, a <semicolon>, zero or more <blank> characters, and a leading **'/'** character, which shall not be interpreted as part of the regular expression. It shall be an error to precede any regular expression with any characters other than these.

Each search shall begin from the character after the first character of the last match (or, if it is the first search, after the cursor). If the **wraps**can edit option is set, the search shall continue to the character before the starting cursor character; otherwise, to the end of the edit buffer. It shall be an error if any search fails to find a match, and an informational message to this effect shall be displayed.

An optional address offset (see [Addressing in ex](#), on page 2668) can be specified after the last regular expression by including a trailing **'/'** character after the regular expression and

specifying the address offset. This offset will be from the line containing the match for the last regular expression specified. It shall be an error if the line offset would indicate a line address less than 1 or greater than the last line in the edit buffer. An address offset of zero shall be supported. It shall be an error to follow the address offset with any other characters than <blank> characters.

If not used as a motion command, an optional **z** command (see [Redraw Window](#), on page 3370) can be specified after the last regular expression by including a trailing ' / ' character after the regular expression, zero or more <blank> characters, a ' z ' , zero or more <blank> characters, an optional new **window** edit option value, zero or more <blank> characters, and a location character. The effect shall be as if the **z** command was executed after the / command. It shall be an error to follow the **z** command with any other characters than <blank> characters.

The remembered search direction shall be set to forward.

If used as a motion command:

1. It shall be an error if the last match references the same character in the edit buffer as the starting cursor.
2. If any address offset is specified, the last match shall be adjusted by the specified offset as described previously.
3. If the starting cursor is after the last match, then the locations of the starting cursor and the last match in the edit buffer shall be logically swapped.
4. If any address offset is specified, the text region shall consist of all lines containing characters from the starting cursor to the last match line, inclusive, and any text copied to a buffer shall be in line mode.
5. Otherwise, if the starting line is empty or the starting cursor is at or before the first non-<blank> non-<newline> of the starting line, and the last match line is empty or the last match starts at the first character of the last match line, the text region shall consist of all lines containing characters from the starting cursor to the line before the last match line, inclusive, and any text copied to a buffer shall be in line mode.
6. Otherwise, if the last match line is empty or the last match begins at a character at or before the first non-<blank> non-<newline> of the last match line, the region of text shall be from the current cursor to the last non-<newline> of the line before the last match line, inclusive, and any text copied to a buffer shall be in character mode.
7. Otherwise, the region of text shall be from the current cursor (inclusive), to the first character of the last match (exclusive), and any text copied to a buffer shall be in character mode.

If not used as a motion command:

*Current line*: If a match is found, set to the last matched line plus the address offset, if any; otherwise, unchanged.

*Current column*: Set to the last column on which any portion of the first character in the last matched string is displayed, if a match is found; otherwise, unchanged.

**Move to First Character in Line**

*Synopsis:*     0   (zero)

Move to the first character on the current line. The character '0' shall not be interpreted as a command if it is immediately preceded by a digit.

If used as a motion command:

1. If the cursor character is the first character in the line, it shall be an error.
2. The text region shall be from the character before the cursor character up to and including the first character in the line.
3. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

*Current line:* Unchanged.

*Current column:* The last column in which any portion of the first character in the line is displayed, or if the line is empty, unchanged.

**Execute an ex Command**

*Synopsis:*     :

Execute one or more *ex* commands.

If any portion of the screen other than the last line of the screen was overwritten by any *ex* command (except **shell**), *vi* shall display a message indicating that it is waiting for an input from the user, and shall then read a character. This action may also be taken for other, unspecified reasons.

If the next character entered is a ' : ', another *ex* command shall be accepted and executed. Any other character shall cause the screen to be refreshed and *vi* shall return to command mode.

*Current line:* As specified for the *ex* command.

*Current column:* As specified for the *ex* command.

**Repeat Find**

*Synopsis:*     [count] ;

This command shall be equivalent to the last **F**, **f**, **T**, or **t** command, with the specified *count*, and with the same search character used for the last **F**, **f**, **T**, or **t** command. If there was no previous **F**, **f**, **T**, or **t** command, it shall be an error.

**Shift Left**

*Synopsis:*     [count] < *motion*

If the motion command is the < command repeated:

1. If there are less than *count* - 1 lines after the current line in the edit buffer, it shall be an error.
2. The text region shall be from the current line, up to and including the next *count* - 1 lines.

Shift any line in the text region specified by the *count* and motion command one shiftwidth (see the *ex* **shiftwidth** option) toward the start of the line, as described by the *ex* < command. The unshifted lines shall be copied to the unnamed buffer in line mode.

*Current line:* If the motion was from the current cursor position toward the end of the edit buffer, unchanged. Otherwise, set to the first line in the edit buffer that is part of the text region specified by the motion command.

*Current column:* Set to non-<blank>.

## Shift Right

*Synopsis:*     [*count*] > *motion*

If the motion command is the > command repeated:

1. If there are less than *count* - 1 lines after the current line in the edit buffer, it shall be an error.
2. The text region shall be from the current line, up to and including the next *count* - 1 lines.

Shift any line with characters in the text region specified by the *count* and motion command one shiftwidth (see the *ex* **shiftwidth** option) away from the start of the line, as described by the *ex* > command. The unshifted lines shall be copied into the unnamed buffer in line mode.

*Current line:* If the motion was from the current cursor position toward the end of the edit buffer, unchanged. Otherwise, set to the first line in the edit buffer that is part of the text region specified by the motion command.

*Current column:* Set to non-<blank>.

## Scan Backwards for Regular Expression

*Synopsis:*     ?

Scan backwards; the ? command shall be equivalent to the / command (see [Find Regular Expression](#), on page 3353) with the following exceptions:

1. The input prompt shall be a ' ? '.
2. Each search shall begin from the character before the first character of the last match (or, if it is the first search, the character before the cursor character).
3. The search direction shall be from the cursor toward the beginning of the edit buffer, and the **wrapscan** edit option shall affect whether the search wraps to the end of the edit buffer and continues.
4. The remembered search direction shall be set to backward.

## Execute

*Synopsis:*     @*buffer*

If the *buffer* is specified as @, the last buffer executed shall be used. If no previous buffer has been executed, it shall be an error.

Behave as if the contents of the named buffer were entered as standard input. After each line of a line-mode buffer, and all but the last line of a character mode buffer, behave as if a <newline> were entered as standard input.

If an error occurs during this process, an error message shall be written, and no more characters resulting from the execution of this command shall be processed.

If a *count* is specified, behave as if that count were entered as user input before the characters from the @ buffer were entered.

112790 *Current line*: As specified for the individual commands.

112791 *Current column*: As specified for the individual commands.

## 112792 **Reverse Case**

112793 *Synopsis*:     [*count*] ~

112794 Reverse the case of the current character and the next *count* -1 characters, such that lowercase  
112795 characters that have uppercase counterparts shall be changed to uppercase characters, and  
112796 uppercase characters that have lowercase counterparts shall be changed to lowercase characters,  
112797 as prescribed by the current locale. No other characters shall be affected by this command.

112798 If there are less than *count* -1 characters after the cursor in the edit buffer, *count* shall be adjusted  
112799 to the number of characters after the cursor in the edit buffer minus 1.

112800 For the purposes of this command, the next character after the last non-<newline> on the line  
112801 shall be the next character in the edit buffer.

112802 *Current line*: Set to the line including the (*count*-1)th character after the cursor.

112803 *Current column*: Set to the last column in which any portion of the (*count*-1)th character after the  
112804 cursor is displayed.

## 112805 **Append**

112806 *Synopsis*:     [*count*] a

112807 Enter text input mode after the current cursor position. No characters already in the edit buffer  
112808 shall be affected by this command. A *count* shall cause the input text to be appended *count* -1  
112809 more times to the end of the input.

112810 *Current line/column*: As specified for the text input commands (see [Input Mode Commands in vi](#),  
112811 on page 3371).

## 112812 **Append at End-of-Line**

112813 *Synopsis*:     [*count*] A

112814 This command shall be equivalent to the *vi* command:

112815 \$ [ *count* ] a

112816 (see [Append](#)).

## 112817 **Move Backward to Preceding Word**

112818 *Synopsis*:     [*count*] b

112819 With the exception that words are used as the delimiter instead of bigwords, this command shall  
112820 be equivalent to the **B** command.

## Move Backward to Preceding Bigword

*Synopsis:*     [*count*] B

If the edit buffer is empty or the cursor is on the first character of the edit buffer, it shall be an error. If less than *count* bigwords begin between the cursor and the start of the edit buffer, *count* shall be adjusted to the number of bigword beginnings between the cursor and the start of the edit buffer.

If used as a motion command:

1. The text region shall be from the first character of the *count*th previous bigword beginning up to but not including the cursor character.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

*Current line:* Set to the line containing the *current column*.

*Current column:* Set to the last column upon which any part of the first character of the *count*th previous bigword is displayed.

## Change

*Synopsis:*     [*buffer*] [*count*] c *motion*

If the motion command is the **c** command repeated:

1. The buffer text shall be in line mode.
2. If there are less than *count* - 1 lines after the current line in the edit buffer, it shall be an error.
3. The text region shall be from the current line up to and including the next *count* - 1 lines.

Otherwise, the buffer text mode and text region shall be as specified by the motion command.

The replaced text shall be copied into *buffer*, if specified, and into the unnamed buffer. If the text to be replaced contains characters from more than a single line, or the buffer text is in line mode, the replaced text shall be copied into the numeric buffers as well.

If the buffer text is in line mode:

1. Any lines that contain characters in the region shall be deleted, and the editor shall enter text input mode at the beginning of a new line which shall replace the first line deleted.
2. If the **autoindent** edit option is set, **autoindent** characters equal to the **autoindent** characters on the first line deleted shall be inserted as if entered by the user.

Otherwise, if characters from more than one line are in the region of text:

1. The text shall be deleted.
2. Any text remaining in the last line in the text region shall be appended to the first line in the region, and the last line in the region shall be deleted.
3. The editor shall enter text input mode after the last character not deleted from the first line in the text region, if any; otherwise, on the first column of the first line in the region.

Otherwise:

1. If the glyph for ' \$ ' is smaller than the region, the end of the region shall be marked with a ' \$ '.
2. The editor shall enter text input mode, overwriting the region of text.

*Current line/column:* As specified for the text input commands (see [Input Mode Commands in vi](#), on page 3371).

### Change to End-of-Line

*Synopsis:*     [*buffer*] [*count*] C

This command shall be equivalent to the *vi* command:

[*buffer*] [*count*] c\$

See the **c** command.

### Delete

*Synopsis:*     [*buffer*] [*count*] d *motion*

If the motion command is the **d** command repeated:

1. The buffer text shall be in line mode.
2. If there are less than *count* - 1 lines after the current line in the edit buffer, it shall be an error.
3. The text region shall be from the current line up to and including the next *count* - 1 lines.

Otherwise, the buffer text mode and text region shall be as specified by the motion command.

If in open mode, and the current line is deleted, and the line remains on the display, an '@' character shall be displayed as the first glyph of that line.

Delete the region of text into *buffer*, if specified, and into the unnamed buffer. If the text to be deleted contains characters from more than a single line, or the buffer text is in line mode, the deleted text shall be copied into the numeric buffers, as well.

*Current line:* Set to the first text region line that appears in the edit buffer, unless that line has been deleted, in which case it shall be set to the last line in the edit buffer, or line 1 if the edit buffer is empty.

*Current column:*

1. If the line is empty, set to column position 1.
2. Otherwise, if the buffer text is in line mode or the motion was from the cursor toward the end of the edit buffer:
  - a. If a character from the current line is displayed in the current column, set to the last column that displays any portion of that character.
  - b. Otherwise, set to the last column in which any portion of any character in the line is displayed.
3. Otherwise, if a character is displayed in the column that began the text region, set to the last column that displays any portion of that character.

- 112894 4. Otherwise, set to the last column in which any portion of any character in the line is  
112895 displayed.

#### 112896 **Delete to End-of-Line**

112897 *Synopsis:*     [*buffer*] D

112898 Delete the text from the current position to the end of the current line; equivalent to the *vi*  
112899 command:

112900 [*buffer*] d\$

#### 112901 **Move to End-of-Word**

112902 *Synopsis:*     [*count*] e

112903 With the exception that words are used instead of bigwords as the delimiter, this command shall  
112904 be equivalent to the **E** command.

#### 112905 **Move to End-of-Bigword**

112906 *Synopsis:*     [*count*] E

112907 If the edit buffer is empty it shall be an error. If less than *count* bigwords end between the cursor  
112908 and the end of the edit buffer, *count* shall be adjusted to the number of bigword endings between  
112909 the cursor and the end of the edit buffer.

112910 If used as a motion command:

- 112911 1. The text region shall be from the last character of the *count*th next bigword up to and  
112912 including the cursor character.
- 112913 2. Any text copied to a buffer shall be in character mode.

112914 If not used as a motion command:

112915 *Current line:* Set to the line containing the current column.

112916 *Current column:* Set to the last column upon which any part of the last character of the *count*th  
112917 next bigword is displayed.

#### 112918 **Find Character in Current Line (Forward)**

112919 *Synopsis:*     [*count*] f *character*

112920 It shall be an error if *count* occurrences of the character do not occur after the cursor in the line.

112921 If used as a motion command:

- 112922 1. The text range shall be from the cursor character up to and including the *count*th  
112923 occurrence of the specified character after the cursor.
- 112924 2. Any text copied to a buffer shall be in character mode.

112925 If not used as a motion command:

112926 *Current line:* Unchanged.

112927 *Current column:* Set to the last column in which any portion of the *count*th occurrence of the  
112928 specified character after the cursor appears in the line.

**Find Character in Current Line (Reverse)**

*Synopsis:*     [*count*] F *character*

It shall be an error if *count* occurrences of the character do not occur before the cursor in the line.

If used as a motion command:

1. The text region shall be from the *count*th occurrence of the specified character before the cursor, up to, but not including the cursor character.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

*Current line:* Unchanged.

*Current column:* Set to the last column in which any portion of the *count*th occurrence of the specified character before the cursor appears in the line.

**Move to Line**

*Synopsis:*     [*count*] G

If *count* is not specified, it shall default to the last line of the edit buffer. If *count* is greater than the last line of the edit buffer, it shall be an error.

If used as a motion command:

1. The text region shall be from the cursor line up to and including the specified line.
2. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

*Current line:* Set to *count* if *count* is specified; otherwise, the last line.

*Current column:* Set to non-<blank>.

**Move to Top of Screen**

*Synopsis:*     [*count*] H

If the beginning of the line *count* greater than the first line of which any portion appears on the display does not exist, it shall be an error.

If used as a motion command:

1. If in open mode, the text region shall be the current line.
2. Otherwise, the text region shall be from the starting line up to and including (the first line of the display + *count* - 1).
3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

If in open mode, this command shall set the current column to non-<blank> and do nothing else.

Otherwise, it shall set the current line and current column as follows.

*Current line:* Set to (the first line of the display + *count* - 1).

*Current column:* Set to non-<blank>.

**Insert Before Cursor**

*Synopsis:*     [*count*] i

Enter text input mode before the current cursor position. No characters already in the edit buffer shall be affected by this command. A *count* shall cause the input text to be appended *count* -1 more times to the end of the input.

*Current line/column:* As specified for the text input commands (see [Input Mode Commands in vi](#), on page 3371).

**Insert at Beginning of Line**

*Synopsis:*     [*count*] I

This command shall be equivalent to the *vi* command `^[count]i`.

**Join**

*Synopsis:*     [*count*] J

If the current line is the last line in the edit buffer, it shall be an error.

This command shall be equivalent to the *ex* **join** command with no addresses, and an *ex* command *count* value of 1 if *count* was not specified or if a *count* of 1 was specified, and an *ex* command *count* value of *count* -1 for any other value of *count*, except that the current line and column shall be set as follows.

*Current line:* Unchanged.

*Current column:* The last column in which any portion of the character following the last character in the initial line is displayed, or the last non-<newline> in the line if no characters were appended.

**Move to Bottom of Screen**

*Synopsis:*     [*count*] L

If the beginning of the line *count* less than the last line of which any portion appears on the display does not exist, it shall be an error.

If used as a motion command:

1. If in open mode, the text region shall be the current line.
2. Otherwise, the text region shall include all lines from the starting cursor line to (the last line of the display -(*count* -1)).
3. Any text copied to a buffer shall be in line mode.

If not used as a motion command:

1. If in open mode, this command shall set the current column to non-<blank> and do nothing else.
2. Otherwise, it shall set the current line and current column as follows.

*Current line:* Set to (the last line of the display -(*count* -1)).

*Current column:* Set to non-<blank>.

## 113000 **Mark Position**

113001 *Synopsis:*     m letter

113002 This command shall be equivalent to the *ex* **mark** command with the specified character as an  
113003 argument.

## 113004 **Move to Middle of Screen**

113005 *Synopsis:*     M

113006 The middle line of the display shall be calculated as follows:

113007 (the top line of the display) + (((number of lines displayed) + 1) / 2) - 1

113008 If used as a motion command:

- 113009     1. If in open mode, the text region shall be the current line.
- 113010     2. Otherwise, the text region shall include all lines from the starting cursor line up to and  
113011         including the middle line of the display.
- 113012     3. Any text copied to a buffer shall be in line mode.

113013 If not used as a motion command:

113014 If in open mode, this command shall set the current column to non-<blank> and do nothing else.

113015 Otherwise, it shall set the current line and current column as follows.

113016 *Current line:* Set to the middle line of the display.

113017 *Current column:* Set to non-<blank>.

## 113018 **Repeat Regular Expression Find (Forward)**

113019 *Synopsis:*     n

113020 If the remembered search direction was forward, the **n** command shall be equivalent to the *vi* /  
113021 command with no characters entered by the user. Otherwise, it shall be equivalent to the *vi* ?  
113022 command with no characters entered by the user.

113023 If the **n** command is used as a motion command for the **!** command, the editor shall not enter  
113024 text input mode on the last line on the screen, and shall behave as if the user entered a single  
113025 '!' character as the text input.

## 113026 **Repeat Regular Expression Find (Reverse)**

113027 *Synopsis:*     N

113028 Scan for the next match of the last pattern given to / or ?, but in the reverse direction; this is the  
113029 reverse of **n**.

113030 If the remembered search direction was forward, the **N** command shall be equivalent to the *vi* ?  
113031 command with no characters entered by the user. Otherwise, it shall be equivalent to the *vi* /  
113032 command with no characters entered by the user. If the **N** command is used as a motion  
113033 command for the **!** command, the editor shall not enter text input mode on the last line on the  
113034 screen, and shall behave as if the user entered a single **!** character as the text input.

**Insert Empty Line Below**

*Synopsis:*      ○

Enter text input mode in a new line appended after the current line. A *count* shall cause the input text to be appended *count* -1 more times to the end of the already added text, each time starting on a new, appended line.

*Current line/column:* As specified for the text input commands (see [Input Mode Commands in vi](#), on page 3371).

**Insert Empty Line Above**

*Synopsis:*      ○

Enter text input mode in a new line inserted before the current line. A *count* shall cause the input text to be appended *count* -1 more times to the end of the already added text, each time starting on a new, appended line.

*Current line/column:* As specified for the text input commands (see [Input Mode Commands in vi](#), on page 3371).

**Put from Buffer Following**

*Synopsis:*      [*buffer*] p

If no *buffer* is specified, the unnamed buffer shall be used.

If the buffer text is in line mode, the text shall be appended below the current line, and each line of the buffer shall become a new line in the edit buffer. A *count* shall cause the buffer text to be appended *count* -1 more times to the end of the already added text, each time starting on a new, appended line.

If the buffer text is in character mode, the text shall be appended into the current line after the cursor, and each line of the buffer other than the first and last shall become a new line in the edit buffer. A *count* shall cause the buffer text to be appended *count* -1 more times to the end of the already added text, each time starting after the last added character.

*Current line:* If the buffer text is in line mode, set the line to line +1; otherwise, unchanged.

*Current column:* If the buffer text is in line mode:

1. If there is a non-<blank> in the first line of the buffer, set to the last column on which any portion of the first non-<blank> in the line is displayed.
2. If there is no non-<blank> in the first line of the buffer, set to the last column on which any portion of the last non-<newline> in the first line of the buffer is displayed.

If the buffer text is in character mode:

1. If the text in the buffer is from more than a single line, then set to the last column on which any portion of the first character from the buffer is displayed.
2. Otherwise, if the buffer is the unnamed buffer, set to the last column on which any portion of the last character from the buffer is displayed.
3. Otherwise, set to the first column on which any portion of the first character from the buffer is displayed.

**Put from Buffer Before**

*Synopsis:*      **[buffer]** P

If no *buffer* is specified, the unnamed buffer shall be used.

If the buffer text is in line mode, the text shall be inserted above the current line, and each line of the buffer shall become a new line in the edit buffer. A *count* shall cause the buffer text to be appended *count* -1 more times to the end of the already added text, each time starting on a new, appended line.

If the buffer text is in character mode, the text shall be inserted into the current line before the cursor, and each line of the buffer other than the first and last shall become a new line in the edit buffer. A *count* shall cause the buffer text to be appended *count* -1 more times to the end of the already added text, each time starting after the last added character.

*Current line:* Unchanged.

*Current column:* If the buffer text is in line mode:

1. If there is a non-<blank> in the first line of the buffer, set to the last column on which any portion of that character is displayed.
2. If there is no non-<blank> in the first line of the buffer, set to the last column on which any portion of the last non-<newline> in the first line of the buffer is displayed.

If the buffer text is in character mode:

1. If the text in the buffer is from more than a single line, then set to the last column on which any portion of the first character from the buffer is displayed.
2. Otherwise, if the buffer is the unnamed buffer, set to the last column on which any portion of the last character from the buffer is displayed.
3. Otherwise, set to the first column on which any portion of the first character from the buffer is displayed.

**Enter ex Mode**

*Synopsis:*      Q

Leave visual or open mode and enter *ex* command mode.

*Current line:* Unchanged.

*Current column:* Unchanged.

**Replace Character**

*Synopsis:*      **[count]** r *character*

Replace the *count* characters at and after the cursor with the specified character. If there are less than *count* non-<newline> characters at and after the cursor on the line, it shall be an error.

If character is <control>-V, any next character other than the <newline> shall be stripped of any special meaning and used as a literal character.

If character is <ESC>, no replacement shall be made and the current line and current column shall be unchanged.

If character is <carriage-return> or <newline>, *count* new lines shall be appended to the current line. All but the last of these lines shall be empty. *count* characters at and after the cursor shall be

discarded, and any remaining characters after the cursor in the current line shall be moved to the last of the new lines. If the **autoindent** edit option is set, they shall be preceded by the same number of **autoindent** characters found on the line from which the command was executed.

*Current line*: Unchanged unless the replacement character is a <carriage-return> or <newline>, in which case it shall be set to line + *count*.

*Current column*: Set to the last column position on which a portion of the last replaced character is displayed, or if the replacement character caused new lines to be created, set to non-<blank>.

### Replace Characters

*Synopsis*:       R

Enter text input mode at the current cursor position possibly replacing text on the current line. A *count* shall cause the input text to be appended *count* - 1 more times to the end of the input.

*Current line/column*: As specified for the text input commands (see [Input Mode Commands in vi](#), on page 3371).

### Substitute Character

*Synopsis*:       [*buffer*] [*count*] s

This command shall be equivalent to the *vi* command:

[*buffer*] [*count*] c<space>

### Substitute Lines

*Synopsis*:       [*buffer*] [*count*] S

This command shall be equivalent to the *vi* command:

[*buffer*] [*count*] c\_

### Move Cursor to Before Character (Forward)

*Synopsis*:       [*count*] t *character*

It shall be an error if *count* occurrences of the character do not occur after the cursor in the line.

If used as a motion command:

1. The text region shall be from the cursor up to but not including the *count*th occurrence of the specified character after the cursor.
2. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

*Current line*: Unchanged.

*Current column*: Set to the last column in which any portion of the character before the *count*th occurrence of the specified character after the cursor appears in the line.

**Move Cursor to After Character (Reverse)**

*Synopsis:*     `[count] T character`

It shall be an error if *count* occurrences of the character do not occur before the cursor in the line.

If used as a motion command:

1. If the character before the cursor is the specified character, it shall be an error.
2. The text region shall be from the character before the cursor up to but not including the *count*th occurrence of the specified character before the cursor.
3. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

*Current line:* Unchanged.

*Current column:* Set to the last column in which any portion of the character after the *count*th occurrence of the specified character before the cursor appears in the line.

**Undo**

*Synopsis:*     `u`

This command shall be equivalent to the *ex* **undo** command except that the current line and current column shall be set as follows:

*Current line:* Set to the first line added or changed if any; otherwise, move to the line preceding any deleted text if one exists; otherwise, move to line 1.

*Current column:* If undoing an *ex* command, set to the first non-<blank>.

Otherwise, if undoing a text input command:

1. If the command was a **C**, **c**, **O**, **o**, **R**, **S**, or **s** command, the current column shall be set to the value it held when the text input command was entered.
2. Otherwise, set to the last column in which any portion of the first character after the deleted text is displayed, or, if no non-<newline> characters follow the text deleted from this line, set to the last column in which any portion of the last non-<newline> in the line is displayed, or 1 if the line is empty.

Otherwise, if a single line was modified (that is, not added or deleted) by the **u** command:

1. If text was added or changed, set to the last column in which any portion of the first character added or changed is displayed.
2. If text was deleted, set to the last column in which any portion of the first character after the deleted text is displayed, or, if no non-<newline> characters follow the deleted text, set to the last column in which any portion of the last non-<newline> in the line is displayed, or 1 if the line is empty.

Otherwise, set to non-<blank>.

**Undo Current Line**

*Synopsis:*     U

Restore the current line to its state immediately before the most recent time that it became the current line.

*Current line:* Unchanged.

*Current column:* Set to the first column in the line in which any portion of the first character in the line is displayed.

**Move to Beginning of Word**

*Synopsis:*     [count] w

With the exception that words are used as the delimiter instead of bigwords, this command shall be equivalent to the **W** command.

**Move to Beginning of Bigword**

*Synopsis:*     [count] W

If the edit buffer is empty, it shall be an error. If there are less than *count* bigwords between the cursor and the end of the edit buffer, *count* shall be adjusted to move the cursor to the last bigword in the edit buffer.

If used as a motion command:

1. If the associated command is **c**, *count* is 1, and the cursor is on a <blank>, the region of text shall be the current character and no further action shall be taken.
2. If there are less than *count* bigwords between the cursor and the end of the edit buffer, then the command shall succeed, and the region of text shall include the last character of the edit buffer.
3. If there are <blank> characters or an end-of-line that precede the *count*th bigword, and the associated command is **c**, the region of text shall be up to and including the last character before the preceding <blank> characters or end-of-line.
4. If there are <blank> characters or an end-of-line that precede the bigword, and the associated command is **d** or **y**, the region of text shall be up to and including the last <blank> before the start of the bigword or end-of-line.
5. Any text copied to a buffer shall be in character mode.

If not used as a motion command:

1. If the cursor is on the last character of the edit buffer, it shall be an error.

*Current line:* Set to the line containing the current column.

*Current column:* Set to the last column in which any part of the first character of the *count*th next bigword is displayed.

**Delete Character at Cursor**

*Synopsis:*      `[buffer] [count] x`

Delete the *count* characters at and after the current character into *buffer*, if specified, and into the unnamed buffer.

If the line is empty, it shall be an error. If there are less than *count* non-<newline> characters at and after the cursor on the current line, *count* shall be adjusted to the number of non-<newline> characters at and after the cursor.

*Current line:* Unchanged.

*Current column:* If the line is empty, set to column position 1. Otherwise, if there were *count* or less non-<newline> characters at and after the cursor on the current line, set to the last column that displays any part of the last non-<newline> of the line. Otherwise, unchanged.

**Delete Character Before Cursor**

*Synopsis:*      `[buffer] [count] X`

Delete the *count* characters before the current character into *buffer*, if specified, and into the unnamed buffer.

If there are no characters before the current character on the current line, it shall be an error. If there are less than *count* previous characters on the current line, *count* shall be adjusted to the number of previous characters on the line.

*Current line:* Unchanged.

*Current column:* Set to (current column – the width of the deleted characters).

**Yank**

*Synopsis:*      `[buffer] [count] y motion`

Copy (yank) the region of text into *buffer*, if specified, and into the unnamed buffer.

If the motion command is the *y* command repeated:

1. The buffer shall be in line mode.
2. If there are less than *count* – 1 lines after the current line in the edit buffer, it shall be an error.
3. The text region shall be from the current line up to and including the next *count* – 1 lines.

Otherwise, the buffer text mode and text region shall be as specified by the motion command.

*Current line:* If the motion was from the current cursor position toward the end of the edit buffer, unchanged. Otherwise, set to the first line in the edit buffer that is part of the text region specified by the motion command.

*Current column:*

1. If the motion was from the current cursor position toward the end of the edit buffer, unchanged.
2. Otherwise, if the current line is empty, set to column position 1.
3. Otherwise, set to the last column that displays any part of the first character in the file that is part of the text region specified by the motion command.

**Yank Current Line**

*Synopsis:*     [*buffer*] [*count*] Y

This command shall be equivalent to the *vi* command:

[*buffer*] [*count*] y\_

**Redraw Window**

If in open mode, the **z** command shall have the Synopsis:

*Synopsis:*     [*count*] z

If *count* is not specified, it shall default to the **window** edit option *-1*. The **z** command shall be equivalent to the *ex z* command, with a type character of **=** and a *count* of *count -2*, except that the current line and current column shall be set as follows, and the **window** edit option shall not be affected. If the calculation for the *count* argument would result in a negative number, the *count* argument to the *ex z* command shall be zero. A blank line shall be written after the last line is written.

*Current line:* Unchanged.

*Current column:* Unchanged.

If not in open mode, the **z** command shall have the following Synopsis:

*Synopsis:*     [*line*] z [*count*] *character*

If *line* is not specified, it shall default to the current line. If *line* is specified, but is greater than the number of lines in the edit buffer, it shall default to the number of lines in the edit buffer.

If *count* is specified, the value of the **window** edit option shall be set to *count* (as described in the *ex window* command), and the screen shall be redrawn.

*line* shall be placed as specified by the following characters:

<newline>, <carriage-return>

Place the beginning of the line on the first line of the display.

. Place the beginning of the line in the center of the display. The middle line of the display shall be calculated as described for the **M** command.

– Place an unspecified portion of the line on the last line of the display.

+ If *line* was specified, equivalent to the <newline> case. If *line* was not specified, display a screen where the first line of the display shall be (current last line) +1. If there are no lines after the last line in the display, it shall be an error.

^ If *line* was specified, display a screen where the last line of the display shall contain an unspecified portion of the first line of a display that had an unspecified portion of the specified line on the last line of the display. If this calculation results in a line before the beginning of the edit buffer, display the first screen of the edit buffer.

Otherwise, display a screen where the last line of the display shall contain an unspecified portion of (current first line *-1*). If this calculation results in a line before the beginning of the edit buffer, it shall be an error.

Current line: If *line* and the ' ^ ' character were specified:

1. If the first screen was displayed as a result of the command attempting to display lines before the beginning of the edit buffer: if the first screen was already displayed, unchanged; otherwise, set to (current first line -1).
2. Otherwise, set to the last line of the display.

If *line* and the ' +' character were specified, set to the first line of the display.

Otherwise, if *line* was specified, set to *line*.

Otherwise, unchanged.

Current column: Set to non-<blank>.

## Exit

Synopsis:      ZZ

This command shall be equivalent to the *ex xit* command with no addresses, trailing *!*, or filename (see the *ex xit* command).

## Input Mode Commands in vi

In text input mode, the current line shall consist of zero or more of the following categories, plus the terminating <newline>:

1. Characters preceding the text input entry point

Characters in this category shall not be modified during text input mode.

2. **autoindent** characters

**autoindent** characters shall be automatically inserted into each line that is created in text input mode, either as a result of entering a <newline> or <carriage-return> while in text input mode, or as an effect of the command itself; for example, **O** or **o** (see the *ex autoindent* command), as if entered by the user.

It shall be possible to erase **autoindent** characters with the <control>-D command; it is unspecified whether they can be erased by <control>-H, <control>-U, and <control>-W characters. Erasing any **autoindent** character turns the glyph into erase-columns and deletes the character from the edit buffer, but does not change its representation on the screen.

3. Text input characters

Text input characters are the characters entered by the user. Erasing any text input character turns the glyph into erase-columns and deletes the character from the edit buffer, but does not change its representation on the screen.

Each text input character entered by the user (that does not have a special meaning) shall be treated as follows:

- a. The text input character shall be appended to the last character in the edit buffer from the first, second, or third categories.
- b. If there are no erase-columns on the screen, the text input command was the **R** command, and characters in the fifth category from the original line follow the cursor, the next such character shall be deleted from the edit buffer. If the **slowopen** edit option is not set, the corresponding glyph on the screen shall

- 113327 become erase-columns.
- 113328 c. If there are erase-columns on the screen, as many columns as they occupy, or as are  
113329 necessary, shall be overwritten to display the text input character. (If only part of a  
113330 multi-column glyph is overwritten, the remainder shall be left on the screen, and  
113331 continue to be treated as erase-columns; it is unspecified whether the remainder of  
113332 the glyph is modified in any way.)
- 113333 d. If additional display line columns are needed to display the text input character:
- 113334 i. If the **slowopen** edit option is set, the text input characters shall be  
113335 displayed on subsequent display line columns, overwriting any characters  
113336 displayed in those columns.
- 113337 ii. Otherwise, any characters currently displayed on or after the column on the  
113338 display line where the text input character is to be displayed shall be  
113339 pushed ahead the number of display line columns necessary to display the  
113340 rest of the text input character.
- 113341 4. Erase-columns
- 113342 Erase-columns are not logically part of the edit buffer, appearing only on the screen, and  
113343 may be overwritten on the screen by subsequent text input characters. When text input  
113344 mode ends, all erase-columns shall no longer appear on the screen.
- 113345 Erase-columns are initially the region of text specified by the **c** command (see [Change](#), on  
113346 page 3358); however, erasing **autoindent** or text input characters causes the glyphs of the  
113347 erased characters to be treated as erase-columns.
- 113348 5. Characters following the text region for the **c** command, or the text input entry point for  
113349 all other commands
- 113350 Characters in this category shall not be modified during text input mode, except as  
113351 specified in category 3.b. for the **R** text input command, or as <blank> characters deleted  
113352 when a <newline> or <carriage-return> is entered.
- 113353 It is unspecified whether it is an error to attempt to erase past the beginning of a line that was  
113354 created by the entry of a <newline> or <carriage-return> during text input mode. If it is not an  
113355 error, the editor shall behave as if the erasing character was entered immediately after the last  
113356 text input character entered on the previous line, and all of the non-<newline> characters on the  
113357 current line shall be treated as erase-columns.
- 113358 When text input mode is entered, or after a text input mode character is entered (except as  
113359 specified for the special characters below), the cursor shall be positioned as follows:
- 113360 1. On the first column that displays any part of the first erase-column, if one exists
- 113361 2. Otherwise, if the **slowopen** edit option is set, on the first display line column after the last  
113362 character in the first, second, or third categories, if one exists
- 113363 3. Otherwise, the first column that displays any part of the first character in the fifth  
113364 category, if one exists
- 113365 4. Otherwise, the display line column after the last character in the first, second, or third  
113366 categories, if one exists
- 113367 5. Otherwise, on column position 1
- 113368 The characters that are updated on the screen during text input mode are unspecified, other than  
113369 that the last text input character shall always be updated, and, if the **slowopen** edit option is not

113370 set, the current cursor character shall always be updated.

113371 The following specifications are for command characters entered during text input mode.

113372 **NUL**

113373 *Synopsis:* NUL

113374 If the first character of the text input is a NUL, the most recently input text shall be input as if  
 113375 entered by the user, and then text input mode shall be exited. The text shall be input literally;  
 113376 that is, characters are neither macro or abbreviation expanded, nor are any characters interpreted  
 113377 in any special manner. It is unspecified whether implementations shall support more than 256  
 113378 bytes of remembered input text.

113379 **<control>-D**

113380 *Synopsis:* <control>-D

113381 The <control>-D character shall have no special meaning when in text input mode for a line-  
 113382 oriented command (see [Command Descriptions in vi](#), on page 3337).

113383 This command need not be supported on block-mode terminals.

113384 If the cursor does not follow an **autoindent** character, or an **autoindent** character and a '0' or  
 113385 '^' character:

- 113386 1. If the cursor is in column position 1, the <control>-D character shall be discarded and no  
 113387 further action taken.
- 113388 2. Otherwise, the <control>-D character shall have no special meaning.

113389 If the last input character was a '0', the cursor shall be moved to column position 1.

113390 Otherwise, if the last input character was a '^', the cursor shall be moved to column position 1.  
 113391 In addition, the **autoindent** level for the next input line shall be derived from the same line from  
 113392 which the **autoindent** level for the current input line was derived.

113393 Otherwise, the cursor shall be moved back to the column after the previous shiftwidth (see the  
 113394 *ex* **shiftwidth** command) boundary.

113395 All of the glyphs on columns between the starting cursor position and (inclusively) the ending  
 113396 cursor position shall become erase-columns as described in [Input Mode Commands in vi](#) (on  
 113397 page 3371).

113398 *Current line:* Unchanged.

113399 *Current column:* Set to 1 if the <control>-D was preceded by a '^' or '0'; otherwise, set to  
 113400 (column -1) - ((column -2) % **shiftwidth**).

113401 **<control>-H**

113402 *Synopsis:* <control>-H

113403 If in text input mode for a line-oriented command, and there are no characters to erase, text  
 113404 input mode shall be terminated, no further action shall be done for this command, and the  
 113405 current line and column shall be unchanged.

113406 If there are characters other than **autoindent** characters that have been input on the current line  
 113407 before the cursor, the cursor shall move back one character.

113408 Otherwise, if there are **autoindent** characters on the current line before the cursor, it is

implementation-defined whether the <control>-H command is an error or if the cursor moves back one **autoindent** character.

Otherwise, if the cursor is in column position 1 and there are previous lines that have been input, it is implementation-defined whether the <control>-H command is an error or if it is equivalent to entering <control>-H after the last input character on the previous input line.

Otherwise, it shall be an error.

All of the glyphs on columns between the starting cursor position and (inclusively) the ending cursor position shall become erase-columns as described in [Input Mode Commands in vi](#) (on page 3371).

The current erase character (see *stty*) shall cause an equivalent action to the <control>-H command, unless the previously inserted character was a <backslash>, in which case it shall be as if the literal current erase character had been inserted instead of the <backslash>.

*Current line*: Unchanged, unless previously input lines are erased, in which case it shall be set to line -1.

*Current column*: Set to the first column that displays any portion of the character backed up over.

#### <newline>

*Synopsis*:     <newline>  
                   <carriage-return>  
                   <control>-J  
                   <control>-M

If input was part of a line-oriented command, text input mode shall be terminated and the command shall continue execution with the input provided.

Otherwise, terminate the current line. If there are no characters other than **autoindent** characters on the line, all characters on the line shall be discarded. Otherwise, it is unspecified whether the **autoindent** characters in the line are modified by entering these characters.

Continue text input mode on a new line appended after the current line. If the **slowopen** edit option is set, the lines on the screen below the current line shall not be pushed down, but the first of them shall be cleared and shall appear to be overwritten. Otherwise, the lines of the screen below the current line shall be pushed down.

If the **autoindent** edit option is set, an appropriate number of **autoindent** characters shall be added as a prefix to the line as described by the *ex* **autoindent** edit option.

All columns after the cursor that are erase-columns (as described in [Input Mode Commands in vi](#), on page 3371) shall be discarded.

If the **autoindent** edit option is set, all <blank> characters immediately following the cursor shall be discarded.

All remaining characters after the cursor shall be transferred to the new line, positioned after any **autoindent** characters.

*Current line*: Set to current line +1.

*Current column*: Set to the first column that displays any portion of the first character after the **autoindent** characters on the new line, if any, or the first column position after the last **autoindent** character, if any, or column position 1.

113450 **<control>-T**113451 *Synopsis:*      <control>-T113452 The <control>-T character shall have no special meaning when in text input mode for a line-  
113453 oriented command (see [Command Descriptions in vi](#), on page 3337).

113454 This command need not be supported on block-mode terminals.

113455 Behave as if the user entered the minimum number of <blank> characters necessary to move the  
113456 cursor forward to the column position after the next **shiftwidth** (see the *ex* **shiftwidth**  
113457 command) boundary.113458 *Current line:* Unchanged.113459 *Current column:* Set to  $column + shiftwidth - ((column - 1) \% shiftwidth)$ .113460 **<control>-U**113461 *Synopsis:*      <control>-U113462 If there are characters other than **autoindent** characters that have been input on the current line  
113463 before the cursor, the cursor shall move to the first character input after the **autoindent**  
113464 characters.113465 Otherwise, if there are **autoindent** characters on the current line before the cursor, it is  
113466 implementation-defined whether the <control>-U command is an error or if the cursor moves to  
113467 the first column position on the line.113468 Otherwise, if the cursor is in column position 1 and there are previous lines that have been  
113469 input, it is implementation-defined whether the <control>-U command is an error or if it is  
113470 equivalent to entering <control>-U after the last input character on the previous input line.

113471 Otherwise, it shall be an error.

113472 All of the glyphs on columns between the starting cursor position and (inclusively) the ending  
113473 cursor position shall become erase-columns as described in [Input Mode Commands in vi](#) (on  
113474 page 3371).113475 The current *kill* character (see *stty*) shall cause an equivalent action to the <control>-U command,  
113476 unless the previously inserted character was a <backslash>, in which case it shall be as if the  
113477 literal current *kill* character had been inserted instead of the <backslash>.113478 *Current line:* Unchanged, unless previously input lines are erased, in which case it shall be set to  
113479 line -1.113480 *Current column:* Set to the first column that displays any portion of the last character backed up  
113481 over.113482 **<control>-V**113483 *Synopsis:*      <control>-V  
113484                      <control>-Q113485 Allow the entry of any subsequent character, other than <control>-J or the <newline>, as a literal  
113486 character, removing any special meaning that it may have to the editor in text input mode. If a  
113487 <control>-V or <control>-Q is entered before a <control>-J or <newline>, the <control>-V or  
113488 <control>-Q character shall be discarded, and the <control>-J or <newline> shall behave as  
113489 described in the <newline> command character during input mode.

113490 For purposes of the display only, the editor shall behave as if a ' ^ ' character was entered, and

113491 the cursor shall be positioned as if overwriting the ' ^ ' character. When a subsequent character  
 113492 is entered, the editor shall behave as if that character was entered instead of the original  
 113493 <control>-V or <control>-Q character.

113494 *Current line:* Unchanged.

113495 *Current column:* Unchanged.

#### 113496 <control>-W

113497 *Synopsis:* <control>-W

113498 If there are characters other than **autoindent** characters that have been input on the current line  
 113499 before the cursor, the cursor shall move back over the last word preceding the cursor (including  
 113500 any <blank> characters between the end of the last word and the current cursor); the cursor shall  
 113501 not move to before the first character after the end of any **autoindent** characters.

113502 Otherwise, if there are **autoindent** characters on the current line before the cursor, it is  
 113503 implementation-defined whether the <control>-W command is an error or if the cursor moves to  
 113504 the first column position on the line.

113505 Otherwise, if the cursor is in column position 1 and there are previous lines that have been  
 113506 input, it is implementation-defined whether the <control>-W command is an error or if it is  
 113507 equivalent to entering <control>-W after the last input character on the previous input line.

113508 Otherwise, it shall be an error.

113509 All of the glyphs on columns between the starting cursor position and (inclusively) the ending  
 113510 cursor position shall become erase-columns as described in [Input Mode Commands in vi](#) (on  
 113511 page 3371).

113512 *Current line:* Unchanged, unless previously input lines are erased, in which case it shall be set to  
 113513 line -1.

113514 *Current column:* Set to the first column that displays any portion of the last character backed up  
 113515 over.

#### 113516 <ESC>

113517 *Synopsis:* <ESC>

113518 If input was part of a line-oriented command:

- 113519 1. If *interrupt* was entered, text input mode shall be terminated and the editor shall return to  
 113520 command mode. The terminal shall be alerted.
- 113521 2. If <ESC> was entered, text input mode shall be terminated and the command shall  
 113522 continue execution with the input provided.

113523 Otherwise, terminate text input mode and return to command mode.

113524 Any **autoindent** characters entered on newly created lines that have no other non-<newline>  
 113525 characters shall be deleted.

113526 Any leading **autoindent** and <blank> characters on newly created lines shall be rewritten to be  
 113527 the minimum number of <blank> characters possible.

113528 The screen shall be redisplayed as necessary to match the contents of the edit buffer.

113529 *Current line:* Unchanged.

113530 *Current column:*

- 113531 1. If there are text input characters on the current line, the column shall be set to the last  
113532 column where any portion of the last text input character is displayed.
- 113533 2. Otherwise, if a character is displayed in the current column, unchanged.
- 113534 3. Otherwise, set to column position 1.

#### 113535 **EXIT STATUS**

113536 The following exit values shall be returned:

- 113537 0 Successful completion.
- 113538 >0 An error occurred.

#### 113539 **CONSEQUENCES OF ERRORS**

113540 When any error is encountered and the standard input is not a terminal device file, *vi* shall not  
113541 write the file or return to command or text input mode, and shall terminate with a non-zero exit  
113542 status.

113543 Otherwise, when an unrecoverable error is encountered it shall be equivalent to a SIGHUP  
113544 asynchronous event.

113545 Otherwise, when an error is encountered, the editor shall behave as specified in [Command](#)  
113546 [Descriptions in vi](#) (on page 3337).

#### 113547 **APPLICATION USAGE**

113548 None.

#### 113549 **EXAMPLES**

113550 None.

#### 113551 **RATIONALE**

113552 See the RATIONALE for [ex](#) for more information on *vi*. Major portions of the *vi* utility  
113553 specification point to *ex* to avoid inadvertent divergence. While *ex* and *vi* have historically been  
113554 implemented as a single utility, this is not required by POSIX.1-2008.

113555 It is recognized that portions of *vi* would be difficult, if not impossible, to implement  
113556 satisfactorily on a block-mode terminal, or a terminal without any form of cursor addressing,  
113557 thus it is not a mandatory requirement that such features should work on all terminals. It is the  
113558 intention, however, that a *vi* implementation should provide the full set of capabilities on all  
113559 terminals capable of supporting them.

113560 Historically, *vi* exited immediately if the standard input was not a terminal. POSIX.1-2008  
113561 permits, but does not require, this behavior. An end-of-file condition is not equivalent to an end-  
113562 of-file character. A common end-of-file character, <control>-D, is historically a *vi* command.

113563 The text in the STDOUT section reflects the usage of the verb *display* in this section; some  
113564 implementations of *vi* use standard output to write to the terminal, but POSIX.1-2008 does not  
113565 require that to be the case.

113566 Historically, implementations reverted to open mode if the terminal was incapable of supporting  
113567 full visual mode. POSIX.1-2008 requires this behavior. Historically, the open mode of *vi* behaved  
113568 roughly equivalently to the visual mode, with the exception that only a single line from the edit  
113569 buffer (one “buffer line”) was kept current at any time. This line was normally displayed on the  
113570 next-to-last line of a terminal with cursor addressing (and the last line performed its normal  
113571 visual functions for line-oriented commands and messages). In addition, some few commands  
113572 behaved differently in open mode than in visual mode. POSIX.1-2008 requires conformance to  
113573 historical practice.

Historically, *ex* and *vi* implementations have expected text to proceed in the usual European/Latin order of left to right, top to bottom. There is no requirement in POSIX.1-2008 that this be the case. The specification was deliberately written using words like “before”, “after”, “first”, and “last” in order to permit implementations to support the natural text order of the language.

Historically, lines past the end of the edit buffer were marked with single <tilde> ('~') characters; that is, if the one-based display was 20 lines in length, and the last line of the file was on line one, then lines 2-20 would contain only a single '~' character.

Historically, the *vi* editor attempted to display only complete lines at the bottom of the screen (it did display partial lines at the top of the screen). If a line was too long to fit in its entirety at the bottom of the screen, the screen lines where the line would have been displayed were displayed as single '@' characters, instead of displaying part of the line. POSIX.1-2008 permits, but does not require, this behavior. Implementations are encouraged to attempt always to display a complete line at the bottom of the screen when doing scrolling or screen positioning by buffer lines.

Historically, lines marked with '@' were also used to minimize output to dumb terminals over slow lines; that is, changes local to the cursor were updated, but changes to lines on the screen that were not close to the cursor were simply marked with an '@' sign instead of being updated to match the current text. POSIX.1-2008 permits, but does not require this feature because it is used ever less frequently as terminals become smarter and connections are faster.

### Initialization in *ex* and *vi*

Historically, *vi* always had a line in the edit buffer, even if the edit buffer was “empty”. For example:

1. The *ex* command = executed from visual mode wrote “1” when the buffer was empty.
2. Writes from visual mode of an empty edit buffer wrote files of a single character (a <newline>), while writes from *ex* mode of an empty edit buffer wrote empty files.
3. Put and read commands into an empty edit buffer left an empty line at the top of the edit buffer.

For consistency, POSIX.1-2008 does not permit any of these behaviors.

Historically, *vi* did not always return the terminal to its original modes; for example, ICRNL was modified if it was not originally set. POSIX.1-2008 does not permit this behavior.

### Command Descriptions in *vi*

Motion commands are among the most complicated aspects of *vi* to describe. With some exceptions, the text region and buffer type effect of a motion command on a *vi* command are described on a case-by-case basis. The descriptions of text regions in POSIX.1-2008 are not intended to imply direction; that is, an inclusive region from line *n* to line *n*+5 is identical to a region from line *n*+5 to line *n*. This is of more than academic interest—movements to marks can be in either direction, and, if the **wraps** option is set, so can movements to search points. Historically, lines are always stored into buffers in text order; that is, from the start of the edit buffer to the end. POSIX.1-2008 requires conformance to historical practice.

Historically, command counts were applied to any associated motion, and were multiplicative to any supplied motion count. For example, **2cw** is the same as **c2w**, and **2c3w** is the same as **c6w**. POSIX.1-2008 requires this behavior. Historically, *vi* commands that used bigwords, words, paragraphs, and sentences as objects treated groups of empty lines, or lines that contained only

<blank> characters, inconsistently. Some commands treated them as a single entity, while others treated each line separately. For example, the **w**, **W**, and **B** commands treated groups of empty lines as individual words; that is, the command would move the cursor to each new empty line. The **e** and **E** commands treated groups of empty lines as a single word; that is, the first use would move past the group of lines. The **b** command would just beep at the user, or if done from the start of the line as a motion command, fail in unexpected ways. If the lines contained only (or ended with) <blank> characters, the **w** and **W** commands would just beep at the user, the **E** and **e** commands would treat the group as a single word, and the **B** and **b** commands would treat the lines as individual words. For consistency and simplicity of specification, POSIX.1-2008 requires that all *vi* commands treat groups of empty or blank lines as a single entity, and that movement through lines ending with <blank> characters be consistent with other movements.

Historically, *vi* documentation indicated that any number of double-quotes were skipped after punctuation marks at sentence boundaries; however, implementations only skipped single-quotes. POSIX.1-2008 requires both to be skipped.

Historically, the first and last characters in the edit buffer were word boundaries. This historical practice is required by POSIX.1-2008.

Historically, *vi* attempted to update the minimum number of columns on the screen possible, which could lead to misleading information being displayed. POSIX.1-2008 makes no requirements other than that the current character being entered is displayed correctly, leaving all other decisions in this area up to the implementation.

Historically, lines were arbitrarily folded between columns of any characters that required multiple column positions on the screen, with the exception of tabs, which terminated at the right-hand margin. POSIX.1-2008 permits the former and requires the latter. Implementations that do not arbitrarily break lines between columns of characters that occupy multiple column positions should not permit the cursor to rest on a column that does not contain any part of a character.

The historical *vi* had a problem in that all movements were by buffer lines, not by display or screen lines. This is often the right thing to do; for example, single line movements, such as **j** or **k**, should work on buffer lines. Commands like **dj**, or **j.**, where **.** is a change command, only make sense for buffer lines. It is not, however, the right thing to do for screen motion or scrolling commands like <control>-D, <control>-F, and **H**. If the window is fairly small, using buffer lines in these cases can result in completely random motion; for example, **1<control>-D** can result in a completely changed screen, without any overlap. This is clearly not what the user wanted. The problem is even worse in the case of the **H**, **L**, and **M** commands—as they position the cursor at the first non-<blank> of the line, they may all refer to the same location in large lines, and will result in no movement at all.

In addition, if the line is larger than the screen, using buffer lines can make it impossible to display parts of the line—there are not any commands that do not display the beginning of the line in historical *vi*, and if both the beginning and end of the line cannot be on the screen at the same time, the user suffers. Finally, the page and half-page scrolling commands historically moved to the first non-<blank> in the new line. If the line is approximately the same size as the screen, this is inadequate because the cursor before and after a <control>-D command will refer to the same location on the screen.

Implementations of *ex* and *vi* exist that do not have these problems because the relevant commands (<control>-B, <control>-D, <control>-F, <control>-U, <control>-Y, <control>-E, **H**, **L**, and **M**) operate on display (screen) lines, not (edit) buffer lines.

POSIX.1-2008 does not permit this behavior by default because the standard developers believed that users would find it too confusing. However, historical practice has been relaxed. For

example, *ex* and *vi* historically attempted, albeit sometimes unsuccessfully, to never put part of a line on the last lines of a screen; for example, if a line would not fit in its entirety, no part of the line was displayed, and the screen lines corresponding to the line contained single '@' characters. This behavior is permitted, but not required by POSIX.1-2008, so that it is possible for implementations to support long lines in small screens more reasonably without changing the commands to be oriented to the display (instead of oriented to the buffer). POSIX.1-2008 also permits implementations to refuse to edit any edit buffer containing a line that will not fit on the screen in its entirety.

The display area (for example, the value of the **window** edit option) has historically been “grown”, or expanded, to display new text when local movements are done in displays where the number of lines displayed is less than the maximum possible. Expansion has historically been the first choice, when the target line is less than the maximum possible expansion value away. Scrolling has historically been the next choice, done when the target line is less than half a display away, and otherwise, the screen was redrawn. There were exceptions, however, in that *ex* commands generally always caused the screen to be redrawn. POSIX.1-2008 does not specify a standard behavior because there may be external issues, such as connection speed, the number of characters necessary to redraw as opposed to scroll, or terminal capabilities that implementations will have to accommodate.

The current line in POSIX.1-2008 maps one-to-one to a buffer line in the file. The current column does not. There are two different column values that are described by POSIX.1-2008. The first is the current column value as set by many of the *vi* commands. This value is remembered for the lifetime of the editor. The second column value is the actual position on the screen where the cursor rests. The two are not always the same. For example, when the cursor is backed by a multi-column character, the actual cursor position on the screen has historically been the last column of the character in command mode, and the first column of the character in input mode.

Commands that set the current line, but that do not set the current cursor value (for example, **j** and **k**) attempt to get as close as possible to the remembered column position, so that the cursor tends to restrict itself to a vertical column as the user moves around in the edit buffer. POSIX.1-2008 requires conformance to historical practice, requiring that the display location of the cursor on the display line be adjusted from the current column value as necessary to support this historical behavior.

Historically, only a single line (and for some terminals, a single line minus 1 column) of characters could be entered by the user for the line-oriented commands; that is, **:**, **!**, **/**, or **?**. POSIX.1-2008 permits, but does not require, this limitation.

Historically, “soft” errors in *vi* caused the terminal to be alerted, but no error message was displayed. As a general rule, no error message was displayed for errors in command execution in *vi*, when the error resulted from the user attempting an invalid or impossible action, or when a searched-for object was not found. Examples of soft errors included **h** at the left margin, **<control>-B** or **[** at the beginning of the file, **2G** at the end of the file, and so on. In addition, errors such as **%**, **]**, **]**, **)**, **N**, **n**, **f**, **F**, **t**, and **T** failing to find the searched-for object were soft as well. Less consistently, **/** and **?** displayed an error message if the pattern was not found, **/**, **?**, **N**, and **n** displayed an error message if no previous regular expression had been specified, and **;** did not display an error message if no previous **f**, **F**, **t**, or **T** command had occurred. Also, behavior in this area might reasonably be based on a runtime evaluation of the speed of a network connection. Finally, some implementations have provided error messages for soft errors in order to assist naive users, based on the value of a verbose edit option. POSIX.1-2008 does not list specific errors for which an error message shall be displayed. Implementations should conform to historical practice in the absence of any strong reason to diverge.

## Page Backwards

The <control>-B and <control>-F commands historically considered it an error to attempt to page past the beginning or end of the file, whereas the <control>-D and <control>-U commands simply moved to the beginning or end of the file. For consistency, POSIX.1-2008 requires the latter behavior for all four commands. All four commands still consider it an error if the current line is at the beginning (<control>-B, <control>-U) or end (<control>-F, <control>-D) of the file. Historically, the <control>-B and <control>-F commands skip two lines in order to include overlapping lines when a single command is entered. This makes less sense in the presence of a *count*, as there will be, by definition, no overlapping lines. The actual calculation used by historical implementations of the *vi* editor for <control>-B was:

```
((current first line) - count x (window edit option)) +2
```

and for <control>-F was:

```
((current first line) + count x (window edit option)) -2
```

This calculation does not work well when intermixing commands with and without counts; for example, **3<control>-F is not equivalent to entering the <control>-F command three times, and is not reversible by entering the <control>-B command three times. For consistency with other *vi* commands that take counts, POSIX.1-2008 requires a different calculation.**

## Scroll Forward

The 4BSD and System V implementations of *vi* differed on the initial value used by the **scroll** command. 4BSD used:

```
((window edit option) +1) /2
```

while System V used the value of the **scroll** edit option. The System V version is specified by POSIX.1-2008 because the standard developers believed that it was more intuitive and permitted the user a method of setting the scroll value initially without also setting the number of lines that are displayed.

## Scroll Forward by Line

Historically, the <control>-E and <control>-Y commands considered it an error if the last and first lines, respectively, were already on the screen. POSIX.1-2008 requires conformance to historical practice. Historically, the <control>-E and <control>-Y commands had no effect in open mode. For simplicity and consistency of specification, POSIX.1-2008 requires that they behave as usual, albeit with a single line screen.

## Clear and Redisplay

The historical <control>-L command refreshed the screen exactly as it was supposed to be currently displayed, replacing any '@' characters for lines that had been deleted but not updated on the screen with refreshed '@' characters. The intent of the <control>-L command is to refresh when the screen has been accidentally overwritten; for example, by a **write** command from another user, or modem noise.

## Redraw Screen

The historical <control>-R command redisplayed only when necessary to update lines that had been deleted but not updated on the screen and that were flagged with '@' characters. There is no requirement that the screen be in any way refreshed if no lines of this form are currently displayed. POSIX.1-2008 permits implementations to extend this command to refresh lines on the screen flagged with '@' characters because they are too long to be displayed in the current framework; however, the current line and column need not be modified.

## Search for tagstring

Historically, the first non-<blank> at or after the cursor was the first character, and all subsequent characters that were word characters, up to the end of the line, were included. For example, with the cursor on the leading <space> or on the '#' character in the text "#bar@", the tag was "#bar". On the character 'b' it was "bar", and on the 'a' it was "ar". POSIX.1-2008 requires this behavior.

## Replace Text with Results from Shell Command

Historically, the <, >, and ! commands considered most cursor motions other than line-oriented motions an error; for example, the command >/foo<CR> succeeded, while the command >I failed, even though the text region described by the two commands might be identical. For consistency, all three commands only consider entire lines and not partial lines, and the region is defined as any line that contains a character that was specified by the motion.

## Move to Matching Character

Other matching characters have been left implementation-defined in order to allow extensions such as matching '<' and '>' for searching HTML, or #ifdef, #else, and #endif for searching C source.

## Repeat Substitution

POSIX.1-2008 requires that any c and g flags specified to the previous substitute command be ignored; however, the r flag may still apply, if supported by the implementation.

## Return to Previous (Context or Section)

The [I, ]I, (, ), {, and } commands are all affected by "section boundaries", but in some historical implementations not all of the commands recognize the same section boundaries. This is a bug, not a feature, and a unique section-boundary algorithm was not described for each command. One special case that is preserved is that the sentence command moves to the end of the last line of the edit buffer while the other commands go to the beginning, in order to preserve the traditional character cut semantics of the sentence command. Historically, vi section boundaries at the beginning and end of the edit buffer were the first non-<blank> on the first and last lines of the edit buffer if one exists; otherwise, the last character of the first and last lines of the edit buffer if one exists. To increase consistency with other section locations, this has been simplified by POSIX.1-2008 to the first character of the first and last lines of the edit buffer, or the first and the last lines of the edit buffer if they are empty.

Sentence boundaries were problematic in the historical vi. They were not only the boundaries as defined for the section and paragraph commands, but they were the first non-<blank> that occurred after those boundaries, as well. Historically, the vi section commands were documented as taking an optional window size as a count preceding the command. This was not implemented in historical versions, so POSIX.1-2008 requires that the count repeat the command,

113794 for consistency with other *vi* commands.

### 113795 **Repeat**

113796 Historically, mapped commands other than text input commands could not be repeated using  
113797 the **period** command. POSIX.1-2008 requires conformance to historical practice.

113798 The restrictions on the interpretation of special characters (for example, <control>-H) in the  
113799 repetition of text input mode commands is intended to match historical practice. For example,  
113800 given the input sequence:

```
113801 iab<control>-H<control>-H<control>-Hdef<escape>
```

113802 the user should be informed of an error when the sequence is first entered, but not during a  
113803 command repetition. The character <control>-T is specifically exempted from this restriction.  
113804 Historical implementations of *vi* ignored <control>-T characters that were input in the original  
113805 command during command repetition. POSIX.1-2008 prohibits this behavior.

### 113806 **Find Regular Expression**

113807 Historically, commands did not affect the line searched to or from if the motion command was a  
113808 search (*/*, *?*, *N*, *n*) and the final position was the start/end of the line. There were some special  
113809 cases and *vi* was not consistent. POSIX.1-2008 does not permit this behavior, for consistency.  
113810 Historical implementations permitted but were unable to handle searches as motion commands  
113811 that wrapped (that is, due to the edit option **wraps**) to the original location. POSIX.1-2008  
113812 requires that this behavior be treated as an error.

113813 Historically, the syntax *"/RE/0"* was used to force the command to cut text in line mode.  
113814 POSIX.1-2008 requires conformance to historical practice.

113815 Historically, in open mode, a **z** specified to a search command redisplayed the current line  
113816 instead of displaying the current screen with the current line highlighted. For consistency and  
113817 simplicity of specification, POSIX.1-2008 does not permit this behavior.

113818 Historically, trailing **z** commands were permitted and ignored if entered as part of a search used  
113819 as a motion command. For consistency and simplicity of specification, POSIX.1-2008 does not  
113820 permit this behavior.

### 113821 **Execute an ex Command**

113822 Historically, *vi* implementations restricted the commands that could be entered on the colon  
113823 command line (for example, **append** and **change**), and some other commands were known to  
113824 cause them to fail catastrophically. For consistency, POSIX.1-2008 does not permit these  
113825 restrictions. When executing an *ex* command by entering *:*, it is not possible to enter a <newline>  
113826 as part of the command because it is considered the end of the command. A different approach  
113827 is to enter *ex* command mode by using the *vi* **Q** command (and later resuming visual mode with  
113828 the *ex* **vi** command). In *ex* command mode, the single-line limitation does not exist. So, for  
113829 example, the following is valid:

```
113830 Q
113831 s/break here/break\
113832 here/
113833 vi
```

113834 POSIX.1-2008 requires that, if the *ex* command overwrites any part of the screen that would be  
113835 erased by a refresh, *vi* pauses for a character from the user. Historically, this character could be  
113836 any character; for example, a character input by the user before the message appeared, or even a

mapped character. This is probably a bug, but implementations that have tried to be more rigorous by requiring that the user enter a specific character, or that the user enter a character after the message was displayed, have been forced by user indignation back into historical behavior. POSIX.1-2008 requires conformance to historical practice.

### Shift Left (Right)

Refer to the Rationale for the **!** and **/** commands. Historically, the **<** and **>** commands sometimes moved the cursor to the first non-**<blank>** (for example if the command was repeated or with **\_** as the motion command), and sometimes left it unchanged. POSIX.1-2008 does not permit this inconsistency, requiring instead that the cursor always move to the first non-**<blank>**. Historically, the **<** and **>** commands did not support buffer arguments, although some implementations allow the specification of an optional buffer. This behavior is neither required nor disallowed by POSIX.1-2008.

### Execute

Historically, buffers could execute other buffers, and loops, infinite and otherwise, were possible. POSIX.1-2008 requires conformance to historical practice. The *\*buffer* syntax of *ex* is not required in *vi*, because it is not historical practice and has been used in some *vi* implementations to support additional scripting languages.

### Reverse Case

Historically, the **~** command ignored any associated *count*, and acted only on the characters in the current line. For consistency with other *vi* commands, POSIX.1-2008 requires that an associated *count* act on the next *count* characters, and that the command move to subsequent lines if warranted by *count*, to make it possible to modify large pieces of text in a reasonably efficient manner. There exist *vi* implementations that optionally require an associated motion command for the **~** command. Implementations supporting this functionality are encouraged to base it on the **tildedop** edit option and handle the text regions and cursor positioning identically to the **yank** command.

### Append

Historically, *counts* specified to the **A**, **a**, **I**, and **i** commands repeated the input of the first line *count* times, and did not repeat the subsequent lines of the input text. POSIX.1-2008 requires that the entire text input be repeated *count* times.

### Move Backward to Preceding Word

Historically, *vi* became confused if word commands were used as motion commands in empty files. POSIX.1-2008 requires that this be an error. Historical implementations of *vi* had a large number of bugs in the word movement commands, and they varied greatly in behavior in the presence of empty lines, “words” made up of a single character, and lines containing only **<blank>** characters. For consistency and simplicity of specification, POSIX.1-2008 does not permit this behavior.

### Change to End-of-Line

Some historical implementations of the **C** command did not behave as described by POSIX.1-2008 when the **\$** key was remapped because they were implemented by pushing the **\$** key onto the input queue and reprocessing it. POSIX.1-2008 does not permit this behavior. Historically, the **C**, **S**, and **s** commands did not copy replaced text into the numeric buffers. For consistency and simplicity of specification, POSIX.1-2008 requires that they behave like their respective **c** commands in all respects.

### Delete

Historically, lines in open mode that were deleted were scrolled up, and an **@** glyph written over the beginning of the line. In the case of terminals that are incapable of the necessary cursor motions, the editor erased the deleted line from the screen. POSIX.1-2008 requires conformance to historical practice; that is, if the terminal cannot display the '**@**' character, the line cannot remain on the screen.

### Delete to End-of-Line

Some historical implementations of the **D** command did not behave as described by POSIX.1-2008 when the **\$** key was remapped because they were implemented by pushing the **\$** key onto the input queue and reprocessing it. POSIX.1-2008 does not permit this behavior.

### Join

An historical oddity of *vi* is that the commands **J**, **1J**, and **2J** are all equivalent. POSIX.1-2008 requires conformance to historical practice. The *vi* **J** command is specified in terms of the *ex* **join** command with an *ex* command *count* value. The address correction for a *count* that is past the end of the edit buffer is necessary for historical compatibility for both *ex* and *vi*.

### Mark Position

Historical practice is that only lowercase letters, plus backquote and single-quote, could be used to mark a cursor position. POSIX.1-2008 requires conformance to historical practice, but encourages implementations to support other characters as marks as well.

### Repeat Regular Expression Find (Forward and Reverse)

Historically, the **N** and **n** commands could not be used as motion components for the **c** command. With the exception of the **cN** command, which worked if the search crossed a line boundary, the text region would be discarded, and the user would not be in text input mode. For consistency and simplicity of specification, POSIX.1-2008 does not permit this behavior.

### Insert Empty Line (Below and Above)

Historically, counts to the **O** and **o** commands were used as the number of physical lines to open, if the terminal was dumb and the **slowopen** option was not set. This was intended to minimize traffic over slow connections and repainting for dumb terminals. POSIX.1-2008 does not permit this behavior, requiring that a *count* to the open command behave as for other text input commands. This change to historical practice was made for consistency, and because a superset of the functionality is provided by the **slowopen** edit option.

### Put from Buffer (Following and Before)

Historically, *counts* to the **p** and **P** commands were ignored if the buffer was a line mode buffer, but were (mostly) implemented as described in POSIX.1-2008 if the buffer was a character mode buffer. Because implementations exist that do not have this limitation, and because pasting lines multiple times is generally useful, POSIX.1-2008 requires that *count* be supported for all **p** and **P** commands.

Historical implementations of *vi* were widely known to have major problems in the **p** and **P** commands, particularly when unusual regions of text were copied into the edit buffer. The standard developers viewed these as bugs, and they are not permitted for consistency and simplicity of specification.

Historically, a **P** or **p** command (or an *ex* **put** command executed from open or visual mode) executed in an empty file, left an empty line as the first line of the file. For consistency and simplicity of specification, POSIX.1-2008 does not permit this behavior.

### Replace Character

Historically, the **r** command did not correctly handle the *erase* and *word erase* characters as arguments, nor did it handle an associated *count* greater than 1 with a <carriage-return> argument, for which it replaced *count* characters with a single <newline>. POSIX.1-2008 does not permit these inconsistencies.

Historically, the **r** command permitted the <control>-V escaping of entered characters, such as <ESC> and the <carriage-return>; however, it required two leading <control>-V characters instead of one. POSIX.1-2008 requires that this be changed for consistency with the other text input commands of *vi*.

Historically, it is an error to enter the **r** command if there are less than *count* characters at or after the cursor in the line. While a reasonable and unambiguous extension would be to permit the **r** command on empty lines, it would require that too large a *count* be adjusted to match the number of characters at or after the cursor for consistency, which is sufficiently different from historical practice to be avoided. POSIX.1-2008 requires conformance to historical practice.

### Replace Characters

Historically, if there were **autoindent** characters in the line on which the **R** command was run, and **autoindent** was set, the first <newline> would be properly indented and no characters would be replaced by the <newline>. Each additional <newline> would replace *n* characters, where *n* was the number of characters that were needed to indent the rest of the line to the proper indentation level. This behavior is a bug and is not permitted by POSIX.1-2008.

### Undo

Historical practice for cursor positioning after undoing commands was mixed. In most cases, when undoing commands that affected a single line, the cursor was moved to the start of added or changed text, or immediately after deleted text. However, if the user had moved from the line being changed, the column was either set to the first non-<blank>, returned to the origin of the command, or remained unchanged. When undoing commands that affected multiple lines or entire lines, the cursor was moved to the first character in the first line restored. As an example of how inconsistent this was, a search, followed by an **o** text input command, followed by an **undo** would return the cursor to the location where the **o** command was entered, but a **cw** command followed by an **o** command followed by an **undo** would return the cursor to the first non-<blank> of the line. POSIX.1-2008 requires the most useful of these behaviors, and discards the least useful, in the interest of consistency and simplicity of specification.

## Yank

Historically, the **yank** command did not move to the end of the motion if the motion was in the forward direction. It moved to the end of the motion if the motion was in the backward direction, except for the **\_** command, or for the **G** and **'** commands when the end of the motion was on the current line. This was further complicated by the fact that for a number of motion commands, the **yank** command moved the cursor but did not update the screen; for example, a subsequent command would move the cursor from the end of the motion, even though the cursor on the screen had not reflected the cursor movement for the **yank** command. POSIX.1-2008 requires that all **yank** commands associated with backward motions move the cursor to the end of the motion for consistency, and specifically, to make **'** commands as motions consistent with search patterns as motions.

## Yank Current Line

Some historical implementations of the **Y** command did not behave as described by POSIX.1-2008 when the **' \_ '** key was remapped because they were implemented by pushing the **' \_ '** key onto the input queue and reprocessing it. POSIX.1-2008 does not permit this behavior.

## Redraw Window

Historically, the **z** command always redrew the screen. This is permitted but not required by POSIX.1-2008, because of the frequent use of the **z** command in macros such as **map n nz.** for screen positioning, instead of its use to change the screen size. The standard developers believed that expanding or scrolling the screen offered a better interface for users. The ability to redraw the screen is preserved if the optional new window size is specified, and in the **<control>-L** and **<control>-R** commands.

The semantics of **z^** are confusing at best. Historical practice is that the screen before the screen that ended with the specified line is displayed. POSIX.1-2008 requires conformance to historical practice.

Historically, the **z** command would not display a partial line at the top or bottom of the screen. If the partial line would normally have been displayed at the bottom of the screen, the command worked, but the partial line was replaced with **' @ '** characters. If the partial line would normally have been displayed at the top of the screen, the command would fail. For consistency and simplicity of specification, POSIX.1-2008 does not permit this behavior.

Historically, the **z** command with a line specification of 1 ignored the command. For consistency and simplicity of specification, POSIX.1-2008 does not permit this behavior.

Historically, the **z** command did not set the cursor column to the first non-**<blank>** for the character if the first screen was to be displayed, and was already displayed. For consistency and simplicity of specification, POSIX.1-2008 does not permit this behavior.

## Input Mode Commands in vi

Historical implementations of **vi** did not permit the user to erase more than a single line of input, or to use normal erase characters such as *line erase*, *worderase*, and *erase* to erase **autoindent** characters. As there exist implementations of **vi** that do not have these limitations, both behaviors are permitted, but only historical practice is required. In the case of these extensions, **vi** is required to pause at the **autoindent** and previous line boundaries.

Historical implementations of **vi** updated only the portion of the screen where the current cursor character was displayed. For example, consider the **vi** input keystrokes:

```
iabcd<escape>0C<tab>
```

Historically, the `<tab>` would overwrite the characters "abcd" when it was displayed. Other implementations replace only the 'a' character with the `<tab>`, and then push the rest of the characters ahead of the cursor. Both implementations have problems. The historical implementation is probably visually nicer for the above example; however, for the keystrokes:

```
iabcd<ESC>OR<tab><ESC>
```

the historical implementation results in the string "bcd" disappearing and then magically reappearing when the `<ESC>` character is entered. POSIX.1-2008 requires the former behavior when overwriting erase-columns—that is, overwriting characters that are no longer logically part of the edit buffer—and the latter behavior otherwise.

Historical implementations of *vi* discarded the `<control>-D` and `<control>-T` characters when they were entered at places where their command functionality was not appropriate. POSIX.1-2008 requires that the `<control>-T` functionality always be available, and that `<control>-D` be treated as any other key when not operating on **autoindent** characters.

## NUL

Some historical implementations of *vi* limited the number of characters entered using the NUL input character to 256 bytes. POSIX.1-2008 permits this limitation; however, implementations are encouraged to remove this limit.

## `<control>-D`

See also Rationale for the input mode command `<newline>`. The hidden assumptions in the `<control>-D` command (and in the *vi* **autoindent** specification in general) is that `<space>` characters take up a single column on the screen and that `<tab>` characters are comprised of an integral number of `<space>` characters.

## `<newline>`

Implementations are permitted to rewrite **autoindent** characters in the line when `<newline>`, `<carriage-return>`, `<control>-D`, and `<control>-T` are entered, or when the **shift** commands are used, because historical implementations have both done so and found it necessary to do so. For example, a `<control>-D` when the cursor is preceded by a single `<tab>`, with **tabstop** set to 8, and **shiftwidth** set to 3, will result in the `<tab>` being replaced by several `<space>` characters.

## `<control>-T`

See also the Rationale for the input mode command `<newline>`. Historically, `<control>-T` only worked if no non-`<blank>` characters had yet been input in the current input line. In addition, the characters inserted by `<control>-T` were treated as **autoindent** characters, and could not be erased using normal user erase characters. Because implementations exist that do not have these limitations, and as moving to a column boundary is generally useful, POSIX.1-2008 requires that both limitations be removed.

**<control>-V**

Historically, *vi* used **^V**, regardless of the value of the literal-next character of the terminal. POSIX.1-2008 requires conformance to historical practice.

The uses described for <control>-V can also be accomplished with <control>-Q, which is useful on terminals that use <control>-V for the down-arrow function. However, most historical implementations use <control>-Q for the *termios* START character, so the editor will generally not receive the <control>-Q unless **stty ixon** mode is set to off. (In addition, some historical implementations of *vi* explicitly set **ixon** mode to on, so it was difficult for the user to set it to off.) Any of the command characters described in POSIX.1-2008 can be made ineffective by their selection as *termios* control characters, using the *stty* utility or other methods described in the System Interfaces volume of POSIX.1-2008.

**<ESC>**

Historically, SIGINT alerted the terminal when used to end input mode. This behavior is permitted, but not required, by POSIX.1-2008.

**FUTURE DIRECTIONS**

None.

XBD [Section 12.2](#) (on page 215)

**CHANGE HISTORY**

First released in Issue 2.

**Issue 5**

The FUTURE DIRECTIONS section is added.

**Issue 6**

This utility is marked as part of the User Portability Utilities option.

The APPLICATION USAGE section is added.

The obsolescent SYNOPSIS is removed.

The following new requirements on POSIX implementations derive from alignment with the Single UNIX Specification:

- The **reindent** command description is added.

The *vi* utility has been extensively rewritten for alignment with the IEEE P1003.2b draft standard.

IEEE PASC Interpretations 1003.2 #57, #62, #63, #64, #78, and #188 are applied.

IEEE PASC Interpretation 1003.2 #207 is applied, clarifying the description of the **R** command in a manner similar to the descriptions of other text input mode commands such as **i**, **o**, and **O**.

The **-l** option is removed.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/41 is applied, adding *[count]* to the Synopsis for **[[**.

IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/42 is applied, adding *[count]* to the Synopsis for **]]**.

114076 **Issue 7**

114077 Austin Group Interpretation 1003.1-2001 #027 is applied, clarifying that '+' may be recognized  
114078 as an option delimiter in the OPTIONS section.

114079 Austin Group Interpretation 1003.1-2001 #087 is applied, updating the Put from Buffer Before (P)  
114080 command description to address multi-line requirements.

114081 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

114082 **NAME**

114083       wait — await process completion

114084 **SYNOPSIS**114085       wait [*pid*...]114086 **DESCRIPTION**

114087       When an asynchronous list (see [Section 2.9.3.1](#), on page 2342) is started by the shell, the process  
 114088       ID of the last command in each element of the asynchronous list shall become known in the  
 114089       current shell execution environment; see [Section 2.12](#) (on page 2353).

114090       If the *wait* utility is invoked with no operands, it shall wait until all process IDs known to the  
 114091       invoking shell have terminated and exit with a zero exit status.

114092       If one or more *pid* operands are specified that represent known process IDs, the *wait* utility shall  
 114093       wait until all of them have terminated. If one or more *pid* operands are specified that represent  
 114094       unknown process IDs, *wait* shall treat them as if they were known process IDs that exited with  
 114095       exit status 127. The exit status returned by the *wait* utility shall be the exit status of the process  
 114096       requested by the last *pid* operand.

114097       The known process IDs are applicable only for invocations of *wait* in the current shell execution  
 114098       environment.

114099 **OPTIONS**

114100       None.

114101 **OPERANDS**

114102       The following operand shall be supported:

114103       *pid*           One of the following:

- 114104           1. The unsigned decimal integer process ID of a command, for which the  
 114105           utility is to wait for the termination.
- 114106           2. A job control job ID (see XBD [Section 3.204](#), on page 65) that identifies a  
 114107           background process group to be waited for. The job control job ID notation  
 114108           is applicable only for invocations of *wait* in the current shell execution  
 114109           environment; see [Section 2.12](#) (on page 2353). The exit status of *wait* shall be  
 114110           determined by the last command in the pipeline.

114111       **Note:**       The job control job ID type of *pid* is only available on systems supporting  
 114112       the User Portability Utilities option.

114113 **STDIN**

114114       Not used.

114115 **INPUT FILES**

114116       None.

114117 **ENVIRONMENT VARIABLES**114118       The following environment variables shall affect the execution of *wait*:

114119       *LANG*       Provide a default value for the internationalization variables that are unset or null.  
 114120       (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 114121       variables used to determine the values of locale categories.)

114122       *LC\_ALL*      If set to a non-empty string value, override the values of all the other  
 114123       internationalization variables.

114124 *LC\_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as  
 114125 characters (for example, single-byte as opposed to multi-byte characters in  
 114126 arguments).

114127 *LC\_MESSAGES*  
 114128 Determine the locale that should be used to affect the format and contents of  
 114129 diagnostic messages written to standard error.

114130 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

114131 **ASYNCHRONOUS EVENTS**  
 114132 Default.

114133 **STDOUT**  
 114134 Not used.

114135 **STDERR**  
 114136 The standard error shall be used only for diagnostic messages.

114137 **OUTPUT FILES**  
 114138 None.

114139 **EXTENDED DESCRIPTION**  
 114140 None.

114141 **EXIT STATUS**  
 114142 If one or more operands were specified, all of them have terminated or were not known by the  
 114143 invoking shell, and the status of the last operand specified is known, then the exit status of *wait*  
 114144 shall be the exit status information of the command indicated by the last operand specified. If  
 114145 the process terminated abnormally due to the receipt of a signal, the exit status shall be greater  
 114146 than 128 and shall be distinct from the exit status generated by other signals, but the exact value  
 114147 is unspecified. (See the *kill -l* option.) Otherwise, the *wait* utility shall exit with one of the  
 114148 following values:

114149 0 The *wait* utility was invoked with no operands and all process IDs known by the  
 114150 invoking shell have terminated.

114151 1-126 The *wait* utility detected an error.

114152 127 The command identified by the last *pid* operand specified is unknown.

114153 **CONSEQUENCES OF ERRORS**  
 114154 Default.

114155 **APPLICATION USAGE**  
 114156 On most implementations, *wait* is a shell built-in. If it is called in a subshell or separate utility  
 114157 execution environment, such as one of the following:

114158 (wait)  
 114159 nohup wait ...  
 114160 find . -exec wait ... \;

114161 it returns immediately because there are no known process IDs to wait for in those  
 114162 environments.

114163 Historical implementations of interactive shells have discarded the exit status of terminated  
 114164 background processes before each shell prompt. Therefore, the status of background processes  
 114165 was usually lost unless it terminated while *wait* was waiting for it. This could be a serious  
 114166 problem when a job that was expected to run for a long time actually terminated quickly with a  
 114167 syntax or initialization error because the exit status returned was usually zero if the requested

process ID was not found. This volume of POSIX.1-2008 requires the implementation to keep the status of terminated jobs available until the status is requested, so that scripts like:

```
j1&
p1=$!
j2&
wait $p1
echo Job 1 exited with status $?
wait $!
echo Job 2 exited with status $?
```

work without losing status on any of the jobs. The shell is allowed to discard the status of any process if it determines that the application cannot get the process ID for that process from the shell. It is also required to remember only {CHILD\_MAX} number of processes in this way. Since the only way to get the process ID from the shell is by using the '!' shell parameter, the shell is allowed to discard the status of an asynchronous list if "\$!" was not referenced before another asynchronous list was started. (This means that the shell only has to keep the status of the last asynchronous list started if the application did not reference "\$!". If the implementation of the shell is smart enough to determine that a reference to "\$!" was not saved anywhere that the application can retrieve it later, it can use this information to trim the list of saved information. Note also that a successful call to *wait* with no operands discards the exit status of all asynchronous lists.)

If the exit status of *wait* is greater than 128, there is no way for the application to know if the waited-for process exited with that value or was killed by a signal. Since most utilities exit with small values, there is seldom any ambiguity. Even in the ambiguous cases, most applications just need to know that the asynchronous job failed; it does not matter whether it detected an error and failed or was killed and did not complete its job normally.

#### EXAMPLES

Although the exact value used when a process is terminated by a signal is unspecified, if it is known that a signal terminated a process, a script can still reliably determine which signal by using *kill* as shown by the following script:

```
sleep 1000&
pid=$!
kill -kill $pid
wait $pid
echo $pid was terminated by a SIG$(kill -l $?) signal.
```

If the following sequence of commands is run in less than 31 seconds:

```
sleep 257 | sleep 31 &
jobs -l %%
```

either of the following commands returns the exit status of the second *sleep* in the pipeline:

```
wait <pid of sleep 31>
wait %%
```

#### RATIONALE

The description of *wait* does not refer to the *waitpid()* function from the System Interfaces volume of POSIX.1-2008 because that would needlessly overspecify this interface. However, the wording means that *wait* is required to wait for an explicit process when it is given an argument so that the status information of other processes is not consumed. Historical implementations use the *wait()* function defined in the System Interfaces volume of POSIX.1-2008 until *wait()* returns the requested process ID or finds that the requested process does not exist. Because this

114215 means that a shell script could not reliably get the status of all background children if a second  
114216 background job was ever started before the first job finished, it is recommended that the *wait*  
114217 utility use a method such as the functionality provided by the *waitpid()* function.

114218 The ability to wait for multiple *pid* operands was adopted from the KornShell.

114219 This new functionality was added because it is needed to determine the exit status of any  
114220 asynchronous list accurately. The only compatibility problem that this change creates is for a  
114221 script like

```
114222 while sleep 60 do
114223 job& echo Job started $(date) as $! done
```

114224 which causes the shell to monitor all of the jobs started until the script terminates or runs out of  
114225 memory. This would not be a problem if the loop did not reference "\$!" or if the script would  
114226 occasionally *wait* for jobs it started.

#### 114227 FUTURE DIRECTIONS

114228 None.

#### 114233 CHANGE HISTORY

114234 First released in Issue 2.

114235 **NAME**

114236       wc — word, line, and byte or character count

114237 **SYNOPSIS**114238       wc [-c|-m] [-lw] [*file*...]114239 **DESCRIPTION**114240       The *wc* utility shall read one or more input files and, by default, write the number of <newline>  
114241       characters, words, and bytes contained in each input file to the standard output.114242       The utility also shall write a total count for all named files, if more than one input file is  
114243       specified.114244       The *wc* utility shall consider a *word* to be a non-zero-length string of characters delimited by  
114245       white space.114246 **OPTIONS**114247       The *wc* utility shall conform to XBD [Section 12.2](#) (on page 215).

114248       The following options shall be supported:

114249       -c           Write to the standard output the number of bytes in each input file.

114250       -l           Write to the standard output the number of <newline> characters in each input  
114251       file.

114252       -m           Write to the standard output the number of characters in each input file.

114253       -w           Write to the standard output the number of words in each input file.

114254       When any option is specified, *wc* shall report only the information requested by the specified  
114255       options.114256 **OPERANDS**

114257       The following operand shall be supported:

114258       *file*        A pathname of an input file. If no *file* operands are specified, the standard input  
114259       shall be used.114260 **STDIN**114261       The standard input shall be used if no *file* operands are specified, and shall be used if a *file*  
114262       operand is '-' and the implementation treats the '-' as meaning standard input. Otherwise,  
114263       the standard input shall not be used. See the INPUT FILES section.114264 **INPUT FILES**

114265       The input files may be of any type.

114266 **ENVIRONMENT VARIABLES**114267       The following environment variables shall affect the execution of *wc*:114268       LANG        Provide a default value for the internationalization variables that are unset or null.  
114269                   (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
114270                   variables used to determine the values of locale categories.)114271       LC\_ALL      If set to a non-empty string value, override the values of all the other  
114272       internationalization variables.114273       LC\_CTYPE    Determine the locale for the interpretation of sequences of bytes of text data as  
114274       characters (for example, single-byte as opposed to multi-byte characters in  
114275       arguments and input files) and which characters are defined as white-space  
114276       characters.

- 114277 *LC\_MESSAGES*  
 114278 Determine the locale that should be used to affect the format and contents of  
 114279 diagnostic messages written to standard error and informative messages written to  
 114280 standard output.
- 114281 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.
- 114282 **ASYNCHRONOUS EVENTS**  
 114283 Default.
- 114284 **STDOUT**  
 114285 By default, the standard output shall contain an entry for each input file of the form:  
 114286 "%d %d %d %s\n", <newlines>, <words>, <bytes>, <file>  
 114287 If the **-m** option is specified, the number of characters shall replace the <bytes> field in this  
 114288 format.  
 114289 If any options are specified and the **-l** option is not specified, the number of <newline>  
 114290 characters shall not be written.  
 114291 If any options are specified and the **-w** option is not specified, the number of words shall not be  
 114292 written.  
 114293 If any options are specified and neither **-c** nor **-m** is specified, the number of bytes or characters  
 114294 shall not be written.  
 114295 If no input *file* operands are specified, no name shall be written and no <blank> characters  
 114296 preceding the pathname shall be written.  
 114297 If more than one input *file* operand is specified, an additional line shall be written, of the same  
 114298 format as the other lines, except that the word **total** (in the POSIX locale) shall be written instead  
 114299 of a pathname and the total of each column shall be written as appropriate. Such an additional  
 114300 line, if any, is written at the end of the output.
- 114301 **STDERR**  
 114302 The standard error shall be used only for diagnostic messages.
- 114303 **OUTPUT FILES**  
 114304 None.
- 114305 **EXTENDED DESCRIPTION**  
 114306 None.
- 114307 **EXIT STATUS**  
 114308 The following exit values shall be returned:  
 114309 0 Successful completion.  
 114310 >0 An error occurred.
- 114311 **CONSEQUENCES OF ERRORS**  
 114312 Default.

**114313 APPLICATION USAGE**

114314 The **-m** option is not a switch, but an option at the same level as **-c**. Thus, to produce the full  
114315 default output with character counts instead of bytes, the command required is:

114316 `wc -mlw`

**114317 EXAMPLES**

114318 None.

**114319 RATIONALE**

114320 The output file format *pseudo-printf()* string differs from the System V version of *wc*:

114321 `"%7d%7d%7d %s\n"`

114322 which produces possibly ambiguous and unparseable results for very large files, as it assumes no  
114323 number shall exceed six digits.

114324 Some historical implementations use only `<space>`, `<tab>`, and `<newline>` as word separators.  
114325 The equivalent of the ISO C standard *isspace()* function is more appropriate.

114326 The **-c** option stands for “character” count, even though it counts bytes. This stems from the  
114327 sometimes erroneous historical view that bytes and characters are the same size. Due to  
114328 international requirements, the **-m** option (reminiscent of “multi-byte”) was added to obtain  
114329 actual character counts.

114330 Early proposals only specified the results when input files were text files. The current  
114331 specification more closely matches historical practice. (Bytes, words, and `<newline>` characters  
114332 are counted separately and the results are written when an end-of-file is detected.)

114333 Historical implementations of the *wc* utility only accepted one argument to specify the options  
114334 **-c**, **-l**, and **-w**. Some of them also had multiple occurrences of an option cause the  
114335 corresponding count to be written multiple times and had the order of specification of the  
114336 options affect the order of the fields on output, but did not document either of these. Because  
114337 common usage either specifies no options or only one option, and because none of this was  
114338 documented, the changes required by this volume of POSIX.1-2008 should not break many  
114339 historical applications (and do not break any historical conforming applications).

**114340 FUTURE DIRECTIONS**

114341 None.

**114342 SEE ALSO**

114343 [\*cksum\*](#)

114344 XBD [Chapter 8](#) (on page 173), [Section 12.2](#) (on page 215)

**114345 CHANGE HISTORY**

114346 First released in Issue 2.

**114347 Issue 7**

114348 Austin Group Interpretation 1003.1-2001 #092 is applied.

114349 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

114350 **NAME**114351        what — identify SCCS files (**DEVELOPMENT**)114352 **SYNOPSIS**114353 XSI        `what [-s] file...`114354 **DESCRIPTION**

114355        The *what* utility shall search the given files for all occurrences of the pattern that *get* (see *get*)  
 114356        substitutes for the %Z% keyword ("@(#)") and shall write to standard output what follows  
 114357        until the first occurrence of one of the following:

114358        "    &gt;    newline    \    NUL

114359 **OPTIONS**114360        The *what* utility shall conform to XBD [Section 12.2](#) (on page 215).

114361        The following option shall be supported:

114362        -s            Quit after finding the first occurrence of the pattern in each file.

114363 **OPERANDS**

114364        The following operands shall be supported:

114365        *file*            A pathname of a file to search.114366 **STDIN**

114367        Not used.

114368 **INPUT FILES**

114369        The input files shall be of any file type.

114370 **ENVIRONMENT VARIABLES**114371        The following environment variables shall affect the execution of *what*:

114372        *LANG*            Provide a default value for the internationalization variables that are unset or null.  
 114373                            (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 114374                            variables used to determine the values of locale categories.)

114375        *LC\_ALL*          If set to a non-empty string value, override the values of all the other  
 114376                            internationalization variables.

114377        *LC\_CTYPE*        Determine the locale for the interpretation of sequences of bytes of text data as  
 114378                            characters (for example, single-byte as opposed to multi-byte characters in  
 114379                            arguments and input files).

114380        *LC\_MESSAGES*

114381                            Determine the locale that should be used to affect the format and contents of  
 114382                            diagnostic messages written to standard error.

114383        *NLSPATH*        Determine the location of message catalogs for the processing of *LC\_MESSAGES*.114384 **ASYNCHRONOUS EVENTS**

114385        Default.

114386 **STDOUT**114387        The standard output shall consist of the following for each *file* operand:

114388        "%s:\n\t%s\n", &lt;pathname&gt;, &lt;identification string&gt;

**114389 STDERR**

114390 The standard error shall be used only for diagnostic messages.

**114391 OUTPUT FILES**

114392 None.

**114393 EXTENDED DESCRIPTION**

114394 None.

**114395 EXIT STATUS**

114396 The following exit values shall be returned:

114397 0 Any matches were found.

114398 1 Otherwise.

**114399 CONSEQUENCES OF ERRORS**

114400 Default.

**114401 APPLICATION USAGE**

114402 The *what* utility is intended to be used in conjunction with the SCCS command *get*, which  
114403 automatically inserts identifying information, but it can also be used where the information is  
114404 inserted by any other means.

114405 When the string "@ (#) " is included in a library routine in a shared library, it might not be found  
114406 in an **a.out** file using that library routine.

**114407 EXAMPLES**

114408 If the C-language program in file **f.c** contains:

114409 `char ident[] = "@(#)identification information";`

114410 and **f.c** is compiled to yield **f.o** and **a.out**, then the command:

114411 `what f.c f.o a.out`

114412 writes:

114413 **f.c:**  
114414     identification information  
114415     ...  
114416 **f.o:**  
114417     identification information  
114418     ...  
114419 **a.out:**  
114420     identification information  
114421     ...

**114422 RATIONALE**

114423 None.

**114424 FUTURE DIRECTIONS**

114425 None.

**114426 SEE ALSO**

114427 *get*

114429 **CHANGE HISTORY**  
114430 First released in Issue 2.

114431 NAME

114432            who — display who is on the system

114433 **SYNOPSIS**

```
114434 XSI who [-mTu] [-abdHlprt] [file]
```

```
114435 XSI who [-mu] -s [-bHlprt] [file]
```

```
114436 who -q [file]
```

114437 who am i

|        |          |
|--------|----------|
| 114438 | who am I |
|--------|----------|

114439 DESCRIPTION

114440 The *who* utility shall list various pieces of information about accessible users. The domain of  
114441 accessibility is implementation-defined.

```
114442 XSI Based on the options given, who can also list the user's name, terminal line, login time, elapsed
114443 time since activity occurred on the line, and the process ID of the command interpreter for each
114444 current system user.
```

114445 **OPTIONS**

114446 The *who* utility shall conform to XBD [Section 12.2](#) (on page 215).

114447 The following options shall be supported. The metavariables, such as *<line>*, refer to fields  
114448 described in the STDOUT section.

|        |     |                                                                    |                                                                                                                    |
|--------|-----|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| 114449 | XSI | <b>-a</b>                                                          | Process the implementation-defined database or named file with the <b>-b</b> , <b>-d</b> , <b>-l</b> , <b>-p</b> , |
| 114450 |     | <b>-r</b> , <b>-t</b> , <b>-T</b> and <b>-u</b> options turned on. |                                                                                                                    |

|        |     |           |                                                                                  |
|--------|-----|-----------|----------------------------------------------------------------------------------|
| 114451 | XSI | <b>-b</b> | Write the time and date of the last system reboot. The system reboot time is the |
| 114452 |     |           | time at which the implementation is able to commence running processes.          |

114453 XSI **-d** Write a list of all processes that have expired and not been respawned by the *init*  
114454 system process. The *<exit>* field shall appear for dead processes and contain the  
114455 termination and exit values of the dead process. This can be useful in determining  
114456 why a process terminated.

|        |     |    |                                                 |
|--------|-----|----|-------------------------------------------------|
| 114457 | XSI | -H | Write column headings above the regular output. |
|--------|-----|----|-------------------------------------------------|

|        |     |           |                                                                                                                                                                                                                                                                               |
|--------|-----|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 114458 | XSI | <b>-1</b> | (The letter ell.) List only those lines on which the system is waiting for someone to login. The <i>&lt;name&gt;</i> field shall be <b>LOGIN</b> in such cases. Other fields shall be the same as for user entries except that the <i>&lt;state&gt;</i> field does not exist. |
| 114459 |     |           |                                                                                                                                                                                                                                                                               |
| 114460 |     |           |                                                                                                                                                                                                                                                                               |

```
114461 -m Output only information about the current terminal.
```

```
114462 XSI -p List any other process that is currently active and has been previously spawned by
114463 init.
```

|        |     |           |                                                                                |
|--------|-----|-----------|--------------------------------------------------------------------------------|
| 114464 | XSI | <b>-q</b> | (Quick.) List only the names and the number of users currently logged on. When |
| 114465 |     |           | this option is used, all other options shall be ignored.                       |

```
114466 XSI -r Write the current run-level of the init process.
```

|            |                                                                                                                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 114467 XSI | <div style="background-color: #f0f0f0; padding: 2px 5px; display: inline-block;"><b>-s</b></div> List only the <i>&lt;name&gt;</i> , <i>&lt;line&gt;</i> , and <i>&lt;time&gt;</i> fields. This is the default case. |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|        |     |           |                                               |
|--------|-----|-----------|-----------------------------------------------|
| 114468 | XSI | <b>-t</b> | Indicate the last change to the system clock. |
|--------|-----|-----------|-----------------------------------------------|

```
114469 -T Show the state of each terminal, as described in the STDOUT section.
```

114470           **-u**           Write “idle time” for each displayed user in addition to any other information. The  
 114471 idle time is the time since any activity occurred on the user’s terminal. The method  
 114472 XSI of determining this is unspecified. This option shall list only those users who are  
 114473 currently logged in. The *<name>* is the user’s login name. The *<line>* is the name  
 114474 of the line as found in the directory */dev*. The *<time>* is the time that the user  
 114475 logged in. The *<activity>* is the number of hours and minutes since activity last  
 114476 occurred on that particular line. A dot indicates that the terminal has seen activity  
 114477 in the last minute and is therefore “current”. If more than twenty-four hours have  
 114478 elapsed or the line has not been used since boot time, the entry shall be marked  
 114479 *<old>*. This field is useful when trying to determine whether a person is working at  
 114480 the terminal or not. The *<pid>* is the process ID of the user’s login process.

#### 114481 OPERANDS

114482 XSI           The following operands shall be supported:

114483           **am i, am I**       In the POSIX locale, limit the output to describing the invoking user, equivalent to  
 114484 the **-m** option. The **am** and **i** or **I** must be separate arguments.

114485           *file*           Specify a pathname of a file to substitute for the implementation-defined database  
 114486 of logged-on users that *who* uses by default.

#### 114487 STDIN

114488           Not used.

#### 114489 INPUT FILES

114490           None.

#### 114491 ENVIRONMENT VARIABLES

114492           The following environment variables shall affect the execution of *who*:

114493           **LANG**           Provide a default value for the internationalization variables that are unset or null.  
 114494 (See XBD Section 8.2 (on page 174) for the precedence of internationalization  
 114495 variables used to determine the values of locale categories.)

114496           **LC\_ALL**          If set to a non-empty string value, override the values of all the other  
 114497 internationalization variables.

114498           **LC\_CTYPE**       Determine the locale for the interpretation of sequences of bytes of text data as  
 114499 characters (for example, single-byte as opposed to multi-byte characters in  
 114500 arguments).

114501           **LC\_MESSAGES**   Determine the locale that should be used to affect the format and contents of  
 114502 diagnostic messages written to standard error.

114503           **LC\_TIME**        Determine the locale used for the format and contents of the date and time strings.

114504           **NLSPATH**       Determine the location of message catalogs for the processing of **LC\_MESSAGES**.

114505 XSI           **TZ**           Determine the timezone used when writing date and time information. If **TZ** is  
 114506 unset or null, an unspecified default timezone shall be used.

#### 114508 ASYNCHRONOUS EVENTS

114509           Default.

#### 114510 STDOUT

114511           The *who* utility shall write its default format to the standard output in an implementation-  
 114512 defined format, subject only to the requirement of containing the information described above.

114513 XSI OF XSI-conformant systems shall write the default information to the standard output in the  
 114514 following general format:

114515 `<name>[<state>]<line><time>[<activity>][<pid>][<comment>][<exit>]`

114516 For the `-b` option, `<line>` shall be "system boot". The `<name>` is unspecified.

114517 The following format shall be used for the `-T` option:

114518 `"%s %c %s %s\n" <name>, <terminal state>, <terminal name>,  
 114519 <time of login>`

114520 where `<terminal state>` is one of the following characters:

114521 + The terminal allows write access to other users.

114522 - The terminal denies write access to other users.

114523 ? The terminal write-access state cannot be determined.

114524 `<space>` This entry is not associated with a terminal.

114525 In the POSIX locale, the `<time of login>` shall be equivalent in format to the output of:

114526 `date +"%b %e %H:%M"`

114527 If the `-u` option is used with `-T`, the idle time shall be added to the end of the previous format in  
 114528 an unspecified format.

#### 114529 **STDERR**

114530 The standard error shall be used only for diagnostic messages.

#### 114531 **OUTPUT FILES**

114532 None.

#### 114533 **EXTENDED DESCRIPTION**

114534 None.

#### 114535 **EXIT STATUS**

114536 The following exit values shall be returned:

114537 0 Successful completion.

114538 >0 An error occurred.

#### 114539 **CONSEQUENCES OF ERRORS**

114540 Default.

#### 114541 **APPLICATION USAGE**

114542 The name *init* used for the system process is the most commonly used on historical systems, but  
 114543 it may vary.

114544 The "domain of accessibility" referred to is a broad concept that permits interpretation either on  
 114545 a very secure basis or even to allow a network-wide implementation like the historical *rwwho*.

#### 114546 **EXAMPLES**

114547 None.

#### 114548 **RATIONALE**

114549 Due to differences between historical implementations, the base options provided were a  
 114550 compromise to allow users to work with those functions. The standard developers also  
 114551 considered removing all the options, but felt that these options offered users valuable  
 114552 functionality. Additional options to match historical systems are available on XSI-conformant

- 114553 systems.
- 114554 It is recognized that the *who* command may be of limited usefulness, especially in a multi-level  
114555 secure environment. The standard developers considered, however, that having some standard  
114556 method of determining the “accessibility” of other users would aid user portability.
- 114557 No format was specified for the default *who* output for systems not supporting the XSI option. In  
114558 such a user-oriented command, designed only for human use, this was not considered to be a  
114559 deficiency.
- 114560 The format of the terminal name is unspecified, but the descriptions of *ps*, *talk*, and *write* require  
114561 that they use the same format.
- 114562 It is acceptable for an implementation to produce no output for an invocation of *who* **mil**.
- 114563 **FUTURE DIRECTIONS**
- 114564 None.
- 114565 **SEE ALSO**
- 114566 *mesg*
- 114567 XBD [Chapter 8](#) (on page 173), [Section 12.2](#) (on page 215)
- 114568 **CHANGE HISTORY**
- 114569 First released in Issue 2.
- 114570 **Issue 6**
- 114571 This utility is marked as part of the User Portability Utilities option.
- 114572 The *TZ* entry is added to the ENVIRONMENT VARIABLES section.
- 114573 **Issue 7**
- 114574 SD5-XCU-ERN-58 is applied, clarifying the **-b** option.
- 114575 The *who* utility is moved from the User Portability Utilities option to the Base. User Portability  
114576 Utilities is now an option for interactive utilities.
- 114577 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

114578 **NAME**

114579       write — write to another user

114580 **SYNOPSIS**114581       write *user\_name* [*terminal*]114582 **DESCRIPTION**

114583       The *write* utility shall read lines from the standard input and write them to the terminal of the  
 114584       specified user. When first invoked, it shall write the message:

114585       **Message from** *sender-login-id* (*sending-terminal*) [*date*]...

114586       to *user\_name*. When it has successfully completed the connection, the sender's terminal shall be  
 114587       alerted twice to indicate that what the sender is typing is being written to the recipient's  
 114588       terminal.

114589       If the recipient wants to reply, this can be accomplished by typing:

114590       write *sender-login-id* [*sending-terminal*]

114591       upon receipt of the initial message. Whenever a line of input as delimited by an NL, EOF, or  
 114592       EOL special character (see XBD [Chapter 11](#), on page 199) is accumulated while in canonical  
 114593       input mode, the accumulated data shall be written on the other user's terminal. Characters shall  
 114594       be processed as follows:

- 114595       • Typing <alert> shall write the <alert> character to the recipient's terminal.
- 114596       • Typing the erase and kill characters shall affect the sender's terminal in the manner  
 114597       described by the **termios** interface in XBD [Chapter 11](#) (on page 199).
- 114598       • Typing the interrupt or end-of-file characters shall cause *write* to write an appropriate  
 114599       message ("EOT\n" in the POSIX locale) to the recipient's terminal and exit.
- 114600       • Typing characters from *LC\_CTYPE* classifications **print** or **space** shall cause those  
 114601       characters to be sent to the recipient's terminal.
- 114602       • When and only when the *stty* **ixten** local mode is enabled, the existence and processing of  
 114603       additional special control characters and multi-byte or single-byte functions is  
 114604       implementation-defined.
- 114605       • Typing other non-printable characters shall cause implementation-defined sequences of  
 114606       printable characters to be written to the recipient's terminal.

114607       To write to a user who is logged in more than once, the *terminal* argument can be used to  
 114608       indicate which terminal to write to; otherwise, the recipient's terminal is selected in an  
 114609       implementation-defined manner and an informational message is written to the sender's  
 114610       standard output, indicating which terminal was chosen.

114611       Permission to be a recipient of a *write* message can be denied or granted by use of the *mesg*  
 114612       utility. However, a user's privilege may further constrain the domain of accessibility of other  
 114613       users' terminals. The *write* utility shall fail when the user lacks appropriate privileges to perform  
 114614       the requested action.

114615 **OPTIONS**

114616       None.

114617 **OPERANDS**

- 114618 The following operands shall be supported:
- 114619 *user\_name* Login name of the person to whom the message shall be written. The application  
114620 shall ensure that this operand is of the form returned by the *who* utility.
- 114621 *terminal* Terminal identification in the same format provided by the *who* utility.
- 114622 **STDIN**
- 114623 Lines to be copied to the recipient's terminal are read from standard input.
- 114624 **INPUT FILES**
- 114625 None.
- 114626 **ENVIRONMENT VARIABLES**
- 114627 The following environment variables shall affect the execution of *write*:
- 114628 *LANG* Provide a default value for the internationalization variables that are unset or null.  
114629 (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
114630 variables used to determine the values of locale categories.)
- 114631 *LC\_ALL* If set to a non-empty string value, override the values of all the other  
114632 internationalization variables.
- 114633 *LC\_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as  
114634 characters (for example, single-byte as opposed to multi-byte characters in  
114635 arguments and input files). If the recipient's locale does not use an *LC\_CTYPE*  
114636 equivalent to the sender's, the results are undefined.
- 114637 *LC\_MESSAGES*
- 114638 Determine the locale that should be used to affect the format and contents of  
114639 diagnostic messages written to standard error and informative messages written to  
114640 standard output.
- 114641 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.
- 114642 **ASYNCHRONOUS EVENTS**
- 114643 If an interrupt signal is received, *write* shall write an appropriate message on the recipient's  
114644 terminal and exit with a status of zero. It shall take the standard action for all other signals.
- 114645 **STDOUT**
- 114646 An informational message shall be written to standard output if a recipient is logged in more  
114647 than once.
- 114648 **STDERR**
- 114649 The standard error shall be used only for diagnostic messages.
- 114650 **OUTPUT FILES**
- 114651 The recipient's terminal is used for output.
- 114652 **EXTENDED DESCRIPTION**
- 114653 None.
- 114654 **EXIT STATUS**
- 114655 The following exit values shall be returned:
- 114656 0 Successful completion.
- 114657 >0 The addressed user is not logged on or the addressed user denies permission.

114658 **CONSEQUENCES OF ERRORS**

114659 Default.

114660 **APPLICATION USAGE**114661 The *talk* utility is considered by some users to be a more usable utility on full-screen terminals.114662 **EXAMPLES**

114663 None.

114664 **RATIONALE**

114665 The *write* utility was included in this volume of POSIX.1-2008 since it can be implemented on all  
114666 terminal types. The standard developers considered the *talk* utility, which cannot be  
114667 implemented on certain terminals, to be a “better” communications interface. Both of these  
114668 programs are in widespread use on historical implementations. Therefore, the standard  
114669 developers decided that both utilities should be specified.

114670 The format of the terminal name is unspecified, but the descriptions of *ps*, *talk*, *who*, and *write*  
114671 require that they all use or accept the same format.

114672 **FUTURE DIRECTIONS**

114673 None.

114674 **SEE ALSO**114675 *mesg*, *talk*, *who*114676 XBD [Chapter 8](#) (on page 173), [Chapter 11](#) (on page 199)114677 **CHANGE HISTORY**

114678 First released in Issue 2.

114679 **Issue 5**

114680 The FUTURE DIRECTIONS section is added.

114681 **Issue 6**

114682 This utility is marked as part of the User Portability Utilities option.

114683 The normative text is reworded to avoid use of the term “must” for application requirements.

114684 **Issue 7**

114685 The *write* utility is moved from the User Portability Utilities option to the Base. User Portability  
114686 Utilities is now an option for interactive utilities.

114687 **NAME**114688 **xargs** — construct argument lists and invoke utility114689 **SYNOPSIS**

```
114690 XSI xargs [-ptx] [-E eofstr] [-I replstr|-L number|-n number]
114691 [-s size] [utility [argument...]]
```

114692 **DESCRIPTION**

114693 The *xargs* utility shall construct a command line consisting of the *utility* and *argument* operands  
 114694 specified followed by as many arguments read in sequence from standard input as fit in length  
 114695 and number constraints specified by the options. The *xargs* utility shall then invoke the  
 114696 constructed command line and wait for its completion. This sequence shall be repeated until one  
 114697 of the following occurs:

- 114698 • An end-of-file condition is detected on standard input.
- 114699 • An argument consisting of just the logical end-of-file string (see the `-E eofstr` option) is  
 114700 found on standard input after double-quote processing, <apostrophe> processing, and  
 114701 <backslash>-escape processing (see next paragraph). All arguments up to but not  
 114702 including the argument consisting of just the logical end-of-file string shall be used as  
 114703 arguments in constructed command lines.
- 114704 • An invocation of a constructed command line returns an exit status of 255.

114705 The application shall ensure that arguments in the standard input are separated by unquoted  
 114706 <blank> characters, unescaped <blank> characters, or <newline> characters. A string of zero or  
 114707 more non-double-quote ( ' ' ) characters and non-<newline> characters can be quoted by  
 114708 enclosing them in double-quotes. A string of zero or more non-<apostrophe> ( ' \ ' ' ) characters  
 114709 and non-<newline> characters can be quoted by enclosing them in <apostrophe> characters.  
 114710 Any unquoted character can be escaped by preceding it with a <backslash>. The utility named  
 114711 by *utility* shall be executed one or more times until the end-of-file is reached or the logical end-of  
 114712 file string is found. The results are unspecified if the utility named by *utility* attempts to read  
 114713 from its standard input.

114714 The generated command line length shall be the sum of the size in bytes of the utility name and  
 114715 each argument treated as strings, including a null byte terminator for each of these strings. The  
 114716 *xargs* utility shall limit the command line length such that when the command line is invoked,  
 114717 the combined argument and environment lists (see the *exec* family of functions in the System  
 114718 Interfaces volume of POSIX.1-2008) shall not exceed {ARG\_MAX}-2048 bytes. Within this  
 114719 constraint, if neither the `-n` nor the `-s` option is specified, the default command line length shall  
 114720 be at least {LINE\_MAX}.

114721 **OPTIONS**114722 The *xargs* utility shall conform to XBD [Section 12.2](#) (on page 215).

114723 The following options shall be supported:

114724 `-E eofstr` Use *eofstr* as the logical end-of-file string. If `-E` is not specified, it is unspecified  
 114725 whether the logical end-of-file string is the <underscore> character ( ' \_ ' ) or the  
 114726 end-of-file string capability is disabled. When *eofstr* is the null string, the logical  
 114727 end-of-file string capability shall be disabled and <underscore> characters shall be  
 114728 taken literally.

114729 XSI `-I replstr` Insert mode: *utility* is executed for each logical line from standard input.  
 114730 Arguments in the standard input shall be separated only by unescaped <newline>  
 114731 characters, not by <blank> characters. Any unquoted unescaped <blank>  
 114732 characters at the beginning of each line shall be ignored. The resulting argument  
 114733 shall be inserted in *arguments* in place of each occurrence of *replstr*. At least five

|        |     |                                                                                                                   |
|--------|-----|-------------------------------------------------------------------------------------------------------------------|
| 114734 |     | arguments in <i>arguments</i> can each contain one or more instances of <i>replstr</i> . Each of                  |
| 114735 |     | these constructed arguments cannot grow larger than an implementation-defined                                     |
| 114736 |     | limit greater than or equal to 255 bytes. Option <b>-x</b> shall be forced on.                                    |
| 114737 | XSI | <b>-L number</b> The <i>utility</i> shall be executed for each non-empty <i>number</i> lines of arguments from    |
| 114738 |     | standard input. The last invocation of <i>utility</i> shall be with fewer lines of arguments                      |
| 114739 |     | if fewer than <i>number</i> remain. A line is considered to end with the first <newline>                          |
| 114740 |     | unless the last character of the line is a <blank>; a trailing <blank> signals                                    |
| 114741 |     | continuation to the next non-empty line, inclusive.                                                               |
| 114742 |     | <b>-n number</b> Invoke <i>utility</i> using as many standard input arguments as possible, up to <i>number</i> (a |
| 114743 |     | positive decimal integer) arguments maximum. Fewer arguments shall be used if:                                    |
| 114744 |     | • The command line length accumulated exceeds the size specified by the <b>-s</b>                                 |
| 114745 |     | option (or {LINE_MAX} if there is no <b>-s</b> option).                                                           |
| 114746 |     | • The last iteration has fewer than <i>number</i> , but not zero, operands remaining.                             |
| 114747 |     | <b>-p</b> Prompt mode: the user is asked whether to execute <i>utility</i> at each invocation. Trace              |
| 114748 |     | mode ( <b>-t</b> ) is turned on to write the command instance to be executed, followed by                         |
| 114749 |     | a prompt to standard error. An affirmative response read from <b>/dev/tty</b> shall                               |
| 114750 |     | execute the command; otherwise, that particular invocation of <i>utility</i> shall be                             |
| 114751 |     | skipped.                                                                                                          |
| 114752 |     | <b>-s size</b> Invoke <i>utility</i> using as many standard input arguments as possible yielding a                |
| 114753 |     | command line length less than <i>size</i> (a positive decimal integer) bytes. Fewer                               |
| 114754 |     | arguments shall be used if:                                                                                       |
| 114755 |     | • The total number of arguments exceeds that specified by the <b>-n</b> option.                                   |
| 114756 | XSI | • The total number of lines exceeds that specified by the <b>-L</b> option.                                       |
| 114757 |     | • End-of-file is encountered on standard input before <i>size</i> bytes are                                       |
| 114758 |     | accumulated.                                                                                                      |
| 114759 |     | Values of <i>size</i> up to at least {LINE_MAX} bytes shall be supported, provided that                           |
| 114760 |     | the constraints specified in the DESCRIPTION are met. It shall not be considered                                  |
| 114761 |     | an error if a value larger than that supported by the implementation or exceeding                                 |
| 114762 |     | the constraints specified in the DESCRIPTION is given; <i>xargs</i> shall use the largest                         |
| 114763 |     | value it supports within the constraints.                                                                         |
| 114764 |     | <b>-t</b> Enable trace mode. Each generated command line shall be written to standard                             |
| 114765 |     | error just prior to invocation.                                                                                   |
| 114766 |     | <b>-x</b> Terminate if a constructed command line will not fit in the implied or specified size                   |
| 114767 |     | (see the <b>-s</b> option above).                                                                                 |

## 114768 OPERANDS

114769 The following operands shall be supported:

|        |                 |                                                                                                       |
|--------|-----------------|-------------------------------------------------------------------------------------------------------|
| 114770 | <i>utility</i>  | The name of the utility to be invoked, found by search path using the <i>PATH</i>                     |
| 114771 |                 | environment variable, described in XBD Chapter 8 (on page 173). If <i>utility</i> is                  |
| 114772 |                 | omitted, the default shall be the <i>echo</i> utility. If the <i>utility</i> operand names any of the |
| 114773 |                 | special built-in utilities in Section 2.14 (on page 2356), the results are undefined.                 |
| 114774 | <i>argument</i> | An initial option or operand for the invocation of <i>utility</i> .                                   |

114775 **STDIN**

114776 The standard input shall be a text file. The results are unspecified if an end-of-file condition is  
 114777 detected immediately following an escaped <newline>.

114778 **INPUT FILES**

114779 The file `/dev/tty` shall be used to read responses required by the `-p` option.

114780 **ENVIRONMENT VARIABLES**

114781 The following environment variables shall affect the execution of *xargs*:

114782 *LANG* Provide a default value for the internationalization variables that are unset or null.  
 114783 (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 114784 variables used to determine the values of locale categories.)

114785 *LC\_ALL* If set to a non-empty string value, override the values of all the other  
 114786 internationalization variables.

114787 *LC\_COLLATE*

114788 Determine the locale for the behavior of ranges, equivalence classes, and multi-  
 114789 character collating elements used in the extended regular expression defined for  
 114790 the **yesexpr** locale keyword in the *LC\_MESSAGES* category.

114791 *LC\_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as  
 114792 characters (for example, single-byte as opposed to multi-byte characters in  
 114793 arguments and input files) and the behavior of character classes used in the  
 114794 extended regular expression defined for the **yesexpr** locale keyword in the  
 114795 *LC\_MESSAGES* category.

114796 *LC\_MESSAGES*

114797 Determine the locale used to process affirmative responses, and the locale used to  
 114798 affect the format and contents of diagnostic messages and prompts written to  
 114799 standard error.

114800 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

114801 *PATH* Determine the location of *utility*, as described in XBD [Chapter 8](#) (on page 173).

114802 **ASYNCHRONOUS EVENTS**

114803 Default.

114804 **STDOUT**

114805 Not used.

114806 **STDERR**

114807 The standard error shall be used for diagnostic messages and the `-t` and `-p` options. If the `-t`  
 114808 option is specified, the *utility* and its constructed argument list shall be written to standard error,  
 114809 as it will be invoked, prior to invocation. If `-p` is specified, a prompt of the following format  
 114810 shall be written (in the POSIX locale):

114811 " ? . . . "

114812 at the end of the line of the output from `-t`.

114813 **OUTPUT FILES**

114814 None.

114815 **EXTENDED DESCRIPTION**

114816 None.

114817 **EXIT STATUS**

114818 The following exit values shall be returned:

114819 0 All invocations of *utility* returned exit status zero.

114820 1-125 A command line meeting the specified requirements could not be assembled, one or  
 114821 more of the invocations of *utility* returned a non-zero exit status, or some other error  
 114822 occurred.

114823 126 The utility specified by *utility* was found but could not be invoked.114824 127 The utility specified by *utility* could not be found.114825 **CONSEQUENCES OF ERRORS**

114826 If a command line meeting the specified requirements cannot be assembled, the utility cannot be  
 114827 invoked, an invocation of the utility is terminated by a signal, or an invocation of the utility exits  
 114828 with exit status 255, the *xargs* utility shall write a diagnostic message and exit without  
 114829 processing any remaining input.

114830 **APPLICATION USAGE**

114831 The 255 exit status allows a utility being used by *xargs* to tell *xargs* to terminate if it knows no  
 114832 further invocations using the current data stream will succeed. Thus, *utility* should explicitly *exit*  
 114833 with an appropriate value to avoid accidentally returning with 255.

114834 Note that since input is parsed as lines, <blank> characters separate arguments, and  
 114835 <backslash>, <apostrophe>, and double-quote characters are used for quoting, if *xargs* is used to  
 114836 bundle the output of commands like *find dir -print* or *ls* into commands to be executed,  
 114837 unexpected results are likely if any filenames contain <blank>, <newline>, or quoting characters.  
 114838 This can be solved by using *find* to call a script that converts each file found into a quoted string  
 114839 that is then piped to *xargs*, but in most cases it is preferable just to have *find* do the argument  
 114840 aggregation itself by using *-exec* with a '+' terminator instead of ';' . Note that the quoting  
 114841 rules used by *xargs* are not the same as in the shell. They were not made consistent here because  
 114842 existing applications depend on the current rules. An easy (but inefficient) method that can be  
 114843 used to transform input consisting of one argument per line into a quoted form that *xargs*  
 114844 interprets correctly is to precede each non-<newline> character with a <backslash>. More  
 114845 efficient alternatives are shown in Example 2 and Example 5 below.

114846 On implementations with a large value for {ARG\_MAX}, *xargs* may produce command lines  
 114847 longer than {LINE\_MAX}. For invocation of utilities, this is not a problem. If *xargs* is being used  
 114848 to create a text file, users should explicitly set the maximum command line length with the *-s*  
 114849 option.

114850 The *command*, *env*, *nice*, *nohup*, *time*, and *xargs* utilities have been specified to use exit code 127 if  
 114851 an error occurs so that applications can distinguish "failure to find a utility" from "invoked  
 114852 utility exited with an error indication". The value 127 was chosen because it is not commonly  
 114853 used for other meanings; most utilities use small values for "normal error conditions" and the  
 114854 values above 128 can be confused with termination due to receipt of a signal. The value 126 was  
 114855 chosen in a similar manner to indicate that the utility could be found, but not invoked. Some  
 114856 scripts produce meaningful error messages differentiating the 126 and 127 cases. The distinction  
 114857 between exit codes 126 and 127 is based on KornShell practice that uses 127 when all attempts to  
 114858 *exec* the utility fail with [ENOENT], and uses 126 when any attempt to *exec* the utility fails for  
 114859 any other reason.

## 114860 EXAMPLES

- 114861 1. The following command combines the output of the parenthesized commands (minus the  
114862 <apostrophe> characters) onto one line, which is then appended to the file log. It assumes  
114863 that the expansion of "\$0 \$" does not include any <apostrophe> or <newline>  
114864 characters.

114865 `(logname; date; printf "'%s'\n" "$0 $*") | xargs -E "" >>log`

- 114866 2. The following command invokes *diff* with successive pairs of arguments originally typed  
114867 as command line arguments. It assumes there are no embedded <newline> characters in  
114868 the elements of the original argument list.

114869 `printf "%s\n" "$@" | sed 's/^[[:alnum:]]/\&/g' |`  
114870 `xargs -E "" -n 2 -x diff`

- 114871 3. In the following commands, the user is asked which files in the current directory  
114872 (excluding dotfiles) are to be archived. The files are archived into **arch**; *a*, one at a time or  
114873 *b*, many at a time. The commands assume that no filenames contain <blank>, <newline>,  
114874 <backslash>, <apostrophe>, or double-quote characters.

114875 `a. ls | xargs -E "" -p -L 1 ar -r arch`

114876 `b. ls | xargs -E "" -p -L 1 | xargs -E "" ar -r arch`

- 114877 4. The following command invokes *command1* one or more times with multiple arguments,  
114878 stopping if an invocation of *command1* has a non-zero exit status.

114879 `xargs -E "" sh -c 'command1 "$@" || exit 255' sh < xargs_input`

- 114880 5. On XSI-conformant systems, the following command moves all files from directory **\$1** to  
114881 directory **\$2**, and echoes each move command just before doing it. It assumes no  
114882 filenames contain <newline> characters and that neither **\$1** nor **\$2** contains the sequence  
114883 "{}".

114884 `ls -A "$1" | sed -e 's/"\/"\/"/g' -e 's/.*/"&"/' |`  
114885 `xargs -E "" -I {} -t mv "$1"/{} "$2"/{}`

## 114886 RATIONALE

114887 The *xargs* utility was usually found only in System V-based systems; BSD systems included an  
114888 *apply* utility that provided functionality similar to *xargs -n number*. The SVID lists *xargs* as a  
114889 software development extension. This volume of POSIX.1-2008 does not share the view that it is  
114890 used only for development, and therefore it is not optional.

114891 The classic application of the *xargs* utility is in conjunction with the *find* utility to reduce the  
114892 number of processes launched by a simplistic use of the *find -exec* combination. The *xargs* utility  
114893 is also used to enforce an upper limit on memory required to launch a process. With this basis in  
114894 mind, this volume of POSIX.1-2008 selected only the minimal features required.

114895 Although the 255 exit status is mostly an accident of historical implementations, it allows a  
114896 utility being used by *xargs* to tell *xargs* to terminate if it knows no further invocations using the  
114897 current data stream shall succeed. Any non-zero exit status from a utility falls into the 1-125  
114898 range when *xargs* exits. There is no statement of how the various non-zero utility exit status  
114899 codes are accumulated by *xargs*. The value could be the addition of all codes, their highest  
114900 value, the last one received, or a single value such as 1. Since no algorithm is arguably better  
114901 than the others, and since many of the standard utilities say little more (portably) than  
114902 "pass/fail", no new algorithm was invented.

114903 Several other *xargs* options were removed because simple alternatives already exist within this

volume of POSIX.1-2008. For example, the `-i replstr` option can be just as efficiently performed using a shell **for** loop. Since *xargs* calls an *exec* function with each input line, the `-i` option does not usually exploit the grouping capabilities of *xargs*.

The requirement that *xargs* never produces command lines such that invocation of *utility* is within 2048 bytes of hitting the POSIX *exec* {ARG\_MAX} limitations is intended to guarantee that the invoked utility has room to modify its environment variables and command line arguments and still be able to invoke another utility. Note that the minimum {ARG\_MAX} allowed by the System Interfaces volume of POSIX.1-2008 is 4096 bytes and the minimum value allowed by this volume of POSIX.1-2008 is 2048 bytes; therefore, the 2048 bytes difference seems reasonable. Note, however, that *xargs* may never be able to invoke a utility if the environment passed in to *xargs* comes close to using {ARG\_MAX} bytes.

The version of *xargs* required by this volume of POSIX.1-2008 is required to wait for the completion of the invoked command before invoking another command. This was done because historical scripts using *xargs* assumed sequential execution. Implementations wanting to provide parallel operation of the invoked utilities are encouraged to add an option enabling parallel invocation, but should still wait for termination of all of the children before *xargs* terminates normally.

The `-e` option was omitted from the ISO POSIX-2:1993 standard in the belief that the *eofstr* option-argument was recognized only when it was on a line by itself and before quote and escape processing were performed, and that the logical end-of-file processing was only enabled if a `-e` option was specified. In that case, a simple *sed* script could be used to duplicate the `-e` functionality. Further investigation revealed that:

- The logical end-of-file string was checked for after quote and escape processing, making a *sed* script that provided equivalent functionality much more difficult to write.
- The default was to perform logical end-of-file processing with an `<underscore>` as the logical end-of-file string.

To correct this misunderstanding, the `-E eofstr` option was adopted from the X/Open Portability Guide. Users should note that the description of the `-E` option matches historical documentation of the `-e` option (which was not adopted because it did not support the Utility Syntax Guidelines), by saying that if *eofstr* is the null string, logical end-of-file processing is disabled. Historical implementations of *xargs* actually did not disable logical end-of-file processing; they treated a null argument found in the input as a logical end-of-file string. (A null *string* argument could be generated using single or double-quotes (' ' or " "). Since this behavior was not documented historically, it is considered to be a bug.

The `-I`, `-L`, and `-n` options are mutually-exclusive. Some implementations use the last one specified if more than one is given on a command line; other implementations treat combinations of the options in different ways.

## FUTURE DIRECTIONS

None.

114947 **CHANGE HISTORY**

114948 First released in Issue 2.

114949 **Issue 5**

114950 A second FUTURE DIRECTION is added.

114951 **Issue 6**114952 The obsolescent `-e`, `-i`, and `-l` options are removed.114953 The following new requirements on POSIX implementations derive from alignment with the  
114954 Single UNIX Specification:

- 114955 • The `-p` option is added.
- 114956 • In the INPUT FILES section, the file `/dev/tty` is used to read responses required by the `-p`  
114957 option.
- 114958 • The STDERR section is updated to describe the `-p` option.

114959 The description of the `-E` option is aligned with the ISO POSIX-2: 1993 standard.

114960 The normative text is reworded to avoid use of the term “must” for application requirements.

114961 **Issue 7**114962 Austin Group Interpretation 1003.1-2001 #123 is applied, changing the description of the *xargs* `-I`  
114963 option.114964 Austin Group Interpretation 1003.1-2001 #126 is applied, changing the description of the  
114965 `LC_MESSAGES` environment variable.

114966 SD5-XCU-ERN-68 is applied.

114967 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

114968 SD5-XCU-ERN-128 is applied, clarifying the DESCRIPTION of the logical end-of-file string.

114969 SD5-XCU-ERN-132 is applied, updating the EXAMPLES section.

114970 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0149 [342] is applied.

114971 **NAME**114972 yacc — yet another compiler compiler (**DEVELOPMENT**)114973 **SYNOPSIS**114974 CD `yacc [-dltv] [-b file_prefix] [-p sym_prefix] grammar`114975 **DESCRIPTION**

114976 The *yacc* utility shall read a description of a context-free grammar in *grammar* and write C source  
 114977 code, conforming to the ISO C standard, to a code file, and optionally header information into a  
 114978 header file, in the current directory. The generated source code shall not depend on any  
 114979 undefined, unspecified, or implementation-defined behavior, except in cases where it is copied  
 114980 directly from the supplied grammar, or in cases that are documented by the implementation.  
 114981 The C code shall define a function and related routines and macros for an automaton that  
 114982 executes a parsing algorithm meeting the requirements in [Algorithms](#) (on page 3426).

114983 The form and meaning of the grammar are described in the EXTENDED DESCRIPTION section.

114984 The C source code and header file shall be produced in a form suitable as input for the C  
 114985 compiler (see [c99](#)).

114986 **OPTIONS**

114987 The *yacc* utility shall conform to XBD [Section 12.2](#) (on page 215), except for Guideline 9.

114988 The following options shall be supported:

114989 **-b *file\_prefix*** Use *file\_prefix* instead of **y** as the prefix for all output filenames. The code file  
 114990 **y.tab.c**, the header file **y.tab.h** (created when **-d** is specified), and the description  
 114991 file **y.output** (created when **-v** is specified), shall be changed to *file\_prefix.tab.c*,  
 114992 *file\_prefix.tab.h*, and *file\_prefix.output*, respectively.

114993 **-d** Write the header file; by default only the code file is written. The **#define**  
 114994 statements associate the token codes assigned by *yacc* with the user-declared token  
 114995 names. This allows source files other than **y.tab.c** to access the token codes.

114996 **-l** Produce a code file that does not contain any **#line** constructs. If this option is not  
 114997 present, it is unspecified whether the code file or header file contains **#line**  
 114998 directives. This should only be used after the grammar and the associated actions  
 114999 are fully debugged.

115000 **-p *sym\_prefix***  
 115001 Use *sym\_prefix* instead of **yy** as the prefix for all external names produced by *yacc*.  
 115002 The names affected shall include the functions *yyparse()*, *yylex()*, and *yyerror()*,  
 115003 and the variables *yyval*, *yychar*, and *yydebug*. (In the remainder of this section, the  
 115004 six symbols cited are referenced using their default names only as a notational  
 115005 convenience.) Local names may also be affected by the **-p** option; however, the **-p**  
 115006 option shall not affect **#define** symbols generated by *yacc*.

115007 **-t** Modify conditional compilation directives to permit compilation of debugging  
 115008 code in the code file. Runtime debugging statements shall always be contained in  
 115009 the code file, but by default conditional compilation directives prevent their  
 115010 compilation.

115011 **-v** Write a file containing a description of the parser and a report of conflicts  
 115012 generated by ambiguities in the grammar.

**115013 OPERANDS**

115014 The following operand is required:

115015 *grammar* A pathname of a file containing instructions, hereafter called *grammar*, for which a  
 115016 parser is to be created. The format for the grammar is described in the EXTENDED  
 115017 DESCRIPTION section.

**115018 STDIN**

115019 Not used.

**115020 INPUT FILES**

115021 The file *grammar* shall be a text file formatted as specified in the EXTENDED DESCRIPTION  
 115022 section.

**115023 ENVIRONMENT VARIABLES**

115024 The following environment variables shall affect the execution of *yacc*:

115025 *LANG* Provide a default value for the internationalization variables that are unset or null.  
 115026 (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 115027 variables used to determine the values of locale categories.)

115028 *LC\_ALL* If set to a non-empty string value, override the values of all the other  
 115029 internationalization variables.

115030 *LC\_CTYPE* Determine the locale for the interpretation of sequences of bytes of text data as  
 115031 characters (for example, single-byte as opposed to multi-byte characters in  
 115032 arguments and input files).

115033 *LC\_MESSAGES*

115034 Determine the locale that should be used to affect the format and contents of  
 115035 diagnostic messages written to standard error.

115036 XSI *NLSPATH* Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

115037 The *LANG* and *LC\_\** variables affect the execution of the *yacc* utility as stated. The *main()*  
 115038 function defined in [Yacc Library](#) (on page 3426) shall call:

115039 `setlocale(LC_ALL, "")`

115040 and thus the program generated by *yacc* shall also be affected by the contents of these variables  
 115041 at runtime.

**115042 ASYNCHRONOUS EVENTS**

115043 Default.

**115044 STDOUT**

115045 Not used.

**115046 STDERR**

115047 If shift/reduce or reduce/reduce conflicts are detected in *grammar*, *yacc* shall write a report of  
 115048 those conflicts to the standard error in an unspecified format.

115049 Standard error shall also be used for diagnostic messages.

**115050 OUTPUT FILES**

115051 The code file, the header file, and the description file shall be text files. All are described in the  
 115052 following sections.

**Code File**

This file shall contain the C source code for the *yyparse()* function. It shall contain code for the various semantic actions with macro substitution performed on them as described in the EXTENDED DESCRIPTION section. It also shall contain a copy of the **#define** statements in the header file. If a **%union** declaration is used, the declaration for YYSTYPE shall also be included in this file.

**Header File**

The header file shall contain **#define** statements that associate the token numbers with the token names. This allows source files other than the code file to access the token codes. If a **%union** declaration is used, the declaration for YYSTYPE and an *extern YYSTYPE yylval* declaration shall also be included in this file.

**Description File**

The description file shall be a text file containing a description of the state machine corresponding to the parser, using an unspecified format. Limits for internal tables (see [Limits](#), on page 3427) shall also be reported, in an implementation-defined manner. (Some implementations may use dynamic allocation techniques and have no specific limit values to report.)

**EXTENDED DESCRIPTION**

The *yacc* command accepts a language that is used to define a grammar for a target language to be parsed by the tables and code generated by *yacc*. The language accepted by *yacc* as a grammar for the target language is described below using the *yacc* input language itself.

The input *grammar* includes rules describing the input structure of the target language and code to be invoked when these rules are recognized to provide the associated semantic action. The code to be executed shall appear as bodies of text that are intended to be C-language code. These bodies of text shall not contain C-language trigraphs. The C-language inclusions are presumed to form a correct function when processed by *yacc* into its output files. The code included in this way shall be executed during the recognition of the target language.

Given a grammar, the *yacc* utility generates the files described in the OUTPUT FILES section. The code file can be compiled and linked using *c99*. If the declaration and programs sections of the grammar file did not include definitions of *main()*, *yylex()*, and *yyerror()*, the compiled output requires linking with externally supplied versions of those functions. Default versions of *main()* and *yyerror()* are supplied in the *yacc* library and can be linked in by using the *-ly* operand to *c99*. The *yacc* library interfaces need not support interfaces with other than the default **yy** symbol prefix. The application provides the lexical analyzer function, *yylex()*; the *lex* utility is specifically designed to generate such a routine.

**Input Language**

The application shall ensure that every specification file consists of three sections in order: *declarations*, *grammar rules*, and *programs*, separated by double <percent-sign> characters ("%"). The declarations and programs sections can be empty. If the latter is empty, the preceding "%" mark separating it from the rules section can be omitted.

The input is free form text following the structure of the grammar defined below.

## Lexical Structure of the Grammar

The <blank>, <newline>, and <form-feed> character shall be ignored, except that the application shall ensure that they do not appear in names or multi-character reserved symbols. Comments shall be enclosed in `"/* . . . */"`, and can appear wherever a name is valid.

Names are of arbitrary length, made up of letters, periods (`'.'`), underscores (`'_'`), and non-initial digits. Uppercase and lowercase letters are distinct. Conforming applications shall not use names beginning in `yy` or `YY` since the *yacc* parser uses such names. Many of the names appear in the final output of *yacc*, and thus they should be chosen to conform with any additional rules created by the C compiler to be used. In particular they appear in `#define` statements.

A literal shall consist of a single character enclosed in single-quote characters. All of the escape sequences supported for character constants by the ISO C standard shall be supported by *yacc*.

The relationship with the lexical analyzer is discussed in detail below.

The application shall ensure that the NUL character is not used in grammar rules or literals.

## Declarations Section

The declarations section is used to define the symbols used to define the target language and their relationship with each other. In particular, much of the additional information required to resolve ambiguities in the context-free grammar for the target language is provided here.

Usually *yacc* assigns the relationship between the symbolic names it generates and their underlying numeric value. The declarations section makes it possible to control the assignment of these values.

It is also possible to keep semantic information associated with the tokens currently on the parse stack in a user-defined C-language **union**, if the members of the union are associated with the various names in the grammar. The declarations section provides for this as well.

The first group of declarators below all take a list of names as arguments. That list can optionally be preceded by the name of a C union member (called a *tag* below) appearing within `'<'` and `'>'`. (As an exception to the typographical conventions of the rest of this volume of POSIX.1-2008, in this case `<tag>` does not represent a metavariable, but the literal angle bracket characters surrounding a symbol.) The use of *tag* specifies that the tokens named on this line shall be of the same C type as the union member referenced by *tag*. This is discussed in more detail below.

For lists used to define tokens, the first appearance of a given token can be followed by a positive integer (as a string of decimal digits). If this is done, the underlying value assigned to it for lexical purposes shall be taken to be that number.

The following declares *name* to be a token:

```
%token [<tag>] name [number] [name [number]]...
```

If *tag* is present, the C type for all tokens on this line shall be declared to be the type referenced by *tag*. If a positive integer, *number*, follows a *name*, that value shall be assigned to the token.

The following declares *name* to be a token, and assigns precedence to it:

```
%left [<tag>] name [number] [name [number]]...
```

```
%right [<tag>] name [number] [name [number]]...
```

One or more lines, each beginning with one of these symbols, can appear in this section. All tokens on the same line have the same precedence level and associativity; the lines are in order

of increasing precedence or binding strength. **%left** denotes that the operators on that line are left associative, and **%right** similarly denotes right associative operators. If *tag* is present, it shall declare a C type for *names* as described for **%token**.

The following declares *name* to be a token, and indicates that this cannot be used associatively:

```
%nonassoc [<tag>] name [number] [name [number]]...
```

If the parser encounters associative use of this token it reports an error. If *tag* is present, it shall declare a C type for *names* as described for **%token**.

The following declares that union member *names* are non-terminals, and thus it is required to have a *tag* field at its beginning:

```
%type <tag> name...
```

Because it deals with non-terminals only, assigning a token number or using a literal is also prohibited. If this construct is present, *yacc* shall perform type checking; if this construct is not present, the parse stack shall hold only the **int** type.

Every name used in *grammar* not defined by a **%token**, **%left**, **%right**, or **%nonassoc** declaration is assumed to represent a non-terminal symbol. The *yacc* utility shall report an error for any non-terminal symbol that does not appear on the left side of at least one grammar rule.

Once the type, precedence, or token number of a name is specified, it shall not be changed. If the first declaration of a token does not assign a token number, *yacc* shall assign a token number. Once this assignment is made, the token number shall not be changed by explicit assignment.

The following declarators do not follow the previous pattern.

The following declares the non-terminal *name* to be the *start symbol*, which represents the largest, most general structure described by the grammar rules:

```
%start name
```

By default, it is the left-hand side of the first grammar rule; this default can be overridden with this declaration.

The following declares the *yacc* value stack to be a union of the various types of values desired.

```
%union { body of union (in C) }
```

The body of the union shall not contain unbalanced curly brace preprocessing tokens.

By default, the values returned by actions (see below) and the lexical analyzer shall be of type **int**. The *yacc* utility keeps track of types, and it shall insert corresponding union member names in order to perform strict type checking of the resulting parser.

Alternatively, given that at least one *<tag>* construct is used, the union can be declared in a header file (which shall be included in the declarations section by using a **#include** construct within **%{** and **%}**), and a **typedef** used to define the symbol **YYSTYPE** to represent this union. The effect of **%union** is to provide the declaration of **YYSTYPE** directly from the *yacc* input.

C-language declarations and definitions can appear in the declarations section, enclosed by the following marks:

```
%{ ... %}
```

These statements shall be copied into the code file, and have global scope within it so that they can be used in the rules and program sections. The statements shall not contain **"%}"** outside a comment, string literal, or multi-character constant.

115178 The application shall ensure that the declarations section is terminated by the token `%%`.

## 115179 Grammar Rules in yacc

115180 The rules section defines the context-free grammar to be accepted by the function *yacc* generates,  
115181 and associates with those rules C-language actions and additional precedence information. The  
115182 grammar is described below, and a formal definition follows.

115183 The rules section is comprised of one or more grammar rules. A grammar rule has the form:

115184 `A : BODY ;`

115185 The symbol **A** represents a non-terminal name, and **BODY** represents a sequence of zero or  
115186 more *names*, *literals*, and *semantic actions* that can then be followed by optional *precedence rules*.  
115187 Only the names and literals participate in the formation of the grammar; the semantic actions  
115188 and precedence rules are used in other ways. The `<colon>` and the `<semicolon>` are *yacc*  
115189 punctuation. If there are several successive grammar rules with the same left-hand side, the  
115190 `<vertical-line>` (`'|'`) can be used to avoid rewriting the left-hand side; in this case the  
115191 `<semicolon>` appears only after the last rule. The BODY part can be empty (or empty of names  
115192 and literals) to indicate that the non-terminal symbol matches the empty string.

115193 The *yacc* utility assigns a unique number to each rule. Rules using the vertical bar notation are  
115194 distinct rules. The number assigned to the rule appears in the description file.

115195 The elements comprising a BODY are:

115196 *name, literal* These form the rules of the grammar: *name* is either a *token* or a *non-terminal*; *literal*  
115197 stands for itself (less the lexically required quotation marks).

115198 *semantic action*

115199 With each grammar rule, the user can associate actions to be performed each time  
115200 the rule is recognized in the input process. (Note that the word “action” can also  
115201 refer to the actions of the parser—shift, reduce, and so on.)

115202 These actions can return values and can obtain the values returned by previous  
115203 actions. These values are kept in objects of type YYSTYPE (see **%union**). The  
115204 result value of the action shall be kept on the parse stack with the left-hand side of  
115205 the rule, to be accessed by other reductions as part of their right-hand side. By  
115206 using the `<tag>` information provided in the declarations section, the code  
115207 generated by *yacc* can be strictly type checked and contain arbitrary information. In  
115208 addition, the lexical analyzer can provide the same kinds of values for tokens, if  
115209 desired.

115210 An action is an arbitrary C statement and as such can do input or output, call  
115211 subprograms, and alter external variables. An action is one or more C statements  
115212 enclosed in curly braces `'{'` and `'}'`. The statements shall not contain  
115213 unbalanced curly brace preprocessing tokens.

115214 Certain pseudo-variables can be used in the action. These are macros for access to  
115215 data structures known internally to *yacc*.

115216 **\$\$** The value of the action can be set by assigning it to **\$\$**. If type  
115217 checking is enabled and the type of the value to be assigned cannot  
115218 be determined, a diagnostic message may be generated.

115219 **\$number** This refers to the value returned by the component specified by the  
115220 token *number* in the right side of a rule, reading from left to right;  
115221 *number* can be zero or negative. If *number* is zero or negative, it refers

115222 to the data associated with the name on the parser's stack preceding  
 115223 the leftmost symbol of the current rule. (That is, "\$0" refers to the  
 115224 name immediately preceding the leftmost name in the current rule to  
 115225 be found on the parser's stack and "\$-1" refers to the symbol to *its*  
 115226 left.) If *number* refers to an element past the current point in the rule,  
 115227 or beyond the bottom of the stack, the result is undefined. If type  
 115228 checking is enabled and the type of the value to be assigned cannot  
 115229 be determined, a diagnostic message may be generated.

115230 \$<*tag*>*number*

115231 These correspond exactly to the corresponding symbols without the  
 115232 *tag* inclusion, but allow for strict type checking (and preclude  
 115233 unwanted type conversions). The effect is that the macro is expanded  
 115234 to use *tag* to select an element from the YYSTYPE union (using  
 115235 *dataname.tag*). This is particularly useful if *number* is not positive.

115236 \$<*tag*>\$

115237 This imposes on the reference the type of the union member  
 115238 referenced by *tag*. This construction is applicable when a reference to  
 115239 a left context value occurs in the grammar, and provides *yacc* with a  
 means for selecting a type.

115240 Actions can occur anywhere in a rule (not just at the end); an action can access  
 115241 values returned by actions to its left, and in turn the value it returns can be  
 115242 accessed by actions to its right. An action appearing in the middle of a rule shall be  
 115243 equivalent to replacing the action with a new non-terminal symbol and adding an  
 115244 empty rule with that non-terminal symbol on the left-hand side. The semantic  
 115245 action associated with the new rule shall be equivalent to the original action. The  
 115246 use of actions within rules might introduce conflicts that would not otherwise  
 115247 exist.

115248 By default, the value of a rule shall be the value of the first element in it. If the first  
 115249 element does not have a type (particularly in the case of a literal) and type  
 115250 checking is turned on by **%type**, an error message shall result.

115251 *precedence* The keyword **%prec** can be used to change the precedence level associated with a  
 115252 particular grammar rule. Examples of this are in cases where a unary and binary  
 115253 operator have the same symbolic representation, but need to be given different  
 115254 precedences, or where the handling of an ambiguous if-else construction is  
 115255 necessary. The reserved symbol **%prec** can appear immediately after the body of  
 115256 the grammar rule and can be followed by a token name or a literal. It shall cause  
 115257 the precedence of the grammar rule to become that of the following token name or  
 115258 literal. The action for the rule as a whole can follow **%prec**.

115259 If a program section follows, the application shall ensure that the grammar rules are terminated  
 115260 by **%%**.

## 115261 Programs Section

115262 The *programs* section can include the definition of the lexical analyzer *yylex()*, and any other  
 115263 functions; for example, those used in the actions specified in the grammar rules. It is unspecified  
 115264 whether the programs section precedes or follows the semantic actions in the output file;  
 115265 therefore, if the application contains any macro definitions and declarations intended to apply to  
 115266 the code in the semantic actions, it shall place them within "%{ . . . %}" in the declarations  
 115267 section.

**Input Grammar**

The following input to *yacc* yields a parser for the input to *yacc*. This formal syntax takes precedence over the preceding text syntax description.

The lexical structure is defined less precisely; [Lexical Structure of the Grammar](#) (on page 3418) defines most terms. The correspondence between the previous terms and the tokens below is as follows.

**IDENTIFIER** This corresponds to the concept of *name*, given previously. It also includes literals as defined previously.

**C\_IDENTIFIER** This is a name, and additionally it is known to be followed by a <colon>. A literal cannot yield this token.

**NUMBER** A string of digits (a non-negative decimal integer).

**TYPE, LEFT, MARK, LCURL, RCURL**

These correspond directly to **%type**, **%left**, **%%**, **%{**, and **%}**.

**{...}** This indicates C-language source code, with the possible inclusion of '\$' macros as discussed previously.

## Conflicts

The parser produced for an input grammar may contain states in which conflicts occur. The conflicts occur because the grammar is not LALR(1). An ambiguous grammar always contains at least one LALR(1) conflict. The *yacc* utility shall resolve all conflicts, using either default rules or user-specified precedence rules.

Conflicts are either shift/reduce conflicts or reduce/reduce conflicts. A shift/reduce conflict is where, for a given state and lookahead symbol, both a shift action and a reduce action are possible. A reduce/reduce conflict is where, for a given state and lookahead symbol, reductions by two different rules are possible.

The rules below describe how to specify what actions to take when a conflict occurs. Not all shift/reduce conflicts can be successfully resolved this way because the conflict may be due to something other than ambiguity, so incautious use of these facilities can cause the language accepted by the parser to be much different from that which was intended. The description file shall contain sufficient information to understand the cause of the conflict. Where ambiguity is the reason either the default or explicit rules should be adequate to produce a working parser.

The declared precedences and associativities (see [Declarations Section](#), on page 3418) are used to resolve parsing conflicts as follows:

1. A precedence and associativity is associated with each grammar rule; it is the precedence and associativity of the last token or literal in the body of the rule. If the **%prec** keyword is used, it overrides this default. Some grammar rules might not have both precedence and associativity.
2. If there is a shift/reduce conflict, and both the grammar rule and the input symbol have precedence and associativity associated with them, then the conflict is resolved in favor of the action (shift or reduce) associated with the higher precedence. If the precedences are the same, then the associativity is used; left associative implies reduce, right associative implies shift, and non-associative implies an error in the string being parsed.
3. When there is a shift/reduce conflict that cannot be resolved by rule 2, the shift is done. Conflicts resolved this way are counted in the diagnostic output described in [Error Handling](#).
4. When there is a reduce/reduce conflict, a reduction is done by the grammar rule that occurs earlier in the input sequence. Conflicts resolved this way are counted in the diagnostic output described in [Error Handling](#).

Conflicts resolved by precedence or associativity shall not be counted in the shift/reduce and reduce/reduce conflicts reported by *yacc* on either standard error or in the description file.

## Error Handling

The token **error** shall be reserved for error handling. The name **error** can be used in grammar rules. It indicates places where the parser can recover from a syntax error. The default value of **error** shall be 256. Its value can be changed using a **%token** declaration. The lexical analyzer should not return the value of **error**.

The parser shall detect a syntax error when it is in a state where the action associated with the lookahead symbol is **error**. A semantic action can cause the parser to initiate error handling by executing the macro YYERROR. When YYERROR is executed, the semantic action passes control back to the parser. YYERROR cannot be used outside of semantic actions.

When the parser detects a syntax error, it normally calls *yyerror()* with the character string "syntax error" as its argument. The call shall not be made if the parser is still recovering

from a previous error when the error is detected. The parser is considered to be recovering from a previous error until the parser has shifted over at least three normal input symbols since the last error was detected or a semantic action has executed the macro *yyerrok*. The parser shall not call *yyerror()* when YYERROR is executed.

The macro function YYRECOVERING shall return 1 if a syntax error has been detected and the parser has not yet fully recovered from it. Otherwise, zero shall be returned.

When a syntax error is detected by the parser, the parser shall check if a previous syntax error has been detected. If a previous error was detected, and if no normal input symbols have been shifted since the preceding error was detected, the parser checks if the lookahead symbol is an endmarker (see [Interface to the Lexical Analyzer](#)). If it is, the parser shall return with a non-zero value. Otherwise, the lookahead symbol shall be discarded and normal parsing shall resume.

When YYERROR is executed or when the parser detects a syntax error and no previous error has been detected, or at least one normal input symbol has been shifted since the previous error was detected, the parser shall pop back one state at a time until the parse stack is empty or the current state allows a shift over **error**. If the parser empties the parse stack, it shall return with a non-zero value. Otherwise, it shall shift over **error** and then resume normal parsing. If the parser reads a lookahead symbol before the error was detected, that symbol shall still be the lookahead symbol when parsing is resumed.

The macro *yyerrok* in a semantic action shall cause the parser to act as if it has fully recovered from any previous errors. The macro *yyclearin* shall cause the parser to discard the current lookahead token. If the current lookahead token has not yet been read, *yyclearin* shall have no effect.

The macro YYACCEPT shall cause the parser to return with the value zero. The macro YYABORT shall cause the parser to return with a non-zero value.

### Interface to the Lexical Analyzer

The *yylex()* function is an integer-valued function that returns a *token number* representing the kind of token read. If there is a value associated with the token returned by *yylex()* (see the discussion of *tag* above), it shall be assigned to the external variable *yyval*.

If the parser and *yylex()* do not agree on these token numbers, reliable communication between them cannot occur. For (single-byte character) literals, the token is simply the numeric value of the character in the current character set. The numbers for other tokens can either be chosen by *yacc*, or chosen by the user. In either case, the **#define** construct of C is used to allow *yylex()* to return these numbers symbolically. The **#define** statements are put into the code file, and the header file if that file is requested. The set of characters permitted by *yacc* in an identifier is larger than that permitted by C. Token names found to contain such characters shall not be included in the **#define** declarations.

If the token numbers are chosen by *yacc*, the tokens other than literals shall be assigned numbers greater than 256, although no order is implied. A token can be explicitly assigned a number by following its first appearance in the declarations section with a number. Names and literals not defined this way retain their default definition. All token numbers assigned by *yacc* shall be unique and distinct from the token numbers used for literals and user-assigned tokens. If duplicate token numbers cause conflicts in parser generation, *yacc* shall report an error; otherwise, it is unspecified whether the token assignment is accepted or an error is reported.

The end of the input is marked by a special token called the *endmarker*, which has a token number that is zero or negative. (These values are invalid for any other token.) All lexical analyzers shall return zero or negative as a token number upon reaching the end of their input.

If the tokens up to, but excluding, the endmarker form a structure that matches the start symbol, the parser shall accept the input. If the endmarker is seen in any other context, it shall be considered an error.

### Completing the Program

In addition to *yyparse()* and *yylex()*, the functions *yyerror()* and *main()* are required to make a complete program. The application can supply *main()* and *yyerror()*, or those routines can be obtained from the *yacc* library.

### Yacc Library

The following functions shall appear only in the *yacc* library accessible through the **-l y** operand to *c99*; they can therefore be redefined by a conforming application:

#### **int main(void)**

This function shall call *yyparse()* and exit with an unspecified value. Other actions within this function are unspecified.

#### **int yyerror(const char \*s)**

This function shall write the NUL-terminated argument to standard error, followed by a <newline>.

The order of the **-l y** and **-l l** operands given to *c99* is significant; the application shall either provide its own *main()* function or ensure that **-l y** precedes **-l l**.

### Debugging the Parser

The parser generated by *yacc* shall have diagnostic facilities in it that can be optionally enabled at either compile time or at runtime (if enabled at compile time). The compilation of the runtime debugging code is under the control of *YYDEBUG*, a preprocessor symbol. If *YYDEBUG* has a non-zero value, the debugging code shall be included. If its value is zero, the code shall not be included.

In parsers where the debugging code has been included, the external **int yydebug** can be used to turn debugging on (with a non-zero value) and off (zero value) at runtime. The initial value of *yydebug* shall be zero.

When **-t** is specified, the code file shall be built such that, if *YYDEBUG* is not already defined at compilation time (using the *c99* **-D YYDEBUG** option, for example), *YYDEBUG* shall be set explicitly to 1. When **-t** is not specified, the code file shall be built such that, if *YYDEBUG* is not already defined, it shall be set explicitly to zero.

The format of the debugging output is unspecified but includes at least enough information to determine the shift and reduce actions, and the input symbols. It also provides information about error recovery.

### Algorithms

The parser constructed by *yacc* implements an LALR(1) parsing algorithm as documented in the literature. It is unspecified whether the parser is table-driven or direct-coded.

A parser generated by *yacc* shall never request an input symbol from *yylex()* while in a state where the only actions other than the error action are reductions by a single rule.

The literature of parsing theory defines these concepts.

## Limits

The *yacc* utility may have several internal tables. The minimum maximums for these tables are shown in the following table. The exact meaning of these values is implementation-defined. The implementation shall define the relationship between these values and between them and any error messages that the implementation may generate should it run out of space for any internal structure. An implementation may combine groups of these resources into a single pool as long as the total available to the user does not fall below the sum of the sizes specified by this section.

**Table 4-23** Internal Limits in *yacc*

| Limit      | Minimum<br>Maximum | Description                                                                                                                                                                                                                                                        |
|------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| {NTERMS}   | 126                | Number of tokens.                                                                                                                                                                                                                                                  |
| {NNONTERM} | 200                | Number of non-terminals.                                                                                                                                                                                                                                           |
| {NPROD}    | 300                | Number of rules.                                                                                                                                                                                                                                                   |
| {NSTATES}  | 600                | Number of states.                                                                                                                                                                                                                                                  |
| {MEMSIZE}  | 5 200              | Length of rules. The total length, in names (tokens and non-terminals), of all the rules of the grammar. The left-hand side is counted for each rule, even if it is not explicitly repeated, as specified in <a href="#">Grammar Rules in yacc</a> (on page 3420). |
| {ACTSIZE}  | 4 000              | Number of actions. “Actions” here (and in the description file) refer to parser actions (shift, reduce, and so on) not to semantic actions defined in <a href="#">Grammar Rules in yacc</a> (on page 3420).                                                        |

## EXIT STATUS

The following exit values shall be returned:

0 Successful completion.

>0 An error occurred.

## CONSEQUENCES OF ERRORS

If any errors are encountered, the run is aborted and *yacc* exits with a non-zero status. Partial code files and header files may be produced. The summary information in the description file shall always be produced if the *-v* flag is present.

## APPLICATION USAGE

Historical implementations experience name conflicts on the names **yacc.tmp**, **yacc.acts**, **yacc.debug**, **y.tab.c**, **y.tab.h**, and **y.output** if more than one copy of *yacc* is running in a single directory at one time. The *-b* option was added to overcome this problem. The related problem of allowing multiple *yacc* parsers to be placed in the same file was addressed by adding a *-p* option to override the previously hard-coded **yy** variable prefix.

The description of the *-p* option specifies the minimal set of function and variable names that cause conflict when multiple parsers are linked together. **YYSTYPE** does not need to be changed. Instead, the programmer can use *-b* to give the header files for different parsers different names, and then the file with the *yylex()* for a given parser can include the header for that parser. Names such as *yyclearerr* do not need to be changed because they are used only in the actions; they do not have linkage. It is possible that an implementation has other names, either internal ones for implementing things such as *yyclearerr*, or providing non-standard features that it wants

to change with `-p`.

Unary operators that are the same token as a binary operator in general need their precedence adjusted. This is handled by the `%prec` advisory symbol associated with the particular grammar rule defining that unary operator. (See [Grammar Rules in yacc](#) (on page 3420).) Applications are not required to use this operator for unary operators, but the grammars that do not require it are rare.

## EXAMPLES

Access to the *yacc* library is obtained with library search operands to *c99*. To use the *yacc* library *main()*:

```
c99 y.tab.c -l y
```

Both the *lex* library and the *yacc* library contain *main()*. To access the *yacc main()*:

```
c99 y.tab.c lex.yy.c -l y -l l
```

This ensures that the *yacc* library is searched first, so that its *main()* is used.

The historical *yacc* libraries have contained two simple functions that are normally coded by the application programmer. These functions are similar to the following code:

```
#include <locale.h>
int main(void)
{
 extern int yyparse();
 setlocale(LC_ALL, "");

 /* If the following parser is one created by lex, the
 application must be careful to ensure that LC_CTYPE
 and LC_COLLATE are set to the POSIX locale. */
 (void) yyparse();
 return (0);
}

#include <stdio.h>

int yyerror(const char *msg)
{
 (void) fprintf(stderr, "%s\n", msg);
 return (0);
}
```

## RATIONALE

The references in **Referenced Documents** may be helpful in constructing the parser generator. The referenced DeRemer and Pennello article (along with the works it references) describes a technique to generate parsers that conform to this volume of POSIX.1-2008. Work in this area continues to be done, so implementors should consult current literature before doing any new implementations. The original Knuth article is the theoretical basis for this kind of parser, but the tables it generates are impractically large for reasonable grammars and should not be used. The “equivalent to” wording is intentional to assure that the best tables that are LALR(1) can be generated.

There has been confusion between the class of grammars, the algorithms needed to generate parsers, and the algorithms needed to parse the languages. They are all reasonably orthogonal. In particular, a parser generator that accepts the full range of LR(1) grammars need not generate a table any more complex than one that accepts SLR(1) (a relatively weak class of LR grammars)

for a grammar that happens to be SLR(1). Such an implementation need not recognize the case, either; table compression can yield the SLR(1) table (or one even smaller than that) without recognizing that the grammar is SLR(1). The speed of an LR(1) parser for any class is dependent more upon the table representation and compression (or the code generation if a direct parser is generated) than upon the class of grammar that the table generator handles.

The speed of the parser generator is somewhat dependent upon the class of grammar it handles. However, the original Knuth article algorithms for constructing LR parsers were judged by its author to be impractically slow at that time. Although full LR is more complex than LALR(1), as computer speeds and algorithms improve, the difference (in terms of acceptable wall-clock execution time) is becoming less significant.

Potential authors are cautioned that the referenced DeRemer and Pennello article previously cited identifies a bug (an over-simplification of the computation of LALR(1) lookahead sets) in some of the LALR(1) algorithm statements that preceded it to publication. They should take the time to seek out that paper, as well as current relevant work, particularly Aho's.

The **-b** option was added to provide a portable method for permitting *yacc* to work on multiple separate parsers in the same directory. If a directory contains more than one *yacc* grammar, and both grammars are constructed at the same time (by, for example, a parallel *make* program), conflict results. While the solution is not historical practice, it corrects a known deficiency in historical implementations. Corresponding changes were made to all sections that referenced the filenames **y.tab.c** (now "the code file"), **y.tab.h** (now "the header file"), and **y.output** (now "the description file").

The grammar for *yacc* input is based on System V documentation. The textual description shows there that the **' ; '** is required at the end of the rule. The grammar and the implementation do not require this. (The use of **C\_IDENTIFIER** causes a reduce to occur in the right place.)

Also, in that implementation, the constructs such as **%token** can be terminated by a **<semicolon>**, but this is not permitted by the grammar. The keywords such as **%token** can also appear in uppercase, which is again not discussed. In most places where **' % '** is used, **<backslash>** can be substituted, and there are alternate spellings for some of the symbols (for example, **%LEFT** can be **"%<"** or even **"\<"**).

Historically, **<tag>** can contain any characters except **' > '**, including white space, in the implementation. However, since the *tag* must reference an ISO C standard union member, in practice conforming implementations need to support only the set of characters for ISO C standard identifiers in this context.

Some historical implementations are known to accept actions that are terminated by a period. Historical implementations often allow **' \$ '** in names. A conforming implementation does not need to support either of these behaviors.

Deciding when to use **%prec** illustrates the difficulty in specifying the behavior of *yacc*. There may be situations in which the *grammar* is not, strictly speaking, in error, and yet *yacc* cannot interpret it unambiguously. The resolution of ambiguities in the grammar can in many instances be resolved by providing additional information, such as using **%type** or **%union** declarations. It is often easier and it usually yields a smaller parser to take this alternative when it is appropriate.

The size and execution time of a program produced without the runtime debugging code is usually smaller and slightly faster in historical implementations.

Statistics messages from several historical implementations include the following types of information:

115627 *n*/512 terminals, *n*/300 non-terminals  
 115628 *n*/600 grammar rules, *n*/1500 states  
 115629 *n* shift/reduce, *n* reduce/reduce conflicts reported  
 115630 *n*/350 working sets used  
 115631 Memory: states, etc. *n*/15 000, parser *n*/15 000  
 115632 *n*/600 distinct lookahead sets  
 115633 *n* extra closures  
 115634 *n* shift entries, *n* exceptions  
 115635 *n* goto entries  
 115636 *n* entries saved by goto default  
 115637 Optimizer space used: input *n*/15 000, output *n*/15 000  
 115638 *n* table entries, *n* zero  
 115639 Maximum spread: *n*, Maximum offset: *n*

115640 The report of internal tables in the description file is left implementation-defined because all  
 115641 aspects of these limits are also implementation-defined. Some implementations may use  
 115642 dynamic allocation techniques and have no specific limit values to report.

115643 The format of the **y.output** file is not given because specification of the format was not seen to  
 115644 enhance applications portability. The listing is primarily intended to help human users  
 115645 understand and debug the parser; use of **y.output** by a conforming application script would be  
 115646 unusual. Furthermore, implementations have not produced consistent output and no popular  
 115647 format was apparent. The format selected by the implementation should be human-readable, in  
 115648 addition to the requirement that it be a text file.

115649 Standard error reports are not specifically described because they are seldom of use to  
 115650 conforming applications and there was no reason to restrict implementations.

115651 Some implementations recognize "`={"`" as equivalent to '`{`' because it appears in historical  
 115652 documentation. This construction was recognized and documented as obsolete as long ago as  
 115653 1978, in the referenced *Yacc: Yet Another Compiler-Compiler*. This volume of POSIX.1-2008 chose to  
 115654 leave it as obsolete and omit it.

115655 Multi-byte characters should be recognized by the lexical analyzer and returned as tokens. They  
 115656 should not be returned as multi-byte character literals. The token **error** that is used for error  
 115657 recovery is normally assigned the value 256 in the historical implementation. Thus, the token  
 115658 value 256, which is used in many multi-byte character sets, is not available for use as the value  
 115659 of a user-defined token.

#### 115660 FUTURE DIRECTIONS

115661 None.

#### 115662 SEE ALSO

115663 *c99*, *lex*

115664 XBD [Chapter 8](#) (on page 173), [Section 12.2](#) (on page 215)

#### 115665 CHANGE HISTORY

115666 First released in Issue 2.

#### 115667 Issue 5

115668 The FUTURE DIRECTIONS section is added.

#### 115669 Issue 6

115670 This utility is marked as part of the C-Language Development Utilities option.

115671 Minor changes have been added to align with the IEEE P1003.2b draft standard.

- 115672 The normative text is reworded to avoid use of the term “must” for application requirements.
- 115673 IEEE PASC Interpretation 1003.2 #177 is applied, changing the comment on **RCURL** from the }%  
115674 token to the %}.
- 115675 **Issue 7**
- 115676 Austin Group Interpretation 1003.1-2001 #190 is applied, clarifying the requirements for  
115677 generated code to conform to the ISO C standard.
- 115678 Austin Group Interpretation 1003.1-2001 #191 is applied, clarifying the handling of C-language  
115679 trigraphs and curly brace preprocessing tokens.
- 115680 SD5-XCU-ERN-6 is applied, clarifying that Guideline 9 of the Utility Syntax Guidelines does not  
115681 apply.
- 115682 SD5-XCU-ERN-97 is applied, updating the SYNOPSIS.

115683 **NAME**

115684           zcat — expand and concatenate data

115685 **SYNOPSIS**115686 XSI        zcat [*file...*]115687 **DESCRIPTION**

115688       The *zcat* utility shall write to standard output the uncompressed form of files that have been  
 115689       compressed using the *compress* utility. It is the equivalent of *uncompress -c*. Input files are not  
 115690       affected.

115691 **OPTIONS**

115692       None.

115693 **OPERANDS**

115694       The following operand shall be supported:

115695       *file*        The pathname of a file previously processed by the *compress* utility. If *file* already  
 115696       has the *.Z* suffix specified, it is used as submitted. Otherwise, the *.Z* suffix is  
 115697       appended to the filename prior to processing.

115698 **STDIN**115699       The standard input shall be used only if no *file* operands are specified, or if a *file* operand is *'-'*.115700 **INPUT FILES**115701       Input files shall be compressed files that are in the format produced by the *compress* utility.115702 **ENVIRONMENT VARIABLES**115703       The following environment variables shall affect the execution of *zcat*:

115704       *LANG*        Provide a default value for the internationalization variables that are unset or null.  
 115705       (See XBD [Section 8.2](#) (on page 174) for the precedence of internationalization  
 115706       variables used to determine the values of locale categories.)

115707       *LC\_ALL*      If set to a non-empty string value, override the values of all the other  
 115708       internationalization variables.

115709       *LC\_CTYPE*    Determine the locale for the interpretation of sequences of bytes of text data as  
 115710       characters (for example, single-byte as opposed to multi-byte characters in  
 115711       arguments).

115712       *LC\_MESSAGES* Determine the locale that should be used to affect the format and contents of  
 115713       diagnostic messages written to standard error.  
 115714

115715       *NLSPATH*    Determine the location of message catalogs for the processing of *LC\_MESSAGES*.

115716 **ASYNCHRONOUS EVENTS**

115717       Default.

115718 **STDOUT**

115719       The compressed files given as input shall be written on standard output in their uncompressed  
 115720       form.

115721 **STDERR**

115722       The standard error shall be used only for diagnostic messages.

115723 **OUTPUT FILES**

115724       None.

115725 **EXTENDED DESCRIPTION**

115726       None.

115727 **EXIT STATUS**

115728       The following exit values shall be returned:

115729       0   Successful completion.

115730       &gt;0   An error occurred.

115731 **CONSEQUENCES OF ERRORS**

115732       Default.

115733 **APPLICATION USAGE**

115734       None.

115735 **EXAMPLES**

115736       None.

115737 **RATIONALE**

115738       None.

115739 **FUTURE DIRECTIONS**

115740       None.

# Rationale for Base Definitions

## 115758 A.1 Introduction

### 115759 A.1.1 Scope

115760 POSIX.1-2008 is one of a family of standards known as POSIX. The family of standards extends  
 115761 to many topics; POSIX.1 consists of both operating system interfaces and shell and utilities.  
 115762 POSIX.1-2008 is technically identical to The Open Group Base Specifications, Issue 7.

#### 115763 Scope of POSIX.1-2008

115764 The (paraphrased) goals of this development were to revise the single document that is ISO/IEC  
 115765 9945:2003 Parts 1 through 4, IEEE Std 1003.1, 2004 Edition, and the appropriate parts of The  
 115766 Open Group Single UNIX Specification, Version 3. This work has been undertaken by the  
 115767 Austin Group, a joint working group of IEEE, The Open Group, and ISO/IEC JTC 1/SC 22.

115768 The following are the base documents in this version:

- 115769 • IEEE Std 1003.1, 2004 Edition
- 115770 • ISO/IEC 9899:1999, Programming Languages — C, including ISO/IEC  
 115771 9899:1999/Cor.1:2001(E), ISO/IEC 9899:1999/Cor.2:2004(E), and ISO/IEC  
 115772 9899:1999/Cor.3
- 115773 • The Open Group Extended API Sets, Parts 1 through 4

115774 This version has addressed the following areas:

- 115775 • Issues raised by Austin Group defect reports, IEEE Interpretations against IEEE Std 1003.1,  
 115776 and ISO/IEC defect reports against ISO/IEC 9945

115777 The repository of interpretations can be accessed at [www.opengroup.org/austin/interps](http://www.opengroup.org/austin/interps).

- 115778 • Issues raised in corrigenda for The Open Group Technical Standards and working group  
 115779 resolutions from The Open Group
- 115780 • Issues arising from ISO TR 24715:2006, Conflicts between POSIX and the LSB

115781 This is a Type 3 informative technical report highlighting differences between the LSB 3.1  
 115782 and the 2004 Edition of this standard.

- 115783 • Changes to make the text self-consistent with the additional material merged

115784 The new material merged has come from the The Open Group Extended API Sets, Parts 1  
 115785 through 4. A list of the new interfaces is included in [Section B.1.1](#) (on page 3521).

- 115786 • Features, marked legacy or obsolescent in the base documents, have been considered for  
 115787 removal in this version

115788 See [Section B.1.1](#) (on page 3521) and [Section C.1.1](#) (on page 3665).

- A review and reorganization of the options within the standard

This has included marking the following options obsolescent:

- Batch Environment Services and Utilities
- Tracing
- XSI STREAMS

The UUCP Utilities option is a new option for this version.

Functionality from the following former options is now mandatory in this version:

|     |                                                        |
|-----|--------------------------------------------------------|
| AIO | _POSIX_ASYNCHRONOUS_IO (Asynchronous Input and Output) |
| BAR | _POSIX_BARRIERS (Barriers)                             |
| CS  | _POSIX_CLOCK_SELECTION (Clock Selection)               |
| MF  | _POSIX_MAPPED_FILES (Memory Mapped Files)              |
| MPR | _POSIX_MEMORY_PROTECTION (Memory Protection)           |
| RTS | _POSIX_REALTIME_SIGNALS (Realtime Signals Extension)   |
| RWL | _POSIX_READER_WRITER_LOCKS (Read-Write Locks)          |
| SEM | _POSIX_SEMAPHORES (Semaphores)                         |
| SPI | _POSIX_SPIN_LOCKS (Spin Locks)                         |
| THR | _POSIX_THREADS (Threads)                               |
| TMO | _POSIX_TIMEOUTS (Timeouts)                             |
| TMR | _POSIX_TIMERS (Timers)                                 |
| TSF | _POSIX_THREAD_SAFE_FUNCTIONS (Thread-Safe Functions)   |

- Alignment with the ISO/IEC 9899:1999 standard, including ISO/IEC 9899:1999/Cor.2:2004(E)

- A review of the use of fixed path filenames within the standard

For example, the *at*, *batch*, and *crontab* utilities previously had a requirement for use of the directory **/usr/lib/cron**.

The following were requirements on POSIX.1-2008:

- Backward-compatibility

For interfaces carried forward, it was agreed that there should be no breakage of functionality in the existing base documents. All strictly conforming applications will be conforming but not necessarily strictly conforming to the revised standard. The goal is for system implementations to be able to support the existing and revised standards simultaneously.

- Architecture and *n*-bit-neutral

The common standard should not make any implicit assumptions about the system architecture or size of data types; for example, previously some 32-bit implicit assumptions had crept into the standards.

- Extensibility

It should be possible to extend the common standard without breaking backwards-compatibility; for example, the name space should be reserved and structured to avoid duplication of names between the standard and extensions to it.

**POSIX.1 and the ISO C Standard**

The standard developers believed it essential for a programmer to have a single complete reference place, but recognized that deference to the formal standard has to be addressed for the duplicate interface definitions between the ISO C standard and POSIX.1-2008.

Where an interface has a version in the ISO C standard, the DESCRIPTION section describes the relationship to the ISO C standard and markings are included as appropriate to show where the ISO C standard has been extended in the text.

A block of text is included at the start of each affected reference page stating whether the page is aligned with the ISO C standard or extended. Each page has been parsed for additions beyond the ISO C standard (that is, including both POSIX and UNIX extensions), and these extensions are marked as CX extensions (for C extensions).

**FIPS Requirements**

The Federal Information Processing Standards (FIPS) are a series of US government procurement standards managed and maintained on behalf of the US Department of Commerce by the National Institute of Standards and Technology (NIST).

The following restrictions were integrated into IEEE Std 1003.1-2001. They originally came from FIPS 151-2 which was withdrawn by NIST on February 25 2000.

- The implementation supports `_POSIX_CHOWN_RESTRICTED`.
- The limit `{NGROUPS_MAX}` is greater than or equal to 8.
- The implementation supports the setting of the group ID of a file (when it is created) to that of the parent directory.
- The implementation supports `_POSIX_SAVED_IDS`.
- The implementation supports `_POSIX_VDISABLE`.
- The implementation supports `_POSIX_JOB_CONTROL`.
- The implementation supports `_POSIX_NO_TRUNC`.
- The `read()` function returns the number of bytes read when interrupted by a signal and does not return `-1`.
- The `write()` function returns the number of bytes written when interrupted by a signal and does not return `-1`.
- In the environment for the login shell, the environment variables `LOGNAME` and `HOME` are defined and have the properties described in POSIX.1-2008.
- The value of `{CHILD_MAX}` is greater than or equal to 25.
- The value of `{OPEN_MAX}` is greater than or equal to 20.
- The implementation supports the functionality associated with the symbols `CS7`, `CS8`, `CSTOPB`, `PARODD`, and `PARENB` defined in **<termios.h>**.

115864 **A.1.2 Conformance**115865 See [Section A.2](#) (on page 3445).115866 **A.1.3 Normative References**

115867 There is no additional rationale provided for this section.

115868 **A.1.4 Change History**

115869 For Issue 7 onwards, in references to Technical Corrigenda, the original Austin Group defect  
 115870 report numbers that gave rise to the change are included in square brackets after the change  
 115871 number from the Technical Corrigendum. For more information on Austin Group defect reports  
 115872 see [www.opengroup.org/austin/defectform.html](http://www.opengroup.org/austin/defectform.html).

115873 **A.1.5 Terminology**

115874 The meanings specified in POSIX.1-2008 for the words *shall*, *should*, and *may* are mandated by  
 115875 ISO/IEC directives.

115876 In the Rationale (Informative) volume of POSIX.1-2008, the words *shall*, *should*, and *may* are  
 115877 sometimes used to illustrate similar usages in POSIX.1-2008. However, the rationale itself does  
 115878 not specify anything regarding implementations or applications.

115879 **conformance document**

115880 As a practical matter, the conformance document is effectively part of the system  
 115881 documentation. Conformance documents are distinguished by POSIX.1-2008 so that they  
 115882 can be referred to distinctly.

115883 **implementation-defined**

115884 This definition is analogous to that of the ISO C standard and, together with “undefined”  
 115885 and “unspecified”, provides a range of specification of freedom allowed to the interface  
 115886 implementor.

115887 **may**

115888 The use of *may* has been limited as much as possible, due both to confusion stemming from  
 115889 its ordinary English meaning and to objections regarding the desirability of having as few  
 115890 options as possible and those as clearly specified as possible.

115891 The usage of *can* and *may* were selected to contrast optional application behavior (can)  
 115892 against optional implementation behavior (may).

115893 **shall**

115894 Declarative sentences are sometimes used in POSIX.1-2008 as if they included the word  
 115895 *shall*, and facilities thus specified are no less required. For example, the two statements:

- 115896 1. The *foo()* function shall return zero.
- 115897 2. The *foo()* function returns zero.

115898 are meant to be exactly equivalent.

115899 **should**

115900 In POSIX.1-2008, the word *should* does not usually apply to the implementation, but rather  
 115901 to the application. Thus, the important words regarding implementations are *shall*, which  
 115902 indicates requirements, and *may*, which indicates options.

**obsolescent**

The term “obsolescent” means “do not use this feature in new applications”. A feature noted as obsolescent is supported by all implementations, but may be removed in a future version; new applications should not use these features. The obsolescence concept is not an ideal solution, but was used as a method of increasing consensus: many more objections would be heard from the user community if some of these historical features were suddenly removed without the grace period obsolescence implies. The phrase “may be removed in a future version” implies that the result of that consideration might in fact keep those features indefinitely if the predominance of applications do not migrate away from them quickly.

**legacy**

The term “legacy” was included in earlier versions of this standard but is no longer used in the current version.

**system documentation**

The system documentation should normally describe the whole of the implementation, including any extensions provided by the implementation. Such documents normally contain information at least as detailed as the specifications in POSIX.1-2008. Few requirements are made on the system documentation, but the term is needed to avoid a dangling pointer where the conformance document is permitted to point to the system documentation.

**undefined**

See *implementation-defined*.

**unspecified**

See *implementation-defined*.

The definitions for “unspecified” and “undefined” appear nearly identical at first examination, but are not. The term “unspecified” means that a conforming application may deal with the unspecified behavior, and it should not care what the outcome is. The term “undefined” says that a conforming application should not do it because no definition is provided for what it does (and implicitly it would care what the outcome was if it tried it). It is important to remember, however, that if the syntax permits the statement at all, it must have some outcome in a real implementation.

Thus, the terms “undefined” and “unspecified” apply to the way the application should think about the feature. In terms of the implementation, it is always “defined”—there is always some result, even if it is an error. The implementation is free to choose the behavior it prefers.

This also implies that an implementation, or another standard, could specify or define the result in a useful fashion. The terms apply to POSIX.1-2008 specifically.

The term “implementation-defined” implies requirements for documentation that are not required for “undefined” (or “unspecified”). Where there is no need for a conforming program to know the definition, the term “undefined” is used, even though “implementation-defined” could also have been used in this context. There could be a fourth term, specifying “this standard does not say what this does; it is acceptable to define it in an implementation, but it does not need to be documented”, and undefined would then be used very rarely for the few things for which any definition is not useful. In particular, implementation-defined is used where it is believed that certain classes of application will need to know such details to determine whether the application can be successfully ported to the implementation. Such applications are not always strictly portable, but nevertheless are common and useful; often the requirements met by the application cannot be met without dealing with the issues implied by “implementation-defined”. In some places the text refers to facilities supplied by the implementation that are

115952 outside the standard as implementation-supplied or implementation-provided. This is not  
 115953 intended to imply a requirement for documentation. If it were, the term “implementation-  
 115954 defined” would have been used.

115955 In many places POSIX.1-2008 is silent about the behavior of some possible construct. For  
 115956 example, a variable may be defined for a specified range of values and behaviors are  
 115957 described for those values; nothing is said about what happens if the variable has any other  
 115958 value. That kind of silence can imply an error in the standard, but it may also imply that the  
 115959 standard was intentionally silent and that any behavior is permitted. There is a natural  
 115960 tendency to infer that if the standard is silent, a behavior is prohibited. That is not the intent.  
 115961 Silence is intended to be equivalent to the term “unspecified”.

115962 The term “application” is not defined in POSIX.1-2008; it is assumed to be a part of general  
 115963 computer science terminology.

115964 Three terms used within POSIX.1-2008 overlap in meaning: “macro”, “symbolic name”, and  
 115965 “symbolic constant”.

#### 115966 **macro**

115967 This usually describes a C preprocessor symbol, the result of the **#define** operator, with or  
 115968 without an argument. It may also be used to describe similar mechanisms in editors and  
 115969 text processors.

#### 115970 **symbolic name**

115971 In earlier versions of this standard this was also sometimes used to refer to a C preprocessor  
 115972 symbol (without arguments), but the intention is for all such uses to have been removed. It  
 115973 is now mainly used to refer to the names for characters in character sets, but is sometimes  
 115974 used to refer to host names and even filenames.

#### 115975 **symbolic constant**

115976 This also refers to a C preprocessor symbol, with specific associated requirements. See the  
 115977 definition in [Section 3.374](#) (on page 93).

### 115978 **A.1.6 Definitions and Concepts**

115979 There is no additional rationale provided for this section.

### 115980 **A.1.7 Portability**

115981 To aid the identification of options within POSIX.1-2008, a notation consisting of margin codes  
 115982 and shading is used. This is based on the notation used in earlier versions of The Open Group  
 115983 Base specifications.

115984 The benefit of this approach is a reduction in the number of *if* statements within the running  
 115985 text, that makes the text easier to read, and also an identification to the programmer that they  
 115986 need to ensure that their target platforms support the underlying options. For example, if  
 115987 functionality is marked with RPP in the margin, it will be available on all systems supporting  
 115988 the Robust Mutex Priority Protection option, but may not be available on some others.

## 115989 A.1.7.1 Codes

115990 This section includes codes for options defined in XBD [Section 2.1.6](#) (on page 26), and the  
 115991 following additional codes for other purposes:

115992 CX This margin code is used to denote extensions beyond the ISO C standard. For  
 115993 interfaces that are duplicated between POSIX.1-2008 and the ISO C standard, a CX  
 115994 introduction block describes the nature of the duplication, with any extensions  
 115995 appropriately CX marked and shaded.

115996 Where an interface is added to an ISO C standard header, within the header the  
 115997 interface has an appropriate margin marker and shading (for example, CX, XSI, TSE,  
 115998 and so on) and the same marking appears on the reference page in the SYNOPSIS  
 115999 section. This enables a programmer to easily identify that the interface is extending an  
 116000 ISO C standard header.

## 116001 MX and MXX

116002 These two margin codes both relate to the IEC 60559 Floating-Point option. The MX  
 116003 code denotes functionality that is mandated by the ISO C standard for IEC 60559  
 116004 implementations; the MXX code denotes IEC 60559 functionality that is an extension to  
 116005 the ISO C standard.

116006 OB This margin code is used to denote obsolescent behavior and thus flag a possible future  
 116007 applications portability warning.

116008 OH The Single UNIX Specification has historically tried to reduce the number of headers an  
 116009 application has had to include when using a particular interface. Sometimes this was  
 116010 fewer than the base standard, and hence a notation is used to flag which headers are  
 116011 optional if you are using a system supporting the XSI option.

## 116012 A.1.7.2 Margin Code Notation

116013 Since some features may depend on one or more options, or require more than one option, a  
 116014 notation is used. Where a feature requires support of a single option, a single margin code will  
 116015 occur in the margin. If it depends on two options and both are required, then the codes will  
 116016 appear with a <space> separator. If either of two options are required, then a logical OR is  
 116017 denoted using the ' | ' symbol. If more than two codes are used, a special notation is used.

## 116018 A.2 Conformance

116019 The terms “profile” and “profiling” are used throughout this section.

116020 A profile of a standard or standards is a codified set of option selections, such that by being  
 116021 conformant to a profile, particular classes of users are specifically supported.

## 116022 A.2.1 Implementation Conformance

116023 These definitions allow application developers to know what to depend on in an  
 116024 implementation.

116025 There is no definition of a “strictly conforming implementation”; that would be an  
 116026 implementation that provides *only* those facilities specified by POSIX.1 with no extensions  
 116027 whatsoever. This is because no actual operating system implementation can exist without  
 116028 system administration and initialization facilities that are beyond the scope of POSIX.1.

## 116029 A.2.1.1 Requirements

116030 The word “support” is used in certain instances, rather than “provide”, in order to allow an  
116031 implementation that has no resident software development facilities, but that supports the  
116032 execution of a *Strictly Conforming POSIX.1 Application*, to be a *conforming implementation*.

## 116033 A.2.1.2 Documentation

116034 The conformance documentation is required to use the same numbering scheme as POSIX.1 for  
116035 purposes of cross-referencing. All options that an implementation chooses are reflected in  
116036 **<limits.h>** and **<unistd.h>**.

116037 Note that the use of “may” in terms of where conformance documents record where  
116038 implementations may vary, implies that it is not required to describe those features identified as  
116039 undefined or unspecified.

116040 Other aspects of systems must be evaluated by purchasers for suitability. Many systems  
116041 incorporate buffering facilities, maintaining updated data in volatile storage and transferring  
116042 such updates to non-volatile storage asynchronously. Various exception conditions, such as a  
116043 power failure or a system crash, can cause this data to be lost. The data may be associated with a  
116044 file that is still open, with one that has been closed, with a directory, or with any other internal  
116045 system data structures associated with permanent storage. This data can be lost, in whole or  
116046 part, so that only careful inspection of file contents could determine that an update did not  
116047 occur.

116048 Also, interrelated file activities, where multiple files and/or directories are updated, or where  
116049 space is allocated or released in the file system structures, can leave inconsistencies in the  
116050 relationship between data in the various files and directories, or in the file system itself. Such  
116051 inconsistencies can break applications that expect updates to occur in a specific sequence, so that  
116052 updates in one place correspond with related updates in another place.

116053 For example, if a user creates a file, places information in the file, and then records this action in  
116054 another file, a system or power failure at this point followed by restart may result in a state in  
116055 which the record of the action is permanently recorded, but the file created (or some of its  
116056 information) has been lost. The consequences of this to the user may be undesirable. For a user  
116057 on such a system, the only safe action may be to require the system administrator to have a  
116058 policy that requires, after any system or power failure, that the entire file system must be  
116059 restored from the most recent backup copy (causing all intervening work to be lost).

116060 The characteristics of each implementation will vary in this respect and may or may not meet  
116061 the requirements of a given application or user. Enforcement of such requirements is beyond the  
116062 scope of POSIX.1. It is up to the purchaser to determine what facilities are provided in an  
116063 implementation that affect the exposure to possible data or sequence loss, and also what  
116064 underlying implementation techniques and/or facilities are provided that reduce or limit such  
116065 loss or its consequences.

## 116066 A.2.1.3 POSIX Conformance

116067 This really means conformance to the base standard; however, since this document includes the  
116068 core material of the Single UNIX Specification, the standard developers decided that it was  
116069 appropriate to segment the conformance requirements into two, the former for the base  
116070 standard, and the latter for the Single UNIX Specification (denoted XSI Conformance).

116071 Within POSIX.1 there are some symbolic constants that, if defined to a certain value or range of  
116072 values, indicate that a certain option is enabled. Other symbolic constants exist in POSIX.1 for  
116073 other reasons.

116074 In this version, some features that were previously optional have been made mandatory. For  
 116075 backwards compatibility, the symbolic constants associated with the option are still required  
 116076 now with fixed allowable ranges or values. The following options from the previous version of  
 116077 this standard are now mandatory:

116078        \_POSIX\_ASYNCHRONOUS\_IO  
 116079        \_POSIX\_BARRIERS  
 116080        \_POSIX\_CLOCK\_SELECTION  
 116081        \_POSIX\_MAPPED\_FILES  
 116082        \_POSIX\_MEMORY\_PROTECTION  
 116083        \_POSIX\_READER\_WRITER\_LOCKS  
 116084        \_POSIX\_REALTIME\_SIGNALS  
 116085        \_POSIX\_SEMAPHORES  
 116086        \_POSIX\_SPIN\_LOCKS  
 116087        \_POSIX\_THREAD\_SAFE\_FUNCTIONS  
 116088        \_POSIX\_THREADS  
 116089        \_POSIX\_TIMEOUTS  
 116090        \_POSIX\_TIMERS

116091 A POSIX-conformant system may support the XSI option required by the Single UNIX  
 116092 Specification. This was intentional since the standard developers intend them to be upwards-  
 116093 compatible, so that a system conforming to the Single UNIX Specification can also conform to  
 116094 the base standard at the same time.

#### 116095 A.2.1.4 XSI Conformance

116096 This section is included to describe the conformance requirements for the base volumes of the  
 116097 Single UNIX Specification.

116098 XSI conformance can be thought of as a profile, selecting certain options from POSIX.1-2008.

#### 116099 A.2.1.5 Option Groups

116100 The concept of “Option Groups” is included to allow collections of related functions or options  
 116101 to be grouped together. This has been used as follows: the “XSI Option Groups” have been  
 116102 created to allow super-options, collections of underlying options and related functions, to be  
 116103 collectively supported by XSI-conforming systems.

116104 The standard developers considered the matter of subprofiling and decided it was better to  
 116105 include an enabling mechanism rather than detailed normative requirements. A set of  
 116106 subprofiling options was developed and included later in this volume of POSIX.1-2008 as an  
 116107 informative illustration.

#### 116108 Subprofiling Considerations

116109 The goal of not simultaneously fixing maximums and minimums was to allow implementations  
 116110 of the base standard or standards to support multiple profiles without conflict.

The following summarizes the rules for the limit types:

| Limit Type       | Fixed Value                          | Minimum Acceptable Value                            | Maximum Acceptable Value                            |
|------------------|--------------------------------------|-----------------------------------------------------|-----------------------------------------------------|
| Standard Profile | $X_s$<br>$X_p == X_s$<br>(No change) | $Y_s$<br>$Y_p \geq Y_s$<br>(May increase the limit) | $Z_s$<br>$Z_p \leq Z_s$<br>(May decrease the limit) |

The intent is that ranges specified by limits in profiles be entirely contained within the corresponding ranges of the base standard or standards being profiled, and that the unlimited end of a range in a base standard must remain unlimited in any profile of that standard.

Thus, the fixed `_POSIX_*` limits are constants and must not be changed by a profile. The variable counterparts (typically without the leading `_POSIX_`) can be changed but still remain semantically the same; that is, they still allow implementation values to vary as long as they meet the requirements for that value (be it a minimum or maximum).

Where a profile does not provide a feature upon which a limit is based, the limit is not relevant. Applications written to that profile should be written to operate independently of the value of the limit.

An example which has previously allowed implementations to support both the base standard and two other profiles in a compatible manner follows:

```
Base standard (POSIX.1-1996): _POSIX_CHILD_MAX 6
Base standard: CHILD_MAX minimum maximum _POSIX_CHILD_MAX
FIPS profile/SUSv2 CHILD_MAX 25 (minimum maximum)
```

Another example:

```
Base standard (POSIX.1-1996): _POSIX_NGROUPS_MAX 0
Base standard: NGROUPS_MAX minimum maximum _POSIX_NGROUP_MAX
FIPS profile/SUSv2 NGROUPS_MAX 8
```

A profile may lower a minimum maximum below the equivalent `_POSIX` value:

```
Base standard: _POSIX_foo_MAX Z
Base standard: foo_MAX _POSIX_foo_MAX
profile standard : foo_MAX X (X can be less than, equal to,
 or greater than _POSIX_foo_MAX)
```

In this case an implementation conforming to the profile may not conform to the base standard, but an implementation to the base standard will conform to the profile.

#### A.2.1.6 Options

The final subsections within *Implementation Conformance* list the core options within POSIX.1-2008. This includes both options for the System Interfaces volume of POSIX.1-2008 and the Shell and Utilities volume of POSIX.1-2008.

## 116147 A.2.2 Application Conformance

116148 These definitions guide users or adapters of applications in determining on which  
116149 implementations an application will run and how much adaptation would be required to make  
116150 it run on others. These definitions are modeled after related ones in the ISO C standard.

116151 POSIX.1 occasionally uses the expressions “portable application” or “conforming application”.  
116152 As they are used, these are synonyms for any of these terms. The differences between the classes  
116153 of application conformance relate to the requirements for other standards, the options supported  
116154 (such as the XSI option) or, in the case of the Conforming POSIX.1 Application Using Extensions,  
116155 to implementation extensions. When one of the less explicit expressions is used, it should be  
116156 apparent from the context of the discussion which of the more explicit names is appropriate

### 116157 A.2.2.1 Strictly Conforming POSIX Application

116158 This definition is analogous to that of an ISO C standard “conforming program”.

116159 The major difference between a Strictly Conforming POSIX Application and an ISO C standard  
116160 strictly conforming program is that the latter is not allowed to use features of POSIX that are not  
116161 in the ISO C standard.

### 116162 A.2.2.2 Conforming POSIX Application

116163 Examples of <National Bodies> include ANSI, BSI, and AFNOR.

### 116164 A.2.2.3 Conforming POSIX Application Using Extensions

116165 Due to possible requirements for configuration or implementation characteristics in excess of the  
116166 specifications in <limits.h> or related to the hardware (such as array size or file space), not  
116167 every Conforming POSIX Application Using Extensions will run on every conforming  
116168 implementation.

### 116169 A.2.2.4 Strictly Conforming XSI Application

116170 This is intended to be upwards-compatible with the definition of a Strictly Conforming POSIX  
116171 Application, with the addition of the facilities and functionality included in the XSI option.

### 116172 A.2.2.5 Conforming XSI Application Using Extensions

116173 Such applications may use extensions beyond the facilities defined by POSIX.1-2008 including  
116174 the XSI option, but need to document the additional requirements.

## 116175 A.2.3 Language-Dependent Services for the C Programming Language

116176 POSIX.1 is, for historical reasons, both a specification of an operating system interface, shell and  
116177 utilities, and a C binding for that specification. Efforts had been previously undertaken to  
116178 generate a language-independent specification; however, that had failed, and the fact that the  
116179 ISO C standard is the *de facto* primary language on POSIX and the UNIX system makes this a  
116180 necessary and workable situation.

#### 116181 **A.2.4 Other Language-Related Specifications**

116182 There is no additional rationale provided for this section.

### 116183 **A.3 Definitions**

116184 The definitions in this section are stated so that they can be used as exact substitutes for the  
116185 terms in text. They should not contain requirements or cross-references to sections within  
116186 POSIX.1-2008; that is accomplished by using an informative note. In addition, the term should  
116187 not be included in its own definition. Where requirements or descriptions need to be addressed  
116188 but cannot be included in the definitions, due to not meeting the above criteria, these occur in  
116189 the General Concepts chapter.

116190 In this version, the definitions have been reworked extensively to meet style requirements and to  
116191 include terms from the base documents (see the Scope).

116192 Many of these definitions are necessarily circular, and some of the terms (such as “process”) are  
116193 variants of basic computing science terms that are inherently hard to define. Where some  
116194 definitions are more conceptual and contain requirements, these appear in the General Concepts  
116195 chapter. Those listed in this section appear in an alphabetical glossary format of terms.

116196 Some definitions must allow extension to cover terms or facilities that are not explicitly  
116197 mentioned in POSIX.1-2008. For example, the definition of “Extended Security Controls”  
116198 permits implementations beyond those defined in POSIX.1-2008.

116199 Some terms in the following list of notes do not appear in POSIX.1-2008; these are marked  
116200 suffixed with an asterisk (\*). Many of them have been specifically excluded from POSIX.1-2008  
116201 because they concern system administration, implementation, or other issues that are not  
116202 specific to the programming interface. Those are marked with a reason, such as  
116203 “implementation-defined”.

#### 116204 **Appropriate Privileges**

116205 One of the fundamental security problems with many historical UNIX systems has been that the  
116206 privilege mechanism is monolithic—a user has either no privileges or *all* privileges. Thus, a  
116207 successful “trojan horse” attack on a privileged process defeats all security provisions.  
116208 Therefore, POSIX.1 allows more granular privilege mechanisms to be defined. For many  
116209 historical implementations of the UNIX system, the presence of the term “appropriate  
116210 privileges” in POSIX.1 may be understood as a synonym for “superuser” (UID 0). However,  
116211 other systems have emerged where this is not the case and each discrete controllable action has  
116212 *appropriate privileges* associated with it. Because this mechanism is implementation-defined, it  
116213 must be described in the conformance document. Although that description affects several parts  
116214 of POSIX.1 where the term “appropriate privilege” is used, because the term “implementation-  
116215 defined” only appears here, the description of the entire mechanism and its effects on these  
116216 other sections belongs in this equivalent section of the conformance document. This is especially  
116217 convenient for implementations with a single mechanism that applies in all areas, since it only  
116218 needs to be described once.

**Base Character\***

The term “Base Character” has been removed, as it was felt that the use of this term within POSIX.1-2008 was common usage English.

**Byte**

The restriction that a byte is now exactly eight bits was a conscious decision by the standard developers. It came about due to a combination of factors, primarily the use of the type `int8_t` within the networking functions and the alignment with the ISO/IEC 9899:1999 standard, where the `intN_t` types are now defined.

According to the ISO/IEC 9899:1999 standard:

- The `[u]intN_t` types must be two’s complement with no padding bits and no illegal values.
- All types (apart from bit fields, which are not relevant here) must occupy an integral number of bytes.
- If a type with width  $W$  occupies  $B$  bytes with  $C$  bits per byte ( $C$  is the value of `{CHAR_BIT}`), then it has  $P$  padding bits where  $P+W=B*C$ .
- Therefore, for `int8_t`  $P=0$ ,  $W=8$ . Since  $B \geq 1$ ,  $C \geq 8$ , the only solution is  $B=1$ ,  $C=8$ .

The standard developers also felt that this was not an undue restriction for the current state-of-the-art for this version of the standard, but recognize that if industry trends continue, a wider character type may be required in the future.

**Character**

The term “character” is used to mean a sequence of one or more bytes representing a single graphic symbol. The deviation in the exact text of the ISO C standard definition for “byte” meets the intent of the rationale of the ISO C standard also clears up the ambiguity raised by the term “basic execution character set”. The octet-minimum requirement is a reflection of the `{CHAR_BIT}` value.

**Child Process**

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/3 is applied, adding the `vfork()` function to those listed.

**Clock Tick**

The ISO C standard defines a similar interval for use by the `clock()` function. There is no requirement that these intervals be the same. In historical implementations these intervals are different.

**Command**

The terms “command” and “utility” are related but have distinct meanings. Command is defined as “a directive to a shell to perform a specific task”. The directive can be in the form of a single utility name (for example, `ls`), or the directive can take the form of a compound command (for example, `"ls | grep name | pr"`). A utility is a program that can be called by name from a shell. Issuing only the name of the utility to a shell is the equivalent of a one-word command. A utility may be invoked as a separate program that executes in a different process than the command language interpreter, or it may be implemented as a part of the command language interpreter. For example, the `echo` command (the directive to perform a specific task) may be implemented such that the `echo` utility (the logic that performs the task of echoing) is in a separate program; therefore, it is executed in a process that is different from the command

language interpreter. Conversely, the logic that performs the *echo* utility could be built into the command language interpreter; therefore, it could execute in the same process as the command language interpreter.

The terms “tool” and “application” can be thought of as being synonymous with “utility” from the perspective of the operating system kernel. Tools, applications, and utilities historically have run, typically, in processes above the kernel level. Tools and utilities historically have been a part of the operating system non-kernel code and have performed system-related functions, such as listing directory contents, checking file systems, repairing file systems, or extracting system status information. Applications have not generally been a part of the operating system, and they perform non-system-related functions, such as word processing, architectural design, mechanical design, workstation publishing, or financial analysis. Utilities have most frequently been provided by the operating system distributor, applications by third-party software distributors, or by the users themselves. Nevertheless, POSIX.1-2008 does not differentiate between tools, utilities, and applications when it comes to receiving services from the system, a shell, or the standard utilities. (For example, the *xargs* utility invokes another utility; it would be of fairly limited usefulness if the users could not run their own applications in place of the standard utilities.) Utilities are not applications in the sense that they are not themselves subject to the restrictions of POSIX.1-2008 or any other standard—there is no requirement for *grep*, *stty*, or any of the utilities defined here to be any of the classes of conforming applications.

### Column Positions

In most 1-byte character sets, such as ASCII, the concept of column positions is identical to character positions and to bytes. Therefore, it has been historically acceptable for some implementations to describe line folding or tab stops or table column alignment in terms of bytes or character positions. Other character sets pose complications, as they can have internal representations longer than one octet and they can have display characters that have different widths on the terminal screen or printer.

In POSIX.1-2008 the term “column positions” has been defined to mean character—not byte—positions in input files (such as “column position 7 of the FORTRAN input”). Output files describe the column position in terms of the display width of the narrowest printable character in the character set, adjusted to fit the characteristics of the output device. It is very possible that *n* column positions will not be able to hold *n* characters in some character sets, unless all of those characters are of the narrowest width. It is assumed that the implementation is aware of the width of the various characters, deriving this information from the value of *LC\_CTYPE*, and thus can determine how many column positions to allot for each character in those utilities where it is important.

The term “column position” was used instead of the more natural “column” because the latter is frequently used in the different contexts of columns of figures, columns of table values, and so on. Wherever confusion might result, these latter types of columns are referred to as “text columns”.

### Controlling Terminal

The question of which of possibly several special files referring to the terminal is meant is not addressed in POSIX.1. The pathname */dev/tty* is a synonym for the controlling terminal associated with a process.

**116304 Device Number\***

116305 The concept is handled in *stat()* as *ID of device*.

**116306 Direct I/O**

116307 Historically, direct I/O refers to the system bypassing intermediate buffering, but may be  
116308 extended to cover implementation-defined optimizations.

**116309 Directory**

116310 The format of the directory file is implementation-defined and differs radically between  
116311 System V and 4.3 BSD. However, routines (derived from 4.3 BSD) for accessing directories and  
116312 certain constraints on the format of the information returned by those routines are described in  
116313 the **<dirent.h>** header.

**116314 Directory Entry**

116315 Throughout POSIX.1-2008, the term “link” is used (about the *link()* function, for example) in  
116316 describing the objects that point to files from directories.

**116317 Display**

116318 The Shell and Utilities volume of POSIX.1-2008 assigns precise requirements for the terms  
116319 “display” and “write”. Some historical systems have chosen to implement certain utilities  
116320 without using the traditional file descriptor model. For example, the *vi* editor might employ  
116321 direct screen memory updates on a personal computer, rather than a *write()* system call. An  
116322 instance of user prompting might appear in a dialog box, rather than with standard error. When  
116323 the Shell and Utilities volume of POSIX.1-2008 uses the term “display”, the method of  
116324 outputting to the terminal is unspecified; many historical implementations use *termcap* or  
116325 *terminfo*, but this is not a requirement. The term “write” is used when the Shell and Utilities  
116326 volume of POSIX.1-2008 mandates that a file descriptor be used and that the output can be  
116327 redirected. However, it is assumed that when the writing is directly to the terminal (it has not  
116328 been redirected elsewhere), there is no practical way for a user or test suite to determine whether  
116329 a file descriptor is being used. Therefore, the use of a file descriptor is mandated only for the  
116330 redirection case and the implementation is free to use any method when the output is not  
116331 redirected. The verb *write* is used almost exclusively, with the very few exceptions of those  
116332 utilities where output redirection need not be supported: *tabs*, *talk*, *tput*, and *vi*.

**116333 Dot**

116334 The symbolic name *dot* is carefully used in POSIX.1 to distinguish the working directory  
116335 filename from a period or a decimal point.

**116336 Dot-Dot**

116337 Historical implementations permit the use of these filenames without their special meanings.  
116338 Such use precludes any meaningful use of these filenames by a Conforming POSIX.1  
116339 Application. Therefore, such use is considered an extension, the use of which makes an  
116340 implementation non-conforming; see also [Section A.4.12](#) (on page 3478).

**Epoch**

Historically, the origin of UNIX system time was referred to as “00:00:00 GMT, January 1, 1970”. Greenwich Mean Time is actually not a term acknowledged by the international standards community; therefore, this term, “Epoch”, is used to abbreviate the reference to the actual standard, Coordinated Universal Time.

**FIFO Special File**

See [Pipe](#) (on page 3462).

**File**

It is permissible for an implementation-defined file type to be non-readable or non-writable.

**File Classes**

These classes correspond to the historical sets of permission bits. The classes are general to allow implementations flexibility in expanding the access mechanism for more stringent security environments. Note that a process is in one and only one class, so there is no ambiguity.

**Filename**

Filenames are sequences of bytes, not sequences of characters. The only bytes that this standard says cannot appear in any filename are the slash byte and the null byte. This is a side-effect of the fact that no conforming implementations of the standard currently provide a way to pass information specifying the locale associated with strings passed between user-level applications and the kernel. This decision could be revisited if implementations develop a way to associate a locale with the strings passed between kernel space and user space.

Implementations may add other restrictions to the byte sequences allowed in filenames except that any filename consisting of no more than {NAME\_MAX} bytes from the set of characters in the portable filename character set must be allowed.

See [Pathname](#) (on page 3461).

**File System**

Historically, the meaning of this term has been overloaded with two meanings: that of the complete file hierarchy, and that of a mountable subset of that hierarchy; that is, a mounted file system. POSIX.1 uses the term “file system” in the second sense, except that it is limited to the scope of a process (and root directory of a process). This usage also clarifies the domain in which a file serial number is unique.

**Graphic Character**

This definition is made available for those definitions (in particular, *TZ*) which must exclude control characters.

**116374 Group Database**

116375 IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/4 is applied, removing the words “of  
116376 implementation-defined format”. See [User Database](#) (on page 3471).

**116377 Group File\***

116378 Implementation-defined; see [User Database](#) (on page 3471).

**116379 Historical Implementations\***

116380 This refers to previously existing implementations of programming interfaces and operating  
116381 systems that are related to the interface specified by POSIX.1.

**116382 Hosted Implementation\***

116383 This refers to a POSIX.1 implementation that is accomplished through interfaces from the  
116384 POSIX.1 services to some alternate form of operating system kernel services. Note that the line  
116385 between a hosted implementation and a native implementation is blurred, since most  
116386 implementations will provide some services directly from the kernel and others through some  
116387 indirect path. (For example, *fopen()* might use *open()*; or *mkfifo()* might use *mknod()*.) There is  
116388 no necessary relationship between the type of implementation and its correctness, performance,  
116389 and/or reliability.

**116390 Implementation\***

116391 This term is generally used instead of its synonym, “system”, to emphasize the consequences of  
116392 decisions to be made by system implementors. Perhaps if no options or extensions to POSIX.1  
116393 were allowed, this usage would not have occurred.

116394 The term “specific implementation” is sometimes used as a synonym for “implementation”.  
116395 This should not be interpreted too narrowly; both terms can represent a relatively broad group  
116396 of systems. For example, a hardware vendor could market a very wide selection of systems that  
116397 all used the same instruction set, with some systems desktop models and others large multi-user  
116398 minicomputers. This wide range would probably share a common POSIX.1 operating system,  
116399 allowing an application compiled for one to be used on any of the others; this is a [*specific*]  
116400 *implementation*. However, such a wide range of machines probably has some differences  
116401 between the models. Some may have different clock rates, different file systems, different  
116402 resource limits, different network connections, and so on, depending on their sizes or intended  
116403 usages. Even on two identical machines, the system administrators may configure them  
116404 differently. Each of these different systems is known by the term “a specific instance of a specific  
116405 implementation”. This term is only used in the portions of POSIX.1 dealing with runtime  
116406 queries: *sysconf()* and *pathconf()*.

**116407 Incomplete Pathname\***

116408 Absolute pathname has been adequately defined.

**Job Control**

In order to understand the job control facilities in POSIX.1 it is useful to understand how they are used by a job control-cognizant shell to create the user interface effect of job control.

While the job control facilities supplied by POSIX.1 can, in theory, support different types of interactive job control interfaces supplied by different types of shells, there was historically one particular interface that was most common when the standard was originally developed (provided by BSD C Shell).

This discussion describes that interface as a means of illustrating how the POSIX.1 job control facilities can be used.

Job control allows users to selectively stop (suspend) the execution of processes and continue (resume) their execution at a later point. The user typically employs this facility via the interactive interface jointly supplied by the terminal I/O driver and a command interpreter (shell).

The user can launch jobs (command pipelines) in either the foreground or background. When launched in the foreground, the shell waits for the job to complete before prompting for additional commands. When launched in the background, the shell does not wait, but immediately prompts for new commands.

If the user launches a job in the foreground and subsequently regrets this, the user can type the suspend character (typically set to <control>-Z), which causes the foreground job to stop and the shell to begin prompting for new commands. The stopped job can be continued by the user (via special shell commands) either as a foreground job or as a background job. Background jobs can also be moved into the foreground via shell commands.

If a background job attempts to access the login terminal (controlling terminal), it is stopped by the terminal driver and the shell is notified, which, in turn, notifies the user. (Terminal access includes *read()* and certain terminal control functions, and conditionally includes *write()*.) The user can continue the stopped job in the foreground, thus allowing the terminal access to succeed in an orderly fashion. After the terminal access succeeds, the user can optionally move the job into the background via the suspend character and shell commands.

*Implementing Job Control Shells*

The interactive interface described previously can be accomplished using the POSIX.1 job control facilities in the following way.

The key feature necessary to provide job control is a way to group processes into jobs. This grouping is necessary in order to direct signals to a single job and also to identify which job is in the foreground. (There is at most one job that is in the foreground on any controlling terminal at a time.)

The concept of process groups is used to provide this grouping. The shell places each job in a separate process group via the *setpgid()* function. To do this, the *setpgid()* function is invoked by the shell for each process in the job. It is actually useful to invoke *setpgid()* twice for each process: once in the child process, after calling *fork()* to create the process, but before calling one of the *exec* family of functions to begin execution of the program, and once in the parent shell process, after calling *fork()* to create the child. The redundant invocation avoids a race condition by ensuring that the child process is placed into the new process group before either the parent or the child relies on this being the case. The process group ID for the job is selected by the shell to be equal to the process ID of one of the processes in the job. Some shells choose to make one process in the job be the parent of the other processes in the job (if any). Other shells (for example, the C Shell) choose to make themselves the parent of all processes in the pipeline (job). In order to support this latter case, the *setpgid()* function accepts a process group ID parameter

116456 since the correct process group ID cannot be inherited from the shell. The shell itself is  
116457 considered to be a job and is the sole process in its own process group.

116458 The shell also controls which job is currently in the foreground. A foreground and background  
116459 job differ in two ways: the shell waits for a foreground command to complete (or stop) before  
116460 continuing to read new commands, and the terminal I/O driver inhibits terminal access by  
116461 background jobs (causing the processes to stop). Thus, the shell must work cooperatively with  
116462 the terminal I/O driver and have a common understanding of which job is currently in the  
116463 foreground. It is the user who decides which command should be currently in the foreground,  
116464 and the user informs the shell via shell commands. The shell, in turn, informs the terminal I/O  
116465 driver via the *tcsetpgrp()* function. This indicates to the terminal I/O driver the process group ID  
116466 of the foreground process group (job). When the current foreground job either stops or  
116467 terminates, the shell places itself in the foreground via *tcsetpgrp()* before prompting for  
116468 additional commands. Note that when a job is created the new process group begins as a  
116469 background process group. It requires an explicit act of the shell via *tcsetpgrp()* to move a  
116470 process group (job) into the foreground.

116471 When a process in a job stops or terminates, its parent (for example, the shell) receives  
116472 synchronous notification by calling the *waitpid()* function with the WUNTRACED flag set.  
116473 Asynchronous notification is also provided when the parent establishes a signal handler for  
116474 SIGCHLD and does not specify the SA\_NOCLDSTOP flag. Usually all processes in a job stop as  
116475 a unit since the terminal I/O driver always sends job control stop signals to all processes in the  
116476 process group.

116477 To continue a stopped job, the shell sends the SIGCONT signal to the process group of the job. In  
116478 addition, if the job is being continued in the foreground, the shell invokes *tcsetpgrp()* to place the  
116479 job in the foreground before sending SIGCONT. Otherwise, the shell leaves itself in the  
116480 foreground and reads additional commands.

116481 There is additional flexibility in the POSIX.1 job control facilities that allows deviations from the  
116482 typical interface. Clearing the TOSTOP terminal flag allows background jobs to perform *write()*  
116483 functions without stopping. The same effect can be achieved on a per-process basis by having a  
116484 process set the signal action for SIGTTOU to SIG\_IGN.

116485 Note that the terms “job” and “process group” can be used interchangeably. A login session that  
116486 is not using the job control facilities can be thought of as a large collection of processes that are  
116487 all in the same job (process group). Such a login session may have a partial distinction between  
116488 foreground and background processes; that is, the shell may choose to wait for some processes  
116489 before continuing to read new commands and may not wait for other processes. However, the  
116490 terminal I/O driver will consider all these processes to be in the foreground since they are all  
116491 members of the same process group.

116492 In addition to the basic job control operations already mentioned, a job control-cognizant shell  
116493 needs to perform the following actions.

116494 When a foreground (not background) job stops, the shell must sample and remember the current  
116495 terminal settings so that it can restore them later when it continues the stopped job in the  
116496 foreground (via the *tcgetattr()* and *tcsetattr()* functions).

116497 Because a shell itself can be spawned from a shell, it must take special action to ensure that  
116498 subshells interact well with their parent shells.

116499 A subshell can be spawned to perform an interactive function (prompting the terminal for  
116500 commands) or a non-interactive function (reading commands from a file). When operating non-  
116501 interactively, the job control shell will refrain from performing the job control-specific actions  
116502 described above. It will behave as a shell that does not support job control. For example, all jobs  
116503 will be left in the same process group as the shell, which itself remains in the process group

established for it by its parent. This allows the shell and its children to be treated as a single job by a parent shell, and they can be affected as a unit by terminal keyboard signals.

An interactive subshell can be spawned from another job control-cognizant shell in either the foreground or background. (For example, from the C Shell, the user can execute the command, `csh &`.) Before the subshell activates job control by calling `setpgid()` to place itself in its own process group and `tcsetpgrp()` to place its new process group in the foreground, it needs to ensure that it has already been placed in the foreground by its parent. (Otherwise, there could be multiple job control shells that simultaneously attempt to control mediation of the terminal.) To determine this, the shell retrieves its own process group via `getpgrp()` and the process group of the current foreground job via `tcgetpgrp()`. If these are not equal, the shell sends SIGTTIN to its own process group, causing itself to stop. When continued later by its parent, the shell repeats the process group check. When the process groups finally match, the shell is in the foreground and it can proceed to take control. After this point, the shell ignores all the job control stop signals so that it does not inadvertently stop itself.

#### *Implementing Job Control Applications*

Most applications do not need to be aware of job control signals and operations; the intuitively correct behavior happens by default. However, sometimes an application can inadvertently interfere with normal job control processing, or an application may choose to overtly effect job control in cooperation with normal shell procedures.

An application can inadvertently subvert job control processing by “blindly” altering the handling of signals. A common application error is to learn how many signals the system supports and to ignore or catch them all. Such an application makes the assumption that it does not know what this signal is, but knows the right handling action for it. The system may initialize the handling of job control stop signals so that they are being ignored. This allows shells that do not support job control to inherit and propagate these settings and hence to be immune to stop signals. A job control shell will set the handling to the default action and propagate this, allowing processes to stop. In doing so, the job control shell is taking responsibility for restarting the stopped applications. If an application wishes to catch the stop signals itself, it should first determine their inherited handling states. If a stop signal is being ignored, the application should continue to ignore it. This is directly analogous to the recommended handling of SIGINT described in the referenced UNIX Programmer’s Manual.

If an application is reading the terminal and has disabled the interpretation of special characters (by clearing the ISIG flag), the terminal I/O driver will not send SIGTSTP when the suspend character is typed. Such an application can simulate the effect of the suspend character by recognizing it and sending SIGTSTP to its process group as the terminal driver would have done. Note that the signal is sent to the process group, not just to the application itself; this ensures that other processes in the job also stop. (Note also that other processes in the job could be children, siblings, or even ancestors.) Applications should not assume that the suspend character is `<control>-Z` (or any particular value); they should retrieve the current setting at startup.

#### *Implementing Job Control Systems*

The intent in adding 4.2 BSD-style job control functionality was to adopt the necessary 4.2 BSD programmatic interface with only minimal changes to resolve syntactic or semantic conflicts with System V or to close recognized security holes. The goal was to maximize the ease of providing both conforming implementations and Conforming POSIX.1 Applications.

It is only useful for a process to be affected by job control signals if it is the descendant of a job control shell. Otherwise, there will be nothing that continues the stopped process.

POSIX.1 does not specify how controlling terminal access is affected by a user logging out (that

116552 is, by a controlling process terminating). 4.2 BSD uses the *vhangup()* function to prevent any  
116553 access to the controlling terminal through file descriptors opened prior to logout. System V does  
116554 not prevent controlling terminal access through file descriptors opened prior to logout (except  
116555 for the case of the special file, */dev/tty*). Some implementations choose to make processes  
116556 immune from job control after logout (that is, such processes are always treated as if in the  
116557 foreground); other implementations continue to enforce foreground/background checks after  
116558 logout. Therefore, a Conforming POSIX.1 Application should not attempt to access the  
116559 controlling terminal after logout since such access is unreliable. If an implementation chooses to  
116560 deny access to a controlling terminal after its controlling process exits, POSIX.1 requires a certain  
116561 type of behavior (see [Controlling Terminal](#), on page 3452).

#### 116562 **Kernel\***

116563 See [System Call\\*](#) (on page 3469).

#### 116564 **Library Routine\***

116565 See [System Call\\*](#) (on page 3469).

#### 116566 **Logical Device\***

116567 Implementation-defined.

#### 116568 **Map**

116569 The definition of map is included to clarify the usage of mapped pages in the description of the  
116570 behavior of process memory locking.

#### 116571 **Memory-Resident**

116572 The term “memory-resident” is historically understood to mean that the so-called resident pages  
116573 are actually present in the physical memory of the computer system and are immune from  
116574 swapping, paging, copy-on-write faults, and so on. This is the actual intent of POSIX.1-2008 in  
116575 the process memory locking section for implementations where this is logical. But for some  
116576 implementations—primarily mainframes—actually locking pages into primary storage is not  
116577 advantageous to other system objectives, such as maximizing throughput. For such  
116578 implementations, memory locking is a “hint” to the implementation that the application wishes  
116579 to avoid situations that would cause long latencies in accessing memory. Furthermore, there are  
116580 other implementation-defined issues with minimizing memory access latencies that “memory  
116581 residency” does not address—such as MMU reload faults. The definition attempts to  
116582 accommodate various implementations while allowing conforming applications to specify to the  
116583 implementation that they want or need the best memory access times that the implementation  
116584 can provide.

#### 116585 **Memory Object\***

116586 The term “memory object” usually implies shared memory. If the object is the same as a  
116587 filename in the file system name space of the implementation, it is expected that the data written  
116588 into the memory object be preserved on disk. A memory object may also apply to a physical  
116589 device on an implementation. In this case, writes to the memory object are sent to the controller  
116590 for the device and reads result in control registers being returned.

**Mount Point\***

The directory on which a “mounted file system” is mounted. This term, like *mount()* and *umount()*, was not included because it was implementation-defined.

**Mounted File System\***

See [File System](#) (on page 3454).

**Name**

There are no explicit limits in POSIX.1-2008 on the sizes of names, words (see the definition of word in the Base Definitions volume of POSIX.1-2008), lines, or other objects. However, other implicit limits do apply: shell script lines produced by many of the standard utilities cannot exceed {LINE\_MAX} and the sum of exported variables comes under the {ARG\_MAX} limit. Historical shells dynamically allocate memory for names and words and parse incoming lines a character at a time. Lines cannot have an arbitrary {LINE\_MAX} limit because of historical practice, such as *makefiles*, where *make* removes the <newline> characters associated with the commands for a target and presents the shell with one very long line. The text on INPUT FILES in XCU [Section 1.4](#) (on page 2310) does allow a shell to run out of memory, but it cannot have arbitrary programming limits.

**Native Implementation\***

This refers to an implementation of POSIX.1 that interfaces directly to an operating system kernel; see also *hosted implementation*. A similar concept is a native UNIX system, which would be a kernel derived from one of the original UNIX system products.

**Nice Value**

This definition is not intended to suggest that all processes in a system have priorities that are comparable. Scheduling policy extensions, such as adding realtime priorities, make the notion of a single underlying priority for all scheduling policies problematic. Some implementations may implement the features related to *nice* to affect all processes on the system, others to affect just the general time-sharing activities implied by POSIX.1-2008, and others may have no effect at all. Because of the use of “implementation-defined” in *nice* and *renice*, a wide range of implementation strategies is possible.

**Open File Description**

An “open file description”, as it is currently named, describes how a file is being accessed. What is currently called a “file descriptor” is actually just an identifier or “handle”; it does not actually describe anything.

The following alternate names were discussed:

- For “open file description”:  
“open instance”, “file access description”, “open file information”, and “file access information”.
- For “file descriptor”:  
“file handle”, “file number” (cf., *fileno()*). Some historical implementations use the term “file table entry”.

## 116630 Orphaned Process Group

116631 Historical implementations have a concept of an orphaned process, which is a process whose  
 116632 parent process has exited. When job control is in use, it is necessary to prevent processes from  
 116633 being stopped in response to interactions with the terminal after they no longer are controlled by  
 116634 a job control-cognizant program. Because signals generated by the terminal are sent to a process  
 116635 group and not to individual processes, and because a signal may be provoked by a process that  
 116636 is not orphaned, but sent to another process that is orphaned, it is necessary to define an  
 116637 orphaned process group. The definition assumes that a process group will be manipulated as a  
 116638 group and that the job control-cognizant process controlling the group is outside of the group  
 116639 and is the parent of at least one process in the group (so that state changes may be reported via  
 116640 *waitpid()*). Therefore, a group is considered to be controlled as long as at least one process in the  
 116641 group has a parent that is outside of the process group, but within the session.

116642 This definition of orphaned process groups ensures that a session leader's process group is  
 116643 always considered to be orphaned, and thus it is prevented from stopping in response to  
 116644 terminal signals.

## 116645 Page

116646 The term "page" is defined to support the description of the behavior of memory mapping for  
 116647 shared memory and memory mapped files, and the description of the behavior of process  
 116648 memory locking. It is not intended to imply that shared memory/file mapping and memory  
 116649 locking are applicable only to "paged" architectures. For the purposes of POSIX.1-2008,  
 116650 whatever the granularity on which an architecture supports mapping or locking, this is  
 116651 considered to be a "page". If an architecture cannot support the memory mapping or locking  
 116652 functions specified by POSIX.1-2008 on any granularity, then these options will not be  
 116653 implemented on the architecture.

## 116654 Pathname

116655 Pathnames historically allowed all bytes except for the <slash> and <NUL> characters. For +  
 116656 compatibility with existing file systems, this usage is maintained throughout the standard by +  
 116657 noting that a pathname need not be a valid character string in all locales. However, the +  
 116658 properties of the portable filename character set are such that a pathname using only those +  
 116659 characters and the <slash> is portable in all locales as a character string.

## 116660 Passwd File\*

116661 Implementation-defined; see [User Database](#) (on page 3471).

## 116662 Parent Directory

116663 There may be more than one directory entry pointing to a given directory in some  
 116664 implementations. The wording here identifies that exactly one of those is the parent directory. In  
 116665 pathname resolution, dot-dot is identified as the way that the unique directory is identified.  
 116666 (That is, the parent directory is the one to which dot-dot points.) In the case of a remote file  
 116667 system, if the same file system is mounted several times, it would appear as if they were distinct  
 116668 file systems (with interesting synchronization properties).

**116669 Pipe**

116670 It proved convenient to define a pipe as a special case of a FIFO, even though historically the  
116671 latter was not introduced until System III and does not exist at all in 4.3 BSD.

**116672 Portable Filename Character Set**

116673 The encoding of this character set is not specified—specifically, ASCII is not required. But the  
116674 implementation must provide a unique character code for each of the printable graphics  
116675 specified by POSIX.1; see also [Section A.4.6](#) (on page 3474).

116676 Situations where characters beyond the portable filename character set (or historically ASCII or  
116677 the ISO/IEC 646:1991 standard) would be used (in a context where the portable filename  
116678 character set or the ISO/IEC 646:1991 standard is required by POSIX.1) are expected to be  
116679 common. Although such a situation renders the use technically non-compliant, mutual  
116680 agreement among the users of an extended character set will make such use portable between  
116681 those users. Such a mutual agreement could be formalized as an optional extension to POSIX.1.  
116682 (Making it required would eliminate too many possible systems, as even those systems using the  
116683 ISO/IEC 646:1991 standard as a base character set extend their character sets for Western  
116684 Europe and the rest of the world in different ways.)

116685 Nothing in POSIX.1 is intended to preclude the use of extended characters where interchange is  
116686 not required or where mutual agreement is obtained. It has been suggested that in several places  
116687 “should” be used instead of “shall”. Because (in the worst case) use of any character beyond the  
116688 portable filename character set would render the program or data not portable to all possible  
116689 systems, no extensions are permitted in this context.

**116690 Process Lifetime**

116691 IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/5 is applied, adding *fork()*, *posix\_spawn()*,  
116692 *posix\_spawnp()*, and *vfork()* to the list of functions.

**116693 Process Termination**

116694 IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/6 is applied, rewording the definition to  
116695 address the “passive exit” on termination of the last thread or the *\_Exit()* function.

**116696 Regular File**

116697 POSIX.1 does not intend to preclude the addition of structuring data (for example, record  
116698 lengths) in the file, as long as such data is not visible to an application that uses the features  
116699 described in POSIX.1.

**116700 Root Directory**

116701 This definition permits the operation of *chroot()*, even though that function is not in POSIX.1; see  
116702 also [Section A.4.5](#) (on page 3473).

**116703 Root File System\***

116704 Implementation-defined.

**Root of a File System\***

Implementation-defined; see [Mount Point\\*](#) (on page 3460).

**Signal**

The definition implies a double meaning for the term. Although a signal is an event, common usage implies that a signal is an identifier of the class of event.

**Superuser\***

This concept, with great historical significance to UNIX system users, has been replaced with the notion of appropriate privileges.

**Supplementary Group ID**

The POSIX.1-1990 standard is inconsistent in its treatment of supplementary groups. The definition of supplementary group ID explicitly permits the effective group ID to be included in the set, but wording in the description of the *setuid()* and *setgid()* functions states: “Any supplementary group IDs of the calling process remain unchanged by these function calls”. In the case of *setgid()* this contradicts that definition. In addition, some felt that the unspecified behavior in the definition of supplementary group IDs adds unnecessary portability problems. The standard developers considered several solutions to this problem:

1. Reword the description of *setgid()* to permit it to change the supplementary group IDs to reflect the new effective group ID. A problem with this is that it adds more “may”s to the wording and does not address the portability problems of this optional behavior.
2. Mandate the inclusion of the effective group ID in the supplementary set (giving {NGROUPS\_MAX} a minimum value of 1). This is the behavior of 4.4 BSD. In that system, the effective group ID is the first element of the array of supplementary group IDs (there is no separate copy stored, and changes to the effective group ID are made only in the supplementary group set). By convention, the initial value of the effective group ID is duplicated elsewhere in the array so that the initial value is not lost when executing a set-group-ID program.
3. Change the definition of supplementary group ID to exclude the effective group ID and specify that the effective group ID does not change the set of supplementary group IDs. This is the behavior of 4.2 BSD, 4.3 BSD, and System V Release 4.
4. Change the definition of supplementary group ID to exclude the effective group ID, and require that *getgroups()* return the union of the effective group ID and the supplementary group IDs.
5. Change the definition of {NGROUPS\_MAX} to be one more than the number of supplementary group IDs, so it continues to be the number of values returned by *getgroups()* and existing applications continue to work. This alternative is effectively the same as the second (and might actually have the same implementation).

The standard developers decided to permit either 2 or 3. The effective group ID is orthogonal to the set of supplementary group IDs, and it is implementation-defined whether *getgroups()* returns this. If the effective group ID is returned with the set of supplementary group IDs, then all changes to the effective group ID affect the supplementary group set returned by *getgroups()*. It is permissible to eliminate duplicates from the list returned by *getgroups()*. However, if a group ID is contained in the set of supplementary group IDs, setting the group ID to that value and then to a different value should not remove that value from the supplementary group IDs.

The definition of supplementary group IDs has been changed to not include the effective group

ID. This simplifies permanent rationale and makes the relevant functions easier to understand. The `getgroups()` function has been modified so that it can, on an implementation-defined basis, return the effective group ID. By making this change, functions that modify the effective group ID do not need to discuss adding to the supplementary group list; the only view into the supplementary group list that the application developer has is through the `getgroups()` function.

## Symbolic Constant

Earlier versions of this standard used a variety of terms other than “macro” for many of the constants defined in headers, and it was not clear in which of these cases they were required to be macros or not, or to be pre-processor constants (i.e., usable in `#if`) or not. In cases where the symbols had a reserved prefix or suffix, there was often inconsistency between whether the prefix/suffix was reserved only for macros or for any use, and whether the term “macro” or a different term was used in the descriptions of the symbols. There were also some unintentional differences from the ISO C standard.

One of the most commonly used terms was “symbolic constant”. This has now been designated as the default term to be used wherever appropriate, and a formal definition of the term has been added giving the exact requirements for symbols that are described as symbolic constants.

The standard developers have performed a major rationalization of the header descriptions of symbols with constant values according to the following policy:

- Where symbols are from the ISO C standard, the wording from the ISO C standard (or equivalent, in cases where the exact wording is not appropriate) is used to describe them.
- For all other constants, the first choice is to use “symbolic constant” when the requirements for the symbol are a reasonably close fit with those of the term.

The description of the symbol can override individual requirements for symbolic constants; e.g., to specify a non-integer type, or to add a requirement that the symbol is usable in `#if` preprocessor directives.

- When neither of the above apply, the exact requirements are stated in the description. (Note that macros are not required to be usable in `#if`, or even to expand to constant expressions, unless explicitly stated.)
- In cases where there is a reserved prefix or suffix, if the symbol(s) with that prefix/suffix are from the ISO C standard and are required to be macros, or if the symbol is required to be usable in `#if`, then the prefix/suffix is reserved for use only as macros. If the symbol(s) are “symbolic constants” and not required to be usable in `#if`, the prefix/suffix is reserved for any use except in a few special cases.

Where a constant is required to be a macro but is also allowed to be another type of constant such as an enumeration constant, on implementations which do define it as another type of constant the macro is typically defined as follows:

```
#define macro_name macro_name
```

This allows applications to use `#ifdef`, etc. to determine whether the macro is defined, but the macro is not usable in `#if` preprocessor directives because the preprocessor will treat the unexpanded word `macro_name` as having the value zero.

## Symbolic Link

Earlier versions of this standard did not require symbolic links to have attributes such as ownership and a file serial number. This was because the 4.4 BSD implementation did not have them, and it was expected that other implementations may wish to do the same. However, experience with 4.4 BSD has shown that symbolic links implemented in this way cause problems for users and application developers, and later BSD systems have reverted to using *inodes* to implement symbolic links. Allowing *no-inode* symbolic links also caused problems in the standard. For example, leaving the *st\_ino* value for symbolic links unspecified meant that the common technique of comparing the *st\_dev* and *st\_ino* values for two pathnames to see if they refer to the same file could only be used with *stat()* in conforming applications and not with *lstat()*. The standard now requires symbolic links to have meaningful values for the same **struct stat** fields as regular files, except for the file mode bits in *st\_mode*. Historically, the file mode bits were unused (the contents of a symbolic link could always be read), but implementations differed as to whether the file mode bits (as returned in *st\_mode* or reported by *ls -l*) were set according to the *umask* or just to a fixed value such as 0777. Accordingly, the standard requires the file mode bits to be ignored by *readlink()* and when a symbolic link is followed during pathname resolution, but leaves the corresponding part of the value returned in *st\_mode* unspecified.

Historical implementations were followed when determining which interfaces should apply to symbolic links. Interfaces that historically followed symbolic links include *chmod()*, *stat()*, and *utime()*. Interfaces that historically did not follow symbolic links include *lstat()*, *rename()*, *remove()*, *rmdir()*, and *unlink()*. For *chown()* and *link()*, historical implementations differed. POSIX.1-2008 inherited the *lchown()* function from the Single UNIX Specification, Version 2, and therefore requires *chown()* to follow symbolic links. Earlier versions of this standard required *link()* to follow symbolic links, but with the addition of the *linkat()* function (which has a flag to indicate whether to follow symbolic links), both behaviors are now allowed for *link()*.

When the final component of a pathname is a symbolic link, the standard requires that a trailing *<slash>* causes the link to be followed. This is the behavior of historical implementations. For example, for */a/b* and */a/b/*, if */a/b* is a symbolic link to a directory, then */a/b* refers to the symbolic link, and */a/b/* refers to the directory to which the symbolic link points.

Because a symbolic link and its referenced object coexist in the file system name space, confusion can arise in distinguishing between the link itself and the referenced object. Historically, utilities and system calls have adopted their own link following conventions in a somewhat *ad hoc* fashion. Rules for a uniform approach are outlined here, although historical practice has been adhered to as much as was possible. To promote consistent system use, user-written utilities are encouraged to follow these same rules.

Symbolic links are handled either by operating on the link itself, or by operating on the object referenced by the link. In the latter case, an application or system call is said to “follow” the link. Symbolic links may reference other symbolic links, in which case links are dereferenced until an object that is not a symbolic link is found, a symbolic link that references a file that does not exist is found, or a loop is detected. (Current implementations do not detect loops, but have a limit on the number of symbolic links that they will dereference before declaring it an error.)

There are four domains for which default symbolic link policy is established in a system. In almost all cases, there are utility options that override this default behavior. The four domains are as follows:

1. Symbolic links specified to system calls that take pathname arguments |
2. Symbolic links specified as command line pathname arguments to utilities that are not performing a traversal of a file hierarchy |

3. Symbolic links referencing files not of type directory, specified to utilities that are performing a traversal of a file hierarchy

4. Symbolic links referencing files of type directory, specified to utilities that are performing a traversal of a file hierarchy

#### First Domain

The first domain is considered in earlier rationale.

#### Second Domain

The reason this category is restricted to utilities that are not traversing the file hierarchy is that some standard utilities take an option that specifies a hierarchical traversal, but by default operate on the arguments themselves. Generally, users specifying the option for a file hierarchy traversal wish to operate on a single, physical hierarchy, and therefore symbolic links, which may reference files outside of the hierarchy, are ignored. For example, *chown owner file* is a different operation from the same command with the **-R** option specified. In this example, the behavior of the command *chown owner file* is described here, while the behavior of the command *chown -R owner file* is described in the third and fourth domains.

The general rule is that the utilities in this category follow symbolic links named as arguments.

Exceptions in the second domain are:

- The *mv* and *rm* utilities do not follow symbolic links named as arguments, but respectively attempt to rename or delete them.
- The *ls* utility is also an exception to this rule. For compatibility with historical systems, when the **-R** option is not specified, the *ls* utility follows symbolic links named as arguments if the **-L** option is specified or if the **-F**, **-d**, or **-l** options are not specified. (If the **-L** option is specified, *ls* always follows symbolic links; it is the only utility where the **-L** option affects its behavior even though a tree walk is not being performed.)

All other standard utilities, when not traversing a file hierarchy, always follow symbolic links named as arguments.

Historical practice is that the **-h** option is specified if standard utilities are to act upon symbolic links instead of upon their targets. Examples of commands that have historically had a **-h** option for this purpose are the *chgrp*, *chown*, *file*, and *test* utilities.

#### Third Domain

The third domain is symbolic links, referencing files not of type directory, specified to utilities that are performing a traversal of a file hierarchy. (This includes symbolic links specified as command line pathname arguments or encountered during the traversal.)

The intention of the Shell and Utilities volume of POSIX.1-2008 is that the operation that the utility is performing is applied to the symbolic link itself, if that operation is applicable to symbolic links. If the operation is not applicable to symbolic links, the symbolic link should be ignored. Specifically, by default, no change should be made to the file referenced by the symbolic link.

#### Fourth Domain

The fourth domain is symbolic links referencing files of type directory, specified to utilities that are performing a traversal of a file hierarchy. (This includes symbolic links specified as command line pathname arguments or encountered during the traversal.)

Most standard utilities do not, by default, indirect into the file hierarchy referenced by the symbolic link. (The Shell and Utilities volume of POSIX.1-2008 uses the informal term “physical

walk” to describe this case. The case where the utility does indirect through the symbolic link is termed a “logical walk”.)

There are three reasons for the default to be a physical walk:

1. With very few exceptions, a physical walk has been the historical default on UNIX systems supporting symbolic links. Because some utilities (that is, *rm*) must default to a physical walk, regardless, changing historical practice in this regard would be confusing to users and needlessly incompatible.
2. For systems where symbolic links have the historical file attributes (that is, *owner*, *group*, *mode*), defaulting to a logical traversal would require the addition of a new option to the commands to modify the attributes of the link itself. This is painful and more complex than the alternatives.
3. There is a security issue with defaulting to a logical walk. Historically, the command *chown -R user file* has been safe for the superuser because *setuid* and *setgid* bits were lost when the ownership of the file was changed. If the walk were logical, changing ownership would no longer be safe because a user might have inserted a symbolic link pointing to any file in the tree. Again, this would necessitate the addition of an option to the commands doing hierarchy traversal to not indirect through the symbolic links, and historical scripts doing recursive walks would instantly become security problems. While this is mostly an issue for system administrators, it is preferable to not have different defaults for different classes of users.

However, the standard developers agreed to leave it unspecified to achieve consensus.

As consistently as possible, users may cause standard utilities performing a file hierarchy traversal to follow any symbolic links named on the command line, regardless of the type of file they reference, by specifying the **-H** (for half logical) option. This option is intended to make the command line name space look like the logical name space.

As consistently as possible, users may cause standard utilities performing a file hierarchy traversal to follow any symbolic links named on the command line as well as any symbolic links encountered during the traversal, regardless of the type of file they reference, by specifying the **-L** (for logical) option. This option is intended to make the entire name space look like the logical name space.

For consistency, implementors are encouraged to use the **-P** (for “physical”) flag to specify the physical walk in utilities that do logical walks by default for whatever reason.

When one or more of the **-H**, **-L**, and **-P** flags can be specified, the last one specified determines the behavior of the utility. This permits users to alias commands so that the default behavior is a logical walk and then override that behavior on the command line.

#### *Exceptions in the Third and Fourth Domains*

The *ls* and *rm* utilities are exceptions to these rules. The *rm* utility never follows symbolic links and does not support the **-H**, **-L**, or **-P** options. Some historical versions of *ls* always followed symbolic links given on the command line whether the **-L** option was specified or not. Historical versions of *ls* did not support the **-H** option. In POSIX.1-2008, unless one of the **-H** or **-L** options is specified, the *ls* utility only follows symbolic links to directories that are given as operands. The *ls* utility does not support the **-P** option.

The Shell and Utilities volume of POSIX.1-2008 requires that the standard utilities *ls*, *find*, and *pax* detect infinite loops when doing logical walks; that is, a directory, or more commonly a symbolic link, that refers to an ancestor in the current file hierarchy. If the file system itself is corrupted, causing the infinite loop, it may be impossible to recover. Because *find* and *ls* are often used in system administration and security applications, they should attempt to recover and

116928 continue as best as they can. The *pax* utility should terminate because the archive it was creating  
116929 is by definition corrupted. Other, less vital, utilities should probably simply terminate as well.  
116930 Implementations are strongly encouraged to detect infinite loops in all utilities.

116931 Historical practice is shown in [Table A-1](#) (on page 3469). The heading **SVID3** stands for the  
116932 Third Edition of the System V Interface Definition.

116933 Historically, several shells have had built-in versions of the *pwd* utility. In some of these shells,  
116934 *pwd* reported the physical path, and in others, the logical path. Implementations of the shell  
116935 corresponding to POSIX.1-2008 must report the logical path by default.

116936 The *cd* command is required, by default, to treat the filename dot-dot logically. Implementors are  
116937 required to support the **-P** flag in *cd* so that users can have their current environment handled  
116938 physically. In 4.3 BSD, *chgrp* during tree traversal changed the group of the symbolic link, not  
116939 the target. Symbolic links in 4.4 BSD did not have *owner*, *group*, *mode*, or other standard UNIX  
116940 system file attributes.

| <i>cpio</i>  | –L      |         | –L      |       | Follow symlinks.                        |
| <i>du</i>    |         |         | –H      | –H    | Follow command line symlinks.           |
| <i>du</i>    |         |         | –h      | –L    | Follow symlinks.                        |
| <i>file</i>  | –h      |         |         | –h    | Affect the symlink.                     |
| <i>find</i>  |         |         | –H      | –H    | Follow command line symlinks.           |
| <i>find</i>  |         |         | –h      | –L    | Follow symlinks.                        |
| <i>find</i>  | –follow |         | –follow |       | Follow symlinks.                        |
| <i>ln</i>    | –s      | –s      | –s      | –s    | Create a symbolic link.                 |
| <i>ls</i>    | –L      | –L      | –L      | –L    | Follow symlinks.                        |
| <i>ls</i>    |         |         |         | –H    | Follow command line symlinks.           |
| <i>mv</i>    |         |         |         |       | Operates on the symlink.                |
| <i>pax</i>   |         |         | –H      | –H    | Follow command line symlinks.           |
| <i>pax</i>   |         |         | –h      | –L    | Follow symlinks.                        |
| <i>pwd</i>   |         |         |         | –L    | Printed path may contain symlinks.      |
| <i>pwd</i>   |         |         |         | –P    | Printed path will not contain symlinks. |
| <i>rm</i>    |         |         |         |       | Operates on the symlink.                |
| <i>tar</i>   |         |         | –H      |       | Follow command line symlinks.           |
| <i>tar</i>   |         | –h      | –h      |       | Follow symlinks.                        |
| <i>test</i>  | –h      |         | –h      | –h    | Affect the symlink.                     |

116975

**Synchronously-Generated Signal**

116976

116977

Those signals that may be generated synchronously include SIGABRT, SIGBUS, SIGILL, SIGFPE, SIGPIPE, and SIGSEGV.

116978

116979

Any signal sent via the *raise()* function or a *kill()* function targeting the current process is also considered synchronous.

116980

**System Call\***

116981

116982

The distinction between a “system call” and a “library routine” is an implementation detail that may differ between implementations and has thus been excluded from POSIX.1.

116983

See “Interface, Not Implementation” in the Preface.

**116984 System Console**

116985 IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/7 is applied, changing from “An  
116986 implementation-defined device” to “A device”.

**116987 System Databases**

116988 IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/9 is applied, rewording the definition to  
116989 reference the existing definitions for “group database” and “user database”.

**116990 System Process**

116991 IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/8 is applied, rewording the definition to  
116992 remove the requirement for an implementation to define the object.

**116993 System Reboot**

116994 A “system reboot” is an event initiated by an unspecified circumstance that causes all processes  
116995 (other than special system processes) to be terminated in an implementation-defined manner,  
116996 after which any changes to the state and contents of files created or written to by a Conforming  
116997 POSIX.1 Application prior to the event are implementation-defined.

116998 IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/10 is applied, changing “An  
116999 implementation-defined sequence of events” to “An unspecified sequence of events”.

**117000 Synchronized I/O Data (and File) Integrity Completion**

117001 These terms specify that for synchronized read operations, pending writes must be successfully  
117002 completed before the read operation can complete. This is motivated by two circumstances.  
117003 Firstly, when synchronizing processes can access the same file, but not share common buffers  
117004 (such as for a remote file system), this requirement permits the reading process to guarantee that  
117005 it can read data written remotely. Secondly, having data written synchronously is insufficient to  
117006 guarantee the order with respect to a subsequent write by a reading process, and thus this extra  
117007 read semantic is necessary.

**117008 Text File**

117009 The term “text file” does not prevent the inclusion of control or other non-printable characters  
117010 (other than NUL). Therefore, standard utilities that list text files as inputs or outputs are either  
117011 able to process the special characters or they explicitly describe their limitations within their  
117012 individual descriptions. The definition of “text file” has caused controversy. The only difference  
117013 between text and binary files is that text files have lines of less than {LINE\_MAX} bytes, with no  
117014 NUL characters, each terminated by a <newline>. The definition allows a file with a single  
117015 <newline>, or a totally empty file, to be called a text file. If a file ends with an incomplete line it  
117016 is not strictly a text file by this definition. The <newline> referred to in POSIX.1-2008 is not some  
117017 generic line separator, but a single character; files created on systems where they use multiple  
117018 characters for ends of lines are not portable to all conforming systems without some translation  
117019 process unspecified by POSIX.1-2008.

**Thread**

POSIX.1-2008 defines a thread to be a flow of control within a process. Each thread has a minimal amount of private state; most of the state associated with a process is shared among all of the threads in the process. While most multi-thread extensions to POSIX have taken this approach, others have made different decisions.

**Note:** The choice to put threads within a process does not constrain implementations to implement threads in that manner. However, all functions have to behave as though threads share the indicated state information with the process from which they were created.

Threads need to share resources in order to cooperate. Memory has to be widely shared between threads in order for the threads to cooperate at a fine level of granularity. Threads keep data structures and the locks protecting those data structures in shared memory. For a data structure to be usefully shared between threads, such structures should not refer to any data that can only be interpreted meaningfully by a single thread. Thus, any system resources that might be referred to in data structures need to be shared between all threads. File descriptors, pathnames, and pointers to stack variables are all things that programmers want to share between their threads. Thus, the file descriptor table, the root directory, the current working directory, and the address space have to be shared.

Library implementations are possible as long as the effective behavior is as if system services invoked by one thread do not suspend other threads. This may be difficult for some library implementations on systems that do not provide asynchronous facilities.

See [Section B.2.9](#) (on page 3592) for additional rationale.

**Thread ID**

See [Section B.2.9.2](#) (on page 3609) for additional rationale.

**Thread-Safe Function**

All functions required by POSIX.1-2008 need to be thread-safe; see [Section A.4.17](#) (on page 3481) and [Section B.2.9.1](#) (on page 3606) for additional rationale.

**User Database**

There are no references in POSIX.1-2008 to a “passwd file” or a “group file”, and there is no requirement that the *group* or *passwd* databases be kept in files containing editable text. Many large timesharing systems use *passwd* databases that are hashed for speed. Certain security classifications prohibit certain information in the *passwd* database from being publicly readable.

The term “encoded” is used instead of “encrypted” in order to avoid the implementation connotations (such as reversibility or use of a particular algorithm) of the latter term.

The *getgrent()*, *setgrent()*, *endgrent()*, *getpwent()*, *setpwent()*, and *endpwent()* functions are not included as part of the base standard because they provide a linear database search capability that is not generally useful (the *getpwuid()*, *getpwnam()*, *getgrgid()*, and *getgrnam()* functions are provided for keyed lookup) and because in certain distributed systems, especially those with different authentication domains, it may not be possible or desirable to provide an application with the ability to browse the system databases indiscriminately. They are provided on XSI-conformant systems due to their historical usage by many existing applications.

A change from historical implementations is that the structures used by these functions have fields of the types **gid\_t** and **uid\_t**, which are required to be defined in the **<sys/types.h>** header. POSIX.1-2008 requires implementations to ensure that these types are defined by inclusion of **<grp.h>** and **<pwd.h>**, respectively, without imposing any name space pollution or errors from redefinition of types.

117065 POSIX.1-2008 is silent about the content of the strings containing user or group names. These  
 117066 could be digit strings. POSIX.1-2008 is also silent as to whether such digit strings bear any  
 117067 relationship to the corresponding (numeric) user or group ID.

117068 *Database Access*

117069 The thread-safe versions of the user and group database access functions return values in user-  
 117070 supplied buffers instead of possibly using static data areas that may be overwritten by each call.

117071 IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/11 is applied, removing the words “of  
 117072 implementation-defined format”.

117073 **Virtual Processor\***

117074 The term “virtual processor” was chosen as a neutral term describing all kernel-level  
 117075 schedulable entities, such as processes, Mach tasks, or lightweight processes. Implementing  
 117076 threads using multiple processes as virtual processors, or implementing multiplexed threads  
 117077 above a virtual processor layer, should be possible, provided some mechanism has also been  
 117078 implemented for sharing state between processes or virtual processors. Many systems may also  
 117079 wish to provide implementations of threads on systems providing “shared processes” or  
 117080 “variable-weight processes”. It was felt that exposing such implementation details would  
 117081 severely limit the type of systems upon which the threads interface could be supported and  
 117082 prevent certain types of valid implementations. It was also determined that a virtual processor  
 117083 interface was out of the scope of the Rationale (Informative) volume of POSIX.1-2008.

117084 **XSI**

117085 This is included to allow POSIX.1-2008 to be adopted as an IEEE standard and an Open Group  
 117086 Technical Standard, serving both the POSIX and the Single UNIX Specification in a core set of  
 117087 volumes.

117088 The term “XSI” has been used for 10 years in connection with the XPG series and the first and  
 117089 second versions of the base volumes of the Single UNIX Specification. The XSI margin code was  
 117090 introduced to denote the extended or more restrictive semantics beyond POSIX that are  
 117091 applicable to UNIX systems.

## 117092 **A.4 General Concepts**

117093 The general concepts are similar in nature to the definitions section, with the exception that a  
 117094 term defined in general concepts can contain normative requirements.

### 117095 **A.4.1 Concurrent Execution**

117096 There is no additional rationale provided for this section.

**117097 A.4.2 Directory Protection**

117098 There is no additional rationale provided for this section.

**117099 A.4.3 Extended Security Controls**

117100 Allowing an implementation to define extended security controls enables the use of  
117101 POSIX.1-2008 in environments that require different or more rigorous security than that  
117102 provided in POSIX.1. Extensions are allowed in two areas: privilege and file access permissions.  
117103 The semantics of these areas have been defined to permit extensions with reasonable, but not  
117104 exact, compatibility with all existing practices. For example, the elimination of the superuser  
117105 definition precludes identifying a process as privileged or not by virtue of its effective user ID.

**117106 A.4.4 File Access Permissions**

117107 A process should not try to anticipate the result of an attempt to access data by *a priori* use of  
117108 these rules. Rather, it should make the attempt to access data and examine the return value (and  
117109 possibly *errno* as well), or use *access()*. An implementation may include other security  
117110 mechanisms in addition to those specified in POSIX.1, and an access attempt may fail because of  
117111 those additional mechanisms, even though it would succeed according to the rules given in this  
117112 section. (For example, the user's security level might be lower than that of the object of the  
117113 access attempt.) The supplementary group IDs provide another reason for a process to not  
117114 attempt to anticipate the result of an access attempt.

117115 Since the current standard does not specify a method for opening a directory for searching, it is  
117116 unspecified whether search permission on the *fd* argument to *openat()* and related functions is  
117117 based on whether the directory was opened with search mode or on the current permissions  
117118 allowed by the directory at the time a search is performed. When there is existing practice that  
117119 supports opening directories for searching, it is expected that these functions will be modified to  
117120 specify that the search permissions will be granted based on the file access modes of the  
117121 directory's file descriptor identified by *fd*, and not on the mode of the directory at the time the  
117122 directory is searched.

**117123 A.4.5 File Hierarchy**

117124 Though the file hierarchy is commonly regarded to be a tree, POSIX.1 does not define it as such  
117125 for three reasons:

- 117126 1. Links may join branches.
- 117127 2. In some network implementations, there may be no single absolute root directory; see  
117128 *pathname resolution*.
- 117129 3. With symbolic links, the file system need not be a tree or even a directed acyclic graph.

117130 **A.4.6 Filenames**

117131 Historically, certain filenames and pathnames have been reserved. This list includes **core**,  
 117132 **/etc/passwd**, and so on. Conforming applications should avoid these.

117133 Most historical implementations prohibit case folding in filenames; that is, treating uppercase  
 117134 and lowercase alphabetic characters as identical. However, some consider case folding desirable:

- 117135 • For user convenience
- 117136 • For ease-of-implementation of the POSIX.1 interface as a hosted system on some popular  
 117137 operating systems

117138 Variants, such as maintaining case distinctions in filenames, but ignoring them in comparisons,  
 117139 have been suggested. Methods of allowing escaped characters of the case opposite the default  
 117140 have been proposed.

117141 Many reasons have been expressed for not allowing case folding, including:

- 117142 • No solid evidence has been produced as to whether case-sensitivity or case-insensitivity is  
 117143 more convenient for users.
- 117144 • Making case-insensitivity a POSIX.1 implementation option would be worse than either  
 117145 having it or not having it, because:
  - 117146 — More confusion would be caused among users.
  - 117147 — Application developers would have to account for both cases in their code.
  - 117148 — POSIX.1 implementors would still have other problems with native file systems, such  
 117149 as short or otherwise constrained filenames or pathnames, and the lack of  
 117150 hierarchical directory structure.
- 117151 • Case folding is not easily defined in many European languages, both because many of  
 117152 them use characters outside the US ASCII alphabetic set, and because:
  - 117153 — In Spanish, the digraph "ll" is considered to be a single letter, the capitalized form  
 117154 of which may be either "Ll" or "LL", depending on context.
  - 117155 — In French, the capitalized form of a letter with an accent may or may not retain the  
 117156 accent, depending on the country in which it is written.
  - 117157 — In German, the sharp ess may be represented as a single character resembling a  
 117158 Greek beta ( $\beta$ ) in lowercase, but as the digraph "SS" in uppercase.
  - 117159 — In Greek, there are several lowercase forms of some letters; the one to use depends on  
 117160 its position in the word. Arabic has similar rules.
- 117161 • Many East Asian languages, including Japanese, Chinese, and Korean, do not distinguish  
 117162 case and are sometimes encoded in character sets that use more than one byte per  
 117163 character.
- 117164 • Multiple character codes may be used on the same machine simultaneously. There are  
 117165 several ISO character sets for European alphabets. In Japan, several Japanese character  
 117166 codes are commonly used together, sometimes even in filenames; this is evidently also the  
 117167 case in China. To handle case insensitivity, the kernel would have to at least be able to  
 117168 distinguish for which character sets the concept made sense.
- 117169 • The file system implementation historically deals only with bytes, not with characters.  
 117170 Limitations on valid encodings ensure that the byte sequences for the <slash> character,  
 117171 <period> character, and <NUL> character will not be confused with any other character in  
 117172 any locale. However, there exist common single-shift encodings where other single-byte

- 117173 characters from the portable filename character set can also occur as a subset of a multi- |  
 117174 byte character, making case folding of portable filename bytes dependent on the context of |  
 117175 whether a shift-state is active.
- 117176 • The purpose of POSIX.1 is to standardize the common, existing definition, not to change it. |  
 117177 Mandating case-insensitivity would make all historical implementations non-standard.
  - 117178 • Not only the interface, but also application programs would need to change, counter to the |  
 117179 purpose of having minimal changes to existing application code.
  - 117180 • At least one of the original developers of the UNIX system has expressed objection in the |  
 117181 strongest terms to either requiring case-insensitivity or making it an option, mostly on the |  
 117182 basis that POSIX.1 should not hinder portability of application programs across related |  
 117183 implementations in order to allow compatibility with unrelated operating systems.
- 117184 Two proposals were entertained regarding case folding in filenames:
- 117185 1. Remove all wording that previously permitted case folding.
- 117186 Rationale Case folding is inconsistent with the portable filename character set and |  
 117187 filename definitions (all bytes except <slash> and null). No known |  
 117188 implementations allowing all bytes except <slash> and null also do case |  
 117189 folding.
- 117190 2. Change “though this practice is not recommended:” to “although this practice is strongly |  
 117191 discouraged.”
- 117192 Rationale If case folding must be included in POSIX.1, the wording should be stronger |  
 117193 to discourage the practice.
- 117194 The consensus selected the first proposal. Otherwise, a conforming application would have to |  
 117195 assume that case folding would occur when it was not wanted, but that it would not occur when |  
 117196 it was wanted.

#### 117197 **A.4.7 Filename Portability**

- 117198 Filenames should be constructed from the portable filename character set because the use of |  
 117199 other characters can be confusing or ambiguous in certain contexts. (For example, the use of a |  
 117200 <colon> ( ' : ' ) in a pathname could cause ambiguity if that pathname were included in a *PATH* |  
 117201 definition.)
- 117202 The constraint on use of the <hyphen> character as the first character of a portable filename is a |  
 117203 constraint on application behavior and not on implementations, since applications might not |  
 117204 work as expected when such a filename is passed as a command line argument.

#### 117205 **A.4.8 File Times Update**

- 117206 This section reflects the actions of historical implementations. The times are not updated |  
 117207 immediately, but are only marked for update by the functions. An implementation may update |  
 117208 these times immediately.
- 117209 The accuracy of the time update values is intentionally left unspecified so that systems can |  
 117210 control the bandwidth of a possible covert channel.
- 117211 The wording was carefully chosen to make it clear that there is no requirement that the |  
 117212 conformance document contain information that might incidentally affect file timestamps. Any |  
 117213 function that performs pathname resolution might update several last data access timestamps.

117214 Functions such as *getpwnam()* and *getgrnam()* might update the last data access timestamp of  
 117215 some specific file or files. It is intended that these are not required to be documented in the  
 117216 conformance document, but they should appear in the system documentation.

#### 117217 **A.4.9 Host and Network Byte Order**

117218 There is no additional rationale provided for this section.

#### 117219 **A.4.10 Measurement of Execution Time**

117220 The methods used to measure the execution time of processes and threads, and the precision of  
 117221 these measurements, may vary considerably depending on the software architecture of the  
 117222 implementation, and on the underlying hardware. Implementations can also make tradeoffs  
 117223 between the scheduling overhead and the precision of the execution time measurements.  
 117224 POSIX.1-2008 does not impose any requirement on the accuracy of the execution time; it instead  
 117225 specifies that the measurement mechanism and its precision are implementation-defined.

#### 117226 **A.4.11 Memory Synchronization**

117227 In older multi-processors, access to memory by the processors was strictly multiplexed. This  
 117228 meant that a processor executing program code interrogates or modifies memory in the order  
 117229 specified by the code and that all the memory operation of all the processors in the system  
 117230 appear to happen in some global order, though the operation histories of different processors are  
 117231 interleaved arbitrarily. The memory operations of such machines are said to be sequentially  
 117232 consistent. In this environment, threads can synchronize using ordinary memory operations. For  
 117233 example, a producer thread and a consumer thread can synchronize access to a circular data  
 117234 buffer as follows:

```
117235 int rdptr = 0;
117236 int wrptr = 0;
117237 data_t buf[BUFSIZE];

117238 Thread 1:
117239 while (work_to_do) {
117240 int next;

117241 buf[wrptr] = produce();
117242 next = (wrptr + 1) % BUFSIZE;
117243 while (rdptr == next)
117244 ;
117245 wrptr = next;
117246 }

117247 Thread 2:
117248 while (work_to_do) {
117249 while (rdptr == wrptr)
117250 ;
117251 consume(buf[rdptr]);
117252 rdptr = (rdptr + 1) % BUFSIZE;
117253 }
```

117254 In modern multi-processors, these conditions are relaxed to achieve greater performance. If one  
 117255 processor stores values in location A and then location B, then other processors loading data

from location B and then location A may see the new value of B but the old value of A. The memory operations of such machines are said to be weakly ordered. On these machines, the circular buffer technique shown in the example will fail because the consumer may see the new value of *wrptr* but the old value of the data in the buffer. In such machines, synchronization can only be achieved through the use of special instructions that enforce an order on memory operations. Most high-level language compilers only generate ordinary memory operations to take advantage of the increased performance. They usually cannot determine when memory operation order is important and generate the special ordering instructions. Instead, they rely on the programmer to use synchronization primitives correctly to ensure that modifications to a location in memory are ordered with respect to modifications and/or access to the same location in other threads. Access to read-only data need not be synchronized. The resulting program is said to be data race-free.

Synchronization is still important even when accessing a single primitive variable (for example, an integer). On machines where the integer may not be aligned to the bus data width or be larger than the data width, a single memory load may require multiple memory cycles. This means that it may be possible for some parts of the integer to have an old value while other parts have a newer value. On some processor architectures this cannot happen, but portable programs cannot rely on this.

In summary, a portable multi-threaded program, or a multi-process program that shares writable memory between processes, has to use the synchronization primitives to synchronize data access. It cannot rely on modifications to memory being observed by other threads in the order written in the application or even on modification of a single variable being seen atomically.

Conforming applications may only use the functions listed to synchronize threads of control with respect to memory access. There are many other candidates for functions that might also be used. Examples are: signal sending and reception, or pipe writing and reading. In general, any function that allows one thread of control to wait for an action caused by another thread of control is a candidate. POSIX.1-2008 does not require these additional functions to synchronize memory access since this would imply the following:

- All these functions would have to be recognized by advanced compilation systems so that memory operations and calls to these functions are not reordered by optimization.
- All these functions would potentially have to have memory synchronization instructions added, depending on the particular machine.
- The additional functions complicate the model of how memory is synchronized and make automatic data race detection techniques impractical.

Formal definitions of the memory model were rejected as unreadable by the vast majority of programmers. In addition, most of the formal work in the literature has concentrated on the memory as provided by the hardware as opposed to the application programmer through the compiler and runtime system. It was believed that a simple statement intuitive to most programmers would be most effective. POSIX.1-2008 defines functions that can be used to synchronize access to memory, but it leaves open exactly how one relates those functions to the semantics of each function as specified elsewhere in POSIX.1-2008. POSIX.1-2008 also does not make a formal specification of the partial ordering in time that the functions can impose, as that is implied in the description of the semantics of each function. It simply states that the programmer has to ensure that modifications do not occur “simultaneously” with other access to a memory location.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/4 is applied, adding a new paragraph beneath the table of functions: “The *pthread\_once()* function shall synchronize memory for the first call in each thread for a given *pthread\_once\_t* object.”.

117305 **A.4.12 Pathname Resolution**

117306 It is necessary to differentiate between the definition of pathname and the concept of pathname  
 117307 resolution with respect to the handling of trailing <slash> characters. By specifying the behavior  
 117308 here, it is not possible to provide an implementation that is conforming but extends all interfaces  
 117309 that handle pathnames to also handle strings that are not legal pathnames (because they have  
 117310 trailing <slash> characters).

117311 Pathnames that end with one or more trailing <slash> characters must refer to directory paths.  
 117312 Earlier versions of this standard were not specific about the distinction between trailing <slash>  
 117313 characters on files and directories, and both were permitted.

117314 Two types of implementation have been prevalent; those that ignored trailing <slash> characters  
 117315 on all pathnames regardless, and those that permitted them only on existing directories.

117316 An earlier version of this standard required that a pathname with a trailing <slash> character be  
 117317 treated as if it had a trailing " / . " everywhere. This specification was ambiguous. In situations  
 117318 where the intent was that the application wanted to require the implementation to accept the  
 117319 pathname only if it named a directory (existing or to be created as a result of the call performing  
 117320 pathname resolution), literally adding a ' . ' after the trailing <slash> could be interpreted to  
 117321 require use of that pathname to fail. Some of the uses that created ambiguous requirements  
 117322 included `mkdir("newdir /")` and `rmdir("existing-dir /")`. POSIX.1-2008 requires that a pathname  
 117323 with a trailing <slash> be rejected unless it refers to a file that is a directory or to a file that is to  
 117324 be created as a directory. The `rename()` function and the `mv` utility further specify that a trailing  
 117325 <slash> cannot be used on a pathname naming a file that does not exist when used as the last  
 117326 argument to `rename()` or `renameat()`, or as the last operand to `mv`.

117327 Note that this change does not break any conforming applications; since there were two different  
 117328 types of implementation, no application could have portably depended on either behavior. This  
 117329 change does however require some implementations to be altered to remain compliant.  
 117330 Substantial discussion over a three-year period has shown that the benefits to application  
 117331 developers outweighs the disadvantages for some vendors.

117332 On a historical note, some early applications automatically appended a ' / ' to every path.  
 117333 Rather than fix the applications, the system implementation was modified to accept this  
 117334 behavior by ignoring any trailing <slash>.

117335 Each directory has exactly one parent directory which is represented by the name **dot-dot** in the  
 117336 first directory. No other directory, regardless of linkages established by symbolic links, is  
 117337 considered the parent directory by POSIX.1-2008.

117338 There are two general categories of interfaces involving pathname resolution: those that follow  
 117339 the symbolic link, and those that do not. There are several exceptions to this rule; for example,  
 117340 `open(path, O_CREAT | O_EXCL)` will fail when `path` names a symbolic link. However, in all other  
 117341 situations, the `open()` function will follow the link.

117342 What the filename **dot-dot** refers to relative to the root directory is implementation-defined. In  
 117343 Version 7 it refers to the root directory itself; this is the behavior mentioned in POSIX.1-2008. In  
 117344 some networked systems the construction `././hostname/` is used to refer to the root directory of  
 117345 another host, and POSIX.1 permits this behavior.

117346 Other networked systems use the construct `//hostname` for the same purpose; that is, a double  
 117347 initial <slash> is used. There is a potential problem with existing applications that create full  
 117348 pathnames by taking a trunk and a relative pathname and making them into a single string  
 117349 separated by ' / ', because they can accidentally create networked pathnames when the trunk is  
 117350 ' / '. This practice is not prohibited because such applications can be made to conform by  
 117351 simply changing to use " / / " as a separator instead of ' / ':

- If the trunk is `'/'`, the full pathname will begin with `"/"` (the initial `'/'` and the separator `"/"`). This is the same as `'/'`, which is what is desired. (This is the general case of making a relative pathname into an absolute one by prefixing with `"/"` instead of `'/'`.)
- If the trunk is `"/A"`, the result is `"/A/. . ."`; since non-leading sequences of two or more `<slash>` characters are treated as a single `<slash>`, this is equivalent to the desired `"/A/. . ."`.
- If the trunk is `"//A"`, the implementation-defined semantics will apply. (The multiple `<slash>` rule would apply.)

Application developers should avoid generating pathnames that start with `"/"`. Implementations are strongly encouraged to avoid using this special interpretation since a number of applications currently do not follow this practice and may inadvertently generate `"/. . ."`.

The term “root directory” is only defined in POSIX.1 relative to the process. In some implementations, there may be no absolute root directory. The initialization of the root directory of a process is implementation-defined.

When the standard says: “Pathname resolution for a given pathname shall yield the same results when used by any interface in POSIX.1-2008 as long as there are no changes to any files evaluated during pathname resolution for the given pathname between resolutions”, this applies to absolute pathnames or to relative pathnames from the same current working directory. Using the same relative pathname from two different working directories may yield different results.

Earlier versions of this standard were unclear as to whether a pathname was required to be a character string or just a string. This standard is now clear that filenames are just strings, and that pathname processing is locale-independent.

#### A.4.13 Process ID Reuse

There is no additional rationale provided for this section.

#### A.4.14 Scheduling Policy

There is no additional rationale provided for this section.

#### A.4.15 Seconds Since the Epoch

Coordinated Universal Time (UTC) includes leap seconds. However, in POSIX time (seconds since the Epoch), leap seconds are ignored (not applied) to provide an easy and compatible method of computing time differences. Broken-down POSIX time is therefore not necessarily UTC, despite its appearance.

As of December 2007, 23 leap seconds had been added to UTC since the Epoch, 1 January, 1970. Historically, one leap second is added every 15 months on average, so this offset can be expected to grow with time.

Most systems’ notion of “time” is that of a continuously increasing value, so this value should increase even during leap seconds. However, not only do most systems not keep track of leap seconds, but most systems are probably not synchronized to any standard time reference. Therefore, it is inappropriate to require that a time represented as seconds since the Epoch

precisely represent the number of seconds between the referenced time and the Epoch.

It is sufficient to require that applications be allowed to treat this time as if it represented the number of seconds between the referenced time and the Epoch. It is the responsibility of the vendor of the system, and the administrator of the system, to ensure that this value represents the number of seconds between the referenced time and the Epoch as closely as necessary for the application being run on that system.

It is important that the interpretation of time names and seconds since the Epoch values be consistent across conforming systems; that is, it is important that all conforming systems interpret “536 457 599 seconds since the Epoch” as 59 seconds, 59 minutes, 23 hours 31 December 1986, regardless of the accuracy of the system’s idea of the current time. The expression is given to ensure a consistent interpretation, not to attempt to specify the calendar. The relationship between *tm\_yday* and the day of week, day of month, and month is in accordance with the Gregorian calendar, and so is not specified in POSIX.1.

Consistent interpretation of seconds since the Epoch can be critical to certain types of distributed applications that rely on such timestamps to synchronize events. The accrual of leap seconds in a time standard is not predictable. The number of leap seconds since the Epoch will likely increase. POSIX.1 is more concerned about the synchronization of time between applications of astronomically short duration.

Note that *tm\_yday* is zero-based, not one-based, so the day number in the example above is 364. Note also that the division is an integer division (discarding remainder) as in the C language.

Note also that the meaning of *gmtime()*, *localtime()*, and *mktime()* is specified in terms of this expression. However, the ISO C standard computes *tm\_yday* from *tm\_mday*, *tm\_mon*, and *tm\_year* in *mktime()*. Because it is stated as a (bidirectional) relationship, not a function, and because the conversion between month-day-year and day-of-year dates is presumed well known and is also a relationship, this is not a problem.

Implementations that implement **time\_t** as a signed 32-bit integer will overflow in 2038. This standard requires that **time\_t** be an integer type with implementation-defined size, but does not mandate a particular size. The requirement that **time\_t** be integral is an additional constraint beyond the ISO C standard, which allows a real-floating **time\_t**. Implementation practice has shown that much existing code is unprepared to deal with a floating-point **time\_t**, and that use of **struct timespec** is a more uniform way to provide sub-second time manipulation within applications.

See also [Epoch](#) (on page 3454).

The topic of whether seconds since the Epoch should account for leap seconds has been debated on a number of occasions, and each time consensus was reached (with acknowledged dissent each time) that the majority of users are best served by treating all days identically. (That is, the majority of applications were judged to assume a single length—as measured in seconds since the Epoch—for all days. Thus, leap seconds are not applied to seconds since the Epoch.) Those applications which do care about leap seconds can determine how to handle them in whatever way those applications feel is best. This was particularly emphasized because there was disagreement about what the best way of handling leap seconds might be. It is a practical impossibility to mandate that a conforming implementation must have a fixed relationship to any particular official clock (consider isolated systems, or systems performing “reruns” by setting the clock to some arbitrary time).

Note that as a practical consequence of this, the length of a second as measured by some external standard is not specified. This unspecified second is nominally equal to an International System (SI) second in duration. Applications must be matched to a system that provides the particular handling of external time in the way required by the application.

117441 IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/12 is applied, making an editorial  
117442 correction to the paragraph commencing “How any changes to the value of seconds ...”.

117443 **A.4.16 Semaphore**

117444 There is no additional rationale provided for this section.

117445 **A.4.17 Thread-Safety**

117446 Where the interface of a function required by POSIX.1-2008 precludes thread-safety, an alternate  
117447 thread-safe form is provided. The names of these thread-safe forms are the same as the non-  
117448 thread-safe forms with the addition of the suffix “\_r”. The suffix “\_r” is historical, where the  
117449 ‘r’ stood for “reentrant”.

117450 In some cases, thread-safety is provided by restricting the arguments to an existing function.

117451 See also [Section B.2.9.1](#) (on page 3606).

117452 **A.4.18 Tracing**

117453 Refer to [Section B.2.11](#) (on page 3622).

117454 **A.4.19 Treatment of Error Conditions for Mathematical Functions**

117456 **A.4.20 Treatment of NaN Arguments for Mathematical Functions**

117457 There is no additional rationale provided for this section.

117458 **A.4.21 Utility**

117459 There is no additional rationale provided for this section.

117460 **A.4.22 Variable Assignment**

117461 There is no additional rationale provided for this section.

## A.5 File Format Notation

The notation for spaces allows some flexibility for application output. Note that an empty character position in *format* represents one or more <blank> characters on the output (not *white space*, which can include <newline> characters). Therefore, another utility that reads that output as its input must be prepared to parse the data using *scanf()*, *awk*, and so on. The 'Δ' character is used when exactly one <space> is output.

The treatment of integers and spaces is different from the *printf()* function in that they can be surrounded with <blank> characters. This was done so that, given a format such as:

```
"%d\n", <foo>
```

the implementation could use a *printf()* call such as:

```
printf("%6d\n", foo);
```

and still conform. This notation is thus somewhat like *scanf()* in addition to *printf()*.

The *printf()* function was chosen as a model because most of the standard developers were familiar with it. One difference from the C function *printf()* is that the *l* and *h* conversion specifier characters are not used. As expressed by the Shell and Utilities volume of POSIX.1-2008, there is no differentiation between decimal values for type **int**, type **long**, or type **short**. The conversion specifications *%d* or *%i* should be interpreted as an arbitrary length sequence of digits. Also, no distinction is made between single precision and double precision numbers (**float** or **double** in C). These are simply referred to as floating-point numbers.

Many of the output descriptions in the Shell and Utilities volume of POSIX.1-2008 use the term "line", such as:

```
"%s", <input line>
```

Since the definition of *line* includes the trailing <newline> already, there is no need to include a '\n' in the format; a double <newline> would otherwise result.

## A.6 Character Set

### A.6.1 Portable Character Set

The portable character set is listed in full so there is no dependency on the ISO/IEC 646:1991 standard (or historically ASCII) encoded character set, although the set is identical to the characters defined in the International Reference version of the ISO/IEC 646:1991 standard.

POSIX.1-2008 poses no requirement that multiple character sets or codesets be supported, leaving this as a marketing differentiation for implementors. Although multiple charmap files are supported, it is the responsibility of the implementation to provide the file(s); if only one is provided, only that one will be accessible using the *localedef -f* option.

The statement about invariance in codesets for the portable character set is worded to avoid precluding implementations where multiple incompatible codesets are available (for instance, ASCII and EBCDIC). The standard utilities cannot be expected to produce predictable results if they access portable characters that vary on the same implementation.

Not all character sets need include the portable character set, but each locale must include it. For

117500 example, a Japanese-based locale might be supported by a mixture of character sets: JIS X 0201  
 117501 Roman (a Japanese version of the ISO/IEC 646:1991 standard), JIS X 0208, and JIS X 0201  
 117502 Katakana. Not all of these character sets include the portable characters, but at least one does  
 117503 (JIS X 0201 Roman).

## 117504 **A.6.2 Character Encoding**

117505 Encoding mechanisms based on single shifts, such as the EUC encoding used in some Asian and  
 117506 other countries, can be supported via the current charmap mechanism. With single-shift  
 117507 encoding, each character is preceded by a shift code (SS2 or SS3). A complete EUC code,  
 117508 consisting of the portable character set (G0) and up to three additional character sets (G1, G2,  
 117509 G3), can be described using the current charmap mechanism; the encoding for each character in  
 117510 additional character sets G2 and G3 must then include their single-shift code. Other mechanisms  
 117511 to support locales based on encoding mechanisms such as locking shift are not addressed by this  
 117512 volume of POSIX.1-2008.

117513 The encodings for <slash> and <period> are required to be the same across all locales, in part +  
 117514 because pathname resolution requires recognition of these bytes. It is a fortunate accident that all +  
 117515 common shift-based encodings did not use either <slash> or <period> as a valid second byte in +  
 117516 a multi-byte character.

## 117517 **A.6.3 C Language Wide-Character Codes**

117518 The standard does not specify how wide characters are encoded or provide a method for  
 117519 defining wide characters in a charmap. It specifies ways of translating between wide characters  
 117520 and multi-byte characters. The standard does not prevent an extension from providing a method  
 117521 to define wide characters.

117522 IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/13 is applied, adding a statement that the  
 117523 standard has no means of defining a wide-character codeset.

## 117524 **A.6.4 Character Set Description File**

117525 IEEE PASC Interpretation 1003.2 #196 is applied, removing three lines of text dealing with  
 117526 ranges of symbolic names using position constant values which had been erroneously included  
 117527 in the final IEEE P1003.2b draft standard.

117528 IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/14 is applied, correcting the example and  
 117529 adding a statement that the standard provides no means of defining a wide-character codeset.

117530 IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/15 is applied, allowing the value zero for  
 117531 the width value of **WIDTH** and **WIDTH\_DEFAULT**. This is required to cover some existing  
 117532 locales.

### 117533 *A.6.4.1 State-Dependent Character Encodings*

117534 A requirement was considered that would force utilities to eliminate any redundant locking  
 117535 shifts, but this was left as a quality of implementation issue.

117536 This change satisfies the following requirement from the ISO POSIX-2:1993 standard, Annex  
 117537 H.1:

117538 The support of state-dependent (shift encoding) character sets should be addressed fully. See  
 117539 descriptions of these in XBD [Section 6.2](#) (on page 128). If such character encodings are supported,  
 117540 it is expected that this will impact XBD [Section 6.2](#) (on page 128), [Chapter 7](#) (on page 135),  
 117541 [Chapter 9](#) (on page 181), and the *comm*, *cut*, *diff*, *grep*, *head*, *join*, *paste*, and *tail* utilities.

117542 The character set description file provides:

- 117543 • The capability to describe character set attributes (such as collation order or character  
 117544 classes) independent of character set encoding, and using only the characters in the  
 117545 portable character set. This makes it possible to create generic *localedef* source files for all  
 117546 codesets that share the portable character set (such as the ISO 8859 family or IBM Extended  
 117547 ASCII).
- 117548 • Standardized symbolic names for all characters in the portable character set, making it  
 117549 possible to refer to any such character regardless of encoding.

117550 Implementations are free to choose their own symbolic names, as long as the names identified  
 117551 by the Base Definitions volume of POSIX.1-2008 are also defined; this provides support for  
 117552 already existing “character names”.

117553 The names selected for the members of the portable character set follow the  
 117554 ISO/IEC 8859-1:1998 standard and the ISO/IEC 10646-1:2000 standard. However, several  
 117555 commonly used UNIX system names occur as synonyms in the list:

- 117556 • The historical UNIX system names are used for control characters.
- 117557 • The word “slash” is given in addition to “solidus”.
- 117558 • The word “backslash” is given in addition to “reverse-solidus”.
- 117559 • The word “hyphen” is given in addition to “hyphen-minus”.
- 117560 • The word “period” is given in addition to “full-stop”.
- 117561 • For digits, the word “digit” is eliminated.
- 117562 • For letters, the words “Latin Capital Letter” and “Latin Small Letter” are eliminated.
- 117563 • The words “left brace” and “right brace” are given in addition to “left-curly-bracket” and  
 117564 “right-curly-bracket”.
- 117565 • The names of the digits are preferred over the numbers to avoid possible confusion  
 117566 between ‘0’ and ‘o’, and between ‘1’ and ‘l’ (one and the letter ell).

117567 The names for the control characters in XBD [Chapter 6](#) (on page 125) were taken from the  
 117568 ISO/IEC 4873: 1991 standard.

117569 The charmap file was introduced to resolve problems with the portability of, especially, *localedef*  
 117570 sources. POSIX.1-2008 assumes that the portable character set is constant across all locales, but  
 117571 does not prohibit implementations from supporting two incompatible codings, such as both  
 117572 ASCII and EBCDIC. Such dual-support implementations should have all charmaps and *localedef*  
 117573 sources encoded using one portable character set, in effect cross-compiling for the other  
 117574 environment. Naturally, charmaps (and *localedef* sources) are only portable without  
 117575 transformation between systems using the same encodings for the portable character set. They  
 117576 can, however, be transformed between two sets using only a subset of the actual characters (the  
 117577 portable character set). However, the particular coded character set used for an application or an  
 117578 implementation does not necessarily imply different characteristics or collation; on the contrary,  
 117579 these attributes should in many cases be identical, regardless of codeset. The charmap provides  
 117580 the capability to define a common locale definition for multiple codesets (the same *localedef*  
 117581 source can be used for codesets with different extended characters; the ability in the charmap to

- 117582 define empty names allows for characters missing in certain codesets).
- 117583 The **<escape\_char>** declaration was added at the request of the international community to ease  
 117584 the creation of portable charmap files on terminals not implementing the default  
 117585 **<backslash>-escape**. The **<comment\_char>** declaration was added at the request of the  
 117586 international community to eliminate the potential confusion between the **<number-sign>** and  
 117587 the hash sign.
- 117588 The octal number notation with no leading zero required was selected to match those of *awk* and  
 117589 *tr* and is consistent with that used by *localedef*. To avoid confusion between an octal constant and  
 117590 the back-references used in *localedef* source, the octal, hexadecimal, and decimal constants must  
 117591 contain at least two digits. As single-digit constants are relatively rare, this should not impose  
 117592 any significant hardship. Provision is made for more digits to account for systems in which the  
 117593 byte size is larger than 8 bits. For example, a Unicode (ISO/IEC 10646-1:2000 standard) system  
 117594 that has defined 16-bit bytes may require six octal, four hexadecimal, and five decimal digits.
- 117595 The decimal notation is supported because some newer international standards define character  
 117596 values in decimal, rather than in the old column/row notation.
- 117597 The charmap identifies the coded character sets supported by an implementation. At least one  
 117598 charmap must be provided, but no implementation is required to provide more than one.  
 117599 Likewise, implementations can allow users to generate new charmaps (for instance, for a new  
 117600 version of the ISO 8859 family of coded character sets), but does not have to do so. If users are  
 117601 allowed to create new charmaps, the system documentation describes the rules that apply (for  
 117602 instance, “only coded character sets that are supersets of the ISO/IEC 646:1991 standard IRV, no  
 117603 multi-byte characters”).
- 117604 This addition of the **WIDTH** specification satisfies the following requirement from the  
 117605 ISO POSIX-2:1993 standard, Annex H.1:
- 117606 (9) *The definition of column position relies on the implementation’s knowledge of the integral*  
 117607 *width of the characters. The charmap or LC\_CTYPE locale definitions should be enhanced to*  
 117608 *allow application specification of these widths.*
- 117609 The character “width” information was first considered for inclusion under *LC\_CTYPE* but was  
 117610 moved because it is more closely associated with the information in the charmap than  
 117611 information in the locale source (cultural conventions information). Concerns were raised that  
 117612 formalizing this type of information is moving the locale source definition from the codeset-  
 117613 independent entity that it was designed to be to a repository of codeset-specific information. A  
 117614 similar issue occurred with the **<code\_set\_name>**, **<mb\_cur\_max>**, and **<mb\_cur\_min>**  
 117615 information, which was resolved to reside in the charmap definition.
- 117616 The width definition was added to the IEEE P1003.2b draft standard with the intent that the  
 117617 *wcswidth()* and/or *wcwidth()* functions (currently specified in the System Interfaces volume of  
 117618 POSIX.1-2008) be the mechanism to retrieve the character width information.

## 117619 A.7 Locale

### 117620 A.7.1 General

117621 The description of locales is based on work performed in the UniForum Technical Committee,  
117622 Subcommittee on Internationalization. Wherever appropriate, keywords are taken from the  
117623 ISO C standard or the X/Open Portability Guide.

117624 The value used to specify a locale with environment variables is the name specified as the *name*  
117625 operand to the *localedef* utility when the locale was created. This provides a verifiable method to  
117626 create and invoke a locale.

117627 The “object” definitions need not be portable, as long as “source” definitions are. Strictly  
117628 speaking, source definitions are portable only between implementations using the same  
117629 character set(s). Such source definitions, if they use symbolic names only, easily can be ported  
117630 between systems using different codesets, as long as the characters in the portable character set  
117631 (see XBD [Section 6.1](#), on page 125) have common values between the codesets; this is frequently  
117632 the case in historical implementations. Of source, this requires that the symbolic names used for  
117633 characters outside the portable character set be identical between character sets. The definition  
117634 of symbolic names for characters is outside the scope of POSIX.1-2008, but is certainly within the  
117635 scope of other standards organizations.

117636 Applications can select the desired locale by invoking the *setlocale()* function (or equivalent)  
117637 with the appropriate value. If the function is invoked with an empty string, the value of the  
117638 corresponding environment variable is used. If the environment variable is not set or is set to the  
117639 empty string, the implementation sets the appropriate environment as defined in XBD [Chapter 8](#)  
117640 (on page 173).

### 117641 A.7.2 POSIX Locale

117642 The POSIX locale is equal to the C locale. To avoid being classified as a C-language function, the  
117643 name has been changed to the POSIX locale; the environment variable value can be either  
117644 "POSIX" or, for historical reasons, "C".

117645 The POSIX definitions mirror the historical UNIX system behavior.

117646 The use of symbolic names for characters in the tables does not imply that the POSIX locale must  
117647 be described using symbolic character names, but merely that it may be advantageous to do so.

### 117648 A.7.3 Locale Definition

117649 The decision to separate the file format from the *localedef* utility description was only partially  
117650 editorial. Implementations may provide other interfaces than *localedef*. Requirements on “the  
117651 utility”, mostly concerning error messages, are described in this way because they are meant to  
117652 affect the other interfaces implementations may provide as well as *localedef*.

117653 The text about POSIX2\_LOCALEDEF does not mean that internationalization is optional; only  
117654 that the functionality of the *localedef* utility is. REs, for instance, must still be able to recognize,  
117655 for example, character class expressions such as "[[:alpha:]]". A possible analogy is with  
117656 an applications development environment; while all conforming implementations must be  
117657 capable of executing applications, not all need to have the development environment installed.  
117658 The assumption is that the capability to modify the behavior of utilities (and applications) via

locale settings must be supported. If the *localedef* utility is not present, then the only choice is to select an existing (presumably implementation-documented) locale. An implementation could, for example, choose to support only the POSIX locale, which would in effect limit the amount of changes from historical implementations quite drastically. The *localedef* utility is still required, but would always terminate with an exit code indicating that no locale could be created. Supported locales must be documented using the syntax defined in this chapter. (This ensures that users can accurately determine what capabilities are provided. If the implementation decides to provide additional capabilities to the ones in this chapter, that is already provided for.)

If the option is present (that is, locales can be created), then the *localedef* utility must be capable of creating locales based on the syntax and rules defined in this chapter. This does not mean that the implementation cannot also provide alternate means for creating locales.

The octal, decimal, and hexadecimal notations are the same employed by the charmap facility (see XBD Section 6.4, on page 129). To avoid confusion between an octal constant and a back-reference, the octal, hexadecimal, and decimal constants must contain at least two digits. As single-digit constants are relatively rare, this should not impose any significant hardship. Provision is made for more digits to account for systems in which the byte size is larger than 8 bits. For example, a Unicode (see the ISO/IEC 10646-1:2000 standard) system that has defined 16-bit bytes may require six octal, four hexadecimal, and five decimal digits. As with the charmap file, multi-byte characters are described in the locale definition file using “big-endian” notation for reasons of portability. There is no requirement that the internal representation in the computer memory be in this same order.

One of the guidelines used for the development of this volume of POSIX.1-2008 is that characters outside the invariant part of the ISO/IEC 646:1991 standard should not be used in portable specifications. The <backslash> character is not in the invariant part; the <number-sign> is, but with multiple representations: as a <number-sign>, and as a hash sign. As far as general usage of these symbols, they are covered by the “grandfather clause”, but for newly defined interfaces, the WG15 POSIX working group has requested that POSIX provide alternate representations. Consequently, while the default escape character remains the <backslash> and the default comment character is the <number-sign>, implementations are required to recognize alternative representations, identified in the applicable source file via the <escape\_char> and <comment\_char> keywords.

#### A.7.3.1 LC\_CTYPE

The *LC\_CTYPE* category is primarily used to define the encoding-independent aspects of a character set, such as character classification. In addition, certain encoding-dependent characteristics are also defined for an application via the *LC\_CTYPE* category. POSIX.1-2008 does not mandate that the encoding used in the locale is the same as the one used by the application because an implementation may decide that it is advantageous to define locales in a system-wide encoding rather than having multiple, logically identical locales in different encodings, and to convert from the application encoding to the system-wide encoding on usage. Other implementations could require encoding-dependent locales.

In either case, the *LC\_CTYPE* attributes that are directly dependent on the encoding, such as <mb\_cur\_max> and the display width of characters, are not user-specifiable in a locale source and are consequently not defined as keywords.

Implementations may define additional keywords or extend the *LC\_CTYPE* mechanism to allow application-defined keywords.

The text “The ellipsis specification shall only be valid within a single encoded character set” is present because it is possible to have a locale supported by multiple character encodings, as

117707 explained in the rationale for XBD [Section 6.1](#) (on page 125). An example given there is of a  
 117708 possible Japanese-based locale supported by a mixture of the character sets JIS X 0201 Roman,  
 117709 JIS X 0208, and JIS X 0201 Katakana. Attempting to express a range of characters across these sets  
 117710 is not logical and the implementation is free to reject such attempts.

117711 As the `LC_CTYPE` character classes are based on the ISO C standard character class definition,  
 117712 the category does not support multi-character elements. For instance, the German character  
 117713 <sharp-s> is traditionally classified as a lowercase letter. There is no corresponding uppercase  
 117714 letter; in proper capitalization of German text, the <sharp-s> will be replaced by "SS"; that is, by  
 117715 two characters. This kind of conversion is outside the scope of the **toupper** and **tolower**  
 117716 keywords.

117717 Where POSIX.1-2008 specifies that only certain characters can be specified, as for the keywords  
 117718 **digit** and **xdigit**, the specified characters must be from the portable character set, as shown. As  
 117719 an example, only the Arabic digits 0 through 9 are acceptable as digits.

117720 The character classes **digit**, **xdigit**, **lower**, **upper**, and **space** have a set of automatically included  
 117721 characters. These only need to be specified if the character values (that is, encoding) differs from  
 117722 the implementation default values. It is not possible to define a locale without these  
 117723 automatically included characters unless some implementation extension is used to prevent  
 117724 their inclusion. Such a definition would not be a proper superset of the C locale, and thus, it  
 117725 might not be possible for the standard utilities to be implemented as programs conforming to  
 117726 the ISO C standard.

117727 The definition of character class **digit** requires that only ten characters—the ones defining  
 117728 digits—can be specified; alternate digits (for example, Hindi or Kanji) cannot be specified here.  
 117729 However, the encoding may vary if an implementation supports more than one encoding.

117730 The definition of character class **xdigit** requires that the characters included in character class  
 117731 **digit** are included here also and allows for different symbols for the hexadecimal digits 10  
 117732 through 15.

117733 The inclusion of the **charclass** keyword satisfies the following requirement from the  
 117734 ISO POSIX-2: 1993 standard, Annex H.1:

117735 (3) *The `LC_CTYPE` (2.5.2.1) locale definition should be enhanced to allow user-specified additional*  
 117736 *character classes, similar in concept to the ISO C standard Multibyte Support Extension (MSE)*  
 117737 *`iswctype()` function.*

117738 This keyword was previously included in The Open Group specifications and is now mandated  
 117739 in the Shell and Utilities volume of POSIX.1-2008.

117740 The symbolic constant `{CHARCLASS_NAME_MAX}` was also adopted from The Open Group  
 117741 specifications. Applications portability is enhanced by the use of symbolic constants.

#### 117742 A.7.3.2 `LC_COLLATE`

117743 The rules governing collation depend to some extent on the use. At least five different levels of  
 117744 increasingly complex collation rules can be distinguished:

- 117745 1. *Byte/machine code order*: This is the historical collation order in the UNIX system and many  
 117746 proprietary operating systems. Collation is here performed character by character,  
 117747 without any regard to context. The primary virtue is that it usually is quite fast and also  
 117748 completely deterministic; it works well when the native machine collation sequence  
 117749 matches the user expectations.

2. *Character order*: On this level, collation is also performed character by character, without regard to context. The order between characters is, however, not determined by the code values, but on the expectations by the user of the “correct” order between characters. In addition, such a (simple) collation order can specify that certain characters collate equally (for example, uppercase and lowercase letters).
3. *String ordering*: On this level, entire strings are compared based on relatively straightforward rules. Several “passes” may be required to determine the order between two strings. Characters may be ignored in some passes, but not in others; the strings may be compared in different directions; and simple string substitutions may be performed before strings are compared. This level is best described as “dictionary” ordering; it is based on the spelling, not the pronunciation, or meaning, of the words.
4. *Text search ordering*: This is a further refinement of the previous level, best described as “telephone book ordering”; some common homonyms (words spelled differently but with the same pronunciation) are collated together; numbers are collated as if they were spelled out, and so on.
5. *Semantic-level ordering*: Words and strings are collated based on their meaning; entire words (such as “the”) are eliminated; the ordering is not deterministic. This usually requires special software and is highly dependent on the intended use.

While the historical collation order formally is at level 1, for the English language it corresponds roughly to elements at level 2. The user expects to see the output from the *ls* utility sorted very much as it would be in a dictionary. While telephone book ordering would be an optimal goal for standard collation, this was ruled out as the order would be language-dependent. Furthermore, a requirement was that the order must be determined solely from the text string and the collation rules; no external information (for example, “pronunciation dictionaries”) could be required.

As a result, the goal for the collation support is at level 3. This also matches the requirements for the Canadian collation order, as well as other, known collation requirements for alphabetic scripts. It specifically rules out collation based on pronunciation rules or based on semantic analysis of the text.

The syntax for the *LC\_COLLATE* category source meets the requirements for level 3 and has been verified to produce the correct result with examples based on French, Canadian, and Danish collation order. Because it supports multi-character collating elements, it is also capable of supporting collation in codesets where a character is expressed using non-spacing characters followed by the base character (such as the ISO/IEC 6937: 2001 standard).

The directives that can be specified in an operand to the **order\_start** keyword are based on the requirements specified in several proposed standards and in customary use. The following is a rephrasing of rules defined for “lexical ordering in English and French” by the Canadian Standards Association (the text in square brackets is rephrased):

- Once special characters [punctuation] have been removed from original strings, the ordering is determined by scanning forwards (left to right) [disregarding case and diacriticals].
- In case of equivalence, special characters are once again removed from original strings and the ordering is determined by scanning backwards (starting from the rightmost character of the string and back), character by character [disregarding case but considering diacriticals].
- In case of repeated equivalence, special characters are removed again from original strings and the ordering is determined by scanning forwards, character by character [considering both case and diacriticals].

- If there is still an ordering equivalence after the first three rules have been applied, then only special characters and the position they occupy in the string are considered to determine ordering. The string that has a special character in the lowest position comes first. If two strings have a special character in the same position, the character [with the lowest collation value] comes first. In case of equality, the other special characters are considered until there is a difference or until all special characters have been exhausted.

It is estimated that this part of POSIX.1-2008 covers the requirements for all European languages, and no particular problems are anticipated with Slavic or Middle East character sets.

The Far East (particularly Japanese/Chinese) collations are often based on contextual information and pronunciation rules (the same ideogram can have different meanings and different pronunciations). Such collation, in general, falls outside the desired goal of POSIX.1-2008. There are, however, several other collation rules (stroke/radical or “most common pronunciation”) that can be supported with the mechanism described here.

The character order is defined by the order in which characters and elements are specified between the **order\_start** and **order\_end** keywords. Weights assigned to the characters and elements define the collation sequence; in the absence of weights, the character order is also the collation sequence.

The **position** keyword provides the capability to consider, in a compare, the relative position of characters not subject to **IGNORE**. As an example, consider the two strings "o-ring" and "or-ing". Assuming the <hyphen> is subject to **IGNORE** on the first pass, the two strings compare equal, and the position of the <hyphen> is immaterial. On second pass, all characters except the <hyphen> are subject to **IGNORE**, and in the normal case the two strings would again compare equal. By taking position into account, the first collates before the second.

#### 117821 A.7.3.3 LC\_MONETARY

The currency symbol does not appear in *LC\_MONETARY* because it is not defined in the C locale of the ISO C standard.

The ISO C standard limits the size of decimal points and thousands delimiters to single-byte values. In locales based on multi-byte coded character sets, this cannot be enforced; POSIX.1-2008 does not prohibit such characters, but makes the behavior unspecified (in the text “In contexts where other standards ...”).

The grouping specification is based on, but not identical to, the ISO C standard. The -1 indicates that no further grouping is performed; the equivalent of {CHAR\_MAX} in the ISO C standard.

The text “the value is not available in the locale” is taken from the ISO C standard and is used instead of the “unspecified” text in early proposals. There is no implication that omitting these keywords or assigning them values of " " or -1 produces unspecified results; such omissions or assignments eliminate the effects described for the keyword or produce zero-length strings, as appropriate.

The locale definition is an extension of the ISO C standard *localeconv()* specification. In particular, rules on how **currency\_symbol** is treated are extended to also cover **int\_curr\_symbol**, and **p\_set\_by\_space** and **n\_sep\_by\_space** have been augmented with the value 2, which places a <space> between the sign and the symbol. This has been updated to match the ISO/IEC 9899: 1999 standard requirements and is an incompatible change from UNIX 98 and the ISO POSIX-2 standard and the ISO POSIX-1: 1996 standard requirements. The following table shows the result of various combinations:

|                          |                        | <b>p_sep_by_space</b> |           |          |
|--------------------------|------------------------|-----------------------|-----------|----------|
|                          |                        | <b>2</b>              | <b>1</b>  | <b>0</b> |
| <b>p_cs_precedes = 1</b> | <b>p_sign_posn = 0</b> | (\$1.25)              | (\$ 1.25) | (\$1.25) |
|                          | <b>p_sign_posn = 1</b> | + \$1.25              | +\$ 1.25  | +\$1.25  |
|                          | <b>p_sign_posn = 2</b> | \$1.25 +              | \$ 1.25+  | \$1.25+  |
|                          | <b>p_sign_posn = 3</b> | + \$1.25              | +\$ 1.25  | +\$1.25  |
|                          | <b>p_sign_posn = 4</b> | \$ +1.25              | \$+ 1.25  | \$+1.25  |
| <b>p_cs_precedes = 0</b> | <b>p_sign_posn = 0</b> | (1.25 \$)             | (1.25 \$) | (1.25\$) |
|                          | <b>p_sign_posn = 1</b> | +1.25 \$              | +1.25 \$  | +1.25\$  |

|                          | <b>p_sign_posn = 3</b> | 1.25+ \$              | 1.25 +\$  | 1.25+\$  |
|                          | <b>p_sign_posn = 4</b> | 1.25\$ +              | 1.25 \$+  | 1.25\$+  |

The following is an example of the interpretation of the **mon\_grouping** keyword. Assuming that the value to be formatted is 123 456 789 and the **mon\_thousands\_sep** is <apostrophe>, then the following table shows the result. The third column shows the equivalent string in the ISO C standard that would be used by the *localeconv()* function to accommodate this grouping.

| <b>mon_grouping</b> | <b>Formatted Value</b> | <b>ISO C String</b> |
|---------------------|------------------------|---------------------|
| 3;-1                | 123456'789             | "\3\177"            |
| 3                   | 123'456'789            | "\3"                |
| 3;2;-1              | 1234'56'789            | "\3\2\177"          |
| 3;2                 | 12'34'56'789           | "\3\2"              |
| -1                  | 123456789              | "\177"              |

In these examples, the octal value of {CHAR\_MAX} is 177.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/6 adds a correction that permits the Euro currency symbol and addresses extensibility. The correction is stated using the term “should” intentionally, in order to make this a recommendation rather than a restriction on implementations. This allows for flexibility in implementations on how they handle future currency symbol additions.

IEEE Std 1003.1-2001/Cor 1-2002, tem XBD/TC1/D6/5 is applied, adding the **int\_[np]\_\*** values to the POSIX locale definition of *LC\_MONETARY*.

IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/16 is applied, updating the descriptions of **p\_sep\_by\_space**, **n\_sep\_by\_space**, **int\_p\_sep\_by\_space**, and **int\_n\_sep\_by\_space** to match the description of these keywords in the ISO C standard and the System Interfaces volume of POSIX.1-2008, *localeconv()*.

#### A.7.3.4 *LC\_NUMERIC*

See the rationale for *LC\_MONETARY* for a description of the behavior of grouping.

#### A.7.3.5 *LC\_TIME*

Although certain of the conversion specifications in the POSIX locale (such as the name of the month) are shown with initial capital letters, this need not be the case in other locales. Programs using these conversion specifications may need to adjust the capitalization if the output is going to be used at the beginning of a sentence.

The *LC\_TIME* descriptions of **abday**, **day**, **mon**, and **abmon** imply a Gregorian style calendar (7-day weeks, 12-month years, leap years, and so on). Formatting time strings for other types of

117885 calendars is outside the scope of POSIX.1-2008.

117886 While the ISO 8601:2004 standard numbers the weekdays starting with Monday, historical  
 117887 practice is to use the Sunday as the first day. Rather than change the order and introduce  
 117888 potential confusion, the days must be specified beginning with Sunday; previous references to  
 117889 "first day" have been removed. Note also that the Shell and Utilities volume of POSIX.1-2008  
 117890 *date* utility supports numbering compliant with the ISO 8601:2004 standard.

117891 As specified under *date* in the Shell and Utilities volume of POSIX.1-2008 and *strftime()* in the  
 117892 System Interfaces volume of POSIX.1-2008, the conversion specifications corresponding to the  
 117893 optional keywords consist of a modifier followed by a traditional conversion specification (for  
 117894 instance, %Ex). If the optional keywords are not supported by the implementation or are  
 117895 unspecified for the current locale, these modified conversion specifications are treated as the  
 117896 traditional conversion specifications. For example, assume the following keywords:

117897 alt\_digits "0th"; "1st"; "2nd"; "3rd"; "4th"; "5th"; \  
 117898 "6th"; "7th"; "8th"; "9th"; "10th"

117899 d\_fmt "The %Od day of %B in %Y"

117900 On July 4th 1776, the %x conversion specifications would result in "The 4th day of July  
 117901 in 1776", while on July 14th 1789 it would result in "The 14 day of July in 1789". It  
 117902 can be noted that the above example is for illustrative purposes only; the %O modifier is  
 117903 primarily intended to provide for Kanji or Hindi digits in *date* formats.

117904 The following is an example for Japan that supports the current plus last three Emperors and  
 117905 reverts to Western style numbering for years prior to the Meiji era. The example also allows for  
 117906 the custom of using a special name for the first year of an era instead of using 1. (The examples  
 117907 substitute romaji where kanji should be used.)

117908 era\_d\_fmt "%EY%mgatsu%dnichi (%a)"

117909 era "+:2:1990/01/01:+\*:Heisei:%EC%Eynen";\  
 117910 "+:1:1989/01/08:1989/12/31:Heisei:%ECgannen";\  
 117911 "+:2:1927/01/01:1989/01/07:Shouwa:%EC%Eynen";\  
 117912 "+:1:1926/12/25:1926/12/31:Shouwa:%ECgannen";\  
 117913 "+:2:1913/01/01:1926/12/24:Taishou:%EC%Eynen";\  
 117914 "+:1:1912/07/30:1912/12/31:Taishou:%ECgannen";\  
 117915 "+:2:1869/01/01:1912/07/29:Meiji:%EC%Eynen";\  
 117916 "+:1:1868/09/08:1868/12/31:Meiji:%ECgannen";\  
 117917 "-:1868:1868/09/07:-\*::%Ey"

117918 Assuming that the current date is September 21, 1991, a request to *date* or *strftime()* would yield  
 117919 the following results:

117920 %Ec - Heisei3nen9gatsu2lnichi (Sat) 14:39:26  
 117921 %EC - Heisei  
 117922 %Ex - Heisei3nen9gatsu2lnichi (Sat)  
 117923 %Ey - 3  
 117924 %EY - Heisei3nen

117925 Example era definitions for the Republic of China:

117926 era "+:2:1913/01/01:+\*:ChungHwaMingGuo:%EC%EyNen";\  
 117927 "+:1:1912/1/1:1912/12/31:ChungHwaMingGuo:%ECYuenNen";\  
 117928 "+:1:1911/12/31:-\*:MingChien:%EC%EyNen"

117929 Example definitions for the Christian Era:

117930 era "+:1:0001/01/01:+\*:AD:%EC %Ey";\  
 117931 "-:0:0000/01/01:-\*:BC:%EC %Ey";\

|        |                                                                                                                 |   |
|--------|-----------------------------------------------------------------------------------------------------------------|---|
| 117931 | "+:1:-0001/12/31:-*:BC:%Ey %EC"                                                                                 |   |
| 117932 | A.7.3.6 LC_MESSAGES                                                                                             |   |
| 117933 | The <b>yesstr</b> and <b>nostr</b> locale keywords and the YESSTR and NOSTR <i>langinfo</i> items were formerly |   |
| 117934 | used to match user affirmative and negative responses. In POSIX.1-2008, the <b>yesexpr</b> , <b>noexpr</b> ,    |   |
| 117935 | YESEXPR, and NOEXPR extended regular expressions have replaced them. Applications                               |   |
| 117936 | should use the general locale-based messaging facilities to issue prompting messages which                      |   |
| 117937 | include sample desired responses.                                                                               |   |
| 117938 | Affirmative responses like:                                                                                     | + |
| 117939 | y                                                                                                               | + |
| 117940 | Yes                                                                                                             | + |
| 117941 | Yes!                                                                                                            | + |
| 117942 | and negative responses like:                                                                                    | + |
| 117943 | N                                                                                                               | + |
| 117944 | No                                                                                                              | + |
| 117945 | Never                                                                                                           | + |
| 117946 | No way!                                                                                                         | + |
| 117947 | should all be recognized as affirmative and negative responses, respectively, by the EREs                       | + |
| 117948 | identified by the <b>yesexpr</b> and <b>noexpr</b> keywords for English language-based locales. There is no     | + |
| 117949 | requirement that multi-line responses nor ambiguous responses like:                                             | + |
| 117950 | no or yes                                                                                                       | + |
| 117951 | yes or no                                                                                                       | + |
| 117952 | maybe                                                                                                           | + |
| 117953 | be correctly classified by either of these EREs. Application writers are encouraged to include                  | + |
| 117954 | locale-specific suggestions for affirmative and negative responses in prompts.                                  |   |
| 117955 | A.7.4 Locale Definition Grammar                                                                                 |   |
| 117956 | There is no additional rationale provided for this section.                                                     |   |
| 117957 | A.7.4.1 Locale Lexical Conventions                                                                              |   |
| 117958 | There is no additional rationale provided for this section.                                                     |   |
| 117959 | A.7.4.2 Locale Grammar                                                                                          |   |
| 117960 | There is no additional rationale provided for this section.                                                     |   |

117961 **A.7.5 Locale Definition Example**

117962 The following is an example of a locale definition file that could be used as input to the *localedf*  
 117963 utility. It assumes that the utility is executed with the *-f* option, naming a charmap file with (at  
 117964 least) the following content:

```
117965 CHARMAP
117966 <space> \x20
117967 <dollar> \x24
117968 <A> \101
117969 <a> \141
117970 <A-acute> \346
117971 <a-acute> \365
117972 <A-grave> \300
117973 <a-grave> \366
117974 \142
117975 <C> \103
117976 <c> \143
117977 <c-cedilla> \347
117978 <d> \x64
117979 <H> \110
117980 <h> \150
117981 <eszet> \xb7
117982 <s> \x73
117983 <z> \x7a
117984 END CHARMAP
```

117985 It should not be taken as complete or to represent any actual locale, but only to illustrate the  
 117986 syntax.

```
117987 #
117988 LC_CTYPE
117989 lower <a>;;<c>;<c-cedilla>;<d>;...;<z>
117990 upper A;B;C;Ç;...;Z
117991 space \x20;\x09;\x0a;\x0b;\x0c;\x0d
117992 blank \040;\011
117993 toupper (<a>,<A>);(b,B);(c,C);(ç,Ç);(d,D);(z,Z)
117994 END LC_CTYPE
117995 #
117996 LC_COLLATE
117997 #
117998 # The following example of collation is based on
117999 # Canadian standard Z243.4.1-1998, "Canadian Alphanumeric
118000 # Ordering Standard for Character Sets of CSA Z234.4 Standard".
118001 # (Other parts of this example locale definition file do not
118002 # purport to relate to Canada, or to any other real culture.)
118003 # The proposed standard defines a 4-weight collation, such that
118004 # in the first pass, characters are compared without regard to
118005 # case or accents; in the second pass, backwards-compare without
118006 # regard to case; in the third pass, forwards-compare without
118007 # regard to diacriticals. In the 3 first passes, non-alphabetic
118008 # characters are ignored; in the fourth pass, only special
118009 # characters are considered, such that "The string that has a
118010 # special character in the lowest position comes first. If two
118011 # strings have a special character in the same position, the
```

```

118012 # collation value of the special character determines ordering.
118013 #
118014 # Only a subset of the character set is used here; mostly to
118015 # illustrate the set-up.
118016 #
118017 collating-symbol <NULL>
118018 collating-symbol <LOW_VALUE>
118019 collating-symbol <LOWER-CASE>
118020 collating-symbol <SUBSCRIPT-LOWER>
118021 collating-symbol <SUPERScript-LOWER>

## 118135 A.8 Environment Variables

### 118136 A.8.1 Environment Variable Definition

118137 The variable *environ* is not intended to be declared in any header, but rather to be declared by  
 118138 the user for accessing the array of strings that is the environment. This is the traditional usage of  
 118139 the symbol. Putting it into a header could break some programs that use the symbol for their  
 118140 own purposes.

118141 The decision to restrict conforming systems to the use of digits, uppercase letters, and  
 118142 underscores for environment variable names allows applications to use lowercase letters in their  
 118143 environment variable names without conflicting with any conforming system.

118144 In addition to the obvious conflict with the shell syntax for positional parameter substitution,  
 118145 some historical applications (including some shells) exclude names with leading digits from the  
 118146 environment.

### 118147 A.8.2 Internationalization Variables

118148 Utilities conforming to the Shell and Utilities volume of POSIX.1-2008 and written in standard C  
 118149 can access the locale variables by issuing the following call:

```
118150 setlocale(LC_ALL, "")
```

118151 If this were omitted, the ISO C standard specifies that the C locale would be used.

118152 The DESCRIPTION of *setlocale()* requires that when setting all categories of a locale, if the value  
 118153 of any of the environment variable searches yields a locale that is not supported (and non-null),  
 118154 the *setlocale()* function returns a null pointer and the global locale is unchanged.

118155 For the standard utilities, if any of the environment variables are invalid, it makes sense to  
 118156 default to an implementation-defined, consistent locale environment. It is more confusing for a

user to have partial settings occur in case of a mistake. All utilities would then behave in one language/cultural environment. Furthermore, it provides a way of forcing the whole environment to be the implementation-defined default. Disastrous results could occur if a pipeline of utilities partially uses the environment variables in different ways. In this case, it would be appropriate for utilities that use *LANG* and related variables to exit with an error if any of the variables are invalid. For example, users typing individual commands at a terminal might want *date* to work if *LC\_MONETARY* is invalid as long as *LC\_TIME* is valid. Since these are conflicting reasonable alternatives, POSIX.1-2008 leaves the results unspecified if the locale environment variables would not produce a complete locale matching the specification of the user.

The locale settings of individual categories cannot be truly independent and still guarantee correct results. For example, when collating two strings, characters must first be extracted from each string (governed by *LC\_CTYPE*) before being mapped to collating elements (governed by *LC\_COLLATE*) for comparison. That is, if *LC\_CTYPE* is causing parsing according to the rules of a large, multi-byte code set (potentially returning 20 000 or more distinct character codeset values), but *LC\_COLLATE* is set to handle only an 8-bit codeset with 256 distinct characters, meaningful results are obviously impossible.

The *LC\_MESSAGES* variable affects the language of messages generated by the standard utilities.

The description of the environment variable names starting with the characters “LC\_” acknowledges the fact that the interfaces presented may be extended as new international functionality is required. In the ISO C standard, names preceded by “LC\_” are reserved in the name space for future categories.

To avoid name clashes, new categories and environment variables are divided into two classifications: “implementation-independent” and “implementation-defined”.

Implementation-independent names will have the following format:

*LC\_NAME*

where *NAME* is the name of the new category and environment variable. Capital letters must be used for implementation-independent names.

Implementation-defined names must be in lowercase letters, as below:

*LC\_name*

### A.8.3 Other Environment Variables

#### COLUMNS, LINES

The default values for the number of column positions, *COLUMNS*, and screen height, *LINES*, are unspecified because historical implementations use different methods to determine values corresponding to the size of the screen in which the utility is run. This size is typically known to the implementation through the value of *TERM*, or by more elaborate methods such as extensions to the *stty* utility or knowledge of how the user is dynamically resizing windows on a bit-mapped display terminal. Users should not need to set these variables in the environment unless there is a specific reason to override the default behavior of the implementation, such as to display data in an area arbitrarily smaller than the terminal or window. Values for these variables that are not decimal integers greater than zero are implicitly undefined values; it is unnecessary to enumerate all of the possible values outside of the acceptable set.

**LOGNAME**

In most implementations, the value of such a variable is easily forged, so security-critical applications should rely on other means of determining user identity. *LOGNAME* is required to be constructed from the portable filename character set for reasons of interchange. No diagnostic condition is specified for violating this rule, and no requirement for enforcement exists. The intent of the requirement is that if extended characters are used, the “guarantee” of portability implied by a standard is void.

**PATH**

Many historical implementations of the Bourne shell do not interpret a trailing <colon> to represent the current working directory and are thus non-conforming. The C Shell and the KornShell conform to POSIX.1-2008 on this point. The usual name of dot may also be used to refer to the current working directory.

Many implementations historically have used a default value of */bin* and */usr/bin* for the *PATH* variable. POSIX.1-2008 does not mandate this default path be identical to that retrieved from *getconf PATH* because it is likely that the standardized utilities may be provided in another directory separate from the directories used by some historical applications.

**SHELL**

The *SHELL* variable names the preferred shell of the user; it is a guide to applications. There is no direct requirement that that shell conform to POSIX.1-2008; that decision should rest with the user. It is the intention of the standard developers that alternative shells be permitted, if the user chooses to develop or acquire one. An operating system that builds its shell into the “kernel” in such a manner that alternative shells would be impossible does not conform to the spirit of POSIX.1-2008.

**TZ**

The quoted form of the timezone variable allows timezone names of the form UTC+1 (or any name that contains the character plus ('+'), the character minus ('-'), or digits), which may be appropriate for countries that do not have an official timezone name. It would be coded as <UTC+1>+1<UTC+2>, which would cause *std* to have a value of UTC+1 and *dst* a value of UTC+2, each with a length of 5 characters. This does not appear to conflict with any existing usage. The characters '<' and '>' were chosen for quoting because they are easier to parse visually than a quoting character that does not provide some sense of bracketing (and in a string like this, such bracketing is helpful). They were also chosen because they do not need special treatment when assigning to the *TZ* variable. Users are often confused by embedding quotes in a string. Because '<' and '>' are meaningful to the shell, the whole string would have to be quoted, but that is easily explained. (Parentheses would have presented the same problems.) Although the '>' symbol could have been permitted in the string by either escaping it or doubling it, it seemed of little value to require that. This could be provided as an extension if there was a need. Timezone names of this new form lead to a requirement that the value of {\_POSIX\_TZNAME\_MAX} change from 3 to 6.

Since the *TZ* environment variable is usually inherited by all applications started by a user after the value of the *TZ* environment variable is changed and since many applications run using the C or POSIX locale, using characters that are not in the portable character set in the *std* and *dst* fields could cause unexpected results.

The format of the *TZ* environment variable is changed in Issue 6 to allow for the quoted form, as defined in earlier versions of the ISO POSIX-1 standard.

IEEE Std 1003.1-2001/Cor 1-2002, item XBD/TC1/D6/7 is applied, adding the *ctime\_r()* and

118246 `localtime_r()` functions to the list of functions that use the *TZ* environment variable.

## 118247 **A.9 Regular Expressions**

118248 Rather than repeating the description of REs for each utility supporting REs, the standard  
 118249 developers preferred a common, comprehensive description of regular expressions in one place.  
 118250 The most common behavior is described here, and exceptions or extensions to this are  
 118251 documented for the respective utilities, as appropriate.

118252 The BRE corresponds to the *ed* or historical *grep* type, and the ERE corresponds to the historical  
 118253 *egrep* type (now *grep -E*).

118254 The text is based on the *ed* description and substantially modified, primarily to aid developers  
 118255 and others in the understanding of the capabilities and limitations of REs. Much of this was  
 118256 influenced by internationalization requirements.

118257 It should be noted that the definitions in this section do not cover the *tr* utility; the *tr* syntax does  
 118258 not employ REs.

118259 The specification of REs is particularly important to internationalization because pattern  
 118260 matching operations are very basic operations in business and other operations. The syntax and  
 118261 rules of REs are intended to be as intuitive as possible to make them easy to understand and use.  
 118262 The historical rules and behavior do not provide that capability to non-English language users,  
 118263 and do not provide the necessary support for commonly used characters and language  
 118264 constructs. It was necessary to provide extensions to the historical RE syntax and rules to  
 118265 accommodate other languages.

118266 As they are limited to bracket expressions, the rationale for these modifications is in XBD [Section](#)  
 118267 [9.3.5](#) (on page 184).

### 118268 **A.9.1 Regular Expression Definitions**

118269 It is possible to determine what strings correspond to subexpressions by recursively applying  
 118270 the leftmost longest rule to each subexpression, but only with the proviso that the overall match  
 118271 is leftmost longest. For example, matching "`\(ac*\\)c*d[ac]*\1`" against *acdacaaa* matches  
 118272 *acdacaaa* (with `\1=a`); simply matching the longest match for "`\(ac*\\)`" would yield `\1=ac`, but  
 118273 the overall match would be smaller (*acdac*). Conceptually, the implementation must examine  
 118274 every possible match and among those that yield the leftmost longest total matches, pick the one  
 118275 that does the longest match for the leftmost subexpression, and so on. Note that this means that  
 118276 matching by subexpressions is context-dependent: a subexpression within a larger RE may  
 118277 match a different string from the one it would match as an independent RE, and two instances of  
 118278 the same subexpression within the same larger RE may match different lengths even in similar  
 118279 sequences of characters. For example, in the ERE "`(a.*b)(a.*b)`", the two identical  
 118280 subexpressions would match four and six characters, respectively, of *acbbaccccb*.

118281 The definition of single character has been expanded to include also collating elements  
 118282 consisting of two or more characters; this expansion is applicable only when a bracket  
 118283 expression is included in the BRE or ERE. An example of such a collating element may be the  
 118284 Dutch *ij*, which collates as a 'y'. In some encodings, a ligature "i with j" exists as a character  
 118285 and would represent a single-character collating element. In another encoding, no such ligature  
 118286 exists, and the two-character sequence *ij* is defined as a multi-character collating element.  
 118287 Outside brackets, the *ij* is treated as a two-character RE and matches the same characters in a  
 118288 string. Historically, a bracket expression only matched a single character. The ISO POSIX-2: 1993

standard required bracket expressions like "[[:lower:]]" to match multi-character collating elements such as "ij". However, this requirement led to behavior that many users did not expect and that could not feasibly be mimicked in user code, and it was rarely if ever implemented correctly. The current standard leaves it unspecified whether a bracket expression matches a multi-character collating element, allowing both historical and ISO POSIX-2:1993 standard implementations to conform.

Also, in the current standard, it is unspecified whether character class expressions like "[[:lower:]]" can include multi-character collating elements like "ij"; hence "[[:lower:]]" can match "ij", and "[^[:lower:]]" can fail to match "ij". Common practice is for a character class expression to match a collating element if it matches the collating element's first character.

## A.9.2 Regular Expression General Requirements

The definition of which sequence is matched when several are possible is based on the leftmost-longest rule historically used by deterministic recognizers. This rule is easier to define and describe, and arguably more useful, than the first-match rule historically used by non-deterministic recognizers. It is thought that dependencies on the choice of rule are rare; carefully contrived examples are needed to demonstrate the difference.

A formal expression of the leftmost-longest rule is:

The search is performed as if all possible suffixes of the string were tested for a prefix matching the pattern; the longest suffix containing a matching prefix is chosen, and the longest possible matching prefix of the chosen suffix is identified as the matching sequence.

Historically, most RE implementations only match lines, not strings. However, that is more an effect of the usage than of an inherent feature of REs themselves. Consequently, POSIX.1-2008 does not regard <newline> characters as special; they are ordinary characters, and both a <period> and a non-matching list can match them. Those utilities (like *grep*) that do not allow <newline> characters to match are responsible for eliminating any <newline> from strings before matching against the RE. The *regcomp()* function, however, can provide support for such processing without violating the rules of this section.

Some implementations of *egrep* have had very limited flexibility in handling complex EREs. POSIX.1-2008 does not attempt to define the complexity of a BRE or ERE, but does place a lower limit on it—any RE must be handled, as long as it can be expressed in 256 bytes or less. (Of course, this does not place an upper limit on the implementation.) There are historical programs using a non-deterministic-recognizer implementation that should have no difficulty with this limit. It is possible that a good approach would be to attempt to use the faster, but more limited, deterministic recognizer for simple expressions and to fall back on the non-deterministic recognizer for those expressions requiring it. Non-deterministic implementations must be careful to observe the rules on which match is chosen; the longest match, not the first match, starting at a given character is used.

The term “invalid” highlights a difference between this section and some others: POSIX.1-2008 frequently avoids mandating of errors for syntax violations because they can be used by implementors to trigger extensions. However, the authors of the internationalization features of REs wanted to mandate errors for certain conditions to identify usage problems or non-portable constructs. These are identified within this rationale as appropriate. The remaining syntax violations have been left implicitly or explicitly undefined. For example, the BRE construct "{1,2,3}" does not comply with the grammar. A conforming application cannot rely on it producing an error nor matching the literal characters "{1,2,3}".

118336 The term “undefined” was used in favor of “unspecified” because many of the situations are  
 118337 considered errors on some implementations, and the standard developers considered that  
 118338 consistency throughout the section was preferable to mixing undefined and unspecified.

### 118339 **A.9.3 Basic Regular Expressions**

118340 There is no additional rationale provided for this section.

#### 118341 *A.9.3.1 BREs Matching a Single Character or Collating Element*

118342 There is no additional rationale provided for this section.

#### 118343 *A.9.3.2 BRE Ordinary Characters*

118344 There is no additional rationale provided for this section.

#### 118345 *A.9.3.3 BRE Special Characters*

118346 There is no additional rationale provided for this section.

#### 118347 *A.9.3.4 Periods in BREs*

118348 There is no additional rationale provided for this section.

#### 118349 *A.9.3.5 RE Bracket Expression*

118350 Range expressions are, historically, an integral part of REs. However, the requirements of  
 118351 “natural language behavior” and portability do conflict. In the POSIX locale, ranges must be  
 118352 treated according to the collating sequence and include such characters that fall within the range  
 118353 based on that collating sequence, regardless of character values. In other locales, ranges have  
 118354 unspecified behavior.

118355 Some historical implementations allow range expressions where the ending range point of one  
 118356 range is also the starting point of the next (for instance, "[a-m-o]"). This behavior should not  
 118357 be permitted, but to avoid breaking historical implementations, it is now *undefined* whether it is  
 118358 a valid expression and how it should be interpreted.

118359 Current practice in *awk* and *lex* is to accept escape sequences in bracket expressions as per XBD  
 118360 [Table 5-1](#) (on page 121), while the normal ERE behavior is to regard such a sequence as  
 118361 consisting of two characters. Allowing the *awk/lex* behavior in EREs would change the normal  
 118362 behavior in an unacceptable way; it is expected that *awk* and *lex* will decode escape sequences in  
 118363 EREs before passing them to *regcomp()* or comparable routines. Each utility describes the escape  
 118364 sequences it accepts as an exception to the rules in this section; the list is not the same, for  
 118365 historical reasons.

118366 As noted previously, the new syntax and rules have been added to accommodate other  
 118367 languages than English. The remainder of this section describes the rationale for these  
 118368 modifications.

118369 In the POSIX locale, a regular expression that starts with a range expression matches a set of  
 118370 strings that are contiguously sorted, but this is not necessarily true in other locales. For example,  
 118371 a French locale might have the following behavior:

```

118372 $ ls
118373 alpha Alpha estimé ESTIMÉ été eurêka
118374 $ ls [a-e]*
118375 alpha Alpha estimé eurêka

```

Such disagreements between matching and contiguous sorting are unavoidable because POSIX sorting cannot be implemented in terms of a deterministic finite-state automaton (DFA), but range expressions by design are implementable in terms of DFAs.

Historical implementations used native character order to interpret range expressions. The ISO POSIX-2:1993 standard instead required collating element order (CEO): the order that collating elements were specified between the **order\_start** and **order\_end** keywords in the *LC\_COLLATE* category of the current locale. CEO had some advantages in portability over the native character order, but it also had some disadvantages:

- CEO could not feasibly be mimicked in user code, leading to inconsistencies between POSIX matchers and matchers in popular user programs like Emacs, *ksh*, and Perl.
- CEO caused range expressions to match accented and capitalized letters contrary to many users' expectations. For example, "[a-e]" typically matched both 'É' and 'á' but neither 'A' nor 'é'.
- CEO was not consistent across implementations. In practice, CEO was often less portable than native character order. For example, it was common for the CEOs of two implementation-supplied locales to disagree, even if both locales were named "da\_DK".

Because of these problems, some implementations of regular expressions continued to use native character order. Others used the collation sequence, which is more consistent with sorting than either CEO or native order, but which departs further from the traditional POSIX semantics because it generally requires "[a-e]" to match either 'A' or 'E' but not both. As a result of this kind of implementation variation, programmers who wanted to write portable regular expressions could not rely on the ISO POSIX-2:1993 standard guarantees in practice.

While revising the standard, lengthy consideration was given to proposals to attack this problem by adding an API for querying the CEO to allow user-mode matchers, but none of these proposals had implementation experience and none achieved consensus. Leaving the standard alone was also considered, but rejected due to the problems described above.

The current standard leaves unspecified the behavior of a range expression outside the POSIX locale. This makes it clearer that conforming applications should avoid range expressions outside the POSIX locale, and it allows implementations and compatible user-mode matchers to interpret range expressions using native order, CEO, collation sequence, or other, more advanced techniques. The concerns which led to this change were raised in IEEE PASC interpretation 1003.2 #43 and others, and related to ambiguities in the specification of how multi-character collating elements should be handled in range expressions. These ambiguities had led to multiple interpretations of the specification, in conflicting ways, which led to varying implementations. As noted above, efforts were made to resolve the differences, but no solution has been found that would be specific enough to allow for portable software while not invalidating existing implementations.

The standard developers recognize that collating elements are important, such elements being common in several European languages; for example, 'ch' or 'll' in traditional Spanish; 'aa' in several Scandinavian languages. Existing internationalized implementations have processed, and continue to process, these elements in range expressions. Efforts are expected to continue in the future to find a way to define the behavior of these elements precisely and portably.

The ISO POSIX-2:1993 standard required "[b-a]" to be an invalid expression in the POSIX

118420 locale, but this requirement has been relaxed in this version of the standard so that "[b-a]" can  
 118421 instead be treated as a valid expression that does not match any string.

118422 The standard specifies three possible behaviors for regular expressions such as "[alpha:]". +  
 118423 One behavior is the traditional implementation, which behaves like "[ahlp]". Another, for +  
 118424 alignment with the *tr* utility, is to treat it like "[[:alpha:]]". And finally, the standard allows +  
 118425 rejecting the regular expression as invalid, as a means of alerting a user to the non-portable +  
 118426 aspect of that regular expression. The set of regular expressions with this undefined behavior is +  
 118427 limited solely to the expressions where the outer '[' and ']' of the bracket expression can be +  
 118428 confused with the missing bracket pair '[' and ']' necessary to form a collating symbol, +  
 118429 equivalence class, or character class; thus "[\_alpha:]" or "[::]" do not trigger the +  
 118430 unspecified behavior.

#### 118431 A.9.3.6 BREs Matching Multiple Characters

118432 The limit of nine back-references to subexpressions in the RE is based on the use of a single-digit  
 118433 identifier; increasing this to multiple digits would break historical applications. This does not  
 118434 imply that only nine subexpressions are allowed in REs. The following is a valid BRE with ten  
 118435 subexpressions:

```
118436 \(\(ab\) *c\) *d\) \(ef\) *\ (gh\) \{2\} \(ij\) *\ (kl\) *\ (mn\) *\ (op\) *\ (qr\) *
```

118437 The standard developers regarded the common historical behavior, which supported "\n\*", but  
 118438 not "\n{min,max\}", "\(...\)\*", or "\(...\){min,max\}", as a non-intentional  
 118439 result of a specific implementation, and they supported both duplication and interval  
 118440 expressions following subexpressions and back-references.

118441 The changes to the processing of the back-reference expression remove an unspecified or  
 118442 ambiguous behavior in the Shell and Utilities volume of POSIX.1-2008, aligning it with the  
 118443 requirements specified for the *regcomp()* expression, and is the result of PASC Interpretation  
 118444 1003.2-92 #43 submitted for the ISO POSIX-2: 1993 standard.

#### 118445 A.9.3.7 BRE Precedence

118446 There is no additional rationale provided for this section.

#### 118447 A.9.3.8 BRE Expression Anchoring

118448 Often, the <dollar-sign> is viewed as matching the ending <newline> in text files. This is not  
 118449 strictly true; the <newline> is typically eliminated from the strings to be matched, and the  
 118450 <dollar-sign> matches the terminating null character.

118451 The ability of '^', '\$', and '\*' to be non-special in certain circumstances may be confusing to  
 118452 some programmers, but this situation was changed only in a minor way from historical practice  
 118453 to avoid breaking many historical scripts. Some consideration was given to making the use of  
 118454 the anchoring characters undefined if not escaped and not at the beginning or end of strings.  
 118455 This would cause a number of historical BREs, such as "2^10", "\$HOME", and "\$1.35", that  
 118456 relied on the characters being treated literally, to become invalid.

118457 However, one relatively uncommon case was changed to allow an extension used on some  
 118458 implementations. Historically, the BREs "^foo" and "\(^foo\)" did not match the same  
 118459 string, despite the general rule that subexpressions and entire BREs match the same strings. To  
 118460 increase consensus, POSIX.1-2008 has allowed an extension on some implementations to treat  
 118461 these two cases in the same way by declaring that anchoring *may* occur at the beginning or end  
 118462 of a subexpression. Therefore, portable BREs that require a literal <circumflex> at the beginning

118463 or a <dollar-sign> at the end of a subexpression must escape them. Note that a BRE such as  
 118464 "a\ (^bc\ )" will either match "a^bc" or nothing on different systems under the rules.

118465 ERE anchoring has been different from BRE anchoring in all historical systems. An unescaped  
 118466 anchor character has never matched its literal counterpart outside a bracket expression. Some  
 118467 implementations treated "foo\$bar" as a valid expression that never matched anything; others  
 118468 treated it as invalid. POSIX.1-2008 mandates the former, valid unmatched behavior.

118469 Some implementations have extended the BRE syntax to add alternation. For example, the  
 118470 subexpression "\ (foo\$|bar\ )" would match either "foo" at the end of the string or "bar"  
 118471 anywhere. The extension is triggered by the use of the undefined "\|" sequence. Because the  
 118472 BRE is undefined for portable scripts, the extending system is free to make other assumptions,  
 118473 such that the '\$' represents the end-of-line anchor in the middle of a subexpression. If it were  
 118474 not for the extension, the '\$' would match a literal <dollar-sign> under the rules.

#### 118475 A.9.4 Extended Regular Expressions

118476 As with BREs, the standard developers decided to make the interpretation of escaped ordinary  
 118477 characters undefined.

118478 The <right-parenthesis> is not listed as an ERE special character because it is only special in the  
 118479 context of a preceding <left-parenthesis>. If found without a preceding <left-parenthesis>, the  
 118480 <right-parenthesis> has no special meaning.

118481 The interval expression, "{m, n}", has been added to EREs. Historically, the interval expression  
 118482 has only been supported in some ERE implementations. The standard developers estimated that  
 118483 the addition of interval expressions to EREs would not decrease consensus and would also make  
 118484 BREs more of a subset of EREs than in many historical implementations.

118485 It was suggested that, in addition to interval expressions, back-references ('\n') should also be  
 118486 added to EREs. This was rejected by the standard developers as likely to decrease consensus.

118487 In historical implementations, multiple duplication symbols are usually interpreted from left to  
 118488 right and treated as additive. As an example, "a+b" matches zero or more instances of 'a'  
 118489 followed by a 'b'. In POSIX.1-2008, multiple duplication symbols are undefined; that is, they  
 118490 cannot be relied upon for conforming applications. One reason for this is to provide some scope  
 118491 for future enhancements.

118492 The precedence of operations differs between EREs and those in *lex*; in *lex*, for historical reasons,  
 118493 interval expressions have a lower precedence than concatenation.

##### 118494 A.9.4.1 EREs Matching a Single Character or Collating Element

118495 There is no additional rationale provided for this section.

##### 118496 A.9.4.2 ERE Ordinary Characters

118497 There is no additional rationale provided for this section.

118498 A.9.4.3 *ERE Special Characters*

118499 There is no additional rationale provided for this section.

118500 A.9.4.4 *Periods in EREs*

118501 There is no additional rationale provided for this section.

118502 A.9.4.5 *ERE Bracket Expression*

118503 There is no additional rationale provided for this section.

118504 A.9.4.6 *EREs Matching Multiple Characters*

118505 There is no additional rationale provided for this section.

118506 A.9.4.7 *ERE Alternation*

118507 There is no additional rationale provided for this section.

118508 A.9.4.8 *ERE Precedence*

118509 There is no additional rationale provided for this section.

118510 A.9.4.9 *ERE Expression Anchoring*

118511 There is no additional rationale provided for this section.

118512 **A.9.5 Regular Expression Grammar**

118513 The grammars are intended to represent the range of acceptable syntaxes available to  
 118514 conforming applications. There are instances in the text where undefined constructs are  
 118515 described; as explained previously, these allow implementation extensions. There is no intended  
 118516 requirement that an implementation extension must somehow fit into the grammars shown  
 118517 here.

118518 The BRE grammar does not permit L\_ANCHOR or R\_ANCHOR inside "\ (" and "\ )" (which  
 118519 implies that '^' and '\$' are ordinary characters). This reflects the semantic limits on the  
 118520 application, as noted in XBD [Section 9.3.8](#) (on page 187). Implementations are permitted to  
 118521 extend the language to interpret '^' and '\$' as anchors in these locations, and as such,  
 118522 conforming applications cannot use unescaped '^' and '\$' in positions inside "\ (" and "\ )"   
 118523 that might be interpreted as anchors.

118524 The ERE grammar does not permit several constructs that XBD [Section 9.4.2](#) (on page 188) and  
 118525 [Section 9.4.3](#) (on page 188) specify as having undefined results:

- 118526 • ORD\_CHAR preceded by <backslash>
- 118527 • ERE\_dupl\_symbol(s) appearing first in an ERE, or immediately following '|', '^', or '('
- 118528 • '{' not part of a valid ERE\_dupl\_symbol

- 118529 • ' | ' appearing first or last in an ERE, or immediately following ' | ' or ' (', or  
118530 immediately preceding ' ) '

118531 Implementations are permitted to extend the language to allow these. Conforming applications  
118532 cannot use such constructs.

## 118533 A.9.5.1 BRE/ERE Grammar Lexical Conventions

118534 There is no additional rationale provided for this section.

## 118535 A.9.5.2 RE and Bracket Expression Grammar

The removal of the *Back\_open\_paren Back\_close\_paren* option from the *nondupl\_RE* specification is the result of PASC Interpretation 1003.2-92 #43 submitted for the ISO POSIX-2:1993 standard. Although the grammar required support for null subexpressions, this section does not describe the meaning of, and historical practice did not support, this construct.

118540 A.9.5.3 *ERE Grammar*

118541 There is no additional rationale provided for this section.

## 118542 A.10 Directory Structure and Devices

## 118543 A.10.1 Directory Structure and Files

A description of the historical **/usr/tmp** was omitted, removing any concept of differences in emphasis between the **/** and **/usr** directories. The descriptions of **/bin**, **/usr/bin**, **/lib**, and **/usr/lib** were omitted because they are not useful for applications. In an early draft, a distinction was made between system and application directory usage, but this was not found to be useful.

The directories `/` and `/dev` are included because the notion of a hierarchical directory structure is key to other information presented elsewhere in POSIX.1-2008. In early drafts, it was argued that special devices and temporary files could conceivably be handled without a directory structure on some implementations. For example, the system could treat the characters `"/tmp"` as a special token that would store files using some non-POSIX file system structure. This notion was rejected by the standard developers, who required that all the files in this section be implemented via POSIX file systems.

The **/tmp** directory is retained in POSIX.1-2008 to accommodate historical applications that assume its availability. Implementations are encouraged to provide suitable directory names in the environment variable *TMPDIR* and applications are encouraged to use the contents of *TMPDIR* for creating temporary files.

118559 The standard files **/dev/null** and **/dev/tty** are required to be both readable and writable to allow  
118560 applications to have the intended historical access to these files.

118561 The standard file **/dev/console** has been added for alignment with the Single UNIX  
118562 Specification.

## 118563 A.10.2 Output Devices and Terminal Types

118564 IEEE Std 1003.1-2001/Cor 2-2004, item XBD/TC2/D6/17 is applied, making it clear that the  
118565 requirements for documenting terminal support are in the system documentation.

## 118566 A.11 General Terminal Interface

118567 If the implementation does not support this interface on any device types, it should behave as if  
118568 it were being used on a device that is not a terminal device (in most cases *errno* will be set to  
118569 [ENOTTY] on return from functions defined by this interface). This is based on the fact that  
118570 many applications are written to run both interactively and in some non-interactive mode, and  
118571 they adapt themselves at runtime. Requiring that they all be modified to test an environment  
118572 variable to determine whether they should try to adapt is unnecessary. On a system that  
118573 provides no general terminal interface, providing all the entry points as stubs that return  
118574 [ENOTTY] (or an equivalent, as appropriate) has the same effect and requires no changes to the  
118575 application.

118576 Although the needs of both interface implementors and application developers were addressed  
118577 throughout POSIX.1-2008, this section pays more attention to the needs of the latter. This is  
118578 because, while many aspects of the programming interface can be hidden from the user by the  
118579 application developer, the terminal interface is usually a large part of the user interface.  
118580 Although to some extent the application developer can build missing features or work around  
118581 inappropriate ones, the difficulties of doing that are greater in the terminal interface than  
118582 elsewhere. For example, efficiency prohibits the average program from interpreting every  
118583 character passing through it in order to simulate character erase, line kill, and so on. These  
118584 functions should usually be done by the operating system, possibly at the interrupt level.

118585 The *tc\**() functions were introduced as a way of avoiding the problems inherent in the  
118586 traditional *ioctl*() function and in variants of it that were proposed. For example, *tcsetattr*() is  
118587 specified in place of the use of the TCSETA *ioctl*() command function. This allows specification  
118588 of all the arguments in a manner consistent with the ISO C standard unlike the varying third  
118589 argument of *ioctl*(), which is sometimes a pointer (to any of many different types) and  
118590 sometimes an *int*.

118591 The advantages of this new method include:

- 118592 • It allows strict type checking.
- 118593 • The direction of transfer of control data is explicit.
- 118594 • Portable capabilities are clearly identified.
- 118595 • The need for a general interface routine is avoided.
- 118596 • Size of the argument is well-defined (there is only one type).

118597 The disadvantages include:

- 118598 • No historical implementation used the new method.
- 118599 • There are many small routines instead of one general-purpose one.
- 118600 • The historical parallel with *fcntl*() is broken.

118601 The issue of modem control was excluded from POSIX.1-2008 on the grounds that:

- 118602 • It was concerned with setting and control of hardware timers.
- 118603 • The appropriate timers and settings vary widely internationally.
- 118604 • Feedback from European computer manufacturers indicated that this facility was not
- 118605 consistent with European needs and that specification of such a facility was not a
- 118606 requirement for portability.

### 118607 A.11.1 Interface Characteristics

#### 118608 A.11.1.1 Opening a Terminal Device File

118609 The O\_TTY\_INIT flag for *open()* has been added to POSIX.1-2008 to solve a problem  
 118610 encountered by applications written for earlier versions of this standard which need to open a  
 118611 modem or similar device and initialize all of the parameter settings. Using the  
 118612 *tcgetattr()*-modify-*tcsetattr()* method mandated by the standard could result in non-conforming  
 118613 behavior if the device had previously been used with non-conforming parameter settings, on  
 118614 implementations which do not reset the parameter settings in between the last close of the  
 118615 device by one application and the first open by another application. To avoid this problem, some  
 118616 application developers were resorting to using *memset()* to zero the **termios** structure before  
 118617 setting all of the standard parameters, but this risks non-conforming behavior on systems where  
 118618 some non-standard parameter needs a non-zero value in order for the terminal to behave in a  
 118619 conforming manner.

118620 On systems which do reset the parameter settings to defaults between uses of a terminal device,  
 118621 it is expected that either O\_TTY\_INIT will have the value zero or *open(ttypath,*  
 118622 *O\_RDWR|O\_TTY\_INIT)* will do nothing additional.

118623 The standard developers considered an alternative solution of a special *fildev* argument for the  
 118624 *tcgetattr()* call to obtain default parameters. However, this would not be adequate if a system  
 118625 supports several different types of terminal device and the default settings need to differ  
 118626 between the different types. With the O\_TTY\_INIT open flag, the implementor can determine  
 118627 which device type is being opened.

118628 The standard developers also considered a special POSIX\_TTY\_INIT value for the **termios**  
 118629 structure used in *tcsetattr()*, which would reset the values if used immediately after an *open()*  
 118630 call. However, it was felt that this would lead to confusion amongst application developers who  
 118631 wanted to reset the parameters at other points, and implementations might diverge.

#### 118632 A.11.1.2 Process Groups

118633 There is a potential race when the members of the foreground process group on a terminal leave  
 118634 that process group, either by exit or by changing process groups. After the last process exits the  
 118635 process group, but before the foreground process group ID of the terminal is changed (usually  
 118636 by a job control shell), it would be possible for a new process to be created with its process ID  
 118637 equal to the terminal's foreground process group ID. That process might then become the  
 118638 process group leader and accidentally be placed into the foreground on a terminal that was not  
 118639 necessarily its controlling terminal. As a result of this problem, the controlling terminal is  
 118640 defined to not have a foreground process group during this time.

118641 The cases where a controlling terminal has no foreground process group occur when all  
 118642 processes in the foreground process group either terminate and are waited for or join other  
 118643 process groups via *setpgid()* or *setsid()*. If the process group leader terminates, this is the first

case described; if it leaves the process group via *setpgid()*, this is the second case described (a process group leader cannot successfully call *setsid()*). When one of those cases causes a controlling terminal to have no foreground process group, it has two visible effects on applications. The first is the value returned by *tcgetpgrp()*. The second (which occurs only in the case where the process group leader terminates) is the sending of signals in response to special input characters. The intent of POSIX.1-2008 is that no process group be wrongly identified as the foreground process group by *tcgetpgrp()* or unintentionally receive signals because of placement into the foreground.

In 4.3 BSD, the old process group ID continues to be used to identify the foreground process group and is returned by the function equivalent to *tcgetpgrp()*. In that implementation it is possible for a newly created process to be assigned the same value as a process ID and then form a new process group with the same value as a process group ID. The result is that the new process group would receive signals from this terminal for no apparent reason, and POSIX.1-2008 precludes this by forbidding a process group from entering the foreground in this way. It would be more direct to place part of the requirement made by the last sentence under *fork()*, but there is no convenient way for that section to refer to the value that *tcgetpgrp()* returns, since in this case there is no process group and thus no process group ID.

One possibility for a conforming implementation is to behave similarly to 4.3 BSD, but to prevent this reuse of the ID, probably in the implementation of *fork()*, as long as it is in use by the terminal.

Another possibility is to recognize when the last process stops using the terminal's foreground process group ID, which is when the process group lifetime ends, and to change the terminal's foreground process group ID to a reserved value that is never used as a process ID or process group ID. (See the definition of *process group lifetime* in the definitions section.) The process ID can then be reserved until the terminal has another foreground process group.

The 4.3 BSD implementation permits the leader (and only member) of the foreground process group to leave the process group by calling the equivalent of *setpgid()* and to later return, expecting to return to the foreground. There are no known application needs for this behavior, and POSIX.1-2008 neither requires nor forbids it (except that it is forbidden for session leaders) by leaving it unspecified.

#### A.11.1.3 The Controlling Terminal

POSIX.1-2008 does not specify a mechanism by which to allocate a controlling terminal. This is normally done by a system utility (such as *getty*) and is considered an administrative feature outside the scope of POSIX.1-2008.

Historical implementations allocate controlling terminals on certain *open()* calls. Since *open()* is part of POSIX.1, its behavior had to be dealt with. The traditional behavior is not required because it is not very straightforward or flexible for either implementations or applications. However, because of its prevalence, it was not practical to disallow this behavior either. Thus, a mechanism was standardized to ensure portable, predictable behavior in *open()*.

Some historical implementations deallocate a controlling terminal on the last system-wide close. This behavior is neither required nor prohibited. Even on implementations that do provide this behavior, applications generally cannot depend on it due to its system-wide nature.

## 118686 A.11.1.4 Terminal Access Control

118687 The access controls described in this section apply only to a process that is accessing its  
 118688 controlling terminal. A process accessing a terminal that is not its controlling terminal is  
 118689 effectively treated the same as a member of the foreground process group. While this may seem  
 118690 unintuitive, note that these controls are for the purpose of job control, not security, and job  
 118691 control relates only to the controlling terminal of a process. Normal file access permissions  
 118692 handle security.

118693 If the process calling *read()* or *write()* is in a background process group that is orphaned, it is not  
 118694 desirable to stop the process group, as it is no longer under the control of a job control shell that  
 118695 could put it into the foreground again. Accordingly, calls to *read()* or *write()* functions by such  
 118696 processes receive an immediate error return. This is different from 4.2 BSD, which kills orphaned  
 118697 processes that receive terminal stop signals.

118698 The foreground/background/orphaned process group check performed by the terminal driver  
 118699 must be repeatedly performed until the calling process moves into the foreground or until the  
 118700 process group of the calling process becomes orphaned. That is, when the terminal driver  
 118701 determines that the calling process is in the background and should receive a job control signal,  
 118702 it sends the appropriate signal (SIGTTIN or SIGTTOU) to every process in the process group of  
 118703 the calling process and then it allows the calling process to immediately receive the signal. The  
 118704 latter is typically performed by blocking the process so that the signal is immediately noticed.  
 118705 Note, however, that after the process finishes receiving the signal and control is returned to the  
 118706 driver, the terminal driver must re-execute the foreground/background/orphaned process  
 118707 group check. The process may still be in the background, either because it was continued in the  
 118708 background by a job control shell, or because it caught the signal and did nothing.

118709 The terminal driver repeatedly performs the foreground/background/orphaned process group  
 118710 checks whenever a process is about to access the terminal. In the case of *write()* or the control  
 118711 *tc\*()* functions, the check is performed at the entry of the function. In the case of *read()*, the  
 118712 check is performed not only at the entry of the function, but also after blocking the process to  
 118713 wait for input characters (if necessary). That is, once the driver has determined that the process  
 118714 calling the *read()* function is in the foreground, it attempts to retrieve characters from the input  
 118715 queue. If the queue is empty, it blocks the process waiting for characters. When characters are  
 118716 available and control is returned to the driver, the terminal driver must return to the repeated  
 118717 foreground/background/orphaned process group check again. The process may have moved  
 118718 from the foreground to the background while it was blocked waiting for input characters.

## 118719 A.11.1.5 Input Processing and Reading Data

118720 There is no additional rationale provided for this section.

## 118721 A.11.1.6 Canonical Mode Input Processing

118722 The term “character” is intended here. ERASE should erase the last character, not the last byte.  
 118723 In the case of multi-byte characters, these two may be different.

118724 4.3 BSD has a WERASE character that erases the last “word” typed (but not any preceding  
 118725 <blank> or <tab> characters). A word is defined as a sequence of non-<blank> characters, with  
 118726 <tab> characters counted as <blank> characters. Like ERASE, WERASE does not erase beyond  
 118727 the beginning of the line. This WERASE feature has not been specified in POSIX.1 because it is  
 118728 difficult to define in the international environment. It is only useful for languages where words  
 118729 are delimited by <blank> characters. In some ideographic languages, such as Japanese and  
 118730 Chinese, words are not delimited at all. The WERASE character should presumably go back to  
 118731 the beginning of a sentence in those cases; practically, this means it would not be used much for

118732 those languages.

118733 It should be noted that there is a possible inherent deadlock if the application and  
118734 implementation conflict on the value of {MAX\_CANON}. With ICANON set (if IXOFF is  
118735 enabled) and more than {MAX\_CANON} characters transmitted without a <linefeed>,  
118736 transmission will be stopped, the <linefeed> (or <carriage-return> when ICRLF is set) will never  
118737 arrive, and the *read()* will never be satisfied.

118738 An application should not set IXOFF if it is using canonical mode unless it knows that (even in  
118739 the face of a transmission error) the conditions described previously cannot be met or unless it is  
118740 prepared to deal with the possible deadlock in some other way, such as timeouts.

118741 It should also be noted that this can be made to happen in non-canonical mode if the trigger  
118742 value for sending IXOFF is less than VMIN and VTIME is zero.

#### 118743 A.11.1.7 Non-Canonical Mode Input Processing

118744 Some points to note about MIN and TIME:

- 118745 1. The interactions of MIN and TIME are not symmetric. For example, when MIN>0 and  
118746 TIME=0, TIME has no effect. However, in the opposite case where MIN=0 and TIME>0,  
118747 both MIN and TIME play a role in that MIN is satisfied with the receipt of a single  
118748 character.
- 118749 2. Also note that in case A (MIN>0, TIME>0), TIME represents an inter-character timer,  
118750 while in case C (MIN=0, TIME>0), TIME represents a read timer.

118751 These two points highlight the dual purpose of the MIN/TIME feature. Cases A and B, where  
118752 MIN>0, exist to handle burst-mode activity (for example, file transfer programs) where a  
118753 program would like to process at least MIN characters at a time. In case A, the inter-character  
118754 timer is activated by a user as a safety measure; in case B, it is turned off.

118755 Cases C and D exist to handle single-character timed transfers. These cases are readily adaptable  
118756 to screen-based applications that need to know if a character is present in the input queue before  
118757 refreshing the screen. In case C, the read is timed; in case D, it is not.

118758 Another important note is that MIN is always just a minimum. It does not denote a record  
118759 length. That is, if a program does a read of 20 bytes, MIN is 10, and 25 characters are present, 20  
118760 characters are returned to the user. In the special case of MIN=0, this still applies: if more than  
118761 one character is available, they all will be returned immediately.

#### 118762 A.11.1.8 Writing Data and Output Processing

118763 There is no additional rationale provided for this section.

#### 118764 A.11.1.9 Special Characters

118765 There is no additional rationale provided for this section.

#### 118766 A.11.1.10 Modem Disconnect

118767 There is no additional rationale provided for this section.

118768 A.11.1.11 *Closing a Terminal Device File*

118769 POSIX.1-2008 does not specify that a *close()* on a terminal device file include the equivalent of a  
118770 call to *tcflow(fd,TCOON)*.

118771 An implementation that discards output at the time *close()* is called after reporting the return  
118772 value to the *write()* call that data was written does not conform with POSIX.1-2008. An  
118773 application has functions such as *tcdrain()*, *tcflush()*, and *tcflow()* available to obtain the detailed  
118774 behavior it requires with respect to flushing of output.

118775 At the time of the last close on a terminal device, an application relinquishes any ability to exert  
118776 flow control via *tcflow()*.

118777 **A.11.2 Parameters that Can be Set**118778 A.11.2.1 *The termios Structure*

118779 This structure is part of an interface that, in general, retains the historic grouping of flags.  
118780 Although a more optimal structure for implementations may be possible, the degree of change  
118781 to applications would be significantly larger.

118782 A.11.2.2 *Input Modes*

118783 Some historical implementations treated a long break as multiple events, as many as one per  
118784 character time. The wording in POSIX.1 explicitly prohibits this.

118785 Although the ISTRIP flag is normally superfluous with today's terminal hardware and software,  
118786 it is historically supported. Therefore, applications may be using ISTRIP, and there is no  
118787 technical problem with supporting this flag. Also, applications may wish to receive only 7-bit  
118788 input bytes and may not be connected directly to the hardware terminal device (for example,  
118789 when a connection traverses a network).

118790 Also, there is no requirement in general that the terminal device ensures that high-order bits  
118791 beyond the specified character size are cleared. ISTRIP provides this function for 7-bit  
118792 characters, which are common.

118793 In dealing with multi-byte characters, the consequences of a parity error in such a character, or  
118794 in an escape sequence affecting the current character set, are beyond the scope of POSIX.1 and  
118795 are best dealt with by the application processing the multi-byte characters.

118796 A.11.2.3 *Output Modes*

118797 POSIX.1 does not describe post-processing of output to a terminal or detailed control of that  
118798 from a conforming application. (That is, translation of <newline> to <carriage-return> followed  
118799 by <linefeed> or <tab> processing.) There is nothing that a conforming application should do to  
118800 its output for a terminal because that would require knowledge of the operation of the terminal.  
118801 It is the responsibility of the operating system to provide post-processing appropriate to the  
118802 output device, whether it is a terminal or some other type of device.

118803 Extensions to POSIX.1 to control the type of post-processing already exist and are expected to  
118804 continue into the future. The control of these features is primarily to adjust the interface between  
118805 the system and the terminal device so the output appears on the display correctly. This should  
118806 be set up before use by any application.

118807 In general, both the input and output modes should not be set absolutely, but rather modified  
 118808 from the inherited state.

#### 118809 A.11.2.4 Control Modes

118810 This section could be misread that the symbol “CSIZE” is a title in the **termios** *c\_cflag* field.  
 118811 Although it does serve that function, it is also a required symbol, as a literal reading of POSIX.1  
 118812 (and the caveats about typography) would indicate.

#### 118813 A.11.2.5 Local Modes

118814 Non-canonical mode is provided to allow fast bursts of input to be read efficiently while still  
 118815 allowing single-character input.

118816 The ECHONL function historically has been in many implementations. Since there seems to be  
 118817 no technical problem with supporting ECHONL, it is included in POSIX.1 to increase consensus.

118818 The alternate behavior possible when ECHOK or ECHOE are specified with ICANON is  
 118819 permitted as a compromise depending on what the actual terminal hardware can do. Erasing  
 118820 characters and lines is preferred, but is not always possible.

#### 118821 A.11.2.6 Special Control Characters

118822 Permitting VMIN and VTIME to overlap with VEOF and VEOL was a compromise for historical  
 118823 implementations. Only when backwards-compatibility of object code is a serious concern to an  
 118824 implementor should an implementation continue this practice. Correct applications that work  
 118825 with the overlap (at the source level) should also work if it is not present, but not the reverse.

## 118826 A.12 Utility Conventions

### 118827 A.12.1 Utility Argument Syntax

118828 The standard developers considered that recent trends toward diluting the SYNOPSIS sections  
 118829 of historical reference pages to the equivalent of:

118830 `command [options] [operands]`

118831 were a disservice to the reader. Therefore, considerable effort was placed into rigorous  
 118832 definitions of all the command line arguments and their interrelationships. The relationships  
 118833 depicted in the synopses are normative parts of POSIX.1-2008; this information is sometimes  
 118834 repeated in textual form, but that is only for clarity within context.

118835 The use of “undefined” for conflicting argument usage and for repeated usage of the same  
 118836 option is meant to prevent conforming applications from using conflicting arguments or  
 118837 repeated options unless specifically allowed (as is the case with *ls*, which allows simultaneous,  
 118838 repeated use of the *-C*, *-l*, and *-1* options). Many historical implementations will tolerate this  
 118839 usage, choosing either the first or the last applicable argument. This tolerance can continue, but  
 118840 conforming applications cannot rely upon it. (Other implementations may choose to print usage  
 118841 messages instead.)

118842 The use of “undefined” for conflicting argument usage also allows an implementation to make

reasonable extensions to utilities where the implementor considers mutually-exclusive options according to POSIX.1-2008 to have a sensible meaning and result.

POSIX.1-2008 does not define the result of a command when an option-argument or operand is not followed by ellipses and the application specifies more than one of that option-argument or operand. This allows an implementation to define valid (although non-standard) behavior for the utility when more than one such option or operand is specified.

The requirements for option-arguments are summarized as follows:

|                                      | SYNOPSIS Shows:                            |                                        |
|--------------------------------------|--------------------------------------------|----------------------------------------|
|                                      | <code>-a arg</code>                        | <code>-c [arg]</code>                  |
| Conforming application uses:         | <code>-a arg</code>                        | <code>-carg</code> or <code>-c</code>  |
| System supports:                     | <code>-a arg</code> and <code>-aarg</code> | <code>-carg</code> and <code>-c</code> |
| Non-conforming applications may use: | <code>-aarg</code>                         | N/A                                    |

Earlier versions of this standard included obsolescent syntax which showed some options with (mandatory) adjacent option-arguments in the SYNOPSIS for some utilities. These have since been removed. For all options with mandatory option-arguments, the SYNOPSIS now shows <blank> characters between the option and the option-argument; however, historical usage has not been consistent in this area; therefore, <blank> characters are required to be used by conforming applications and to be handled by all implementations, but implementations are also required to handle an adjacent option-argument in order to preserve backwards-compatibility for old scripts. One of the justifications for selecting the multiple-argument method was that the single-argument case is inherently ambiguous when the option-argument can legitimately be a null string.

POSIX.1-2008 explicitly states that digits are permitted as operands and option-arguments. The lower and upper bounds for the values of the numbers used for operands and option-arguments were derived from the ISO C standard values for {LONG\_MIN} and {LONG\_MAX}. The requirement on the standard utilities is that numbers in the specified range do not cause a syntax error, although the specification of a number need not be semantically correct for a particular operand or option-argument of a utility. For example, the specification of:

```
dd obs=3000000000
```

would yield undefined behavior for the application and could be a syntax error because the number 3 000 000 000 is outside of the range -2 147 483 647 to +2 147 483 647. On the other hand:

```
dd obs=2000000000
```

may cause some error, such as “blocksize too large”, rather than a syntax error.

**A.12.2 Utility Syntax Guidelines**

This section is based on the rules listed in the SVID. It was included for two reasons:

1. The individual utility descriptions in XCU Chapter 4 (on page 2423) needed a set of common (although not universal) actions on which they could anchor their descriptions of option and operand syntax. Most of the standard utilities actually do use these guidelines, and many of their historical implementations use the `getopt()` function for their parsing. Therefore, it was simpler to cite the rules and merely identify exceptions.
2. Developers of conforming applications need suggested guidelines if the POSIX community is to avoid the chaos of historical UNIX system command syntax.

It is recommended that all *future* utilities and applications use these guidelines to enhance “user

portability". The fact that some historical utilities could not be changed (to avoid breaking historical applications) should not deter this future goal.

The voluntary nature of the guidelines is highlighted by repeated uses of the word *should* throughout. This usage should not be misinterpreted to imply that utilities that claim conformance in their OPTIONS sections do not always conform.

Guidelines 1 and 2 encourage utility writers to use only characters from the portable character set because use of locale-specific characters may make the utility inaccessible from other locales. Use of uppercase letters is discouraged due to problems associated with porting utilities to systems that do not distinguish between uppercase and lowercase characters in filenames. Use of non-alphanumeric characters is discouraged due to the number of utilities that treat non-alphanumeric characters in "special" ways depending on context (such as the shell using white-space characters to delimit arguments, various quote characters for quoting, the <dollar-sign> to introduce variable expansion, etc.).

In XCU [Section 2.9.1](#) (on page 2338), it is further stated that a command used in the Shell Command Language cannot be named with a trailing <colon>.

Guideline 3 was changed to allow alphanumeric characters (letters and digits) from the character set to allow compatibility with historical usage. Historical practice allows the use of digits wherever practical, and there are no portability issues that would prohibit the use of digits. In fact, from an internationalization viewpoint, digits (being non-language-dependent) are preferable over letters (a -2 is intuitively self-explanatory to any user, while in the -f *filename* the letter 'f' is a mnemonic aid only to speakers of Latin-based languages where "filename" happens to translate to a word that begins with 'f'). Since Guideline 3 still retains the word "single", multi-digit options are not allowed. Instances of historical utilities that used them have been marked obsolescent, with the numbers being changed from option names to option-arguments.

It was difficult to achieve a satisfactory solution to the problem of name space in option characters. When the standard developers desired to extend the historical *cc* utility to accept ISO C standard programs, they found that all of the portable alphabet was already in use by various vendors. Thus, they had to devise a new name, *c89* (now superseded by *c99*), rather than something like *cc -X*. There were suggestions that implementors be restricted to providing extensions through various means (such as using a <plus-sign> as the option delimiter or using option characters outside the alphanumeric set) that would reserve all of the remaining alphanumeric characters for future POSIX standards. These approaches were resisted because they lacked the historical style of UNIX systems. Furthermore, if a vendor-provided option should become commonly used in the industry, it would be a candidate for standardization. It would be desirable to standardize such a feature using historical practice for the syntax (the semantics can be standardized with any syntax). This would not be possible if the syntax was one reserved for the vendor. However, since the standardization process may lead to minor changes in the semantics, it may prove to be better for a vendor to use a syntax that will not be affected by standardization.

Guideline 8 includes the concept of <comma>-separated lists in a single argument. It is up to the utility to parse such a list itself because *getopt()* just returns the single string. This situation was retained so that certain historical utilities would not violate the guidelines. Applications preparing for international use should be aware of an occasional problem with <comma>-separated lists: in some locales, the <comma> is used as the radix character. Thus, if an application is preparing operands for a utility that expects a <comma>-separated list, it should avoid generating non-integer values through one of the means that is influenced by setting the *LC\_NUMERIC* variable (such as *awk*, *bc*, *printf*, or *printf()*).

Unless explicitly stated otherwise in the utility description, Guideline 9 requires applications to

put options before operands, and requires utilities to accept any such usage without misinterpreting operands as options. For example, if an implementation of the *printf* utility supports a *-e* option as an extension, the command:

```
printf %s -e
```

must output the string "-e" without interpreting the *-e* as an option. Similarly, the command:

```
ls myfile -l
```

must interpret the *-l* argument as a second file operand, not as a *-l* option.

Applications calling any utility with a first operand starting with '-' should usually specify *--*, as indicated by Guideline 10, to mark the end of the options. This is true even if the SYNOPSIS in the Shell and Utilities volume of POSIX.1-2008 does not specify any options; implementations may provide options as extensions to the Shell and Utilities volume of POSIX.1-2008. The standard utilities that do not support Guideline 10 indicate that fact in the OPTIONS section of the utility description.

Guideline 7 allows any string to be an option-argument; an option-argument can begin with any character, can be - or --, and can be an empty string. For example, the commands *pr -h -*, *pr -h --*, *pr -h -d*, *pr -h +2*, and *pr -h ''* contain the option-arguments -, --, -d, +2, and an empty string, respectively. Conversely, the command *pr -h -- -d* treats -d as an option, not as an argument, because the -- is an option-argument here, not a delimiter.

Guideline 11 was modified to clarify that the order of different options should not matter relative to one another. However, the order of repeated options that also have option-arguments may be significant; therefore, such options are required to be interpreted in the order that they are specified. The *make* utility is an instance of a historical utility that uses repeated options in which the order is significant. Multiple files are specified by giving multiple instances of the *-f* option; for example:

```
make -f common_header -f specific_rules target
```

Guideline 13 does not imply that all of the standard utilities automatically accept the operand '-' to mean standard input or output, nor does it specify the actions of the utility upon encountering multiple '-' operands. It simply says that, by default, '-' operands are not used for other purposes in the file reading or writing (but not when using *stat()*, *unlink()*, *touch*, and so on) utilities. In earlier versions of this standard, all information concerning actual treatment of the '-' operand is found in the individual utility sections. Many implementations, however, treated '-' as standard input or output and many applications depended on this behavior even though it was not standard. This behavior is now implementation-defined. Portable applications should not use '-' to mean standard input or output unless it is explicitly stated to do so in the utility description and they should always use './-' if they intend to refer to a file named - in the current working directory.

Guideline 14 is intended to prohibit implementations that would treat the command *ls -l -d* as if it were *ls -- -l -d* or *ls -l -- -d*.

The standard permits implementations to have extensions that violate the Utility Syntax Guidelines so long as when the utility is used in line with the forms defined by the standard it follows the Utility Syntax Guidelines. Thus, *head-42file* and *ls--help* are permitted extensions. The intent is to allow extensions so long as the standard form is accepted and follows the guidelines.

An area of concern was that as implementations mature, implementation-defined utilities and implementation-defined utility options will result. The idea was expressed that there needed to be a standard way, say an environment variable or some such mechanism, to identify implementation-defined utilities separately from standard utilities that may have the same

118982 name. It was decided that there already exist several ways of dealing with this situation and that  
 118983 it is outside of the scope to attempt to standardize in the area of non-standard items. A method  
 118984 that exists on some historical implementations is the use of the so-called **/local/bin** or  
 118985 **/usr/local/bin** directory to separate local or additional copies or versions of utilities. Another  
 118986 method that is also used is to isolate utilities into completely separate domains. Still another  
 118987 method to ensure that the desired utility is being used is to request the utility by its full  
 118988 pathname. There are many approaches to this situation; the examples given above serve to  
 118989 illustrate that there is more than one.

## 118990 **A.13 Headers**

### 118991 **A.13.1 Format of Entries**

118992 Each header reference page has a common layout of sections describing the interface. This  
 118993 layout is similar to the manual page or “man” page format shipped with most UNIX systems,  
 118994 and each header has sections describing the SYNOPSIS and DESCRIPTION. These are the two  
 118995 sections that relate to conformance.

118996 Additional sections are informative, and add considerable information for the application  
 118997 developer. APPLICATION USAGE sections provide additional caveats, issues, and  
 118998 recommendations to the developer. RATIONALE sections give additional information on the  
 118999 decisions made in defining the interface.

119000 FUTURE DIRECTIONS sections act as pointers to related work that may impact the interface in  
 119001 the future, and often cautions the developer to architect the code to account for a change in this  
 119002 area. Note that a future directions statement should not be taken as a commitment to adopt a  
 119003 feature or interface in the future.

119004 The CHANGE HISTORY section describes when the interface was introduced, and how it has  
 119005 changed.

119006 Option labels and margin markings in the page can be useful in guiding the application  
 119007 developer.

### 119008 **A.13.2 Removed Headers in Issue 7**

119009 The headers removed in Issue 7 (from the Issue 6 base document) are as follows:

119010  
119011

| Removed Headers in Issue 7 |              |
|----------------------------|--------------|
| <sys/timeb.h>              | <ucontext.h> |

119012

# *Rationale (Informative)*

119013

## **Part B:**

119014

## **System Interfaces**

119015

*The Open Group*

119016

*The Institute of Electrical and Electronics Engineers, Inc.*

# *Rationale for System Interfaces*

## 119019 **B.1 Introduction**

### 119020 **B.1.1 Change History**

119021 The change history is provided as an informative section, to track changes from earlier versions  
119022 of this standard.

119023 The following sections describe changes made to the System Interfaces volume of POSIX.1-2008  
119024 since Issue 6 of the base document. The CHANGE HISTORY section for each entry details the  
119025 technical changes that have been made to that entry from Issue 5. Changes between earlier  
119026 versions of the base document and Issue 5 are not included.

#### 119027 **Changes from Issue 6 to Issue 7 (POSIX.1-2008)**

119028 The following list summarizes the major changes that were made in the System Interfaces  
119029 volume of POSIX.1-2008 from Issue 6 to Issue 7:

- 119030 • The Open Group Technical Standard, 2006, Extended API Set Part 1 is incorporated.
- 119031 • The Open Group Technical Standard, 2006, Extended API Set Part 2 is incorporated.
- 119032 • The Open Group Technical Standard, 2006, Extended API Set Part 3 is incorporated.
- 119033 • The Open Group Technical Standard, 2006, Extended API Set Part 4 is incorporated.
- 119034 • Existing functionality is aligned with ISO/IEC 9899:1999, Programming Languages — C,  
119035 ISO/IEC 9899:1999/Cor.2:2004(E)
- 119036 • Austin Group defect reports, IEEE Interpretations against IEEE Std 1003.1, and responses  
119037 to ISO/IEC defect reports against ISO/IEC 9945 are applied.
- 119038 • The Open Group corrigenda and resolutions are applied.
- 119039 • Features, marked legacy or obsolescent in the base document, have been considered for  
119040 removal in this version.
- 119041 • The options within the standard have been revised.

**New Features in Issue 7**

The functions first introduced in Issue 7 (over the Issue 6 base document) are as follows:

**New Functions in Issue 7**

|                      |                                      |                       |
|----------------------|--------------------------------------|-----------------------|
| <i>alphasort()</i>   | <i>iswdigit_l()</i>                  | <i>strfmon_l()</i>    |
| <i>dirfd()</i>       | <i>iswgraph_l()</i>                  | <i>strncascmp_l()</i> |
| <i>dprintf()</i>     | <i>iswlower_l()</i>                  | <i>strndup()</i>      |
| <i>duplocale()</i>   | <i>iswprint_l()</i>                  | <i>strnlen()</i>      |
| <i>faccessat()</i>   | <i>iswpunct_l()</i>                  | <i>strsignal()</i>    |
| <i>fchmodat()</i>    | <i>iswspace_l()</i>                  | <i>strxfrm_l()</i>    |
| <i>fchownat()</i>    | <i>iswupper_l()</i>                  | <i>symlinkat()</i>    |
| <i>fdopendir()</i>   | <i>iswxdigit_l()</i>                 | <i>tolower_l()</i>    |
| <i>fexecve()</i>     | <i>isxdigit_l()</i>                  | <i>toupper_l()</i>    |
| <i>fnmopen()</i>     | <i>linkat()</i>                      | <i>towctrans_l()</i>  |
| <i>freelocale()</i>  | <i>mbsnrtowcs()</i>                  | <i>tolower_l()</i>    |
| <i>fstatat()</i>     | <i>mkdirat()</i>                     | <i>towupper_l()</i>   |
| <i>futimens()</i>    | <i>mkdtemp()</i>                     | <i>unlinkat()</i>     |
| <i>getdelim()</i>    | <i>mkffloat()</i>                    | <i>uselocale()</i>    |
| <i>getline()</i>     | <i>mknodat()</i>                     | <i>utimensat()</i>    |
| <i>isalnum_l()</i>   | <i>newlocale()</i>                   | <i>vdprintf()</i>     |
| <i>isalpha_l()</i>   | <i>openat()</i>                      | <i>wcpcpy()</i>       |
| <i>isblank_l()</i>   | <i>open_memstream()</i>              | <i>wcpncpy()</i>      |
| <i>iscntrl_l()</i>   | <i>open_wmemstream()</i>             | <i>wscascmp_l()</i>   |
| <i>isdigit_l()</i>   | <i>psiginfo()</i>                    | <i>wscascmp_l()</i>   |
| <i>isgraph_l()</i>   | <i>psignal()</i>                     | <i>wscoll_l()</i>     |
| <i>islower_l()</i>   | <i>pthread_mutexattr_getrobust()</i> | <i>wcsdup()</i>       |
| <i>isprint_l()</i>   | <i>pthread_mutexattr_setrobust()</i> | <i>wcsncascmp_l()</i> |
| <i>ispunct_l()</i>   | <i>pthread_mutex_consistent()</i>    | <i>wcsncascmp_l()</i> |
| <i>isspace_l()</i>   | <i>readlinkat()</i>                  | <i>wcsnlen()</i>      |
| <i>isupper_l()</i>   | <i>renameat()</i>                    | <i>wcsnrtombs()</i>   |
| <i>iswalnum_l()</i>  | <i>scandir()</i>                     | <i>wcsxfrm_l()</i>    |
| <i>iswalphal_l()</i> | <i>stpcpy()</i>                      | <i>wctrans_l()</i>    |
| <i>iswblank_l()</i>  | <i>stpncpy()</i>                     | <i>wctype_l()</i>     |
| <i>iswcntrl_l()</i>  | <i>strcascmp_l()</i>                 |                       |
| <i>iswctype_l()</i>  | <i>strcoll_l()</i>                   |                       |

**Newly Mandated Functions in Issue 7**

The functions that were previously part of an option group but are now mandatory in Issue 7 are as follows:

119079

**Newly Mandated Functions in Issue 7**

|        |                                         |                                      |                                     |
|--------|-----------------------------------------|--------------------------------------|-------------------------------------|
| 119080 | <i>aio_cancel()</i>                     | <i>pthread_atfork()</i>              | <i>pthread_rwlock_tryrdlock()</i>   |
| 119081 | <i>aio_error()</i>                      | <i>pthread_attr_destroy()</i>        | <i>pthread_rwlock_trywrlock()</i>   |
| 119082 | <i>aio_fsync()</i>                      | <i>pthread_attr_getdetachstate()</i> | <i>pthread_rwlock_unlock()</i>      |
| 119083 | <i>aio_read()</i>                       | <i>pthread_attr_getguardsize()</i>   | <i>pthread_rwlock_wrlock()</i>      |
| 119084 | <i>aio_return()</i>                     | <i>pthread_attr_getschedparam()</i>  | <i>pthread_rwlockattr_destroy()</i> |
| 119085 | <i>aio_suspend()</i>                    | <i>pthread_attr_init()</i>           | <i>pthread_rwlockattr_init()</i>    |

**B.1.2 Relationship to Other Formal Standards**

There is no additional rationale provided for this section.

**B.1.3 Format of Entries**

Each system interface reference page has a common layout of sections describing the interface. This layout is similar to the manual page or “man” page format shipped with most UNIX systems, and each header has sections describing the SYNOPSIS, DESCRIPTION, RETURN VALUE, and ERRORS. These are the four sections that relate to conformance.

Additional sections are informative, and add considerable information for the application developer. EXAMPLES sections provide example usage. APPLICATION USAGE sections

119171 provide additional caveats, issues, and recommendations to the developer. RATIONALE  
 119172 sections give additional information on the decisions made in defining the interface.

119173 FUTURE DIRECTIONS sections act as pointers to related work that may impact the interface in  
 119174 the future, and often cautions the developer to architect the code to account for a change in this  
 119175 area. Note that a future directions statement should not be taken as a commitment to adopt a  
 119176 feature or interface in the future.

119177 The CHANGE HISTORY section describes when the interface was introduced, and how it has  
 119178 changed.

119179 Option labels and margin markings in the page can be useful in guiding the application  
 119180 developer.

## 119181 B.2 General Information

### 119182 B.2.1 Use and Implementation of Interfaces

119183 The information concerning the use of functions was adapted from a description in the ISO C  
 119184 standard. Here is an example of how an application program can protect itself from functions  
 119185 that may or may not be macros, rather than true functions:

119186 The *atoi()* function may be used in any of several ways:

- 119187 • By use of its associated header (possibly generating a macro expansion):

```
119188 #include <stdlib.h>
119189 /* ... */
119190 i = atoi(str);
```

- 119191 • By use of its associated header (assuredly generating a true function call):

```
119192 #include <stdlib.h>
119193 #undef atoi
119194 /* ... */
119195 i = atoi(str);
```

119196 or:

```
119197 #include <stdlib.h>
119198 /* ... */
119199 i = (atoi) (str);
```

- 119200 • By explicit declaration:

```
119201 extern int atoi (const char *);
119202 /* ... */
119203 i = atoi(str);
```

- 119204 • By implicit declaration:

```
119205 /* ... */
119206 i = atoi(str);
```

119207 (Assuming no function prototype is in scope. This is not allowed by the ISO C standard for  
 119208 functions with variable arguments; furthermore, parameter type conversion “widening” is

119209 subject to different rules in this case.)

119210 Note that the ISO C standard reserves names starting with ‘\_’ for the compiler. Therefore, the  
 119211 compiler could, for example, implement an intrinsic, built-in function `_asm_builtin_atoi()`, which  
 119212 it recognized and expanded into inline assembly code. Then, in `<stdlib.h>`, there could be the  
 119213 following:

```
119214 #define atoi(X) _asm_builtin_atoi(X)
```

119215 The user’s “normal” call to `atoi()` would then be expanded inline, but the implementor would  
 119216 also be required to provide a callable function named `atoi()` for use when the application  
 119217 requires it; for example, if its address is to be stored in a function pointer variable.

119218 Implementors should note that since applications can **#undef** a macro in order to ensure that the  
 119219 function is used, this means that it is not safe for implementations to use the names of any  
 119220 standard functions in macro values, since the application could use **#undef** to ensure that no  
 119221 macro exists and then use the same name for an identifier with local scope. For example,  
 119222 historically it was common for a `getchar()` macro to be defined in `<stdio.h>` as:

```
119223 #define getchar() getc(stdin)
```

119224 This definition does not conform, because an application is allowed to use the identifier `getc`  
 119225 with local scope, and the expansion of the `getchar()` macro would then pick up the local `getc`.  
 119226 The following is conforming code, but would not compile with the above definition of `getchar()`:

```
119227 #include <stdio.h>
```

```
119228 #undef getc
```

```
119229 int main(void)
```

```
119230 {
```

```
119231 int getc;
```

```
119232 getc = getchar();
```

```
119233 return getc;
```

```
119234 }
```

119235 This does not only affect function-like macros. For example, the following definition does not  
 119236 conform because there could be a local `sysconf` variable in scope when `SIGRTMIN` is expanded:

```
119237 #define SIGRTMIN ((int)sysconf(_SC_SIGRT_MIN))
```

119238 Implementors can avoid the problem by using aliases for standard functions instead of the  
 119239 actual function, with names that conforming applications cannot use for local variables. For  
 119240 example:

```
119241 #define SIGRTMIN ((int)__sysconf(_SC_SIGRT_MIN))
```

## 119242 B.2.2 The Compilation Environment

### 119243 B.2.2.1 POSIX.1 Symbols

119244 This and the following section address the issue of “name space pollution”. The ISO C standard  
 119245 requires that the name space beyond what it reserves not be altered except by explicit action of  
 119246 the application developer. This section defines the actions to add the POSIX.1 symbols for those  
 119247 headers where both the ISO C standard and POSIX.1 need to define symbols, and also where the

119248 XSI option extends the base standard.

119249 When headers are used to provide symbols, there is a potential for introducing symbols that the  
 119250 application developer cannot predict. Ideally, each header should only contain one set of  
 119251 symbols, but this is not practical for historical reasons. Thus, the concept of feature test macros is  
 119252 included. Two feature test macros are explicitly defined by POSIX.1-2008; it is expected that  
 119253 future versions may add to this.

119254 **Note:** Feature test macros allow an application to announce to the implementation its desire to have  
 119255 certain symbols and prototypes exposed. They should not be confused with the version test  
 119256 macros and constants for options in `<unistd.h>` which are the implementation's way of  
 119257 announcing functionality to the application.

119258 It is further intended that these feature test macros apply only to the headers specified by  
 119259 POSIX.1-2008. Implementations are expressly permitted to make visible symbols not specified  
 119260 by POSIX.1-2008, within both POSIX.1 and other headers, under the control of feature test  
 119261 macros that are not defined by POSIX.1-2008.

#### 119262 **The `_POSIX_C_SOURCE` Feature Test Macro**

119263 The POSIX.1-1990 standard specified a macro called `_POSIX_SOURCE`. This has been  
 119264 superseded by `_POSIX_C_SOURCE`. This symbol will allow implementations to support various  
 119265 versions of this standard simultaneously. For instance, when `_POSIX_C_SOURCE` is defined as  
 119266 200809L, the system should make visible the same name space as permitted and required by the  
 119267 POSIX.1-2008 standard. A special case is the one where the implementation wishes to make  
 119268 available support for the 1990 version of the POSIX standard, in which instance when either  
 119269 `_POSIX_SOURCE` is defined or `_POSIX_C_SOURCE` is defined as 1, the system should make  
 119270 visible the same name space as permitted and required by the POSIX.1-1990 standard.

119271 It is expected that C bindings to future POSIX standards will define new values for  
 119272 `_POSIX_C_SOURCE`, with each new value reserving the name space for that new standard.

#### 119273 **The `_XOPEN_SOURCE` Feature Test Macro**

119274 The feature test macro `_XOPEN_SOURCE` is provided as the announcement mechanism for the  
 119275 application that it requires functionality from the Single UNIX Specification. `_XOPEN_SOURCE`  
 119276 must be defined to the value 700 before the inclusion of any header to enable the functionality in  
 119277 the Single UNIX Specification Version 4. Its definition subsumes the use of `_POSIX_C_SOURCE`.

119278 An extract of code from a conforming application, that appears before any **#include** statements,  
 119279 is given below:

```
119280 #define _XOPEN_SOURCE 700 /* Single UNIX Specification, Version 4 */
119281 #include ...
```

119282 Note that the definition of `_XOPEN_SOURCE` with the value 700 makes the definition of  
 119283 `_POSIX_C_SOURCE` redundant and it can safely be omitted.

#### 119284 **B.2.2.2 The Name Space**

119285 The reservation of identifiers is paraphrased from the ISO C standard. The text is included  
 119286 because it needs to be part of POSIX.1-2008, regardless of possible changes in future versions of  
 119287 the ISO C standard.

119288 These identifiers may be used by implementations, particularly for feature test macros.  
 119289 Implementations should not use feature test macro names that might be reasonably used by a  
 119290 standard.

Including headers more than once is a reasonably common practice, and it should be carried forward from the ISO C standard. More significantly, having definitions in more than one header is explicitly permitted. Where the potential declaration is “benign” (the same definition twice) the declaration can be repeated, if that is permitted by the compiler. (This is usually true of macros, for example.) In those situations where a repetition is not benign (for example, **typedefs**), conditional compilation must be used. The situation actually occurs both within the ISO C standard and within POSIX.1: **time\_t** should be in **<sys/types.h>**, and the ISO C standard mandates that it be in **<time.h>**.

The area of name space pollution *versus* additions to structures is difficult because of the macro structure of C. The following discussion summarizes all the various problems with and objections to the issue.

Note the phrase “user-defined macro”. Users are not permitted to define macro names (or any other name) beginning with “\_**[A-Z\_]**”. Thus, the conflict cannot occur for symbols reserved to the vendor’s name space, and the permission to add fields automatically applies, without qualification, to those symbols.

1. Data structures (and unions) need to be defined in headers by implementations to meet certain requirements of POSIX.1 and the ISO C standard.

2. The structures defined by POSIX.1 are typically minimal, and any practical implementation would wish to add fields to these structures either to hold additional related information or for backwards-compatibility (or both). Future standards (and *de facto* standards) would also wish to add to these structures. Issues of field alignment make it impractical (at least in the general case) to simply omit fields when they are not defined by the particular standard involved.

The **dirent** structure is an example of such a minimal structure (although one could argue about whether the other fields need visible names). The **st\_rdev** field of most implementations’ **stat** structure is a common example where extension is needed and where a conflict could occur.

3. Fields in structures are in an independent name space, so the addition of such fields presents no problem to the C language itself in that such names cannot interact with identically named user symbols because access is qualified by the specific structure name.

4. There is an exception to this: macro processing is done at a lexical level. Thus, symbols added to a structure might be recognized as user-provided macro names at the location where the structure is declared. This only can occur if the user-provided name is declared as a macro before the header declaring the structure is included. The user’s use of the name after the declaration cannot interfere with the structure because the symbol is hidden and only accessible through access to the structure. Presumably, the user would not declare such a macro if there was an intention to use that field name.

5. Macros from the same or a related header might use the additional fields in the structure, and those field names might also collide with user macros. Although this is a less frequent occurrence, since macros are expanded at the point of use, no constraint on the order of use of names can apply.

6. An “obvious” solution of using names in the reserved name space and then redefining them as macros when they should be visible does not work because this has the effect of exporting the symbol into the general name space. For example, given a (hypothetical) system-provided header **<h.h>**, and two parts of a C program in **a.c** and **b.c**, in header **<h.h>**:

```
struct foo {
 int __i;
```

```

119339 }
119340 #ifdef _FEATURE_TEST
119341 #define i __i;
119342 #endif

```

119343 In file **a.c**:

```

119344 #include h.h
119345 extern int i;
119346 ...

```

119347 In file **b.c**:

```

119348 extern int i;
119349 ...

```

119350 The symbol that the user thinks of as *i* in both files has an external name of `__i` in **a.c**; the  
 119351 same symbol *i* in **b.c** has an external name *i* (ignoring any hidden manipulations the  
 119352 compiler might perform on the names). This would cause a mysterious name resolution  
 119353 problem when **a.o** and **b.o** are linked.

119354 Simply avoiding definition then causes alignment problems in the structure.

119355 A structure of the form:

```

119356 struct foo {
119357 union {
119358 int __i;
119359 #ifdef _FEATURE_TEST
119360 int i;
119361 #endif
119362 } __ii;
119363 }

```

119364 does not work because the name of the logical field *i* is `__ii.i`, and introduction of a macro  
 119365 to restore the logical name immediately reintroduces the problem discussed previously  
 119366 (although its manifestation might be more immediate because a syntax error would result  
 119367 if a recursive macro did not cause it to fail first).

119368 7. A more workable solution would be to declare the structure:

```

119369 struct foo {
119370 #ifdef _FEATURE_TEST
119371 int i;
119372 #else
119373 int __i;
119374 #endif
119375 }

```

119376 However, if a macro (particularly one required by a standard) is to be defined that uses  
 119377 this field, two must be defined: one that uses *i*, the other that uses `__i`. If more than one  
 119378 additional field is used in a macro and they are conditional on distinct combinations of  
 119379 features, the complexity goes up as  $2^n$ .

119380 All this leaves a difficult situation: vendors must provide very complex headers to deal with  
 119381 what is conceptually simple and safe—adding a field to a structure. It is the possibility of user-  
 119382 provided macros with the same name that makes this difficult.

119383 Several alternatives were proposed that involved constraining the user's access to part of the

name space available to the user (as specified by the ISO C standard). In some cases, this was only until all the headers had been included. There were two proposals discussed that failed to achieve consensus:

1. Limiting it for the whole program.
2. Restricting the use of identifiers containing only uppercase letters until after all system headers had been included. It was also pointed out that because macros might wish to access fields of a structure (and macro expansion occurs totally at point of use) restricting names in this way would not protect the macro expansion, and thus the solution was inadequate.

It was finally decided that reservation of symbols would occur, but as constrained.

The current wording also allows the addition of fields to a structure, but requires that user macros of the same name not interfere. This allows vendors to do one of the following:

- Not create the situation (do not extend the structures with user-accessible names or use the solution in (7) above)
- Extend their compilers to allow some way of adding names to structures and macros safely

There are at least two ways that the compiler might be extended: add new preprocessor directives that turn off and on macro expansion for certain symbols (without changing the value of the macro) and a function or lexical operation that suppresses expansion of a word. The latter seems more flexible, particularly because it addresses the problem in macros as well as in declarations.

The following seems to be a possible implementation extension to the C language that will do this: any token that during macro expansion is found to be preceded by three '#' symbols shall not be further expanded in exactly the same way as described for macros that expand to their own name as in Section 3.8.3.4 of the ISO C standard. A vendor may also wish to implement this as an operation that is lexically a function, which might be implemented as:

```
#define __safe_name(x) ###x
```

Using a function notation would insulate vendors from changes in standards until such a functionality is standardized (if ever). Standardization of such a function would be valuable because it would then permit third parties to take advantage of it portably in software they may supply.

The symbols that are “explicitly permitted, but not required by POSIX.1-2008” include those classified below. (That is, the symbols classified below might, but are not required to, be present when `_POSIX_C_SOURCE` is defined to have the value 200809L.)

- Symbols in `<limits.h>` and `<unistd.h>` that are defined to indicate support for options or limits that are constant at compile-time
- Symbols in the name space reserved for the implementation by the ISO C standard
- Symbols in a name space reserved for a particular type of extension (for example, type names ending with `_t` in `<sys/types.h>`)
- Additional members of structures or unions whose names do not reduce the name space reserved for applications

Since both implementations and future versions of this standard and other POSIX standards may use symbols in the reserved spaces described in these tables, there is a potential for name space clashes. To avoid future name space clashes when adding symbols, implementations should not use the `posix_`, `POSIX_`, or `_POSIX_` prefixes.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/2 is applied, deleting the entries `POSIX_`, `_POSIX_`, and `posix_` from the column of allowed name space prefixes for use by an implementation in the first table. The presence of these prefixes was contradicting later text which states that: “The prefixes `posix_`, `POSIX_`, and `_POSIX` are reserved for use by XCU Chapter 2 (on page 2319) and other POSIX standards. Implementations may add symbols to the headers shown in the following table, provided the identifiers ... do not use the reserved prefixes `posix_`, `POSIX_`, or `_POSIX`.”.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/3 is applied, correcting the reserved macro prefix from: “`PRI[a-z]`, `SCN[a-z]`” to: “`PRI[Xa-z]`, `SCN[Xa-z]`” in the second table. The change was needed since the ISO C standard allows implementations to define macros of the form `PRI` or `SCN` followed by any lowercase letter or ‘`x`’ in `<inttypes.h>`. (The ISO/IEC 9899:1999 standard, Subclause 7.26.4.)

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/4 is applied, adding a new section listing reserved names for the `<stdint.h>` header. This change is for alignment with the ISO C standard.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/2 is applied, making it clear that implementations are permitted to have symbols with the prefix `_POSIX_` visible in any header.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/3 is applied, updating the table of allowed macro prefixes to include the prefix `FP_[A-Z]` for `<math.h>`. This text is added for consistency with the `<math.h>` reference page in the Base Definitions volume of POSIX.1-2008 which permits additional implementation-defined floating-point classifications.

Austin Group Interpretation 1003.1-2001 #048 is applied, reserving `SEEK_` in the name space.

### 119449 B.2.3 Error Numbers

It was the consensus of the standard developers that to allow the conformance document to state that an error occurs and under what conditions, but to disallow a statement that it never occurs, does not make sense. It could be implied by the current wording that this is allowed, but to reduce the possibility of future interpretation requests, it is better to make an explicit statement.

The ISO C standard requires that `errno` be an assignable lvalue. Originally, the definition in POSIX.1 was stricter than that in the ISO C standard, `extern int errno`, in order to support historical usage. In a multi-threaded environment, implementing `errno` as a global variable results in non-deterministic results when accessed. It is required, however, that `errno` work as a per-thread error reporting mechanism. In order to do this, a separate `errno` value has to be maintained for each thread. The following section discusses the various alternative solutions that were considered.

In order to avoid this problem altogether for new functions, these functions avoid using `errno` and, instead, return the error number directly as the function return value; a return value of zero indicates that no error was detected.

For any function that can return errors, the function return value is not used for any purpose other than for reporting errors. Even when the output of the function is scalar, it is passed through a function argument. While it might have been possible to allow some scalar outputs to be coded as negative function return values and mixed in with positive error status returns, this was rejected—using the return value for a mixed purpose was judged to be of limited use and error prone.

Checking the value of `errno` alone is not sufficient to determine the existence or type of an error, since it is not required that a successful function call clear `errno`. The variable `errno` should only be examined when the return value of a function indicates that the value of `errno` is meaningful. In that case, the function is required to set the variable to something other than zero.

- 119474 The variable *errno* is never set to zero by any function call; to do so would contradict the ISO C  
119475 standard.
- 119476 POSIX.1 requires (in the ERRORS sections of function descriptions) certain error values to be set  
119477 in certain conditions because many existing applications depend on them. Some error numbers,  
119478 such as [EFAULT], are entirely implementation-defined and are noted as such in their  
119479 description in the ERRORS section. This section otherwise allows wide latitude to the  
119480 implementation in handling error reporting.
- 119481 Some of the ERRORS sections in POSIX.1-2008 have two subsections. The first:  
119482 “The function shall fail if:”
- 119483 could be called the “mandatory” section.
- 119484 The second:  
119485 “The function may fail if:”
- 119486 could be informally known as the “optional” section.
- 119487 Attempting to infer the quality of an implementation based on whether it detects optional error  
119488 conditions is not useful.
- 119489 Following each one-word symbolic name for an error, there is a description of the error. The  
119490 rationale for some of the symbolic names follows:
- 119491 [ECANCELED] This spelling was chosen as being more common.
- 119492 [EFAULT] Most historical implementations do not catch an error and set *errno* when an  
119493 invalid address is given to the functions *wait()*, *time()*, or *times()*. Some  
119494 implementations cannot reliably detect an invalid address. And most systems  
119495 that detect invalid addresses will do so only for a system call, not for a library  
119496 routine.
- 119497 [EFTYPE] This error code was proposed in earlier proposals as “Inappropriate operation  
119498 for file type”, meaning that the operation requested is not appropriate for the  
119499 file specified in the function call. This code was proposed, although the same  
119500 idea was covered by [ENOTTY], because the connotations of the name would  
119501 be misleading. It was pointed out that the *fcntl()* function uses the error code  
119502 [EINVAL] for this notion, and hence all instances of [EFTYPE] were changed  
119503 to this code.
- 119504 [EINTR] POSIX.1 prohibits conforming implementations from restarting interrupted  
119505 system calls of conforming applications unless the SA\_RESTART flag is in  
119506 effect for the signal. However, it does not require that [EINTR] be returned  
119507 when another legitimate value may be substituted; for example, a partial  
119508 transfer count when *read()* or *write()* are interrupted. This is only given when  
119509 the signal-catching function returns normally as opposed to returns by  
119510 mechanisms like *longjmp()* or *siglongjmp()*.
- 119511 [ELOOP] In specifying conditions under which implementations would generate this  
119512 error, the following goals were considered:
- 119513 • To ensure that actual loops are detected, including loops that result from  
119514 symbolic links across distributed file systems.
  - 119515 • To ensure that during pathname resolution an application can rely on  
119516 the ability to follow at least {SYMLOOP\_MAX} symbolic links in the  
119517 absence of a loop.

|        |                |                                                                                                     |
|--------|----------------|-----------------------------------------------------------------------------------------------------|
| 119518 |                | • To allow implementations to provide the capability of traversing more                             |
| 119519 |                | than {SYMLOOP_MAX} symbolic links in the absence of a loop.                                         |
| 119520 |                | • To allow implementations to detect loops and generate the error prior to                          |
| 119521 |                | encountering {SYMLOOP_MAX} symbolic links.                                                          |
| 119522 | [ENAMETOOLONG] |                                                                                                     |
| 119523 |                | When a symbolic link is encountered during pathname resolution, the                                 |
| 119524 |                | contents of that symbolic link are used to create a new pathname. The                               |
| 119525 |                | standard developers intended to allow, but not require, that implementations                        |
| 119526 |                | enforce the restriction of {PATH_MAX} on the result of this pathname                                |
| 119527 |                | substitution.                                                                                       |
| 119528 |                | Implementations are allowed, but not required, to treat a pathname longer                           |
| 119529 |                | than {PATH_MAX} passed into the system as an error. Implementations are                             |
| 119530 |                | required to return a pathname (even if it is longer than {PATH_MAX}) when                           |
| 119531 |                | the user supplies a buffer with an interface that specifies the buffer size, as                     |
| 119532 |                | long as the user-supplied buffer is large enough to hold the entire pathname                        |
| 119533 |                | (see XSH <i>getcwd()</i> for an example of this type of interface). Implementations                 |
| 119534 |                | are required to treat a request to pass a pathname longer than {PATH_MAX}                           |
| 119535 |                | from the system to a user-supplied buffer of an unspecified size (usually                           |
| 119536 |                | assumed to be of size {PATH_MAX}) as an error (see XSH <i>realpath()</i> for an                     |
| 119537 |                | example of this type of interface).                                                                 |
| 119538 | [ENOMEM]       | The term “main memory” is not used in POSIX.1 because it is                                         |
| 119539 |                | implementation-defined.                                                                             |
| 119540 | [ENOTSUP]      | This error code is to be used when an implementation chooses to implement                           |
| 119541 |                | the required functionality of POSIX.1-2008 but does not support optional                            |
| 119542 |                | facilities defined by POSIX.1-2008. The return of [ENOSYS] is to be taken to                        |
| 119543 |                | indicate that the function of the interface is not supported at all; the function                   |
| 119544 |                | will always fail with this error code.                                                              |
| 119545 | [ENOTTY]       | The symbolic name for this error is derived from a time when device control                         |
| 119546 |                | was done by <i>ioctl()</i> and that operation was only permitted on a terminal                      |
| 119547 |                | interface. The term “TTY” is derived from “teletypewriter”, the devices to                          |
| 119548 |                | which this error originally applied.                                                                |
| 119549 | [EOVERFLOW]    | Most of the uses of this error code are related to large file support. Typically,                   |
| 119550 |                | these cases occur on systems which support multiple programming                                     |
| 119551 |                | environments with different sizes for <b>off_t</b> , but they may also occur in                     |
| 119552 |                | connection with remote file systems.                                                                |
| 119553 |                | In addition, when different programming environments have different widths                          |
| 119554 |                | for types such as <b>int</b> and <b>uid_t</b> , several functions may encounter a condition         |
| 119555 |                | where a value in a particular environment is too wide to be represented. In                         |
| 119556 |                | that case, this error should be raised. For example, suppose the currently                          |
| 119557 |                | running process has 64-bit <b>int</b> , and file descriptor 9 223 372 036 854 775 807 is            |
| 119558 |                | open and does not have the close-on-exec flag set. If the process then uses                         |
| 119559 |                | <i>execl()</i> to <i>exec</i> a file compiled in a programming environment with 32-bit <b>int</b> , |
| 119560 |                | the call to <i>execl()</i> can fail with <i>errno</i> set to [EOVERFLOW]. A similar failure         |
| 119561 |                | can occur with <i>execl()</i> if any of the user IDs or any of the group IDs to be                  |
| 119562 |                | assigned to the new process image are out of range for the executed file’s                          |
| 119563 |                | programming environment.                                                                            |
| 119564 |                | Note, however, that this condition cannot occur for functions that are                              |
| 119565 |                | explicitly described as always being successful, such as <i>getpid()</i> .                          |

119566 [EPIPE] This condition normally generates the signal SIGPIPE; the error is returned if  
 119567 the generation of the signal is suppressed or the signal does not terminate the  
 119568 process.

119569 [EROFS] In historical implementations, attempting to *unlink()* or *rmdir()* a mount point  
 119570 would generate an [EBUSY] error. An implementation could be envisioned  
 119571 where such an operation could be performed without error. In this case, if  
 119572 *either* the directory entry or the actual data structures reside on a read-only file  
 119573 system, [EROFS] is the appropriate error to generate. (For example, changing  
 119574 the link count of a file on a read-only file system could not be done, as is  
 119575 required by *unlink()*, and thus an error should be reported.)

119576 Three error numbers, [EDOM], [EILSEQ], and [ERANGE], were added to this section primarily  
 119577 for consistency with the ISO C standard.

#### 119578 **Alternative Solutions for Per-Thread *errno***

119579 The usual implementation of *errno* as a single global variable does not work in a multi-threaded  
 119580 environment. In such an environment, a thread may make a POSIX.1 call and get a -1 error  
 119581 return, but before that thread can check the value of *errno*, another thread might have made a  
 119582 second POSIX.1 call that also set *errno*. This behavior is unacceptable in robust programs. There  
 119583 were a number of alternatives that were considered for handling the *errno* problem:

- 119584 • Implement *errno* as a per-thread integer variable.
- 119585 • Implement *errno* as a service that can access the per-thread error number.
- 119586 • Change all POSIX.1 calls to accept an extra status argument and avoid setting *errno*.
- 119587 • Change all POSIX.1 calls to raise a language exception.

119588 The first option offers the highest level of compatibility with existing practice but requires  
 119589 special support in the linker, compiler, and/or virtual memory system to support the new  
 119590 concept of thread private variables. When compared with current practice, the third and fourth  
 119591 options are much cleaner, more efficient, and encourage a more robust programming style, but  
 119592 they require new versions of all of the POSIX.1 functions that might detect an error. The second  
 119593 option offers compatibility with existing code that uses the **<errno.h>** header to define the  
 119594 symbol *errno*. In this option, *errno* may be a macro defined:

```
119595 #define errno (*__errno())
119596 extern int *__errno();
```

119597 This option may be implemented as a per-thread variable whereby an *errno* field is allocated in  
 119598 the user space object representing a thread, and whereby the function *\_\_errno()* makes a system  
 119599 call to determine the location of its user space object and returns the address of the *errno* field of  
 119600 that object. Another implementation, one that avoids calling the kernel, involves allocating  
 119601 stacks in chunks. The stack allocator keeps a side table indexed by chunk number containing a  
 119602 pointer to the thread object that uses that chunk. The *\_\_errno()* function then looks at the stack  
 119603 pointer, determines the chunk number, and uses that as an index into the chunk table to find its  
 119604 thread object and thus its private value of *errno*. On most architectures, this can be done in four  
 119605 to five instructions. Some compilers may wish to implement *\_\_errno()* inline to improve  
 119606 performance.

## Disallowing Return of the [EINTR] Error Code

Many blocking interfaces defined by POSIX.1-2008 may return [EINTR] if interrupted during their execution by a signal handler. Blocking interfaces introduced under the threads functionality do not have this property. Instead, they require that the interface appear to be atomic with respect to interruption. In particular, clients of blocking interfaces need not handle any possible [EINTR] return as a special case since it will never occur. If it is necessary to restart operations or complete incomplete operations following the execution of a signal handler, this is handled by the implementation, rather than by the application.

Requiring applications to handle [EINTR] errors on blocking interfaces has been shown to be a frequent source of often unreproducible bugs, and it adds no compelling value to the available functionality. Thus, blocking interfaces introduced for use by multi-threaded programs do not use this paradigm. In particular, in none of the functions *flockfile()*, *pthread\_cond\_timedwait()*, *pthread\_cond\_wait()*, *pthread\_join()*, *pthread\_mutex\_lock()*, and *sigwait()* did providing [EINTR] returns add value, or even particularly make sense. Thus, these functions do not provide for an [EINTR] return, even when interrupted by a signal handler. The same arguments can be applied to *sem\_wait()*, *sem\_trywait()*, *sigwaitinfo()*, and *sigtimedwait()*, but implementations are permitted to return [EINTR] error codes for these functions for compatibility with earlier versions of this standard. Applications cannot rely on calls to these functions returning [EINTR] error codes when signals are delivered to the calling thread, but they should allow for the possibility.

Austin Group Interpretation 1003.1-2001 #050 is applied, allowing [ENOTSUP] and [EOPNOTSUP] to be the same values.

### B.2.3.1 Additional Error Numbers

The ISO C standard defines the name space for implementations to add additional error numbers.

## B.2.4 Signal Concepts

Historical implementations of signals, using the *signal()* function, have shortcomings that make them unreliable for many application uses. Because of this, a new signal mechanism, based very closely on the one of 4.2 BSD and 4.3 BSD, was added to POSIX.1.

### Signal Names

The restriction on the actual type used for **sigset\_t** is intended to guarantee that these objects can always be assigned, have their address taken, and be passed as parameters by value. It is not intended that this type be a structure including pointers to other data structures, as that could impact the portability of applications performing such operations. A reasonable implementation could be a structure containing an array of some integer type.

The signals described in POSIX.1-2008 must have unique values so that they may be named as parameters of **case** statements in the body of a C-language **switch** clause. However, implementation-defined signals may have values that overlap with each other or with signals specified in POSIX.1-2008. An example of this is SIGABRT, which traditionally overlaps some other signal, such as SIGIOT.

SIGKILL, SIGTERM, SIGUSR1, and SIGUSR2 are ordinarily generated only through the explicit use of the *kill()* function, although some implementations generate SIGKILL under extraordinary circumstances. SIGTERM is traditionally the default signal sent by the *kill* command.

The signals SIGBUS, SIGEMT, SIGIOT, SIGTRAP, and SIGSYS were omitted from POSIX.1 because their behavior is implementation-defined and could not be adequately categorized. Conforming implementations may deliver these signals, but must document the circumstances under which they are delivered and note any restrictions concerning their delivery. The signals SIGFPE, SIGILL, and SIGSEGV are similar in that they also generally result only from programming errors. They were included in POSIX.1 because they do indicate three relatively well-categorized conditions. They are all defined by the ISO C standard and thus would have to be defined by any system with an ISO C standard binding, even if not explicitly included in POSIX.1.

There is very little that a Conforming POSIX.1 Application can do by catching, ignoring, or masking any of the signals SIGILL, SIGTRAP, SIGIOT, SIGEMT, SIGBUS, SIGSEGV, SIGSYS, or SIGFPE. They will generally be generated by the system only in cases of programming errors. While it may be desirable for some robust code (for example, a library routine) to be able to detect and recover from programming errors in other code, these signals are not nearly sufficient for that purpose. One portable use that does exist for these signals is that a command interpreter can recognize them as the cause of termination of a process (with *wait()*) and print an appropriate message. The mnemonic tags for these signals are derived from their PDP-11 origin.

The signals SIGSTOP, SIGTSTP, SIGTTIN, SIGTTOU, and SIGCONT are provided for job control and are unchanged from 4.2 BSD. The signal SIGCHLD is also typically used by job control shells to detect children that have terminated or, as in 4.2 BSD, stopped.

Some implementations, including System V, have a signal named SIGCLD, which is similar to SIGCHLD in 4.2 BSD. POSIX.1 permits implementations to have a single signal with both names. POSIX.1 carefully specifies ways in which conforming applications can avoid the semantic differences between the two different implementations. The name SIGCHLD was chosen for POSIX.1 because most current application usages of it can remain unchanged in conforming applications. SIGCLD in System V has more cases of semantics that POSIX.1 does not specify, and thus applications using it are more likely to require changes in addition to the name change.

The signals SIGUSR1 and SIGUSR2 are commonly used by applications for notification of exceptional behavior and are described as “reserved as application-defined” so that such use is not prohibited. Implementations should not generate SIGUSR1 or SIGUSR2, except when explicitly requested by *kill()*. It is recommended that libraries not use these two signals, as such use in libraries could interfere with their use by applications calling the libraries. If such use is unavoidable, it should be documented. It is prudent for non-portable libraries to use non-standard signals to avoid conflicts with use of standard signals by portable libraries.

There is no portable way for an application to catch or ignore non-standard signals. Some implementations define the range of signal numbers, so applications can install signal-catching functions for all of them. Unfortunately, implementation-defined signals often cause problems when caught or ignored by applications that do not understand the reason for the signal. While the desire exists for an application to be more robust by handling all possible signals (even those only generated by *kill()*), no existing mechanism was found to be sufficiently portable to include in POSIX.1. The value of such a mechanism, if included, would be diminished given that SIGKILL would still not be catchable.

A number of new signal numbers are reserved for applications because the two user signals defined by POSIX.1 are insufficient for many realtime applications. A range of signal numbers is specified, rather than an enumeration of additional reserved signal names, because different applications and application profiles will require a different number of application signals. It is not desirable to burden all application domains and therefore all implementations with the maximum number of signals required by all possible applications. Note that in this context, signal numbers are essentially different signal priorities.

119701 The relatively small number of required additional signals, {\_POSIX\_RTSIG\_MAX}, was chosen  
 119702 so as not to require an unreasonably large signal mask/set. While this number of signals  
 119703 defined in POSIX.1 will fit in a single 32-bit word signal mask, it is recognized that most existing  
 119704 implementations define many more signals than are specified in POSIX.1 and, in fact, many  
 119705 implementations have already exceeded 32 signals (including the “null signal”). Support of  
 119706 {\_POSIX\_RTSIG\_MAX} additional signals may push some implementation over the single 32-bit  
 119707 word line, but is unlikely to push any implementations that are already over that line beyond  
 119708 the 64-signal line.

#### 119709 B.2.4.1 Signal Generation and Delivery

119710 The terms defined in this section are not used consistently in documentation of historical  
 119711 systems. Each signal can be considered to have a lifetime beginning with generation and ending  
 119712 with delivery or acceptance. The POSIX.1 definition of “delivery” does not exclude ignored  
 119713 signals; this is considered a more consistent definition. This revised text in several parts of  
 119714 POSIX.1-2008 clarifies the distinct semantics of asynchronous signal delivery and synchronous  
 119715 signal acceptance. The previous wording attempted to categorize both under the term  
 119716 “delivery”, which led to conflicts over whether the effects of asynchronous signal delivery  
 119717 applied to synchronous signal acceptance.

119718 Signals generated for a process are delivered to only one thread. Thus, if more than one thread  
 119719 is eligible to receive a signal, one has to be chosen. The choice of threads is left entirely up to the  
 119720 implementation both to allow the widest possible range of conforming implementations and to  
 119721 give implementations the freedom to deliver the signal to the “easiest possible” thread should  
 119722 there be differences in ease of delivery between different threads.

119723 Note that should multiple delivery among cooperating threads be required by an application,  
 119724 this can be trivially constructed out of the provided single-delivery semantics. The construction  
 119725 of a *sigwait\_multiple()* function that accomplishes this goal is presented with the rationale for  
 119726 *sigwaitinfo()*.

119727 Implementations should deliver unblocked signals as soon after they are generated as possible.  
 119728 However, it is difficult for POSIX.1 to make specific requirements about this, beyond those in  
 119729 *kill()* and *sigprocmask()*. Even on systems with prompt delivery, scheduling of higher priority  
 119730 processes is always likely to cause delays.

119731 In general, the interval between the generation and delivery of unblocked signals cannot be  
 119732 detected by an application. Thus, references to pending signals generally apply to blocked,  
 119733 pending signals. An implementation registers a signal as pending on the process when no  
 119734 thread has the signal unblocked and there are no threads blocked in a *sigwait()* function for that  
 119735 signal. Thereafter, the implementation delivers the signal to the first thread that unblocks the  
 119736 signal or calls a *sigwait()* function on a signal set containing this signal rather than choosing the  
 119737 recipient thread at the time the signal is sent.

119738 In the 4.3 BSD system, signals that are blocked and set to SIG\_IGN are discarded immediately  
 119739 upon generation. For a signal that is ignored as its default action, if the action is SIG\_DFL and  
 119740 the signal is blocked, a generated signal remains pending. In the 4.1 BSD system and in  
 119741 System V Release 3 (two other implementations that support a somewhat similar signal  
 119742 mechanism), all ignored blocked signals remain pending if generated. Because it is not normally  
 119743 useful for an application to simultaneously ignore and block the same signal, it was unnecessary  
 119744 for POSIX.1 to specify behavior that would invalidate any of the historical implementations.

119745 There is one case in some historical implementations where an unblocked, pending signal does  
 119746 not remain pending until it is delivered. In the System V implementation of *signal()*, pending  
 119747 signals are discarded when the action is set to SIG\_DFL or a signal-catching routine (as well as  
 119748 to SIG\_IGN). Except in the case of setting SIGCHLD to SIG\_DFL, implementations that do this

do not conform completely to POSIX.1. Some earlier proposals for POSIX.1 explicitly stated this, but these statements were redundant due to the requirement that functions defined by POSIX.1 not change attributes of processes defined by POSIX.1 except as explicitly stated.

POSIX.1 specifically states that the order in which multiple, simultaneously pending signals are delivered is unspecified. This order has not been explicitly specified in historical implementations, but has remained quite consistent and been known to those familiar with the implementations. Thus, there have been cases where applications (usually system utilities) have been written with explicit or implicit dependencies on this order. Implementors and others porting existing applications may need to be aware of such dependencies.

When there are multiple pending signals that are not blocked, implementations should arrange for the delivery of all signals at once, if possible. Some implementations stack calls to all pending signal-catching routines, making it appear that each signal-catcher was interrupted by the next signal. In this case, the implementation should ensure that this stacking of signals does not violate the semantics of the signal masks established by *sigaction()*. Other implementations process at most one signal when the operating system is entered, with remaining signals saved for later delivery. Although this practice is widespread, this behavior is neither standardized nor endorsed. In either case, implementations should attempt to deliver signals associated with the current state of the process (for example, SIGFPE) before other signals, if possible.

In 4.2 BSD and 4.3 BSD, it is not permissible to ignore or explicitly block SIGCONT, because if blocking or ignoring this signal prevented it from continuing a stopped process, such a process could never be continued (only killed by SIGKILL). However, 4.2 BSD and 4.3 BSD do block SIGCONT during execution of its signal-catching function when it is caught, creating exactly this problem. A proposal was considered to disallow catching SIGCONT in addition to ignoring and blocking it, but this limitation led to objections. The consensus was to require that SIGCONT always continue a stopped process when generated. This removed the need to disallow ignoring or explicit blocking of the signal; note that SIG\_IGN and SIG\_DFL are equivalent for SIGCONT.

#### B.2.4.2 Realtime Signal Generation and Delivery

The realtime signals functionality is required in this version of the standard for the following reasons:

- The **sigevent** structure is used by other POSIX.1 functions that result in asynchronous event notifications to specify the notification mechanism to use and other information needed by the notification mechanism. POSIX.1-2008 defines only three symbolic values for the notification mechanism:
  - SIGEV\_NONE is used to indicate that no notification is required when the event occurs. This is useful for applications that use asynchronous I/O with polling for completion.
  - SIGEV\_SIGNAL indicates that a signal is generated when the event occurs.
  - SIGEV\_THREAD provides for “callback functions” for asynchronous notifications done by a function call within the context of a new thread. This provides a multi-threaded process with a more natural means of notification than signals.

The primary difficulty with previous notification approaches has been to specify the environment of the notification routine.

- One approach is to limit the notification routine to call only functions permitted in a signal handler. While the list of permissible functions is clearly stated, this is overly restrictive.

- 119795 — A second approach is to define a new list of functions or classes of functions that are  
 119796 explicitly permitted or not permitted. This would give a programmer more lists to  
 119797 deal with, which would be awkward.
- 119798 — The third approach is to define completely the environment for execution of the  
 119799 notification function. A clear definition of an execution environment for notification  
 119800 is provided by executing the notification function in the environment of a newly  
 119801 created thread.
- 119802 Implementations may support additional notification mechanisms by defining new values  
 119803 for *sigev\_notify*.
- 119804 For a notification type of SIGEV\_SIGNAL, the other members of the **sigevent** structure  
 119805 defined by POSIX.1-2008 specify the realtime signal—that is, the signal number and  
 119806 application-defined value that differentiates between occurrences of signals with the same  
 119807 number—that will be generated when the event occurs. The structure is defined in  
 119808 **<signal.h>**, even though the structure is not directly used by any of the signal functions,  
 119809 because it is part of the signals interface used by the POSIX.1b “client functions”. When the  
 119810 client functions include **<signal.h>** to define the signal names, the **sigevent** structure will  
 119811 also be defined.
- 119812 An application-defined value passed to the signal handler is used to differentiate between  
 119813 different “events” instead of requiring that the application use different signal numbers for  
 119814 several reasons:
- 119815 — Realtime applications potentially handle a very large number of different events.  
 119816 Requiring that implementations support a correspondingly large number of distinct  
 119817 signal numbers will adversely impact the performance of signal delivery because the  
 119818 signal masks to be manipulated on entry and exit to the handlers will become large.
- 119819 — Event notifications are prioritized by signal number (the rationale for this is  
 119820 explained in the following paragraphs) and the use of different signal numbers to  
 119821 differentiate between the different event notifications overloads the signal number  
 119822 more than has already been done. It also requires that the application developer  
 119823 make arbitrary assignments of priority to events that are logically of equal priority.
- 119824 A union is defined for the application-defined value so that either an integer constant or a  
 119825 pointer can be portably passed to the signal-catching function. On some architectures a  
 119826 pointer cannot be cast to an **int** and *vice versa*.
- 119827 Use of a structure here with an explicit notification type discriminant rather than explicit  
 119828 parameters to realtime functions, or embedded in other realtime structures, provides for  
 119829 future extensions to POSIX.1-2008. Additional, perhaps more efficient, notification  
 119830 mechanisms can be supported for existing realtime function interfaces, such as timers and  
 119831 asynchronous I/O, by extending the **sigevent** structure appropriately. The existing  
 119832 realtime function interfaces will not have to be modified to use any such new notification  
 119833 mechanism. The revised text concerning the SIGEV\_SIGNAL value makes consistent the  
 119834 semantics of the members of the **sigevent** structure, particularly in the definitions of  
 119835 *lio\_listio()* and *aio\_fsync()*. For uniformity, other revisions cause this specification to be  
 119836 referred to rather than inaccurately duplicated in the descriptions of functions and  
 119837 structures using the **sigevent** structure. The revised wording does not relax the  
 119838 requirement that the signal number be in the range SIGRTMIN to SIGRTMAX to guarantee  
 119839 queuing and passing of the application value, since that requirement is still implied by the  
 119840 signal names.

- POSIX.1-2008 is intentionally vague on whether “non-realtime” signal-generating mechanisms can result in a **siginfo\_t** being supplied to the handler on delivery. In one existing implementation, a **siginfo\_t** is posted on signal generation, even though the implementation does not support queuing of multiple occurrences of a signal. It is not the intent of POSIX.1-2008 to preclude this, independent of the mandate to define signals that do support queuing. Any interpretation that appears to preclude this is a mistake in the reading or writing of the standard.
- Signals handled by realtime signal handlers might be generated by functions or conditions that do not allow the specification of an application-defined value and do not queue. POSIX.1-2008 specifies the *si\_code* member of the **siginfo\_t** structure used in existing practice and defines additional codes so that applications can detect whether an application-defined value is present or not. The code `SI_USER` for *kill()*-generated signals is adopted from existing practice.
- The *sigaction()* *sa\_flags* value `SA_SIGINFO` tells the implementation that the signal-catching function expects two additional arguments. When the flag is not set, a single argument, the signal number, is passed as specified by POSIX.1-2008. Although POSIX.1-2008 does not explicitly allow the *info* argument to the handler function to be `NULL`, this is existing practice. This provides for compatibility with programs whose signal-catching functions are not prepared to accept the additional arguments. POSIX.1-2008 is explicitly unspecified as to whether signals actually queue when `SA_SIGINFO` is not set for a signal, as there appear to be no benefits to applications in specifying one behavior or another. One existing implementation queues a **siginfo\_t** on each signal generation, unless the signal is already pending, in which case the implementation discards the new **siginfo\_t**; that is, the queue length is never greater than one. This implementation only examines `SA_SIGINFO` on signal delivery, discarding the queued **siginfo\_t** if its delivery was not requested.

The third argument to the signal-catching function, *context*, is left undefined by POSIX.1-2008, but is specified in the interface because it matches existing practice for the `SA_SIGINFO` flag. It was considered undesirable to require a separate implementation for `SA_SIGINFO` for POSIX conformance on implementations that already support the two additional parameters.
- The requirement to deliver lower numbered signals in the range `SIGRTMIN` to `SIGRTMAX` first, when multiple unblocked signals are pending, results from several considerations:

  - A method is required to prioritize event notifications. The signal number was chosen instead of, for instance, associating a separate priority with each request, because an implementation has to check pending signals at various points and select one for delivery when more than one is pending. Specifying a selection order is the minimal additional semantic that will achieve prioritized delivery. If a separate priority were to be associated with queued signals, it would be necessary for an implementation to search all non-empty, non-blocked signal queues and select from among them the pending signal with the highest priority. This would significantly increase the cost of and decrease the determinism of signal delivery.
  - Given the specified selection of the lowest numeric unblocked pending signal, preemptive priority signal delivery can be achieved using signal numbers and signal masks by ensuring that the *sa\_mask* for each signal number blocks all signals with a higher numeric value.

For realtime applications that want to use only the newly defined realtime signal numbers without interference from the standard signals, this can be achieved by blocking all of the standard signals in the thread signal mask and in the *sa\_mask*

- 119890 installed by the signal action for the realtime signal handlers.
- 119891 POSIX.1-2008 explicitly leaves unspecified the ordering of signals outside of the range of  
 119892 realtime signals and the ordering of signals within this range with respect to those outside  
 119893 the range. It was believed that this would unduly constrain implementations or standards  
 119894 in the future definition of new signals.
- 119895 *B.2.4.3 Signal Actions*
- 119896 Early proposals mentioned SIGCONT as a second exception to the rule that signals are not  
 119897 delivered to stopped processes until continued. Because POSIX.1-2008 now specifies that  
 119898 SIGCONT causes the stopped process to continue when it is generated, delivery of SIGCONT is  
 119899 not prevented because a process is stopped, even without an explicit exception to this rule.
- 119900 Ignoring a signal by setting the action to SIG\_IGN (or SIG\_DFL for signals whose default action  
 119901 is to ignore) is not the same as installing a signal-catching function that simply returns. Invoking  
 119902 such a function will interrupt certain system functions that block processes (for example, *wait()*,  
 119903 *sigsuspend()*, *pause()*, *read()*, *write()*) while ignoring a signal has no such effect on the process.
- 119904 Historical implementations discard pending signals when the action is set to SIG\_IGN.  
 119905 However, they do not always do the same when the action is set to SIG\_DFL and the default  
 119906 action is to ignore the signal. POSIX.1-2008 requires this for the sake of consistency and also for  
 119907 completeness, since the only signal this applies to is SIGCHLD, and POSIX.1-2008 disallows  
 119908 setting its action to SIG\_IGN.
- 119909 Some implementations (System V, for example) assign different semantics for SIGCHLD  
 119910 depending on whether the action is set to SIG\_IGN or SIG\_DFL. Since POSIX.1 requires that the  
 119911 default action for SIGCHLD be to ignore the signal, applications should always set the action to  
 119912 SIG\_DFL in order to avoid SIGCHLD.
- 119913 Whether or not an implementation allows SIG\_IGN as a SIGCHLD disposition to be inherited  
 119914 across a call to one of the *exec* family of functions or *posix\_spawn()* is explicitly left as  
 119915 unspecified. This change was made as a result of IEEE PASC Interpretation 1003.1 #132, and  
 119916 permits the implementation to decide between the following alternatives:
- 119917 • Unconditionally leave SIGCHLD set to SIG\_IGN, in which case the implementation would  
 119918 not allow applications that assume inheritance of SIG\_DFL to conform to POSIX.1-2008  
 119919 without change. The implementation would, however, retain an ability to control  
 119920 applications that create child processes but never call on the *wait* family of functions,  
 119921 potentially filling up the process table.
  - 119922 • Unconditionally reset SIGCHLD to SIG\_DFL, in which case the implementation would  
 119923 allow applications that assume inheritance of SIG\_DFL to conform. The implementation  
 119924 would, however, lose an ability to control applications that spawn child processes but  
 119925 never reap them.
  - 119926 • Provide some mechanism, not specified in POSIX.1-2008, to control inherited SIGCHLD  
 119927 dispositions.
- 119928 Some implementations (System V, for example) will deliver a SIGCHLD signal immediately when  
 119929 a process establishes a signal-catching function for SIGCHLD when that process has a child that  
 119930 has already terminated. Other implementations, such as 4.3 BSD, do not generate a new  
 119931 SIGCHLD signal in this way. In general, a process should not attempt to alter the signal action  
 119932 for the SIGCHLD signal while it has any outstanding children. However, it is not always  
 119933 possible for a process to avoid this; for example, shells sometimes start up processes in pipelines  
 119934 with other processes from the pipeline as children. Processes that cannot ensure that they have  
 119935 no children when altering the signal action for SIGCHLD thus need to be prepared for, but not

depend on, generation of an immediate SIGCHLD signal.

The default action of the stop signals (SIGSTOP, SIGTSTP, SIGTTIN, SIGTTOU) is to stop a process that is executing. If a stop signal is delivered to a process that is already stopped, it has no effect. In fact, if a stop signal is generated for a stopped process whose signal mask blocks the signal, the signal will never be delivered to the process since the process must receive a SIGCONT, which discards all pending stop signals, in order to continue executing.

The SIGCONT signal continues a stopped process even if SIGCONT is blocked (or ignored). However, if a signal-catching routine has been established for SIGCONT, it will not be entered until SIGCONT is unblocked.

If a process in an orphaned process group stops, it is no longer under the control of a job control shell and hence would not normally ever be continued. Because of this, orphaned processes that receive terminal-related stop signals (SIGTSTP, SIGTTIN, SIGTTOU, but not SIGSTOP) must not be allowed to stop. The goal is to prevent stopped processes from languishing forever. (As SIGSTOP is sent only via *kill()*, it is assumed that the process or user sending a SIGSTOP can send a SIGCONT when desired.) Instead, the system must discard the stop signal. As an extension, it may also deliver another signal in its place. 4.3 BSD sends a SIGKILL, which is overly effective because SIGKILL is not catchable. Another possible choice is SIGHUP. 4.3 BSD also does this for orphaned processes (processes whose parent has terminated) rather than for members of orphaned process groups; this is less desirable because job control shells manage process groups. POSIX.1 also prevents SIGTTIN and SIGTTOU signals from being generated for processes in orphaned process groups as a direct result of activity on a terminal, preventing infinite loops when *read()* and *write()* calls generate signals that are discarded; see [Section A.11.1.4](#) (on page 3511). A similar restriction on the generation of SIGTSTP was considered, but that would be unnecessary and more difficult to implement due to its asynchronous nature.

Although POSIX.1 requires that signal-catching functions be called with only one argument, there is nothing to prevent conforming implementations from extending POSIX.1 to pass additional arguments, as long as Strictly Conforming POSIX.1 Applications continue to compile and execute correctly. Most historical implementations do, in fact, pass additional, signal-specific arguments to certain signal-catching routines.

There was a proposal to change the declared type of the signal handler to:

```
void func (int sig, ...);
```

The usage of ellipses ("*...*") is ISO C standard syntax to indicate a variable number of arguments. Its use was intended to allow the implementation to pass additional information to the signal handler in a standard manner.

Unfortunately, this construct would require all signal handlers to be defined with this syntax because the ISO C standard allows implementations to use a different parameter passing mechanism for variable parameter lists than for non-variable parameter lists. Thus, all existing signal handlers in all existing applications would have to be changed to use the variable syntax in order to be standard and portable. This is in conflict with the goal of Minimal Changes to Existing Application Code.

When terminating a process from a signal-catching function, processes should be aware of any interpretation that their parent may make of the status returned by *wait()*, *waitid()*, or *waitpid()*. In particular, a signal-catching function should not call *exit(0)* or *\_exit(0)* unless it wants to indicate successful termination. A non-zero argument to *exit()* or *\_exit()* can be used to indicate unsuccessful termination. Alternatively, the process can use *kill()* to send itself a fatal signal (first ensuring that the signal is set to the default action and not blocked). See also the RATIONALE section of the *\_exit()* function.

The behavior of *unsafe* functions, as defined by this section, is undefined when they are invoked

from signal-catching functions in certain circumstances. The behavior of async-signal-safe functions, as defined by this section, is as specified by POSIX.1, regardless of invocation from a signal-catching function. This is the only intended meaning of the statement that async-signal-safe functions may be used in signal-catching functions without restriction. Applications must still consider all effects of such functions on such things as data structures, files, and process state. In particular, application developers need to consider the restrictions on interactions when interrupting *sleep()* (see *sleep()*) and interactions among multiple handles for a file description. The fact that any specific function is listed as async-signal-safe does not necessarily mean that invocation of that function from a signal-catching function is recommended.

In order to prevent errors arising from interrupting non-async-signal-safe function calls, applications should protect calls to these functions either by blocking the appropriate signals or through the use of some programmatic semaphore. POSIX.1 does not address the more general problem of synchronizing access to shared data structures. Note in particular that even the “safe” functions may modify the global variable *errno*; the signal-catching function may want to save and restore its value. The same principles apply to the async-signal-safety of application routines and asynchronous data access.

Note that *longjmp()* and *siglongjmp()* are not in the list of async-signal-safe functions. This is because the code executing after *longjmp()* or *siglongjmp()* can call any unsafe functions with the same danger as calling those unsafe functions directly from the signal handler. Applications that use *longjmp()* or *siglongjmp()* out of signal handlers require rigorous protection in order to be portable. Many of the other functions that are excluded from the list are traditionally implemented using either the C language *malloc()* or *free()* functions or the ISO C standard I/O library, both of which traditionally use data structures in a non-async-signal-safe manner. Because any combination of different functions using a common data structure can cause async-signal-safety problems, POSIX.1 does not define the behavior when any unsafe function is called in a signal handler that interrupts any unsafe function.

The only realtime extension to signal actions is the addition of the additional parameters to the signal-catching function. This extension has been explained and motivated in the previous section. In making this extension, though, developers of POSIX.1b ran into issues relating to function prototypes. In response to input from the POSIX.1 standard developers, members were added to the **sigaction** structure to specify function prototypes for the newer signal-catching function specified by POSIX.1b. These members follow changes that are being made to POSIX.1. Note that POSIX.1-2008 explicitly states that these fields may overlap so that a union can be defined. This enabled existing implementations of POSIX.1 to maintain binary-compatibility when these extensions were added.

The **siginfo\_t** structure was adopted for passing the application-defined value to match existing practice, but the existing practice has no provision for an application-defined value, so this was added. Note that POSIX normally reserves the “\_t” type designation for opaque types. The **siginfo\_t** structure breaks with this convention to follow existing practice and thus promote portability.

POSIX.1-2008 specifies several values for the *si\_code* member of the **siginfo\_t** structure. Some were introduced in POSIX.1b; others were XSI functionality in the Single UNIX Specification, Version 2 and Version 3, that has now become Base functionality. Historically, an *si\_code* value of less than or equal to zero indicated that the signal was generated by a process via the *kill()* function, and values of *si\_code* that provided additional information for implementation-generated signals, such as SIGFPE or SIGSEGV, were all positive. This functionality is partially specified for XSI systems in that if *si\_code* is less than or equal to zero, the signal was generated by a process. However, since POSIX.1b did not specify that SI\_USER (or SI\_QUEUE) had a value less than or equal to zero, it is not true that when the signal is generated by a process, the value of *si\_code* will always be less than or equal to zero. XSI applications should check whether *si\_code*

120034 is `SI_USER` or `SI_QUEUE` in addition to checking whether it is less than or equal to zero.  
 120035 Applications on systems that do not support the XSI option should just check for `SI_USER` and  
 120036 `SI_QUEUE`.

120037 If an implementation chooses to define additional values for *si\_code*, these values have to be  
 120038 different from the values of the non-signal-specific symbols specified by POSIX.1-2008. This will  
 120039 allow conforming applications to differentiate between signals generated by standard events  
 120040 and those generated by other implementation events in a manner compatible with existing  
 120041 practice.

120042 The unique values of *si\_code* for the POSIX.1b asynchronous events have implications for  
 120043 implementations of, for example, asynchronous I/O or message passing in user space library  
 120044 code. Such an implementation will be required to provide a hidden interface to the signal  
 120045 generation mechanism that allows the library to specify the standard values of *si\_code*.

120046 POSIX.1-2008 also specifies additional members of `siginfo_t`, beyond those that were in  
 120047 POSIX.1b. Like the *si\_code* values mentioned above, these were XSI functionality in the Single  
 120048 UNIX Specification, Version 2 and Version 3, that has now become Base functionality. They  
 120049 provide additional information when *si\_code* has one of the values that moved from XSI to Base.

120050 Although it is not explicitly visible to applications, there are additional semantics for signal  
 120051 actions implied by queued signals and their interaction with other POSIX.1b realtime functions.  
 120052 Specifically:

- 120053 • It is not necessary to queue signals whose action is `SIG_IGN`.
- 120054 • For implementations that support POSIX.1b timers, some interaction with the timer  
 120055 functions at signal delivery is implied to manage the timer overrun count.

120056 IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/5 is applied, reordering the RTS shaded  
 120057 text under the third and fourth paragraphs of the `SIG_DFL` description. This corrects an earlier  
 120058 editorial error in this section.

120059 IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/6 is applied, adding the *abort()* function  
 120060 to the list of async-signal-safe functions.

120061 IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/4 is applied, adding the *socketmark()*  
 120062 function to the list of functions that shall be either reentrant or non-interruptible by signals and  
 120063 shall be async-signal-safe.

#### 120064 B.2.4.4 Signal Effects on Other Functions

120065 The most common behavior of an interrupted function after a signal-catching function returns is  
 120066 for the interrupted function to give an `[EINTR]` error unless the `SA_RESTART` flag is in effect for  
 120067 the signal. However, there are a number of specific exceptions, including *sleep()* and certain  
 120068 situations with *read()* and *write()*.

120069 The historical implementations of many functions defined by POSIX.1-2008 are not interruptible,  
 120070 but delay delivery of signals generated during their execution until after they complete. This is  
 120071 never a problem for functions that are guaranteed to complete in a short (imperceptible to a  
 120072 human) period of time. It is normally those functions that can suspend a process indefinitely or  
 120073 for long periods of time (for example, *wait()*, *pause()*, *sigsuspend()*, *sleep()*, or *read()/write()* on a  
 120074 slow device like a terminal) that are interruptible. This permits applications to respond to  
 120075 interactive signals or to set timeouts on calls to most such functions with *alarm()*. Therefore,  
 120076 implementations should generally make such functions (including ones defined as extensions)  
 120077 interruptible.

120078 Functions not mentioned explicitly as interruptible may be so on some implementations,

possibly as an extension where the function gives an [EINTR] error. There are several functions (for example, *getpid()*, *getuid()*) that are specified as never returning an error, which can thus never be extended in this way.

If a signal-catching function returns while the SA\_RESTART flag is in effect, an interrupted function is restarted at the point it was interrupted. Conforming applications cannot make assumptions about the internal behavior of interrupted functions, even if the functions are async-signal-safe. For example, suppose the *read()* function is interrupted with SA\_RESTART in effect, the signal-catching function closes the file descriptor being read from and returns, and the *read()* function is then restarted; in this case the application cannot assume that the *read()* function will give an [EBADF] error, since *read()* might have checked the file descriptor for validity before being interrupted.

## 120090 B.2.5 Standard I/O Streams

Although the ISO C standard guarantees that, at program start-up, *stdin* is open for reading and *stdout* and *stderr* are open for writing, this guarantee is contingent (as are all guarantees made by the ISO C and POSIX standards) on the program being executed in a conforming environment. Programs executed with file descriptor 0 not open for reading or with file descriptor 1 or 2 not open for writing are executed in a non-conforming environment. Application writers are warned (in *exec*, *posix\_spawn()*, and Section C.2.7, on page 3689) not to execute a standard utility or a conforming application with file descriptor 0 not open for reading or with file descriptor 1 or 2 not open for writing.

### 120099 B.2.5.1 Interaction of File Descriptors and Standard I/O Streams

120100 There is no additional rationale provided for this section.

### 120101 B.2.5.2 Stream Orientation and Encoding Rules

120102 There is no additional rationale provided for this section.

## 120103 B.2.6 STREAMS

STREAMS are included into POSIX.1-2008 as part of the alignment with the Single UNIX Specification, but marked as an option in recognition that not all systems may wish to implement the facility. The option within POSIX.1-2008 is denoted by the XSR margin marker. The standard developers made this option independent of the XSI option. In this version of the standard this option is marked obsolescent.

STREAMS are a method of implementing network services and other character-based input/output mechanisms, with the STREAM being a full-duplex connection between a process and a device. STREAMS provides direct access to protocol modules, and optional protocol modules can be interposed between the process-end of the STREAM and the device-driver at the device-end of the STREAM. Pipes can be implemented using the STREAMS mechanism, so they can provide process-to-process as well as process-to-device communications.

This section introduces STREAMS I/O, the message types used to control them, an overview of the priority mechanism, and the interfaces used to access them.

120117 B.2.6.1 *Accessing STREAMS*

120118 There is no additional rationale provided for this section.

120119 **B.2.7 XSI Interprocess Communication**

120120 There are two forms of IPC supported as options in POSIX.1-2008. The traditional System V IPC  
 120121 routines derived from the SVID—that is, the *msg\**(), *sem\**(), and *shm\**() interfaces—are  
 120122 mandatory on XSI-conformant systems. Thus, all XSI-conformant systems provide the same  
 120123 mechanisms for manipulating messages, shared memory, and semaphores.

120124 In addition, the POSIX Realtime Extension provides an alternate set of routines for those systems  
 120125 supporting the appropriate options.

120126 The application developer is presented with a choice: the System V interfaces or the POSIX  
 120127 interfaces (loosely derived from the Berkeley interfaces). The XSI profile prefers the System V  
 120128 interfaces, but the POSIX interfaces may be more suitable for realtime or other performance-  
 120129 sensitive applications.

120130 B.2.7.1 *IPC General Information*

120131 General information that is shared by all three mechanisms is described in this section. The  
 120132 common permissions mechanism is briefly introduced, describing the mode bits, and how they  
 120133 are used to determine whether or not a process has access to read or write/alter the appropriate  
 120134 instance of one of the IPC mechanisms. All other relevant information is contained in the  
 120135 reference pages themselves.

120136 The semaphore type of IPC allows processes to communicate through the exchange of  
 120137 semaphore values. A semaphore is a positive integer. Since many applications require the use of  
 120138 more than one semaphore, XSI-conformant systems have the ability to create sets or arrays of  
 120139 semaphores.

120140 Calls to support semaphores include:

120141 *semctl()*, *semget()*, *semop()*

120142 Semaphore sets are created by using the *semget()* function.

120143 The message type of IPC allows processes to communicate through the exchange of data stored  
 120144 in buffers. This data is transmitted between processes in discrete portions known as messages.

120145 Calls to support message queues include:

120146 *msgctl()*, *msgget()*, *msgrcv()*, *msgsnd()*

120147 The shared memory type of IPC allows two or more processes to share memory and  
 120148 consequently the data contained therein. This is done by allowing processes to set up access to a  
 120149 common memory address space. This sharing of memory provides a fast means of exchange of  
 120150 data between processes.

120151 Calls to support shared memory include:

120152 *shmctl()*, *shmdt()*, *shmget()*

120153 The *ftok()* interface is also provided.

**B.2.8 Realtime****Advisory Information**

POSIX.1b contains an Informative Annex with proposed interfaces for “realtime files”. These interfaces could determine groups of the exact parameters required to do “direct I/O” or “extents”. These interfaces were objected to by a significant portion of the balloting group as too complex. A conforming application had little chance of correctly navigating the large parameter space to match its desires to the system. In addition, they only applied to a new type of file (realtime files) and they told the implementation exactly what to do as opposed to advising the implementation on application behavior and letting it optimize for the system the (portable) application was running on. For example, it was not clear how a system that had a disk array should set its parameters.

There seemed to be several overall goals:

- Optimizing sequential access
- Optimizing caching behavior
- Optimizing I/O data transfer
- Preallocation

The advisory interfaces, *posix\_fadvise()* and *posix\_madvise()*, satisfy the first two goals. The `POSIX_FADV_SEQUENTIAL` and `POSIX_MADV_SEQUENTIAL` advice tells the implementation to expect serial access. Typically the system will prefetch the next several serial accesses in order to overlap I/O. It may also free previously accessed serial data if memory is tight. If the application is not doing serial access it can use `POSIX_FADV_WILLNEED` and `POSIX_MADV_WILLNEED` to accomplish I/O overlap, as required. When the application advises `POSIX_FADV_RANDOM` or `POSIX_MADV_RANDOM` behavior, the implementation usually tries to fetch a minimum amount of data with each request and it does not expect much locality. `POSIX_FADV_DONTNEED` and `POSIX_MADV_DONTNEED` allow the system to free up caching resources as the data will not be required in the near future.

`POSIX_FADV_NOREUSE` tells the system that caching the specified data is not optimal. For file I/O, the transfer should go directly to the user buffer instead of being cached internally by the implementation. To portably perform direct disk I/O on all systems, the application must perform its I/O transfers according to the following rules:

1. The user buffer should be aligned according to the `{POSIX_REC_XFER_ALIGN} pathconf()` variable.
2. The number of bytes transferred in an I/O operation should be a multiple of the `{POSIX_ALLOC_SIZE_MIN} pathconf()` variable.
3. The offset into the file at the start of an I/O operation should be a multiple of the `{POSIX_ALLOC_SIZE_MIN} pathconf()` variable.
4. The application should ensure that all threads which open a given file specify `POSIX_FADV_NOREUSE` to be sure that there is no unexpected interaction between threads using buffered I/O and threads using direct I/O to the same file.

In some cases, a user buffer must be properly aligned in order to be transferred directly to/from the device. The `{POSIX_REC_XFER_ALIGN} pathconf()` variable tells the application the proper alignment.

The preallocation goal is met by the space control function, *posix\_fallocate()*. The application can use *posix\_fallocate()* to guarantee no `[ENOSPC]` errors and to improve performance by prepaying any overhead required for block allocation.

Implementations may use information conveyed by a previous *posix\_fadvise()* call to influence the manner in which allocation is performed. For example, if an application did the following calls:

```
fd = open("file");
posix_fadvise(fd, offset, len, POSIX_FADV_SEQUENTIAL);
posix_fallocate(fd, len, size);
```

an implementation might allocate the file contiguously on disk.

Finally, the *pathconf()* variables {POSIX\_REC\_MIN\_XFER\_SIZE}, {POSIX\_REC\_MAX\_XFER\_SIZE}, and {POSIX\_REC\_INCR\_XFER\_SIZE} tell the application a range of transfer sizes that are recommended for best I/O performance.

Where bounded response time is required, the vendor can supply the appropriate settings of the advisories to achieve a guaranteed performance level.

The interfaces meet the goals while allowing applications using regular files to take advantage of performance optimizations. The interfaces tell the implementation expected application behavior which the implementation can use to optimize performance on a particular system with a particular dynamic load.

The *posix\_memalign()* function was added to allow for the allocation of specifically aligned buffers; for example, for {POSIX\_REC\_XFER\_ALIGN}.

The working group also considered the alternative of adding a function which would return an aligned pointer to memory within a user-supplied buffer. This was not considered to be the best method, because it potentially wastes large amounts of memory when buffers need to be aligned on large alignment boundaries.

## Message Passing

This section provides the rationale for the definition of the message passing interface in POSIX.1-2008. This is presented in terms of the objectives, models, and requirements imposed upon this interface.

- Objectives

Many applications, including both realtime and database applications, require a means of passing arbitrary amounts of data between cooperating processes comprising the overall application on one or more processors. Many conventional interfaces for interprocess communication are insufficient for realtime applications in that efficient and deterministic data passing methods cannot be implemented. This has prompted the definition of message passing interfaces providing these facilities:

- Open a message queue.
- Send a message to a message queue.
- Receive a message from a queue, either synchronously or asynchronously.
- Alter message queue attributes for flow and resource control.

It is assumed that an application may consist of multiple cooperating processes and that these processes may wish to communicate and coordinate their activities. The message passing facility described in POSIX.1-2008 allows processes to communicate through system-wide queues. These message queues are accessed through names that may be pathnames. A message queue can be opened for use by multiple sending and/or multiple receiving processes.

- Background on Embedded Applications

Interprocess communication utilizing message passing is a key facility for the construction of deterministic, high-performance realtime applications. The facility is present in all realtime systems and is the framework upon which the application is constructed. The performance of the facility is usually a direct indication of the performance of the resulting application.

Realtime applications, especially for embedded systems, are typically designed around the performance constraints imposed by the message passing mechanisms. Applications for embedded systems are typically very tightly constrained. Application developers expect to design and control the entire system. In order to minimize system costs, the writer will attempt to use all resources to their utmost and minimize the requirement to add additional memory or processors.

The embedded applications usually share address spaces and only a simple message passing mechanism is required. The application can readily access common data incurring only mutual-exclusion overheads. The models desired are the simplest possible with the application building higher-level facilities only when needed.

- Requirements

The following requirements determined the features of the message passing facilities defined in POSIX.1-2008:

- Naming of Message Queues

The mechanism for gaining access to a message queue is a pathname evaluated in a context that is allowed to be a file system name space, or it can be independent of any file system. This is a specific attempt to allow implementations based on either method in order to address both embedded systems and to also allow implementation in larger systems.

The interface of `mq_open()` is defined to allow but not require the access control and name conflicts resulting from utilizing a file system for name resolution. All required behavior is specified for the access control case. Yet a conforming implementation, such as an embedded system kernel, may define that there are no distinctions between users and may define that all processes have all access privileges.

- Embedded System Naming

Embedded systems need to be able to utilize independent name spaces for accessing the various system objects. They typically do not have a file system, precluding its utilization as a common name resolution mechanism. The modularity of an embedded system limits the connections between separate mechanisms that can be allowed.

Embedded systems typically do not have any access protection. Since the system does not support the mixing of applications from different areas, and usually does not even have the concept of an authorization entity, access control is not useful.

- Large System Naming

On systems with more functionality, the name resolution must support the ability to use the file system as the name resolution mechanism/object storage medium and to have control over access to the objects. Utilizing the pathname space can result in further errors when the names conflict with other objects.

— Fixed Size of Messages

The interfaces impose a fixed upper bound on the size of messages that can be sent to a specific message queue. The size is set on an individual queue basis and cannot be changed dynamically.

The purpose of the fixed size is to increase the ability of the system to optimize the implementation of *mq\_send()* and *mq\_receive()*. With fixed sizes of messages and fixed numbers of messages, specific message blocks can be pre-allocated. This eliminates a significant amount of checking for errors and boundary conditions. Additionally, an implementation can optimize data copying to maximize performance. Finally, with a restricted range of message sizes, an implementation is better able to provide deterministic operations.

— Prioritization of Messages

Message prioritization allows the application to determine the order in which messages are received. Prioritization of messages is a key facility that is provided by most realtime kernels and is heavily utilized by the applications. The major purpose of having priorities in message queues is to avoid priority inversions in the message system, where a high-priority message is delayed behind one or more lower-priority messages. This allows the applications to be designed so that they do not need to be interrupted in order to change the flow of control when exceptional conditions occur. The prioritization does add additional overhead to the message operations in those cases it is actually used but a clever implementation can optimize for the FIFO case to make that more efficient.

— Asynchronous Notification

The interface supports the ability to have a task asynchronously notified of the availability of a message on the queue. The purpose of this facility is to allow the task to perform other functions and yet still be notified that a message has become available on the queue.

To understand the requirement for this function, it is useful to understand two models of application design: a single task performing multiple functions and multiple tasks performing a single function. Each of these models has advantages.

Asynchronous notification is required to build the model of a single task performing multiple operations. This model typically results from either the expectation that interruption is less expensive than utilizing a separate task or from the growth of the application to include additional functions.

## Semaphores

Semaphores are a high-performance process synchronization mechanism. Semaphores are named by null-terminated strings of characters.

A semaphore is created using the *sem\_init()* function or the *sem\_open()* function with the *O\_CREAT* flag set in *oflag*.

To use a semaphore, a process has to first initialize the semaphore or inherit an open descriptor for the semaphore via *fork()*.

A semaphore preserves its state when the last reference is closed. For example, if a semaphore has a value of 13 when the last reference is closed, it will have a value of 13 when it is next opened.

When a semaphore is created, an initial state for the semaphore has to be provided. This value is

a non-negative integer. Negative values are not possible since they indicate the presence of blocked processes. The persistence of any of these objects across a system crash or a system reboot is undefined. Conforming applications must not depend on any sort of persistence across a system reboot or a system crash.

- Models and Requirements

A realtime system requires synchronization and communication between the processes comprising the overall application. An efficient and reliable synchronization mechanism has to be provided in a realtime system that will allow more than one schedulable process mutually-exclusive access to the same resource. This synchronization mechanism has to allow for the optimal implementation of synchronization or systems implementors will define other, more cost-effective methods.

At issue are the methods whereby multiple processes (tasks) can be designed and implemented to work together in order to perform a single function. This requires interprocess communication and synchronization. A semaphore mechanism is the lowest level of synchronization that can be provided by an operating system.

A semaphore is defined as an object that has an integral value and a set of blocked processes associated with it. If the value is positive or zero, then the set of blocked processes is empty; otherwise, the size of the set is equal to the absolute value of the semaphore value. The value of the semaphore can be incremented or decremented by any process with access to the semaphore and must be done as an indivisible operation. When a semaphore value is less than or equal to zero, any process that attempts to lock it again will block or be informed that it is not possible to perform the operation.

A semaphore may be used to guard access to any resource accessible by more than one schedulable task in the system. It is a global entity and not associated with any particular process. As such, a method of obtaining access to the semaphore has to be provided by the operating system. A process that wants access to a critical resource (section) has to wait on the semaphore that guards that resource. When the semaphore is locked on behalf of a process, it knows that it can utilize the resource without interference by any other cooperating process in the system. When the process finishes its operation on the resource, leaving it in a well-defined state, it posts the semaphore, indicating that some other process may now obtain the resource associated with that semaphore.

In this section, mutexes and condition variables are specified as the synchronization mechanisms between threads.

These primitives are typically used for synchronizing threads that share memory in a single process. However, this section provides an option allowing the use of these synchronization interfaces and objects between processes that share memory, regardless of the method for sharing memory.

Much experience with semaphores shows that there are two distinct uses of synchronization: locking, which is typically of short duration; and waiting, which is typically of long or unbounded duration. These distinct usages map directly onto mutexes and condition variables, respectively.

Semaphores are provided in POSIX.1-2008 primarily to provide a means of synchronization for processes; these processes may or may not share memory. Mutexes and condition variables are specified as synchronization mechanisms between threads; these threads always share (some) memory. Both are synchronization paradigms that have been in widespread use for a number of years. Each set of primitives is particularly well matched to certain problems.

With respect to binary semaphores, experience has shown that condition variables and

mutexes are easier to use for many synchronization problems than binary semaphores. The primary reason for this is the explicit appearance of a Boolean predicate that specifies when the condition wait is satisfied. This Boolean predicate terminates a loop, including the call to `pthread_cond_wait()`. As a result, extra wakeups are benign since the predicate governs whether the thread will actually proceed past the condition wait. With stateful primitives, such as binary semaphores, the wakeup in itself typically means that the wait is satisfied. The burden of ensuring correctness for such waits is thus placed on *all* signalers of the semaphore rather than on an *explicitly coded* Boolean predicate located at the condition wait. Experience has shown that the latter creates a major improvement in safety and ease-of-use.

Counting semaphores are well matched to dealing with producer/consumer problems, including those that might exist between threads of different processes, or between a signal handler and a thread. In the former case, there may be little or no memory shared by the processes; in the latter case, one is not communicating between co-equal threads, but between a thread and an interrupt-like entity. It is for these reasons that POSIX.1-2008 allows semaphores to be used by threads.

Mutexes and condition variables have been effectively used with and without priority inheritance, priority ceiling, and other attributes to synchronize threads that share memory. The efficiency of their implementation is comparable to or better than that of other synchronization primitives that are sometimes harder to use (for example, binary semaphores). Furthermore, there is at least one known implementation of Ada tasking that uses these primitives. Mutexes and condition variables together constitute an appropriate, sufficient, and complete set of inter-thread synchronization primitives.

Efficient multi-threaded applications require high-performance synchronization primitives. Considerations of efficiency and generality require a small set of primitives upon which more sophisticated synchronization functions can be built.

#### • Standardization Issues

It is possible to implement very high-performance semaphores using test-and-set instructions on shared memory locations. The library routines that implement such a high-performance interface have to properly ensure that a `sem_wait()` or `sem_trywait()` operation that cannot be performed will issue a blocking semaphore system call or properly report the condition to the application. The same interface to the application program would be provided by a high-performance implementation.

### 120412 B.2.8.1 Realtime Signals

#### 120413 Realtime Signals Extension

This portion of the rationale presents models, requirements, and standardization issues relevant to the Realtime Signals Extension. This extension provides the capability required to support reliable, deterministic, asynchronous notification of events. While a new mechanism, unencumbered by the historical usage and semantics of POSIX.1 signals, might allow for a more efficient implementation, the application requirements for event notification can be met with a small number of extensions to signals. Therefore, a minimal set of extensions to signals to support the application requirements is specified.

The realtime signal extensions specified in this section are used by other realtime functions requiring asynchronous notification:

#### • Models

The model supported is one of multiple cooperating processes, each of which handles

multiple asynchronous external events. Events represent occurrences that are generated as the result of some activity in the system. Examples of occurrences that can constitute an event include:

- Completion of an asynchronous I/O request
- Expiration of a POSIX.1b timer
- Arrival of an interprocess message
- Generation of a user-defined event

Processing of these events may occur synchronously via polling for event notifications or asynchronously via a software interrupt mechanism. Existing practice for this model is well established for traditional proprietary realtime operating systems, realtime executives, and realtime extended POSIX-like systems.

A contrasting model is that of “cooperating sequential processes” where each process handles a single priority of events via polling. Each process blocks while waiting for events, and each process depends on the preemptive, priority-based process scheduling mechanism to arbitrate between events of different priority that need to be processed concurrently. Existing practice for this model is also well established for small realtime executives that typically execute in an unprotected physical address space, but it is just emerging in the context of a fuller function operating system with multiple virtual address spaces.

It could be argued that the cooperating sequential process model, and the facilities supported by the POSIX Threads Extension obviate a software interrupt model. But, even with the cooperating sequential process model, the need has been recognized for a software interrupt model to handle exceptional conditions and process aborting, so the mechanism must be supported in any case. Furthermore, it is not the purview of POSIX.1-2008 to attempt to convince realtime practitioners that their current application models based on software interrupts are “broken” and should be replaced by the cooperating sequential process model. Rather, it is the charter of POSIX.1-2008 to provide standard extensions to mechanisms that support existing realtime practice.

#### • Requirements

This section discusses the following realtime application requirements for asynchronous event notification:

- Reliable delivery of asynchronous event notification

The events notification mechanism guarantees delivery of an event notification. Asynchronous operations (such as asynchronous I/O and timers) that complete significantly after they are invoked have to guarantee that delivery of the event notification can occur at the time of completion.

- Prioritized handling of asynchronous event notifications

The events notification mechanism supports the assigning of a user function as an event notification handler. Furthermore, the mechanism supports the preemption of an event handler function by a higher priority event notification and supports the selection of the highest priority pending event notification when multiple notifications (of different priority) are pending simultaneously.

The model here is based on hardware interrupts. Asynchronous event handling allows the application to ensure that time-critical events are immediately processed when delivered, without the indeterminism of being at a random location within a polling loop. Use of handler priority allows the specification of how handlers are

- 120471 interrupted by other higher priority handlers.
- 120472 — Differentiation between multiple occurrences of event notifications of the same type
- 120473 The events notification mechanism passes an application-defined value to the event
- 120474 handler function. This value can be used for a variety of purposes, such as enabling
- 120475 the application to identify which of several possible events of the same type (for
- 120476 example, timer expirations) has occurred.
- 120477 — Polled reception of asynchronous event notifications
- 120478 The events notification mechanism supports blocking and non-blocking polls for
- 120479 asynchronous event notification.
- 120480 The polled mode of operation is often preferred over the interrupt mode by those
- 120481 practitioners accustomed to this model. Providing support for this model facilitates
- 120482 the porting of applications based on this model to POSIX.1b conforming systems.
- 120483 — Deterministic response to asynchronous event notifications
- 120484 The events notification mechanism does not preclude implementations that provide
- 120485 deterministic event dispatch latency and minimizes the number of system calls
- 120486 needed to use the event facilities during realtime processing.
- 120487 • Rationale for Extension
- 120488 POSIX.1 signals have many of the characteristics necessary to support the asynchronous
- 120489 handling of event notifications, and the Realtime Signals Extension addresses the
- 120490 following deficiencies in the POSIX.1 signal mechanism:
- 120491 — Signals do not support reliable delivery of event notification. Subsequent
- 120492 occurrences of a pending signal are not guaranteed to be delivered.
- 120493 — Signals do not support prioritized delivery of event notifications. The order of signal
- 120494 delivery when multiple unblocked signals are pending is undefined.
- 120495 — Signals do not support the differentiation between multiple signals of the same type.
- 120496 *B.2.8.2 Asynchronous I/O*
- 120497 Many applications need to interact with the I/O subsystem in an asynchronous manner. The
- 120498 asynchronous I/O mechanism provides the ability to overlap application processing and I/O
- 120499 operations initiated by the application. The asynchronous I/O mechanism allows a single
- 120500 process to perform I/O simultaneously to a single file multiple times or to multiple files
- 120501 multiple times.
- 120502 **Overview**
- 120503 Asynchronous I/O operations proceed in logical parallel with the processing done by the
- 120504 application after the asynchronous I/O has been initiated. Other than this difference,
- 120505 asynchronous I/O behaves similarly to normal I/O using *read()*, *write()*, *lseek()*, and *fsync()*.
- 120506 The effect of issuing an asynchronous I/O request is as if a separate thread of execution were to
- 120507 perform atomically the implied *lseek()* operation, if any, and then the requested I/O operation
- 120508 (either *read()*, *write()*, or *fsync()*). There is no seek implied with a call to *aio\_fsync()*. Concurrent
- 120509 asynchronous operations and synchronous operations applied to the same file update the file as
- 120510 if the I/O operations had proceeded serially.
- 120511 When asynchronous I/O completes, a signal can be delivered to the application to indicate the
- 120512 completion of the I/O. This signal can be used to indicate that buffers and control blocks used
- 120513 for asynchronous I/O can be reused. Signal delivery is not required for an asynchronous

operation and may be turned off on a per-operation basis by the application. Signals may also be synchronously polled using *aio\_suspend()*, *sigtimedwait()*, or *sigwaitinfo()*.

Normal I/O has a return value and an error status associated with it. Asynchronous I/O returns a value and an error status when the operation is first submitted, but that only relates to whether the operation was successfully queued up for servicing. The I/O operation itself also has a return status and an error value. To allow the application to retrieve the return status and the error value, functions are provided that, given the address of an asynchronous I/O control block, yield the return and error status associated with the operation. Until an asynchronous I/O operation is done, its error status is [EINPROGRESS]. Thus, an application can poll for completion of an asynchronous I/O operation by waiting for the error status to become equal to a value other than [EINPROGRESS]. The return status of an asynchronous I/O operation is undefined so long as the error status is equal to [EINPROGRESS].

Storage for asynchronous operation return and error status may be limited. Submission of asynchronous I/O operations may fail if this storage is exceeded. When an application retrieves the return status of a given asynchronous operation, therefore, any system-maintained storage used for this status and the error status may be reclaimed for use by other asynchronous operations.

Asynchronous I/O can be performed on file descriptors that have been enabled for POSIX.1b synchronized I/O. In this case, the I/O operation still occurs asynchronously, as defined herein; however, the asynchronous operation I/O in this case is not completed until the I/O has reached either the state of synchronized I/O data integrity completion or synchronized I/O file integrity completion, depending on the sort of synchronized I/O that is enabled on the file descriptor.

## Models

Three models illustrate the use of asynchronous I/O: a journalization model, a data acquisition model, and a model of the use of asynchronous I/O in supercomputing applications.

- Journalization Model

Many realtime applications perform low-priority journalizing functions. Journalizing requires that logging records be queued for output without blocking the initiating process.

- Data Acquisition Model

A data acquisition process may also serve as a model. The process has two or more channels delivering intermittent data that must be read within a certain time. The process issues one asynchronous read on each channel. When one of the channels needs data collection, the process reads the data and posts it through an asynchronous write to secondary memory for future processing.

- Supercomputing Model

The supercomputing community has used asynchronous I/O much like that specified in POSIX.1 for many years. This community requires the ability to perform multiple I/O operations to multiple devices with a minimal number of entries to “the system”; each entry to “the system” provokes a major delay in operations when compared to the normal progress made by the application. This existing practice motivated the use of combined *lseek()* and *read()* or *write()* calls, as well as the *lio\_listio()* call. Another common practice is to disable signal notification for I/O completion, and simply poll for I/O completion at some interval by which the I/O should be completed. Likewise, interfaces like *aio\_cancel()* have been in successful commercial use for many years. Note also that an underlying implementation of asynchronous I/O will require the ability, at least internally, to cancel outstanding asynchronous I/O, at least when the process exits. (Consider an asynchronous read from a terminal, when the process intends to exit immediately.)

**Requirements**

Asynchronous input and output for realtime implementations have these requirements:

- The ability to queue multiple asynchronous read and write operations to a single open instance. Both sequential and random access should be supported.
- The ability to queue asynchronous read and write operations to multiple open instances.
- The ability to obtain completion status information by polling and/or asynchronous event notification.
- Asynchronous event notification on asynchronous I/O completion is optional.
- It has to be possible for the application to associate the event with the *aioctx* for the operation that generated the event.
- The ability to cancel queued requests.
- The ability to wait upon asynchronous I/O completion in conjunction with other types of events.
- The ability to accept an *aio\_read()* and an *aio\_cancel()* for a device that accepts a *read()*, and the ability to accept an *aio\_write()* and an *aio\_cancel()* for a device that accepts a *write()*. This does not imply that the operation is asynchronous.

**Standardization Issues**

The following issues are addressed by the standardization of asynchronous I/O:

- Rationale for New Interface

Non-blocking I/O does not satisfy the needs of either realtime or high-performance computing models; these models require that a process overlap program execution and I/O processing. Realtime applications will often make use of direct I/O to or from the address space of the process, or require synchronized (unbuffered) I/O; they also require the ability to overlap this I/O with other computation. In addition, asynchronous I/O allows an application to keep a device busy at all times, possibly achieving greater throughput. Supercomputing and database architectures will often have specialized hardware that can provide true asynchrony underlying the logical asynchrony provided by this interface. In addition, asynchronous I/O should be supported by all types of files and devices in the same manner.

- Effect of Buffering

If asynchronous I/O is performed on a file that is buffered prior to being actually written to the device, it is possible that asynchronous I/O will offer no performance advantage over normal I/O; the cycles *stolen* to perform the asynchronous I/O will be taken away from the running process and the I/O will occur at interrupt time. This potential lack of gain in performance in no way obviates the need for asynchronous I/O by realtime applications, which very often will use specialized hardware support, multiple processors, and/or unbuffered, synchronized I/O.

**B.2.8.3 Memory Management**

All memory management and shared memory definitions are located in the `<sys/mman.h>` header. This is for alignment with historical practice.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/7 is applied, correcting the shading and margin markers in the introduction to Section 2.8.3.1.

## Memory Locking Functions

This portion of the rationale presents models, requirements, and standardization issues relevant to process memory locking.

- Models

Realtime systems that conform to POSIX.1-2008 are expected (and desired) to be supported on systems with demand-paged virtual memory management, non-paged swapping memory management, and physical memory systems with no memory management hardware. The general case, however, is the demand-paged, virtual memory system with each POSIX process running in a virtual address space. Note that this includes architectures where each process resides in its own virtual address space and architectures where the address space of each process is only a portion of a larger global virtual address space.

The concept of memory locking is introduced to eliminate the indeterminacy introduced by paging and swapping, and to support an upper bound on the time required to access the memory mapped into the address space of a process. Ideally, this upper bound will be the same as the time required for the processor to access “main memory”, including any address translation and cache miss overheads. But some implementations—primarily on mainframes—will not actually force locked pages to be loaded and held resident in main memory. Rather, they will handle locked pages so that accesses to these pages will meet the performance metrics for locked process memory in the implementation. Also, although it is not, for example, the intention that this interface, as specified, be used to lock process memory into “cache”, it is conceivable that an implementation could support a large static RAM memory and define this as “main memory” and use a large[r] dynamic RAM as “backing store”. These interfaces could then be interpreted as supporting the locking of process memory into the static RAM. Support for multiple levels of backing store would require extensions to these interfaces.

Implementations may also use memory locking to guarantee a fixed translation between virtual and physical addresses where such is beneficial to improving determinacy for direct-to/from-process input/output. POSIX.1-2008 does not guarantee to the application that the virtual-to-physical address translations, if such exist, are fixed, because such behavior would not be implementable on all architectures on which implementations of POSIX.1-2008 are expected. But POSIX.1-2008 does mandate that an implementation define, for the benefit of potential users, whether or not locking guarantees fixed translations.

Memory locking is defined with respect to the address space of a process. Only the pages mapped into the address space of a process may be locked by the process, and when the pages are no longer mapped into the address space—for whatever reason—the locks established with respect to that address space are removed. Shared memory areas warrant special mention, as they may be mapped into more than one address space or mapped more than once into the address space of a process; locks may be established on pages within these areas with respect to several of these mappings. In such a case, the lock state of the underlying physical pages is the logical OR of the lock state with respect to each of the mappings. Only when all such locks have been removed are the shared pages considered unlocked.

In recognition of the page granularity of Memory Management Units (MMU), and in order to support locking of ranges of address space, memory locking is defined in terms of “page” granularity. That is, for the interfaces that support an address and size specification for the region to be locked, the address must be on a page boundary, and all pages mapped by the specified range are locked, if valid. This means that the length is implicitly rounded

up to a multiple of the page size. The page size is implementation-defined and is available to applications as a compile-time symbolic constant or at runtime via *sysconf()*.

A “real memory” POSIX.1b implementation that has no MMU could elect not to support these interfaces, returning [ENOSYS]. But an application could easily interpret this as meaning that the implementation would unconditionally page or swap the application when such is not the case. It is the intention of POSIX.1-2008 that such a system could define these interfaces as “NO-OPs”, returning success without actually performing any function except for mandated argument checking.

- Requirements

For realtime applications, memory locking is generally considered to be required as part of application initialization. This locking is performed after an application has been loaded (that is, *exec'd*) and the program remains locked for its entire lifetime. But to support applications that undergo major mode changes where, in one mode, locking is required, but in another it is not, the specified interfaces allow repeated locking and unlocking of memory within the lifetime of a process.

When a realtime application locks its address space, it should not be necessary for the application to then “touch” all of the pages in the address space to guarantee that they are resident or else suffer potential paging delays the first time the page is referenced. Thus, POSIX.1-2008 requires that the pages locked by the specified interfaces be resident when the locking functions return successfully.

Many architectures support system-managed stacks that grow automatically when the current extent of the stack is exceeded. A realtime application has a requirement to be able to “preallocate” sufficient stack space and lock it down so that it will not suffer page faults to grow the stack during critical realtime operation. There was no consensus on a portable way to specify how much stack space is needed, so POSIX.1-2008 supports no specific interface for preallocating stack space. But an application can portably lock down a specific amount of stack space by specifying *MCL\_FUTURE* in a call to *mlockall()* and then calling a dummy function that declares an automatic array of the desired size.

Memory locking for realtime applications is also generally considered to be an “all or nothing” proposition. That is, the entire process, or none, is locked down. But, for applications that have well-defined sections that need to be locked and others that do not, POSIX.1-2008 supports an optional set of interfaces to lock or unlock a range of process addresses. Reasons for locking down a specific range include:

- An asynchronous event handler function that must respond to external events in a deterministic manner such that page faults cannot be tolerated
- An input/output “buffer” area that is the target for direct-to-process I/O, and the overhead of implicit locking and unlocking for each I/O call cannot be tolerated

Finally, locking is generally viewed as an “application-wide” function. That is, the application is globally aware of which regions are locked and which are not over time. This is in contrast to a function that is used temporarily within a “third party” library routine whose function is unknown to the application, and therefore must have no “side-effects”. The specified interfaces, therefore, do not support “lock stacking” or “lock nesting” within a process. But, for pages that are shared between processes or mapped more than once into a process address space, “lock stacking” is essentially mandated by the requirement that unlocking of pages that are mapped by more than one process or more than once by the same process does not affect locks established on the other mappings.

There was some support for “lock stacking” so that locking could be transparently used in functions or opaque modules. But the consensus was not to burden all implementations

120700 with lock stacking (and reference counting), and an implementation option was proposed.  
120701 There were strong objections to the option because applications would have to support  
120702 both options in order to remain portable. The consensus was to eliminate lock stacking  
120703 altogether, primarily through overwhelming support for the System V “m[un]lock[all]”  
120704 interface on which POSIX.1-2008 is now based.

120705 Locks are not inherited across *fork()*s because some implementations implement *fork()* by  
120706 creating new address spaces for the child. In such an implementation, requiring locks to be  
120707 inherited would lead to new situations in which a fork would fail due to the inability of  
120708 the system to lock sufficient memory to lock both the parent and the child. The consensus  
120709 was that there was no benefit to such inheritance. Note that this does not mean that locks  
120710 are removed when, for instance, a thread is created in the same address space.

120711 Similarly, locks are not inherited across *exec* because some implementations implement *exec*  
120712 by unmapping all of the pages in the address space (which, by definition, removes the  
120713 locks on these pages), and maps in pages of the *exec*'d image. In such an implementation,  
120714 requiring locks to be inherited would lead to new situations in which *exec* would fail.  
120715 Reporting this failure would be very cumbersome to detect in time to report to the calling  
120716 process, and no appropriate mechanism exists for informing the *exec*'d process of its status.

120717 It was determined that, if the newly loaded application required locking, it was the  
120718 responsibility of that application to establish the locks. This is also in keeping with the  
120719 general view that it is the responsibility of the application to be aware of all locks that are  
120720 established.

120721 There was one request to allow (not mandate) locks to be inherited across *fork()*, and a  
120722 request for a flag, *MCL\_INHERIT*, that would specify inheritance of memory locks across  
120723 *execs*. Given the difficulties raised by this and the general lack of support for the feature in  
120724 POSIX.1-2008, it was not added. POSIX.1-2008 does not preclude an implementation from  
120725 providing this feature for administrative purposes, such as a “run” command that will  
120726 lock down and execute a specified application. Additionally, the rationale for the objection  
120727 equated *fork()* with creating a thread in the address space. POSIX.1-2008 does not mandate  
120728 releasing locks when creating additional threads in an existing process.

120729 • Standardization Issues

120730 One goal of POSIX.1-2008 is to define a set of primitives that provide the necessary  
120731 functionality for realtime applications, with consideration for the needs of other  
120732 application domains where such were identified, which is based to the extent possible on  
120733 existing industry practice.

120734 The Memory Locking option is required by many realtime applications to tune  
120735 performance. Such a facility is accomplished by placing constraints on the virtual memory  
120736 system to limit paging of time of the process or of critical sections of the process. This  
120737 facility should not be used by most non-realtime applications.

120738 Optional features provided in POSIX.1-2008 allow applications to lock selected address  
120739 ranges with the caveat that the process is responsible for being aware of the page  
120740 granularity of locking and the unnested nature of the locks.

## Mapped Files Functions

The memory mapped files functionality provides a mechanism that allows a process to access files by directly incorporating file data into its address space. Once a file is “mapped” into a process address space, the data can be manipulated by instructions as memory. The use of mapped files can significantly reduce I/O data movement since file data does not have to be copied into process data buffers as in *read()* and *write()*. If more than one process maps a file, its contents are shared among them. This provides a low overhead mechanism by which processes can synchronize and communicate.

- Historical Perspective

Realtime applications have historically been implemented using a collection of cooperating processes or tasks. In early systems, these processes ran on bare hardware (that is, without an operating system) with no memory relocation or protection. The application paradigms that arose from this environment involve the sharing of data between the processes.

When realtime systems were implemented on top of vendor-supplied operating systems, the paradigm or performance benefits of direct access to data by multiple processes was still deemed necessary. As a result, operating systems that claim to support realtime applications must support the shared memory paradigm.

Additionally, a number of realtime systems provide the ability to map specific sections of the physical address space into the address space of a process. This ability is required if an application is to obtain direct access to memory locations that have specific properties (for example, refresh buffers or display devices, dual ported memory locations, DMA target locations). The use of this ability is common enough to warrant some degree of standardization of its interface. This ability overlaps the general paradigm of shared memory in that, in both instances, common global objects are made addressable by individual processes or tasks.

Finally, a number of systems also provide the ability to map process addresses to files. This provides both a general means of sharing persistent objects, and using files in a manner that optimizes memory and swapping space usage.

Simple shared memory is clearly a special case of the more general file mapping capability. In addition, there is relatively widespread agreement and implementation of the file mapping interface. In these systems, many different types of objects can be mapped (for example, files, memory, devices, and so on) using the same mapping interfaces. This approach both minimizes interface proliferation and maximizes the generality of programs using the mapping interfaces.

- Memory Mapped Files Usage

A memory object can be concurrently mapped into the address space of one or more processes. The *mmap()* and *munmap()* functions allow a process to manipulate their address space by mapping portions of memory objects into it and removing them from it. When multiple processes map the same memory object, they can share access to the underlying data. Implementations may restrict the size and alignment of mappings to be on *page*-size boundaries. The page size, in bytes, is the value of the system-configurable variable {PAGESIZE}, typically accessed by calling *sysconf()* with a *name* argument of *\_SC\_PAGESIZE*. If an implementation has no restrictions on size or alignment, it may specify a 1-byte page size.

To map memory, a process first opens a memory object. The *ftruncate()* function can be used to contract or extend the size of the memory object even when the object is currently mapped. If the memory object is extended, the contents of the extended areas are zeros.

120788 After opening a memory object, the application maps the object into its address space  
 120789 using the *mmap()* function call. Once a mapping has been established, it remains mapped  
 120790 until unmapped with *munmap()*, even if the memory object is closed. The *mprotect()*  
 120791 function can be used to change the memory protections initially established by *mmap()*.

120792 A *close()* of the file descriptor, while invalidating the file descriptor itself, does not unmap  
 120793 any mappings established for the memory object. The address space, including all mapped  
 120794 regions, is inherited on *fork()*. The entire address space is unmapped on process  
 120795 termination or by successful calls to any of the *exec* family of functions.

120796 The *msync()* function is used to force mapped file data to permanent storage.

120797 • Effects on Other Functions

120798 With memory mapped files, the operation of the *open()*, *creat()*, and *unlink()* functions are  
 120799 a natural result of using the file system name space to map the global names for memory  
 120800 objects.

120801 The *ftruncate()* function can be used to set the length of a sharable memory object.

120802 The meaning of *stat()* fields other than the size and protection information is undefined on  
 120803 implementations where memory objects are not implemented using regular files. When  
 120804 regular files are used, the times reflect when the implementation updated the file image of  
 120805 the data, not when a process updated the data in memory.

120806 The operations of *fdopen()*, *write()*, *read()*, and *lseek()* were made unspecified for objects  
 120807 opened with *shm\_open()*, so that implementations that did not implement memory objects  
 120808 as regular files would not have to support the operation of these functions on shared  
 120809 memory objects.

120810 The behavior of memory objects with respect to *close()*, *dup()*, *dup2()*, *open()*, *close()*,  
 120811 *fork()*, *\_exit()*, and the *exec* family of functions is the same as the behavior of the existing  
 120812 practice of the *mmap()* function.

120813 A memory object can still be referenced after a close. That is, any mappings made to the  
 120814 file are still in effect, and reads and writes that are made to those mappings are still valid  
 120815 and are shared with other processes that have the same mapping. Likewise, the memory  
 120816 object can still be used if any references remain after its name(s) have been deleted. Any  
 120817 references that remain after a close must not appear to the application as file descriptors.

120818 This is existing practice for *mmap()* and *close()*. In addition, there are already mappings  
 120819 present (text, data, stack) that do not have open file descriptors. The text mapping in  
 120820 particular is considered a reference to the file containing the text. The desire was to treat all  
 120821 mappings by the process uniformly. Also, many modern implementations use *mmap()* to  
 120822 implement shared libraries, and it would not be desirable to keep file descriptors for each  
 120823 of the many libraries an application can use. It was felt there were many other existing  
 120824 programs that used this behavior to free a file descriptor, and thus POSIX.1-2008 could not  
 120825 forbid it and still claim to be using existing practice.

120826 For implementations that implement memory objects using memory only, memory objects  
 120827 will retain the memory allocated to the file after the last close and will use that same  
 120828 memory on the next open. Note that closing the memory object is not the same as deleting  
 120829 the name, since the memory object is still defined in the memory object name space.

120830 The locks of *fcntl()* do not block any read or write operation, including read or write access  
 120831 to shared memory or mapped files. In addition, implementations that only support shared  
 120832 memory objects should not be required to implement record locks. The reference to *fcntl()*  
 120833 is added to make this point explicitly. The other *fcntl()* commands are useful with shared  
 120834 memory objects.

120835 The size of pages that mapping hardware may be able to support may be a configurable  
 120836 value, or it may change based on hardware implementations. The addition of the  
 120837 `_SC_PAGESIZE` parameter to the `sysconf()` function is provided for determining the  
 120838 mapping page size at runtime.

## 120839 Shared Memory Functions

120840 Implementations may support the Shared Memory Objects option independently of memory  
 120841 mapped files. Shared memory objects are named regions of storage that may be independent of  
 120842 the file system and can be mapped into the address space of one or more processes to allow  
 120843 them to share the associated memory.

### 120844 • Requirements

120845 Shared memory is used to share data among several processes, each potentially running at  
 120846 different priority levels, responding to different inputs, or performing separate tasks.  
 120847 Shared memory is not just simply providing common access to data, it is providing the  
 120848 fastest possible communication between the processes. With one memory write operation,  
 120849 a process can pass information to as many processes as have the memory region mapped.

120850 As a result, shared memory provides a mechanism that can be used for all other  
 120851 interprocess communication facilities. It may also be used by an application for  
 120852 implementing more sophisticated mechanisms than semaphores and message queues.

120853 The need for a shared memory interface is obvious for virtual memory systems, where the  
 120854 operating system is directly preventing processes from accessing each other's data.  
 120855 However, in unprotected systems, such as those found in some embedded controllers, a  
 120856 shared memory interface is needed to provide a portable mechanism to allocate a region of  
 120857 memory to be shared and then to communicate the address of that region to other  
 120858 processes.

120859 This, then, provides the minimum functionality that a shared memory interface must have  
 120860 in order to support realtime applications: to allocate and name an object to be mapped into  
 120861 memory for potential sharing (`open()` or `shm_open()`), and to make the memory object  
 120862 available within the address space of a process (`mmap()`). To complete the interface, a  
 120863 mechanism to release the claim of a process on a shared memory object (`munmap()`) is also  
 120864 needed, as well as a mechanism for deleting the name of a sharable object that was  
 120865 previously created (`unlink()` or `shm_unlink()`).

120866 After a mapping has been established, an implementation should not have to provide  
 120867 services to maintain that mapping. All memory writes into that area will appear  
 120868 immediately in the memory mapping of that region by any other processes.

120869 Thus, requirements include:

- 120870 — Support creation of sharable memory objects and the mapping of these objects into  
 120871 the address space of a process.
- 120872 — Sharable memory objects should be accessed by global names accessible from all  
 120873 processes.
- 120874 — Support the mapping of specific sections of physical address space (such as a  
 120875 memory mapped device) into the address space of a process. This should not be  
 120876 done by the process specifying the actual address, but again by an implementation-  
 120877 defined global name (such as a special device name) dedicated to this purpose.
- 120878 — Support the mapping of discrete portions of these memory objects.

- 120879 — Support for minimum hardware configurations that contain no physical media on  
120880 which to store shared memory contents permanently.
- 120881 — The ability to preallocate the entire shared memory region so that minimum  
120882 hardware configurations without virtual memory support can guarantee contiguous  
120883 space.
- 120884 — The maximizing of performance by not requiring functionality that would require  
120885 implementation interaction above creating the shared memory area and returning  
120886 the mapping.

120887 Note that the above requirements do not preclude:

- 120888 — The sharable memory object from being implemented using actual files on an actual  
120889 file system.
- 120890 — The global name that is accessible from all processes being restricted to a file system  
120891 area that is dedicated to handling shared memory.
- 120892 — An implementation not providing implementation-defined global names for the  
120893 purpose of physical address mapping.

#### 120894 • Shared Memory Objects Usage

120895 If the Shared Memory Objects option is supported, a shared memory object may be  
120896 created, or opened if it already exists, with the *shm\_open()* function. If the shared memory  
120897 object is created, it has a length of zero. The *ftruncate()* function can be used to set the size  
120898 of the shared memory object after creation. The *shm\_unlink()* function removes the name  
120899 for a shared memory object created by *shm\_open()*.

#### 120900 • Shared Memory Overview

120901 The shared memory facility defined by POSIX.1-2008 usually results in memory locations  
120902 being added to the address space of the process. The implementation returns the address  
120903 of the new space to the application by means of a pointer. This works well in languages  
120904 like C. However, in languages without pointer types it will not work. In the bindings for  
120905 such a language, either a special COMMON section will need to be defined (which is  
120906 unlikely), or the binding will have to allow existing structures to be mapped. The  
120907 implementation will likely have to place restrictions on the size and alignment of such  
120908 structures or will have to map a suitable region of the address space of the process into the  
120909 memory object, and thus into other processes. These are issues for that particular language  
120910 binding. For POSIX.1-2008, however, the practice will not be forbidden, merely undefined.

120911 Two potentially different name spaces are used for naming objects that may be mapped  
120912 into process address spaces. When using memory mapped files, files may be accessed via  
120913 *open()*. When the Shared Memory Objects option is supported, sharable memory objects  
120914 that might not be files may be accessed via the *shm\_open()* function. These operations are  
120915 not mutually-exclusive.

120916 Some implementations supporting the Shared Memory Objects option may choose to  
120917 implement the shared memory object name space as part of the file system name space.  
120918 There are several reasons for this:

- 120919 — It allows applications to prevent name conflicts by use of the directory structure.
- 120920 — It uses an existing mechanism for accessing global objects and prevents the creation  
120921 of a new mechanism for naming global objects.

120922 In such implementations, memory objects can be implemented using regular files, if that is  
120923 what the implementation chooses. The *shm\_open()* function can be implemented as an

120924 *open()* call in a fixed directory with the `O_CLOEXEC` flag set. The *shm\_unlink()* function  
120925 can be implemented as an *unlink()* call.

120926 On the other hand, it is also expected that small embedded systems that support the  
120927 Shared Memory Objects option may wish to implement shared memory without having  
120928 any file systems present. In this case, the implementations may choose to use a simple  
120929 string valued name space for shared memory regions. The *shm\_open()* function permits  
120930 either type of implementation.

120931 Some implementations have hardware that supports protection of mapped data from  
120932 certain classes of access and some do not. Systems that supply this functionality support  
120933 the memory protection functionality.

120934 Some implementations restrict size, alignment, and protections to be on *page*-size  
120935 boundaries. If an implementation has no restrictions on size or alignment, it may specify a  
120936 1-byte page size. Applications on implementations that do support larger pages must be  
120937 cognizant of the page size since this is the alignment and protection boundary.

120938 Simple embedded implementations may have a 1-byte page size and only support the  
120939 Shared Memory Objects option. This provides simple shared memory between processes  
120940 without requiring mapping hardware.

120941 POSIX.1-2008 specifically allows a memory object to remain referenced after a close  
120942 because that is existing practice for the *mmap()* function.

## 120943 **Typed Memory Functions**

120944 Implementations may support the Typed Memory Objects option without supporting either the  
120945 Shared Memory option or memory mapped files. Types memory objects are pools of specialized  
120946 storage, different from the main memory resource normally used by a processor to hold code  
120947 and data, that can be mapped into the address space of one or more processes.

### 120948 • Model

120949 Realtime systems conforming to one of the POSIX.13 realtime profiles are expected (and  
120950 desired) to be supported on systems with more than one type or pool of memory (for  
120951 example, SRAM, DRAM, ROM, EPROM, EEPROM), where each type or pool of memory  
120952 may be accessible by one or more processors via one or more buses (ports). Memory  
120953 mapped files, shared memory objects, and the language-specific storage allocation  
120954 operators (*malloc()* for the ISO C standard, *new* for ISO Ada) fail to provide application  
120955 program interfaces versatile enough to allow applications to control their utilization of  
120956 such diverse memory resources. The typed memory interfaces *posix\_typed\_mem\_open()*,  
120957 *posix\_mem\_offset()*, *posix\_typed\_mem\_get\_info()*, *mmap()*, and *munmap()* defined herein  
120958 support the model of typed memory described below.

120959 For purposes of this model, a system comprises several processors (for example,  $P_1$  and  
120960  $P_2$ ), several physical memory pools (for example,  $M_1$ ,  $M_2$ ,  $M_{2a}$ ,  $M_{2b}$ ,  $M_3$ ,  $M_4$ , and  $M_5$ ), and  
120961 several buses or “ports” (for example,  $B_1$ ,  $B_2$ ,  $B_3$ , and  $B_4$ ) interconnecting the various  
120962 processors and memory pools in some system-specific way. Notice that some memory  
120963 pools may be contained in others (for example,  $M_{2a}$  and  $M_{2b}$  are contained in  $M_2$ ).

120964 **Figure B-1** (on page 3565) shows an example of such a model. In a system like this, an  
120965 application should be able to perform the following operations:

\* All addresses in pool M<sub>2</sub> (comprising pools M<sub>2a</sub> and M<sub>2b</sub>) accessible via port B<sub>1</sub>.  
 Addresses in pool M<sub>2b</sub> are also accessible via port B<sub>2</sub>.  
 Addresses in pool M<sub>2a</sub> are *not* accessible via port B<sub>2</sub>.

**Figure B-1** Example of a System with Typed Memory

#### — Typed Memory Allocation

An application should be able to allocate memory dynamically from the desired pool using the desired bus, and map it into the address space of a process. For example, processor P<sub>1</sub> can allocate some portion of memory pool M<sub>1</sub> through port B<sub>1</sub>, treating all unmapped subareas of M<sub>1</sub> as a heap-storage resource from which memory may be allocated. This portion of memory is mapped into address space of the process, and subsequently deallocated when unmapped from all processes.

#### — Using the Same Storage Region from Different Buses

An application process with a mapped region of storage that is accessed from one bus should be able to map that same storage area at another address (subject to page size restrictions detailed in *mmap()*), to allow it to be accessed from another bus. For example, processor P<sub>1</sub> may wish to access the same region of memory pool M<sub>2b</sub> both through ports B<sub>1</sub> and B<sub>2</sub>.

#### — Sharing Typed Memory Regions

Several application processes running on the same or different processors may wish to share a particular region of a typed memory pool. Each process or processor may wish to access this region through different buses. For example, processor P<sub>1</sub> may want to share a region of memory pool M<sub>4</sub> with processor P<sub>2</sub>, and they may be required to use buses B<sub>2</sub> and B<sub>3</sub>, respectively, to minimize bus contention. A problem arises here when a process allocates and maps a portion of fragmented memory and then wants to share this region of memory with another process, either in the same processor or different processors. The solution adopted is to allow the first process to find out the memory map (offsets and lengths) of all the different fragments of memory that were mapped into its address space, by repeatedly calling *posix\_mem\_offset()*. Then, this process can pass the offsets and lengths obtained to the second process, which can then map the same memory fragments into its address space.

#### — Contiguous Allocation

The problem of finding the memory map of the different fragments of the memory pool that were mapped into logically contiguous addresses of a given process can be

solved by requesting contiguous allocation. For example, a process in  $P_1$  can allocate 10 Kbytes of physically contiguous memory from  $M_3-B_1$ , and obtain the offset (within pool  $M_3$ ) of this block of memory. Then, it can pass this offset (and the length) to a process in  $P_2$  using some interprocess communication mechanism. The second process can map the same block of memory by using the offset transferred and specifying  $M_3-B_2$ .

#### 121003 — Unallocated Mapping

Any subarea of a memory pool that is mapped to a process, either as the result of an allocation request or an explicit mapping, is normally unavailable for allocation. Special processes such as debuggers, however, may need to map large areas of a typed memory pool, yet leave those areas available for allocation.

Typed memory allocation and mapping has to coexist with storage allocation operators like *malloc()*, but systems are free to choose how to implement this coexistence. For example, it may be system configuration-dependent if all available system memory is made part of one of the typed memory pools or if some part will be restricted to conventional allocation operators. Equally system configuration-dependent may be the availability of operators like *malloc()* to allocate storage from certain typed memory pools. It is not excluded to configure a system such that a given named pool,  $P_1$ , is in turn split into non-overlapping named subpools. For example,  $M_1-B_1$ ,  $M_2-B_1$ , and  $M_3-B_1$  could also be accessed as one common pool  $M_{123}-B_1$ . A call to *malloc()* on  $P_1$  could work on such a larger pool while full optimization of memory usage by  $P_1$  would require typed memory allocation at the subpool level.

#### 121019 • Existing Practice

OS-9 provides for the naming (numbering) and prioritization of memory types by a system administrator. It then provides APIs to request memory allocation of typed (colored) memory by number, and to generate a bus address from a mapped memory address (translate). When requesting colored memory, the user can specify type 0 to signify allocation from the first available type in priority order.

HP-RT presents interfaces to map different kinds of storage regions that are visible through a VME bus, although it does not provide allocation operations. It also provides functions to perform address translation between VME addresses and virtual addresses. It represents a VME-bus unique solution to the general problem.

The PSOS approach is similar (that is, based on a pre-established mapping of bus address ranges to specific memories) with a concept of segments and regions (regions dynamically allocated from a heap which is a special segment). Therefore, PSOS does not fully address the general allocation problem either. PSOS does not have a “process”-based model, but more of a “thread”-only-based model of multi-tasking. So mapping to a process address space is not an issue.

QNX uses the System V approach of opening specially named devices (shared memory segments) and using *mmap()* to then gain access from the process. They do not address allocation directly, but once typed shared memory can be mapped, an “allocation manager” process could be written to handle requests for allocation.

The System V approach also included allocation, implemented by opening yet other special “devices” which allocate, rather than appearing as a whole memory object.

The Orkid realtime kernel interface definition has operations to manage memory “regions” and “pools”, which are areas of memory that may reflect the differing physical nature of the memory. Operations to allocate memory from these regions and pools are also provided.

- Requirements

Existing practice in SVID-derived UNIX systems relies on functionality similar to *mmap()* and its related interfaces to achieve mapping and allocation of typed memory. However, the issue of sharing typed memory (allocated or mapped) and the complication of multiple ports are not addressed in any consistent way by existing UNIX system practice. Part of this functionality is existing practice in specialized realtime operating systems. In order to solidify the capabilities implied by the model above, the following requirements are imposed on the interface:

- Identification of Typed Memory Pools and Ports

All processes (running in all processors) in the system are able to identify a particular (system configured) typed memory pool accessed through a particular (system configured) port by a name. That name is a member of a name space common to all these processes, but need not be the same name space as that containing ordinary pathnames. The association between memory pools/ports and corresponding names is typically established when the system is configured. The “open” operation for typed memory objects should be distinct from the *open()* function, for consistency with other similar services, but implementable on top of *open()*. This implies that the handle for a typed memory object will be a file descriptor.

- Allocation and Mapping of Typed Memory

Once a typed memory object has been identified by a process, it is possible to both map user-selected subareas of that object into process address space and to map system-selected (that is, dynamically allocated) subareas of that object, with user-specified length, into process address space. It is also possible to determine the maximum length of memory allocation that may be requested from a given typed memory object.

- Sharing Typed Memory

Two or more processes are able to share portions of typed memory, either user-selected or dynamically allocated. This requirement applies also to dynamically allocated regions of memory that are composed of several non-contiguous pieces.

- Contiguous Allocation

For dynamic allocation, it is the user’s option whether the system is required to allocate a contiguous subarea within the typed memory object, or whether it is permitted to allocate discontinuous fragments which appear contiguous in the process mapping. Contiguous allocation simplifies the process of sharing allocated typed memory, while discontinuous allocation allows for potentially better recovery of deallocated typed memory.

- Accessing Typed Memory Through Different Ports

Once a subarea of a typed memory object has been mapped, it is possible to determine the location and length corresponding to a user-selected portion of that object within the memory pool. This location and length can then be used to remap that portion of memory for access from another port. If the referenced portion of typed memory was allocated discontinuously, the length thus determined may be shorter than anticipated, and the user code must adapt to the value returned.

- Deallocation

When a previously mapped subarea of typed memory is no longer mapped by any process in the system—as a result of a call or calls to *munmap()*—that subarea

121091 becomes potentially reusable for dynamic allocation; actual reuse of the subarea is a  
 121092 function of the dynamic typed memory allocation policy.

121093 — Unallocated Mapping

121094 It must be possible to map user-selected subareas of a typed memory object without  
 121095 marking that subarea as unavailable for allocation. This option is not the default  
 121096 behavior, and requires appropriate privileges.

121097 • Scenario

121098 The following scenario will serve to clarify the use of the typed memory interfaces.

121099 Process A running on  $P_1$  (see Figure B-1, on page 3565) wants to allocate some memory  
 121100 from memory pool  $M_2$ , and it wants to share this portion of memory with process B  
 121101 running on  $P_2$ . Since  $P_2$  only has access to the lower part of  $M_2$ , both processes will use the  
 121102 memory pool named  $M_{2b}$  which is the part of  $M_2$  that is accessible both from  $P_1$  and  $P_2$ . The  
 121103 operations that both processes need to perform are shown below:

121104 — Allocating Typed Memory

121105 Process A calls *posix\_typed\_mem\_open()* with the name **/typed.m2b-b1** and a *tflag* of  
 121106 POSIX\_TYPED\_MEM\_ALLOCATE to get a file descriptor usable for allocating from  
 121107 pool  $M_{2b}$  accessed through port  $B_1$ . It then calls *mmap()* with this file descriptor  
 121108 requesting a length of 4096 bytes. The system allocates two discontinuous blocks of  
 121109 sizes 1024 and 3072 bytes within  $M_{2b}$ . The *mmap()* function returns a pointer to a  
 121110 4096-byte array in process A's logical address space, mapping the allocated blocks  
 121111 contiguously. Process A can then utilize the array, and store data in it.

121112 — Determining the Location of the Allocated Blocks

121113 Process A can determine the lengths and offsets (relative to  $M_{2b}$ ) of the two blocks  
 121114 allocated, by using the following procedure: First, process A calls *posix\_mem\_offset()*  
 121115 with the address of the first element of the array and length 4096. Upon return, the  
 121116 offset and length (1024 bytes) of the first block are returned. A second call to  
 121117 *posix\_mem\_offset()* is then made using the address of the first element of the array  
 121118 plus 1024 (the length of the first block), and a new length of 4096–1024. If there were  
 121119 more fragments allocated, this procedure could have been continued within a loop  
 121120 until the offsets and lengths of all the blocks were obtained. Notice that this relatively  
 121121 complex procedure can be avoided if contiguous allocation is requested (by opening  
 121122 the typed memory object with the *tflag*  
 121123 POSIX\_TYPED\_MEM\_ALLOCATE\_CONTIG).

121124 — Sharing Data Across Processes

121125 Process A passes the two offset values and lengths obtained from the  
 121126 *posix\_mem\_offset()* calls to process B running on  $P_2$ , via some form of interprocess  
 121127 communication. Process B can gain access to process A's data by calling  
 121128 *posix\_typed\_mem\_open()* with the name **/typed.m2b-b2** and a *tflag* of zero, then using  
 121129 two *mmap()* calls on the resulting file descriptor to map the two subareas of that  
 121130 typed memory object to its own address space.

121131 • Rationale for no *mem\_alloc()* and *mem\_free()*

121132 The standard developers had originally proposed a pair of new flags to *mmap()* which,  
 121133 when applied to a typed memory object descriptor, would cause *mmap()* to allocate  
 121134 dynamically from an unallocated and unmapped area of the typed memory object.  
 121135 Deallocation was similarly accomplished through the use of *munmap()*. This was rejected  
 121136 by the ballot group because it excessively complicated the (already rather complex)

*mmap()* interface and introduced semantics useful only for typed memory, to a function which must also map shared memory and files. They felt that a memory allocator should be built on top of *mmap()* instead of being incorporated within the same interface, much as the ISO C standard libraries build *malloc()* on top of the virtual memory mapping functions *brk()* and *sbrk()*. This would eliminate the complicated semantics involved with unmapping only part of an allocated block of typed memory.

To attempt to achieve ballot group consensus, typed memory allocation and deallocation was first migrated from *mmap()* and *munmap()* to a pair of complementary functions modeled on the ISO C standard *malloc()* and *free()*. The *mem\_alloc()* function specified explicitly the typed memory object (typed memory pool/access port) from which allocation takes place, unlike *malloc()* where the memory pool and port are unspecified. The *mem\_free()* function handled deallocation. These new semantics still met all of the requirements detailed above without modifying the behavior of *mmap()* except to allow it to map specified areas of typed memory objects. An implementation would have been free to implement *mem\_alloc()* and *mem\_free()* over *mmap()*, through *mmap()*, or independently but cooperating with *mmap()*.

The ballot group was queried to see if this was an acceptable alternative, and while there was some agreement that it achieved the goal of removing the complicated semantics of allocation from the *mmap()* interface, several balloters realized that it just created two additional functions that behaved, in great part, like *mmap()*. These balloters proposed an alternative which has been implemented here in place of a separate *mem\_alloc()* and *mem\_free()*. This alternative is based on four specific suggestions:

1. The *posix\_typed\_mem\_open()* function should provide a flag which specifies "allocate on *mmap()*" (otherwise, *mmap()* just maps the underlying object). This allows things roughly similar to */dev/zero* versus */dev/swap*. Two such flags have been implemented, one of which forces contiguous allocation.
2. The *posix\_mem\_offset()* function is acceptable because it can be applied usefully to mapped objects in general. It should return the file descriptor of the underlying object.
3. The *mem\_get\_info()* function in an earlier draft should be renamed *posix\_typed\_mem\_get\_info()* because it is not generally applicable to memory objects. It should probably return the file descriptor's allocation attribute. The renaming of the function has been implemented, but having it return a piece of information which is readily known by an application without this function has been rejected. Its whole purpose is to query the typed memory object for attributes that are not user-specified, but determined by the implementation.
4. There should be no separate *mem\_alloc()* or *mem\_free()* functions. Instead, using *mmap()* on a typed memory object opened with an "allocate on *mmap()*" flag should be used to force allocation. These are precisely the semantics defined in the current draft.

- Rationale for no Typed Memory Access Management

The working group had originally defined an additional interface (and an additional kind of object: typed memory master) to establish and dissolve mappings to typed memory on behalf of devices or processors which were independent of the operating system and had no inherent capability to directly establish mappings on their own. This was to have provided functionality similar to device driver interfaces such as *physio()* and their underlying bus-specific interfaces (for example, *mballoc()*) which serve to set up and break down DMA pathways, and derive mapped addresses for use by hardware devices and processor cards.

121186 The ballot group felt that this was beyond the scope of POSIX.1 and its amendments.  
 121187 Furthermore, the removal of interrupt handling interfaces from a preceding amendment  
 121188 (the IEEE Std 1003.1d-1999) during its balloting process renders these typed memory  
 121189 access management interfaces an incomplete solution to portable device management from  
 121190 a user process; it would be possible to initiate a device transfer to/from typed memory, but  
 121191 impossible to handle the transfer-complete interrupt in a portable way.

121192 To achieve ballot group consensus, all references to typed memory access management  
 121193 capabilities were removed. The concept of portable interfaces from a device driver to both  
 121194 operating system and hardware is being addressed by the Uniform Driver Interface (UDI)  
 121195 industry forum, with formal standardization deferred until proof of concept and industry-  
 121196 wide acceptance and implementation.

#### 121197 B.2.8.4 Process Scheduling

121198 IEEE PASC Interpretation 1003.1 #96 has been applied, adding the *pthread\_setschedprio()*  
 121199 function. This was added since previously there was no way for a thread to lower its own  
 121200 priority without going to the tail of the threads list for its new priority. This capability is  
 121201 necessary to bound the duration of priority inversion encountered by a thread.

121202 The following portion of the rationale presents models, requirements, and standardization  
 121203 issues relevant to process scheduling; see also [Section B.2.9.4](#) (on page 3610).

121204 In an operating system supporting multiple concurrent processes, the system determines the  
 121205 order in which processes execute to meet implementation-defined goals. For time-sharing  
 121206 systems, the goal is to enhance system throughput and promote fairness; the application is  
 121207 provided with little or no control over this sequencing function. While this is acceptable and  
 121208 desirable behavior in a time-sharing system, it is inappropriate in a realtime system; realtime  
 121209 applications must specifically control the execution sequence of their concurrent processes in  
 121210 order to meet externally defined response requirements.

121211 In POSIX.1-2008, the control over process sequencing is provided using a concept of scheduling  
 121212 policies. These policies, described in detail in this section, define the behavior of the system  
 121213 whenever processor resources are to be allocated to competing processes. Only the behavior of  
 121214 the policy is defined; conforming implementations are free to use any mechanism desired to  
 121215 achieve the described behavior.

#### 121216 • Models

121217 In an operating system supporting multiple concurrent processes, the system determines  
 121218 the order in which processes execute and might force long-running processes to yield to  
 121219 other processes at certain intervals. Typically, the scheduling code is executed whenever an  
 121220 event occurs that might alter the process to be executed next.

121221 The simplest scheduling strategy is a “first-in, first-out” (FIFO) dispatcher. Whenever a  
 121222 process becomes runnable, it is placed on the end of a ready list. The process at the front of  
 121223 the ready list is executed until it exits or becomes blocked, at which point it is removed  
 121224 from the list. This scheduling technique is also known as “run-to-completion” or “run-to-  
 121225 block”.

121226 A natural extension to this scheduling technique is the assignment of a “non-migrating  
 121227 priority” to each process. This policy differs from strict FIFO scheduling in only one  
 121228 respect: whenever a process becomes runnable, it is placed at the end of the list of  
 121229 processes runnable at that priority level. When selecting a process to run, the system  
 121230 always selects the first process from the highest priority queue with a runnable process.  
 121231 Thus, when a process becomes unblocked, it will preempt a running process of lower  
 121232 priority without otherwise altering the ready list. Further, if a process elects to alter its

|        |                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------|
| 121233 | priority, it is removed from the ready list and reinserted, using its new priority, according             |
| 121234 | to the policy above.                                                                                      |
| 121235 | While the above policy might be considered unfriendly in a time-sharing environment in                    |
| 121236 | which multiple users require more balanced resource allocation, it could be ideal in a                    |
| 121237 | realtime environment for several reasons. The most important of these is that it is                       |
| 121238 | deterministic: the highest-priority process is always run and, among processes of equal                   |
| 121239 | priority, the process that has been runnable for the longest time is executed first. Because of           |
| 121240 | this determinism, cooperating processes can implement more complex scheduling simply                      |
| 121241 | by altering their priority. For instance, if processes at a single priority were to reschedule            |
| 121242 | themselves at fixed time intervals, a time-slice policy would result.                                     |
| 121243 | In a dedicated operating system in which all processes are well-behaved realtime                          |
| 121244 | applications, non-migrating priority scheduling is sufficient. However, many existing                     |
| 121245 | implementations provide for more complex scheduling policies.                                             |
| 121246 | POSIX.1-2008 specifies a linear scheduling model. In this model, every process in the                     |
| 121247 | system has a priority. The system scheduler always dispatches a process that has the                      |
| 121248 | highest (generally the most time-critical) priority among all runnable processes in the                   |
| 121249 | system. As long as there is only one such process, the dispatching policy is trivial. When                |
| 121250 | multiple processes of equal priority are eligible to run, they are ordered according to a                 |
| 121251 | strict run-to-completion (FIFO) policy.                                                                   |
| 121252 | The priority is represented as a positive integer and is inherited from the parent process.               |
| 121253 | For processes running under a fixed priority scheduling policy, the priority is never altered             |
| 121254 | except by an explicit function call.                                                                      |
| 121255 | It was determined arbitrarily that larger integers correspond to “higher priorities”.                     |
| 121256 | Certain implementations might impose restrictions on the priority ranges to which                         |
| 121257 | processes can be assigned. There also can be restrictions on the set of policies to which                 |
| 121258 | processes can be set.                                                                                     |
| 121259 | • Requirements                                                                                            |
| 121260 | Realtime processes require that scheduling be fast and deterministic, and that it guarantees              |
| 121261 | to preempt lower priority processes.                                                                      |
| 121262 | Thus, given the linear scheduling model, realtime processes require that they be run at a                 |
| 121263 | priority that is higher than other processes. Within this framework, realtime processes are               |
| 121264 | free to yield execution resources to each other in a completely portable and                              |
| 121265 | implementation-defined manner.                                                                            |
| 121266 | As there is a generally perceived requirement for processes at the same priority level to                 |
| 121267 | share processor resources more equitably, provisions are made by providing a scheduling                   |
| 121268 | policy (that is, SCHED_RR) intended to provide a timeslice-like facility.                                 |
| 121269 | <b>Note:</b> The following topics assume that low numeric priority implies low scheduling criticality     |
| 121270 | and <i>vice versa</i> .                                                                                   |
| 121271 | • Rationale for New Interface                                                                             |
| 121272 | Realtime applications need to be able to determine when processes will run in relation to                 |
| 121273 | each other. It must be possible to guarantee that a critical process will run whenever it is              |
| 121274 | runnable; that is, whenever it wants to for as long as it needs. SCHED_FIFO satisfies this                |
| 121275 | requirement. Additionally, SCHED_RR was defined to meet a realtime requirement for a                      |
| 121276 | well-defined time-sharing policy for processes at the same priority.                                      |
| 121277 | It would be possible to use the BSD <i>setpriority()</i> and <i>getpriority()</i> functions by redefining |
| 121278 | the meaning of the “nice” parameter according to the scheduling policy currently in use by                |

|        |                                                                                                      |
|--------|------------------------------------------------------------------------------------------------------|
| 121279 | the process. The System V <i>nice()</i> interface was felt to be undesirable for realtime because it |
| 121280 | specifies an adjustment to the “nice” value, rather than setting it to an explicit value.            |
| 121281 | Realtime applications will usually want to set priority to an explicit value. Also, System V         |
| 121282 | <i>nice()</i> does not allow for changing the priority of another process.                           |
| 121283 | With the POSIX.1b interfaces, the traditional “nice” value does not affect the SCHED_FIFO            |
| 121284 | or SCHED_RR scheduling policies. If a “nice” value is supported, it is implementation-               |
| 121285 | defined whether it affects the SCHED_OTHER policy.                                                   |
| 121286 | An important aspect of POSIX.1-2008 is the explicit description of the queuing and                   |
| 121287 | preemption rules. It is critical, to achieve deterministic scheduling, that such rules be            |
| 121288 | stated clearly in POSIX.1-2008.                                                                      |
| 121289 | POSIX.1-2008 does not address the interaction between priority and swapping. The issues              |
| 121290 | involved with swapping and virtual memory paging are extremely implementation-                       |
| 121291 | defined and would be nearly impossible to standardize at this point. The proposed                    |
| 121292 | scheduling paradigm, however, fully describes the scheduling behavior of runnable                    |
| 121293 | processes, of which one criterion is that the working set be resident in memory. Assuming            |
| 121294 | the existence of a portable interface for locking portions of a process in memory, paging            |
| 121295 | behavior need not affect the scheduling of realtime processes.                                       |
| 121296 | POSIX.1-2008 also does not address the priorities of “system” processes. In general, these           |
| 121297 | processes should always execute in low-priority ranges to avoid conflict with other                  |
| 121298 | realtime processes. Implementations should document the priority ranges in which system              |
| 121299 | processes run.                                                                                       |
| 121300 | The default scheduling policy is not defined. The effect of I/O interrupts and other system          |
| 121301 | processing activities is not defined. The temporary lending of priority from one process to          |
| 121302 | another (such as for the purposes of affecting freeing resources) by the system is not               |
| 121303 | addressed. Preemption of resources is not addressed. Restrictions on the ability of a                |
| 121304 | process to affect other processes beyond a certain level (influence levels) is not addressed.        |
| 121305 | The rationale used to justify the simple time-quantum scheduler is that it is common                 |
| 121306 | practice to depend upon this type of scheduling to ensure “fair” distribution of processor           |
| 121307 | resources among portions of the application that must interoperate in a serial fashion. Note         |
| 121308 | that POSIX.1-2008 is silent with respect to the setting of this time quantum, or whether it is       |
| 121309 | a system-wide value or a per-process value, although it appears that the prevailing                  |
| 121310 | realtime practice is for it to be a system-wide value.                                               |
| 121311 | In a system with $N$ processes at a given priority, all processor-bound, in which the time           |
| 121312 | quantum is equal for all processes at a specific priority level, the following assumptions           |
| 121313 | are made of such a scheduling policy:                                                                |
| 121314 | 1. A time quantum $Q$ exists and the current process will own control of the processor               |
| 121315 | for at least a duration of $Q$ and will have the processor for a duration of $Q$ .                   |
| 121316 | 2. The $N$ th process at that priority will control a processor within a duration of $(N-1)$         |
| 121317 | $\times Q$ .                                                                                         |
| 121318 | These assumptions are necessary to provide equal access to the processor and bounded                 |
| 121319 | response from the application.                                                                       |
| 121320 | The assumptions hold for the described scheduling policy only if no system overhead,                 |
| 121321 | such as interrupt servicing, is present. If the interrupt servicing load is non-zero, then one       |
| 121322 | of the two assumptions becomes fallacious, based upon how $Q$ is measured by the system.             |
| 121323 | If $Q$ is measured by clock time, then the assumption that the process obtains a duration $Q$        |
| 121324 | processor time is false if interrupt overhead exists. Indeed, a scenario can be constructed          |
| 121325 | with $N$ processes in which a single process undergoes complete processor starvation if a            |

121326 peripheral device, such as an analog-to-digital converter, generates significant interrupt  
 121327 activity periodically with a period of  $N \times Q$ .

121328 If  $Q$  is measured as actual processor time, then the assumption that the  $N$ th process runs in  
 121329 within the duration  $(N-1) \times Q$  is false.

121330 It should be noted that SCHED\_FIFO suffers from interrupt-based delay as well. However,  
 121331 for SCHED\_FIFO, the implied response of the system is “as soon as possible”, so that the  
 121332 interrupt load for this case is a vendor selection and not a compliance issue.

121333 With this in mind, it is necessary either to complete the definition by including bounds on  
 121334 the interrupt load, or to modify the assumptions that can be made about the scheduling  
 121335 policy.

121336 Since the motivation of inclusion of the policy is common usage, and since current  
 121337 applications do not enjoy the luxury of bounded interrupt load, item (2) above is sufficient  
 121338 to express existing application needs and is less restrictive in the standard definition. No  
 121339 difference in interface is necessary.

121340 In an implementation in which the time quantum is equal for all processes at a specific  
 121341 priority, our assumptions can then be restated as:

- 121342 — A time quantum  $Q$  exists, and a processor-bound process will be rescheduled after a  
 121343 duration of, at most,  $Q$ . Time quantum  $Q$  may be defined in either wall clock time or  
 121344 execution time.
- 121345 — In general, the  $N$ th process of a priority level should wait no longer than  $(N-1) \times Q$   
 121346 time to execute, assuming no processes exist at higher priority levels.
- 121347 — No process should wait indefinitely.

121348 For implementations supporting per-process time quanta, these assumptions can be  
 121349 readily extended.

### 121350 **Sporadic Server Scheduling Policy**

121351 The sporadic server is a mechanism defined for scheduling aperiodic activities in time-critical  
 121352 realtime systems. This mechanism reserves a certain bounded amount of execution capacity for  
 121353 processing aperiodic events at a high priority level. Any aperiodic events that cannot be  
 121354 processed within the bounded amount of execution capacity are executed in the background at a  
 121355 low priority level. Thus, a certain amount of execution capacity can be guaranteed to be  
 121356 available for processing periodic tasks, even under burst conditions in the arrival of aperiodic  
 121357 processing requests (that is, a large number of requests in a short time interval). The sporadic  
 121358 server also simplifies the schedulability analysis of the realtime system, because it allows  
 121359 aperiodic processes or threads to be treated as if they were periodic. The sporadic server was  
 121360 first described by Sprunt, et al.

121361 The key concept of the sporadic server is to provide and limit a certain amount of computation  
 121362 capacity for processing aperiodic events at their assigned normal priority, during a time interval  
 121363 called the “replenishment period”. Once the entity controlled by the sporadic server mechanism  
 121364 is initialized with its period and execution-time budget attributes, it preserves its execution  
 121365 capacity until an aperiodic request arrives. The request will be serviced (if there are no higher  
 121366 priority activities pending) as long as there is execution capacity left. If the request is completed,  
 121367 the actual execution time used to service it is subtracted from the capacity, and a replenishment  
 121368 of this amount of execution time is scheduled to happen one replenishment period after the  
 121369 arrival of the aperiodic request. If the request is not completed, because there is no execution  
 121370 capacity left, then the aperiodic process or thread is assigned a lower background priority. For  
 121371 each portion of consumed execution capacity the execution time used is replenished after one

replenishment period. At the time of replenishment, if the sporadic server was executing at a background priority level, its priority is elevated to the normal level. Other similar replenishment policies have been defined, but the one presented here represents a compromise between efficiency and implementation complexity.

The interface that appears in this section defines a new scheduling policy for threads and processes that behaves according to the rules of the sporadic server mechanism. Scheduling attributes are defined and functions are provided to allow the user to set and get the parameters that control the scheduling behavior of this mechanism, namely the normal and low priority, the replenishment period, the maximum number of pending replenishment operations, and the initial execution-time budget.

- Scheduling Aperiodic Activities

Virtually all realtime applications are required to process aperiodic activities. In many cases, there are tight timing constraints that the response to the aperiodic events must meet. Usual timing requirements imposed on the response to these events are:

- The effects of an aperiodic activity on the response time of lower priority activities must be controllable and predictable.
- The system must provide the fastest possible response time to aperiodic events.
- It must be possible to take advantage of all the available processing bandwidth not needed by time-critical activities to enhance average-case response times to aperiodic events.

Traditional methods for scheduling aperiodic activities are background processing, polling tasks, and direct event execution:

- Background processing consists of assigning a very low priority to the processing of aperiodic events. It utilizes all the available bandwidth in the system that has not been consumed by higher priority threads. However, it is very difficult, or impossible, to meet requirements on average-case response time, because the aperiodic entity has to wait for the execution of all other entities which have higher priority.
- Polling consists of creating a periodic process or thread for servicing aperiodic requests. At regular intervals, the polling entity is started and its services accumulated pending aperiodic requests. If no aperiodic requests are pending, the polling entity suspends itself until its next period. Polling allows the aperiodic requests to be processed at a higher priority level. However, worst and average-case response times of polling entities are a direct function of the polling period, and there is execution overhead for each polling period, even if no event has arrived. If the deadline of the aperiodic activity is short compared to the inter-arrival time, the polling frequency must be increased to guarantee meeting the deadline. For this case, the increase in frequency can dramatically reduce the efficiency of the system and, therefore, its capacity to meet all deadlines. Yet, polling represents a good way to handle a large class of practical problems because it preserves system predictability, and because the amortized overhead drops as load increases.
- Direct event execution consists of executing the aperiodic events at a high fixed-priority level. Typically, the aperiodic event is processed by an interrupt service routine as soon as it arrives. This technique provides predictable response times for aperiodic events, but makes the response times of all lower priority activities completely unpredictable under burst arrival conditions. Therefore, if the density of aperiodic event arrivals is unbounded, it may be a dangerous technique for time-critical systems. Yet, for those cases in which the physics of the system imposes a

bound on the event arrival rate, it is probably the most efficient technique.

- The sporadic server scheduling algorithm combines the predictability of the polling approach with the short response times of the direct event execution. Thus, it allows systems to meet an important class of application requirements that cannot be met by using the traditional approaches. Multiple sporadic servers with different attributes can be applied to the scheduling of multiple classes of aperiodic events, each with different kinds of timing requirements, such as individual deadlines, average response times, and so on. It also has many other interesting applications for realtime, such as scheduling producer/consumer tasks in time-critical systems, limiting the effects of faults on the estimation of task execution-time requirements, and so on.

- Existing Practice

The sporadic server has been used in different kinds of applications, including military avionics, robot control systems, industrial automation systems, and so on. There are examples of many systems that cannot be successfully scheduled using the classic approaches, such as direct event execution, or polling, and are schedulable using a sporadic server scheduler. The sporadic server algorithm itself can successfully schedule all systems scheduled with direct event execution or polling.

The sporadic server scheduling policy has been implemented as a commercial product in the run-time system of the Verdex Ada compiler. There are also many applications that have used a much less efficient application-level sporadic server. These realtime applications would benefit from a sporadic server scheduler implemented at the scheduler level.

- Library-Level *versus* Kernel-Level Implementation

The sporadic server interface described in this section requires the sporadic server policy to be implemented at the same level as the scheduler. This means that the process sporadic server must be implemented at the kernel level and the thread sporadic server policy implemented at the same level as the thread scheduler; that is, kernel or library level.

In an earlier interface for the sporadic server, this mechanism was implementable at a different level than the scheduler. This feature allowed the implementor to choose between an efficient scheduler-level implementation, or a simpler user or library-level implementation. However, the working group considered that this interface made the use of sporadic servers more complex, and that library-level implementations would lack some of the important functionality of the sporadic server, namely the limitation of the actual execution time of aperiodic activities. The working group also felt that the interface described in this chapter does not preclude library-level implementations of threads intended to provide efficient low-overhead scheduling for those threads that are not scheduled under the sporadic server policy.

- Range of Scheduling Priorities

Each of the scheduling policies supported in POSIX.1-2008 has an associated range of priorities. The priority ranges for each policy might or might not overlap with the priority ranges of other policies. For time-critical realtime applications it is usual for periodic and aperiodic activities to be scheduled together in the same processor. Periodic activities will usually be scheduled using the SCHED\_FIFO scheduling policy, while aperiodic activities may be scheduled using SCHED\_SPORADIC. Since the application developer will require complete control over the relative priorities of these activities in order to meet his timing requirements, it would be desirable for the priority ranges of SCHED\_FIFO and SCHED\_SPORADIC to overlap completely. Therefore, although POSIX.1-2008 does not

121468 require any particular relationship between the different priority ranges, it is  
121469 recommended that these two ranges should coincide.

121470 • Dynamically Setting the Sporadic Server Policy

121471 Several members of the working group requested that implementations should not be  
121472 required to support dynamically setting the sporadic server scheduling policy for a thread.  
121473 The reason is that this policy may have a high overhead for library-level implementations  
121474 of threads, and if threads are allowed to dynamically set this policy, this overhead can be  
121475 experienced even if the thread does not use that policy. By disallowing the dynamic setting  
121476 of the sporadic server scheduling policy, these implementations can accomplish efficient  
121477 scheduling for threads using other policies. If a strictly conforming application needs to  
121478 use the sporadic server policy, and is therefore willing to pay the overhead, it must set this  
121479 policy at the time of thread creation.

121480 • Limitation of the Number of Pending Replenishments

121481 The number of simultaneously pending replenishment operations must be limited for each  
121482 sporadic server for two reasons: an unlimited number of replenishment operations would  
121483 need an unlimited number of system resources to store all the pending replenishment  
121484 operations; on the other hand, in some implementations each replenishment operation will  
121485 represent a source of priority inversion (just for the duration of the replenishment  
121486 operation) and thus, the maximum amount of replenishments must be bounded to  
121487 guarantee bounded response times. The way in which the number of replenishments is  
121488 bounded is by lowering the priority of the sporadic server to *sched\_ss\_low\_priority* when  
121489 the number of pending replenishments has reached its limit. In this way, no new  
121490 replenishments are scheduled until the number of pending replenishments decreases.

121491 In the sporadic server scheduling policy defined in POSIX.1-2008, the application can  
121492 specify the maximum number of pending replenishment operations for a single sporadic  
121493 server, by setting the value of the *sched\_ss\_max\_repl* scheduling parameter. This value must  
121494 be between one and {SS\_REPL\_MAX}, which is a maximum limit imposed by the  
121495 implementation. The limit {SS\_REPL\_MAX} must be greater than or equal to  
121496 {\_POSIX\_SS\_REPL\_MAX}, which is defined to be four in POSIX.1-2008. The minimum  
121497 limit of four was chosen so that an application can at least guarantee that four different  
121498 aperiodic events can be processed during each interval of length equal to the  
121499 replenishment period.

121500 B.2.8.5 Clocks and Timers

121501 • Clocks

121502 POSIX.1-2008 and the ISO C standard both define functions for obtaining system time.  
121503 Implicit behind these functions is a mechanism for measuring passage of time. This  
121504 specification makes this mechanism explicit and calls it a clock. The CLOCK\_REALTIME  
121505 clock required by POSIX.1-2008 is a higher resolution version of the clock that maintains  
121506 POSIX.1 system time. This is a “system-wide” clock, in that it is visible to all processes  
121507 and, were it possible for multiple processes to all read the clock at the same time, they  
121508 would see the same value.

121509 An extensible interface was defined, with the ability for implementations to define  
121510 additional clocks. This was done because of the observation that many realtime platforms  
121511 support multiple clocks, and it was desired to fit this model within the standard interface.  
121512 But implementation-defined clocks need not represent actual hardware devices, nor are  
121513 they necessarily system-wide.

- Timers

Two timer types are required for a system to support realtime applications:

1. One-shot

A one-shot timer is a timer that is armed with an initial expiration time, either relative to the current time or at an absolute time (based on some timing base, such as time in seconds and nanoseconds since the Epoch). The timer expires once and then is disarmed. With the specified facilities, this is accomplished by setting the *it\_value* member of the *value* argument to the desired expiration time and the *it\_interval* member to zero.

2. Periodic

A periodic timer is a timer that is armed with an initial expiration time, again either relative or absolute, and a repetition interval. When the initial expiration occurs, the timer is reloaded with the repetition interval and continues counting. With the specified facilities, this is accomplished by setting the *it\_value* member of the *value* argument to the desired initial expiration time and the *it\_interval* member to the desired repetition interval.

For both of these types of timers, the time of the initial timer expiration can be specified in two ways:

1. Relative (to the current time)
2. Absolute

- Examples of Using Realtime Timers

In the diagrams below, *S* indicates a program schedule, *R* shows a schedule method request, and *E* suggests an internal operating system event.

— Periodic Timer: Data Logging

During an experiment, it might be necessary to log realtime data periodically to an internal buffer or to a mass storage device. With a periodic scheduling method, a logging module can be started automatically at fixed time intervals to log the data.

Program schedule is requested every 10 seconds.

[Time (in Seconds)]

To achieve this type of scheduling using the specified facilities, one would allocate a per-process timer based on clock ID `CLOCK_REALTIME`. Then the timer would be armed via a call to `timer_settime()` with the `TIMER_ABSTIME` flag reset, and with an initial expiration value and a repetition interval of 10 seconds.

— One-shot Timer (Relative Time): Device Initialization

In an emission test environment, large sample bags are used to capture the exhaust from a vehicle. The exhaust is purged from these bags before each and every test. With a one-shot timer, a module could initiate the purge function and then suspend itself for a predetermined period of time while the sample bags are prepared.

Program schedule requested 20 seconds after call is issued.

effectively to minimize bottlenecks and delays and maximize facility throughput.

Program schedule requested for 2:00 a.m. and every 15 minutes thereafter.

```

 R S S S S S S
-----+-----+-----+-----+-----+-----+-----+----->
 23:00 23:30 24:00 00:30 01:00 01:30 02:00 02:30 03:00

```

[Time of Day]

To achieve this type of scheduling using the specified facilities, one would allocate a per-process timer based on clock ID `CLOCK_REALTIME`. Then the timer would be armed via a call to `timer_settime()` with `TIMER_ABSTIME` flag set, and with an initial expiration value equal to 2:00 a.m. and a repetition interval equal to 15 minutes.

- Relationship of Timers to Clocks

The relationship between clocks and timers armed with an absolute time is straightforward: a timer expiration signal is requested when the associated clock reaches or exceeds the specified time. The relationship between clocks and timers armed with a relative time (an interval) is less obvious, but not unintuitive. In this case, a timer expiration signal is requested when the specified interval, *as measured by the associated clock*, has passed. For the required `CLOCK_REALTIME` clock, this allows timer expiration signals to be requested at specified “wall clock” times (absolute), or when a specified interval of “realtime” has passed (relative). For an implementation-defined clock—say, a process virtual time clock—timer expirations could be requested when the process has used a specified total amount of virtual time (absolute), or when it has used a specified *additional* amount of virtual time (relative).

The interfaces also allow flexibility in the implementation of the functions. For example, an implementation could convert all absolute times to intervals by subtracting the clock value at the time of the call from the requested expiration time and “counting down” at the supported resolution. Or it could convert all relative times to absolute expiration time by adding in the clock value at the time of the call and comparing the clock value to the expiration time at the supported resolution. Or it might even choose to maintain absolute times as absolute and compare them to the clock value at the supported resolution for absolute timers, and maintain relative times as intervals and count them down at the resolution supported for relative timers. The choice will be driven by efficiency considerations and the underlying hardware or software clock implementation.

- Data Definitions for Clocks and Timers

POSIX.1-2008 uses a time representation capable of supporting nanosecond resolution timers for the following reasons:

- To enable POSIX.1-2008 to represent those computer systems already using nanosecond or submicrosecond resolution clocks.
- To accommodate those per-process timers that might need nanoseconds to specify an absolute value of system-wide clocks, even though the resolution of the per-process timer may only be milliseconds, or *vice versa*.
- Because the number of nanoseconds in a second can be represented in 32 bits.

Time values are represented in the **timespec** structure. The `tv_sec` member is of type **time\_t** so that this member is compatible with time values used by POSIX.1 functions and the ISO C standard. The `tv_nsec` member is a **signed long** in order to simplify and clarify code that decrements or finds differences of time values. Note that because 1 billion (number of nanoseconds per second) is less than half of the value representable by a signed 32-bit

121647 value, it is always possible to add two valid fractional seconds represented as integral  
121648 nanoseconds without overflowing the signed 32-bit value.

121649 A maximum allowable resolution for the CLOCK\_REALTIME clock of 20 ms (1/50  
121650 seconds) was chosen to allow line frequency clocks in European countries to be  
121651 conforming. 60 Hz clocks in the US will also be conforming, as will finer granularity  
121652 clocks, although a Strictly Conforming Application cannot assume a granularity of less  
121653 than 20 ms (1/50 seconds).

121654 The minimum allowable maximum time allowed for the CLOCK\_REALTIME clock and  
121655 the function *nanosleep()*, and timers created with *clock\_id=CLOCK\_REALTIME*, is  
121656 determined by the fact that the *tv\_sec* member is of type **time\_t**.

121657 POSIX.1-2008 specifies that timer expirations must not be delivered early, and *nanosleep()*  
121658 must not return early due to quantization error. POSIX.1-2008 discusses the various  
121659 implementations of *alarm()* in the rationale and states that implementations that do not  
121660 allow alarm signals to occur early are the most appropriate, but refrained from mandating  
121661 this behavior. Because of the importance of predictability to realtime applications,  
121662 POSIX.1-2008 takes a stronger stance.

121663 The standard developers considered using a time representation that differs from  
121664 POSIX.1b in the second 32 bit of the 64-bit value. Whereas POSIX.1b defines this field as a  
121665 fractional second in nanoseconds, the other methodology defines this as a binary fraction  
121666 of one second, with the radix point assumed before the most significant bit.

121667 POSIX.1b is a software, source-level standard and most of the benefits of the alternate  
121668 representation are enjoyed by hardware implementations of clocks and algorithms. It was  
121669 felt that mandating this format for POSIX.1b clocks and timers would unnecessarily  
121670 burden the application developer with writing, possibly non-portable, multiple precision  
121671 arithmetic packages to perform conversion between binary fractions and integral units  
121672 such as nanoseconds, milliseconds, and so on.

## 121673 **Rationale for the Monotonic Clock**

121674 For those applications that use time services to achieve realtime behavior, changing the value of  
121675 the clock on which these services rely may cause erroneous timing behavior. For these  
121676 applications, it is necessary to have a monotonic clock which cannot run backwards, and which  
121677 has a maximum clock jump that is required to be documented by the implementation.  
121678 Additionally, it is desirable (but not required by POSIX.1-2008) that the monotonic clock  
121679 increases its value uniformly. This clock should not be affected by changes to the system time;  
121680 for example, to synchronize the clock with an external source or to account for leap seconds.  
121681 Such changes would cause errors in the measurement of time intervals for those time services  
121682 that use the absolute value of the clock.

121683 One could argue that by defining the behavior of time services when the value of a clock is  
121684 changed, deterministic realtime behavior can be achieved. For example, one could specify that  
121685 relative time services should be unaffected by changes in the value of a clock. However, there are  
121686 time services that are based upon an absolute time, but that are essentially intended as relative  
121687 time services. For example, *pthread\_cond\_timedwait()* uses an absolute time to allow it to wake  
121688 up after the required interval despite spurious wakeups. Although sometimes the  
121689 *pthread\_cond\_timedwait()* timeouts are absolute in nature, there are many occasions in which they  
121690 are relative, and their absolute value is determined from the current time plus a relative time  
121691 interval. In this latter case, if the clock changes while the thread is waiting, the wait interval will  
121692 not be the expected length. If a *pthread\_cond\_timedwait()* function were created that would take a  
121693 relative time, it would not solve the problem because to retain the intended “deadline” a thread  
121694 would need to compensate for latency due to the spurious wakeup, and preemption between

121695 wakeup and the next wait.

121696 The solution is to create a new monotonic clock, whose value does not change except for the  
 121697 regular ticking of the clock, and use this clock for implementing the various relative timeouts  
 121698 that appear in the different POSIX interfaces, as well as allow *pthread\_cond\_timedwait()* to choose  
 121699 this new clock for its timeout. A new *clock\_nanosleep()* function is created to allow an application  
 121700 to take advantage of this newly defined clock. Notice that the monotonic clock may be  
 121701 implemented using the same hardware clock as the system clock.

121702 Relative timeouts for *sigtimedwait()* and *aio\_suspend()* have been redefined to use the monotonic  
 121703 clock, if present. The *alarm()* function has not been redefined, because the same effect but with  
 121704 better resolution can be achieved by creating a timer (for which the appropriate clock may be  
 121705 chosen).

121706 The *pthread\_cond\_timedwait()* function has been treated in a different way, compared to other  
 121707 functions with absolute timeouts, because it is used to wait for an event, and thus it may have a  
 121708 deadline, while the other timeouts are generally used as an error recovery mechanism, and for  
 121709 them the use of the monotonic clock is not so important. Since the desired timeout for the  
 121710 *pthread\_cond\_timedwait()* function may either be a relative interval or an absolute time of day  
 121711 deadline, a new initialization attribute has been created for condition variables to specify the  
 121712 clock that is used for measuring the timeout in a call to *pthread\_cond\_timedwait()*. In this way, if  
 121713 a relative timeout is desired, the monotonic clock will be used; if an absolute deadline is  
 121714 required instead, the *CLOCK\_REALTIME* or another appropriate clock may be used. This  
 121715 capability has not been added to other functions with absolute timeouts because for those  
 121716 functions the expected use of the timeout is mostly to prevent errors, and not so often to meet  
 121717 precise deadlines. As a consequence, the complexity of adding this capability is not justified by  
 121718 its perceived application usage.

121719 The *nanosleep()* function has not been modified with the introduction of the monotonic clock.  
 121720 Instead, a new *clock\_nanosleep()* function has been created, in which the desired clock may be  
 121721 specified in the function call.

#### 121722 • History of Resolution Issues

121723 Due to the shift from relative to absolute timeouts in IEEE Std 1003.1d-1999, the  
 121724 amendments to the *sem\_timedwait()*, *pthread\_mutex\_timedlock()*, *mq\_timedreceive()*, and  
 121725 *mq\_timedsend()* functions of that standard have been removed. Those amendments  
 121726 specified that *CLOCK\_MONOTONIC* would be used for the (relative) timeouts if the  
 121727 Monotonic Clock option was supported.

121728 Having these functions continue to be tied solely to *CLOCK\_MONOTONIC* would not  
 121729 work. Since the absolute value of a time value obtained from *CLOCK\_MONOTONIC* is  
 121730 unspecified, under the absolute timeouts interface, applications would behave differently  
 121731 depending on whether the Monotonic Clock option was supported or not (because the  
 121732 absolute value of the clock would have different meanings in either case).

121733 Two options were considered:

- 121734 1. Leave the current behavior unchanged, which specifies the *CLOCK\_REALTIME*  
 121735 clock for these (absolute) timeouts, to allow portability of applications between  
 121736 implementations supporting or not the Monotonic Clock option.
- 121737 2. Modify these functions in the way that *pthread\_cond\_timedwait()* was modified to  
 121738 allow a choice of clock, so that an application could use *CLOCK\_REALTIME* when  
 121739 it is trying to achieve an absolute timeout and *CLOCK\_MONOTONIC* when it is  
 121740 trying to achieve a relative timeout.

121741 It was decided that the features of *CLOCK\_MONOTONIC* are not as critical to these

functions as they are to `pthread_cond_timedwait()`. The `pthread_cond_timedwait()` function is given a relative timeout; the timeout may represent a deadline for an event. When these functions are given relative timeouts, the timeouts are typically for error recovery purposes and need not be so precise.

Therefore, it was decided that these functions should be tied to `CLOCK_REALTIME` and not complicated by being given a choice of clock.

## Execution Time Monitoring

- Introduction

The main goals of the execution time monitoring facilities defined in this chapter are to measure the execution time of processes and threads and to allow an application to establish CPU time limits for these entities.

The analysis phase of time-critical realtime systems often relies on the measurement of execution times of individual threads or processes to determine whether the timing requirements will be met. Also, performance analysis techniques for soft deadline realtime systems rely heavily on the determination of these execution times. The execution time monitoring functions provide application developers with the ability to measure these execution times online and open the possibility of dynamic execution-time analysis and system reconfiguration, if required.

The second goal of allowing an application to establish execution time limits for individual processes or threads and detecting when they overrun allows program robustness to be increased by enabling online checking of the execution times.

If errors are detected—possibly because of erroneous program constructs, the existence of errors in the analysis phase, or a burst of event arrivals—online detection and recovery is possible in a portable way. This feature can be extremely important for many time-critical applications. Other applications require trapping CPU-time errors as a normal way to exit an algorithm; for instance, some realtime artificial intelligence applications trigger a number of independent inference processes of varying accuracy and speed, limit how long they can run, and pick the best answer available when time runs out. In many periodic systems, overrun processes are simply restarted in the next resource period, after necessary end-of-period actions have been taken. This allows algorithms that are inherently data-dependent to be made predictable.

The interface that appears in this chapter defines a new type of clock, the CPU-time clock, which measures execution time. Each process or thread can invoke the clock and timer functions defined in POSIX.1 to use them. Functions are also provided to access the CPU-time clock of other processes or threads to enable remote monitoring of these clocks. Monitoring of threads of other processes is not supported, since these threads are not visible from outside of their own process with the interfaces defined in POSIX.1.

- Execution Time Monitoring Interface

The clock and timer interface defined in POSIX.1 historically only defined one clock, which measures wall-clock time. The requirements for measuring execution time of processes and threads, and setting limits to their execution time by detecting when they overrun, can be accomplished with that interface if a new kind of clock is defined. These new clocks measure execution time, and one is associated with each process and with each thread. The clock functions currently defined in POSIX.1 can be used to read and set these CPU-time clocks, and timers can be created using these clocks as their timing base. These timers can then be used to send a signal when some specified execution time has been exceeded. The CPU-time clocks of each process or thread can be accessed by using the symbols

121789 CLOCK\_PROCESS\_CPUTIME\_ID or CLOCK\_THREAD\_CPUTIME\_ID.

121790 The clock and timer interface defined in POSIX.1 and extended with the new kind of CPU-  
 121791 time clock would only allow processes or threads to access their own CPU-time clocks.  
 121792 However, many realtime systems require the possibility of monitoring the execution time  
 121793 of processes or threads from independent monitoring entities. In order to allow  
 121794 applications to construct independent monitoring entities that do not require cooperation  
 121795 from or modification of the monitored entities, two functions have been added:  
 121796 *clock\_getcpuclockid()*, for accessing CPU-time clocks of other processes, and  
 121797 *pthread\_getcpuclockid()*, for accessing CPU-time clocks of other threads. These functions  
 121798 return the clock identifier associated with the process or thread specified in the call. These  
 121799 clock IDs can then be used in the rest of the clock function calls.

121800 The clocks accessed through these functions could also be used as a timing base for the  
 121801 creation of timers, thereby allowing independent monitoring entities to limit the CPU time  
 121802 consumed by other entities. However, this possibility would imply additional complexity  
 121803 and overhead because of the need to maintain a timer queue for each process or thread, to  
 121804 store the different expiration times associated with timers created by different processes or  
 121805 threads. The working group decided this additional overhead was not justified by  
 121806 application requirements. Therefore, creation of timers attached to the CPU-time clocks of  
 121807 other processes or threads has been specified as implementation-defined.

#### 121808 • Overhead Considerations

121809 The measurement of execution time may introduce additional overhead in the thread  
 121810 scheduling, because of the need to keep track of the time consumed by each of these  
 121811 entities. In library-level implementations of threads, the efficiency of scheduling could be  
 121812 somehow compromised because of the need to make a kernel call, at each context switch,  
 121813 to read the process CPU-time clock. Consequently, a thread creation attribute called *cpu-  
 121814 clock-requirement* was defined, to allow threads to disconnect their respective CPU-time  
 121815 clocks. However, the Ballot Group considered that this attribute itself introduced some  
 121816 overhead, and that in current implementations it was not worth the effort. Therefore, the  
 121817 attribute was deleted, and thus thread CPU-time clocks are required for all threads if the  
 121818 Thread CPU-Time Clocks option is supported.

#### 121819 • Accuracy of CPU-Time Clocks

121820 The mechanism used to measure the execution time of processes and threads is specified in  
 121821 POSIX.1-2008 as implementation-defined. The reason for this is that both the underlying  
 121822 hardware and the implementation architecture have a very strong influence on the  
 121823 accuracy achievable for measuring CPU time. For some implementations, the specification  
 121824 of strict accuracy requirements would represent very large overheads, or even the  
 121825 impossibility of being implemented.

121826 Since the mechanism for measuring execution time is implementation-defined, realtime  
 121827 applications will be able to take advantage of accurate implementations using a portable  
 121828 interface. Of course, strictly conforming applications cannot rely on any particular degree  
 121829 of accuracy, in the same way as they cannot rely on a very accurate measurement of wall  
 121830 clock time. There will always exist applications whose accuracy or efficiency requirements  
 121831 on the implementation are more rigid than the values defined in POSIX.1-2008 or any  
 121832 other standard.

121833 In any case, there is a minimum set of characteristics that realtime applications would  
 121834 expect from most implementations. One such characteristic is that the sum of all the  
 121835 execution times of all the threads in a process equals the process execution time, when no  
 121836 CPU-time clocks are disabled. This need not always be the case because implementations  
 121837 may differ in how they account for time during context switches. Another characteristic is

that the sum of the execution times of all processes in a system equals the number of processors, multiplied by the elapsed time, assuming that no processor is idle during that elapsed time. However, in some implementations it might not be possible to relate CPU time to elapsed time. For example, in a heterogeneous multi-processor system in which each processor runs at a different speed, an implementation may choose to define each “second” of CPU time to be a certain number of “cycles” that a CPU has executed.

- Existing Practice

Measuring and limiting the execution time of each concurrent activity are common features of most industrial implementations of realtime systems. Almost all critical realtime systems are currently built upon a cyclic executive. With this approach, a regular timer interrupt kicks off the next sequence of computations. It also checks that the current sequence has completed. If it has not, then some error recovery action can be undertaken (or at least an overrun is avoided). Current software engineering principles and the increasing complexity of software are driving application developers to implement these systems on multi-threaded or multi-process operating systems. Therefore, if a POSIX operating system is to be used for this type of application, then it must offer the same level of protection.

Execution time clocks are also common in most UNIX implementations, although these clocks usually have requirements different from those of realtime applications. The POSIX.1 *times()* function supports the measurement of the execution time of the calling process, and its terminated child processes. This execution time is measured in clock ticks and is supplied as two different values with the user and system execution times, respectively. BSD supports the function *getrusage()*, which allows the calling process to get information about the resources used by itself and/or all of its terminated child processes. The resource usage includes user and system CPU time. Some UNIX systems have options to specify high resolution (up to one microsecond) CPU-time clocks using the *times()* or the *getrusage()* functions.

The *times()* and *getrusage()* interfaces do not meet important realtime requirements, such as the possibility of monitoring execution time from a different process or thread, or the possibility of detecting an execution time overrun. The latter requirement is supported in some UNIX implementations that are able to send a signal when the execution time of a process has exceeded some specified value. For example, BSD defines the functions *getitimer()* and *setitimer()*, which can operate either on a realtime clock (wall-clock), or on virtual-time or profile-time clocks which measure CPU time in two different ways. These functions do not support access to the execution time of other processes.

The IBM MVS operating system supports per-process and per-thread execution time clocks. It also supports limiting the execution time of a given process.

Given all this existing practice, the working group considered that the POSIX.1 clocks and timers interface was appropriate to meet most of the requirements that realtime applications have for execution time clocks. Functions were added to get the CPU time clock IDs, and to allow/disallow the thread CPU-time clocks (in order to preserve the efficiency of some implementations of threads).

- Clock Constants

The definition of the manifest constants `CLOCK_PROCESS_CPUTIME_ID` and `CLOCK_THREAD_CPUTIME_ID` allows processes or threads, respectively, to access their own execution-time clocks. However, given a process or thread, access to its own execution-time clock is also possible if the clock ID of this clock is obtained through a call to *clock\_getcpuclockid()* or *pthread\_getcpuclockid()*. Therefore, these constants are not necessary and could be deleted to make the interface simpler. Their existence saves one

121887 system call in the first access to the CPU-time clock of each process or thread. The working  
 121888 group considered this issue and decided to leave the constants in POSIX.1-2008 because  
 121889 they are closer to the POSIX.1b use of clock identifiers.

121890 • Library Implementations of Threads

121891 In library implementations of threads, kernel entities and library threads can coexist. In  
 121892 this case, if the CPU-time clocks are supported, most of the clock and timer functions will  
 121893 need to have two implementations: one in the thread library, and one in the system calls  
 121894 library. The main difference between these two implementations is that the thread library  
 121895 implementation will have to deal with clocks and timers that reside in the thread space,  
 121896 while the kernel implementation will operate on timers and clocks that reside in kernel  
 121897 space. In the library implementation, if the clock ID refers to a clock that resides in the  
 121898 kernel, a kernel call will have to be made. The correct version of the function can be chosen  
 121899 by specifying the appropriate order for the libraries during the link process.

121900 • History of Resolution Issues: Deletion of the *enable* Attribute

121901 In early proposals, consideration was given to inclusion of an attribute called *enable* for  
 121902 CPU-time clocks. This would allow implementations to avoid the overhead of measuring  
 121903 execution time for those processes or threads for which this measurement was not  
 121904 required. However, this is unnecessary since processes are already required to measure  
 121905 execution time by the POSIX.1 *times()* function. Consequently, the *enable* attribute is not  
 121906 present.

121907 **Rationale Relating to Timeouts**

121908 • Requirements for Timeouts

121909 Realtime systems which must operate reliably over extended periods without human  
 121910 intervention are characteristic in embedded applications such as avionics, machine control,  
 121911 and space exploration, as well as more mundane applications such as cable TV, security  
 121912 systems, and plant automation. A multi-tasking paradigm, in which many independent  
 121913 and/or cooperating software functions relinquish the processor(s) while waiting for a  
 121914 specific stimulus, resource, condition, or operation completion, is very useful in producing  
 121915 well engineered programs for such systems. For such systems to be robust and fault-  
 121916 tolerant, expected occurrences that are unduly delayed or that never occur must be  
 121917 detected so that appropriate recovery actions may be taken. This is difficult if there is no  
 121918 way for a task to regain control of a processor once it has relinquished control (blocked)  
 121919 awaiting an occurrence which, perhaps because of corrupted code, hardware malfunction,  
 121920 or latent software bugs, will not happen when expected. Therefore, the common practice  
 121921 in realtime operating systems is to provide a capability to time out such blocking services.  
 121922 Although there are several methods to achieve this already defined by POSIX, none are as  
 121923 reliable or efficient as initiating a timeout simultaneously with initiating a blocking service.  
 121924 This is especially critical in hard-realtime embedded systems because the processors  
 121925 typically have little time reserve, and allowed fault recovery times are measured in  
 121926 milliseconds rather than seconds.

121927 The working group largely agreed that such timeouts were necessary and ought to become  
 121928 part of POSIX.1-2008, particularly vendors of realtime operating systems whose customers  
 121929 had already expressed a strong need for timeouts. There was some resistance to inclusion  
 121930 of timeouts in POSIX.1-2008 because the desired effect, fault tolerance, could, in theory, be  
 121931 achieved using existing facilities and alternative software designs, but there was no  
 121932 compelling evidence that realtime system designers would embrace such designs at the  
 121933 sacrifice of performance and/or simplicity.

- Which Services should be Timed Out?

Originally, the working group considered the prospect of providing timeouts on all blocking services, including those currently existing in POSIX.1, POSIX.1b, and POSIX.1c, and future interfaces to be defined by other working groups, as sort of a general policy. This was rather quickly rejected because of the scope of such a change, and the fact that many of those services would not normally be used in a realtime context. More traditional timesharing solutions to timeout would suffice for most of the POSIX.1 interfaces, while others had asynchronous alternatives which, while more complex to utilize, would be adequate for some realtime and all non-realtime applications.

The list of potential candidates for timeouts was narrowed to the following for further consideration:

- POSIX.1b
  - *sem\_wait()*
  - *mq\_receive()*
  - *mq\_send()*
  - *lio\_listio()*
  - *aio\_suspend()*
  - *sigwait()* (timeout already implemented by *sigtimedwait()*)
- POSIX.1c
  - *pthread\_mutex\_lock()*
  - *pthread\_join()*
  - *pthread\_cond\_wait()*  
(timeout already implemented by *pthread\_cond\_timedwait()*)
- POSIX.1
  - *read()*
  - *write()*

After further review by the working group, the *lio\_listio()*, *read()*, and *write()* functions (all forms of blocking synchronous I/O) were eliminated from the list because of the following:

- Asynchronous alternatives exist
- Timeouts can be implemented, albeit non-portably, in device drivers
- A strong desire not to introduce modifications to POSIX.1 interfaces

The working group ultimately rejected *pthread\_join()* since both that interface and a timed variant of that interface are non-minimal and may be implemented as a function. See below for a library implementation of *pthread\_join()*.

Thus, there was a consensus among the working group members to add timeouts to 4 of the remaining 5 functions (the timeout for *aio\_suspend()* was ultimately added directly to POSIX.1b, while the others were added by POSIX.1d). However, *pthread\_mutex\_lock()* remained contentious.

Many feel that *pthread\_mutex\_lock()* falls into the same class as the other functions; that is, it is desirable to time out a mutex lock because a mutex may fail to be unlocked due to

errant or corrupted code in a critical section (looping or branching outside of the unlock code), and therefore is equally in need of a reliable, simple, and efficient timeout. In fact, since mutexes are intended to guard small critical sections, most `pthread_mutex_lock()` calls would be expected to obtain the lock without blocking nor utilizing any kernel service, even in implementations of threads with global contention scope; the timeout alternative need only be considered after it is determined that the thread must block.

Those opposed to timing out mutexes feel that the very simplicity of the mutex is compromised by adding a timeout semantic, and that to do so is senseless. They claim that if a timed mutex is really deemed useful by a particular application, then it can be constructed from the facilities already in POSIX.1b and POSIX.1c. The following two C-language library implementations of mutex locking with timeout represent the solutions offered (in both implementations, the timeout parameter is specified as absolute time, not relative time as in the proposed POSIX.1c interfaces).

- Spinlock Implementation

```
#include <pthread.h>
#include <time.h>
#include <errno.h>

int pthread_mutex_timedlock(pthread_mutex_t *mutex,
 const struct timespec *timeout)
{
 struct timespec timenow;

 while (pthread_mutex_trylock(mutex) == EBUSY)
 {
 clock_gettime(CLOCK_REALTIME, &timenow);
 if (timespec_cmp(&timenow, timeout) >= 0)
 {
 return ETIMEDOUT;
 }
 pthread_yield();
 }
 return 0;
}
```

The Spinlock implementation is generally unsuitable for any application using priority-based thread scheduling policies such as SCHED\_FIFO or SCHED\_RR, since the mutex could currently be held by a thread of lower priority within the same allocation domain, but since the waiting thread never blocks, only threads of equal or higher priority will ever run, and the mutex cannot be unlocked. Setting priority inheritance or priority ceiling protocol on the mutex does not solve this problem, since the priority of a mutex owning thread is only boosted if higher priority threads are blocked waiting for the mutex; clearly not the case for this spinlock.

- Condition Wait Implementation

```
#include <pthread.h>
#include <time.h>
#include <errno.h>

struct timed_mutex
{
 int locked;
 pthread_mutex_t mutex;
}
```

```

122023 pthread_cond_t cond;
122024 };
122025 typedef struct timed_mutex timed_mutex_t;
122026 int timed_mutex_lock(timed_mutex_t *tm,
122027 const struct timespec *timeout)
122028 {
122029 int timedout=FALSE;
122030 int error_status;
122031
122032 pthread_mutex_lock(&tm->mutex);
122033
122034 while (tm->locked && !timedout)
122035 {
122036 if ((error_status=pthread_cond_timedwait(&tm->cond,
122037 &tm->mutex,
122038 timeout))!=0)
122039 {
122040 if (error_status==ETIMEDOUT) timedout = TRUE;
122041 }
122042 }
122043
122044 if(timedout)
122045 {
122046 pthread_mutex_unlock(&tm->mutex);
122047 return ETIMEDOUT;
122048 }
122049 else
122050 {
122051 tm->locked = TRUE;
122052 pthread_mutex_unlock(&tm->mutex);
122053 return 0;
122054 }
122055 }
122056
122057 void timed_mutex_unlock(timed_mutex_t *tm)
122058 {
122059 pthread_mutex_lock(&tm->mutex); / for case assignment not atomic /
122060 tm->locked = FALSE;
122061 pthread_mutex_unlock(&tm->mutex);
122062 pthread_cond_signal(&tm->cond);
122063 }

```

The Condition Wait implementation effectively substitutes the *pthread\_cond\_timedwait()* function (which is currently timed out) for the desired *pthread\_mutex\_timedlock()*. Since waits on condition variables currently do not include protocols which avoid priority inversion, this method is generally unsuitable for realtime applications because it does not provide the same priority inversion protection as the untimed *pthread\_mutex\_lock()*. Also, for any given implementations of the current mutex and condition variable primitives, this library implementation has a performance cost at least 2.5 times that of the untimed *pthread\_mutex\_lock()* even in the case where the timed mutex is readily locked without blocking (the interfaces required for this case are shown in bold). Even in uniprocessors or where assignment is atomic, at least an additional *pthread\_cond\_signal()* is required. *pthread\_mutex\_timedlock()* could be implemented at effectively no performance penalty in this case because the timeout parameters need only be considered after it is determined that the mutex cannot be locked immediately.

Thus it has not yet been shown that the full semantics of mutex locking with timeout can be efficiently and reliably achieved using existing interfaces. Even if the existence of an acceptable library implementation were proven, it is difficult to justify why the interface itself should not be made portable, especially considering approval for the other four timeouts.

- Rationale for Library Implementation of *pthread\_timedjoin()*

Library implementation of *pthread\_timedjoin()*:

```

/*
 * Construct a thread variety entirely from existing functions
 * with which a join can be done, allowing the join to time out.
 */
#include <pthread.h>
#include <time.h>

struct timed_thread {
 pthread_t t;
 pthread_mutex_t m;
 int exiting;
 pthread_cond_t exit_c;
 void *(*start_routine)(void *arg);
 void *arg;
 void *status;
};

typedef struct timed_thread *timed_thread_t;
static pthread_key_t timed_thread_key;
static pthread_once_t timed_thread_once = PTHREAD_ONCE_INIT;

static void timed_thread_init()
{
 pthread_key_create(&timed_thread_key, NULL);
}

static void *timed_thread_start_routine(void *args)
/*
 * Routine to establish thread-specific data value and run the actual
 * thread start routine which was supplied to timed_thread_create().
 */
{
 timed_thread_t tt = (timed_thread_t) args;

 pthread_once(&timed_thread_once, timed_thread_init);
 pthread_setspecific(timed_thread_key, (void *)tt);
 timed_thread_exit((tt->start_routine)(tt->arg));
}

int timed_thread_create(timed_thread_t ttp, const pthread_attr_t *attr,
 void *(*start_routine)(void *), void *arg)
/*
 * Allocate a thread which can be used with timed_thread_join().
 */
{
 timed_thread_t tt;

```

```

122120 int result;
122121 tt = (timed_thread_t) malloc(sizeof(struct timed_thread));
122122 pthread_mutex_init(&tt->m, NULL);
122123 tt->exiting = FALSE;
122124 pthread_cond_init(&tt->exit_c, NULL);
122125 tt->start_routine = start_routine;
122126 tt->arg = arg;
122127 tt->status = NULL;
122128
122129 if ((result = pthread_create(&tt->t, attr,
122130 timed_thread_start_routine, (void *)tt)) != 0) {
122131 free(tt);
122132 return result;
122133 }
122134 pthread_detach(tt->t);
122135 ttp = tt;
122136 return 0;
122137 }
122138
122139 int timed_thread_join(timed_thread_t tt,
122140 struct timespec *timeout,
122141 void **status)
122142 {
122143 int result;
122144
122145 pthread_mutex_lock(&tt->m);
122146 result = 0;
122147 /*
122148 * Wait until the thread announces that it is exiting,
122149 * or until timeout.
122150 */
122151 while (result == 0 && ! tt->exiting) {
122152 result = pthread_cond_timedwait(&tt->exit_c, &tt->m, timeout);
122153 }
122154 pthread_mutex_unlock(&tt->m);
122155 if (result == 0 && tt->exiting) {
122156 *status = tt->status;
122157 free((void *)tt);
122158 return result;
122159 }
122160 return result;
122161 }
122162
122163 void timed_thread_exit(void *status)
122164 {
122165 timed_thread_t tt;
122166 void *specific;
122167
122168 if ((specific=pthread_getspecific(timed_thread_key)) == NULL) {
122169 /*
122170 * Handle cases which won't happen with correct usage.
122171 */
122172 pthread_exit(NULL);
122173 }
122174 }

```

```

122169 tt = (timed_thread_t) specific;
122170 pthread_mutex_lock(&tt->m);
122171 /*
122172 * Tell a joiner that we're exiting.
122173 */
122174 tt->status = status;
122175 tt->exiting = TRUE;
122176 pthread_cond_signal(&tt->exit_c);
122177 pthread_mutex_unlock(&tt->m);
122178 /*
122179 * Call pthread_exit() to call destructors and really
122180 * exit the thread.
122181 */
122182 pthread_exit(NULL);
122183 }

```

The `pthread_join()` C-language example shown above demonstrates that it is possible, using existing pthread facilities, to construct a variety of thread which allows for joining such a thread, but which allows the join operation to time out. It does this by using a `pthread_cond_timedwait()` to wait for the thread to exit. A **timed\_thread\_t** descriptor structure is used to pass parameters from the creating thread to the created thread, and from the exiting thread to the joining thread. This implementation is roughly equivalent to what a normal `pthread_join()` implementation would do, with the single change being that `pthread_cond_timedwait()` is used in place of a simple `pthread_cond_wait()`.

Since it is possible to implement such a facility entirely from existing pthread interfaces, and with roughly equal efficiency and complexity to an implementation which would be provided directly by a pthreads implementation, it was the consensus of the working group members that any `pthread_timedjoin()` facility would be unnecessary, and should not be provided.

- Form of the Timeout Interfaces

The working group considered a number of alternative ways to add timeouts to blocking services. At first, a system interface which would specify a one-shot or persistent timeout to be applied to subsequent blocking services invoked by the calling process or thread was considered because it allowed all blocking services to be timed out in a uniform manner with a single additional interface; this was rather quickly rejected because it could easily result in the wrong services being timed out.

It was suggested that a timeout value might be specified as an attribute of the object (semaphore, mutex, message queue, and so on), but there was no consensus on this, either on a case-by-case basis or for all timeouts.

Looking at the two existing timeouts for blocking services indicates that the working group members favor a separate interface for the timed version of a function. However, `pthread_cond_timedwait()` utilizes an absolute timeout value while `sigtimedwait()` uses a relative timeout value. The working group members agreed that relative timeout values are appropriate where the timeout mechanism's primary use was to deal with an unexpected or error situation, but they are inappropriate when the timeout must expire at a particular time, or before a specific deadline. For the timeouts being introduced in POSIX.1-2008, the working group considered allowing both relative and absolute timeouts as is done with POSIX.1b timers, but ultimately favored the simpler absolute timeout form.

An absolute time measure can be easily implemented on top of an interface that specifies relative time, by reading the clock, calculating the difference between the current time and

122218 the desired wakeup time, and issuing a relative timeout call. But there is a race condition  
122219 with this approach because the thread could be preempted after reading the clock, but  
122220 before making the timed-out call; in this case, the thread would be awakened later than it  
122221 should and, thus, if the wakeup time represented a deadline, it would miss it.

122222 There is also a race condition when trying to build a relative timeout on top of an interface  
122223 that specifies absolute timeouts. In this case, the clock would have to be read to calculate  
122224 the absolute wakeup time as the sum of the current time plus the relative timeout interval.  
122225 In this case, if the thread is preempted after reading the clock but before making the timed-  
122226 out call, the thread would be awakened earlier than desired.

122227 But the race condition with the absolute timeouts interface is not as bad as the one that  
122228 happens with the relative timeout interface, because there are simple workarounds. For the  
122229 absolute timeouts interface, if the timing requirement is a deadline, the deadline can still  
122230 be met because the thread woke up earlier than the deadline. If the timeout is just used as  
122231 an error recovery mechanism, the precision of timing is not really important. If the timing  
122232 requirement is that between actions A and B a minimum interval of time must elapse, the  
122233 absolute timeout interface can be safely used by reading the clock after action A has been  
122234 started. It could be argued that, since the call with the absolute timeout is atomic from the  
122235 application point of view, it is not possible to read the clock after action A, if this action is  
122236 part of the timed-out call. But looking at the nature of the calls for which timeouts are  
122237 specified (locking a mutex, waiting for a semaphore, waiting for a message, or waiting  
122238 until there is space in a message queue), the timeouts that an application would build on  
122239 these actions would not be triggered by these actions themselves, but by some other  
122240 external action. For example, if waiting for a message to arrive to a message queue, and  
122241 waiting for at least 20 milliseconds, this time interval would start to be counted from some  
122242 event that would trigger both the action that produces the message, as well as the action  
122243 that waits for the message to arrive, and not by the wait-for-message operation itself. In  
122244 this case, the workaround proposed above could be used.

122245 For these reasons, the absolute timeout is preferred over the relative timeout interface.

## 122246 B.2.9 Threads

122247 Threads will normally be more expensive than subroutines (or functions, routines, and so on) if  
122248 specialized hardware support is not provided. Nevertheless, threads should be sufficiently  
122249 efficient to encourage their use as a medium to fine-grained structuring mechanism for  
122250 parallelism in an application. Structuring an application using threads then allows it to take  
122251 immediate advantage of any underlying parallelism available in the host environment. This  
122252 means implementors are encouraged to optimize for fast execution at the possible expense of  
122253 efficient utilization of storage. For example, a common thread creation technique is to cache  
122254 appropriate thread data structures. That is, rather than releasing system resources, the  
122255 implementation retains these resources and reuses them when the program next asks to create a  
122256 new thread. If this reuse of thread resources is to be possible, there has to be very little unique  
122257 state associated with each thread, because any such state has to be reset when the thread is  
122258 reused.

## Thread Creation Attributes

Attributes objects are provided for threads, mutexes, and condition variables as a mechanism to support probable future standardization in these areas without requiring that the interface itself be changed.

Attributes objects provide clean isolation of the configurable aspects of threads. For example, “stack size” is an important attribute of a thread, but it cannot be expressed portably. When porting a threaded program, stack sizes often need to be adjusted. The use of attributes objects can help by allowing the changes to be isolated in a single place, rather than being spread across every instance of thread creation.

Attributes objects can be used to set up *classes* of threads with similar attributes; for example, “threads with large stacks and high priority” or “threads with minimal stacks”. These classes can be defined in a single place and then referenced wherever threads need to be created. Changes to “class” decisions become straightforward, and detailed analysis of each `pthread_create()` call is not required.

The attributes objects are defined as opaque types as an aid to extensibility. If these objects had been specified as structures, adding new attributes would force recompilation of all multi-threaded programs when the attributes objects are extended; this might not be possible if different program components were supplied by different vendors.

Additionally, opaque attributes objects present opportunities for improving performance. Argument validity can be checked once when attributes are set, rather than each time a thread is created. Implementations will often need to cache kernel objects that are expensive to create. Opaque attributes objects provide an efficient mechanism to detect when cached objects become invalid due to attribute changes.

Because assignment is not necessarily defined on a given opaque type, implementation-defined default values cannot be defined in a portable way. The solution to this problem is to allow attribute objects to be initialized dynamically by attributes object initialization functions, so that default values can be supplied automatically by the implementation.

The following proposal was provided as a suggested alternative to the supplied attributes:

1. Maintain the style of passing a parameter formed by the bitwise-inclusive OR of flags to the initialization routines (`pthread_create()`, `pthread_mutex_init()`, `pthread_cond_init()`). The parameter containing the flags should be an opaque type for extensibility. If no flags are set in the parameter, then the objects are created with default characteristics. An implementation may specify implementation-defined flag values and associated behavior.
2. If further specialization of mutexes and condition variables is necessary, implementations may specify additional procedures that operate on the `pthread_mutex_t` and `pthread_cond_t` objects (instead of on attributes objects).

The difficulties with this solution are:

1. A bitmask is not opaque if bits have to be set into bit-vector attributes objects using explicitly-coded bitwise-inclusive OR operations. If the set of options exceeds an `int`, application programmers need to know the location of each bit. If bits are set or read by encapsulation (that is, `get*()` or `set*()` functions), then the bitmask is merely an implementation of attributes objects as currently defined and should not be exposed to the programmer.
2. Many attributes are not Boolean or very small integral values. For example, scheduling policy may be placed in 3 bits or 4 bits, but priority requires 5 bits or more, thereby taking up at least 8 bits out of a possible 16 bits on machines with 16-bit integers. Because of this,

the bitmask can only reasonably control whether particular attributes are set or not, and it cannot serve as the repository of the value itself. The value needs to be specified as a function parameter (which is non-extensible), or by setting a structure field (which is non-opaque), or by *get\**() and *set\**() functions (making the bitmask a redundant addition to the attributes objects).

Stack size is defined as an optional attribute because the very notion of a stack is inherently machine-dependent. Some implementations may not be able to change the size of the stack, for example, and others may not need to because stack pages may be discontinuous and can be allocated and released on demand.

The attribute mechanism has been designed in large measure for extensibility. Future extensions to the attribute mechanism or to any attributes object defined in POSIX.1-2008 have to be done with care so as not to affect binary-compatibility.

Attribute objects, even if allocated by means of dynamic allocation functions such as *malloc*(), may have their size fixed at compile time. This means, for example, a *pthread\_create*() in an implementation with extensions to the **pthread\_attr\_t** cannot look beyond the area that the binary application assumes is valid. This suggests that implementations should maintain a size field in the attributes object, as well as possibly version information, if extensions in different directions (possibly by different vendors) are to be accommodated.

### Thread Implementation Models

There are various thread implementation models. At one end of the spectrum is the “library-thread model”. In such a model, the threads of a process are not visible to the operating system kernel, and the threads are not kernel-scheduled entities. The process is the only kernel-scheduled entity. The process is scheduled onto the processor by the kernel according to the scheduling attributes of the process. The threads are scheduled onto the single kernel-scheduled entity (the process) by the runtime library according to the scheduling attributes of the threads. A problem with this model is that it constrains concurrency. Since there is only one kernel-scheduled entity (namely, the process), only one thread per process can execute at a time. If the thread that is executing blocks on I/O, then the whole process blocks.

At the other end of the spectrum is the “kernel-thread model”. In this model, all threads are visible to the operating system kernel. Thus, all threads are kernel-scheduled entities, and all threads can concurrently execute. The threads are scheduled onto processors by the kernel according to the scheduling attributes of the threads. The drawback to this model is that the creation and management of the threads entails operating system calls, as opposed to subroutine calls, which makes kernel threads heavier weight than library threads.

Hybrids of these two models are common. A hybrid model offers the speed of library threads and the concurrency of kernel threads. In hybrid models, a process has some (relatively small) number of kernel scheduled entities associated with it. It also has a potentially much larger number of library threads associated with it. Some library threads may be bound to kernel-scheduled entities, while the other library threads are multiplexed onto the remaining kernel-scheduled entities. There are two levels of thread scheduling:

1. The runtime library manages the scheduling of (unbound) library threads onto kernel-scheduled entities.
2. The kernel manages the scheduling of kernel-scheduled entities onto processors.

For this reason, a hybrid model is referred to as a two-level threads scheduling model. In this model, the process can have multiple concurrently executing threads; specifically, it can have as many concurrently executing threads as it has kernel-scheduled entities.

## Thread-Specific Data

Many applications require that a certain amount of context be maintained on a per-thread basis across procedure calls. A common example is a multi-threaded library routine that allocates resources from a common pool and maintains an active resource list for each thread. The thread-specific data interface provided to meet these needs may be viewed as a two-dimensional array of values with keys serving as the row index and thread IDs as the column index (although the implementation need not work this way).

- Models

Three possible thread-specific data models were considered:

1. No Explicit Support

A standard thread-specific data interface is not strictly necessary to support applications that require per-thread context. One could, for example, provide a hash function that converted a **pthread\_t** into an integer value that could then be used to index into a global array of per-thread data pointers. This hash function, in conjunction with *pthread\_self()*, would be all the interface required to support a mechanism of this sort. Unfortunately, this technique is cumbersome. It can lead to duplicated code as each set of cooperating modules implements their own per-thread data management schemes. This technique would also require that **pthread\_t** not be an opaque type.

2. Single (**void \***) Pointer

Another technique would be to provide a single word of per-thread storage and a pair of functions to fetch and store the value of this word. The word could then hold a pointer to a block of per-thread memory. The allocation, partitioning, and general use of this memory would be entirely up to the application. Although this method is not as problematic as technique 1, it suffers from interoperability problems. For example, all modules using the per-thread pointer would have to agree on a common usage protocol.

3. Key/Value Mechanism

This method associates an opaque key (for example, stored in a variable of type **pthread\_key\_t**) with each per-thread datum. These keys play the role of identifiers for per-thread data. This technique is the most generic and avoids the problems noted above, albeit at the cost of some complexity.

The primary advantage of the third model is its information hiding properties. Modules using this model are free to create and use their own key(s) independent of all other such usage, whereas the other models require that all modules that use thread-specific context explicitly cooperate with all other such modules. The data-independence provided by the third model is worth the additional interface. Therefore, the third model was chosen.

- Requirements

It is important that it be possible to implement the thread-specific data interface without the use of thread private memory. To do otherwise would increase the weight of each thread, thereby limiting the range of applications for which the threads interfaces provided by POSIX.1-2008 is appropriate.

The values that one binds to the key via *pthread\_setspecific()* may, in fact, be pointers to shared storage locations available to all threads. It is only the key/value bindings that are maintained on a per-thread basis, and these can be kept in any portion of the address space that is reserved for use by the calling thread (for example, on the stack). Thus, no per-

thread MMU state is required to implement the interface. On the other hand, there is nothing in the interface specification to preclude the use of a per-thread MMU state if it is available (for example, the key values returned by *pthread\_key\_create()* could be thread private memory addresses).

- Standardization Issues

Thread-specific data is a requirement for a usable thread interface. The binding described in this section provides a portable thread-specific data mechanism for languages that do not directly support a thread-specific storage class. A binding to POSIX.1-2008 for a language that does include such a storage class need not provide this specific interface.

If a language were to include the notion of thread-specific storage, it would be desirable (but *not* required) to provide an implementation of the pthreads thread-specific data interface based on the language feature. For example, assume that a compiler for a C-like language supports a *private* storage class that provides thread-specific storage. Something similar to the following macros might be used to effect a compatible implementation:

```
#define pthread_key_t private void *
#define pthread_key_create(key) /* no-op */
#define pthread_setspecific(key,value) (key)=(value)
#define pthread_getspecific(key) (key)
```

**Note:** For the sake of clarity, this example ignores destructor functions. A correct implementation would have to support them.

## Barriers

- Background

Barriers are typically used in parallel DO/FOR loops to ensure that all threads have reached a particular stage in a parallel computation before allowing any to proceed to the next stage. Highly efficient implementation is possible on machines which support a “Fetch and Add” operation as described in the referenced Almasi and Gottlieb (1989).

The use of return value PTHREAD\_BARRIER\_SERIAL\_THREAD is shown in the following example:

```
if ((status=pthread_barrier_wait(&barrier)) ==
 PTHREAD_BARRIER_SERIAL_THREAD) {
 ...serial section
}
else if (status != 0) {
 ...error processing
}
status=pthread_barrier_wait(&barrier);
...
```

This behavior allows a serial section of code to be executed by one thread as soon as all threads reach the first barrier. The second barrier prevents the other threads from proceeding until the serial section being executed by the one thread has completed.

Although barriers can be implemented with mutexes and condition variables, the referenced Almasi and Gottlieb (1989) provides ample illustration that such implementations are significantly less efficient than is possible. While the relative efficiency of barriers may well vary by implementation, it is important that they be recognized in the POSIX.1-2008 to facilitate applications portability while providing the necessary freedom to implementors.

- Lack of Timeout Feature

Alternate versions of most blocking routines have been provided to support watchdog timeouts. No alternate interface of this sort has been provided for barrier waits for the following reasons:

- Multiple threads may use different timeout values, some of which may be indefinite. It is not clear which threads should break through the barrier with a timeout error if and when these timeouts expire.
- The barrier may become unusable once a thread breaks out of a `pthread_barrier_wait()` with a timeout error. There is, in general, no way to guarantee the consistency of a barrier's internal data structures once a thread has timed out of a `pthread_barrier_wait()`. Even the inclusion of a special barrier reinitialization function would not help much since it is not clear how this function would affect the behavior of threads that reach the barrier between the original timeout and the call to the reinitialization function.

## Spin Locks

- Background

Spin locks represent an extremely low-level synchronization mechanism suitable primarily for use on shared memory multi-processors. It is typically an atomically modified Boolean value that is set to one when the lock is held and to zero when the lock is freed.

When a caller requests a spin lock that is already held, it typically spins in a loop testing whether the lock has become available. Such spinning wastes processor cycles so the lock should only be held for short durations and not across sleep/block operations. Callers should unlock spin locks before calling sleep operations.

Spin locks are available on a variety of systems. The functions included in POSIX.1-2008 are an attempt to standardize that existing practice.

- Lack of Timeout Feature

Alternate versions of most blocking routines have been provided to support watchdog timeouts. No alternate interface of this sort has been provided for spin locks for the following reasons:

- It is impossible to determine appropriate timeout intervals for spin locks in a portable manner. The amount of time one can expect to spend spin-waiting is inversely proportional to the degree of parallelism provided by the system.
- It can vary from a few cycles when each competing thread is running on its own processor, to an indefinite amount of time when all threads are multiplexed on a single processor (which is why spin locking is not advisable on uniprocessors).
- When used properly, the amount of time the calling thread spends waiting on a spin lock should be considerably less than the time required to set up a corresponding watchdog timer. Since the primary purpose of spin locks is to provide a low-overhead synchronization mechanism for multi-processors, the overhead of a timeout mechanism was deemed unacceptable.

It was also suggested that an additional `count` argument be provided (on the `pthread_spin_lock()` call) in lieu of a true timeout so that a spin lock call could fail gracefully if it was unable to apply the lock after `count` attempts. This idea was rejected because it is not existing practice. Furthermore, the same effect can be obtained with `pthread_spin_trylock()`, as illustrated below:

```

122489 int n = MAX_SPIN;
122490 while (--n >= 0)
122491 {
122492 if (!pthread_spin_try_lock(...))
122493 break;
122494 }
122495 if (n >= 0)
122496 {
122497 /* Successfully acquired the lock */
122498 }
122499 else
122500 {
122501 /* Unable to acquire the lock */
122502 }

```

- *process-shared* Attribute

The initialization functions associated with most POSIX synchronization objects (for example, mutexes, barriers, and read-write locks) take an attributes object with a *process-shared* attribute that specifies whether or not the object is to be shared across processes. In the draft corresponding to the first balloting round, two separate initialization functions are provided for spin locks, however: one for spin locks that were to be shared across processes (*spin\_init()*), and one for locks that were only used by multiple threads within a single process (*pthread\_spin\_init()*). This was done so as to keep the overhead associated with spin waiting to an absolute minimum. However, the balloting group requested that, since the overhead associated to a bit check was small, spin locks should be consistent with the rest of the synchronization primitives, and thus the *process-shared* attribute was introduced for spin locks.

- Spin Locks *versus* Mutexes

It has been suggested that mutexes are an adequate synchronization mechanism and spin locks are not necessary. Locking mechanisms typically must trade off the processor resources consumed while setting up to block the thread and the processor resources consumed by the thread while it is blocked. Spin locks require very little resources to set up the blocking of a thread. Existing practice is to simply loop, repeating the atomic locking operation until the lock is available. While the resources consumed to set up blocking of the thread are low, the thread continues to consume processor resources while it is waiting.

On the other hand, mutexes may be implemented such that the processor resources consumed to block the thread are large relative to a spin lock. After detecting that the mutex lock is not available, the thread must alter its scheduling state, add itself to a set of waiting threads, and, when the lock becomes available again, undo all of this before taking over ownership of the mutex. However, while a thread is blocked by a mutex, no processor resources are consumed.

Therefore, spin locks and mutexes may be implemented to have different characteristics. Spin locks may have lower overall overhead for very short-term blocking, and mutexes may have lower overall overhead when a thread will be blocked for longer periods of time. The presence of both interfaces allows implementations with these two different characteristics, both of which may be useful to a particular application.

It has also been suggested that applications can build their own spin locks from the *pthread\_mutex\_trylock()* function:

122537           while (pthread\_mutex\_trylock(&mutex));

122538           The apparent simplicity of this construct is somewhat deceiving, however. While the actual  
122539           wait is quite efficient, various guarantees on the integrity of mutex objects (for example,  
122540           priority inheritance rules) may add overhead to the successful path of the trylock  
122541           operation that is not required of spin locks. One could, of course, add an attribute to the  
122542           mutex to bypass such overhead, but the very act of finding and testing this attribute  
122543           represents more overhead than is found in the typical spin lock.

122544           The need to hold spin lock overhead to an absolute minimum also makes it impossible to  
122545           provide guarantees against starvation similar to those provided for mutexes or read-write  
122546           locks. The overhead required to implement such guarantees (for example, disabling  
122547           preemption before spinning) may well exceed the overhead of the spin wait itself by many  
122548           orders of magnitude. If a “safe” spin wait seems desirable, it can always be provided  
122549           (albeit at some performance cost) via appropriate mutex attributes.

## 122550           **Robust Mutexes**

122551           Robust mutexes are intended to protect applications that use mutexes to protect data shared  
122552           between different processes. If a process is terminated by a signal while a thread is holding a  
122553           mutex, there is no chance for the process to clean up after it. Waiters for the locked mutex might  
122554           wait indefinitely.

122555           With robust mutexes the problem can be solved: whenever a fatal signal terminates a process,  
122556           current or future waiters of the mutex are notified about this fact. The locking function provides  
122557           notification of this condition through the error condition [EOWNERDEAD]. A thread then has  
122558           the chance to clean up the state protected by the mutex and mark the state as consistent again by  
122559           a call to *pthread\_mutex\_consistent()*.

122560           Pre-existing implementations have used the semantics of robust mutexes for a variety of  
122561           situations, some of them not defined in the standard. Where a normally terminated process (i.e.,  
122562           when one thread calls *exit()*) causes notification of other waiters of robust mutexes if the mutex  
122563           is locked by any thread in the process. This behavior is defined in the standard and makes sense  
122564           because no thread other than the thread calling *exit()* has the chance to clean up its data.

122565           If a thread is terminated by cancellation or if it calls *pthread\_exit()*, the situation is different. In  
122566           both these situations the thread has the chance to clean up after itself by registering appropriate  
122567           cleanup handlers. There is no real reason to demand that other waiters for a robust mutex the  
122568           terminating thread owns are notified. The committee felt that this is actively encouraging bad  
122569           practice because programmers are tempted to rely on the robust mutex semantics instead of  
122570           correctly cleaning up after themselves.

122571           Therefore, the standard does not require notification of other waiters at the time a thread is  
122572           terminated while the process continues to run. The mutex is still recognized as being locked by  
122573           the process (with the thread gone it makes no sense to refer to the thread owning the mutex).  
122574           Therefore, a terminating process will cause notifications about the dead owner to be sent to all  
122575           waiters. This delay in the notification is not required, but programmers cannot rely on prompt  
122576           notification after a thread is terminated.

122577           For the same reason is it not required that an implementation supports robust mutexes that are  
122578           not shared between processes. If a robust mutex is used only within one process, all the cleanup  
122579           can be performed by the threads themselves by registering appropriate cleanup handlers. Fatal  
122580           signals are of no importance in this case because after the signal is delivered there is no thread  
122581           remaining to use the mutex.

122582           Some implementations might choose to support intra-process robust mutexes and they might  
122583           also send notification of a dead owner right after the previous owner died. But applications

122584 must not rely on this. Applications should only use robust mutexes for the purpose of handling  
 122585 fatal signals in situations where inter-process mutexes are in use.

## 122586 **Supported Threads Functions**

122587 On POSIX-conforming systems, the following symbolic constants are always conforming:

122588 `_POSIX_READER_WRITER_LOCKS`  
 122589 `_POSIX_THREADS`

122590 Therefore, the following threads functions are always supported:

|                                                   |                                              |
|---------------------------------------------------|----------------------------------------------|
| 122591 <code>pthread_atfork()</code>              | <code>pthread_mutex_destroy()</code>         |
| 122592 <code>pthread_attr_destroy()</code>        | <code>pthread_mutex_init()</code>            |
| 122593 <code>pthread_attr_getdetachstate()</code> | <code>pthread_mutex_lock()</code>            |
| 122594 <code>pthread_attr_getguardsize()</code>   | <code>pthread_mutex_trylock()</code>         |
| 122595 <code>pthread_attr_getschedparam()</code>  | <code>pthread_mutex_unlock()</code>          |
| 122596 <code>pthread_attr_init()</code>           | <code>pthread_mutexattr_destroy()</code>     |
| 122597 <code>pthread_attr_setdetachstate()</code> | <code>pthread_mutexattr_getpshared()</code>  |
| 122598 <code>pthread_attr_setguardsize()</code>   | <code>pthread_mutexattr_gettype()</code>     |
| 122599 <code>pthread_attr_setschedparam()</code>  | <code>pthread_mutexattr_init()</code>        |
| 122600 <code>pthread_cancel()</code>              | <code>pthread_mutexattr_setpshared()</code>  |
| 122601 <code>pthread_cleanup_pop()</code>         | <code>pthread_mutexattr_settype()</code>     |
| 122602 <code>pthread_cleanup_push()</code>        | <code>pthread_once()</code>                  |
| 122603 <code>pthread_cond_broadcast()</code>      | <code>pthread_rwlock_destroy()</code>        |
| 122604 <code>pthread_cond_destroy()</code>        | <code>pthread_rwlock_init()</code>           |
| 122605 <code>pthread_cond_init()</code>           | <code>pthread_rwlock_rdlock()</code>         |
| 122606 <code>pthread_cond_signal()</code>         | <code>pthread_rwlock_tryrdlock()</code>      |
| 122607 <code>pthread_cond_timedwait()</code>      | <code>pthread_rwlock_trywrlock()</code>      |
| 122608 <code>pthread_cond_wait()</code>           | <code>pthread_rwlock_unlock()</code>         |
| 122609 <code>pthread_condattr_destroy()</code>    | <code>pthread_rwlock_wrlock()</code>         |
| 122610 <code>pthread_condattr_getpshared()</code> | <code>pthread_rwlockattr_destroy()</code>    |
| 122611 <code>pthread_condattr_init()</code>       | <code>pthread_rwlockattr_getpshared()</code> |
| 122612 <code>pthread_condattr_setpshared()</code> | <code>pthread_rwlockattr_init()</code>       |
| 122613 <code>pthread_create()</code>              | <code>pthread_rwlockattr_setpshared()</code> |
| 122614 <code>pthread_detach()</code>              | <code>pthread_self()</code>                  |
| 122615 <code>pthread_equal()</code>               | <code>pthread_setcancelstate()</code>        |
| 122616 <code>pthread_exit()</code>                | <code>pthread_setcanceltype()</code>         |
| 122617 <code>pthread_getconcurrency()</code>      | <code>pthread_setconcurrency()</code>        |
| 122618 <code>pthread_getspecific()</code>         | <code>pthread_setspecific()</code>           |
| 122619 <code>pthread_join()</code>                | <code>pthread_sigmask()</code>               |
| 122620 <code>pthread_key_create()</code>          | <code>pthread_testcancel()</code>            |
| 122621 <code>pthread_key_delete()</code>          | <code>sigwait()</code>                       |
| 122622 <code>pthread_kill()</code>                |                                              |

On POSIX-conforming systems, the symbolic constant `_POSIX_THREAD_SAFE_FUNCTIONS` is always defined. Therefore, the following functions are always supported:

|        |                                 |                                 |
|--------|---------------------------------|---------------------------------|
| 122625 | <code>asctime_r()</code>        | <code>getpwuid_r()</code>       |
| 122626 | <code>ctime_r()</code>          | <code>gmtime_r()</code>         |
| 122627 | <code>flockfile()</code>        | <code>localtime_r()</code>      |
| 122628 | <code>ftrylockfile()</code>     | <code>putc_unlocked()</code>    |
| 122629 | <code>funlockfile()</code>      | <code>putchar_unlocked()</code> |
| 122630 | <code>getc_unlocked()</code>    | <code>rand_r()</code>           |
| 122631 | <code>getchar_unlocked()</code> | <code>readdir_r()</code>        |
| 122632 | <code>getgrgid_r()</code>       | <code>strerror_r()</code>       |
| 122633 | <code>getgrnam_r()</code>       | <code>strtok_r()</code>         |
| 122634 | <code>getpwnam_r()</code>       |                                 |

## 122635 Threads Extensions

The following extensions to the IEEE P1003.1c draft standard are now supported in POSIX.1-2008 as part of the alignment with the Single UNIX Specification:

- 122638 • Extended mutex attribute types
- 122639 • Read-write locks and attributes (also introduced by the IEEE Std 1003.1j-2000 amendment)
- 122640 • Thread concurrency level
- 122641 • Thread stack guard size
- 122642 • Parallel I/O
- 122643 • Robust mutexes

These extensions carefully follow the threads programming model specified in POSIX.1c. As with POSIX.1c, all the new functions return zero if successful; otherwise, an error number is returned to indicate the error.

The concept of attribute objects was introduced in POSIX.1c to allow implementations to extend POSIX.1-2008 without changing the existing interfaces. Attribute objects were defined for threads, mutexes, and condition variables. Attributes objects are defined as implementation-defined opaque types to aid extensibility, and functions are defined to allow attributes to be set or retrieved. This model has been followed when adding the new type attribute of **`pthread_mutexattr_t`** or the new read-write lock attributes object **`pthread_rwlockattr_t`**.

- 122653 • Extended Mutex Attributes

POSIX.1c defines a mutex attributes object as an implementation-defined opaque object of type **`pthread_mutexattr_t`**, and specifies a number of attributes which this object must have and a number of functions which manipulate these attributes. These attributes include *detachstate*, *inheritsched*, *schedparm*, *schedpolicy*, *contentionscope*, *stackaddr*, and *stacksize*.

The System Interfaces volume of POSIX.1-2008 specifies another mutex attribute called *type*. The *type* attribute allows applications to specify the behavior of mutex locking operations in situations where POSIX.1c behavior is undefined. The OSF DCE threads implementation, based on Draft 4 of POSIX.1c, specified a similar attribute. Note that the names of the attributes have changed somewhat from the OSF DCE threads implementation.

The System Interfaces volume of POSIX.1-2008 also extends the specification of the following POSIX.1c functions which manipulate mutexes:

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| 122686 | <i>Normal</i> mutexes do not detect deadlock conditions; for example, a thread will hang if it tries to relock a normal mutex that it already owns. Attempting to unlock a mutex locked by another thread, or unlocking an unlocked mutex, results in undefined behavior. Normal mutexes will usually be the fastest type of mutex available on a platform but provide the least error checking.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 122691 | <i>Recursive</i> mutexes are useful for converting old code where it is difficult to establish clear boundaries of synchronization. A thread can relock a recursive mutex without first unlocking it. The relocking deadlock which can occur with normal mutexes cannot occur with this type of mutex. However, multiple locks of a recursive mutex require the same number of unlocks to release the mutex before another thread can acquire the mutex. Furthermore, this type of mutex maintains the concept of an owner. Thus, a thread attempting to unlock a recursive mutex which another thread has locked returns with an error. A thread attempting to unlock a recursive mutex that is not locked returns with an error. Never use a recursive mutex with condition variables because the implicit unlock performed by <code>pthread_cond_wait()</code> or <code>pthread_cond_timedwait()</code> will not actually release the mutex if it had been locked multiple times. |

| 122702 | <i>Errorcheck</i> mutexes provide error checking and are useful primarily as a debugging aid. A thread attempting to relock an errorcheck mutex without first unlocking it returns with an error. Again, this type of mutex maintains the concept of an owner. Thus, a thread attempting to unlock an errorcheck mutex which another thread has locked returns with an error. A thread attempting to unlock an errorcheck mutex that is not locked also returns with an error. It should be noted that errorcheck mutexes will almost always be much slower than normal mutexes due to the extra state checks performed.                                                                                                                                                                                                                                                                                                                                                             |

| 122709 | The default mutex type provides implementation-defined error checking. The default mutex may be mapped to one of the other defined types or may be something entirely different. This enables each vendor to provide the mutex semantics which the vendor feels will be most useful to their target users. Most vendors will probably choose to make normal mutexes the default so as to give applications the benefit of the fastest type of                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 122710 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| 122712 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 122713 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

mutexes available on their platform. Check your implementation's documentation.

An application developer can use any of the mutex types almost interchangeably as long as the application does not depend upon the implementation detecting (or failing to detect) any particular errors. Note that a recursive mutex can be used with condition variable waits as long as the application never recursively locks the mutex.

Two functions are provided for manipulating the *type* attribute of a mutex attributes object. This attribute is set or returned in the *type* parameter of these functions. The `pthread_mutexattr_settype()` function is used to set a specific type value while `pthread_mutexattr_gettype()` is used to return the type of the mutex. Setting the *type* attribute of a mutex attributes object affects only mutexes initialized using that mutex attributes object. Changing the *type* attribute does not affect mutexes previously initialized using that mutex attributes object.

- Read-Write Locks and Attributes

The read-write locks introduced have been harmonized with those in IEEE Std 1003.1j-2000; see also [Section B.2.9.6](#) (on page 3618).

Read-write locks (also known as reader-writer locks) allow a thread to exclusively lock some shared data while updating that data, or allow any number of threads to have simultaneous read-only access to the data.

Unlike a mutex, a read-write lock distinguishes between reading data and writing data. A mutex excludes all other threads. A read-write lock allows other threads access to the data, providing no thread is modifying the data. Thus, a read-write lock is less primitive than either a mutex-condition variable pair or a semaphore.

Application developers should consider using a read-write lock rather than a mutex to protect data that is frequently referenced but seldom modified. Most threads (readers) will be able to read the data without waiting and will only have to block when some other thread (a writer) is in the process of modifying the data. Conversely a thread that wants to change the data is forced to wait until there are no readers. This type of lock is often used to facilitate parallel access to data on multi-processor platforms or to avoid context switches on single processor platforms where multiple threads access the same data.

If a read-write lock becomes unlocked and there are multiple threads waiting to acquire the write lock, the implementation's scheduling policy determines which thread acquires the read-write lock for writing. If there are multiple threads blocked on a read-write lock for both read locks and write locks, it is unspecified whether the readers or a writer acquire the lock first. However, for performance reasons, implementations often favor writers over readers to avoid potential writer starvation.

A read-write lock object is an implementation-defined opaque object of type **pthread\_rwlock\_t** as defined in `<pthread.h>`. There are two different sorts of locks associated with a read-write lock: a read lock and a write lock.

The `pthread_rwlockattr_init()` function initializes a read-write lock attributes object with the default value for all the attributes defined in the implementation. After a read-write lock attributes object has been used to initialize one or more read-write locks, changes to the read-write lock attributes object, including destruction, do not affect previously initialized read-write locks.

Implementations must provide at least the read-write lock attribute *process-shared*. This attribute can have the following values:

|        |                                                                                                                      |
|--------|----------------------------------------------------------------------------------------------------------------------|
| 122759 | PTHREAD_PROCESS_SHARED                                                                                               |
| 122760 | Any thread of any process that has access to the memory where the read-write lock                                    |
| 122761 | resides can manipulate the read-write lock.                                                                          |
| 122762 | PTHREAD_PROCESS_PRIVATE                                                                                              |
| 122763 | Only threads created within the same process as the thread that initialized the read-                                |
| 122764 | write lock can manipulate the read-write lock. This is the default value.                                            |
| 122765 | The <i>pthread_rwlockattr_setpshared()</i> function is used to set the <i>process-shared</i> attribute of an         |
| 122766 | initialized read-write lock attributes object while the function                                                     |
| 122767 | <i>pthread_rwlockattr_getpshared()</i> obtains the current value of the <i>process-shared</i> attribute.             |
| 122768 | A read-write lock attributes object is destroyed using the <i>pthread_rwlockattr_destroy()</i>                       |
| 122769 | function. The effect of subsequent use of the read-write lock attributes object is undefined.                        |
| 122770 | A thread creates a read-write lock using the <i>pthread_rwlock_init()</i> function. The attributes                   |
| 122771 | of the read-write lock can be specified by the application developer; otherwise, the default                         |
| 122772 | implementation-defined read-write lock attributes are used if the pointer to the read-write                          |
| 122773 | lock attributes object is NULL. In cases where the default attributes are appropriate, the                           |
| 122774 | PTHREAD_RWLOCK_INITIALIZER macro can be used to initialize read-write locks.                                         |
| 122775 | A thread which wants to apply a read lock to the read-write lock can use either                                      |
| 122776 | <i>pthread_rwlock_rdlock()</i> or <i>pthread_rwlock_tryrdlock()</i> . If <i>pthread_rwlock_rdlock()</i> is used, the |
| 122777 | thread acquires a read lock if a writer does not hold the write lock and there are no writers                        |
| 122778 | blocked on the write lock. If a read lock is not acquired, the calling thread blocks until it                        |
| 122779 | can acquire a lock. However, if <i>pthread_rwlock_tryrdlock()</i> is used, the function returns                      |
| 122780 | immediately with the error [EBUSY] if any thread holds a write lock or there are blocked                             |
| 122781 | writers waiting for the write lock.                                                                                  |
| 122782 | A thread which wants to apply a write lock to the read-write lock can use either of two                              |
| 122783 | functions: <i>pthread_rwlock_wrlock()</i> or <i>pthread_rwlock_trywrlock()</i> . If <i>pthread_rwlock_wrlock()</i>   |
| 122784 | is used, the thread acquires the write lock if no other reader or writer threads hold the                            |
| 122785 | read-write lock. If the write lock is not acquired, the thread blocks until it can acquire the                       |
| 122786 | write lock. However, if <i>pthread_rwlock_trywrlock()</i> is used, the function returns                              |
| 122787 | immediately with the error [EBUSY] if any thread is holding either a read or a write lock.                           |
| 122788 | The <i>pthread_rwlock_unlock()</i> function is used to unlock a read-write lock object held by the                   |
| 122789 | calling thread. Results are undefined if the read-write lock is not held by the calling thread.                      |
| 122790 | If there are other read locks currently held on the read-write lock object, the read-write                           |
| 122791 | lock object remains in the read locked state but without the current thread as one of its                            |
| 122792 | owners. If this function releases the last read lock for this read-write lock object, the read-                      |
| 122793 | write lock object is put in the unlocked read state. If this function is called to release a write                   |
| 122794 | lock for this read-write lock object, the read-write lock object is put in the unlocked state.                       |
| 122795 | • Thread Concurrency Level                                                                                           |
| 122796 | On threads implementations that multiplex user threads onto a smaller set of kernel                                  |
| 122797 | execution entities, the system attempts to create a reasonable number of kernel execution                            |
| 122798 | entities for the application upon application startup.                                                               |
| 122799 | On some implementations, these kernel entities are retained by user threads that block in                            |
| 122800 | the kernel. Other implementations do not <i>timeslice</i> user threads so that multiple compute-                     |
| 122801 | bound user threads can share a kernel thread. On such implementations, some                                          |
| 122802 | applications may use up all the available kernel execution entities before their user-space                          |
| 122803 | threads are used up. The process may be left with user threads capable of doing work for                             |
| 122804 | the application but with no way to schedule them.                                                                    |
| 122805 | The <i>pthread_setconcurrency()</i> function enables an application to request more kernel                           |

entities; that is, specify a desired concurrency level. However, this function merely provides a hint to the implementation. The implementation is free to ignore this request or to provide some other number of kernel entities. If an implementation does not multiplex user threads onto a smaller number of kernel execution entities, the *pthread\_setconcurrency()* function has no effect.

The *pthread\_setconcurrency()* function may also have an effect on implementations where the kernel mode and user mode schedulers cooperate to ensure that ready user threads are not prevented from running by other threads blocked in the kernel.

The *pthread\_getconcurrency()* function always returns the value set by a previous call to *pthread\_setconcurrency()*. However, if *pthread\_setconcurrency()* was not previously called, this function returns zero to indicate that the threads implementation is maintaining the concurrency level.

- Thread Stack Guard Size

DCE threads introduced the concept of a “thread stack guard size”. Most thread implementations add a region of protected memory to a thread’s stack, commonly known as a “guard region”, as a safety measure to prevent stack pointer overflow in one thread from corrupting the contents of another thread’s stack. The default size of the guard regions attribute is {PAGESIZE} bytes and is implementation-defined.

Some application developers may wish to change the stack guard size. When an application creates a large number of threads, the extra page allocated for each stack may strain system resources. In addition to the extra page of memory, the kernel’s memory manager has to keep track of the different protections on adjoining pages. When this is a problem, the application developer may request a guard size of 0 bytes to conserve system resources by eliminating stack overflow protection.

Conversely an application that allocates large data structures such as arrays on the stack may wish to increase the default guard size in order to detect stack overflow. If a thread allocates two pages for a data array, a single guard page provides little protection against thread stack overflows since the thread can corrupt adjoining memory beyond the guard page.

The System Interfaces volume of POSIX.1-2008 defines a new attribute of a thread attributes object; that is, the *guardsize* attribute which allows applications to specify the size of the guard region of a thread’s stack.

Two functions are provided for manipulating a thread’s stack guard size. The *pthread\_attr\_setguardsize()* function sets the thread *guardsize* attribute, and the *pthread\_attr\_getguardsize()* function retrieves the current value.

An implementation may round up the requested guard size to a multiple of the configurable system variable {PAGESIZE}. In this case, *pthread\_attr\_getguardsize()* returns the guard size specified by the previous *pthread\_attr\_setguardsize()* function call and not the rounded up value.

If an application is managing its own thread stacks using the *stackaddr* attribute, the *guardsize* attribute is ignored and no stack overflow protection is provided. In this case, it is the responsibility of the application to manage stack overflow along with stack allocation.

- Parallel I/O

Suppose two or more threads independently issue read requests on the same file. To read specific data from a file, a thread must first call *lseek()* to seek to the proper offset in the file, and then call *read()* to retrieve the required data. If more than one thread does this at the same time, the first thread may complete its seek call, but before it gets a chance to

122853 issue its read call a second thread may complete its seek call, resulting in the first thread  
 122854 accessing incorrect data when it issues its read call. One workaround is to lock the file  
 122855 descriptor while seeking and reading or writing, but this reduces parallelism and adds  
 122856 overhead.

122857 Instead, the System Interfaces volume of POSIX.1-2008 provides two functions to make  
 122858 seek/read and seek/write operations atomic. The file descriptor's current offset is  
 122859 unchanged, thus allowing multiple read and write operations to proceed in parallel. This  
 122860 improves the I/O performance of threaded applications. The *pread()* function is used to do  
 122861 an atomic read of data from a file into a buffer. Conversely, the *pwrite()* function does an  
 122862 atomic write of data from a buffer to a file.

#### 122863 B.2.9.1 Thread-Safety

122864 All functions required by POSIX.1-2008 need to be thread-safe. Implementations have to  
 122865 provide internal synchronization when necessary in order to achieve this goal. In certain cases—  
 122866 for example, most floating-point implementations—context switch code may have to manage  
 122867 the writable shared state.

122868 While a read from a pipe of `[PIPE_MAX]*2` bytes may not generate a single atomic and thread-  
 122869 safe stream of bytes, it should generate “several” (individually atomic) thread-safe streams of  
 122870 bytes. Similarly, while reading from a terminal device may not generate a single atomic and  
 122871 thread-safe stream of bytes, it should generate some finite number of (individually atomic) and  
 122872 thread-safe streams of bytes. That is, concurrent calls to read for a pipe, FIFO, or terminal device  
 122873 are not allowed to result in corrupting the stream of bytes or other internal data. However,  
 122874 *read()*, in these cases, is not required to return a single contiguous and atomic stream of bytes.

122875 It is not required that all functions provided by POSIX.1-2008 be either async-cancel-safe or  
 122876 async-signal-safe.

122877 As it turns out, some functions are inherently not thread-safe; that is, their interface  
 122878 specifications preclude async-signal-safety. For example, some functions (such as *asctime()*)  
 122879 return a pointer to a result stored in memory space allocated by the function on a per-process  
 122880 basis. Such a function is not thread-safe, because its result can be overwritten by successive  
 122881 invocations. Other functions, while not inherently non-thread-safe, may be implemented in  
 122882 ways that lead to them not being thread-safe. For example, some functions (such as *rand()*) store  
 122883 state information (such as a seed value, which survives multiple function invocations) in  
 122884 memory space allocated by the function on a per-process basis. The implementation of such a  
 122885 function is not thread-safe if the implementation fails to synchronize invocations of the function  
 122886 and thus fails to protect the state information. The problem is that when the state information is  
 122887 not protected, concurrent invocations can interfere with one another (for example, applications  
 122888 using *rand()* may see the same seed value).

#### 122889 Thread-Safety and Locking of Existing Functions

122890 Originally, POSIX.1 was not designed to work in a multi-threaded environment, and some  
 122891 implementations of some existing functions will not work properly when executed concurrently.  
 122892 To provide routines that will work correctly in an environment with threads (“thread-safe”), two  
 122893 problems need to be solved:

- 122894 1. Routines that maintain or return pointers to static areas internal to the routine (which  
 122895 may now be shared) need to be modified. The routines *ttyname()* and *localtime()* are  
 122896 examples.
- 122897 2. Routines that access data space shared by more than one thread need to be modified. The  
 122898 *malloc()* function and the *stdio* family routines are examples.

There are a variety of constraints on these changes. The first is compatibility with the existing versions of these functions—non-thread-safe functions will continue to be in use for some time, as the original interfaces are used by existing code. Another is that the new thread-safe versions of these functions represent as small a change as possible over the familiar interfaces provided by the existing non-thread-safe versions. The new interfaces should be independent of any particular threads implementation. In particular, they should be thread-safe without depending on explicit thread-specific memory. Finally, there should be minimal performance penalty due to the changes made to the functions.

It is intended that the list of functions from POSIX.1 that cannot be made thread-safe and for which corrected versions are provided be complete.

#### *Thread-Safety and Locking Solutions*

Many of the POSIX.1 functions were thread-safe and did not change at all. However, some functions (for example, the math functions typically found in **libm**) are not thread-safe because of writable shared global state. For instance, in IEEE Std 754-1985 floating-point implementations, the computation modes and flags are global and shared.

Some functions are not thread-safe because a particular implementation is not reentrant, typically because of a non-essential use of static storage. These require only a new implementation.

Thread-safe libraries are useful in a wide range of parallel (and asynchronous) programming environments, not just within pthreads. In order to be used outside the context of pthreads, however, such libraries still have to use some synchronization method. These could either be independent of the pthread synchronization operations, or they could be a subset of the pthread interfaces. Either method results in thread-safe library implementations that can be used without the rest of pthreads.

Some functions, such as the *stdio* family interface and dynamic memory allocation functions such as *malloc()*, are inter-dependent routines that share resources (for example, buffers) across related calls. These require synchronization to work correctly, but they do not require any change to their external (user-visible) interfaces.

In some cases, such as *getc()* and *putc()*, adding synchronization is likely to create an unacceptable performance impact. In this case, slower thread-safe synchronized functions are to be provided, but the original, faster (but unsafe) functions (which may be implemented as macros) are retained under new names. Some additional special-purpose synchronization facilities are necessary for these macros to be usable in multi-threaded programs. This also requires changes in **<stdio.h>**.

The other common reason that functions are unsafe is that they return a pointer to static storage, making the functions non-thread-safe. This has to be changed, and there are three natural choices:

1. Return a pointer to thread-specific storage

This could incur a severe performance penalty on those architectures with a costly implementation of the thread-specific data interface.

A variation on this technique is to use *malloc()* to allocate storage for the function output and return a pointer to this storage. This technique may also have an undesirable performance impact, however, and a simplistic implementation requires that the user program explicitly free the storage object when it is no longer needed. This technique is used by some existing POSIX.1 functions. With careful implementation for infrequently used functions, there may be little or no performance or storage penalty, and the maintenance of already-standardized interfaces is a significant benefit.

## 2. Return the actual value computed by the function

This technique can only be used with functions that return pointers to structures—routines that return character strings would have to wrap their output in an enclosing structure in order to return the output on the stack. There is also a negative performance impact inherent in this solution in that the output value has to be copied twice before it can be used by the calling function: once from the called routine's local buffers to the top of the stack, then from the top of the stack to the assignment target. Finally, many older compilers cannot support this technique due to a historical tendency to use internal static buffers to deliver the results of structure-valued functions.

## 3. Have the caller pass the address of a buffer to contain the computed value

The only disadvantage of this approach is that extra arguments have to be provided by the calling program. It represents the most efficient solution to the problem, however, and, unlike the *malloc()* technique, it is semantically clear.

There are some routines (often groups of related routines) whose interfaces are inherently non-thread-safe because they communicate across multiple function invocations by means of static memory locations. The solution is to redesign the calls so that they are thread-safe, typically by passing the needed data as extra parameters. Unfortunately, this may require major changes to the interface as well.

A floating-point implementation using IEEE Std 754-1985 is a case in point. A less problematic example is the *rand48* family of pseudo-random number generators. The functions *getgrgid()*, *getgrnam()*, *getpwnam()*, and *getpwuid()* are another such case.

The problems with *errno* are discussed in [Alternative Solutions for Per-Thread \*errno\*](#) (on page 3534).

Some functions can be thread-safe or not, depending on their arguments. These include the *tmpnam()* and *ctermid()* functions. These functions have pointers to character strings as arguments. If the pointers are not NULL, the functions store their results in the character string; however, if the pointers are NULL, the functions store their results in an area that may be static and thus subject to overwriting by successive calls. These should only be called by multi-thread applications when their arguments are non-NULL.

### *Asynchronous Safety and Thread-Safety*

A floating-point implementation has many modes that effect rounding and other aspects of computation. Functions in some math library implementations may change the computation modes for the duration of a function call. If such a function call is interrupted by a signal or cancellation, the floating-point state is not required to be protected.

There is a significant cost to make floating-point operations async-cancel-safe or async-signal-safe; accordingly, neither form of async safety is required.

### *Functions Returning Pointers to Static Storage*

For those functions that are not thread-safe because they return values in fixed size statically allocated structures, alternate “\_r” forms are provided that pass a pointer to an explicit result structure. Those that return pointers into library-allocated buffers have forms provided with explicit buffer and length parameters.

For functions that return pointers to library-allocated buffers, it makes sense to provide “\_r” versions that allow the application control over allocation of the storage in which results are returned. This allows the state used by these functions to be managed on an application-specific basis, supporting per-thread, per-process, or other application-specific sharing relationships.

Early proposals had provided “\_r” versions for functions that returned pointers to variable-size

122992 buffers without providing a means for determining the required buffer size. This would have  
 122993 made using such functions exceedingly clumsy, potentially requiring iteratively calling them  
 122994 with increasingly larger guesses for the amount of storage required. Hence, *sysconf()* variables  
 122995 have been provided for such functions that return the maximum required buffer size.

122996 Thus, the rule that has been followed by POSIX.1-2008 when adapting single-threaded non-  
 122997 thread-safe functions is as follows: all functions returning pointers to library-allocated storage  
 122998 should have “\_r” versions provided, allowing the application control over the storage  
 122999 allocation. Those with variable-sized return values accept both a buffer address and a length  
 123000 parameter. The *sysconf()* variables are provided to supply the appropriate buffer sizes when  
 123001 required. Implementors are encouraged to apply the same rule when adapting their own  
 123002 existing functions to a pthreads environment.

#### 123003 B.2.9.2 Thread IDs

123004 Separate applications should communicate through well-defined interfaces and should not  
 123005 depend on each other’s implementation. For example, if a programmer decides to rewrite the  
 123006 *sort* utility using multiple threads, it should be easy to do this so that the interface to the *sort*  
 123007 utility does not change. Consider that if the user causes SIGINT to be generated while the *sort*  
 123008 utility is running, keeping the same interface means that the entire *sort* utility is killed, not just  
 123009 one of its threads. As another example, consider a realtime application that manages a reactor.  
 123010 Such an application may wish to allow other applications to control the priority at which it  
 123011 watches the control rods. One technique to accomplish this is to write the ID of the thread  
 123012 watching the control rods into a file and allow other programs to change the priority of that  
 123013 thread as they see fit. A simpler technique is to have the reactor process accept IPCs  
 123014 (Interprocess Communication messages) from other processes, telling it at a semantic level what  
 123015 priority the program should assign to watching the control rods. This allows the programmer  
 123016 greater flexibility in the implementation. For example, the programmer can change the  
 123017 implementation from having one thread per rod to having one thread watching all of the rods  
 123018 without changing the interface. Having threads live inside the process means that the  
 123019 implementation of a process is invisible to outside processes (excepting debuggers and system  
 123020 management tools).

123021 Threads do not provide a protection boundary. Every thread model allows threads to share  
 123022 memory with other threads and encourages this sharing to be widespread. This means that one  
 123023 thread can wipe out memory that is needed for the correct functioning of other threads that are  
 123024 sharing its memory. Consequently, providing each thread with its own user and/or group IDs  
 123025 would not provide a protection boundary between threads sharing memory.

123026 Some applications make the assumption that the implementation can always detect invalid uses  
 123027 of thread IDs of type **pthread\_t**. This is an invalid assumption. Specifically, if **pthread\_t** is  
 123028 defined as a pointer type, no access check needs to be performed before using the ID.

123029 As with other interfaces that take pointer parameters, the outcome of passing an invalid  
 123030 parameter can result in an invalid memory reference or an attempt to access an undefined  
 123031 portion of a memory object, cause signals to be sent (SIGSEGV or SIGBUS) and possible  
 123032 termination of the process. This is a similar case to passing an invalid buffer pointer to *read()*.  
 123033 Some implementations might implement *read()* as a system call and set an [EFAULT] error  
 123034 condition. Other implementations might contain parts of *read()* at user level and the first  
 123035 attempt to access data at an invalid reference will cause a signal to be sent instead.

123036 If an implementation detects use of a thread ID after the end of its lifetime, it is recommended  
 123037 that the function should fail and report an [ESRCH] error. This does not imply that  
 123038 implementations are required to return in this case. It is legitimate behavior to send an “invalid  
 123039 memory reference” signal (SIGSEGV or SIGBUS). It is the application’s responsibility to use only

123040 valid thread IDs and to keep track of the lifetime of the underlying threads.

123041 B.2.9.3 *Thread Mutexes*

123042 There is no additional rationale provided for this section.

123043 B.2.9.4 *Thread Scheduling*

123044 • Scheduling Implementation Models

123045 The following scheduling implementation models are presented in terms of threads and  
123046 “kernel entities”. This is to simplify exposition of the models, and it does not imply that  
123047 an implementation actually has an identifiable “kernel entity”.

123048 A kernel entity is not defined beyond the fact that it has scheduling attributes that are used  
123049 to resolve contention with other kernel entities for execution resources. A kernel entity  
123050 may be thought of as an envelope that holds a thread or a separate kernel thread. It is not a  
123051 conventional process, although it shares with the process the attribute that it has a single  
123052 thread of control; it does not necessarily imply an address space, open files, and so on. It is  
123053 better thought of as a primitive facility upon which conventional processes and threads  
123054 may be constructed.

123055 — System Thread Scheduling Model

123056 This model consists of one thread per kernel entity. The kernel entity is solely  
123057 responsible for scheduling thread execution on one or more processors. This model  
123058 schedules all threads against all other threads in the system using the scheduling  
123059 attributes of the thread.

123060 — Process Scheduling Model

123061 A generalized process scheduling model consists of two levels of scheduling. A  
123062 threads library creates a pool of kernel entities, as required, and schedules threads to  
123063 run on them using the scheduling attributes of the threads. Typically, the size of the  
123064 pool is a function of the simultaneously runnable threads, not the total number of  
123065 threads. The kernel then schedules the kernel entities onto processors according to  
123066 their scheduling attributes, which are managed by the threads library. This set model  
123067 potentially allows a wide range of mappings between threads and kernel entities.

123068 • System and Process Scheduling Model Performance

123069 There are a number of important implications on the performance of applications using  
123070 these scheduling models. The process scheduling model potentially provides lower  
123071 overhead for making scheduling decisions, since there is no need to access kernel-level  
123072 information or functions and the set of schedulable entities is smaller (only the threads  
123073 within the process).

123074 On the other hand, since the kernel is also making scheduling decisions regarding the  
123075 system resources under its control (for example, CPU(s), I/O devices, memory), decisions  
123076 that do not take thread scheduling parameters into account can result in unspecified  
123077 delays for realtime application threads, causing them to miss maximum response time  
123078 limits.

123079 • Rate Monotonic Scheduling

123080 Rate monotonic scheduling was considered, but rejected for standardization in the context  
123081 of pthreads. A sporadic server policy is included.

- Scheduling Options

In POSIX.1-2008, the basic thread scheduling functions are defined under the threads functionality, so that they are required of all threads implementations. However, there are no specific scheduling policies required by this functionality to allow for conforming thread implementations that are not targeted to realtime applications.

Specific standard scheduling policies are defined to be under the Thread Execution Scheduling option, and they are specifically designed to support realtime applications by providing predictable resource-sharing sequences. The name of this option was chosen to emphasize that this functionality is defined as appropriate for realtime applications that require simple priority-based scheduling.

It is recognized that these policies are not necessarily satisfactory for some multi-processor implementations, and work is ongoing to address a wider range of scheduling behaviors. The interfaces have been chosen to create abundant opportunity for future scheduling policies to be implemented and standardized based on this interface. In order to standardize a new scheduling policy, all that is required (from the standpoint of thread scheduling attributes) is to define a new policy name, new members of the thread attributes object, and functions to set these members when the scheduling policy is equal to the new value.

### **Scheduling Contention Scope**

In order to accommodate the requirement for realtime response, each thread has a scheduling contention scope attribute. Threads with a system scheduling contention scope have to be scheduled with respect to all other threads in the system. These threads are usually bound to a single kernel entity that reflects their scheduling attributes and are directly scheduled by the kernel.

Threads with a process scheduling contention scope need be scheduled only with respect to the other threads in the process. These threads may be scheduled within the process onto a pool of kernel entities. The implementation is also free to bind these threads directly to kernel entities and let them be scheduled by the kernel. Process scheduling contention scope allows the implementation the most flexibility and is the default if both contention scopes are supported and none is specified.

Thus, the choice by implementors to provide one or the other (or both) of these scheduling models is driven by the need of their supported application domains for worst-case (that is, realtime) response, or average-case (non-realtime) response.

### **Scheduling Allocation Domain**

The SCHED\_FIFO and SCHED\_RR scheduling policies take on different characteristics on a multi-processor. Other scheduling policies are also subject to changed behavior when executed on a multi-processor. The concept of scheduling allocation domain determines the set of processors on which the threads of an application may run. By considering the application's processor scheduling allocation domain for its threads, scheduling policies can be defined in terms of their behavior for varying processor scheduling allocation domain values. It is conceivable that not all scheduling allocation domain sizes make sense for all scheduling policies on all implementations. The concept of scheduling allocation domain, however, is a useful tool for the description of multi-processor scheduling policies.

The "process control" approach to scheduling obtains significant performance advantages from dynamic scheduling allocation domain sizes when it is applicable.

Non-Uniform Memory Access (NUMA) multi-processors may use a system scheduling structure

that involves reassignment of threads among scheduling allocation domains. In NUMA machines, a natural model of scheduling is to match scheduling allocation domains to clusters of processors. Load balancing in such an environment requires changing the scheduling allocation domain to which a thread is assigned.

### Scheduling Documentation

Implementation-provided scheduling policies need to be completely documented in order to be useful. This documentation includes a description of the attributes required for the policy, the scheduling interaction of threads running under this policy and all other supported policies, and the effects of all possible values for processor scheduling allocation domain. Note that for the implementor wishing to be minimally-compliant, it is (minimally) acceptable to define the behavior as undefined.

### Scheduling Contention Scope Attribute

The scheduling contention scope defines how threads compete for resources. Within POSIX.1-2008, scheduling contention scope is used to describe only how threads are scheduled in relation to one another in the system. That is, either they are scheduled against all other threads in the system ("system scope") or only against those threads in the process ("process scope"). In fact, scheduling contention scope may apply to additional resources, including virtual timers and profiling, which are not currently considered by POSIX.1-2008.

### Mixed Scopes

If only one scheduling contention scope is supported, the scheduling decision is straightforward. To perform the processor scheduling decision in a mixed scope environment, it is necessary to map the scheduling attributes of the thread with process-wide contention scope to the same attribute space as the thread with system-wide contention scope.

Since a conforming implementation has to support one and may support both scopes, it is useful to discuss the effects of such choices with respect to example applications. If an implementation supports both scopes, mixing scopes provides a means of better managing system-level (that is, kernel-level) and library-level resources. In general, threads with system scope will require the resources of a separate kernel entity in order to guarantee the scheduling semantics. On the other hand, threads with process scope can share the resources of a kernel entity while maintaining the scheduling semantics.

The application is free to create threads with dedicated kernel resources, and other threads that multiplex kernel resources. Consider the example of a window server. The server allocates two threads per widget: one thread manages the widget user interface (including drawing), while the other thread takes any required application action. This allows the widget to be "active" while the application is computing. A screen image may be built from thousands of widgets. If each of these threads had been created with system scope, then most of the kernel-level resources might be wasted, since only a few widgets are active at any one time. In addition, mixed scope is particularly useful in a window server where one thread with high priority and system scope handles the mouse so that it tracks well. As another example, consider a database server. For each of the hundreds or thousands of clients supported by a large server, an equivalent number of threads will have to be created. If each of these threads were system scope, the consequences would be the same as for the window server example above. However, the server could be constructed so that actual retrieval of data is done by several dedicated threads. Dedicated threads that do work for all clients frequently justify the added expense of system scope. If it were not permissible to mix system and process threads in the same process, this type of solution would not be possible.

## Dynamic Thread Scheduling Parameters Access

In many time-constrained applications, there is no need to change the scheduling attributes dynamically during thread or process execution, since the general use of these attributes is to reflect directly the time constraints of the application. Since these time constraints are generally imposed to meet higher-level system requirements, such as accuracy or availability, they frequently should remain unchanged during application execution.

However, there are important situations in which the scheduling attributes should be changed. Generally, this will occur when external environmental conditions exist in which the time constraints change. Consider, for example, a space vehicle major mode change, such as the change from ascent to descent mode, or the change from the space environment to the atmospheric environment. In such cases, the frequency with which many of the sensors or actuators need to be read or written will change, which will necessitate a priority change. In other cases, even the existence of a time constraint might be temporary, necessitating not just a priority change, but also a policy change for ongoing threads or processes. For this reason, it is critical that the interface should provide functions to change the scheduling parameters dynamically, but, as with many of the other realtime functions, it is important that applications use them properly to avoid the possibility of unnecessarily degrading performance.

In providing functions for dynamically changing the scheduling behavior of threads, there were two options: provide functions to get and set the individual scheduling parameters of threads, or provide a single interface to get and set all the scheduling parameters for a given thread simultaneously. Both approaches have merit. Access functions for individual parameters allow simpler control of thread scheduling for simple thread scheduling parameters. However, a single function for setting all the parameters for a given scheduling policy is required when first setting that scheduling policy. Since the single all-encompassing functions are required, it was decided to leave the interface as minimal as possible. Note that simpler functions (such as *pthread\_setprio()* for threads running under the priority-based schedulers) can be easily defined in terms of the all-encompassing functions.

If the *pthread\_setschedparam()* function executes successfully, it will have set all of the scheduling parameter values indicated in *param*; otherwise, none of the scheduling parameters will have been modified. This is necessary to ensure that the scheduling of this and all other threads continues to be consistent in the presence of an erroneous scheduling parameter.

The [EPERM] error value is included in the list of possible *pthread\_setschedparam()* error returns as a reflection of the fact that the ability to change scheduling parameters increases risks to the implementation and application performance if the scheduling parameters are changed improperly. For this reason, and based on some existing practice, it was felt that some implementations would probably choose to define specific permissions for changing either a thread's own or another thread's scheduling parameters. POSIX.1-2008 does not include portable methods for setting or retrieving permissions, so any such use of permissions is completely unspecified.

## Mutex Initialization Scheduling Attributes

In a priority-driven environment, a direct use of traditional primitives like mutexes and condition variables can lead to unbounded priority inversion, where a higher priority thread can be blocked by a lower priority thread, or set of threads, for an unbounded duration of time. As a result, it becomes impossible to guarantee thread deadlines. Priority inversion can be bounded and minimized by the use of priority inheritance protocols. This allows thread deadlines to be guaranteed even in the presence of synchronization requirements.

Two useful but simple members of the family of priority inheritance protocols are the basic priority inheritance protocol and the priority ceiling protocol emulation. Under the Basic

123222 Priority Inheritance protocol (governed by the Non-Robust Mutex Priority Inheritance option), a  
 123223 thread that is blocking higher priority threads executes at the priority of the highest priority  
 123224 thread that it blocks. This simple mechanism allows priority inversion to be bounded by the  
 123225 duration of critical sections and makes timing analysis possible.

123226 Under the Priority Ceiling Protocol Emulation protocol (governed by the Thread Priority  
 123227 Protection option), each mutex has a priority ceiling, usually defined as the priority of the  
 123228 highest priority thread that can lock the mutex. When a thread is executing inside critical  
 123229 sections, its priority is unconditionally increased to the highest of the priority ceilings of all the  
 123230 mutexes owned by the thread. This protocol has two very desirable properties in uni-processor  
 123231 systems. First, a thread can be blocked by a lower priority thread for at most the duration of one  
 123232 single critical section. Furthermore, when the protocol is correctly used in a single processor, and  
 123233 if threads do not become blocked while owning mutexes, mutual deadlocks are prevented.

123234 The priority ceiling emulation can be extended to multiple processor environments, in which  
 123235 case the values of the priority ceilings will be assigned depending on the kind of mutex that is  
 123236 being used: local to only one processor, or global, shared by several processors. Local priority  
 123237 ceilings will be assigned the usual way, equal to the priority of the highest priority thread that  
 123238 may lock that mutex. Global priority ceilings will usually be assigned a priority level higher  
 123239 than all the priorities assigned to any of the threads that reside in the involved processors to  
 123240 avoid the effect called remote blocking.

#### 123241 **Change the Priority Ceiling of a Mutex**

123242 In order for the priority protect protocol to exhibit its desired properties of bounding priority  
 123243 inversion and avoidance of deadlock, it is critical that the ceiling priority of a mutex be the same  
 123244 as the priority of the highest thread that can ever hold it, or higher. Thus, if the priorities of the  
 123245 threads using such mutexes never change dynamically, there is no need ever to change the  
 123246 priority ceiling of a mutex.

123247 However, if a major system mode change results in an altered response time requirement for one  
 123248 or more application threads, their priority has to change to reflect it. It will occasionally be the  
 123249 case that the priority ceilings of mutexes held also need to change. While changing priority  
 123250 ceilings should generally be avoided, it is important that POSIX.1-2008 provide these interfaces  
 123251 for those cases in which it is necessary.

#### 123252 *B.2.9.5 Thread Cancellation*

123253 Many existing threads packages have facilities for canceling an operation or canceling a thread.  
 123254 These facilities are used for implementing user requests (such as the CANCEL button in a  
 123255 window-based application), for implementing OR parallelism (for example, telling the other  
 123256 threads to stop working once one thread has found a forced mate in a parallel chess program), or  
 123257 for implementing the ABORT mechanism in Ada.

123258 POSIX programs traditionally have used the signal mechanism combined with either *longjmp()*  
 123259 or polling to cancel operations. Many POSIX programmers have trouble using these facilities to  
 123260 solve their problems efficiently in a single-threaded process. With the introduction of threads,  
 123261 these solutions become even more difficult to use.

123262 The main issues with implementing a cancellation facility are specifying the operation to be  
 123263 canceled, cleanly releasing any resources allocated to that operation, controlling when the target  
 123264 notices that it has been canceled, and defining the interaction between asynchronous signals and  
 123265 cancellation.

### Specifying the Operation to Cancel

Consider a thread that calls through five distinct levels of program abstraction and then, inside the lowest-level abstraction, calls a function that suspends the thread. (An abstraction boundary is a layer at which the client of the abstraction sees only the service being provided and can remain ignorant of the implementation. Abstractions are often layered, each level of abstraction being a client of the lower-level abstraction and implementing a higher-level abstraction.) Depending on the semantics of each abstraction, one could imagine wanting to cancel only the call that causes suspension, only the bottom two levels, or the operation being done by the entire thread. Canceling operations at a finer grain than the entire thread is difficult because threads are active and they may be run in parallel on a multi-processor. By the time one thread can make a request to cancel an operation, the thread performing the operation may have completed that operation and gone on to start another operation whose cancellation is not desired. Thread IDs are not reused until the thread has exited, and either it was created with the *Attr detachstate* attribute set to *PTHREAD\_CREATE\_DETACHED* or the *pthread\_join()* or *pthread\_detach()* function has been called for that thread. Consequently, a thread cancellation will never be misdirected when the thread terminates. For these reasons, the canceling of operations is done at the granularity of the thread. Threads are designed to be inexpensive enough so that a separate thread may be created to perform each separately cancelable operation; for example, each possibly long running user request.

For cancellation to be used in existing code, cancellation scopes and handlers will have to be established for code that needs to release resources upon cancellation, so that it follows the programming discipline described in the text.

### A Special Signal Versus a Special Interface

Two different mechanisms were considered for providing the cancellation interfaces. The first was to provide an interface to direct signals at a thread and then to define a special signal that had the required semantics. The other alternative was to use a special interface that delivered the correct semantics to the target thread.

The solution using signals produced a number of problems. It required the implementation to provide cancellation in terms of signals whereas a perfectly valid (and possibly more efficient) implementation could have both layered on a low-level set of primitives. There were so many exceptions to the special signal (it cannot be used with *kill()*, no POSIX.1 interfaces can be used with it) that it was clearly not a valid signal. Its semantics on delivery were also completely different from any existing POSIX.1 signal. As such, a special interface that did not mandate the implementation and did not confuse the semantics of signals and cancellation was felt to be the better solution.

### Races Between Cancellation and Resuming Execution

Due to the nature of cancellation, there is generally no synchronization between the thread requesting the cancellation of a blocked thread and events that may cause that thread to resume execution. For this reason, and because excess serialization hurts performance, when both an event that a thread is waiting for has occurred and a cancellation request has been made and cancellation is enabled, POSIX.1-2008 explicitly allows the implementation to choose between returning from the blocking call or acting on the cancellation request.

## Interaction of Cancellation with Asynchronous Signals

A typical use of cancellation is to acquire a lock on some resource and to establish a cancellation cleanup handler for releasing the resource when and if the thread is canceled.

A correct and complete implementation of cancellation in the presence of asynchronous signals requires considerable care. An implementation has to push a cancellation cleanup handler on the cancellation cleanup stack while maintaining the integrity of the stack data structure. If an asynchronously-generated signal is posted to the thread during a stack operation, the signal handler cannot manipulate the cancellation cleanup stack. As a consequence, asynchronous signal handlers may not cancel threads or otherwise manipulate the cancellation state of a thread. Threads may, of course, be canceled by another thread that used a *sigwait()* function to wait synchronously for an asynchronous signal.

In order for cancellation to function correctly, it is required that asynchronous signal handlers not change the cancellation state. This requires that some elements of existing practice, such as using *longjmp()* to exit from an asynchronous signal handler implicitly, be prohibited in cases where the integrity of the cancellation state of the interrupt thread cannot be ensured.

## Thread Cancellation Overview

- Cancelability States

The three possible cancelability states (disabled, deferred, and asynchronous) are encoded into two separate bits ((disable, enable) and (deferred, asynchronous)) to allow them to be changed and restored independently. For instance, short code sequences that will not block sometimes disable cancelability on entry and restore the previous state upon exit. Likewise, long or unbounded code sequences containing no convenient explicit cancellation points will sometimes set the cancelability type to asynchronous on entry and restore the previous value upon exit.

- Cancellation Points

Cancellation points are points inside of certain functions where a thread has to act on any pending cancellation request when cancelability is enabled. For functions in the “shall occur” list, a cancellation check must be performed on every call regardless of whether, absent the cancellation, the call would have blocked. For functions in the “may occur” list, a cancellation check may be performed on some calls but not others; i.e., whether or not a cancellation point occurs when one of these functions is being executed can depend on current conditions.

The idea was considered of allowing implementations to define whether blocking calls such as *read()* should be cancellation points. It was decided that it would adversely affect the design of conforming applications if blocking calls were not cancellation points because threads could be left blocked in an uncancelable state.

There are several important blocking routines that are specifically not made cancellation points:

— *pthread\_mutex\_lock()*

If *pthread\_mutex\_lock()* were a cancellation point, every routine that called it would also become a cancellation point (that is, any routine that touched shared state would automatically become a cancellation point). For example, *malloc()*, *free()*, and *rand()* would become cancellation points under this scheme. Having too many cancellation points makes programming very difficult, leading to either much disabling and restoring of cancelability or much difficulty in trying to arrange for reliable cleanup at every possible place.

123354 Since `pthread_mutex_lock()` is not a cancellation point, threads could result in being  
 123355 blocked uninterruptibly for long periods of time if mutexes were used as a general  
 123356 synchronization mechanism. As this is normally not acceptable, mutexes should only  
 123357 be used to protect resources that are held for small fixed lengths of time where not  
 123358 being able to be canceled will not be a problem. Resources that need to be held  
 123359 exclusively for long periods of time should be protected with condition variables.

123360 — `pthread_barrier_wait()`

123361 Canceling a barrier wait will render a barrier unusable. Similar to a barrier timeout  
 123362 (which the standard developers rejected), there is no way to guarantee the  
 123363 consistency of a barrier's internal data structures if a barrier wait is canceled.

123364 — `pthread_spin_lock()`

123365 As with mutexes, spin locks should only be used to protect resources that are held for  
 123366 small fixed lengths of time where not being cancelable will not be a problem.

123367 Every library routine should specify whether or not it includes any cancellation points.  
 123368 Typically, only those routines that may block or compute indefinitely need to include  
 123369 cancellation points.

123370 Correctly coded routines only reach cancellation points after having set up a cancellation  
 123371 cleanup handler to restore invariants if the thread is canceled at that point. Being  
 123372 cancelable only at specified cancellation points allows programmers to keep track of  
 123373 actions needed in a cancellation cleanup handler more easily. A thread should only be  
 123374 made asynchronously cancelable when it is not in the process of acquiring or releasing  
 123375 resources or otherwise in a state from which it would be difficult or impossible to recover.

#### 123376 • Thread Cancellation Cleanup Handlers

123377 The cancellation cleanup handlers provide a portable mechanism, easy to implement, for  
 123378 releasing resources and restoring invariants. They are easier to use than signal handlers  
 123379 because they provide a stack of cancellation cleanup handlers rather than a single handler,  
 123380 and because they have an argument that can be used to pass context information to the  
 123381 handler.

123382 The alternative to providing these simple cancellation cleanup handlers (whose only use is  
 123383 for cleaning up when a thread is canceled) is to define a general exception package that  
 123384 could be used for handling and cleaning up after hardware traps and software-detected  
 123385 errors. This was too far removed from the charter of providing threads to handle  
 123386 asynchrony. However, it is an explicit goal of POSIX.1-2008 to be compatible with existing  
 123387 exception facilities and languages having exceptions.

123388 The interaction of this facility and other procedure-based or language-level exception  
 123389 facilities is unspecified in this version of POSIX.1-2008. However, it is intended that it be  
 123390 possible for an implementation to define the relationship between these cancellation  
 123391 cleanup handlers and Ada, C++, or other language-level exception handling facilities.

123392 It was suggested that the cancellation cleanup handlers should also be called when the  
 123393 process exits or calls the `exec` function. This was rejected partly due to the performance  
 123394 problem caused by having to call the cancellation cleanup handlers of every thread before  
 123395 the operation could continue. The other reason was that the only state expected to be  
 123396 cleaned up by the cancellation cleanup handlers would be the intraprocess state. Any  
 123397 handlers that are to clean up the interprocess state would be registered with `atexit()`. There  
 123398 is the orthogonal problem that the `exec` functions do not honor the `atexit()` handlers, but  
 123399 resolving this is beyond the scope of POSIX.1-2008.

- Async-Cancel Safety

A function is said to be async-cancel-safe if it is written in such a way that entering the function with asynchronous cancelability enabled will not cause any invariants to be violated, even if a cancellation request is delivered at any arbitrary instruction. Functions that are async-cancel-safe are often written in such a way that they need to acquire no resources for their operation and the visible variables that they may write are strictly limited.

Any routine that gets a resource as a side-effect cannot be made async-cancel-safe (for example, *malloc()*). If such a routine were called with asynchronous cancelability enabled, it might acquire the resource successfully, but as it was returning to the client, it could act on a cancellation request. In such a case, the application would have no way of knowing whether the resource was acquired or not.

Indeed, because many interesting routines cannot be made async-cancel-safe, most library routines in general are not async-cancel-safe. Every library routine should specify whether or not it is async-cancel safe so that programmers know which routines can be called from code that is asynchronously cancelable.

IEEE Std 1003.1-2001/Cor 1-2002, item XSH/TC1/D6/8 is applied, adding the *pselect()* function to the list of functions with cancellation points.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/5 is applied, adding the *fdatasync()* function into the table of functions that shall have cancellation points.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/6 is applied, adding the numerous functions into the table of functions that may have cancellation points.

IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/7 is applied, clarifying the requirements in Thread Cancellation Cleanup Handlers.

#### B.2.9.6 Thread Read-Write Locks

##### Background

Read-write locks are often used to allow parallel access to data on multi-processors, to avoid context switches on uni-processors when multiple threads access the same data, and to protect data structures that are frequently accessed (that is, read) but rarely updated (that is, written). The in-core representation of a file system directory is a good example of such a data structure. One would like to achieve as much concurrency as possible when searching directories, but limit concurrent access when adding or deleting files.

Although read-write locks can be implemented with mutexes and condition variables, such implementations are significantly less efficient than is possible. Therefore, this synchronization primitive is included in POSIX.1-2008 for the purpose of allowing more efficient implementations in multi-processor systems.

##### Queuing of Waiting Threads

The *pthread\_rwlock\_unlock()* function description states that one writer or one or more readers must acquire the lock if it is no longer held by any thread as a result of the call. However, the function does not specify which thread(s) acquire the lock, unless the Thread Execution Scheduling option is supported.

The standard developers considered the issue of scheduling with respect to the queuing of threads blocked on a read-write lock. The question turned out to be whether POSIX.1-2008 should require priority scheduling of read-write locks for threads whose execution scheduling

123444 policy is priority-based (for example, SCHED\_FIFO or SCHED\_RR). There are tradeoffs  
 123445 between priority scheduling, the amount of concurrency achievable among readers, and the  
 123446 prevention of writer and/or reader starvation.

123447 For example, suppose one or more readers hold a read-write lock and the following threads  
 123448 request the lock in the listed order:

123449 pthread\_rwlock\_wrlock() - Low priority thread writer\_a  
 123450 pthread\_rwlock\_rdlock() - High priority thread reader\_a  
 123451 pthread\_rwlock\_rdlock() - High priority thread reader\_b  
 123452 pthread\_rwlock\_rdlock() - High priority thread reader\_c

123453 When the lock becomes available, should *writer\_a* block the high priority readers? Or, suppose a  
 123454 read-write lock becomes available and the following are queued:

123455 pthread\_rwlock\_rdlock() - Low priority thread reader\_a  
 123456 pthread\_rwlock\_rdlock() - Low priority thread reader\_b  
 123457 pthread\_rwlock\_rdlock() - Low priority thread reader\_c  
 123458 pthread\_rwlock\_wrlock() - Medium priority thread writer\_a  
 123459 pthread\_rwlock\_rdlock() - High priority thread reader\_d

123460 If priority scheduling is applied then *reader\_d* would acquire the lock and *writer\_a* would block  
 123461 the remaining readers. But should the remaining readers also acquire the lock to increase  
 123462 concurrency? The solution adopted takes into account that when the Thread Execution  
 123463 Scheduling option is supported, high priority threads may in fact starve low priority threads  
 123464 (the application developer is responsible in this case for designing the system in such a way that  
 123465 this starvation is avoided). Therefore, POSIX.1-2008 specifies that high priority readers take  
 123466 precedence over lower priority writers. However, to prevent writer starvation from threads of  
 123467 the same or lower priority, writers take precedence over readers of the same or lower priority.

123468 Priority inheritance mechanisms are non-trivial in the context of read-write locks. When a high  
 123469 priority writer is forced to wait for multiple readers, for example, it is not clear which subset of  
 123470 the readers should inherit the writer's priority. Furthermore, the internal data structures that  
 123471 record the inheritance must be accessible to all readers, and this implies some sort of  
 123472 serialization that could negate any gain in parallelism achieved through the use of multiple  
 123473 readers in the first place. Finally, existing practice does not support the use of priority  
 123474 inheritance for read-write locks. Therefore, no specification of priority inheritance or priority  
 123475 ceiling is attempted. If reliable priority-scheduled synchronization is absolutely required, it can  
 123476 always be obtained through the use of mutexes.

## 123477 **Comparison to fcntl() Locks**

123478 The read-write locks and the *fcntl()* locks in POSIX.1-2008 share a common goal: increasing  
 123479 concurrency among readers, thus increasing throughput and decreasing delay.

123480 However, the read-write locks have two features not present in the *fcntl()* locks. First, under  
 123481 priority scheduling, read-write locks are granted in priority order. Second, also under priority  
 123482 scheduling, writer starvation is prevented by giving writers preference over readers of equal or  
 123483 lower priority.

123484 Also, read-write locks can be used in systems lacking a file system, such as those conforming to  
 123485 the minimal realtime system profile of IEEE Std 1003.13-1998.

## 123486 History of Resolution Issues

123487 Based upon some balloting objections, early drafts specified the behavior of threads waiting on a  
 123488 read-write lock during the execution of a signal handler, as if the thread had not called the lock  
 123489 operation. However, this specified behavior would require implementations to establish  
 123490 internal signal handlers even though this situation would be rare, or never happen for many  
 123491 programs. This would introduce an unacceptable performance hit in comparison to the little  
 123492 additional functionality gained. Therefore, the behavior of read-write locks and signals was  
 123493 reverted back to its previous mutex-like specification.

### 123494 B.2.9.7 Thread Interactions with Regular File Operations

123495 There is no additional rationale provided for this section.

### 123496 B.2.9.8 Use of Application-Managed Thread Stacks

123497 IEEE Std 1003.1-2001/Cor 2-2004, item XSH/TC2/D6/8 is applied, adding this new section. It  
 123498 was added to make it clear that the current standard does not allow an application to determine  
 123499 when a stack can be reclaimed. This may be addressed in a future version.

## 123500 B.2.10 Sockets

123501 The base document for the sockets interfaces in POSIX.1-2008 is the XNS, Issue 5.2 specification.  
 123502 This was primarily chosen as it aligns with IPv6. Additional material has been added from  
 123503 IEEE Std 1003.1g-2000, notably socket concepts, raw sockets, the *pselect()* function, the  
 123504 *socketmark()* function, and the `<sys/select.h>` header.

### 123505 B.2.10.1 Address Families

123506 There is no additional rationale provided for this section.

### 123507 B.2.10.2 Addressing

123508 There is no additional rationale provided for this section.

### 123509 B.2.10.3 Protocols

123510 There is no additional rationale provided for this section.

### 123511 B.2.10.4 Routing

123512 There is no additional rationale provided for this section.

### 123513 B.2.10.5 Interfaces

123514 There is no additional rationale provided for this section.

123515 B.2.10.6 *Socket Types*

123516 The type **socklen\_t** was invented to cover the range of implementations seen in the field. The  
123517 intent of **socklen\_t** is to be the type for all lengths that are naturally bounded in size; that is, that  
123518 they are the length of a buffer which cannot sensibly become of massive size: network addresses,  
123519 host names, string representations of these, ancillary data, control messages, and socket options  
123520 are examples. Truly boundless sizes are represented by **size\_t** as in *read()*, *write()*, and so on.

123521 All **socklen\_t** types were originally (in BSD UNIX) of type **int**. During the development of  
123522 POSIX.1-2008, it was decided to change all buffer lengths to **size\_t**, which appears at face value  
123523 to make sense. When dual mode 32/64-bit systems came along, this choice unnecessarily  
123524 complicated system interfaces because **size\_t** (with **long**) was a different size under ILP32 and  
123525 LP64 models. Reverting to **int** would have happened except that some implementations had  
123526 already shipped 64-bit-only interfaces. The compromise was a type which could be defined to be  
123527 any size by the implementation: **socklen\_t**.

123528 B.2.10.7 *Socket I/O Mode*

123529 There is no additional rationale provided for this section.

123530 B.2.10.8 *Socket Owner*

123531 There is no additional rationale provided for this section.

123532 B.2.10.9 *Socket Queue Limits*

123533 There is no additional rationale provided for this section.

123534 B.2.10.10 *Pending Error*

123535 There is no additional rationale provided for this section.

123536 B.2.10.11 *Socket Receive Queue*

123537 There is no additional rationale provided for this section.

123538 B.2.10.12 *Socket Out-of-Band Data State*

123539 There is no additional rationale provided for this section.

123540 B.2.10.13 *Connection Indication Queue*

123541 There is no additional rationale provided for this section.

123542 B.2.10.14 *Signals*

123543 There is no additional rationale provided for this section.

123544 *B.2.10.15 Asynchronous Errors*

123545 There is no additional rationale provided for this section.

123546 *B.2.10.16 Use of Options*

123547 There is no additional rationale provided for this section.

123548 *B.2.10.17 Use of Sockets for Local UNIX Connections*

123549 There is no additional rationale provided for this section.

123550 *B.2.10.18 Use of Sockets over Internet Protocols*

123551 A raw socket allows privileged users direct access to a protocol; for example, raw access to the  
123552 IP and ICMP protocols is possible through raw sockets. Raw sockets are intended for  
123553 knowledgeable applications that wish to take advantage of some protocol feature not directly  
123554 accessible through the other sockets interfaces.

123555 *B.2.10.19 Use of Sockets over Internet Protocols Based on IPv4*

123556 There is no additional rationale provided for this section.

123557 *B.2.10.20 Use of Sockets over Internet Protocols Based on IPv6*

123558 The Open Group Base Resolution bwg2001-012 is applied, clarifying that IPv6 implementations  
123559 are required to support use of AF\_INET6 sockets over IPv4.

123560 **B.2.11 Tracing**

123561 The organization of the tracing rationale differs from the traditional rationale in that this tracing  
123562 rationale text is written against the trace interface as a whole, rather than against the individual  
123563 components of the trace interface or the normative section in which those components are  
123564 defined. Therefore the sections below do not parallel the sections of normative text in  
123565 POSIX.1-2008.

123566 *B.2.11.1 Objectives*

123567 The intended uses of tracing are application-system debugging during system development, as a  
123568 “flight recorder” for maintenance of fielded systems, and as a performance measurement tool.  
123569 In all of these intended uses, the vendor-supplied computer system and its software are, for this  
123570 discussion, assumed error-free; the intent being to debug the user-written and/or third-party  
123571 application code, and their interactions. Clearly, problems with the vendor-supplied system and  
123572 its software will be uncovered from time to time, but this is a byproduct of the primary activity,  
123573 debugging user code.

123574 Another need for defining a trace interface in POSIX stems from the objective to provide an  
123575 efficient portable way to perform benchmarks. Existing practice shows that such interfaces are  
123576 commonly used in a variety of systems but with little commonality. As part of the benchmarking  
123577 needs, two aspects within the trace interface must be considered.

123578 The first, and perhaps more important one, is the qualitative aspect.

123579 The second is the quantitative aspect.

123580 • Qualitative Aspect

123581 To better understand this aspect, let us consider an example. Suppose that you want to  
 123582 organize a number of actions to be performed during the day. Some of these actions are  
 123583 known at the beginning of the day. Some others, which may be more or less important,  
 123584 will be triggered by reading your mail. During the day you will make some phone calls  
 123585 and synchronously receive some more information. Finally you will receive asynchronous  
 123586 phone calls that also will trigger actions. If you, or somebody else, examines your day at  
 123587 work, you, or he, can discover that you have not efficiently organized your work. For  
 123588 instance, relative to the phone calls you made, would it be preferable to make some of  
 123589 these early in the morning? Or to delay some others until the end of the day? Relative to  
 123590 the phone calls you have received, you might find that somebody you called in the  
 123591 morning has called you 10 times while you were performing some important work. To  
 123592 examine, afterwards, your day at work, you record in sequence all the trace events relative  
 123593 to your work. This should give you a chance of organizing your next day at work.

123594 This is the qualitative aspect of the trace interface. The user of a system needs to keep a  
 123595 trace of particular points the application passes through, so that he can eventually make  
 123596 some changes in the application and/or system configuration, to give the application a  
 123597 chance of running more efficiently.

123598 • Quantitative Aspect

123599 This aspect concerns primarily realtime applications, where missed deadlines can be  
 123600 undesirable. Although there are, in POSIX.1-2008, some interfaces useful for such  
 123601 applications (timeouts, execution time monitoring, and so on), there are no APIs to aid in  
 123602 the tuning of a realtime application's behavior (**timespec** in timeouts, length of message  
 123603 queues, duration of driver interrupt service routine, and so on). The tuning of an  
 123604 application needs a means of recording timestamped important trace events during  
 123605 execution in order to analyze offline, and eventually, to tune some realtime features  
 123606 (redesign the system with less functionalities, readjust timeouts, redesign driver interrupts,  
 123607 and so on).

123608 **Detailed Objectives**

123609 Objectives were defined to build the trace interface and are kept for historical interest. Although  
 123610 some objectives are not fully respected in this trace interface, the concept of the POSIX trace  
 123611 interface assumes the following points:

- 123612 1. It must be possible to trace both system and user trace events concurrently.
- 123613 2. It must be possible to trace per-process trace events and also to trace system trace events  
 123614 which are unrelated to any particular process. A per-process trace event is either user-  
 123615 initiated or system-initiated.
- 123616 3. It must be possible to control tracing on a per-process basis from either inside or outside  
 123617 the process.
- 123618 4. It must be possible to control tracing on a per-thread basis from inside the enclosing  
 123619 process.
- 123620 5. Trace points must be controllable by trace event type ID from inside and outside of the  
 123621 process. Multiple trace points can have the same trace event type ID, and will be  
 123622 controlled jointly.

- 123623 6. Recording of trace events is dependent on both trace event type ID and the  
123624 process/thread. Both must be enabled in order to record trace events. System trace events  
123625 may or may not be handled differently.
- 123626 7. The API must not mandate the ability to control tracing for more than one process at the  
123627 same time.
- 123628 8. There is no objective for trace control on anything bigger than a process; for example,  
123629 group or session.
- 123630 9. Trace propagation and control:
  - 123631 a. Trace propagation across *fork()* is optional; the default is to not trace a child  
123632 process.
  - 123633 b. Trace control must span *pthread\_create()* operations; that is, if a process is being  
123634 traced, any thread will be traced as well if this thread allows tracing. The default is  
123635 to allow tracing.
- 123636 10. Trace control must not span *exec* or *posix\_spawn()* operations.
- 123637 11. A triggering API is not required. The triggering API is the ability to command or stop  
123638 tracing based on the occurrence of a specific trace event other than a  
123639 POSIX\_TRACE\_START trace event or a POSIX\_TRACE\_STOP trace event.
- 123640 12. Trace log entries must have timestamps of implementation-defined resolution.  
123641 Implementations are exhorted to support at least microsecond resolution. When a trace  
123642 log entry is retrieved, it must have timestamp, PC address, PID, and TID of the entity that  
123643 generated the trace event.
- 123644 13. Independently developed code should be able to use trace facilities without coordination  
123645 and without conflict.
- 123646 14. Even if the trace points in the trace calls are not unique, the trace log entries (after any  
123647 processing) must be uniquely identified as to trace point.
- 123648 15. There must be a standard API to read the trace stream.
- 123649 16. The format of the trace stream and the trace log is opaque and unspecified.
- 123650 17. It must be possible to read a completed trace, if recorded on some suitable non-volatile  
123651 storage, even subsequent to a power cycle or subsequent cold boot of the system.
- 123652 18. Support of analysis of a trace log while it is being formed is implementation-defined.
- 123653 19. The API must allow the application to write trace stream identification information into  
123654 the trace stream and to be able to retrieve it, without it being overwritten by trace entries,  
123655 even if the trace stream is full.
- 123656 20. It must be possible to specify the destination of trace data produced by trace events.
- 123657 21. It must be possible to have different trace streams, and for the tracing enabled by one  
123658 trace stream to be completely independent of the tracing of another trace stream.
- 123659 22. It must be possible to trace events from threads in different CPUs.
- 123660 23. The API must support one or more trace streams per-system, and one or more trace  
123661 streams per-process, up to an implementation-defined set of per-system and per-process  
123662 maximums.
- 123663 24. It must be possible to determine the order in which the trace events happened, without  
123664 necessarily depending on the clock, up to an implementation-defined time resolution.

- 123665 25. For performance reasons, the trace event point call(s) must be implementable as a macro  
123666 (see the ISO POSIX-1: 1996 standard, 1.3.4, Statement 2).
- 123667 26. POSIX.1-2008 must not define the trace points which a conforming system must  
123668 implement, except for trace points used in the control of tracing.
- 123669 27. The APIs must be thread-safe, and trace points should be lock-free (that is, not require a  
123670 lock to gain exclusive access to some resource).
- 123671 28. The user-provided information associated with a trace event is variable-sized, up to some  
123672 maximum size.
- 123673 29. Bounds on record and trace stream sizes:
- 123674 a. The API must permit the application to declare the upper bounds on the length of  
123675 an application data record. The system must return the limit it used. The limit used  
123676 may be smaller than requested.
- 123677 b. The API must permit the application to declare the upper bounds on the size of  
123678 trace streams. The system must return the limit it used. The limit used may be  
123679 different, either larger or smaller, than requested.
- 123680 30. The API must be able to pass any fundamental data type, and a structured data type  
123681 composed only of fundamental types. The API must be able to pass data by reference,  
123682 given only as an address and a length. Fundamental types are the POSIX.1 types (see the  
123683 `<sys/types.h>` header) plus those defined in the ISO C standard.
- 123684 31. The API must apply the POSIX notions of ownership and permission to recorded trace  
123685 data, corresponding to the sources of that data.

### Comments on Objectives

**Note:** In the following comments, numbers in square brackets refer to the above objectives.

It is necessary to be able to obtain a trace stream for a complete activity. Thus there is a requirement to be able to trace both application and system trace events. A per-process trace event is either user-initiated, like the `write()` function, or system-initiated, like a timer expiration. There is also a need to be able to trace the activity of an entire process even when it has threads in multiple CPUs. To avoid excess trace activity, it is necessary to be able to control tracing on a trace event type basis.

[Objectives 1,2,5,22]

There is a need to be able to control tracing on a per-process basis, both from inside and outside the process; that is, a process can start a trace activity on itself or any other process. There is also the perceived need to allow the definition of a maximum number of trace streams per system.

[Objectives 3,23]

From within a process, it is necessary to be able to control tracing on a per-thread basis. This provides an additional filtering capability to keep the amount of traced data to a minimum. It also allows for less ambiguity as to the origin of trace events. It is recognized that thread-level control is only valid from within the process itself. It is also desirable to know the maximum number of trace streams per process that can be started. The API should not require thread synchronization or mandate priority inversions that would cause the thread to block. However, the API must be thread-safe.

[Objectives 4,23,24,27]

There was no perceived objective to control tracing on anything larger than a process; for example, a group or session. Also, the ability to start or stop a trace activity on multiple processes atomically may be very difficult or cumbersome in some implementations.

[Objectives 6,8]

123711 It is also necessary to be able to control tracing by trace event type identifier, sometimes called a  
123712 trace hook ID. However, there is no mandated set of system trace events, since such trace points  
123713 are implementation-defined. The API must not require from the operating system facilities that  
123714 are not standard.  
123715 [Objectives 6,26]

123716 Trace control must span *fork()* and *pthread\_create()*. If not, there will be no way to ensure that an  
123717 application's activity is entirely traced. The newly forked child would not be able to turn on its  
123718 tracing until after it obtained control after the fork, and trace control externally would be even  
123719 more problematic.  
123720 [Objective 9]

123721 Since *exec* and *posix\_spawn()* represent a complete change in the execution of a task (a new  
123722 program), trace control need not persist over an *exec* or *posix\_spawn()*.  
123723 [Objective 10]

123724 Where trace activities are started on multiple processes, these trace activities should not interfere  
123725 with each other.  
123726 [Objective 21]

123727 There is no need for a triggering objective, primarily for performance reasons; see also [Section](#)  
123728 [B.2.11.8](#) (on page 3645), rationale on triggering.  
123729 [Objective 11]

123730 It must be possible to determine the origin of each traced event. The process and thread  
123731 identifiers for each trace event are needed. Also there was a perceived need for a user-specifiable  
123732 origin, but it was felt that this would create too much overhead.  
123733 [Objectives 12,14]

123734 An allowance must be made for trace points to come embedded in software components from  
123735 several different sources and vendors without requiring coordination.  
123736 [Objective 13]

123737 There is a requirement to be able to uniquely identify trace points that may have the same trace  
123738 stream identifier. This is only necessary when a trace report is produced.  
123739 [Objectives 12,14]

123740 Tracing is a very performance-sensitive activity, and will therefore likely be implemented at a  
123741 low level within the system. Hence the interface must not mandate any particular buffering or  
123742 storage method. Therefore, a standard API is needed to read a trace stream. Also the interface  
123743 must not mandate the format of the trace data, and the interface must not assume a trace storage  
123744 method. Due to the possibility of a monolithic kernel and the possible presence of multiple  
123745 processes capable of running trace activities, the two kinds of trace events may be stored in two  
123746 separate streams for performance reasons. A mandatory dump mechanism, common in some  
123747 existing practice, has been avoided to allow the implementation of this set of functions on small  
123748 realtime profiles for which the concept of a file system is not defined. The trace API calls should  
123749 be implemented as macros.  
123750 [Objectives 15,16,25,30]

123751 Since a trace facility is a valuable service tool, the output (or log) of a completed trace stream  
123752 that is written to permanent storage must be readable on other systems of the type that  
123753 produced the trace log. Note that there is no objective to be able to interpret a trace log that was  
123754 not successfully completed.  
123755 [Objectives 17,18,19]

123756 For trace streams written to permanent storage, a way to specify the destination of the trace  
123757 stream is needed.  
123758 [Objective 20]

There is a requirement to be able to depend on the ordering of trace events up to some implementation-defined time interval. For example, there is a need to know the time period during which, if trace events are closer together, their ordering is unspecified. Events that occur within an interval smaller than this resolution may or may not be read back in the correct order. [Objective 24]

The application should be able to know how much data can be traced. When trace event types can be filtered, the application should be able to specify the approximate maximum amount of data that will be traced in a trace event so resources can be more efficiently allocated. [Objectives 28,29]

Users should not be able to trace data to which they would not normally have access. System trace events corresponding to a process/thread should be associated with the ownership of that process/thread. [Objective 31]

#### 123772 B.2.11.2 Trace Model

##### 123773 Introduction

The model is based on two base entities: the "Trace Stream" and the "Trace Log", and a recorded unit called the "Trace Event". The possibility of using Trace Streams and Trace Logs separately gives two use dimensions and solves both the performance issue and the full-information system issue. In the case of a trace stream without log, specific information, although reduced in quantity, is required to be registered, in a possibly small realtime system, with as little overhead as possible. The Trace Log option has been added for small realtime systems. In the case of a trace stream with log, considerable complex application-specific information needs to be collected.

##### 123782 Trace Model Description

The trace model can be examined for three different subfunctions: Application Instrumentation, Trace Operation Control, and Trace Analysis.

**Figure B-2** Trace System Overview: for Offline Analysis

Each of these subfunctions requires specific characteristics of the trace mechanism API.

- Application Instrumentation

When instrumenting an application, the programmer is not concerned about the future use of the trace events in the trace stream or the trace log, the full policy of the trace stream, or the eventual pre-filtering of trace events. But he is concerned about the correct determination of the specific trace event type identifier, regardless of how many independent libraries are used in the same user application; see [Figure B-2](#) (on page 3627) and [Figure B-3](#) (on page 3629).

This trace API provides the necessary operations to accomplish this subfunction. This is done by providing functions to associate a programmer-defined name with an implementation-defined trace event type identifier (see the *posix\_trace\_eventid\_open()* function), and to send this trace event into a potential trace stream (see the *posix\_trace\_event()* function).

- Trace Operation Control

When controlling the recording of trace events in a trace stream, the programmer is concerned with the correct initialization of the trace mechanism (that is, the sizing of the trace stream), the correct retention of trace events in a permanent storage, the correct dynamic recording of trace events, and so on.

This trace API provides the necessary material to permit this efficiently. This is done by providing functions to initialize a new trace stream, and optionally a trace log:

- Trace Stream Attributes Object Initialization (see *posix\_trace\_attr\_init()*)
- Functions to Retrieve or Set Information About a Trace Stream (see *posix\_trace\_attr\_getgenversion()*)
- Functions to Retrieve or Set the Behavior of a Trace Stream (see *posix\_trace\_attr\_getinherited()*)
- Functions to Retrieve or Set Trace Stream Size Attributes (see *posix\_trace\_attr\_getmaxusereventsize()*)
- Trace Stream Initialization, Flush, and Shutdown from a Process (see *posix\_trace\_create()*)
- Clear Trace Stream and Trace Log (see *posix\_trace\_clear()*)

To select the trace event types that are to be traced:

- Manipulate Trace Event Type Identifier (see *posix\_trace\_trid\_eventid\_open()*)
- Iterate over a Mapping of Trace Event Type (see *posix\_trace\_eventtypelist\_getnext\_id()*)
- Manipulate Trace Event Type Sets (see *posix\_trace\_eventset\_empty()*)
- Set Filter of an Initialized Trace Stream (see *posix\_trace\_set\_filter()*)

To control the execution of an active trace stream:

- Trace Start and Stop (see *posix\_trace\_start()*)
- Functions to Retrieve the Trace Attributes or Trace Statuses (see *posix\_trace\_get\_attr()*)

**Figure B-3** Trace System Overview: for Online Analysis

### • Trace Analysis

Once correctly recorded, on permanent storage or not, an ultimate activity consists of the analysis of the recorded information. If the recorded data is on permanent storage, a specific open operation is required to associate a trace stream to a trace log.

The first intent of the group was to request the presence of a system identification structure in the trace stream attribute. This was, for the application, to allow some portable way to process the recorded information. However, there is no requirement that the **utsname** structure, on which this system identification was based, be portable from one machine to another, so the contents of the attribute cannot be interpreted correctly by an application conforming to POSIX.1-2008.

This modification has been incorporated and requests that some unspecified information be recorded in the trace log in order to fail opening it if the analysis process and the controller process were running in different types of machine, but does not request that this information be accessible to the application. This modification has implied a modification in the `posix_trace_open()` function error code returns.

This trace API provides functions to:

- Extract trace stream identification attributes (see `posix_trace_attr_getgenversion()`)
- Extract trace stream behavior attributes (see `posix_trace_attr_getinherited()`)
- Extract trace event, stream, and log size attributes (see `posix_trace_attr_getmaxusersize()`)
- Look up trace event type names (see `posix_trace_eventid_get_name()`)
- Iterate over trace event type identifiers (see `posix_trace_eventtypelist_getnext_id()`)
- Open, rewind, and close a trace log (see `posix_trace_open()`)
- Read trace stream attributes and status (see `posix_trace_get_attr()`)
- Read trace events (see `posix_trace_getnext_event()`)

Due to the following two reasons:

1. The requirement that the trace system must not add unacceptable overhead to the traced process and so that the trace event point execution must be fast
2. The traced application does not care about tracing errors

the trace system cannot return any internal error to the application. Internal error conditions can range from unrecoverable errors that will force the active trace stream to abort, to small errors that can affect the quality of tracing without aborting the trace stream. The group decided to define a system trace event to report to the analysis process such internal errors. It is not the intention of POSIX.1-2008 to require an implementation to report an internal error that corrupts or terminates tracing operation. The implementor is free to decide which internal documented errors, if any, the trace system is able to report.

### States of a Trace Stream

**Figure B-4** Trace System Overview: States of a Trace Stream

Figure B-4 shows the different states an active trace stream passes through. After the `posix_trace_create()` function call, a trace stream becomes CREATED and a trace stream is associated for the future collection of trace events. The status of the trace stream is `POSIX_TRACE_SUSPENDED`. The state becomes STARTED after a call to the `posix_trace_start()` function, and the status becomes `POSIX_TRACE_RUNNING`. In this state, all trace events that are not filtered out will be stored into the trace stream. After a call to `posix_trace_stop()`, the trace stream becomes STOPPED (and the status `POSIX_TRACE_SUSPENDED`). In this state, no new trace events will be recorded in the trace stream, but previously recorded trace events may continue to be read.

After a call to `posix_trace_shutdown()`, the trace stream is in the state COMPLETED. The trace stream no longer exists but, if the Trace Log option is supported, all the information contained in it has been logged. If a log object has not been associated with the trace stream at the creation, it

123876 is the responsibility of the trace controller process to not shut the trace stream down while trace  
123877 events remain to be read in the stream.

## 123878 **Tracing All Processes**

123879 Some implementations have a tracing subsystem with the ability to trace all processes. This is  
123880 useful to debug some types of device drivers such as those for ATM or X25 adapters. These  
123881 types of adapters are used by several independent processes, that are not issued from the same  
123882 process.

123883 The POSIX trace interface does not define any constant or option to create a trace stream tracing  
123884 all processes. POSIX.1 does not prevent this type of implementation and an implementor is free  
123885 to add this capability. Nevertheless, the trace interface allows tracing of all the system trace  
123886 events and all the processes issued from the same process.

123887 If such a tracing system capability has to be implemented, when a trace stream is created, it is  
123888 recommended that a constant named `POSIX_TRACE_ALLPROC` be used instead of the process  
123889 identifier in the argument of the `posix_trace_create()` or `posix_trace_create_withlog()` function. A  
123890 possible value for `POSIX_TRACE_ALLPROC` may be `-1` instead of a real process identifier.

123891 The implementor has to be aware that there is some impact on the tracing behavior as defined in  
123892 the POSIX trace interface. For example:

- 123893 • If the default value for the inheritance attribute is set to  
123894 `POSIX_TRACE_CLOSE_FOR_CHILD`, the implementation has to stop tracing for the child  
123895 process.
- 123896 • The trace controller which is creating this type of trace stream must have the appropriate  
123897 privilege to trace all the processes.

## 123898 **Trace Storage**

123899 The model is based on two types of trace events: system trace events and user-defined trace  
123900 events. The internal representation of trace events is implementation-defined, and so the  
123901 implementor is free to choose the more suitable, practical, and efficient way to design the  
123902 internal management of trace events. For the timestamping operation, the model does not  
123903 impose the `CLOCK_REALTIME` or any other clock. The buffering allocation and operation  
123904 follow the same principle. The implementor is free to use one or more buffers to record trace  
123905 events; the interface assumes only a logical trace stream of sequentially recorded trace events.  
123906 Regarding flushing of trace events, the interface allows the definition of a trace log object which  
123907 typically can be a file. But the group was also aware of defining functions to permit the use of  
123908 this interface in small realtime systems, which may not have general file system capabilities. For  
123909 instance, the three functions `posix_trace_getnext_event()` (blocking),  
123910 `posix_trace_timedgetnext_event()` (blocking with timeout), and `posix_trace_trygetnext_event()` (non-  
123911 blocking) are proposed to read the recorded trace events.

123912 The policy to be used when the trace stream becomes full also relies on common practice:

- 123913 • For an active trace stream, the `POSIX_TRACE_LOOP` trace stream policy permits  
123914 automatic overrun (overwrite of oldest trace events) while waiting for some user-defined  
123915 condition to cause tracing to stop. By contrast, the `POSIX_TRACE_UNTIL_FULL` trace  
123916 stream policy requires the system to stop tracing when the trace stream is full. However, if  
123917 the trace stream that is full is at least partially emptied by a call to the `posix_trace_flush()`  
123918 function or by calls to the `posix_trace_getnext_event()` function, the trace system will  
123919 automatically resume tracing.

123920 If the Trace Log option is supported, the operation of the `POSIX_TRACE_FLUSH` policy is  
123921 an extension of the `POSIX_TRACE_UNTIL_FULL` policy. The automatic free operation (by

123922 flushing to the associated trace log) is added.

- 123923 • If a log is associated with the trace stream and this log is a regular file, these policies also  
123924 apply for the log. One more policy, POSIX\_TRACE\_APPEND, is defined to allow  
123925 indefinite extension of the log. Since the log destination can be any device or pseudo-  
123926 device, the implementation may not be able to manipulate the destination as required by  
123927 POSIX.1-2008. For this reason, the behavior of the log full policy may be unspecified  
123928 depending on the trace log type.

123929 The current trace interface does not define a service to preallocate space for a trace log file,  
123930 because this space can be preallocated by means of a call to the *posix\_fallocate()* function.  
123931 This function could be called after the file has been opened, but before the trace stream is  
123932 created. The *posix\_fallocate()* function ensures that any required storage for regular file data  
123933 is allocated on the file system storage media. If *posix\_fallocate()* returns successfully,  
123934 subsequent writes to the specified file data will not fail due to the lack of free space on the  
123935 file system storage media. Besides trace events, a trace stream also includes trace attributes  
123936 and the mapping from trace event names to trace event type identifiers. The implementor  
123937 is free to choose how to store the trace attributes and the trace event type map, but must  
123938 ensure that this information is not lost when a trace stream overrun occurs.

### 123939 B.2.11.3 Trace Programming Examples

123940 Several programming examples are presented to show the code of the different possible  
123941 subfunctions using a trace subsystem. All these programs need to include the **<trace.h>** header.  
123942 In the examples shown, error checking is omitted for more simplicity.

### 123943 Trace Operation Control

123944 These examples show the creation of a trace stream for another process; one which is already  
123945 trace instrumented. All the default trace stream attributes are used to simplify programming in  
123946 the first example. The second example shows more possibilities.

### 123947 First Example

```
123948 /* Caution. Error checks omitted */
123949 {
123950 trace_attr_t attr;
123951 pid_t pid = traced_process_pid;
123952 int fd;
123953 trace_id_t trid;
123954
123955 - - - - -
123956 /* Initialize trace stream attributes */
123957 posix_trace_attr_init(&attr);
123958 /* Open a trace log */
123959 fd=open("/tmp/mytracelog",...);
123960 /*
123961 * Create a new trace associated with a log
123962 * and with default attributes
123963 */
123964 posix_trace_create_withlog(pid, &attr, fd, &trid);
123965 /* Trace attribute structure can now be destroyed */
123966 posix_trace_attr_destroy(&attr);
123967 /* Start of trace event recording */
```

```

123967 posix_trace_start(trid);
123968 - - - - -
123969 - - - - -
123970 /* Duration of tracing */
123971 - - - - -
123972 - - - - -
123973 /* Stop and shutdown of trace activity */
123974 posix_trace_shutdown(trid);
123975 - - - - -
123976 }

```

## Second Example

Between the initialization of the trace stream attributes and the creation of the trace stream, these trace stream attributes may be modified; see [Trace Stream Attribute Manipulation](#) (on page 3637) for a specific programming example. Between the creation and the start of the trace stream, the event filter may be set; after the trace stream is started, the event filter may be changed. The setting of an event set and the change of a filter is shown in [Create a Trace Event Type Set and Change the Trace Event Type Filter](#) (on page 3637).

```

123984 /* Caution. Error checks omitted */
123985 {
123986 trace_attr_t attr;
123987 pid_t pid = traced_process_pid;
123988 int fd;
123989 trace_id_t trid;
123990 - - - - -
123991 /* Initialize trace stream attributes */
123992 posix_trace_attr_init(&attr);
123993 /* Attr default may be changed at this place; see example */
123994 - - - - -
123995 /* Create and open a trace log with R/W user access */
123996 fd=open("/tmp/mytracelog",O_WRONLY|O_CREAT,S_IRUSR|S_IWUSR);
123997 /* Create a new trace associated with a log */
123998 posix_trace_create_withlog(pid, &attr, fd, &trid);
123999 /*
124000 * If the Trace Filter option is supported
124001 * trace event type filter default may be changed at this place;
124002 * see example about changing the trace event type filter
124003 */
124004 posix_trace_start(trid);
124005 - - - - -
124006
124007 /*
124008 * If you have an uninteresting part of the application
124009 * you can stop temporarily.
124010 *
124011 * posix_trace_stop(trid);
124012 * - - - - -
124013 * - - - - -
124014 * posix_trace_start(trid);
124015 */
124016 - - - - -
124017 }

```

```

124017 * If the Trace Filter option is supported
124018 * the current trace event type filter can be changed
124019 * at any time (see example about how to set
124020 * a trace event type filter)
124021 */
124022 - - - - -
124023 /* Stop the recording of trace events */
124024 posix_trace_stop(trid);
124025 /* Shutdown the trace stream */
124026 posix_trace_shutdown(trid);
124027 /*
124028 * Destroy trace stream attributes; attr structure may have
124029 * been used during tracing to fetch the attributes
124030 */
124031 posix_trace_attr_destroy(&attr);
124032 - - - - -
124033 }

```

### Application Instrumentation

This example shows an instrumented application. The code is included in a block of instructions, perhaps a function from a library. Possibly in an initialization part of the instrumented application, two user trace event names are mapped to two trace event type identifiers (function `posix_trace_eventid_open()`). Then two trace points are programmed.

```

124039 /* Caution. Error checks omitted */
124040 {
124041 trace_event_id_t eventidl, eventid2;
124042 - - - - -
124043 /* Initialization of two trace event type ids */
124044 posix_trace_eventid_open("my_first_event",&eventidl);
124045 posix_trace_eventid_open("my_second_event",&eventid2);
124046 - - - - -
124047 - - - - -
124048 - - - - -
124049 /* Trace point */
124050 posix_trace_event(eventidl,NULL,0);
124051 - - - - -
124052 /* Trace point */
124053 posix_trace_event(eventid2,NULL,0);
124054 - - - - -
124055 }

```

### Trace Analyzer

This example shows the manipulation of a trace log resulting from the dumping of a completed trace stream. All the default attributes are used to simplify programming, and data associated with a trace event is not shown in the first example. The second example shows more possibilities.

**First Example**

```

124061
124062 /* Caution. Error checks omitted */
124063 {
124064 int fd;
124065 trace_id_t trid;
124066 posix_trace_event_info trace_event;
124067 char trace_event_name[TRACE_EVENT_NAME_MAX];
124068 int return_value;
124069 size_t returndatasize;
124070 int lost_event_number;
124071
124072 -- -- -- --
124073
124074 /* Open an existing trace log */
124075 fd=open("/tmp/tracelog", O_RDONLY);
124076 /* Open a trace stream on the open log */
124077 posix_trace_open(fd, &trid);
124078 /* Read a trace event */
124079 posix_trace_getnext_event(trid, &trace_event,
124080 NULL, 0, &returndatasize,&return_value);
124081
124082 /* Read and print all trace event names out in a loop */
124083 while (return_value == NULL)
124084 {
124085 /*
124086 * Get the name of the trace event associated
124087 * with trid trace ID
124088 */
124089 posix_trace_eventid_get_name(trid, trace_event.event_id,
124090 trace_event_name);
124091 /* Print the trace event name out */
124092 printf("%s\n",trace_event_name);
124093 /* Read a trace event */
124094 posix_trace_getnext_event(trid, &trace_event,
124095 NULL, 0, &returndatasize,&return_value);
124096 }
124097
124098 /* Close the trace stream */
124099 posix_trace_close(trid);
124100 /* Close the trace log */
124101 close(fd);
124102 }
124103

```

**Second Example**

The complete example includes the two other examples in [Retrieve Information from a Trace Log](#) (on page 3638) and in [Retrieve the List of Trace Event Types Used in a Trace Log](#) (on page 3639). For example, the *maxdatasize* variable is set in [Retrieve the List of Trace Event Types Used in a Trace Log](#) (on page 3639).

```

124104 /* Caution. Error checks omitted */
124105 {
124106 int fd;
124107 trace_id_t trid;
124108 posix_trace_event_info trace_event;

```

```

124109 char trace_event_name[TRACE_EVENT_NAME_MAX];
124110 char * data;
124111 size_t maxdatasize=1024, returndatasize;
124112 int return_value;
124113 - - - - -
124114 /* Open an existing trace log */
124115 fd=open("/tmp/tracelog", O_RDONLY);
124116 /* Open a trace stream on the open log */
124117 posix_trace_open(fd, &trid);
124118 /*
124119 * Retrieve information about the trace stream which
124120 * was dumped in this trace log (see example)
124121 */
124122 - - - - -
124123 /* Allocate a buffer for trace event data */
124124 data=(char *)malloc(maxdatasize);
124125 /*
124126 * Retrieve the list of trace events used in this
124127 * trace log (see example)
124128 */
124129 - - - - -
124130 /* Read and print all trace event names and data out in a loop */
124131 while (1)
124132 {
124133 posix_trace_getnext_event(trid, &trace_event,
124134 data, maxdatasize, &returndatasize,&return_value);
124135 if (return_value != NULL) break;
124136 /*
124137 * Get the name of the trace event type associated
124138 * with trid trace ID
124139 */
124140 posix_trace_eventid_get_name(trid, trace_event.event_id,
124141 trace_event_name);
124142 {
124143 int i;
124144 /* Print the trace event name out */
124145 printf("%s: ", trace_event_name);
124146 /* Print the trace event data out */
124147 for (i=0; i<returndatasize, i++) printf("%02.2X",
124148 (unsigned char)data[i]);
124149 printf("\n");
124150 }
124151 }
124152 /* Close the trace stream */
124153 posix_trace_close(trid);
124154 /* The buffer data is deallocated */
124155 free(data);
124156 /* Now the file can be closed */
124157 close(fd);
124158 }

```

**Several Programming Manipulations**

The following examples show some typical sets of operations needed in some contexts.

**Trace Stream Attribute Manipulation**

This example shows the manipulation of a trace stream attribute object in order to change the default value provided by a previous *posix\_trace\_attr\_init()* call.

```

/* Caution. Error checks omitted */
{
 trace_attr_t attr;
 size_t logsize=100000;
 - - - - -
 /* Initialize trace stream attributes */
 posix_trace_attr_init(&attr);
 /* Set the trace name in the attributes structure */
 posix_trace_attr_setname(&attr, "my_trace");
 /* Set the trace full policy */
 posix_trace_attr_setstreamfullpolicy(&attr, POSIX_TRACE_LOOP);
 /* Set the trace log size */
 posix_trace_attr_setlogsize(&attr, logsize);
 - - - - -
}

```

**Create a Trace Event Type Set and Change the Trace Event Type Filter**

This example is valid only if the Trace Event Filter option is supported. This example shows the manipulation of a trace event type set in order to change the trace event type filter for an existing active trace stream, which may be just-created, running, or suspended. Some sets of trace event types are well-known, such as the set of trace event types not associated with a process, some trace event types are just-built trace event types for this trace stream; one trace event type is the predefined trace event error type which is deleted from the trace event type set.

```

/* Caution. Error checks omitted */
{
 trace_id_t trid = existing_trace;
 trace_event_set_t set;
 trace_event_id_t trace_event1, trace_event2;
 - - - - -
 /* Initialize to an empty set of trace event types */
 /* (not strictly required because posix_trace_event_set_fill() */
 /* will ignore the prior contents of the event set.) */
 posix_trace_eventset_emptyset(&set);
 /*
 * Fill the set with all system trace events
 * not associated with a process
 */
 posix_trace_eventset_fill(&set, POSIX_TRACE_WOPID_EVENTS);
 /*
 * Get the trace event type identifier of the known trace event name
 * my_first_event for the trid trace stream
 */
 posix_trace_trid_eventid_open(trid, "my_first_event", &trace_event1);
}

```

```

124206 /* Add the set with this trace event type identifier */
124207 posix_trace_eventset_add_event(trace_event1, &set);
124208 /*
124209 * Get the trace event type identifier of the known trace event name
124210 * my_second_event for the trid trace stream
124211 */
124212 posix_trace_trid_eventid_open(trid, "my_second_event", &trace_event2);
124213 /* Add the set with this trace event type identifier */
124214 posix_trace_eventset_add_event(trace_event2, &set);
124215 - - - - -
124216 /* Delete the system trace event POSIX_TRACE_ERROR from the set */
124217 posix_trace_eventset_del_event(POSIX_TRACE_ERROR, &set);
124218 - - - - -
124219 /* Modify the trace stream filter making it equal to the new set */
124220 posix_trace_set_filter(trid, &set, POSIX_TRACE_SET_EVENTSET);
124221 - - - - -
124222 /*
124223 * Now trace_event1, trace_event2, and all system trace event types
124224 * not associated with a process, except for the POSIX_TRACE_ERROR
124225 * system trace event type, are filtered out of (not recorded in) the
124226 * existing trace stream.
124227 */
124228 }

```

### Retrieve Information from a Trace Log

This example shows how to extract information from a trace log, the dump of a trace stream. This code:

- Asks if the trace stream has lost trace events
- Extracts the information about the version of the trace subsystem which generated this trace log
- Retrieves the maximum size of trace event data; this may be used to dynamically allocate an array for extracting trace event data from the trace log without overflow

```

124237 /* Caution. Error checks omitted */
124238 {
124239 struct posix_trace_status_info statusinfo;
124240 trace_attr_t attr;
124241 trace_id_t trid = existing_trace;
124242 size_t maxdatasize;
124243 char genversion[TRACE_NAME_MAX];
124244 - - - - -
124245 /* Get the trace stream status */
124246 posix_trace_get_status(trid, &statusinfo);
124247 /* Detect an overrun condition */
124248 if (statusinfo.posix_stream_overrun_status == POSIX_TRACE_OVERRUN)
124249 printf("trace events have been lost\n");
124250 /* Get attributes from the trid trace stream */
124251 posix_trace_get_attr(trid, &attr);
124252 /* Get the trace generation version from the attributes */

```

```

124253 posix_trace_attr_getgenversion(&attr, genversion);
124254 /* Print the trace generation version out */
124255 printf("Information about Trace Generator:%s\n",genversion);

124256 /* Get the trace event max data size from the attributes */
124257 posix_trace_attr_getmaxdatasize(&attr, &maxdatasize);
124258 /* Print the trace event max data size out */
124259 printf("Maximum size of associated data:%d\n",maxdatasize);
124260 /* Destroy the trace stream attributes */
124261 posix_trace_attr_destroy(&attr);
124262 }

```

### Retrieve the List of Trace Event Types Used in a Trace Log

This example shows the retrieval of a trace stream's trace event type list. This operation may be very useful if you are interested only in tracking the type of trace events in a trace log.

```

124266 /* Caution. Error checks omitted */
124267 {
124268 trace_id_t trid = existing_trace;
124269 trace_event_id_t event_id;
124270 char event_name[TRACE_EVENT_NAME_MAX];
124271 int return_value;
124272 - - - - -

124273 /*
124274 * In a loop print all existing trace event names out
124275 * for the trid trace stream
124276 */
124277 while (1)
124278 {
124279 posix_trace_eventtypelist_getnext_id(trid, &event_id
124280 &return_value);
124281 if (return_value != NULL) break;
124282 /*
124283 * Get the name of the trace event associated
124284 * with trid trace ID
124285 */
124286 posix_trace_eventid_get_name(trid, event_id, event_name);
124287 /* Print the name out */
124288 printf("%s\n", event_name);
124289 }
124290 }

```

## 124291 B.2.11.4 Rationale on Trace for Debugging

124292 **Figure B-5** Trace Another Process

124293 Among the different possibilities offered by the trace interface defined in POSIX.1-2008, the  
 124294 debugging of an application is the most interesting one. Typical operations in the controlling  
 124295 debugger process are to filter trace event types, to get trace events from the trace stream, to stop  
 124296 the trace stream when the debugged process is executing uninteresting code, to start the trace  
 124297 stream when some interesting point is reached, and so on. The interface defined in POSIX.1-2008  
 124298 should define all the necessary base functions to allow this dynamic debug handling.

124299 **Figure B-5** shows an example in which the trace stream is created after the call to the `fork()`  
 124300 function. If the user does not want to lose trace events, some synchronization mechanism  
 124301 (represented in the figure) may be needed before calling the `exec()` function, to give the parent a  
 124302 chance to create the trace stream before the child begins the execution of its trace points.

## 124303 B.2.11.5 Rationale on Trace Event Type Name Space

124304 At first, the working group was in favor of the representation of a trace event type by an integer  
 124305 (`event_name`). It seems that existing practice shows the weakness of such a representation. The  
 124306 collision of trace event types is the main problem that cannot be simply resolved using this sort  
 124307 of representation. Suppose, for example, that a third party designs an instrumented library. The  
 124308 user does not have the source of this library and wants to trace his application which uses in  
 124309 some part the third-party library. There is no means for him to know what are the trace event  
 124310 types used in the instrumented library so he has some chance of duplicating some of them and  
 124311 thus to obtain a contaminated tracing of his application.

**Figure B-6** Trace Name Space Overview: With Third-Party Library

There are requirements to allow program images containing pieces from various vendors to be traced without also requiring those of any other vendors to coordinate their uses of the trace facility, and especially the naming of their various trace event types and trace point IDs. The chosen solution is to provide a very large name space, large enough so that the individual vendors can give their trace types and tracepoint IDs sufficiently long and descriptive names making the occurrence of collisions quite unlikely. The probability of collision is thus made sufficiently low so that the problem may, as a practical matter, be ignored. By requirement, the consequence of collisions will be a slight ambiguity in the trace streams; tracing will continue in spite of collisions and ambiguities. “The show must go on”. The *posix\_prog\_address* member of the **posix\_trace\_event\_info** structure is used to allow trace streams to be unambiguously interpreted, despite the fact that trace event types and trace event names need not be unique.

The *posix\_trace\_eventid\_open()* function is required to allow the instrumented third-party library to get a valid trace event type identifier for its trace event names. This operation is, somehow, an allocation, and the group was aware of proposing some deallocation mechanism which the instrumented application could use to recover the resources used by a trace event type identifier. This would have given the instrumented application the benefit of being capable of reusing a possible minimum set of trace event type identifiers, but also the inconvenience to have, possibly in the same trace stream, one trace event type identifier identifying two different trace event types. After some discussions the group decided to not define such a function which would make this API thicker for little benefit, the user having always the possibility of adding identification information in the *data* member of the trace event structure.

The set of the trace event type identifiers the controlling process wants to filter out is initialized in the trace mechanism using the function *posix\_trace\_set\_filter()*, setting the arguments according to the definitions explained in *posix\_trace\_set\_filter()*. This operation can be done statically (when the trace is in the STOPPED state) or dynamically (when the trace is in the STARTED state). The preparation of the filter is normally done using the function defined in *posix\_trace\_eventtypelist\_getnext\_id()* and eventually the function *posix\_trace\_eventtypelist\_rewind()* in order to know (before the recording) the list of the potential

set of trace event types that can be recorded. In the case of an active trace stream, this list may not be exhaustive. Actually, the target process may not have yet called the function `posix_trace_eventid_open()`. But it is a common practice, for a controlling process, to prepare the filtering of a future trace stream before its start. Therefore the user must have a way to get the trace event type identifier corresponding to a well-known trace event name before its future association by the pre-cited function. This is done by calling the `posix_trace_trid_eventid_open()` function, given the trace stream identifier and the trace name, and described hereafter. Because this trace event type identifier is associated with a trace stream identifier, where a unique process has initialized two or more traces, the implementation is expected to return the same trace event type identifier for successive calls to `posix_trace_trid_eventid_open()` with different trace stream identifiers. The `posix_trace_eventid_get_name()` function is used by the controller process to identify, by the name, the trace event type returned by a call to the `posix_trace_eventtypelist_getnext_id()` function.

Afterwards, the set of trace event types is constructed using the functions defined in `posix_trace_eventset_empty()`, `posix_trace_eventset_fill()`, `posix_trace_eventset_add()`, and `posix_trace_eventset_del()`.

A set of functions is provided devoted to the manipulation of the trace event type identifier and names for an active trace stream. All these functions require the trace stream identifier argument as the first parameter. The opacity of the trace event type identifier implies that the user cannot associate directly its well-known trace event name with the system-associated trace event type identifier.

The `posix_trace_trid_eventid_open()` function allows the application to get the system trace event type identifier back from the system, given its well-known trace event name. This function is useful only when a controlling process needs to specify specific events to be filtered.

The `posix_trace_eventid_get_name()` function allows the application to obtain a trace event name given its trace event type identifier. One possible use of this function is to identify the type of a trace event retrieved from the trace stream, and print it. The easiest way to implement this requirement, is to use a single trace event type map for all the processes whose maps are required to be identical. A more difficult way is to attempt to keep multiple maps identical at every call to `posix_trace_eventid_open()` and `posix_trace_trid_eventid_open()`.

#### 124371 B.2.11.6 Rationale on Trace Events Type Filtering

The most basic rationale for runtime and pre-registration filtering (selection/rejection) of trace event types is to prevent choking of the trace collection facility, and/or overloading of the computer system. Any worthwhile trace facility can bring even the largest computer to its knees. Otherwise, everything would be recorded and filtered after the fact; it would be much simpler, but impractical.

To achieve debugging, measurement, or whatever the purpose of tracing, the filtering of trace event types is an important part of trace analysis. Due to the fact that the trace events are put into a trace stream and probably logged afterwards into a file, different levels of filtering—that is, rejection of trace event types—are possible.

### Filtering of Trace Event Types Before Tracing

This function, represented by the `posix_trace_set_filter()` function in POSIX.1-2008 (see `posix_trace_set_filter()`), selects, before or during tracing, the set of trace event types to be filtered out. It should be possible also (as OSF suggested in their ETAP trace specifications) to select the kernel trace event types to be traced in a system-wide fashion. These two functionalities are called the pre-filtering of trace event types.

The restriction on the actual type used for the `trace_event_set_t` type is intended to guarantee that these objects can always be assigned, have their address taken, and be passed by value as parameters. It is not intended that this type be a structure including pointers to other data structures, as that could impact the portability of applications performing such operations. A reasonable implementation could be a structure containing an array of integer types.

### Filtering of Trace Event Types at Runtime

It is possible to build this functionality using the `posix_trace_set_filter()` function. A privileged process or a privileged thread can get trace events from the trace stream of another process or thread, and thus specify the type of trace events to record into a file, using implementation-defined methods and interfaces. This functionality, called inline filtering of trace event types, is used for runtime analysis of trace streams.

### Post-Mortem Filtering of Trace Event Types

The word “post-mortem” is used here to indicate that some unanticipated situation occurs during execution that does not permit a pre or inline filtering of trace events and that it is necessary to record all trace event types to have a chance to discover the problem afterwards. When the program stops, all the trace events recorded previously can be analyzed in order to find the solution. This functionality could be named the post-filtering of trace event types.

### Discussions about Trace Event Type Filtering

After long discussions with the parties involved in the process of defining the trace interface, it seems that the sensitivity to the filtering problem is different, but everybody agrees that the level of the overhead introduced during the tracing operation depends on the filtering method elected. If the time that it takes the trace event to be recorded can be neglected, the overhead introduced by the filtering process can be classified as follows:

Pre-filtering      System and process/thread-level overhead

Inline-filtering    Process/thread-level overhead

Post-filtering      No overhead; done offline

The pre-filtering could be named “critical realtime” filtering in the sense that the filtering of trace event type is manageable at the user level so the user can lower to a minimum the filtering overhead at some user selected level of priority for the inline filtering, or delay the filtering to after execution for the post-filtering. The counterpart of this solution is that the size of the trace stream must be sufficient to record all the trace events. The advantage of the pre-filtering is that the utilization of the trace stream is optimized.

Only pre-filtering is defined by POSIX.1-2008. However, great care must be taken in specifying pre-filtering, so that it does not impose unacceptable overhead. Moreover, it is necessary to isolate all the functionality relative to the pre-filtering.

The result of this rationale is to define a new option, the Trace Event Filter option, not necessarily implemented in small realtime systems, where system overhead is minimized to the extent possible.

## 124425 B.2.11.7 Tracing, pthread API

124426 The objective to be able to control tracing for individual threads may be in conflict with the  
 124427 efficiency expected in threads with a *contentionscope* attribute of PTHREAD\_SCOPE\_PROCESS.  
 124428 For these threads, context switches from one thread that has tracing enabled to another thread  
 124429 that has tracing disabled may require a kernel call to inform the kernel whether it has to trace  
 124430 system events executed by that thread or not. For this reason, it was proposed that the ability to  
 124431 enable or disable tracing for PTHREAD\_SCOPE\_PROCESS threads be made optional, through  
 124432 the introduction of a Trace Scope Process option. A trace implementation which did not  
 124433 implement the Trace Scope Process option would not honor the tracing-state attribute of a thread  
 124434 with PTHREAD\_SCOPE\_PROCESS; it would, however, honor the tracing-state attribute of a  
 124435 thread with PTHREAD\_SCOPE\_SYSTEM. This proposal was rejected as:

- 124436 1. Removing desired functionality (per-thread trace control)
- 124437 2. Introducing counter-intuitive behavior for the tracing-state attribute
- 124438 3. Mixing logically orthogonal ideas (thread scheduling and thread tracing)
- 124439 [Objective 4]

124440 Finally, to solve this complex issue, this API does not provide *pthread\_gettracingstate()*,  
 124441 *pthread\_settracingstate()*, *pthread\_attr\_gettracingstate()*, and *pthread\_attr\_settracingstate()*  
 124442 interfaces. These interfaces force the thread implementation to add to the weight of the thread  
 124443 and cause a revision of the threads libraries, just to support tracing. Worse yet,  
 124444 *posix\_trace\_event()* must always test this per-thread variable even in the common case where it is  
 124445 not used at all. Per-thread tracing is easy to implement using existing interfaces where  
 124446 necessary; see the following example.

124447 **Example**

```

124448 /* Caution. Error checks omitted */
124449 static pthread_key_t my_key;
124450 static trace_event_id_t my_event_id;
124451 static pthread_once_t my_once = PTHREAD_ONCE_INIT;

124452 void my_init(void)
124453 {
124454 (void) pthread_key_create(&my_key, NULL);
124455 (void) posix_trace_eventid_open("my", &my_event_id);
124456 }

124457 int get_trace_flag(void)
124458 {
124459 pthread_once(&my_once, my_init);
124460 return (pthread_getspecific(my_key) != NULL);
124461 }

124462 void set_trace_flag(int f)
124463 {
124464 pthread_once(&my_once, my_init);
124465 pthread_setspecific(my_key, f? &my_event_id: NULL);
124466 }

124467 fn()
124468 {
124469 if (get_trace_flag())
124470 posix_trace_event(my_event_id, ...)
124471 }
```

- 124472 The above example does not implement third-party state setting.
- 124473 Lastly, per-thread tracing works poorly for threads with PTHREAD\_SCOPE\_PROCESS  
124474 contention scope. These “library” threads have minimal interaction with the kernel and would  
124475 have to explicitly set the attributes whenever they are context switched to a new kernel thread in  
124476 order to trace system events. Such state was explicitly avoided in POSIX threads to keep  
124477 PTHREAD\_SCOPE\_PROCESS threads lightweight.
- 124478 The reason that keeping PTHREAD\_SCOPE\_PROCESS threads lightweight is important is that  
124479 such threads can be used not just for simple multi-processors but also for co-routine style  
124480 programming (such as discrete event simulation) without inventing a new threads paradigm.  
124481 Adding extra runtime cost to thread context switches will make using POSIX threads less  
124482 attractive in these situations.
- 124483 *B.2.11.8 Rationale on Triggering*
- 124484 The ability to start or stop tracing based on the occurrence of specific trace event types has been  
124485 proposed as a parallel to similar functionality appearing in logic analyzers. Such triggering, in  
124486 order to be very useful, should be based not only on the trace event type, but on trace event-  
124487 specific data, including tests of user-specified fields for matching or threshold values.
- 124488 Such a facility is unnecessary where the buffering of the stream is not a constraint, since such  
124489 checks can be performed offline during post-mortem analysis.
- 124490 For example, a large system could incorporate a daemon utility to collect the trace records from  
124491 memory buffers and spool them to secondary storage for later analysis. In the instances where  
124492 resources are truly limited, such as embedded applications, the application incorporation of  
124493 application code to test the circumstances of a trace event and call the trace point only if needed  
124494 is usually straightforward.
- 124495 For performance reasons, the *posix\_trace\_event()* function should be implemented using a macro,  
124496 so if the trace is inactive, the trace event point calls are latent code and must cost no more than a  
124497 scalar test.
- 124498 The API proposed in POSIX.1-2008 does not include any triggering functionality.
- 124499 *B.2.11.9 Rationale on Timestamp Clock*
- 124500 It has been suggested that the tracing mechanism should include the possibility of specifying the  
124501 clock to be used in timestamping the trace events. When application trace events must be  
124502 correlated to remote trace events, such a facility could provide a global time reference not  
124503 available from a local clock. Further, the application may be driven by timers based on a clock  
124504 different from that used for the timestamp, and the correlation of the trace to those untraced  
124505 timer activities could be an important part of the analysis of the application.
- 124506 However, the tracing mechanism needs to be fast and just the provision of such an option can  
124507 materially affect its performance. Leaving aside the performance costs of reading some clocks,  
124508 this notion is also ill-defined when kernel trace events are to be traced by two applications  
124509 making use of different tracing clocks. This can even happen within a single application where  
124510 different parts of the application are served by different clocks. Another complication can occur  
124511 when a clock is maintained strictly at the user level and is unavailable at the kernel level.
- 124512 It is felt that the benefits of a selectable trace clock do not match its costs. Applications that wish  
124513 to correlate clocks other than the default tracing clock can include trace events with sample  
124514 values of those other clocks, allowing correlation of timestamps from the various independent  
124515 clocks. In any case, such a technique would be required when applications are sensitive to

124516 multiple clocks.

#### 124517 B.2.11.10 Rationale on Different Overrun Conditions

124518 The analysis of the dynamic behavior of the trace mechanism shows that different overrun  
124519 conditions may occur. The API must provide a means to manage such conditions in a portable  
124520 way.

#### 124521 **Overrun in Trace Streams Initialized with POSIX\_TRACE\_LOOP Policy**

124522 In this case, the user of the trace mechanism is interested in using the trace stream with  
124523 POSIX\_TRACE\_LOOP policy to record trace events continuously, but ideally without losing any  
124524 trace events. The online analyzer process must get the trace events at a mean speed equivalent to  
124525 the recording speed. Should the trace stream become full, a trace stream overrun occurs. This  
124526 condition is detected by getting the status of the active trace stream (function  
124527 *posix\_trace\_get\_status()*) and looking at the member *posix\_stream\_overrun\_status* of the read  
124528 **posix\_stream\_status** structure. In addition, two predefined trace event types are defined:

- 124529 1. The beginning of a trace overflow, to locate the beginning of an overflow when reading a  
124530 trace stream
- 124531 2. The end of a trace overflow, to locate the end of an overflow, when reading a trace stream

124532 As a timestamp is associated with these predefined trace events, it is possible to know the  
124533 duration of the overflow.

#### 124534 **Overrun in Dumping Trace Streams into Trace Logs**

124535 The user lets the trace mechanism dump the trace stream initialized with  
124536 POSIX\_TRACE\_FLUSH policy automatically into a trace log. If the dump operation is slower  
124537 than the recording of trace events, the trace stream can overrun. This condition is detected by  
124538 getting the status of the active trace stream (the *posix\_trace\_get\_status()* function) and looking at  
124539 the member *posix\_stream\_overrun\_status* of the read **posix\_stream\_status** structure. This overrun  
124540 indicates that the trace mechanism is not able to operate in this mode at this speed. It is the  
124541 responsibility of the user to modify one of the trace parameters (the stream size or the trace  
124542 event type filter, for instance) to avoid such overrun conditions, if overruns are to be prevented.  
124543 The same already predefined trace event types (see [Overrun in Trace Streams Initialized with  
124544 POSIX\\_TRACE\\_LOOP Policy](#)) are used to detect and to know the duration of an overflow.

#### 124545 **Reading an Active Trace Stream**

124546 Although this trace API allows one to read an active trace stream with log while it is tracing, this  
124547 feature can lead to false overflow origin interpretation: the trace log or the reader of the trace  
124548 stream. Reading from an active trace stream with log is thus non-portable, and has been left  
124549 unspecified.

124550 **B.2.12 Data Types**124551 *B.2.12.1 Defined Types*

124552 The requirement that additional types defined in this section end in “\_t” was prompted by the  
 124553 problem of name space pollution. It is difficult to define a type (where that type is not one  
 124554 defined by POSIX.1-2008) in one header file and use it in another without adding symbols to the  
 124555 name space of the program. To allow implementors to provide their own types, all conforming  
 124556 applications are required to avoid symbols ending in “\_t”, which permits the implementor to  
 124557 provide additional types. Because a major use of types is in the definition of structure members,  
 124558 which can (and in many cases must) be added to the structures defined in POSIX.1-2008, the  
 124559 need for additional types is compelling.

124560 The types, such as **ushort** and **ulong**, which are in common usage, are not defined in  
 124561 POSIX.1-2008 (although **ushort\_t** would be permitted as an extension). They can be added to  
 124562 **<sys/types.h>** using a feature test macro (see [Section B.2.2.1](#), on page 3526). A suggested symbol  
 124563 for these is **\_SYSIII**. Similarly, the types like **u\_short** would probably be best controlled by **\_BSD**.

124564 Some of these symbols may appear in other headers; see [Section B.2.2.2](#) (on page 3527).

124565 **dev\_t** This type may be made large enough to accommodate host-locality considerations  
 124566 of networked systems.

124567 This type must be arithmetic. Earlier proposals allowed this to be non-arithmetic  
 124568 (such as a structure) and provided a *samefile()* function for comparison.

124569 **gid\_t** Some implementations had separated **gid\_t** from **uid\_t** before POSIX.1 was  
 124570 completed. It would be difficult for them to coalesce them when it was  
 124571 unnecessary. Additionally, it is quite possible that user IDs might be different from  
 124572 group IDs because the user ID might wish to span a heterogeneous network,  
 124573 where the group ID might not.

124574 For current implementations, the cost of having a separate **gid\_t** will be only  
 124575 lexical.

124576 **mode\_t** This type was chosen so that implementations could choose the appropriate  
 124577 integer type, and for compatibility with the ISO C standard. 4.3 BSD uses  
 124578 **unsigned short** and the SVID uses **ushort**, which is the same. Historically, only the  
 124579 low-order sixteen bits are significant.

124580 **nlink\_t** This type was introduced in place of **short** for *st\_nlink* (see the **<sys/stat.h>** header)  
 124581 in response to an objection that **short** was too small.

124582 **off\_t** This type is used to represent a file offset or file size. On systems supporting large  
 124583 files, **off\_t** is larger than 32 bits in at least one programming environment. Other  
 124584 programming environments may use different sizes for **off\_t**, for compatibility or  
 124585 other reasons.

124586 **pid\_t** The inclusion of this symbol was controversial because it is tied to the issue of the  
 124587 representation of a process ID as a number. From the point of view of a  
 124588 conforming application, process IDs should be “magic cookies”<sup>8</sup> that are produced  
 124589 by calls such as *fork()*, used by calls such as *waitpid()* or *kill()*, and not otherwise

---

124590 8. An historical term meaning: “An opaque object, or token, of determinate size, whose significance is known only to the entity which  
 124591 created it. An entity receiving such a token from the generating entity may only make such use of the ‘cookie’ as is defined and permitted  
 124592 by the supplying entity.”

|        |                |                                                                                                                                       |
|--------|----------------|---------------------------------------------------------------------------------------------------------------------------------------|
| 124593 |                | analyzed (except that the sign is used as a flag for certain operations).                                                             |
| 124594 |                | The concept of a {PID_MAX} value interacted with this in early proposals. Treating                                                    |
| 124595 |                | process IDs as an opaque type both removes the requirement for {PID_MAX} and                                                          |
| 124596 |                | allows systems to be more flexible in providing process IDs that span a large range                                                   |
| 124597 |                | of values, or a small one.                                                                                                            |
| 124598 |                | Since the values in <b>uid_t</b> , <b>gid_t</b> , and <b>pid_t</b> will be numbers generally, and                                     |
| 124599 |                | potentially both large in magnitude and sparse, applications that are based on                                                        |
| 124600 |                | arrays of objects of this type are unlikely to be fully portable in any case. Solutions                                               |
| 124601 |                | that treat them as magic cookies will be portable.                                                                                    |
| 124602 |                | {CHILD_MAX} precludes the possibility of a “toy implementation”, where there                                                          |
| 124603 |                | would only be one process.                                                                                                            |
| 124604 | <b>ssize_t</b> | This is intended to be a signed analog of <b>size_t</b> . The wording is such that an                                                 |
| 124605 |                | implementation may either choose to use a longer type or simply to use the signed                                                     |
| 124606 |                | version of the type that underlies <b>size_t</b> . All functions that return <b>ssize_t</b> ( <i>read()</i>                           |
| 124607 |                | and <i>write()</i> ) describe as “implementation-defined” the result of an input exceeding                                            |
| 124608 |                | {SSIZE_MAX}. It is recognized that some implementations might have <b>ints</b> that                                                   |
| 124609 |                | are smaller than <b>size_t</b> . A conforming application would be constrained not to                                                 |
| 124610 |                | perform I/O in pieces larger than {SSIZE_MAX}, but a conforming application                                                           |
| 124611 |                | using extensions would be able to use the full range if the implementation                                                            |
| 124612 |                | provided an extended range, while still having a single type-compatible interface.                                                    |
| 124613 |                | The symbols <b>size_t</b> and <b>ssize_t</b> are also required in <b>&lt;unistd.h&gt;</b> to minimize the                             |
| 124614 |                | changes needed for calls to <i>read()</i> and <i>write()</i> . Implementors are reminded that it                                      |
| 124615 |                | must be possible to include both <b>&lt;sys/types.h&gt;</b> and <b>&lt;unistd.h&gt;</b> in the same                                   |
| 124616 |                | program (in either order) without error.                                                                                              |
| 124617 | <b>uid_t</b>   | Before the addition of this type, the data types used to represent these values                                                       |
| 124618 |                | varied throughout early proposals. The <b>&lt;sys/stat.h&gt;</b> header defined these values                                          |
| 124619 |                | as type <b>short</b> , the <b>&lt;passwd.h&gt;</b> file (now <b>&lt;pwd.h&gt;</b> and <b>&lt;grp.h&gt;</b> ) used an <b>int</b> , and |
| 124620 |                | <i>getuid()</i> returned an <b>int</b> . In response to a strong objection to the inconsistent                                        |
| 124621 |                | definitions, all the types were switched to <b>uid_t</b> .                                                                            |
| 124622 |                | In practice, those historical implementations that use varying types of this sort can                                                 |
| 124623 |                | typedef <b>uid_t</b> to <b>short</b> with no serious consequences.                                                                    |
| 124624 |                | The problem associated with this change concerns object compatibility after                                                           |
| 124625 |                | structure size changes. Since most implementations will define <b>uid_t</b> as a short, the                                           |
| 124626 |                | only substantive change will be a reduction in the size of the <b>passwd</b> structure.                                               |
| 124627 |                | Consequently, implementations with an overriding concern for object                                                                   |
| 124628 |                | compatibility can pad the structure back to its current size. For that reason, this                                                   |
| 124629 |                | problem was not considered critical enough to warrant the addition of a separate                                                      |
| 124630 |                | type to POSIX.1.                                                                                                                      |
| 124631 |                | The types <b>uid_t</b> and <b>gid_t</b> are magic cookies. There is no {UID_MAX} defined by                                           |
| 124632 |                | POSIX.1, and no structure imposed on <b>uid_t</b> and <b>gid_t</b> other than that they be                                            |
| 124633 |                | positive arithmetic types. (In fact, they could be <b>unsigned char</b> .) There is no                                                |
| 124634 |                | maximum or minimum specified for the number of distinct user or group IDs.                                                            |

124635 B.2.12.2 *The char Type*

124636 POSIX.1-2008 explicitly requires that a **char** type is exactly one byte (8 bits).

124637 B.2.12.3 *Pointer Types*

124638 POSIX.1-2008 explicitly requires implementations to convert pointers to **void \*** and back with no  
124639 loss of information. This is an extension over the ISO C standard.

## 124640 B.3 System Interfaces

124641 See the RATIONALE sections on the individual reference pages.

### 124642 B.3.1 System Interfaces Removed in this Version

124643 The following section contains a list of the interfaces removed in POSIX.1-2008, together with  
124644 advice for application developers on the alternative interfaces that should be used for maximum  
124645 portability.

124646 B.3.1.1 *bcmp()*

124647 Applications are recommended to use the *memcmp()* function instead of this function.

124648 For maximum portability, it is recommended to replace the function call to *bcmp()* as follows:

124649 `#define bcmp(b1,b2,len) memcmp((b1), (b2), (size_t)(len))`

124650 B.3.1.2 *bcopy()*

124651 Applications are recommended to use the *memmove()* function instead of this function.

124652 The following are approximately equivalent (note the order of the arguments):

124653 `bcopy(s1,s2,n) ≈ memmove(s2,s1,n)`

124654 For maximum portability, it is recommended to replace the function call to *bcopy()* as follows:

124655 `#define bcopy(b1,b2,len) (void)memmove((b2), (b1), (len))`

124656 B.3.1.3 *bsd\_signal()*

124657 Applications are recommended to use the *sigaction()* function instead of this function.

124658 The *bsd\_signal()* function was supplied as a migration path for the BSD *signal()* function for  
124659 simple applications that installed a single-argument signal handler function.

124660 Historically, the *bsd\_signal()* function differs from *signal()* in that the SA\_RESTART flag is set  
124661 and the SA\_RESETHAND flag is clear when *bsd\_signal()* is used. The state of these flags is not  
124662 specified for *signal()*.

- 124663 B.3.1.4 *bzero()*
- 124664 Applications are recommended to use the *memset()* function instead of this function.
- 124665 For maximum portability, it is recommended to replace the function call to *bzero()* as follows:
- 124666 `#define bzero(b, len) (void) (memset ((b), '\0', (len)))`
- 
- 124667 B.3.1.5 *ecvt()*, *fcvt()*, *gcvt()*
- 124668 Applications are recommended to use the *sprintf()* function instead of these functions.
- 124669 The *sprintf()* function is required by ISO C and is thus more portable.
- 
- 124670 B.3.1.6 *ftime()*
- 124671 Applications are recommended to use the *time()* function to determine the current time.
- 124672 Realtime applications should use *clock\_gettime()* to determine the current time.
- 
- 124673 B.3.1.7 *getcontext()*, *makecontext()*, *swapcontext()*
- 124674 Due to portability issues with these functions, especially with the manipulation of contexts,
- 124675 applications are recommended to be rewritten to use POSIX threads.
- 
- 124676 B.3.1.8 *gethostbyaddr()*, *gethostbyname()*
- 124677 Applications are recommended to use the *getaddrinfo()* and *getnameinfo()* functions instead of
- 124678 these functions.
- 124679 The *gethostbyaddr()* and *gethostbyname()* functions may return pointers to static data, which may
- 124680 be overwritten by subsequent calls to any of these functions. The suggested replacements do not
- 124681 have this problem and are also IPv6-capable.
- 
- 124682 B.3.1.9 *getwd()*
- 124683 Applications are recommended to use the *getcwd()* function to determine the current working
- 124684 directory.
- 
- 124685 B.3.1.10 *h\_errno*
- 124686 Applications are recommended not to use this error return code. Previously it was set by the
- 124687 *gethostbyname()* and *gethostbyaddr()* functions.
- 
- 124688 B.3.1.11 *index()*
- 124689 Applications are recommended to use the *strchr()* function instead of this function.
- 124690 For maximum portability, it is recommended to replace the function call to *index()* as follows:
- 124691 `#define index(a, b) strchr ((a), (b))`

124692 B.3.1.12 *makecontext()*

124693 Applications using the *getcontext()*, *makecontext()*, and *swapcontext()* functions should be  
124694 rewritten to use POSIX threads.

124695 B.3.1.13 *mktemp()*

124696 Applications are recommended to use the *mkstemp()* function instead of this function.

124697 The *mktemp()* function makes an application vulnerable to possible security problems since  
124698 between the time a pathname is created and the file opened, it is possible for some other process  
124699 to create a file with the same name. The *mkstemp()* function does not have this vulnerability.

124700 B.3.1.14 *pthread\_attr\_getstackaddr()*, *pthread\_attr\_setstackaddr()*

124701 Applications are recommended to use the *pthread\_attr\_setstack()* and *pthread\_attr\_getstack()*  
124702 functions instead of these functions.

124703 There are a number of ambiguities in the specification of the *stackaddr* attribute that makes  
124704 portable use of these interfaces impossible.

124705 B.3.1.15 *rindex()*

124706 Applications are recommended to use the *strrchr()* function instead of this function.

124707 For maximum portability, it is recommended to replace the function call to *rindex()* as follows:

124708 `#define rindex(a,b) strrchr((a),(b))`

124709 B.3.1.16 *scalb()*

124710 Applications are recommended to use either *scalbln()*, *scalblnf()*, or *scalblnl()* instead of these  
124711 functions.

124712 The behavior for the *scalb()* function was only defined when the *n* argument is an integer, a  
124713 NaN, or Inf. The behavior of other values for the *n* argument was unspecified.

124714 B.3.1.17 *ualarm()*

124715 Applications are recommended to use *timer\_create()*, *timer\_delete()*, *timer\_getoverrun()*,  
124716 *timer\_gettime()*, or *timer\_settime()* instead of this function.

124717 B.3.1.18 *usleep()*

124718 Applications are recommended to use the *nanosleep()* function instead of this function.

124719 B.3.1.19 *vfork()*

124720 Applications are recommended to use the *fork()* function instead of this function.

124721 The *vfork()* function was previously under-specified.

124722 B.3.1.20 *wcswcs()*

124723 Applications are recommended to use the *wcsstr()* function instead of this function.

124724 The *wcsstr()* function is technically equivalent and is portable across all ISO C implementations.

### 124725 B.3.2 System Interfaces Removed in the Previous Version

124726 The following system interfaces, headers, and external variables were removed in the previous  
124727 version of this standard:

|        |                  |                        |                   |                          |               |
|--------|------------------|------------------------|-------------------|--------------------------|---------------|
| 124728 | <i>advance()</i> | <i>getdtablesize()</i> | <i>re_exec()</i>  | <i>ttyslot()</i>         | <i>loc1</i>   |
| 124729 | <i>brk()</i>     | <i>getpagesize()</i>   | <i>regcmp()</i>   | <i>valloc()</i>          | <i>__loc1</i> |
| 124730 | <i>chroot()</i>  | <i>getpass()</i>       | <i>regex()</i>    | <i>wait3()</i>           | <i>loc2</i>   |
| 124731 | <i>compile()</i> | <i>getw()</i>          | <i>sbrk()</i>     | <b>&lt;re_comp.h&gt;</b> | <i>locs</i>   |
| 124732 | <i>cuserid()</i> | <i>putw()</i>          | <i>sigstack()</i> | <b>&lt;regexp.h&gt;</b>  |               |
| 124733 | <i>gamma()</i>   | <i>re_comp()</i>       | <i>step()</i>     | <b>&lt;varargs.h&gt;</b> |               |

### 124734 B.3.3 Examples for Spawn

124735 The following long examples are provided in the Rationale (Informative) volume of  
124736 POSIX.1-2008 as a supplement to the reference page for *posix\_spawn()*.

#### 124737 Example Library Implementation of Spawn

124738 The *posix\_spawn()* or *posix\_spawnnp()* functions provide the following:

- 124739 • Simply start a process executing a process image. This is the simplest application for  
124740 process creation, and it may cover most executions of *fork()*.
- 124741 • Support I/O redirection, including pipes.
- 124742 • Run the child under a user and group ID in the domain of the parent.
- 124743 • Run the child at any priority in the domain of the parent.

124744 The *posix\_spawn()* or *posix\_spawnnp()* functions do not cover every possible use of the *fork()*  
124745 function, but they do span the common applications: typical use by a shell and a login utility.

124746 The price for an application is that before it calls *posix\_spawn()* or *posix\_spawnnp()*, the parent  
124747 must adjust to a state that *posix\_spawn()* or *posix\_spawnnp()* can map to the desired state for the  
124748 child. Environment changes require the parent to save some of its state and restore it afterwards.  
124749 The effective behavior of a successful invocation of *posix\_spawn()* is as if the operation were  
124750 implemented with POSIX operations as follows:

```

124751 #include <sys/types.h>
124752 #include <stdlib.h>
124753 #include <stdio.h>
124754 #include <unistd.h>
124755 #include <sched.h>
124756 #include <fcntl.h>
124757 #include <signal.h>
124758 #include <errno.h>
124759 #include <string.h>
124760 #include <signal.h>
124761 /* #include <spawn.h> */

```

```

124762 /*****
124763 /* Things that could be defined in spawn.h */
124764 *****/
124765 typedef struct
124766 {
124767 short posix_attr_flags;
124768 #define POSIX_SPAWN_SETPGROUP 0x1
124769 #define POSIX_SPAWN_SETSIGMASK 0x2
124770 #define POSIX_SPAWN_SETSIGDEF 0x4
124771 #define POSIX_SPAWN_SETSCHEDULER 0x8
124772 #define POSIX_SPAWN_SETSCHEDPARAM 0x10
124773 #define POSIX_SPAWN_RESETHIDS 0x20
124774 pid_t posix_attr_pgroup;
124775 sigset_t posix_attr_sigmask;
124776 sigset_t posix_attr_sigdefault;
124777 int posix_attr_schedpolicy;
124778 struct sched_param posix_attr_schedparam;
124779 } posix_spawnattr_t;
124780
124781 typedef char *posix_spawn_file_actions_t;
124782
124783 int posix_spawn_file_actions_init(
124784 posix_spawn_file_actions_t *file_actions);
124785 int posix_spawn_file_actions_destroy(
124786 posix_spawn_file_actions_t *file_actions);
124787 int posix_spawn_file_actions_addclose(
124788 posix_spawn_file_actions_t *file_actions, int fildes);
124789 int posix_spawn_file_actions_adddup2(
124790 posix_spawn_file_actions_t *file_actions, int fildes,
124791 int newfildes);

## 125149 **I/O Redirection with Spawn**

125150 I/O redirection with *posix\_spawn()* or *posix\_spawnnp()* is accomplished by crafting a *file\_actions*  
125151 argument to effect the desired redirection. Such a redirection follows the general outline of the  
125152 following example:

```

125153 /* To redirect new standard output (fd 1) to a file, */
125154 /* and redirect new standard input (fd 0) from my fd socket_pair[1], */
125155 /* and close my fd socket_pair[0] in the new process. */
125156 posix_spawn_file_actions_t file_actions;
125157 posix_spawn_file_actions_init(&file_actions);
125158 posix_spawn_file_actions_addopen(&file_actions, 1, "newout", ...);
125159 posix_spawn_file_actions_dup2(&file_actions, socket_pair[1], 0);
125160 posix_spawn_file_actions_close(&file_actions, socket_pair[0]);
125161 posix_spawn_file_actions_close(&file_actions, socket_pair[1]);
125162 posix_spawn(..., &file_actions, ...);

```

125163        `posix_spawn_file_actions_destroy(&file_actions);`

125164        **Spawning a Process Under a New User ID**

125165        Spawning a process under a new user ID follows the outline shown in the following example:

125166        `Save = getuid();`  
125167        `setuid(newid);`  
125168        `posix_spawn(...);`  
125169        `setuid(Save);`

125170

*The Open Group*

125174

*The Institute of Electrical and Electronics Engineers, Inc.*

125175

125176

*Rationale for Shell and Utilities*125177 **C.1 Introduction**125178 **C.1.1 Change History**

125179 The change history is provided as an informative section, to track changes from earlier versions  
125180 of this standard.

125181 The following sections describe changes made to the Shell and Utilities volume of POSIX.1-2008  
125182 since Issue 6 of the base document. The CHANGE HISTORY section for each utility describes  
125183 technical changes made to that utility from Issue 5. Changes between earlier versions of the base  
125184 document and Issue 5 are not included.

125185 **Changes from Issue 6 to Issue 7 (POSIX.1-2008)**

125186 The following list summarizes the major changes that were made in the Shell and Utilities  
125187 volume of POSIX.1-2008 from Issue 6 to Issue 7:

- 125188 • Austin Group defect reports, IEEE Interpretations against IEEE Std 1003.1, and responses  
125189 to ISO/IEC defect reports against ISO/IEC 9945 are applied.
- 125190 • The Open Group corrigenda and resolutions are applied.
- 125191 • Features, marked legacy or obsolescent in the base document, have been considered for  
125192 removal in this version.
- 125193 • A review of the use of fixed pathnames within the standard has been undertaken; for  
125194 example, the *at*, *batch*, and *crontab* utilities previously had a requirement for use of the  
125195 directory **/usr/lib/cron**.
- 125196 • The options within the standard have been revised.
  - 125197 — The Batch Environment Services and Utilities option is marked obsolescent.
  - 125198 — The UUCP utilities option is added.
  - 125199 — The User Portability Utilities option is revised so that only the *bg*, *ex*, *fc*, *fg*, *jobs*, *more*,  
125200 *talk*, and *vi* utilities are included, the rest being moved to the Base.

125201 **New Features in Issue 7**

125202 There are no new utilities in Issue 7.

125203 **C.1.2 Relationship to Other Documents**

125204 *C.1.2.1 System Interfaces*

125205 It has been pointed out that the Shell and Utilities volume of POSIX.1-2008 assumes that a great  
125206 deal of functionality from the System Interfaces volume of POSIX.1-2008 is present, but never  
125207 states exactly how much (and strictly does not need to since both are mandated on a conforming  
125208 system). This section is an attempt to clarify the assumptions.

125209 **File Read, Write, and Creation**

125210 IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/2 is applied, updating Table 1-1.

125211 **File Removal**

125212 This is intended to be a summary of the *unlink()* and *rmdir()* requirements. Note that it is  
125213 possible using the *unlink()* function for item 4. to occur.

125214 *C.1.2.2 Concepts Derived from the ISO C Standard*

125215 This section was introduced to address the issue that there was insufficient detail presented by  
125216 such utilities as *awk* or *sh* about their procedural control statements and their methods of  
125217 performing arithmetic functions.

125218 The ISO C standard was selected as a model because most historical implementations of the  
125219 standard utilities were written in C. Thus, it was more likely that they would act in the desired  
125220 manner without modification.

125221 Using the ISO C standard is primarily a notational convenience so that the many procedural  
125222 languages in the Shell and Utilities volume of POSIX.1-2008 would not have to be rigorously  
125223 described in every aspect. Its selection does not require that the standard utilities be written in  
125224 Standard C; they could be written in Common Usage C, Ada, Pascal, assembler language, or  
125225 anything else.

125226 The sizes of the various numeric values refer to C-language data types that are allowed to be  
125227 different sizes by the ISO C standard. Thus, like a C-language application, a shell application  
125228 cannot rely on their exact size. However, it can rely on their minimum sizes expressed in the  
125229 ISO C standard, such as {LONG\_MAX} for a **long** type.

125230 The behavior on overflow is undefined for ISO C standard arithmetic. Therefore, the standard  
125231 utilities can use “bignum” representation for integers so that there is no fixed maximum unless  
125232 otherwise stated in the utility description. Similarly, standard utilities can use infinite-precision  
125233 representations for floating-point arithmetic, as long as these representations exceed the ISO C  
125234 standard requirements.

125235 This section addresses only the issue of semantics; it is not intended to specify syntax. For  
125236 example, the ISO C standard requires that 0L be recognized as an integer constant equal to zero,  
125237 but utilities such as *awk* and *sh* are not required to recognize 0L (though they are allowed to, as  
125238 an extension).

The ISO C standard requires that a C compiler must issue a diagnostic for constants that are too large to represent. Most standard utilities are not required to issue these diagnostics; for example, the command:

```
diff -C 2147483648 file1 file2
```

has undefined behavior, and the *diff* utility is not required to issue a diagnostic even if the number 2 147 483 648 cannot be represented.

### C.1.3 Utility Limits

This section grew out of an idea that originated with the original POSIX.1, in the tables of system limits for the *sysconf()* and *pathconf()* functions. The idea being that a conforming application can be written to use the most restrictive values that a minimal system can provide, but it should not have to. The values provided represent compromises so that some vendors can use historically limited versions of UNIX system utilities. They are the highest values that a strictly conforming application can assume, given no other information.

However, by using the *getconf* utility or the *sysconf()* function, the elegant application can be tailored to more liberal values on some of the specific instances of specific implementations.

There is no explicitly stated requirement that an implementation provide finite limits for any of these numeric values; the implementation is free to provide essentially unbounded capabilities (where it makes sense), stopping only at reasonable points such as {ULONG\_MAX} (from the ISO C standard). Therefore, applications desiring to tailor themselves to the values on a particular implementation need to be ready for possibly huge values; it may not be a good idea to allocate blindly a buffer for an input line based on the value of {LINE\_MAX}, for instance. However, unlike the System Interfaces volume of POSIX.1-2008, there is no set of limits that return a special indication meaning “unbounded”. The implementation should always return an actual number, even if the number is very large.

The statement:

“It is not guaranteed that the application ...”

is an indication that many of these limits are designed to ensure that implementors design their utilities without arbitrary constraints related to unimaginative programming. There are certainly conditions under which combinations of options can cause failures that would not render an implementation non-conforming. For example, {EXPR\_NEST\_MAX} and {ARG\_MAX} could collide when expressions are large; combinations of {BC\_SCALE\_MAX} and {BC\_DIM\_MAX} could exceed virtual memory.

In the Shell and Utilities volume of POSIX.1-2008, the notion of a limit being guaranteed for the process lifetime, as it is in the System Interfaces volume of POSIX.1-2008, is not as useful to a shell script. The *getconf* utility is probably a process itself, so the guarantee would be without value. Therefore, the Shell and Utilities volume of POSIX.1-2008 requires the guarantee to be for the session lifetime. This will mean that many vendors will either return very conservative values or possibly implement *getconf* as a built-in.

It may seem confusing to have limits that apply only to a single utility grouped into one global section. However, the alternative, which would be to disperse them out into their utility description sections, would cause great difficulty when *sysconf()* and *getconf* were described. Therefore, the standard developers chose the global approach.

Each language binding could provide symbol names that are slightly different from those shown here. For example, the C-Language Binding option adds a leading <underscore> to the symbols as a prefix.

125284 The following comments describe selection criteria for the symbols and their values:

125285 {ARG\_MAX}

125286 This is defined by the System Interfaces volume of POSIX.1-2008. Unfortunately, it is very

125287 difficult for a conforming application to deal with this value, as it does not know how much

125288 of its argument space is being consumed by the environment variables of the user.

125289 {BC\_BASE\_MAX}

125290 {BC\_DIM\_MAX}

125291 {BC\_SCALE\_MAX}

125292 These were originally one value, {BC\_SCALE\_MAX}, but it was unreasonable to link all

125293 three concepts into one limit.

125294 {CHILD\_MAX}

125295 This is defined by the System Interfaces volume of POSIX.1-2008.

125296 {COLL\_WEIGHTS\_MAX}

125297 The weights assigned to **order** can be considered as “passes” through the collation

125298 algorithm.

125299 {EXPR\_NEST\_MAX}

125300 The value for expression nesting was borrowed from the ISO C standard.

125301 {LINE\_MAX}

125302 This is a global limit that affects all utilities, unless otherwise noted. The {MAX\_CANON}

125303 value from the System Interfaces volume of POSIX.1-2008 may further limit input lines from

125304 terminals. The {LINE\_MAX} value was the subject of much debate and is a compromise

125305 between those who wished to have unlimited lines and those who understood that many

125306 historical utilities were written with fixed buffers. Frequently, utility writers selected the

125307 UNIX system constant BUFSIZ to allocate these buffers; therefore, some utilities were

125308 limited to 512 bytes for I/O lines, while others achieved 4 096 bytes or greater.

125309 It should be noted that {LINE\_MAX} applies only to input line length; there is no

125310 requirement in POSIX.1-2008 that limits the length of output lines. Utilities such as *awk*, *sed*,

125311 and *paste* could theoretically construct lines longer than any of the input lines they received,

125312 depending on the options used or the instructions from the application. They are not

125313 required to truncate their output to {LINE\_MAX}. It is the responsibility of the application

125314 to deal with this. If the output of one of those utilities is to be piped into another of the

125315 standard utilities, line length restrictions will have to be considered; the *fold* utility, among

125316 others, could be used to ensure that only reasonable line lengths reach utilities or

125317 applications.

125318 {LINK\_MAX}

125319 This is defined by the System Interfaces volume of POSIX.1-2008.

125320 {MAX\_CANON}

125321 {MAX\_INPUT}

125322 {NAME\_MAX}

125323 {NGROUPS\_MAX}

125324 {OPEN\_MAX}

125325 {PATH\_MAX}

125326 {PIPE\_BUF}

125327 These limits are defined by the System Interfaces volume of POSIX.1-2008. Note that the

125328 byte lengths described by some of these values continue to represent bytes, even if the

125329 applicable character set uses a multi-byte encoding.

125330 {RE\_DUP\_MAX}  
 125331 The value selected is consistent with historical practice. Although the name implies that it  
 125332 applies to all REs, only BREs use the interval notation  $\{m,n\}$  addressed by this limit.

125333 {POSIX2\_SYMLINKS}  
 125334 The {POSIX2\_SYMLINKS} variable indicates that the underlying operating system supports  
 125335 the creation of symbolic links in specific directories. Many of the utilities defined in  
 125336 POSIX.1-2008 that deal with symbolic links do not depend on this value. For example, a  
 125337 utility that follows symbolic links (or does not, as the case may be) will only be affected by a  
 125338 symbolic link if it encounters one. Presumably, a file system that does not support symbolic  
 125339 links will not contain any. This variable does affect such utilities as *ln -s* and *pax* that  
 125340 attempt to create symbolic links.

125341 There are different limits associated with command lines and input to utilities, depending on the  
 125342 method of invocation. In the case of a C program *exec*-ing a utility, {ARG\_MAX} is the  
 125343 underlying limit. In the case of the shell reading a script and *exec*-ing a utility, {LINE\_MAX}  
 125344 limits the length of lines the shell is required to process, and {ARG\_MAX} will still be a limit. If a  
 125345 user is entering a command on a terminal to the shell, requesting that it invoke the utility,  
 125346 {MAX\_INPUT} may restrict the length of the line that can be given to the shell to a value below  
 125347 {LINE\_MAX}.

125348 When an option is supported, *getconf* returns a value of 1. For example, when C development is  
 125349 supported:

```
125350 if ["$(getconf POSIX2_C_DEV)" -eq 1]; then
125351 echo C supported
125352 fi
```

125353 The *sysconf()* function in the C-Language Binding option would return 1.

125354 The following comments describe selection criteria for the symbols and their values:

125355 POSIX2\_C\_BIND  
 125356 POSIX2\_C\_DEV  
 125357 POSIX2\_FORT\_DEV  
 125358 POSIX2\_FORT\_RUN  
 125359 POSIX2\_SW\_DEV  
 125360 POSIX2\_UPE

125361 It is possible for some (usually privileged) operations to remove utilities that support these  
 125362 options or otherwise to render these options unsupported. The header files, the *sysconf()*  
 125363 function, or the *getconf* utility will not necessarily detect such actions, in which case they  
 125364 should not be considered as rendering the implementation non-conforming. A test suite  
 125365 should not attempt tests such as:

```
125366 rm /usr/bin/c99
125367 getconf POSIX2_C_DEV
```

125368 POSIX2\_LOCALEDEF  
 125369 This symbol was introduced to allow implementations to restrict supported locales to only  
 125370 those supplied by the implementation.

125371 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/2 is applied, deleting the entry for  
 125372 {POSIX2\_VERSION} since it is not a utility limit minimum value.

125373 IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/3 is applied, changing the text in Utility  
 125374 Limits from: “utility (see *getconf*) through the *sysconf()* function defined in the System Interfaces  
 125375 volume of POSIX.1-2008. The literal names shown in Table 1-3 apply only to the *getconf* utility;  
 125376 the high-level language binding describes the exact form of each name to be used by the

125377 interfaces in that binding.” to: “utility (see *getconf*).”.

#### 125378 **C.1.4 Grammar Conventions**

125379 There is no additional rationale provided for this section.

#### 125380 **C.1.5 Utility Description Defaults**

125381 This section is arranged with headings in the same order as all the utility descriptions. It is a  
125382 collection of related and unrelated information concerning:

- 125383 1. The default actions of utilities
- 125384 2. The meanings of notations used in POSIX.1-2008 that are specific to individual utility  
125385 sections

125386 Although this material may seem out of place here, it is important that this information appear  
125387 before any of the utilities to be described later.

#### 125388 **NAME**

125389 There is no additional rationale provided for this section.

#### 125390 **SYNOPSIS**

125391 There is no additional rationale provided for this section.

#### 125392 **DESCRIPTION**

125393 There is no additional rationale provided for this section.

#### 125394 **OPTIONS**

125395 Although it has not always been possible, the standard developers tried to avoid repeating  
125396 information to reduce the risk that duplicate explanations could each be modified differently.

125397 The need to recognize `--` is required because conforming applications need to shield their  
125398 operands from any arbitrary options that the implementation may provide as an extension. For  
125399 example, if the standard utility *foo* is listed as taking no options, and the application needed to  
125400 give it a pathname with a leading `<hyphen>`, it could safely do it as:

125401 `foo -- -myfile`

125402 and avoid any problems with `-m` used as an extension.

#### 125403 **OPERANDS**

125404 The usage of `-` is never shown in the SYNOPSIS. Similarly, the usage of `--` is never shown.

125405 The requirement for processing operands in command-line order is to avoid a “WeirdNIX”  
125406 utility that might choose to sort the input files alphabetically, by size, or by directory order.  
125407 Although this might be acceptable for some utilities, in general the programmer has a right to  
125408 know exactly what order will be chosen.

125409 Some of the standard utilities take multiple *file* operands and act as if they were processing the  
125410 concatenation of those files. For example:

125411 `asa file1 file2`

125412 and:

125413 `cat file1 file2 | asa`

125414 have similar results when questions of file access, errors, and performance are ignored. Other  
 125415 utilities such as *grep* or *wc* have completely different results in these two cases. This latter type of  
 125416 utility is always identified in its DESCRIPTION or OPERANDS sections, whereas the former is  
 125417 not. Although it might be possible to create a general assertion about the former case, the  
 125418 following points must be addressed:

- 125419 • Access times for the files might be different in the operand case *versus* the *cat* case.
- 125420 • The utility may have error messages that are cognizant of the input filename, and this  
 125421 added value should not be suppressed. (As an example, *awk* sets a variable with the  
 125422 filename at each file boundary.)

## 125423 STDIN

125424 There is no additional rationale provided for this section.

## 125425 INPUT FILES

125426 A conforming application cannot assume the following three commands are equivalent:

```
125427 tail -n +2 file
125428 (sed -n 1q; cat) < file
125429 cat file | (sed -n 1q; cat)
```

125430 The second command is equivalent to the first only when the file is seekable. In the third  
 125431 command, if the file offset in the open file description were not unspecified, *sed* would have to  
 125432 be implemented so that it read from the pipe 1 byte at a time or it would have to employ some  
 125433 method to seek backwards on the pipe. Such functionality is not defined currently in POSIX.1  
 125434 and does not exist on all historical systems. Other utilities, such as *head*, *read*, and *sh*, have similar  
 125435 properties, so the restriction is described globally in this section.

125436 The definition of “text file” is strictly enforced for input to the standard utilities; very few of  
 125437 them list exceptions to the undefined results called for here. (Of course, “undefined” here does  
 125438 not mean that historical implementations necessarily have to change to start indicating error  
 125439 conditions. Conforming applications cannot rely on implementations succeeding or failing when  
 125440 non-text files are used.)

125441 The utilities that allow line continuation are generally those that accept input languages, rather  
 125442 than pure data. It would be unusual for an input line of this type to exceed {LINE\_MAX} bytes  
 125443 and unreasonable to require that the implementation allow unlimited accumulation of multiple  
 125444 lines, each of which could reach {LINE\_MAX}. Thus, for a conforming application the total of all  
 125445 the continued lines in a set cannot exceed {LINE\_MAX}.

125446 The format description is intended to be sufficiently rigorous to allow other applications to  
 125447 generate these input files. However, since <blank> characters can legitimately be included in  
 125448 some of the fields described by the standard utilities, particularly in locales other than the POSIX  
 125449 locale, this intent is not always realized.

**ENVIRONMENT VARIABLES**

There is no additional rationale provided for this section.

**ASYNCHRONOUS EVENTS**

Because there is no language prohibiting it, a utility is permitted to catch a signal, perform some additional processing (such as deleting temporary files), restore the default signal action (or action inherited from the parent process), and resignal itself.

**STDOUT**

The format description is intended to be sufficiently rigorous to allow post-processing of output by other programs, particularly by an *awk* or *lex* parser.

**STDERR**

This section does not describe error messages that refer to incorrect operation of the utility. Consider a utility that processes program source code as its input. This section is used to describe messages produced by a correctly operating utility that encounters an error in the program source code on which it is processing. However, a message indicating that the utility had insufficient memory in which to operate would not be described.

Some utilities have traditionally produced warning messages without returning a non-zero exit status; these are specifically noted in their sections. Other utilities shall not write to standard error if they complete successfully, unless the implementation provides some sort of extension to increase the verbosity or debugging level.

The format descriptions are intended to be sufficiently rigorous to allow post-processing of output by other programs.

**OUTPUT FILES**

The format description is intended to be sufficiently rigorous to allow post-processing of output by other programs, particularly by an *awk* or *lex* parser.

Receipt of the SIGQUIT signal should generally cause termination (unless in some debugging mode) that would bypass any attempted recovery actions.

**EXTENDED DESCRIPTION**

There is no additional rationale provided for this section.

**EXIT STATUS**

Note the additional discussion of exit values in *Exit Status for Commands* in the *sh* utility. It describes requirements for returning exit values greater than 125.

A utility may list zero as a successful return, 1 as a failure for a specific reason, and greater than 1 as “an error occurred”. In this case, unspecified conditions may cause a 2 or 3, or other value, to be returned. A strictly conforming application should be written so that it tests for successful exit status values (zero in this case), rather than relying upon the single specific error value listed in POSIX.1-2008. In that way, it will have maximum portability, even on implementations with extensions.

The standard developers are aware that the general non-enumeration of errors makes it difficult to write test suites that test the *incorrect* operation of utilities. There are some historical implementations that have expended effort to provide detailed status messages and a helpful environment to bypass or explain errors, such as prompting, retrying, or ignoring unimportant

125491 syntax errors; other implementations have not. Since there is no realistic way to mandate system  
 125492 behavior in cases of undefined application actions or system problems—in a manner acceptable  
 125493 to all cultures and environments—attention has been limited to the correct operation of utilities  
 125494 by the conforming application. Furthermore, the conforming application does not need detailed  
 125495 information concerning errors that it caused through incorrect usage or that it cannot correct.

125496 There is no description of defaults for this section because all of the standard utilities specify  
 125497 something (or explicitly state “Unspecified”) for exit status.

## 125498 **CONSEQUENCES OF ERRORS**

125499 Several actions are possible when a utility encounters an error condition, depending on the  
 125500 severity of the error and the state of the utility. Included in the possible actions of various  
 125501 utilities are: deletion of temporary or intermediate work files; deletion of incomplete files; and  
 125502 validity checking of the file system or directory.

125503 The text about recursive traversing is meant to ensure that utilities such as *find* process as many  
 125504 files in the hierarchy as they can. They should not abandon all of the hierarchy at the first error  
 125505 and resume with the next command-line operand, but should attempt to keep going.

125506 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0001 [150] is applied.

## 125507 **APPLICATION USAGE**

125508 This section provides additional caveats, issues, and recommendations to the developer.

## 125509 **EXAMPLES**

125510 This section provides sample usage.

## 125511 **RATIONALE**

125512 There is no additional rationale provided for this section.

## 125513 **FUTURE DIRECTIONS**

125514 FUTURE DIRECTIONS sections act as pointers to related work that may impact the interface in  
 125515 the future, and often cautions the developer to architect the code to account for a change in this  
 125516 area. Note that a future directions statement should not be taken as a commitment to adopt a  
 125517 feature or interface in the future.

## 125518 **SEE ALSO**

125519 There is no additional rationale provided for this section.

## 125520 **CHANGE HISTORY**

125521 There is no additional rationale provided for this section.

## C.1.6 Considerations for Utilities in Support of Files of Arbitrary Size

This section is intended to clarify the requirements for utilities in support of large files.

The utilities listed in this section are utilities which are used to perform administrative tasks such as to create, move, copy, remove, change the permissions, or measure the resources of a file. They are useful both as end-user tools and as utilities invoked by applications during software installation and operation.

The *chgrp*, *chmod*, *chown*, *ln*, and *rm* utilities probably require use of large file-capable versions of *stat()*, *lstat()*, *ftw()*, and the **stat** structure.

The *cat*, *cksum*, *cmp*, *cp*, *dd*, *mv*, *sum*, and *touch* utilities probably require use of large file-capable versions of *creat()*, *open()*, and *fopen()*.

The *cat*, *cksum*, *cmp*, *dd*, *df*, *du*, *ls*, and *sum* utilities may require writing large integer values. For example:

- The *cat* utility might have a **-n** option which counts <newline> characters.
- The *cksum* and *ls* utilities report file sizes.
- The *cmp* utility reports the line number at which the first difference occurs, and also has a **-l** option which reports file offsets.
- The *dd*, *df*, *du*, *ls*, and *sum* utilities report block counts.

The *dd*, *find*, and *test* utilities may need to interpret command arguments that contain 64-bit values. For *dd*, the arguments include *skip=n*, *seek=n*, and *count=n*. For *find*, the arguments include **-sizen**. For *test*, the arguments are those associated with algebraic comparisons.

The *df* utility might need to access large file systems with *statvfs()*.

The *ulimit* utility will need to use large file-capable versions of *getrlimit()* and *setrlimit()* and be able to read and write large integer values.

## C.1.7 Built-In Utilities

All of these utilities can be *exec*-ed. There is no requirement that these utilities are actually built into the shell itself, but many shells need the capability to do so because XCU [Section 2.9.1.1](#) (on page 2339) requires that they be found prior to the *PATH* search. The shell could satisfy its requirements by keeping a list of the names and directly accessing the file-system versions regardless of *PATH*. Providing all of the required functionality for those such as *cd* or *read* would be more difficult.

There were originally three justifications for allowing the omission of *exec*-able versions:

1. It would require wasting space in the file system, at the expense of very small systems. However, it has been pointed out that all 16 utilities in the table can be provided with 16 links to a single-line shell script:
2. It is not logical to require invocation of utilities such as *cd* because they have no value outside the shell environment or cannot be useful in a child process. However, counter-examples always seemed to be available for even the most unusual cases:

```
find . -type d -exec cd {} \; -exec foo {} \;
 (which invokes "foo" on accessible directories)
```

```
ps ... | sed ... | xargs kill
```

125563 `find . -exec true \; -a ...`

125564 (where “true” is used for temporary debugging)

- 125565 3. It is confusing to have a utility such as *kill* that can easily be in the file system in the base  
 125566 standard, but that requires built-in status for the User Portability Utilities option (for the  
 125567 % job control job ID notation). It was decided that it was more appropriate to describe the  
 125568 required functionality (rather than the implementation) to the system implementors and  
 125569 let them decide how to satisfy it.

125570 On the other hand, it was realized that any distinction like this between utilities was not useful  
 125571 to applications, and that the cost to correct it was small. These arguments were ultimately the  
 125572 most effective.

125573 There were varying reasons for including utilities in the table of built-ins:

125574 *alias, fc, unalias*

125575 The functionality of these utilities is performed more simply within the shell itself and that  
 125576 is the model most historical implementations have used.

125577 *bg, fg, jobs*

125578 All of the job control-related utilities are eligible for built-in status because that is the model  
 125579 most historical implementations have used.

125580 *cd, getopts, newgrp, read, umask, wait*

125581 The functionality of these utilities is performed more simply within the context of the  
 125582 current process. An example can be taken from the usage of the *cd* utility. The purpose of  
 125583 the *cd* utility is to change the working directory for subsequent operations. The actions of *cd*  
 125584 affect the process in which *cd* is executed and all subsequent child processes of that process.  
 125585 Based on the POSIX standard process model, changes in the process environment of a child  
 125586 process have no effect on the parent process. If the *cd* utility were executed from a child  
 125587 process, the working directory change would be effective only in the child process. Child  
 125588 processes initiated subsequent to the child process that executed the *cd* utility would not  
 125589 have a changed working directory relative to the parent process.

125590 *command*

125591 This utility was placed in the table primarily to protect scripts that are concerned about  
 125592 their *PATH* being manipulated. The “secure” shell script example in the *command* utility in  
 125593 the Shell and Utilities volume of POSIX.1-2008 would not be possible if a *PATH* change  
 125594 retrieved an alien version of *command*. (An alternative would have been to implement  
 125595 *getconf* as a built-in, but the standard developers considered that it carried too many  
 125596 changing configuration strings to require in the shell.)

125597 *kill* Since *kill* provides optional job control functionality using shell notation (%1, %2, and so on),  
 125598 some implementations would find it extremely difficult to provide this outside the shell.

125599 *true, false*

125600 These are in the table as a courtesy to programmers who wish to use the “while true”  
 125601 shell construct without protecting *true* from *PATH* searches. (It is acknowledged that  
 125602 “while :” also works, but the idiom with *true* is historically pervasive.)

125603 All utilities, including those in the table, are accessible via the *system()* and *popen()* functions in  
 125604 the System Interfaces volume of POSIX.1-2008. There are situations where the return  
 125605 functionality of *system()* and *popen()* is not desirable. Applications that require the exit status of  
 125606 the invoked utility will not be able to use *system()* or *popen()*, since the exit status returned is  
 125607 that of the command language interpreter rather than that of the invoked utility. The alternative  
 125608 for such applications is the use of the *exec* family.

## 125609 C.2 Shell Command Language

### 125610 C.2.1 Shell Introduction

125611 The System V shell was selected as the starting point for the Shell and Utilities volume of  
125612 POSIX.1-2008. The BSD C shell was excluded from consideration for the following reasons:

- 125613 • Most historically portable shell scripts assume the Version 7 Bourne shell, from which the  
125614 System V shell is derived.
- 125615 • The majority of tutorial materials on shell programming assume the System V shell.

125616 The construct "#!" is reserved for implementations wishing to provide that extension. If it were  
125617 not reserved, the Shell and Utilities volume of POSIX.1-2008 would disallow it by forcing it to be  
125618 a comment. As it stands, a strictly conforming application must not use "#!" as the first two  
125619 characters of the file.

### 125620 C.2.2 Quoting

125621 There is no additional rationale provided for this section.

#### 125622 C.2.2.1 Escape Character (Backslash)

125623 There is no additional rationale provided for this section.

#### 125624 C.2.2.2 Single-Quotes

125625 A <backslash> cannot be used to escape a single-quote in a single-quoted string. An embedded  
125626 quote can be created by writing, for example: "'a'\''b'", which yields "a'b". (See XCU  
125627 [Section 2.6.5](#) (on page 2333) for a better understanding of how portions of words are either split  
125628 into fields or remain concatenated.) A single token can be made up of concatenated partial  
125629 strings containing all three kinds of quoting or escaping, thus permitting any combination of  
125630 characters.

#### 125631 C.2.2.3 Double-Quotes

125632 The escaped <newline> used for line continuation is removed entirely from the input and is not  
125633 replaced by any white space. Therefore, it cannot serve as a token separator.

125634 In double-quoting, if a <backslash> is immediately followed by a character that would be  
125635 interpreted as having a special meaning, the <backslash> is deleted and the subsequent  
125636 character is taken literally. If a <backslash> does not precede a character that would have a  
125637 special meaning, it is left in place unmodified and the character immediately following it is also  
125638 left unmodified. Thus, for example:

125639 "\$" -> \$

125640 "\a" -> \a

125641 It would be desirable to include the statement “The characters from an enclosed "\${" to the  
125642 matching '}' shall not be affected by the double-quotes”, similar to the one for "\${)".  
125643 However, historical practice in the System V shell prevents this.

The requirement that double-quotes be matched inside "\${...}" within double-quotes and the rule for finding the matching '}' in XCU [Section 2.6.2](#) (on page 2328) eliminate several subtle inconsistencies in expansion for historical shells in rare cases; for example:

```
"${foo-bar}"
```

yields **bar** when **foo** is not defined, and is an invalid substitution when **foo** is defined, in many historical shells. The differences in processing the "\${...}" form have led to inconsistencies between historical systems. A consequence of this rule is that single-quotes cannot be used to quote the '}' within "\${...}"; for example:

```
unset bar
foo="${bar-' }' "
```

is invalid because the "\${...}" substitution contains an unpaired unescaped single-quote. The `<backslash>` can be used to escape the '}' in this example to achieve the desired result:

```
unset bar
foo="${bar-\} } "
```

The differences in processing the "\${...}" form have led to inconsistencies between the historical System V shell, BSD, and KornShells, and the text in the Shell and Utilities volume of POSIX.1-2008 is an attempt to converge them without breaking too many applications. The only alternative to this compromise between shells would be to make the behavior unspecified whenever the literal characters single-quote, '{', '}', and '"' appear within "\${...}". To write a portable script that uses these values, a user would have to assign variables; for example:

```
squote='\ ' dquote=\" lbrace='{ ' rbrace='}'
${foo-$squote$rbrace$squote}
```

rather than:

```
${foo-"' }' " }
```

Some implementations have allowed the end of the word to terminate the backquoted command substitution, such as in:

```
" `echo hello"
```

This usage is undefined; the matching backquote is required by the Shell and Utilities volume of POSIX.1-2008. The other undefined usage can be illustrated by the example:

```
sh -c '` echo "foo`'
```

The description of the recursive actions involving command substitution can be illustrated with an example. Upon recognizing the introduction of command substitution, the shell parses input (in a new context), gathering the source for the command substitution until an unbalanced ')' or '`' is located. For example, in the following:

```
echo "$(date; echo "
 one")"
```

the double-quote following the *echo* does not terminate the first double-quote; it is part of the command substitution script. Similarly, in:

```
echo "$(echo *)"
```

the `<asterisk>` is not quoted since it is inside command substitution; however:

```
echo "$(echo "*)" "
```

is quoted (and represents the `<asterisk>` character itself).

**C.2.3 Token Recognition**

The "(" and ")" symbols are control operators in the KornShell, used for an alternative syntax of an arithmetic expression command. A conforming application cannot use "(" as a single token (with the exception of the "\$(" form for shell arithmetic).

On some implementations, the symbol "(" is a control operator; its use produces unspecified results. Applications that wish to have nested subshells, such as:

```
((echo Hello); (echo World))
```

must separate the "(" characters into two tokens by including white space between them. Some systems may treat these as invalid arithmetic expressions instead of subshells.

Certain combinations of characters are invalid in portable scripts, as shown in the grammar. Implementations may use these combinations (such as "|&") as valid control operators. Portable scripts cannot rely on receiving errors in all cases where this volume of POSIX.1-2008 indicates that a syntax is invalid.

The (3) rule about combining characters to form operators is not meant to preclude systems from extending the shell language when characters are combined in otherwise invalid ways. Conforming applications cannot use invalid combinations, and test suites should not penalize systems that take advantage of this fact. For example, the unquoted combination "|&" is not valid in a POSIX script, but has a specific KornShell meaning.

The (10) rule about '#' as the current character is the first in the sequence in which a new token is being assembled. The '#' starts a comment only when it is at the beginning of a token. This rule is also written to indicate that the search for the end-of-comment does not consider escaped <newline> specially, so that a comment cannot be continued to the next line.

**C.2.3.1 Alias Substitution**

The alias capability was added because it is widely used in historical implementations by interactive users.

The definition of "alias name" precludes an alias name containing a <slash> character. Since the text applies to the command words of simple commands, reserved words (in their proper places) cannot be confused with aliases.

The placement of alias substitution in token recognition makes it clear that it precedes all of the word expansion steps.

An example concerning trailing <blank> characters and reserved words follows. If the user types:

```
$ alias foo="/bin/ls "
$ alias while="/"
```

The effect of executing:

```
$ while true
> do
> echo "Hello, World"
> done
```

is a never-ending sequence of "Hello, World" strings to the screen. However, if the user types:

```
$ foo while
```

125728 the result is an *ls* listing of */*. Since the alias substitution for **foo** ends in a <space>, the next word  
 125729 is checked for alias substitution. The next word, **while**, has also been aliased, so it is substituted  
 125730 as well. Since it is not in the proper position as a command word, it is not recognized as a  
 125731 reserved word.

125732 If the user types:

125733 **\$** foo; while

125734 **while** retains its normal reserved-word properties.

## 125735 C.2.4 Reserved Words

125736 All reserved words are recognized syntactically as such in the contexts described. However, note  
 125737 that **in** is the only meaningful reserved word after a **case** or **for**; similarly, **in** is not meaningful as  
 125738 the first word of a simple command.

125739 Reserved words are recognized only when they are delimited (that is, meet the definition of XBD  
 125740 Section 3.440, on page 104), whereas operators are themselves delimiters. For instance, ' ( ' and  
 125741 ' ) ' are control operators, so that no <space> is needed in (*list*). However, ' { ' and ' } ' are  
 125742 reserved words in { *list*; }, so that in this case the leading <space> and <semicolon> are required.

125743 The list of unspecified reserved words is from the KornShell, so conforming applications cannot  
 125744 use them in places a reserved word would be recognized. This list contained **time** in early  
 125745 proposals, but it was removed when the *time* utility was selected for the Shell and Utilities  
 125746 volume of POSIX.1-2008.

125747 There was a strong argument for promoting braces to operators (instead of reserved words), so  
 125748 they would be syntactically equivalent to subshell operators. Concerns about compatibility  
 125749 outweighed the advantages of this approach. Nevertheless, conforming applications should  
 125750 consider quoting ' { ' and ' } ' when they represent themselves.

125751 The restriction on ending a name with a <colon> is to allow future implementations that support  
 125752 named labels for flow control; see the RATIONALE for the *break* built-in utility.

125753 It is possible that a future version of the Shell and Utilities volume of POSIX.1-2008 may require  
 125754 that ' { ' and ' } ' be treated individually as control operators, although the token "{ }" will  
 125755 probably be a special-case exemption from this because of the often-used *find*{ } construct.

## 125756 C.2.5 Parameters and Variables

### 125757 C.2.5.1 Positional Parameters

125758 There is no additional rationale provided for this section.

### 125759 C.2.5.2 Special Parameters

125760 Most historical implementations implement subshells by forking; thus, the special parameter  
 125761 ' \$ ' does not necessarily represent the process ID of the shell process executing the commands  
 125762 since the subshell execution environment preserves the value of ' \$ '.

125763 If a subshell were to execute a background command, the value of " \$ ! " for the parent would  
 125764 not change. For example:

```

125765 (
125766 date &
125767 echo $!
125768)
125769 echo $!

```

125770 would echo two different values for "\$!".

125771 The "\$-" special parameter can be used to save and restore *set* options:

```

125772 Save=$(echo $- | sed 's/[ics]//g')
125773 ...
125774 set +aCefnuvx
125775 if [-n "$Save"]; then
125776 set -$Save
125777 fi

```

125778 The three options are removed using *sed* in the example because they may appear in the value of  
 125779 "\$-" (from the *sh* command line), but are not valid options to *set*.

125780 The descriptions of parameters '\*' and '@' assume the reader is familiar with the field  
 125781 splitting discussion in XCU [Section 2.6.5](#) (on page 2333) and understands that portions of the  
 125782 word remain concatenated unless there is some reason to split them into separate fields.

125783 Some examples of the '\*' and '@' properties, including the concatenation aspects:

```

125784 set "abc" "def ghi" "jkl"

125785 echo $* => "abc" "def" "ghi" "jkl"
125786 echo "$*" => "abc def ghi jkl"
125787 echo $@ => "abc" "def" "ghi" "jkl"

```

125788 but:

```

125789 echo "$@" => "abc" "def ghi" "jkl"
125790 echo "xx$@yy" => "xxabc" "def ghi" "jkl"yy"
125791 echo "$@$@" => "abc" "def ghi" "jklabc" "def ghi" "jkl"

```

125792 In the preceding examples, the double-quote characters that appear after the "=>" do not  
 125793 appear in the output and are used only to illustrate word boundaries.

125794 The following example illustrates the effect of setting *IFS* to a null string:

```

125795 $ IFS=''
125796 $ set foo bar bam
125797 $ echo "$@"
125798 foo bar bam
125799 $ echo "$*"
125800 foobarbam
125801 $ unset IFS
125802 $ echo "$*"
125803 foo bar bam

```

## 125804 C.2.5.3 Shell Variables

125805 See the discussion of *IFS* in [Section C.2.6.5](#) (on page 3688) and the RATIONALE for the *sh* utility.

125806 The prohibition on *LC\_CTYPE* changes affecting lexical processing protects the shell  
 125807 implementor (and the shell programmer) from the ill effects of changing the definition of  
 125808 <blank> or the set of alphabetic characters in the current environment. It would probably not be  
 125809 feasible to write a compiled version of a shell script without this rule. The rule applies only to  
 125810 the current invocation of the shell and its subshells—invoking a shell script or performing *exec*  
 125811 *sh* would subject the new shell to the changes in *LC\_CTYPE*.

125812 Other common environment variables used by historical shells are not specified by the Shell and  
 125813 Utilities volume of POSIX.1-2008, but they should be reserved for the historical uses.

125814 Tilde expansion for components of *PATH* in an assignment such as:

125815 `PATH=~hlj/bin:~dwc/bin:$PATH`

125816 is a feature of some historical shells and is allowed by the wording of XCU [Section 2.6.1](#) (on page  
 125817 2327). Note that the <tilde> characters are expanded during the assignment to *PATH*, not when  
 125818 *PATH* is accessed during command search.

125819 The following entries represent additional information about variables included in the Shell and  
 125820 Utilities volume of POSIX.1-2008, or rationale for common variables in use by shells that have  
 125821 been excluded:

125822 — (Underscore.) While <underscore> is historical practice, its overloaded usage  
 125823 in the KornShell is confusing, and it has been omitted from the Shell and  
 125824 Utilities volume of POSIX.1-2008.

125825 *ENV* This variable can be used to set aliases and other items local to the invocation  
 125826 of a shell. The file referred to by *ENV* differs from *\$HOME/.profile* in that  
 125827 *.profile* is typically executed at session start-up, whereas the *ENV* file is  
 125828 executed at the beginning of each shell invocation. The *ENV* value is  
 125829 interpreted in a manner similar to a dot script, in that the commands are  
 125830 executed in the current environment and the file needs to be readable, but not  
 125831 executable. However, unlike dot scripts, no *PATH* searching is performed. This  
 125832 is used as a guard against Trojan Horse security breaches.

125833 *ERRNO* This variable was omitted from the Shell and Utilities volume of POSIX.1-2008  
 125834 because the values of error numbers are not defined in POSIX.1-2008 in a  
 125835 portable manner.

125836 *FCEDIT* Since this variable affects only the *fc* utility, it has been omitted from this more  
 125837 global place. The value of *FCEDIT* does not affect the command-line editing  
 125838 mode in the shell; see the description of *set -o vi* in the *set* built-in utility.

125839 *PS1* This variable is used for interactive prompts. Historically, the “superuser”  
 125840 has had a prompt of ' # '. Since privileges are not required to be monolithic, it  
 125841 is difficult to define which privileges should cause the alternate prompt.  
 125842 However, a sufficiently powerful user should be reminded of that power by  
 125843 having an alternate prompt.

125844 *PS3* This variable is used by the KornShell for the *select* command. Since the POSIX  
 125845 shell does not include *select*, *PS3* was omitted.

125846 *PS4* This variable is used for shell debugging. For example, the following script:

125847 `PS4=' [ ${LINENO} ] + '`  
 125848 `set -x`  
 125849 `echo Hello`

125850 writes the following to standard error:

125851 [3]+ echo Hello

125852 *RANDOM* This pseudo-random number generator was not seen as being useful to

125853 interactive users.

125854 *SECONDS* Although this variable is sometimes used with *PS1* to allow the display of the

125855 current time in the prompt of the user, it is not one that would be manipulated

125856 frequently enough by an interactive user to include in the Shell and Utilities

125857 volume of POSIX.1-2008.

125858 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0002 [152] is applied. +

## 125859 C.2.6 Word Expansions

125860 Step (2) refers to the “portions of fields generated by step (1)”. For example, if the word being

125861 expanded were "\$x+\$y" and *IFS*=+, the word would be split only if "\$x" or "\$y" contained

125862 ' + ' ; the ' + ' in the original word was not generated by step (1).

125863 *IFS* is used for performing field splitting on the results of parameter and command substitution;

125864 it is not used for splitting all fields. Earlier versions of the shell used it for splitting all fields

125865 during field splitting, but this has severe problems because the shell can no longer parse its own

125866 script. There are also important security implications caused by this behavior. All useful

125867 applications of *IFS* use it for parsing input of the *read* utility and for splitting the results of

125868 parameter and command substitution.

125869 The rule concerning expansion to a single field requires that if **foo=abc** and **bar=def**, that:

125870 "\$foo"\$bar"

125871 expands to the single field:

125872 abcdef

125873 The rule concerning empty fields can be illustrated by:

```
125874 $ unset foo
125875 $ set $foo bar ' ' xyz "$foo" abc
125876 $ for i
125877 > do
125878 > echo "-$i-"
125879 > done
125880 -bar-
125881 --
125882 -xyz-
125883 --
125884 -abc-
```

125885 Step (1) indicates that parameter expansion, command substitution, and arithmetic expansion

125886 are all processed simultaneously as they are scanned. For example, the following is valid

125887 arithmetic:

```
125888 x=1
125889 echo $(($(echo 3)+$x))
```

125890 An early proposal stated that tilde expansion preceded the other steps, but this is not the case in

125891 known historical implementations; if it were, and if a referenced home directory contained a ' \$ '

125892 character, expansions would result within the directory name.

|        |                                                                                                                 |   |
|--------|-----------------------------------------------------------------------------------------------------------------|---|
| 125893 | POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0003 [49,430] is applied.                                   | + |
| 125894 | <i>C.2.6.1 Tilde Expansion</i>                                                                                  |   |
| 125895 | Tilde expansion generally occurs only at the beginning of words, but an exception based on                      |   |
| 125896 | historical practice has been included:                                                                          |   |
| 125897 | <code>PATH=/posix/bin:~dgtk/bin</code>                                                                          |   |
| 125898 | This is eligible for tilde expansion because <tilde> follows a <colon> and none of the relevant                 |   |
| 125899 | characters is quoted. Consideration was given to prohibiting this behavior because any of the                   |   |
| 125900 | following are reasonable substitutes:                                                                           |   |
| 125901 | <code>PATH=\$(printf %s ~karels/bin : ~bostic/bin)</code>                                                       |   |
| 125902 | <code>for Dir in ~maat/bin ~srb/bin ...</code>                                                                  |   |
| 125903 | <code>do</code>                                                                                                 |   |
| 125904 | <code>    PATH=\${PATH:+\$PATH:}\$Dir</code>                                                                    |   |
| 125905 | <code>done</code>                                                                                               |   |
| 125906 | In the first command, explicit <colon> characters are used for each directory. In all cases, the                |   |
| 125907 | shell performs tilde expansion on each directory because all are separate words to the shell.                   |   |
| 125908 | Note that expressions in operands such as:                                                                      |   |
| 125909 | <code>make -k mumble LIBDIR=~chet/lib</code>                                                                    |   |
| 125910 | do not qualify as shell variable assignments, and tilde expansion is not performed (unless the                  |   |
| 125911 | command does so itself, which <i>make</i> does not).                                                            |   |
| 125912 | Because of the requirement that the word is not quoted, the following are not equivalent; only                  |   |
| 125913 | the last causes tilde expansion:                                                                                |   |
| 125914 | <code>\~hlj/    ~h\lj/    ~"hlj"/    ~hlj\    ~hlj/</code>                                                      |   |
| 125915 | In an early proposal, tilde expansion occurred following any unquoted <equals-sign> or                          |   |
| 125916 | <colon>, but this was removed because of its complexity and to avoid breaking commands such                     |   |
| 125917 | as:                                                                                                             |   |
| 125918 | <code>rcp hostname:~marc/.profile .</code>                                                                      |   |
| 125919 | System administrators on systems where // has an implementation-defined meaning which is                        | + |
| 125920 | different to /, should not create users with a home directory of / or //, since this may lead to                | + |
| 125921 | unexpected filename resolution on those systems.                                                                | + |
| 125922 | A suggestion was made that the special sequence "\$~" should be allowed to force tilde                          |   |
| 125923 | expansion anywhere. Since this is not historical practice, it has been left for future                          |   |
| 125924 | implementations to evaluate. (The description in XCU <a href="#">Section 2.2</a> (on page 2320) requires that a |   |
| 125925 | <dollar-sign> be quoted to represent itself, so the "\$~" combination is already unspecified.)                  |   |
| 125926 | The results of giving <tilde> with an unknown login name are undefined because the KornShell                    |   |
| 125927 | "~+" and "~-" constructs make use of this condition, but in general it is an error to give an                   |   |
| 125928 | incorrect login name with <tilde>. The results of having <i>HOME</i> unset are unspecified because              |   |
| 125929 | some historical shells treat this as an error.                                                                  |   |
| 125930 | Historically, the Korn shell performed field splitting and pathname expansion on the results of                 |   |
| 125931 | tilde expansion, and earlier versions of this standard reflected this. However, tilde expansion                 |   |
| 125932 | results in a pathname, and performing field splitting and pathname expansion on something                       |   |
| 125933 | that is already a pathname is at best redundant and at worst will change the value from the                     |   |
| 125934 | correct pathname to one or more incorrect ones. Later versions of the Korn shell do not perform                 |   |
| 125935 | these expansions and POSIX.1-2008 has been updated to match. Note that although pathname                        |   |

125936 expansion is not performed on the results of tilde expansion, this does not prevent other parts of  
 125937 the same word from being expanded. For example, ~/a\* expands to all files in \$HOME  
 125938 beginning with 'a'.

#### 125939 C.2.6.2 Parameter Expansion

125940 The rule for finding the closing '}' in "\${...}" is the one used in the KornShell and is  
 125941 upwardly-compatible with the Bourne shell, which does not determine the closing '}' until the  
 125942 word is expanded. The advantage of this is that incomplete expansions, such as:

125943 \${foo

125944 can be determined during tokenization, rather than during expansion.

125945 For rationale regarding expansion of "\${...}" within double-quotes, see [Section C.2.2.3](#) (on +  
 125946 page 3676). +

125947 The string length and substring capabilities were included because of the demonstrated need for  
 125948 them, based on their usage in other shells, such as C shell and KornShell.

125949 Historical versions of the KornShell have not performed tilde expansion on the word part of  
 125950 parameter expansion; however, it is more consistent to do so.

125951 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0004 [458], XCU/TC1-2008/0005 +

 125956 XCU/TC1-2008/0018 [458] are applied.

#### 125957 C.2.6.3 Command Substitution

125958 The "\$()" form of command substitution solves a problem of inconsistent behavior when using  
 125959 backquotes. For example:

| 125960 | Command              | Output |
|--------|----------------------|--------|
| 125961 | echo '\\$x'          | \\$x   |
| 125962 | echo `echo '\\$x'`   | \$x    |
| 125963 | echo \$(echo '\\$x') | \\$x   |

125964 Additionally, the backquoted syntax has historical restrictions on the contents of the embedded  
 125965 command. While the newer "\$()" form can process any kind of valid embedded script, the  
 125966 backquoted form cannot handle some valid scripts that include backquotes. For example, these  
 125967 otherwise valid embedded scripts do not work in the left column, but do work on the right:

|        |                             |                             |
|--------|-----------------------------|-----------------------------|
| 125968 | echo `                      | echo \$(                    |
| 125969 | cat <<\eof                  | cat <<\eof                  |
| 125970 | a here-doc with `           | a here-doc with )           |
| 125971 | eof                         | eof                         |
| 125972 | `                           | )                           |
| 125973 | echo `                      | echo \$(                    |
| 125974 | echo abc # a comment with ` | echo abc # a comment with ) |
| 125975 | `                           | )                           |
| 125976 | echo `                      | echo \$(                    |
| 125977 | echo ` `                    | echo ` `                    |

Because of these inconsistent behaviors, the backquoted variety of command substitution is not recommended for new applications that nest command substitutions or attempt to embed complex scripts.

The KornShell feature:

If *command* is of the form *<word*, *word* is expanded to generate a pathname, and the value of the command substitution is the contents of this file with any trailing <newline> characters deleted.

was omitted from the Shell and Utilities volume of POSIX.1-2008 because *\$(cat word)* is an appropriate substitute. However, to prevent breaking numerous scripts relying on this feature, it is unspecified to have a script within "*\$ ( )*" that has only redirections.

Arithmetic expansions have precedence over command substitutions. That is, if the shell can parse an expansion beginning with "*\$ ( (*" as an arithmetic expansion then it will do so. It will only parse the expansion as a command substitution (that starts with a subshell) if it determines that it cannot parse the expansion as an arithmetic expansion. If the syntax is valid for neither type of expansion, then it is unspecified what kind of syntax error the shell reports.

How well the shell performs this determination is a quality of implementation issue. Current shell implementations use heuristics. In particular, the shell need not evaluate nested expansions when determining whether it can parse an expansion beginning with "*\$ ( (*" as an arithmetic expansion. For example:

```
$ ((a $op b))
```

is always an arithmetic expansion if "*\$op*" expands to, say, *' ++ '*, but if "*\$op*" expands to *' ( '* then the shell might still parse the expansion as an arithmetic expansion (resulting in a syntax error due to unbalanced parentheses) or it might perform a command substitution.

This standard requires that conforming applications always separate the "*\$ (*" and *' (* with white space when a command substitution starts with a subshell. This is because implementations may support extensions in arithmetic expressions which could result in the shell parsing the input as an arithmetic expansion even though a minimally conforming shell would not. For example, many shells support arrays with the array index (which can be an expression) in square brackets. Therefore, the presence of "*myfile[0-9]*" within an expansion beginning "*\$ ( (*" is no guarantee that it will be parsed as a command substitution.

The ambiguity is not restricted to the simple case of a single subshell. More complicated ambiguous cases are possible (even with just the standard shell syntax), such as:

```
$ ((cat <<EOH
+ ((
EOH
) && (cat <<EOH
)) + 1 +
EOH
))
```

This can be parsed as an arithmetic expansion, with *cat* and *EOH* as the names of shell variables. Ambiguous cases also exist where the end of the expansion is at a different location for the arithmetic expansion and the command substitution:

```
$ ((cat <<EOF
+ (((
EOF
```

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|
| 126024 | ) && (                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |   |
| 126025 | cat <<EOF                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |   |

| 126029 | This is an incomplete arithmetic expansion, but would have been a (complete) command substitution if it could not have been parsed as an arithmetic expansion. If this expansion occurs at the end of input then the shell reports a syntax error; it does not parse it as a command substitution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |   |

| 126033 | IEEE Std 1003.1-2001/Cor 1-2002, item XCU/TC1/D6/4 is applied, changing the text from: "If a command substitution occurs inside double-quotes, it shall not be performed on the results of the substitution." to: "If a command substitution occurs inside double-quotes, field splitting and pathname expansion shall not be performed on the results of the substitution.". The replacement text taken from the ISO POSIX-2: 1993 standard is clearer about the items that are not performed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |

| 126042 | The standard developers agreed that there was a strong desire for some kind of arithmetic evaluator to provide functionality similar to <i>expr</i> , that relating it to ' \$ ' makes it work well with the standard shell language and provides access to arithmetic evaluation in places where accessing a utility would be inconvenient.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |   |
| 126043 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |
| 126044 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |
| 126045 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |
| 126046 | The syntax and semantics for arithmetic were revised for the ISO/IEC 9945-2:1993 standard. The language represents a simple subset of the previous arithmetic language (which was derived from the KornShell " ( ) " construct). The syntax was changed from that of a command denoted by (( <i>expression</i> )) to an expansion denoted by \$( <i>expression</i> )). The new form is a dollar expansion ( ' \$ ' ) that evaluates the expression and substitutes the resulting value. Objections to the previous style of arithmetic included that it was too complicated, did not fit in well with the use of variables in the shell, and its syntax conflicted with subshells. The justification for the new syntax is that the shell is traditionally a macro language, and if a new feature is to be added, it should be accomplished by extending the capabilities presented by the current model of the shell, rather than by inventing a new one outside the model; adding a new dollar expansion was perceived to be the most intuitive and least destructive way to add such a new capability. |   |

| 126055 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |
| 126056 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |
| 126057 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |
| 126058 | The standard requires assignment operators to be supported (as listed in XCU <a href="#">Section 1.1.2</a> , on page 2305), and since arithmetic expansions are not specified to be evaluated in a subshell environment, changes to variables there have to be in effect after the arithmetic expansion, just as in the parameter expansion "\${x=value}" .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |   |
| 126059 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |
| 126060 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |
| 126061 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |
| 126062 | Note, however, that "\$ ( ( x=5 ) )" need not be equivalent to "\$ ( ( \$x=5 ) )" . If the value of the environment variable <i>x</i> is the string " <i>y</i> =", the expansion of "\$ ( ( x=5 ) )" would set <i>x</i> to 5 and output 5, but "\$ ( ( \$x=5 ) )" would output 0 if the value of the environment variable <i>y</i> is not 5 and would output 1 if the environment variable <i>y</i> is 5. Similarly, if the value of the environment variable is 4, the expansion of "\$ ( ( x=5 ) )" would still set <i>x</i> to 5 and output 5, but "\$ ( ( \$x=5 ) )" (which would be equivalent to "\$ ( ( 4=5 ) )" ) would yield a syntax error.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |   |

| 126069 | In early proposals, a form <code>\$(<i>expression</i>)</code> was used. It was functionally equivalent to the "\$ ( ) " of the current text, but objections were lodged that the 1988 KornShell had already implemented                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |   |
| 126070 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |

126071 "\$ ( ) )" and there was no compelling reason to invent yet another syntax. Furthermore, the  
 126072 "\$ [ ]" syntax had a minor incompatibility involving the patterns in **case** statements.

126073 The portion of the ISO C standard arithmetic operations selected corresponds to the operations  
 126074 historically supported in the KornShell. In addition to the exceptions listed in XCU [Section 2.6.4](#)  
 126075 (on page 2332), the use of the following are explicitly outside the scope of the rules defined in  
 126076 XCU [Section 1.1.2.1](#) (on page 2305):

- 126077 • The prefix operator ' & ' and the " [ ] ", "-> ", and ' . ' operators.
- 126078 • Casts

126079 It was concluded that the *test* command (**I**) was sufficient for the majority of relational arithmetic  
 126080 tests, and that tests involving complicated relational expressions within the shell are rare, yet  
 126081 could still be accommodated by testing the value of "\$ ( ) )" itself. For example:

```
126082 # a complicated relational expression
126083 while [$((($x + $y)/($a * $b)) < ($foo*$bar))) -ne 0]
```

126084 or better yet, the rare script that has many complex relational expressions could define a  
 126085 function like this:

```
126086 val() {
126087 return $(!$1)
126088 }
```

126089 and complicated tests would be less intimidating:

```
126090 while val $((($x + $y)/($a * $b)) < ($foo*$bar)))
126091 do
126092 # some calculations
126093 done
```

126094 A suggestion that was not adopted was to modify *true* and *false* to take an optional argument,  
 126095 and *true* would exit true only if the argument was non-zero, and *false* would exit false only if the  
 126096 argument was non-zero:

```
126097 while true $(($x > 5 && $y <= 25))
```

126098 There is a minor portability concern with the new syntax. The example "\$ ( (2+2) )" could have  
 126099 been intended to mean a command substitution of a utility named "2+2" in a subshell. The  
 126100 standard developers considered this to be obscure and isolated to some KornShell scripts  
 126101 (because "\$ ( )" command substitution existed previously only in the KornShell). The text on  
 126102 command substitution requires that the "\$ ( " and ' ( ' be separate tokens if this usage is  
 126103 needed.

126104 An example such as:

```
126105 echo $((echo hi);(echo there))
```

126106 should not be misinterpreted by the shell as arithmetic because attempts to balance the  
 126107 parentheses pairs would indicate that they are subshells. However, as indicated by XBD [Section 3.113](#)  
 126108 (on page 51), a conforming application must separate two adjacent parentheses with white  
 126109 space to indicate nested subshells.

126110 The standard is intentionally silent about how a variable's numeric value in an expression is  
 126111 determined from its normal "sequence of bytes" value. It could be done as a text substitution, as  
 126112 a conversion like that performed by *strtol()*, or even recursive evaluation. Therefore, the only  
 126113 cases for which the standard is clear are those for which both conversions produce the same  
 126114 result. The cases where they give the same result are those where the sequence of bytes form a  
 126115 valid integer constant. Therefore, if a variable does not contain a valid integer constant, the

126116 behavior is unspecified.

126117 For the commands:

126118 `x=010; echo $((x += 1))`

126119 the output must be 9.

126120 For the commands:

126121 `x=' 1'; echo $((x += 1))`

126122 the results are unspecified.

126123 For the commands:

126124 `x=1+1; echo $((x += 1))`

126125 the results are unspecified.

126126 Although the ISO/IEC 9899:1999 standard now requires support for **long long** and allows  
 126127 extended integer types with higher ranks, POSIX.1-2008 only requires arithmetic expansions to  
 126128 support **signed long** integer arithmetic. Implementations are encouraged to support signed  
 126129 integer values at least as large as the size of the largest file allowed on the implementation.

126130 Implementations are also allowed to perform floating-point evaluations as long as an  
 126131 application won't see different results for expressions that would not overflow **signed long**  
 126132 integer expression evaluation. (This includes appropriate truncation of results to integer values.)

126133 Changes made in response to IEEE PASC Interpretation 1003.2 #208 removed the requirement  
 126134 that the integer constant suffixes `l` and `L` had to be recognized. The ISO POSIX-2: 1993 standard  
 126135 did not require the `u`, `ul`, `uL`, `U`, `Ul`, `UL`, `lu`, `lU`, `Lu`, and `LU` suffixes since only signed integer  
 126136 arithmetic was required. Since all arithmetic expressions were treated as handling **signed long**  
 126137 integer types anyway, the `l` and `L` suffixes were redundant. No known scripts used them and  
 126138 some historic shells did not support them. When the ISO/IEC 9899:1999 standard was used as  
 126139 the basis for the description of arithmetic processing, the `ll` and `LL` suffixes and combinations  
 126140 were also not required. Implementations are still free to accept any or all of these suffixes, but  
 126141 are not required to do so.

126142 There was also some confusion as to whether the shell was required to recognize character  
 126143 constants. Syntactically, character constants were required to be recognized, but the  
 126144 requirements for the handling of `<backslash>` and single-quote characters (needed to specify  
 126145 character constants) within an arithmetic expansion were ambiguous. Furthermore, no known  
 126146 shells supported them. Changes made in response to IEEE PASC Interpretation 1003.2 #208  
 126147 removed the requirement to support them (if they were indeed required before). POSIX.1-2008  
 126148 clearly does not require support for character constants.

126149 IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/3 is applied, clarifying arithmetic  
 126150 expressions.

126151 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0020 [50] is applied.

+

#### 126152 C.2.6.5 *Field Splitting*

126153 The operation of field splitting using *IFS*, as described in early proposals, was based on the way  
 126154 the KornShell splits words, but it is incompatible with other common versions of the shell.  
 126155 However, each has merit, and so a decision was made to allow both. If the *IFS* variable is unset  
 126156 or is `<space><tab><newline>`, the operation is equivalent to the way the System V shell splits  
 126157 words. Using characters outside the `<space><tab><newline>` set yields the KornShell behavior,  
 126158 where each of the non-`<space><tab><newline>`s is significant. This behavior, which affords the

126159 most flexibility, was taken from the way the original *awk* handled field splitting.

126160 Rule (3) can be summarized as a pseudo-ERE:

126161  $(s^*ns^* | s^+)$

126162 where *s* is an *IFS* white-space character and *n* is a character in the *IFS* that is not white space.  
 126163 Any string matching that ERE delimits a field, except that the *s+* form does not delimit fields at  
 126164 the beginning or the end of a line. For example, if *IFS* is <space>/<comma>/<tab>, the string:

126165 <space><space>red<space><space>, <space>white<space>blue

126166 yields the three colors as the delimited fields.

#### 126167 C.2.6.6 Pathname Expansion

126168 There is no additional rationale provided for this section.

#### 126169 C.2.6.7 Quote Removal

126170 There is no additional rationale provided for this section.

### 126171 C.2.7 Redirection

126172 In the System Interfaces volume of POSIX.1-2008, file descriptors are integers in the range  
 126173 0–(OPEN\_MAX–1). The file descriptors discussed in XCU [Section 2.7](#) (on page 2334) are that  
 126174 same set of small integers.

126175 Having multi-digit file descriptor numbers for I/O redirection can cause some obscure  
 126176 compatibility problems. Specifically, scripts that depend on an example command:

126177 `echo 22>/dev/null`

126178 echoing "2" to standard error or "22" to standard output are no longer portable. However, the  
 126179 file descriptor number must still be delimited from the preceding text. For example:

126180 `cat file2>foo`

126181 writes the contents of **file2**, not the contents of **file**.

126182 The ">|" format of output redirection was adopted from the KornShell. Along with the  
 126183 *noclobber* option, *set -C*, it provides a safety feature to prevent inadvertent overwriting of  
 126184 existing files. (See the RATIONALE for the *pathchk* utility for why this step was taken.) The  
 126185 restriction on regular files is historical practice.

126186 The System V shell and the KornShell have differed historically on pathname expansion of *word*;  
 126187 the former never performed it, the latter only when the result was a single field (file). As a  
 126188 compromise, it was decided that the KornShell functionality was useful, but only as a shorthand  
 126189 device for interactive users. No reasonable shell script would be written with a command such  
 126190 as:

126191 `cat foo > a*`

126192 Thus, shell scripts are prohibited from doing it, while interactive users can select the shell with  
 126193 which they are most comfortable.

126194 The construct "2>&1" is often used to redirect standard error to the same file as standard  
 126195 output. Since the redirections take place beginning to end, the order of redirections is significant.  
 126196 For example:

126197 `ls > foo 2>&1`

126198 directs both standard output and standard error to file **foo**. However:

126199 `ls 2>&1 > foo`

126200 only directs standard output to file **foo** because standard error was duplicated as standard  
126201 output before standard output was directed to file **foo**.

126202 Applications should not use the `[n]<&-` or `[n]>&-` operators to execute a utility or application +  
126203 with file descriptor 0 not open for reading or with file descriptor 1 or 2 not open for writing, as +  
126204 this might cause the executed program (or shell built-in) to misbehave. In order not to pass on +  
126205 these file descriptors to an executed utility or application, applications should not just close +  
126206 them but should reopen them on, for example, **/dev/null**. Some implementations may reopen +  
126207 them automatically, but applications should not rely on this being done. +

126208 The "`<>`" operator could be useful in writing an application that worked with several terminals,  
126209 and occasionally wanted to start up a shell. That shell would in turn be unable to run  
126210 applications that run from an ordinary controlling terminal unless it could make use of "`<>`"  
126211 redirection. The specific example is a historical version of the pager *more*, which reads from  
126212 standard error to get its commands, so standard input and standard output are both available  
126213 for their usual usage. There is no way of saying the following in the shell without "`<>`":

126214 `cat food | more - >/dev/tty03 2<>/dev/tty03`

126215 Another example of "`<>`" is one that opens **/dev/tty** on file descriptor 3 for reading and writing:

126216 `exec 3<> /dev/tty`

126217 An example of creating a lock file for a critical code region:

126218 `set -C`  
126219 `until 2> /dev/null > lockfile`  
126220 `do sleep 30`  
126221 `done`  
126222 `set +C`  
126223 `perform critical function`  
126224 `rm lockfile`

126225 Since **/dev/null** is not a regular file, no error is generated by redirecting to it in *noclobber* mode.

126226 Tilde expansion is not performed on a here-document because the data is treated as if it were  
126227 enclosed in double-quotes.

#### 126228 C.2.7.1 *Redirecting Input*

126229 There is no additional rationale provided for this section.

#### 126230 C.2.7.2 *Redirecting Output*

126231 There is no additional rationale provided for this section.

126232 C.2.7.3 *Appending Redirected Output*

126233 Note that when a file is opened (even with the `O_APPEND` flag set), the initial file offset for that  
 126234 file is set to the beginning of the file. Some historic shells set the file offset to the current end-of-  
 126235 file when **append** mode shell redirection was used, but this is not allowed by POSIX.1-2008.

126236 C.2.7.4 *Here-Document*

126237 There is no additional rationale provided for this section.

126238 C.2.7.5 *Duplicating an Input File Descriptor*

126239 There is no additional rationale provided for this section.

126240 C.2.7.6 *Duplicating an Output File Descriptor*

126241 There is no additional rationale provided for this section.

126242 C.2.7.7 *Open File Descriptors for Reading and Writing*

126243 There is no additional rationale provided for this section.

126244 **C.2.8 Exit Status and Errors**

126245 There is no additional rationale provided for this section. +

126246 C.2.8.1 *Consequences of Shell Errors*

126247 There is no additional rationale provided for this section.

126248 C.2.8.2 *Exit Status for Commands*

126249 There is a historical difference in *sh* and *ksh* non-interactive error behavior. When a command  
 126250 named in a script is not found, some implementations of *sh* exit immediately, but *ksh* continues  
 126251 with the next command. Thus, the Shell and Utilities volume of POSIX.1-2008 says that the shell  
 126252 “may” exit in this case. This puts a small burden on the programmer, who has to test for  
 126253 successful completion following a command if it is important that the next command not be  
 126254 executed if the previous command was not found. If it is important for the command to have  
 126255 been found, it was probably also important for it to complete successfully. The test for successful  
 126256 completion would not need to change.

126257 Historically, shells have returned an exit status of  $128+n$ , where  $n$  represents the signal number.  
 126258 Since signal numbers are not standardized, there is no portable way to determine which signal  
 126259 caused the termination. Also, it is possible for a command to exit with a status in the same range  
 126260 of numbers that the shell would use to report that the command was terminated by a signal.  
 126261 Implementations are encouraged to choose exit values greater than 256 to indicate programs that  
 126262 terminate by a signal so that the exit status cannot be confused with an exit status generated by a  
 126263 normal termination.

126264 Historical shells make the distinction between “utility not found” and “utility found but cannot  
 126265 execute” in their error messages. By specifying two seldomly used exit status values for these  
 126266 cases, 127 and 126 respectively, this gives an application the opportunity to make use of this

distinction without having to parse an error message that would probably change from locale to locale. The *command*, *env*, *nohup*, and *xargs* utilities in the Shell and Utilities volume of POSIX.1-2008 have also been specified to use this convention.

When a command fails during word expansion or redirection, most historical implementations exit with a status of 1. However, there was some sentiment that this value should probably be much higher so that an application could distinguish this case from the more normal exit status values. Thus, the language “greater than zero” was selected to allow either method to be implemented.

## 126275 C.2.9 Shell Commands

A description of an “empty command” was removed from an early proposal because it is only relevant in the cases of *sh -c ""*, *system("")*, or an empty shell-script file (such as the implementation of *true* on some historical systems). Since it is no longer mentioned in the Shell and Utilities volume of POSIX.1-2008, it falls into the silently unspecified category of behavior where implementations can continue to operate as they have historically, but conforming applications do not construct empty commands. (However, note that *sh* does explicitly state an exit status for an empty string or file.) In an interactive session or a script with other commands, extra <newline> or <semicolon> characters, such as:

```
126284 $ false
126285 $
126286 $ echo $?
126287 1
```

would not qualify as the empty command described here because they would be consumed by other parts of the grammar.

### 126290 C.2.9.1 Simple Commands

The enumerated list is used only when the command is actually going to be executed. For example, in:

```
126293 true || $foo *
```

no expansions are performed.

The following example illustrates both how a variable assignment without a command name affects the current execution environment, and how an assignment with a command name only affects the execution environment of the command:

```
126298 $ x=red
126299 $ echo $x
126300 red
126301 $ export x
126302 $ sh -c 'echo $x'
126303 red
126304 $ x=blue sh -c 'echo $x'
126305 blue
126306 $ echo $x
126307 red
```

This next example illustrates that redirections without a command name are still performed:

```
126309 $ ls foo
```

```

126310 ls: foo: no such file or directory
126311 $ > foo
126312 $ ls foo
126313 foo

```

126314 A command without a command name, but one that includes a command substitution, has an  
 126315 exit status of the last command substitution that the shell performed. For example:

```

126316 if x=$(command)
126317 then ...
126318 fi

```

126319 An example of redirections without a command name being performed in a subshell shows that  
 126320 the here-document does not disrupt the standard input of the **while** loop:

```

126321 IFS=:
126322 while read a b
126323 do echo $a
126324 <<-eof
126325 Hello
126326 eof
126327 done </etc/passwd

```

126328 Following are examples of commands without command names in AND-OR lists:

```

126329 > foo || {
126330 echo "error: foo cannot be created" >&2
126331 exit 1
126332 }
126333 # set saved if /vmunix.save exists
126334 test -f /vmunix.save && saved=1

```

126335 Command substitution and redirections without command names both occur in subshells, but  
 126336 they are not necessarily the same ones. For example, in:

```

126337 exec 3> file
126338 var=$(echo foo >&3) 3>&1

```

126339 it is unspecified whether **foo** is echoed to the file or to standard output.

126340 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0021 [255] is applied. +

## 126341 Command Search and Execution

126342 This description requires that the shell can execute shell scripts directly, even if the underlying  
 126343 system does not support the common "#!" interpreter convention. That is, if file **foo** contains  
 126344 shell commands and is executable, the following executes **foo**:

```

126345 ./foo

```

126346 The command search shown here does not match all historical implementations. A more typical  
 126347 sequence has been:

- 126348 • Any built-in (special or regular)
- 126349 • Functions
- 126350 • Path search for executable files

126351 But there are problems with this sequence. Since the programmer has no idea in advance which  
 126352 utilities might have been built into the shell, a function cannot be used to override portably a

utility of the same name. (For example, a function named *cd* cannot be written for many historical systems.) Furthermore, the *PATH* variable is partially ineffective in this case, and only a pathname with a <slash> can be used to ensure a specific executable file is invoked.

After the *execve()* failure described, the shell normally executes the file as a shell script. Some implementations, however, attempt to detect whether the file is actually a script and not an executable from some other architecture. The method used by the KornShell is allowed by the text that indicates non-text files may be bypassed.

The sequence selected for the Shell and Utilities volume of POSIX.1-2008 acknowledges that special built-ins cannot be overridden, but gives the programmer full control over which versions of other utilities are executed. It provides a means of suppressing function lookup (via the *command* utility) for the user's own functions and ensures that any regular built-ins or functions provided by the implementation are under the control of the path search. The mechanisms for associating built-ins or functions with executable files in the path are not specified by the Shell and Utilities volume of POSIX.1-2008, but the wording requires that if either is implemented, the application is not able to distinguish a function or built-in from an executable (other than in terms of performance, presumably). The implementation ensures that all effects specified by the Shell and Utilities volume of POSIX.1-2008 resulting from the invocation of the regular built-in or function (interaction with the environment, variables, traps, and so on) are identical to those resulting from the invocation of an executable file.

IEEE Std 1003.1-2001/Cor 2-2004, item XCU/TC2/D6/4 is applied, updating the case where *execve()* fails due to an error equivalent to the [ENOEXEC] error.

POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0022 [168], XCU/TC1-2008/0023 + [168], XCU/TC1-2008/0024 [168], XCU/TC1-2008/0025 [168], XCU/TC1-2008/0026 [168,430], + XCU/TC1-2008/0027 [168,430], and XCU/TC1-2008/0028 [173] are applied.

## Examples

Consider three versions of the *ls* utility:

1. The application includes a shell function named *ls*.
2. The user writes a utility named *ls* and puts it in **/fred/bin**.
3. The example implementation provides *ls* as a regular shell built-in that is invoked (either by the shell or directly by *exec*) when the path search reaches the directory **/posix/bin**.

If *PATH*=**/posix/bin**, various invocations yield different versions of *ls*:

| Invocation                                             | Version of <i>ls</i> |
|--------------------------------------------------------|----------------------|
| <i>ls</i> (from within application script)             | (1) function         |
| <i>command ls</i> (from within application script)     | (3) built-in         |
| <i>ls</i> (from within makefile called by application) | (3) built-in         |
| <i>system("ls")</i>                                    | (3) built-in         |
| <i>PATH="/fred/bin:\$PATH" ls</i>                      | (2) user's version   |

### C.2.9.2 Pipelines

Because pipeline assignment of standard input or standard output or both takes place before redirection, it can be modified by redirection. For example:

```
$ command1 2>&1 | command2
```

sends both the standard output and standard error of *command1* to the standard input of *command2*.

|        |                                                                                                                                                         |   |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------|---|
| 126396 | The reserved word <code>!</code> allows more flexible testing using AND and OR lists.                                                                   |   |
| 126397 | It was suggested that it would be better to return a non-zero value if any command in the                                                               |   |
| 126398 | pipeline terminates with non-zero status (perhaps the bitwise-inclusive OR of all return values).                                                       |   |
| 126399 | However, the choice of the last-specified command semantics are historical practice and would                                                           |   |
| 126400 | cause applications to break if changed. An example of historical behavior:                                                                              |   |
| 126401 | <code>\$ sleep 5   (exit 4)</code>                                                                                                                      |   |
| 126402 | <code>\$ echo \$?</code>                                                                                                                                |   |
| 126403 | <code>4</code>                                                                                                                                          |   |
| 126404 | <code>\$ (exit 4)   sleep 5</code>                                                                                                                      |   |
| 126405 | <code>\$ echo \$?</code>                                                                                                                                |   |
| 126406 | <code>0</code>                                                                                                                                          |   |
| 126407 | POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0029 [205] is applied.                                                                              | + |
| 126408 | <b>Exit Status</b>                                                                                                                                      | + |
| 126409 | POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0030 [52] is applied.                                                                               |   |
| 126410 | <b>C.2.9.3 Lists</b>                                                                                                                                    |   |
| 126411 | The equal precedence of " <code>&amp;&amp;</code> " and " <code>  </code> " is historical practice. The standard developers                             |   |
| 126412 | evaluated the model used more frequently in high-level programming languages, such as C, to                                                             |   |
| 126413 | allow the shell logical operators to be used for complex expressions in an unambiguous way, but                                                         |   |
| 126414 | they could not allow historical scripts to break in the subtle way unequal precedence might                                                             |   |
| 126415 | cause. Some arguments were posed concerning the " <code>{ }</code> " or " <code>()</code> " groupings that are required                                 |   |
| 126416 | historically. There are some disadvantages to these groupings:                                                                                          |   |
| 126417 | <ul style="list-style-type: none"> <li>• The "<code>()</code>" can be expensive, as they spawn other processes on some implementations. This</li> </ul> |   |
| 126418 | performance concern is primarily an implementation issue.                                                                                               |   |
| 126419 | <ul style="list-style-type: none"> <li>• The "<code>{ }</code>" braces are not operators (they are reserved words) and require a trailing</li> </ul>    |   |
| 126420 | <space> after each ' <code>{</code> ', and a <semicolon> before each ' <code>}</code> '. Most programmers (and                                          |   |
| 126421 | certainly interactive users) have avoided braces as grouping constructs because of the                                                                  |   |
| 126422 | problematic syntax required. Braces were not changed to operators because that would                                                                    |   |
| 126423 | generate compatibility issues even greater than the precedence question; braces appear                                                                  |   |
| 126424 | outside the context of a keyword in many shell scripts.                                                                                                 |   |
| 126425 | IEEE PASC Interpretation 1003.2 #204 is applied, clarifying that the operators " <code>&amp;&amp;</code> " and " <code>  </code> "                      |   |
| 126426 | are evaluated with left associativity.                                                                                                                  |   |
| 126427 | POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0031 [45] and XCU/TC1-2008/0032                                                                     | + |
| 126428 | [45] are applied.                                                                                                                                       |   |
| 126429 | <b>Asynchronous Lists</b>                                                                                                                               |   |
| 126430 | The grammar treats a construct such as:                                                                                                                 |   |
| 126431 | <code>foo &amp; bar &amp; bam &amp;</code>                                                                                                              |   |
| 126432 | as one "asynchronous list", but since the status of each element is tracked by the shell, the term                                                      |   |
| 126433 | "element of an asynchronous list" was introduced to identify just one of the <b>foo</b> , <b>bar</b> , or <b>bam</b>                                    |   |
| 126434 | portions of the overall list.                                                                                                                           |   |
| 126435 | Unless the implementation has an internal limit, such as <code>{CHILD_MAX}</code> , on the retained process                                             |   |
| 126436 | IDs, it would require unbounded memory for the following example:                                                                                       |   |
| 126437 | <code>while true</code>                                                                                                                                 |   |

126438       do       foo & echo \$!  
126439       done

126440       The treatment of the signals SIGINT and SIGQUIT with asynchronous lists is described in XCU  
126441       [Section 2.11](#) (on page 2353).

126442       Since the connection of the input to the equivalent of **/dev/null** is considered to occur before  
126443       redirections, the following script would produce no output:

126444       exec < /etc/passwd  
126445       cat <&0 &  
126446       wait

#### 126447       **Sequential Lists**

126448       There is no additional rationale provided for this section.

#### 126449       **AND Lists**

126450       There is no additional rationale provided for this section.

#### 126451       **OR Lists**

126452       There is no additional rationale provided for this section.

### 126453   C.2.9.4   *Compound Commands*

#### 126454       **Grouping Commands**

126455       The semicolon shown in *{compound-list;}* is an example of a control operator delimiting the }  
126456       reserved word. Other delimiters are possible, as shown in XCU [Section 2.10](#) (on page 2347);  
126457       <newline> is frequently used.

126458       A proposal was made to use the **<do-done>** construct in all cases where command grouping in  
126459       the current process environment is performed, identifying it as a construct for the grouping  
126460       commands, as well as for shell functions. This was not included because the shell already has a  
126461       grouping construct for this purpose ("**{ }**"), and changing it would have been counter-  
126462       productive.

126463       The requirement for conforming applications to separate two leading ' ( ' characters with white +  
126464       space if a grouping command would be parsed as an arithmetic expansion if preceded by a ' \$' +  
126465       is to allow shells which implement the "**(( arithmetic expression ))**" extension to +  
126466       apply the same disambiguation rules consistently to **\$((...))** and **((...))**. See [Section](#) +  
126467       [C.2.6.3](#) (on page 3684). +

126468       POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0033 [217] is applied.

#### 126469       **For Loop**

126470       The format is shown with generous usage of <newline> characters. See the grammar in XCU  
126471       [Section 2.10](#) (on page 2347) for a precise description of where <newline> and <semicolon>  
126472       characters can be interchanged.

126473       Some historical implementations support '**{**' and '**}**' as substitutes for **do** and **done**. The  
126474       standard developers chose to omit them, even as an obsolescent feature. (Note that these  
126475       substitutes were only for the **for** command; the **while** and **until** commands could not use them  
126476       historically because they are followed by compound-lists that may contain "**{ . . . }**" grouping  
126477       commands themselves.)

126478 The reserved word pair **do ... done** was selected rather than **do ... od** (which would have  
 126479 matched the spirit of **if ... fi** and **case ... esac**) because *od* is already the name of a standard  
 126480 utility.

126481 PASC Interpretation 1003.2 #169 has been applied changing the grammar.

#### 126482 **Case Conditional Construct**

126483 An optional <left-parenthesis> before *pattern* was added to allow numerous historical KornShell  
 126484 scripts to conform. At one time, using the leading parenthesis was required if the **case** statement  
 126485 was to be embedded within a "\$ ( ) " command substitution; this is no longer the case with the  
 126486 POSIX shell. Nevertheless, many historical scripts use the <left-parenthesis>, if only because it  
 126487 makes matching-parenthesis searching easier in *vi* and other editors. This is a relatively simple  
 126488 implementation change that is upwards-compatible for all scripts.

126489 Consideration was given to requiring *break* inside the *compound-list* to prevent falling through to  
 126490 the next pattern action list. This was rejected as being nonexistent practice. An interesting  
 126491 undocumented feature of the KornShell is that using ";" &" instead of ";;" as a terminator  
 126492 causes the exact opposite behavior—the flow of control continues with the next *compound-list*.

126493 The pattern ' \* ', given as the last pattern in a **case** construct, is equivalent to the default case in  
 126494 a C-language **switch** statement.

126495 The grammar shows that reserved words can be used as patterns, even if one is the first word on  
 126496 a line. Obviously, the reserved word **esac** cannot be used in this manner.

#### 126497 **If Conditional Construct**

126498 The precise format for the command syntax is described in XCU [Section 2.10](#) (on page 2347).

#### 126499 **While Loop**

126500 The precise format for the command syntax is described in XCU [Section 2.10](#) (on page 2347).

#### 126501 **Until Loop**

126502 The precise format for the command syntax is described in XCU [Section 2.10](#) (on page 2347).

#### 126503 C.2.9.5 *Function Definition Command*

126504 The description of functions in an early proposal was based on the notion that functions should  
 126505 behave like miniature shell scripts; that is, except for sharing variables, most elements of an  
 126506 execution environment should behave as if they were a new execution environment, and  
 126507 changes to these should be local to the function. For example, traps and options should be reset  
 126508 on entry to the function, and any changes to them do not affect the traps or options of the caller.  
 126509 There were numerous objections to this basic idea, and the opponents asserted that functions  
 126510 were intended to be a convenient mechanism for grouping common commands that were to be  
 126511 executed in the current execution environment, similar to the execution of the *dot* special  
 126512 built-in.

126513 It was also pointed out that the functions described in that early proposal did not provide a local  
 126514 scope for everything a new shell script would, such as the current working directory, or *umask*,  
 126515 but instead provided a local scope for only a few select properties. The basic argument was that  
 126516 if a local scope is needed for the execution environment, the mechanism already existed: the  
 126517 application can put the commands in a new shell script and call that script. All historical shells  
 126518 that implemented functions, other than the KornShell, have implemented functions that operate  
 126519 in the current execution environment. Because of this, traps and options have a global scope

within a shell script. Local variables within a function were considered and included in another early proposal (controlled by the special built-in *local*), but were removed because they do not fit the simple model developed for functions and because there was some opposition to adding yet another new special built-in that was not part of historical practice. Implementations should reserve the identifier *local* (as well as *typeset*, as used in the KornShell) in case this local variable mechanism is adopted in a future version of this standard.

A separate issue from the execution environment of a function is the availability of that function to child shells. A few objectors maintained that just as a variable can be shared with child shells by exporting it, so should a function. In early proposals, the *export* command therefore had a *-f* flag for exporting functions. Functions that were exported were to be put into the environment as *name()*=*value* pairs, and upon invocation, the shell would scan the environment for these and automatically define these functions. This facility was strongly opposed and was omitted. Some of the arguments against exportable functions were as follows:

- There was little historical practice. The Ninth Edition shell provided them, but there was controversy over how well it worked.
- There are numerous security problems associated with functions appearing in the environment of a user and overriding standard utilities or the utilities owned by the application.
- There was controversy over requiring *make* to import functions, where it has historically used an *exec* function for many of its command line executions.
- Functions can be big and the environment is of a limited size. (The counter-argument was that functions are no different from variables in terms of size: there can be big ones, and there can be small ones—and just as one does not export huge variables, one does not export huge functions. However, this might not apply to the average shell-function writer, who typically writes much larger functions than variables.)

As far as can be determined, the functions in the Shell and Utilities volume of POSIX.1-2008 match those in System V. Earlier versions of the KornShell had two methods of defining functions:

```
function fname { compound-list }
```

and:

```
fname() { compound-list }
```

The latter used the same definition as the Shell and Utilities volume of POSIX.1-2008, but differed in semantics, as described previously. The current edition of the KornShell aligns the latter syntax with the Shell and Utilities volume of POSIX.1-2008 and keeps the former as is.

The name space for functions is limited to that of a *name* because of historical practice. Complications in defining the syntactic rules for the function definition command and in dealing with known extensions such as the "*@()*" usage in the KornShell prevented the name space from being widened to a *word*. Using functions to support synonyms such as the "*!!*" and "*%'*" usage in the C shell is thus disallowed to conforming applications, but acceptable as an extension. For interactive users, the aliasing facilities in the Shell and Utilities volume of POSIX.1-2008 should be adequate for this purpose. It is recognized that the name space for utilities in the file system is wider than that currently supported for functions, if the portable filename character set guidelines are ignored, but it did not seem useful to mandate extensions in systems for so little benefit to conforming applications.

The "*()*" in the function definition command consists of two operators. Therefore, intermixing <blank> characters with the *fname*, '*'*', and '*)*' is allowed, but unnecessary.

126566 An example of how a function definition can be used wherever a simple command is allowed:

```
126567 # If variable i is equal to "yes",
126568 # define function foo to be ls -l
126569 #
126570 ["$i" = yes] && foo() {
126571 ls -l
126572 }
```

126573 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0034 [383] and XCU/TC1-2008/0035 +  
126574 [214] are applied.

## 126575 C.2.10 Shell Grammar

126576 There are several subtle aspects of this grammar where conventional usage implies rules about  
126577 the grammar that in fact are not true.

126578 For *compound\_list*, only the forms that end in a *separator* allow a reserved word to be recognized,  
126579 so usually only a *separator* can be used where a compound list precedes a reserved word (such as  
126580 **Then**, **Else**, **Do**, and **Rbrace**). Explicitly requiring a separator would disallow such valid (if rare)  
126581 statements as:

```
126582 if (false) then (echo x) else (echo y) fi
```

126583 See the Note under special grammar rule (1).

126584 Concerning the third sentence of rule (1) (“Also, if the parser ...”):

- 126585 • This sentence applies rather narrowly: when a compound list is terminated by some clear  
126586 delimiter (such as the closing **fi** of an inner **if\_clause**) then it would apply; where the  
126587 compound list might continue (as in after a ‘;’), rule (7a) (and consequently the first  
126588 sentence of rule (1)) would apply. In many instances the two conditions are identical, but  
126589 this part of rule (1) does not give license to treating a **WORD** as a reserved word unless it  
126590 is in a place where a reserved word has to appear.
- 126591 • The statement is equivalent to requiring that when the LR(1) lookahead set contains  
126592 exactly one reserved word, it must be recognized if it is present. (Here “LR(1)” refers to the  
126593 theoretical concepts, not to any real parser generator.)

126594 For example, in the construct below, and when the parser is at the point marked with ‘^’,  
126595 the only next legal token is **then** (this follows directly from the grammar rules):

```
126596 if if...fi then ... fi
126597 ^
```

126598 At that point, the **then** must be recognized as a reserved word.

126599 (Depending on the parser generator actually used, “extra” reserved words may be in some  
126600 lookahead sets. It does not really matter if they are recognized, or even if any possible  
126601 reserved word is recognized in that state, because if it is recognized and is not in the  
126602 (theoretical) LR(1) lookahead set, an error is ultimately detected. In the example above, if  
126603 some other reserved word (for example, **while**) is also recognized, an error occurs later.

126604 This is approximately equivalent to saying that reserved words are recognized after other  
126605 reserved words (because it is after a reserved word that this condition occurs), but avoids  
126606 the “except for ...” list that would be required for **case**, **for**, and so on. (Reserved words  
126607 are of course recognized anywhere a *simple\_command* can appear, as well. Other rules take  
126608 care of the special cases of non-recognition, such as rule (4) for **case** statements.)

126609 Note that the body of here-documents are handled by token recognition (see XCU [Section 2.3](#), on  
 126610 page 2321) and do not appear in the grammar directly. (However, the here-document I/O  
 126611 redirection operator is handled as part of the grammar.)

126612 The start symbol of the grammar (**complete\_command**) represents either input from the  
 126613 command line or a shell script. It is repeatedly applied by the interpreter to its input and  
 126614 represents a single “chunk” of that input as seen by the interpreter.

#### 126615 C.2.10.1 Shell Grammar Lexical Conventions

126616 There is no additional rationale provided for this section.

#### 126617 C.2.10.2 Shell Grammar Rules

126618 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0036 [44] is applied. |

### 126619 C.2.11 Signals and Error Handling

126620 SD5-XCU-ERN-93 is applied, updating the first paragraph of XCU [Section 2.11](#) (on page 2353).

### 126621 C.2.12 Shell Execution Environment

126622 Some implementations have implemented the last stage of a pipeline in the current environment  
 126623 so that commands such as:

126624 `command | read foo`

126625 set variable **foo** in the current environment. This extension is allowed, but not required;  
 126626 therefore, a shell programmer should consider a pipeline to be in a subshell environment, but  
 126627 not depend on it.

126628 In early proposals, the description of execution environment failed to mention that each  
 126629 command in a multiple command pipeline could be in a subshell execution environment. For  
 126630 compatibility with some historical shells, the wording was phrased to allow an implementation  
 126631 to place any or all commands of a pipeline in the current environment. However, this means that  
 126632 a POSIX application must assume each command is in a subshell environment, but not depend  
 126633 on it.

126634 The wording about shell scripts is meant to convey the fact that describing “trap actions” can  
 126635 only be understood in the context of the shell command language. Outside of this context, such  
 126636 as in a C-language program, signals are the operative condition, not traps.

126637 POSIX.1-2008, Technical Corrigendum 1, XCU/TC1-2008/0037 [238] is applied. +

### 126638 C.2.13 Pattern Matching Notation

126639 Pattern matching is a simpler concept and has a simpler syntax than REs, as the former is  
 126640 generally used for the manipulation of filenames, which are relatively simple collections of  
 126641 characters, while the latter is generally used to manipulate arbitrary text strings of potentially  
 126642 greater complexity. However, some of the basic concepts are the same, so this section points  
 126643 liberally to the detailed descriptions in XBD [Chapter 9](#) (on page 181).

126644 C.2.13.1 *Patterns Matching a Single Character*

126645 Both quoting and escaping are described here because pattern matching must work in three  
126646 separate circumstances:

- 126647 1. Calling directly upon the shell, such as in pathname expansion or in a **case** statement. All  
126648 of the following match the string or file **abc**:

126649 `abc "abc" a"b" c a\bc a[b]c a["b"]c a[\b]c a["\b"]c a?c a*c`

126650 The following do not:

126651 `"a?c" a*c a\[b]c`

- 126652 2. Calling a utility or function without going through a shell, as described for *find* and the  
126653 *fnmatch()* function defined in the System Interfaces volume of POSIX.1-2008.

- 126654 3. Calling utilities such as *find*, *cpio*, *tar*, or *pax* through the shell command line. In this case,  
126655 shell quote removal is performed before the utility sees the argument. For example, in:

126656 `find /bin -name "e\c[\h]o" -print`

126657 after quote removal, the <backslash> characters are presented to *find* and it treats them as  
126658 escape characters. Both precede ordinary characters, so the *c* and *h* represent themselves  
126659 and *echo* would be found on many historical systems (that have it in **/bin**). To find a  
126660 filename that contained shell special characters or pattern characters, both quoting and  
126661 escaping are required, such as:

126662 `pax -r ... "*a\(\?"`

126663 to extract a filename ending with "a(?".

126664 Conforming applications are required to quote or escape the shell special characters (sometimes  
126665 called metacharacters). If used without this protection, syntax errors can result or  
126666 implementation extensions can be triggered. For example, the KornShell supports a series of  
126667 extensions based on parentheses in patterns.

126668 The restriction on a <circumflex> in a bracket expression is to allow implementations that  
126669 support pattern matching using the <circumflex> as the negation character in addition to the  
126670 <exclamation-mark>. A conforming application must use something like "[\^!]" to match  
126671 either character.

126672 C.2.13.2 *Patterns Matching Multiple Characters*

126673 Since each <asterisk> matches zero or more occurrences, the patterns "a\*b" and "a\*\*b" have  
126674 identical functionality.

126675 **Examples**

126676 `a[bc]` Matches the strings "ab" and "ac".

126677 `a*d` Matches the strings "ad", "abd", and "abcd", but not the string "abc".

126678 `a*d*` Matches the strings "ad", "abcd", "abcdef", "aaaad", and "adddd".

126679 `*a*d` Matches the strings "ad", "abcd", "efabcd", "aaaad", and "adddd".

126680 C.2.13.3 *Patterns Used for Filename Expansion*

126681 The caveat about a <slash> within a bracket expression is derived from historical practice. The  
 126682 pattern "a[b/c]d" does not match such pathnames as **abd** or **a/d**. On some implementations  
 126683 (including those conforming to the Single UNIX Specification), it matched a pathname of  
 126684 literally "a[b/c]d". On other systems, it produced an undefined condition (an unescaped '['  
 126685 used outside a bracket expression). In this version, the XSI behavior is now required.

126686 Filenames beginning with a <period> historically have been specially protected from view on  
 126687 UNIX systems. A proposal to allow an explicit <period> in a bracket expression to match a  
 126688 leading <period> was considered; it is allowed as an implementation extension, but a  
 126689 conforming application cannot make use of it. If this extension becomes popular in the future, it  
 126690 will be considered for a future version of the Shell and Utilities volume of POSIX.1-2008.

126691 Historical systems have varied in their permissions requirements. To match **f\*/bar** has required  
 126692 read permissions on the **f\*** directories in the System V shell, but the Shell and Utilities volume of  
 126693 POSIX.1-2008, the C shell, and KornShell require only search permissions.

126694 **C.2.14 Special Built-In Utilities**

126695 See the RATIONALE sections on the individual reference pages.

126696 **C.3 Batch Environment Services and Utilities**126697 **Scope of the Batch Environment Services and Utilities Option**

126698 This section summarizes the deliberations of the IEEE P1003.15 (Batch Environment) working  
 126699 group in the development of the Batch Environment Services and Utilities option, which covers  
 126700 a set of services and utilities defining a batch processing system.

126701 This informative section contains historical information concerning the contents of the  
 126702 amendment and describes why features were included or discarded by the working group.

126703 **History of Batch Systems**

126704 The supercomputing technical committee began as a "Birds Of a Feather" (BOF) at the January  
 126705 1987 Usenix meeting. There was enough general interest to form a supercomputing attachment  
 126706 to the /usr/group working groups. Several subgroups rapidly formed. Of those subgroups, the  
 126707 batch group was the most ambitious. The first early meetings were spent evaluating user needs  
 126708 and existing batch implementations.

126709 To evaluate user needs, individuals from the supercomputing community came and presented  
 126710 their needs. Common requests were flexibility, interoperability, control of resources, and ease-of-  
 126711 use. Backward-compatibility was not an issue. The working group then evaluated some existing  
 126712 systems. The following different systems were evaluated:

- 126713 • PROD
- 126714 • Convex Distributed Batch
- 126715 • NQS
- 126716 • CTSS
- 126717 • MDQS from Ballistics Research Laboratory (BRL)

126718 Finally, NQS was chosen as a model because it satisfied not only the most user requirements, but

126719 because it was public domain, already implemented on a variety of hardware platforms, and  
126720 network-based.

### 126721 **Historical Implementations of Batch Systems**

126722 Deferred processing of work under the control of a scheduler has been a feature of most  
126723 proprietary operating systems from the earliest days of multi-user systems in order to maximize  
126724 utilization of the computer.

126725 The arrival of UNIX systems proved to be a dilemma to many hardware providers and users  
126726 because it did not include the sophisticated batch facilities offered by the proprietary systems.  
126727 This omission was rectified in 1986 by NASA Ames Research Center who developed the  
126728 Network Queuing System (NQS) as a portable UNIX application that allowed the routing and  
126729 processing of batch “jobs” in a network. To encourage its usage, the product was later put into  
126730 the public domain. It was promptly picked up by UNIX hardware providers, and ported and  
126731 developed for their respective hardware and UNIX implementations.

126732 Many major vendors, who traditionally offer a batch-dominated environment, ported the  
126733 public-domain product to their systems, customized it to support the capabilities of their  
126734 systems, and added many customer-requested features.

126735 Due to the strong hardware provider and customer acceptance of NQS, it was decided to use  
126736 NQS as the basis for the POSIX Batch Environment amendment in 1987. Other batch systems  
126737 considered at the time included CTSS, MDQS (a forerunner of NQS from the Ballistics Research  
126738 Laboratory), and PROD (a Los Alamos Labs development). None were thought to have both the  
126739 functionality and acceptability of NQS.

### 126740 **NQS Differences from the *at* utility**

126741 The base standard *at* and *batch* utilities are not sufficient to meet the batch processing needs in a  
126742 supercomputing environment and additional functionality in the areas of resource management,  
126743 job scheduling, system management, and control of output is required.

### 126744 **Batch Environment Services and Utilities Option Definitions**

126745 The concept of a batch job is closely related to a session with a session leader. The main  
126746 difference is that a batch job does not have a controlling terminal. There has been much debate  
126747 over whether to use the term “request” or “job”. Job was the final choice because of the  
126748 historical use of this term in the batch environment.

126749 The current definition for job identifiers is not sufficient with the model of destinations. The  
126750 current definition is:

126751 `sequence_number.originating_host`

126752 Using the model of destination, a host may include multiple batch nodes, the location of which  
126753 is identified uniquely by a name or directory service. If the current definition is used, batch  
126754 nodes running on the same host would have to coordinate their use of sequence numbers, as  
126755 sequence numbers are assigned by the originating host. The alternative is to use the originating  
126756 batch node name instead of the originating host name.

126757 The reasons for wishing to run more than one batch system per host could be the following.

126758 A test and production batch system are maintained on a single host. This is most likely in a  
126759 development facility, but could also arise when a site is moving from one version to another. The  
126760 new batch system could be installed as a test version that is completely separate from the  
126761 production batch system, so that problems can be isolated to the test system. Requiring the batch  
126762 nodes to coordinate their use of sequence numbers creates a dependency between the two

- 126763 nodes, and that defeats the purpose of running two nodes.
- 126764 A site has multiple departments using a single host, with different management policies. An  
126765 example of contention might be in job selection algorithms. One group might want a FIFO type  
126766 of selection, while another group wishes to use a more complex algorithm based on resource  
126767 availability. Again, requiring the batch nodes to coordinate is an unnecessary binding.
- 126768 The proposal eventually accepted was to replace originating host with originating batch node.  
126769 This supplies sufficient granularity to ensure unique job identifiers. If more than one batch node  
126770 is on a particular host, they each have their own unique name.
- 126771 The queue portion of a destination is not part of the job identifier as these are not required to be  
126772 unique between batch nodes. For instance, two batch nodes may both have queues called small,  
126773 medium, and large. It is only the batch node name that is uniquely identifiable throughout the  
126774 batch system. The queue name has no additional function in this context.
- 126775 Assume there are three batch nodes, each of which has its own name server. On batch node one,  
126776 there are no queues. On batch node two, there are fifty queues. On batch node three, there are  
126777 forty queues. The system administrator for batch node one does not have to configure queues,  
126778 because there are none implemented. However, if a user wishes to send a job to either batch  
126779 node two or three, the system administrator for batch node one must configure a destination  
126780 that maps to the appropriate batch node and queue. If every queue is to be made accessible from  
126781 batch node one, the system administrator has to configure ninety destinations.
- 126782 To avoid requiring this, there should be a mechanism to allow a user to separate the destination  
126783 into a batch node name and a queue name. Then, an implementation that is configured to get to  
126784 all the batch nodes does not need any more configuration to allow a user to get to all of the  
126785 queues on all of the batch nodes. The node name is used to locate the batch node, while the  
126786 queue name is sent unchanged to that batch node.
- 126787 The following are requirements that a destination identifier must be capable of providing:
- 126788 • The ability to direct a job to a queue in a particular batch node.
  - 126789 • The ability to direct a job to a particular batch node.
  - 126790 • The ability to group at a higher level than just one queue. This includes grouping similar  
126791 queues across multiple batch nodes (this is a pipe queue).
  - 126792 • The ability to group batch nodes. This allows a user to submit a job to a group name with  
126793 no knowledge of the batch node configuration. This also provides aliasing as a special  
126794 case. Aliasing is a group containing only one batch node name. The group name is the  
126795 alias.
- 126796 In addition, the administrator has the following requirements:
- 126797 • The ability to control access to the queues.
  - 126798 • The ability to control access to the batch nodes.
  - 126799 • The ability to control access to groups of queues (pipe queues).
  - 126800 • The ability to configure retry time intervals and durations.
- 126801 The requirements of the user are met by destination as explained in the following.
- 126802 The user has the ability to specify a queue name, which is known only to the batch node  
126803 specified. There is no configuration of these queues required on the submitting node.
- 126804 The user has the ability to specify a batch node whose name is network-unique. The  
126805 configuration required is that the batch node be defined as an application, just as other  
126806 applications such as FTP are configured.

126807 Once a job reaches a queue, it can again become a user of the batch system. The batch node can  
 126808 choose to send the job to another batch node or queue or both. In other words, the routing is at  
 126809 an application level, and it is up to the batch system to choose where the job will be sent.  
 126810 Configuration is up to the batch node where the queue resides. This provides grouping of  
 126811 queues across batch nodes or within a batch node. The user submits the job to a queue, which by  
 126812 definition routes the job to other queues or nodes or both.

126813 A node name may be given to a naming service, which returns multiple addresses as opposed to  
 126814 just one. This provides grouping at a batch node level. This is a local issue, meaning that the  
 126815 batch node must choose only one of these addresses. The list of addresses is not sent with the  
 126816 job, and once the job is accepted on another node, there is no connection between the list and the  
 126817 job. The requirements of the administrator are met by destination as explained in the following.

126818 The control of queues is a batch system issue, and will be done using the batch administrative  
 126819 utilities.

126820 The control of nodes is a network issue, and will be done through whatever network facilities  
 126821 are available.

126822 The control of access to groups of queues (pipe queues) is covered by the control of any other  
 126823 queue. The fact that the job may then be sent to another destination is not relevant.

126824 The propagation of a job across more than one point-to-point connection was dropped because  
 126825 of its complexity and because all of the issues arising from this capability could not be resolved.  
 126826 It could be provided as additional functionality at some time in the future.

126827 The addition of *network* as a defined term was done to clarify the difference between a network  
 126828 of batch nodes as opposed to a network of hosts. A network of batch nodes is referred to as a  
 126829 batch system. The network refers to the actual host configuration. A single host may have  
 126830 multiple batch nodes.

126831 In the absence of a standard network naming convention, this option establishes its own  
 126832 convention for the sake of consistency and expediency. This is subject to change, should a future  
 126833 working group develop a standard naming convention for network pathnames.

### 126834 C.3.1 Batch General Concepts

126835 During the development of the Batch Environment Services and Utilities option, a number of  
 126836 topics were discussed at length which influenced the wording of the normative text but could  
 126837 not be included in the final text. The following items are some of the most significant terms and  
 126838 concepts of those discussed:

- 126839 • Small and Consistent Command Set

126840 Often, conventional utilities from UNIX systems have a very complicated utility syntax  
 126841 and usage. This can often result in confusion and errors when trying to use them. The  
 126842 Batch Environment Services and Utilities option utility set, on the other hand, has been  
 126843 paired to a small set of robust utilities with an orthogonal calling sequence.

- 126844 • Checkpoint/Restart

126845 This feature permits an already executing process to checkpoint or save its contents. Some  
 126846 implementations permit this at both the batch utility level (for example, checkpointing this  
 126847 job upon its abnormal termination) or from within the job itself via a system call. Support  
 126848 of checkpoint/restart is optional. A conscious, careful effort was made to make the *qsub*  
 126849 utility consistently refer to checkpoint/restart as optional functionality.

- 126850
- Rerunability
- 126851 When a user submits a job for batch processing, they can designate it “rerunnable” in that  
126852 it will automatically resume execution from the start of the job if the machine on which it  
126853 was executing crashes for some reason. The decision on whether the job will be rerun or  
126854 not is entirely up to the submitter of the job and no decisions will be made within the batch  
126855 system. A job that is rerunnable and has been submitted with the proper  
126856 checkpoint/restart switch will first be checkpointed and execution begun from that point.  
126857 Furthermore, use of the implementation-defined checkpoint/restart feature will not be  
126858 defined in this context.
- 126859
- Error Codes
- 126860 All utilities exit with error status zero (0) if successful, one (1) if a user error occurred, and  
126861 two (2) for an internal Batch Environment Services and Utilities option error.
- 126862
- Level of Portability
- 126863 Portability is specified at both the user, operator, and administrator levels. A conforming  
126864 batch implementation prevents identical functionality and behavior at all these levels.  
126865 Additionally, portable batch shell scripts with embedded Batch Environment Services and  
126866 Utilities option utilities add an additional level of portability.
- 126867
- Resource Specification
- 126868 A small set of globally understood resources, such as memory and CPU time, is specified.  
126869 All conforming batch implementations are able to process them in a manner consistent  
126870 with the yet-to-be-developed resource management model. Resources not in this  
126871 amendment set are ignored and passed along as part of the argument stream of the utility.
- 126872
- Queue Position
- 126873 Queue position is the place a job occupies in a queue. It is dependent on a variety of factors  
126874 such as submission time and priority. Since priority may be affected by the implementation  
126875 of fair share scheduling, the definition of queue position is implementation-defined.
- 126876
- Queue ID
- 126877 A numerical queue ID is an external requirement for purposes of accounting. The  
126878 identification number was chosen over queue name for processing convenience.
- 126879
- Job ID
- 126880 A common notion of “jobs” is a collection of processes whose process group cannot be  
126881 altered and is used for resource management and accounting. This concept is  
126882 implementation-defined and, as such, has been omitted from the batch amendment.
- 126883
- Bytes *versus* Words
- 126884 Except for one case, bytes are used as the standard unit for memory size. Furthermore, the  
126885 definition of a word varies from machine to machine. Therefore, bytes will be the default  
126886 unit of memory size.
- 126887
- Regular Expressions
- 126888 The standard definition of regular expressions is much too broad to be used in the batch  
126889 utility syntax. All that is needed is a simple concept of “all”; for example, delete all my jobs  
126890 from the named queue. For this reason, regular expressions have been eliminated from the  
126891 batch amendment.

- 126892 • Display Privacy
  - 126893 How much data should be displayed locally through functions? Local policy dictates the
  - 126894 amount of privacy. Library functions must be used to create and enforce local policy.
  - 126895 Network and local *qstats* must reflect the policy of the server machine.
- 126896 • Remote Host Naming Convention
  - 126897 It was decided that host names would be a maximum of 255 characters in length, with at
  - 126898 most 15 characters being shown in displays. The 255 character limit was chosen because it
  - 126899 is consistent with BSD. The 15-character limit was an arbitrary decision.
- 126900 • Network Administration
  - 126901 Network administration is important, but is outside the scope of the batch amendment.
  - 126902 Network administration could be done with *rsh*. However, authentication becomes two-
  - 126903 sided.
- 126904 • Network Administration Philosophy
  - 126905 Keep it simple. Centralized management should be possible. For example, Los Alamos
  - 126906 needs a dumb set of CPUs to be managed by a central system *versus* several
  - 126907 independently-managed systems as is the general case for the Batch Environment Services
  - 126908 and Utilities option.
- 126909 • Operator Utility Defaults (that is, Default Host, User, Account, and so on)
  - 126910 It was decided that usability would override orthogonality and syntactic consistency.
- 126911 • The Batch System Manager and Operator Distinction
  - 126912 The distinction between manager and operator is that operators can only control the flow
  - 126913 of jobs. A manager can alter the batch system configuration in addition to job flow. POSIX
  - 126914 makes a distinction between user and system administrator but goes no further. The
  - 126915 concepts of manager and operator privileges fall under local policy. The distinction
  - 126916 between manager and operator is historical in batch environments, and the Batch
  - 126917 Environment Services and Utilities option has continued that distinction.
- 126918 • The Batch System Administrator
  - 126919 An administrator is equivalent to a batch system manager.

### 126920 C.3.2 Batch Services

- 126921 This rationale is provided as informative rather than normative text, to avoid placing
- 126922 requirements on implementors regarding the use of symbolic constants, but at the same time to
- 126923 give implementors a preferred practice for assigning values to these constants to promote
- 126924 interoperability.
- 126925 The *Checkpoint* and *Minimum\_Cpu\_Interval* attributes induce a variety of behavior depending
- 126926 upon their values. Some jobs cannot or should not be checkpointed. Other users will simply
- 126927 need to ensure job continuation across planned downtimes; for example, scheduled preventive
- 126928 maintenance. For users consuming expensive resources, or for jobs that run longer than the
- 126929 mean time between failures, however, periodic checkpointing may be essential. However,
- 126930 system administrators must be able to set minimum checkpoint intervals on a queue-by-queue
- 126931 basis to guard against, for example, naive users specifying interval values too small on memory-
- 126932 intensive jobs. Otherwise, system overhead would adversely affect performance.
- 126933 The use of symbolic constants, such as *NO\_CHECKPOINT*, was introduced to lend a degree of
- 126934 formalism and portability to this option.

- 126935 Support for checkpointing is optional for servers. However, clients must provide for the `-c`  
 126936 option, since in a distributed environment the job may run on a server that does provide such  
 126937 support, even if the host of the client does not support the checkpoint feature.
- 126938 If the user does not specify the `-c` option, the default action is left unspecified by this option.  
 126939 Some implementations may wish to do checkpointing by default; others may wish to checkpoint  
 126940 only under an explicit request from the user.
- 126941 The *Priority* attribute has been made non-optional. All clients already had been required to  
 126942 support the `-p` option. The concept of prioritization is common in historical implementations.  
 126943 The default priority is left to the server to establish.
- 126944 The *Hold\_Types* attribute has been modified to allow for implementation-defined hold types to  
 126945 be passed to a batch server.
- 126946 It was the intent of the IEEE P1003.15 working group to mandate the support for the  
 126947 *Resource\_List* attribute in this option by referring to another amendment, specifically the  
 126948 IEEE P1003.1a draft standard. However, during the development of the IEEE P1003.1a draft  
 126949 standard this was excluded. As such this requirement has been removed from the normative  
 126950 text.
- 126951 The *Shell\_Path* attribute has been modified to accept a list of shell paths that are associated with  
 126952 a host. The name of the attribute has been changed to *Shell\_Path\_List*.

### 126953 C.3.3 Common Behavior for Batch Environment Utilities

- 126954 This section was defined to meet the goal of a “Small and Consistent Command Set” for this  
 126955 option.

## 126956 C.4 Utilities

- 126957 For the utilities included in POSIX.1-2008, see the RATIONALE sections on the individual  
 126958 reference pages.

### 126959 C.4.1 Utilities Removed in this Version

- 126960 None.

### 126961 C.4.2 Utilities Removed in the Previous Version

- 126962 The following utilities were removed in the previous version of this standard:

|        |                 |               |               |              |               |
|--------|-----------------|---------------|---------------|--------------|---------------|
| 126963 | <i>calendar</i> | <i>cu</i>     | <i>line</i>   | <i>pcat</i>  | <i>unpack</i> |
| 126964 | <i>cancel</i>   | <i>dircmp</i> | <i>lint</i>   | <i>pg</i>    | <i>uulog</i>  |
| 126965 | <i>cc</i>       | <i>dis</i>    | <i>lpstat</i> | <i>spell</i> | <i>uuname</i> |
| 126966 | <i>col</i>      | <i>egrep</i>  | <i>mail</i>   | <i>sum</i>   | <i>uupick</i> |
| 126967 | <i>cpio</i>     | <i>fgrep</i>  | <i>pack</i>   | <i>tar</i>   | <i>uuto</i>   |

126968 **C.4.3 Exclusion of Utilities**

126969 The set of utilities contained in POSIX.1-2008 is drawn from the base documents, with one  
 126970 addition: the *c99* utility. This section contains rationale for some of the deliberations that led to  
 126971 this set of utilities, and why certain utilities were excluded.

126972 Many utilities were evaluated by the standard developers; more historical utilities were  
 126973 excluded from the base documents than included. The following list contains many common  
 126974 UNIX system utilities that were not included as mandatory utilities, in the User Portability  
 126975 Utilities option, in the XSI option, or in one of the software development groups. It is logistically  
 126976 difficult for this rationale to distribute correctly the reasons for not including a utility among the  
 126977 various utility options. Therefore, this section covers the reasons for all utilities not included in  
 126978 POSIX.1-2008.

126979 This rationale is limited to a discussion of only those utilities actively or indirectly evaluated by  
 126980 the standard developers of the base documents, rather than the list of all known UNIX utilities  
 126981 from all its variants.

126982 *adb* The intent of the various software development utilities was to assist in the  
 126983 installation (rather than the actual development and debugging) of applications.  
 126984 This utility is primarily a debugging tool. Furthermore, many useful aspects of *adb*  
 126985 are very hardware-specific.

126986 *as* Assemblers are hardware-specific and are included implicitly as part of the  
 126987 compilers in POSIX.1-2008.

126988 *banner* The only known use of this command is as part of the *lp* printer header pages. It  
 126989 was decided that the format of the header is implementation-defined, so this utility  
 126990 is superfluous to application portability.

126991 *calendar* This reminder service program is not useful to conforming applications.

126992 *cancel* The *lp* (line printer spooling) system specified is the most basic possible and did  
 126993 not need this level of application control.

126994 *chroot* This is primarily of administrative use, requiring superuser privileges.

126995 *col* No utilities defined in POSIX.1-2008 produce output requiring such a filter. The  
 126996 *nroff* text formatter is present on many historical systems and will continue to  
 126997 remain as an extension; *col* is expected to be shipped by all the systems that ship  
 126998 *nroff*.

126999 *cpio* This has been replaced by *pax*, for reasons explained in the rationale for that utility.

127000 *cpp* This is subsumed by *c99*.

127001 *cu* This utility is terminal-oriented and is not useful from shell scripts or typical  
 127002 application programs.

127003 *dc* The functionality of this utility can be provided by the *bc* utility; *bc* was selected  
 127004 because it was easier to use and had superior functionality. Although the historical  
 127005 versions of *bc* are implemented using *dc* as a base, POSIX.1-2008 prescribes the  
 127006 interface and not the underlying mechanism used to implement it.

127007 *dircmp* Although a useful concept, the historical output of this directory comparison  
 127008 program is not suitable for processing in application programs. Also, the *diff -r*  
 127009 command gives equivalent functionality.

127010 *dis* Disassemblers are hardware-specific.

|        |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 127011 | <i>emacs</i>  | The community of <i>emacs</i> editing enthusiasts was adamant that the full <i>emacs</i> editor not be included in the base documents because they were concerned that an attempt to standardize this very powerful environment would encourage vendors to ship versions conforming strictly to the standard, but lacking the extensibility required by the community. The author of the original <i>emacs</i> program also expressed his desire to omit the program. Furthermore, there were a number of historical UNIX systems that did not include <i>emacs</i> , or included it without supporting it, but there were very few that did not include and support <i>vi</i> . |
| 127012 |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 127013 |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 127014 |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| 127020 | <i>line</i>   | The functionality of <i>line</i> can be provided with <i>read</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 127021 | <i>lint</i>   | This technology is partially subsumed by <i>c99</i> . It is also hard to specify the degree of checking for possible error conditions in programs in any compiler, and specifying what <i>lint</i> would do in these cases is equally difficult.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 127022 |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 127023 |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 127024 |               | It is fairly easy to specify what a compiler does. It requires specifying the language, what it does with that language, and stating that the interpretation of any incorrect program is unspecified. Unfortunately, any description of <i>lint</i> is required to specify what to do with erroneous programs. Since the number of possible errors and questionable programming practices is infinite, one cannot require <i>lint</i> to detect all errors of any given class.                                                                                                                                                                                                   |

| 127029 |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 127030 |               | Additionally, some vendors complained that since many compilers are distributed in a binary form without a <i>lint</i> facility (because the ISO C standard does not require one), implementing the standard as a stand-alone product will be much harder. Rather than being able to build upon a standard compiler component (simply by providing <i>c99</i> as an interface), source to that compiler would most likely need to be modified to provide the <i>lint</i> functionality. This was considered a major burden on system providers for a very small gain to developers (users).                                                                                      |
| 127031 |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| 127066 | <i>prof</i>  | The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications. This utility is primarily a debugging tool.                                                                                                                                                                                                                                                                                                                                                               |
| 127067 |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 127068 |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 127069 | RCS          | RCS was originally considered as part of a version control utilities portion of the scope. However, this aspect was abandoned by the standard developers. SCCS is now included as an optional part of the XSI option.                                                                                                                                                                                                                                                                                                                                                    |
| 127070 |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 127071 |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| 127074 | <i>rsh</i>   | Restricted shell. This was not considered by the standard developers because it does not provide the level of security restriction that is implied by historical documentation.                                                                                                                                                                                                                                                                                                                                                                                          |
| 127075 |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 127076 |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 127077 | <i>sdb</i>   | The intent of the various software development utilities was to assist in the installation (rather than the actual development and debugging) of applications. This utility is primarily a debugging tool. Furthermore, some useful aspects of <i>sdb</i> are very hardware-specific.                                                                                                                                                                                                                                                                                    |
| 127078 |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| 127096 | <i>su</i>    | This utility is not useful from shell scripts or typical application programs. (There was also sentiment to avoid security-related utilities.)                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 127097 |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|        |               |                                                                                                                                                   |
|--------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 127098 | <i>sum</i>    | This utility was renamed <i>cksum</i> .                                                                                                           |
| 127099 | <i>tar</i>    | This has been replaced by <i>pax</i> , for reasons explained in the rationale for that utility.                                                   |
| 127100 | <i>unpack</i> | This compression program was considered inferior to <i>uncompress</i> .                                                                           |
| 127101 | <i>wall</i>   | This utility is terminal-oriented and is not useful in shell scripts or typical applications. It is generally used only by system administrators. |
| 127102 |               |                                                                                                                                                   |

127107

*The Institute of Electrical and Electronics Engineers, Inc.*

127108

127109

## Portability Considerations (Informative)

127110

This section contains information to satisfy various international requirements:

127111

- [Section D.1](#) describes perceived user requirements.

127112

- [Section D.2](#) (on page 3719) indicates how the facilities of POSIX.1-2008 satisfy those requirements.

127113

127114

- [Section D.3](#) (on page 3727) offers guidance to writers of profiles on how the configurable options, limits, and optional behavior of POSIX.1-2008 should be cited in profiles.

127115

### D.1 User Requirements

127117

This section describes the user requirements that were perceived by the standard developers. The primary source for these requirements was an analysis of historical practice in widespread use, as typified by the base documents listed in [Section A.1.1](#) (on page 3439).

127118

127119

127120

POSIX.1-2008 addresses the needs of users requiring open systems solutions for source code portability of applications. It currently addresses users requiring open systems solutions for source-code portability of applications involving multi-programming and process management (creating processes, signaling, and so on); access to files and directories in a hierarchy of file systems (opening, reading, writing, deleting files, and so on); access to asynchronous communications ports and other special devices; access to information about other users of the system; facilities supporting applications requiring bounded (realtime) response.

127121

127122

127123

127124

127125

127126

127127

The following users are identified for POSIX.1-2008:

127128

- Those employing applications written in high-level languages, such as C, Ada, or FORTRAN.

127129

127130

- Users who desire conforming applications that do not necessarily require the characteristics of high-level languages (for example, the speed of execution of compiled languages or the relative security of source code intellectual property inherent in the compilation process).

127131

127132

127133

127134

- Users who desire conforming applications that can be developed quickly and can be modified readily without the use of compilers and other system components that may be unavailable on small systems or those without special application development capabilities.

127135

127136

127137

127138

- Users who interact with a system to achieve general-purpose time-sharing capabilities common to most business or government offices or academic environments: editing, filing, inter-user communications, printing, and so on.

127139

127140

127141

- Users who develop applications for POSIX-conformant systems.

127142

- Users who develop applications for UNIX systems.

127143

An acknowledged restriction on applicable users is that they are limited to the group of individuals who are familiar with the style of interaction characteristic of historically-derived systems based on one of the UNIX operating systems (as opposed to other historical systems

127144

127145

127146 with different models, such as MS/DOS, Macintosh, VMS, MVS, and so on). Typical users  
127147 would include program developers, engineers, or general-purpose time-sharing users.

127148 The requirements of users of POSIX.1-2008 can be summarized as a single goal: *application source*  
127149 *portability*. The requirements of the user are stated in terms of the requirements of portability of  
127150 applications. This in turn becomes a requirement for a standardized set of syntax and semantics  
127151 for operations commonly found on many operating systems.

127152 The following sections list the perceived requirements for application portability.

#### 127153 **D.1.1 Configuration Interrogation**

127154 An application must be able to determine whether and how certain optional features are  
127155 provided and to identify the system upon which it is running, so that it may appropriately adapt  
127156 to its environment.

127157 Applications must have sufficient information to adapt to varying behaviors of the system.

#### 127158 **D.1.2 Process Management**

127159 An application must be able to manage itself, either as a single process or as multiple processes.  
127160 Applications must be able to manage other processes when appropriate.

127161 Applications must be able to identify, control, create, and delete processes, and there must be  
127162 communication of information between processes and to and from the system.

127163 Applications must be able to use multiple flows of control with a process (threads) and  
127164 synchronize operations between these flows of control.

#### 127165 **D.1.3 Access to Data**

127166 Applications must be able to operate on the data stored on the system, access it, and transmit it  
127167 to other applications. Information must have protection from unauthorized or accidental access  
127168 or modification.

#### 127169 **D.1.4 Access to the Environment**

127170 Applications must be able to access the external environment to communicate their input and  
127171 results.

#### 127172 **D.1.5 Access to Determinism and Performance Enhancements**

127173 Applications must have sufficient control of resource allocation to ensure the timeliness of  
127174 interactions with external objects.

**127175 D.1.6 Operating System-Dependent Profile**

127176 The capabilities of the operating system may make certain optional characteristics of the base  
127177 language in effect no longer optional, and this should be specified.

**127178 D.1.7 I/O Interaction**

127179 The interaction between the C language I/O subsystem (*stdio*) and the I/O subsystem of  
127180 POSIX.1-2008 must be specified.

**127181 D.1.8 Internationalization Interaction**

127182 The effects of the environment of POSIX.1-2008 on the internationalization facilities of the C  
127183 language must be specified.

**127184 D.1.9 C-Language Extensions**

127185 Certain functions in the C language must be extended to support the additional capabilities  
127186 provided by POSIX.1-2008.

**127187 D.1.10 Command Language**

127188 Users should be able to define procedures that combine simple tools and/or applications into  
127189 higher-level components that perform to the specific needs of the user. The user should be able  
127190 to store, recall, use, and modify these procedures. These procedures should employ a powerful  
127191 command language that is used for recurring tasks in conforming applications (scripts) in the  
127192 same way that it is used interactively to accomplish one-time tasks. The language and the  
127193 utilities that it uses must be consistent between systems to reduce errors and retraining.

**127194 D.1.11 Interactive Facilities**

127195 Use the system to accomplish individual tasks at an interactive terminal. The interface should be  
127196 consistent, intuitive, and offer usability enhancements to increase the productivity of terminal  
127197 users, reduce errors, and minimize retraining costs. Online documentation or usage assistance  
127198 should be available.

**127199 D.1.12 Accomplish Multiple Tasks Simultaneously**

127200 Access applications and interactive facilities from a single terminal without requiring serial  
127201 execution: switch between multiple interactive tasks; schedule one-time or periodic background  
127202 work; display the status of all work in progress or scheduled; influence the priority scheduling  
127203 of work, when authorized.

**127204 D.1.13 Complex Data Manipulation**

127205 Manipulate data in files in complex ways: sort, merge, compare, translate, edit, format, pattern  
127206 match, select subsets (strings, columns, fields, rows, and so on). These facilities should be  
127207 available to both conforming applications and interactive users.

**127208 D.1.14 File Hierarchy Manipulation**

127209 Create, delete, move/rename, copy, backup/archive, and display files and directories. These  
127210 facilities should be available to both conforming applications and interactive users.

**127211 D.1.15 Locale Configuration**

127212 Customize applications and interactive sessions for the cultural and language conventions of the  
127213 user. Employ a wide variety of standard character encodings. These facilities should be available  
127214 to both conforming applications and interactive users.

**127215 D.1.16 Inter-User Communication**

127216 Send messages or transfer files to other users on the same system or other systems on a network.  
127217 These facilities should be available to both conforming applications and interactive users.

**127218 D.1.17 System Environment**

127219 Display information about the status of the system (activities of users and their interactive and  
127220 background work, file system utilization, system time, configuration, and presence of optional  
127221 facilities) and the environment of the user (terminal characteristics, and so on). Inform the  
127222 system operator/administrator of problems. Control access to user files and other resources.

**127223 D.1.18 Printing**

127224 Output files on a variety of output device classes, accessing devices on local or network-  
127225 connected systems. Control (or influence) the formatting, priority scheduling, and output  
127226 distribution of work. These facilities should be available to both conforming applications and  
127227 interactive users.

**127228 D.1.19 Software Development**

127229 Develop (create and manage source files, compile/interpret, debug) portable open systems  
127230 applications and package them for distribution to, and updating of, other systems.

## D.2 Portability Capabilities

This section describes the significant portability capabilities of POSIX.1-2008 and indicates how the user requirements listed in [Section D.1](#) (on page 3715) are addressed. The capabilities are listed in the same format as the preceding user requirements; they are summarized below:

- Configuration Interrogation
- Process Management
- Access to Data
- Access to the Environment
- Access to Determinism and Performance Enhancements
- Operating System-Dependent Profile
- I/O Interaction
- Internationalization Interaction
- C-Language Extensions
- Command Language
- Interactive Facilities
- Accomplish Multiple Tasks Simultaneously
- Complex Data Manipulation
- File Hierarchy Manipulation
- Locale Configuration
- Inter-User Communication
- System Environment
- Printing
- Software Development

### D.2.1 Configuration Interrogation

The *uname()* operation provides basic identification of the system. The *sysconf()*, *pathconf()*, and *fpathconf()* functions and the *getconf* utility provide means to interrogate the implementation to determine how to adapt to the environment in which it is running. These values can be either static (indicating that all instances of the implementation have the same value) or dynamic (indicating that different instances of the implementation have the different values, or that the value may vary for other reasons, such as reconfiguration).

#### Unsatisfied Requirements

None directly. However, as new areas are added, there will be a need for additional capability in this area.

## D.2.2 Process Management

The *fork()*, *exec* family, *posix\_spawn()*, and *posix\_spawnp()* functions provide for the creation of new processes or the insertion of new applications into existing processes. The *\_Exit()*, *\_exit()*, *exit()*, and *abort()* functions allow for the termination of a process by itself. The *wait()*, *waitid()*, and *waitpid()* functions allow one process to deal with the termination of another.

The *times()* function allows for basic measurement of times used by a process. Various functions, including *fstat()*, *getegid()*, *geteuid()*, *getgid()*, *getgrgid()*, *getgrnam()*, *getlogin()*, *getpid()*, *getppid()*, *getpwnam()*, *getpwuid()*, *getuid()*, *lstat()*, and *stat()*, provide for access to the identifiers of processes and the identifiers and names of owners of processes (and files).

The various functions operating on environment variables provide for communication of information (primarily user-configurable defaults) from a parent to child processes.

The operations on the current working directory control and interrogate the directory from which relative pathname searches start. The *umask()* function controls the default protections applied to files created by the process.

The *alarm()*, *pause()*, *sleep()*, *ualarm()*, and *usleep()* operations allow the process to suspend until a timer has expired or to be notified when a period of time has elapsed. The *time()* operation interrogates the current time and date.

The signal mechanism provides for communication of events either from other processes or from the environment to the application, and the means for the application to control the effect of these events. The mechanism provides for external termination of a process and for a process to suspend until an event occurs. The mechanism also provides for a value to be associated with an event.

Job control provides a means to group processes and control them as groups, and to control their access to the function between the user and the system (the “controlling terminal”). It also provides the means to suspend and resume processes.

The Process Scheduling option provides control of the scheduling and priority of a process.

The Message Passing option provides a means for interprocess communication involving small amounts of data.

The Memory Management facilities provide control of memory resources and for the sharing of memory. This functionality is mandatory on POSIX-conforming systems.

The Threads facilities provide multiple flows of control with a process (threads), synchronization between threads (including mutexes, barriers, and spin locks), association of data with threads, and controlled cancellation of threads.

The XSI interprocess communications functionality provide an alternate set of facilities to manipulate semaphores, message queues, and shared memory. These are provided on XSI-conformant systems to support conforming applications developed to run on UNIX systems.

## D.2.3 Access to Data

The *open()*, *close()*, *fclose()*, *fopen()*, and *pipe()* functions provide for access to files and data. Such files may be regular files, interprocess data channels (pipes), or devices. Additional types of objects in the file system are permitted and are being contemplated for standardization.

The *access()*, *chmod()*, *chown()*, *dup()*, *dup2()*, *fchmod()*, *fcntl()*, *fstat()*, *ftruncate()*, *lstat()*, *readlink()*, *realpath()*, *stat()*, and *utime()* functions allow for control and interrogation of file and file-related objects (including symbolic links), and their ownership, protections, and timestamps.

127307 The *fgetc()*, *fputc()*, *fread()*, *fseek()*, *fsetpos()*, *fwrite()*, *getc()*, *getchar()*, *lseek()*, *putchar()*, *putc()*,  
 127308 *read()*, and *write()* functions provide for data transfer from the application to files (in all their  
 127309 forms).

127310 The *closedir()*, *link()*, *mkdir()*, *opendir()*, *readdir()*, *rename()*, *rmdir()*, *rewinddir()*, and *unlink()*  
 127311 functions provide for a complete set of operations on directories. Directories can arbitrarily  
 127312 contain other directories, and a single file can be mentioned in more than one directory.

127313 The *faccessat()*, *openat()*, *fchmodat()*, *fchownat()*, *fstatat()*, *linkat()*, *renameat()*, *readlinkat()*,  
 127314 *symlinkat()*, and *unlinkat()* functions allow for race-free and thread-safe file access. The  
 127315 motivation for the introduction of these functions was as follows:

- 127316 • Interfaces taking a pathname may be limited by the maximum length of a pathname  
 127317 ({PATH\_MAX}). The absolute path of files can far exceed this length. The alternative  
 127318 solution of changing the working directory and using relative pathnames is not thread-  
 127319 safe.
- 127320 • A second motivation is that files accessed outside the current working directory are subject  
 127321 to attacks caused by the race condition created by changing any of the elements of the  
 127322 pathnames used.
- 127323 • A third motivation is to allow application code which makes use of a virtual current  
 127324 working directory for each individual thread. In the alternative model there is only one  
 127325 current working directory for all threads.

127326 The file-locking mechanism provides for advisory locking (protection during transactions) of  
 127327 ranges of bytes (in effect, records) in a file.

127328 The *confstr()*, *fpathconf()*, *pathconf()*, and *sysconf()* functions provide for enquiry as to the  
 127329 behavior of the system where variability is permitted.

127330 The asynchronous input and output functions *aio\_cancel()*, *aio\_error()*, *aio\_fsync()*, *aio\_read()*,  
 127331 *aio\_return()*, *aio\_suspend()*, *aio\_write()*, and *lio\_listio()* provide for initiation and control of  
 127332 asynchronous data transfers.

127333 The Synchronized Input and Output option provides for assured commitment of data to media.

#### 127334 D.2.4 Access to the Environment

127335 The operations and types in XBD are provided for access to asynchronous serial devices. The  
 127336 primary intended use for these is the controlling terminal for the application (the interaction  
 127337 point between the user and the system). They are general enough to be used to control any  
 127338 asynchronous serial device. The functions are also general enough to be used with many other  
 127339 device types as a user interface when some emulation is provided.

127340 Less detailed access is provided for other device types, but in many instances an application  
 127341 need not know whether an object in the file system is a device or a regular file to operate  
 127342 correctly.

127343 **Unsatisfied Requirements**

127344 Detailed control of common device classes, specifically magnetic tape, is not provided.

127345 **D.2.5 Bounded (Realtime) Response**

127346 The realtime signal functions *sigqueue()*, *sigtimedwait()*, and *sigwaitinfo()* provide queued signals  
127347 and the prioritization of the handling of signals.

127348 The SCHED\_FIFO, SCHED\_SPORADIC, and SCHED\_RR scheduling policies provide control  
127349 over processor allocation.

127350 The semaphore functions *sem\_close()*, *sem\_destroy()*, *sem\_getvalue()*, *sem\_init()*, *sem\_open()*,  
127351 *sem\_post()*, *sem\_timedwait()*, *sem\_trywait()*, *sem\_unlink()*, and *sem\_wait()* provide high-  
127352 performance synchronization.

127353 The memory management functions provide memory locking for control of memory allocation,  
127354 file mapping for high performance, and shared memory for high-performance interprocess  
127355 communication. The Message Passing option provides for interprocess communication without  
127356 being dependent on shared memory.

127357 The timers functions *clock\_getres()*, *clock\_gettime()*, *clock\_settime()*, *nanosleep()*, *timer\_create()*,  
127358 *timer\_delete()*, *timer\_getoverrun()*, *timer\_gettime()*, and *timer\_settime()* provide functionality to  
127359 manipulate clocks and timers and include a high resolution function called *nanosleep()* with a  
127360 finer resolution than the *sleep()* function.

127361 The timeout functions — *pthread\_mutex\_timedlock()*, *pthread\_rwlock\_timedrdlock()*,  
127362 *pthread\_rwlock\_timedwrlock()*, and *sem\_timedwait()* — the Typed Memory Objects option and the  
127363 Monotonic Clock option provide further facilities for applications to use to obtain predictable  
127364 bounded response.

127365 **D.2.6 Operating System-Dependent Profile**

127366 POSIX.1-2008 makes no distinction between text and binary files. The values of EXIT\_SUCCESS  
127367 and EXIT\_FAILURE are further defined.

127368 **Unsatisfied Requirements**

127369 None known, but the ISO C standard may contain some additional options that could be  
127370 specified.

127371 **D.2.7 I/O Interaction**

127372 POSIX.1-2008 defines how each of the ISO C standard *stdio* functions interact with the POSIX.1  
127373 operations, typically specifying the behavior in terms of POSIX.1 operations.

127374 **Unsatisfied Requirements**

127375 None.

127376 **D.2.8 Internationalization Interaction**

127377 The POSIX.1-2008 environment operations provide a means to define the environment for  
 127378 *setlocale()* and time functions such as *ctime()*. The *tzset()* function is provided to set time  
 127379 conversion information.

127380 The *nl\_langinfo()* function is provided to query locale-specific cultural settings.

127381 The multiple concurrent locale functions *duplocale()*, *freelocale()*, *is\*\_l()*, *newlocale()*,  
 127382 *strcasecmp\_l()*, *strcoll\_l()*, *strfmon\_l()*, *strncasecmp\_l()*, *strxfrm\_l()*, *tolower\_l()*, *toupper\_l()*,  
 127383 *towctrans\_l()*, *towlower\_l()*, *towupper\_l()*, *uselocale\_l()*, *wscasecmp\_l()*, *wscoll\_l()*, *wcsncasecmp\_l()*,  
 127384 *wcsxfrm\_l()*, *wctrans\_l()*, and *wctype\_l()* are provide to support per-thread locale information.

127385 **Unsatisfied Requirements**

127386 None.

127387 **D.2.9 C-Language Extensions**

127388 The *setjmp()* and *longjmp()* functions are not defined to be cognizant of the signal masks defined  
 127389 for POSIX.1. The *sigsetjmp()* and *siglongjmp()* functions are provided to fill this gap.

127390 The *\_setjmp()* and *\_longjmp()* functions are provided as XSI options to support historic practice.

127391 **Unsatisfied Requirements**

127392 None.

127393 **D.2.10 Command Language**

127394 The shell command language, as described in XCU [Chapter 2](#) (on page 2319), is a common  
 127395 language useful in batch scripts, through an API to high-level languages (for the C-Language  
 127396 Binding option, *system()* and *popen()*) and through an interactive terminal (see the *sh* utility).  
 127397 The shell language has many of the characteristics of a high-level language, but it has been  
 127398 designed to be more suitable for user terminal entry and includes interactive debugging  
 127399 facilities. Through the use of pipelining, many complex commands can be constructed from  
 127400 combinations of data filters and other common components. Shell scripts can be created, stored,  
 127401 recalled, and modified by the user with simple editors.

127402 In addition to the basic shell language, the following utilities offer features that simplify and  
 127403 enhance programmatic access to the utilities and provide features normally found only in high-  
 127404 level languages: *basename*, *bc*, *command*, *dirname*, *echo*, *env*, *expr*, *false*, *printf*, *read*, *sleep*, *tee*, *test*,  
 127405 *time\**,<sup>9</sup> *true*, *wait*, *xargs*, and all of the special built-in utilities in XCU [Section 2.14](#) (on page 2356).

---

127406 9. The utilities listed with an asterisk here and later in this section are present only on systems which support the User Portability Utilities  
 127407 option. There may be further restrictions on the utilities offered with various configuration option combinations; see the individual utility  
 127408 descriptions.

127409 **Unsatisfied Requirements**

127410 None.

127411 **D.2.11 Interactive Facilities**

127412 The utilities offer a common style of command-line interface through conformance to the Utility  
127413 Syntax Guidelines (see XBD [Section 12.2](#), on page 215) and the common utility defaults (see XCU  
127414 [Section 1.4](#), on page 2310). The *sh* utility offers an interactive command-line history and editing  
127415 facility.

127416 The following utilities can be used interactively as well as by scripts; *alias*, *fc*, *mailx*, *unalias*, and  
127417 *write*.

127418 The following utilities in the User Portability Utilities option provide for interactive use: *ex*, *more*,  
127419 and *vi*; the *man* utility offers online access to system documentation.

127420 **Unsatisfied Requirements**

127421 The command line interface to individual utilities is as intuitive and consistent as historical  
127422 practice allows. Work underway based on graphical user interfaces may be more suitable for  
127423 novice or occasional users of the system.

127424 **D.2.12 Accomplish Multiple Tasks Simultaneously**

127425 The shell command language offers background processing through the asynchronous list  
127426 command form; see XCU [Section 2.9](#) (on page 2338).

127427 The *nohup* utility makes background processing more robust and usable.

127428 The *kill* utility can terminate background jobs.

127429 The following utilities support periodic job scheduling, control, and display: *at*, *batch*, *crontab*,  
127430 *nice*, *ps*, and *renice*.

127431 When the User Portability Utilities option is supported, the following utilities allow  
127432 manipulation of jobs: *bg*, *fg*, and *jobs*.

127433 **Unsatisfied Requirements**

127434 Terminals with multiple windows may be more suitable for some multi-tasking interactive uses  
127435 than the job control approach in POSIX.1-2008. See the comments on graphical user interfaces in  
127436 [Section D.2.11](#). The *nice* and *renice* utilities do not necessarily take advantage of complex system  
127437 scheduling algorithms that are supported by the realtime options within POSIX.1-2008.

127438 **D.2.13 Complex Data Manipulation**

127439 The following utilities address user requirements in this area: *asa*, *awk*, *bc*, *cmp*, *comm*, *csplit*, *cut*,  
127440 *dd*, *diff*, *ed*, *ex\**, *expand*, *expr*, *find*, *fold*, *grep*, *head*, *join*, *od*, *paste*, *pr*, *printf*, *sed*, *sort*, *split*, *tabs*, *tail*, *tr*,  
127441 *unexpand*, *uniq*, *uudecode*, *uuencode*, and *wc*.

127442 **Unsatisfied Requirements**

127443 Sophisticated text formatting utilities, such as *troff* or *TeX*, are not included. Standards work in  
 127444 the area of SGML may satisfy this.

127445 **D.2.14 File Hierarchy Manipulation**

127446 The following utilities address user requirements in this area: *basename*, *cd*, *chgrp*, *chmod*, *chown*,  
 127447 *cksum*, *cp*, *dd*, *df*, *diff*, *dirname*, *du*, *find*, *ls*, *ln*, *mkdir*, *mkfifo*, *mv*, *patch*, *pathchk*, *pax*, *pwd*, *rm*, *rmdir*,  
 127448 *test*, and *touch*.

127449 **Unsatisfied Requirements**

127450 Some graphical user interfaces offer more intuitive file manager components that allow file  
 127451 manipulation through the use of icons for novice users.

127452 **D.2.15 Locale Configuration**

127453 The standard utilities are affected by the various *LC\_* variables to achieve locale-dependent  
 127454 operation: character classification, collation sequences, regular expressions and shell pattern  
 127455 matching, date and time formats, numeric formatting, and monetary formatting. When the  
 127456 POSIX2\_LOCALEDEF option is supported, applications can provide their own locale definition  
 127457 files.

127458 The following utilities address user requirements in this area: *date*, *ed*, *ex\**, *find*, *grep*, *locale*,  
 127459 *localedef*, *more\**, *sed*, *sh*, *sort*, *tr*, *uniq*, and *vi\**.

127460 The *iconv()*, *iconv\_close()*, and *iconv\_open()* functions are available to allow an application to  
 127461 convert character data between supported character sets.

127462 The *gencat* utility and the *catopen()*, *catclose()*, and *catgets()* functions provide for message  
 127463 catalog manipulation.

127464 **Unsatisfied Requirements**

127465 Some aspects of multi-byte character and state-encoded character encodings have not yet been  
 127466 addressed. The C-language functions, such as *getopt()*, are generally limited to single-byte  
 127467 characters. The effect of the *LC\_MESSAGES* variable on message formats is only suggested at  
 127468 this time.

127469 **D.2.16 Inter-User Communication**

127470 The following utilities address user requirements in this area: *cksum*, *mailx*, *mesg*, *patch*, *pax*, *talk*,  
 127471 *uudecode*, *uuencode*, *who*, and *write*.

127472 The historical UUCP utilities are included as a separate UUCP Utilities option.

127473 **Unsatisfied Requirements**

127474 None.

127475 **D.2.17 System Environment**

127476 The following utilities address user requirements in this area: *chgrp*, *chmod*, *chown*, *df*, *du*, *env*,  
127477 *getconf*, *id*, *logger*, *logname*, *mesg*, *newgrp*, *ps*, *stty*, *tput*, *tty*, *umask*, *uname*, and *who*.

127478 The *closelog()*, *openlog()*, *setlogmask()*, and *syslog()* functions provide system logging facilities on  
127479 XSI-conformant systems; these are analogous to the *logger* utility.

127480 **Unsatisfied Requirements**

127481 None.

127482 **D.2.18 Printing**

127483 The following utilities address user requirements in this area: *pr* and *lp*.

127484 **Unsatisfied Requirements**

127485 There are no features to control the formatting or scheduling of the print jobs.

127486 **D.2.19 Software Development**

127487 The following utilities address user requirements in this area: *ar*, *asa*, *awk*, *c99*, *ctags*, *fort77*,  
127488 *getconf*, *getopts*, *lex*, *localedef*, *make*, *nm*, *od*, *patch*, *pax*, *strings*, *strip*, *time*, and *yacc*.

127489 The *system()*, *popen()*, *pclose()*, *regcomp()*, *regex()*, *regerror()*, *regfree()*, *fnmatch()*, *getopt()*,  
127490 *glob()*, *globfree()*, *wordexp()*, and *wordfree()* functions allow C-language programmers to access  
127491 some of the interfaces used by the utilities, such as argument processing, regular expressions,  
127492 and pattern matching.

127493 The SCCS source-code control system utilities are available on systems supporting the XSI  
127494 Development option.

127495 **Unsatisfied Requirements**

127496 There are no language-specific development tools related to languages other than C and  
127497 FORTRAN. The C tools are more complete and varied than the FORTRAN tools. There is no  
127498 data dictionary or other CASE-like development tools.

127499 **D.2.20 Future Growth**

127500 It is arguable whether or not all functionality to support applications is potentially within the  
127501 scope of POSIX.1-2008. As a simple matter of practicality, it cannot be. Areas such as graphics,  
127502 application domain-specific functionality, windowing, and so on, should be in unique standards.  
127503 As such, they are properly “Unsatisfied Requirements” in terms of providing fully conforming  
127504 applications, but ones which are outside the scope of POSIX.1-2008.

127505 However, as the standards evolve, certain functionality once considered “exotic” enough to be  
127506 part of a separate standard become common enough to be included in a core standard such as  
127507 this. Realtime and networking, for example, have both moved from separate standards (with

127508 much difficult cross-referencing) into this standard over time, and although no specific areas  
 127509 have been identified for inclusion in a future version, such inclusions seem likely.

### 127510 **D.3 Profiling Considerations**

127511 This section offers guidance to writers of profiles on how the configurable options, limits, and  
 127512 optional behavior of POSIX.1-2008 should be cited in profiles. Profile writers should consult the  
 127513 general guidance in POSIX.0 when writing POSIX Standardized Profiles.

127514 The information in this section is an inclusive list of features that should be considered by profile  
 127515 writers. Subsetting of POSIX.1-2008 should follow XBD [Section 2.1.5.1](#) (on page 20). A set of  
 127516 profiling options is described in [Appendix E](#) (on page 3741).

#### 127517 **D.3.1 Configuration Options**

127518 There are two set of options suggested by POSIX.1-2008: those for POSIX-conforming systems  
 127519 and those for X/Open System Interface (XSI) conformance. The requirements for XSI  
 127520 conformance are documented in the Base Definitions volume of POSIX.1-2008 and not discussed  
 127521 further here, as they superset the POSIX conformance requirements.

#### 127522 **D.3.2 Configuration Options (Shell and Utilities)**

127523 There are three broad optional configurations for the Shell and Utilities volume of POSIX.1-2008:  
 127524 basic execution system, development system, and user portability interactive system. The  
 127525 options to support these, and other minor configuration options, are listed in XBD [Chapter 2](#) (on  
 127526 page 15). Profile writers should consult the following list and the comments concerning user  
 127527 requirements addressed by various components in [Section D.2](#) (on page 3719).

127528 POSIX2\_UPE

127529 The system supports the User Portability Utilities option.

127530 This option is a requirement for a user portability interactive system. It is required  
 127531 frequently except for those systems, such as embedded realtime or dedicated application  
 127532 systems, that support little or no interactive time-sharing work by users or operators. XSI-  
 127533 conformant systems support this option.

127534 POSIX2\_SW\_DEV

127535 The system supports the Software Development Utilities option.

127536 This option is required by many systems, even those in which actual software development  
 127537 does not occur. The *make* utility, in particular, is required by many application software  
 127538 packages as they are installed onto the system. If POSIX2\_C\_DEV is supported,  
 127539 POSIX2\_SW\_DEV is almost a mandatory requirement because of *ar* and *make*.

127540 POSIX2\_C\_BIND

127541 The system supports the C-Language Bindings option.

127542 This option is required on some implementations developing complex C applications or on  
 127543 any system installing C applications in source form that require the functions in this option.  
 127544 The *system()* and *popen()* functions, in particular, are widely used by applications; the  
 127545 others are rather more specialized.

- 127546 POSIX2\_C\_DEV  
 127547 The system supports the C-Language Development Utilities option.
- 127548 This option is required by many systems, even those in which actual C-language software  
 127549 development does not occur. The *c99* utility, in particular, is required by many application  
 127550 software packages as they are installed onto the system. The *lex* and *yacc* utilities are used  
 127551 less frequently.
- 127552 POSIX2\_FORT\_DEV  
 127553 The system supports the FORTRAN Development Utilities option
- 127554 As with C, this option is needed on any system developing or installing FORTRAN  
 127555 applications in source form.
- 127556 POSIX2\_FORT\_RUN  
 127557 The system supports the FORTRAN Runtime Utilities option.
- 127558 This option is required for some FORTRAN applications that need the *asa* utility to convert  
 127559 Hollerith printing statement output. It is unknown how frequently this occurs.
- 127560 POSIX2\_LOCALEDEF  
 127561 The system supports the creation of locales.
- 127562 This option is needed if applications require their own customized locale definitions to  
 127563 operate. It is presently unknown whether many applications are dependent on this.  
 127564 However, the option is virtually mandatory for systems in which internationalized  
 127565 applications are developed.
- 127566 XSI-conformant systems support this option.
- 127567 POSIX2\_PBS  
 127568 The system supports the Batch Environment Services and Utilities option.
- 127569 POSIX2\_PBS\_ACCOUNTING  
 127570 The system supports the optional feature of accounting within the Batch Environment  
 127571 Services and Utilities option. It will be required in servers that implement the optional  
 127572 feature of accounting.
- 127573 POSIX2\_PBS\_CHECKPOINT  
 127574 The system supports the optional feature of checkpoint/restart within the Batch  
 127575 Environment Services and Utilities option.
- 127576 POSIX2\_PBS\_LOCATE  
 127577 The system supports the optional feature of locating batch jobs within the Batch  
 127578 Environment Services and Utilities option.
- 127579 POSIX2\_PBS\_MESSAGE  
 127580 The system supports the optional feature of sending messages to batch jobs within the Batch  
 127581 Environment Services and Utilities option.
- 127582 POSIX2\_PBS\_TRACK  
 127583 The system supports the optional feature of tracking batch jobs within the Batch  
 127584 Environment Services and Utilities option.
- 127585 POSIX2\_CHAR\_TERM  
 127586 The system supports at least one terminal type capable of all operations described in  
 127587 POSIX.1-2008.
- 127588 On systems with POSIX2\_UPE, this option is almost always required. It was developed  
 127589 solely to allow certain specialized vendors and user applications to bypass the requirement  
 127590 for general-purpose asynchronous terminal support. For example, an application and

127591 system that was suitable for block-mode terminals, such as IBM 3270s, would not need this  
 127592 option.  
 127593 XSI-conformant systems support this option.

### 127594 D.3.3 Configurable Limits

127595 Very few of the limits need to be increased for profiles. No profile can cite lower values.  
 127596 {POSIX2\_BC\_BASE\_MAX}  
 127597 {POSIX2\_BC\_DIM\_MAX}  
 127598 {POSIX2\_BC\_SCALE\_MAX}  
 127599 {POSIX2\_BC\_STRING\_MAX}  
 127600 No increase is anticipated for any of these *bc* values, except for very specialized applications  
 127601 involving huge numbers.  
 127602 {POSIX2\_COLL\_WEIGHTS\_MAX}  
 127603 Some natural languages with complex collation requirements require an increase from the  
 127604 default 2 to 4; no higher numbers are anticipated.  
 127605 {POSIX2\_EXPR\_NEST\_MAX}  
 127606 No increase is anticipated.  
 127607 {POSIX2\_LINE\_MAX}  
 127608 This number is much larger than most historical applications have been able to use. At some  
 127609 future time, applications may be rewritten to take advantage of even larger values.  
 127610 {POSIX2\_RE\_DUP\_MAX}  
 127611 No increase is anticipated.  
 127612 {POSIX2\_VERSION}  
 127613 This is actually not a limit, but a standard version stamp. Generally, a profile should specify  
 127614 XCU [Chapter 2](#) (on page 2319) by name in the normative references section, not this value.

### 127615 D.3.4 Configuration Options (System Interfaces)

127616 {NGROUPS\_MAX}  
 127617 A non-zero value indicates that the implementation supports supplementary groups.  
 127618 This option is needed where there is a large amount of shared use of files, but where a  
 127619 certain amount of protection is needed. Many profiles<sup>10</sup> are known to require this option; it  
 127620 should only be required if needed, but it should never be prohibited.  
 127621 \_POSIX\_ADVISORY\_INFO  
 127622 The system provides advisory information for file management.  
 127623 This option allows the application to specify advisory information that can be used to  
 127624 achieve better or even deterministic response time in file manager or input and output  
 127625 operations.  
 127626 \_POSIX\_ASYNCHRONOUS\_IO  
 127627 Support for asynchronous input and output is mandatory in POSIX.1-2008.

---

127628 10. There are no formally approved profiles of POSIX.1-2008 at the time of publication; the reference here is to various profiles generated by  
 127629 private bodies or governments.

127630 `_POSIX_BARRIERS`

127631 Support for barrier synchronization is mandatory in POSIX.1-2008.

127632 This facility allows efficient synchronization of multiple parallel threads in multi-processor  
127633 systems in which the operation is supported in part by the hardware architecture.127634 `_POSIX_CHOWN_RESTRICTED`127635 The system restricts the right to “give away” files to other users. It is mandatory that an  
127636 implementation be able to support this facility in POSIX.1-2008; however, it is recognized  
127637 that implementations need not enable the functionality by default.127638 Some applications expect that they can change the ownership of files in this way. It is  
127639 provided where either security or system account requirements cause this ability to be a  
127640 problem. It is also known to be specified in many profiles.127641 `_POSIX_CLOCK_SELECTION`

127642 Support for clock selection is mandatory in POSIX.1-2008.

127643 This facility allows applications to request a high resolution sleep in order to suspend a  
127644 thread during a relative time interval, or until an absolute time value, using the desired  
127645 clock. It also allows the application to select the clock used in a *pthread\_cond\_timedwait()*  
127646 function call.127647 `_POSIX_CPUTIME`

127648 The system supports the Process CPU-Time Clocks option.

127649 This option allows applications to use a new clock that measures the execution times of  
127650 processes or threads, and the possibility to create timers based upon these clocks, for  
127651 runtime detection (and treatment) of execution time overruns.127652 `_POSIX_FSYNC`

127653 The system supports file synchronization requests.

127654 This option was created to support historical systems that did not provide the feature.  
127655 Applications that are expecting guaranteed completion of their input and output operations  
127656 should require the `_POSIX_SYNC_IO` option. This option should never be prohibited.

127657 XSI-conformant systems support this option.

127658 `_POSIX_IPV6`

127659 The system supports facilities related to Internet Protocol Version 6 (IPv6).

127660 This option was created to allow systems to transition to IPv6.

127661 `_POSIX_JOB_CONTROL`

127662 Support for job control is mandatory in POSIX.1-2008.

127663 Most applications that use it can run when it is not present, although with a degraded level  
127664 of user convenience.127665 `_POSIX_MAPPED_FILES`

127666 Support for memory mapped files is mandatory in POSIX.1-2008.

127667 This facility provides for the mapping of regular files into the process address space.

127668 Both this facility and the Shared Memory Objects option provide shared access to memory  
127669 objects in the process address space. The *mmap()* and *munmap()* functions provide the  
127670 functionality of existing practice for mapping regular files. This functionality was deemed  
127671 unnecessary, if not inappropriate, for embedded systems applications and is expected to be  
127672 optional in subprofiles.

127673 `_POSIX_MEMLOCK`

127674 The system supports the locking of the address space.

127675 This option was created to support historical systems that did not provide the feature. It  
127676 should only be required if needed, but it should never be prohibited.127677 `_POSIX_MEMLOCK_RANGE`

127678 The system supports the locking of specific ranges of the address space.

127679 For applications that have well-defined sections that need to be locked and others that do  
127680 not, POSIX.1-2008 supports an optional set of functions to lock or unlock a range of process  
127681 addresses. The following are two reasons for having a means to lock down a specific range:

- 127682 1. An asynchronous event handler function that must respond to external events in a  
127683 deterministic manner such that page faults cannot be tolerated
- 127684 2. An input/output “buffer” area that is the target for direct-to-process I/O, and the  
127685 overhead of implicit locking and unlocking for each I/O call cannot be tolerated

127686 It should only be required if needed, but it should never be prohibited.

127687 `_POSIX_MEMORY_PROTECTION`

127688 Support for memory protection is mandatory in POSIX.1-2008.

127689 The provision of this facility typically imposes additional hardware requirements.

127690 `_POSIX_PRIORITIZED_IO`

127691 The system provides prioritization for input and output operations.

127692 The use of this option may interfere with the ability of the system to optimize input and  
127693 output throughput. It should only be required if needed, but it should never be prohibited.127694 `_POSIX_MESSAGE_PASSING`

127695 The system supports the passing of messages between processes.

127696 This option was created to support historical systems that did not provide the feature. The  
127697 functionality adds a high-performance XSI interprocess communication facility for local  
127698 communication. It should only be required if needed, but it should never be prohibited.127699 `_POSIX_MONOTONIC_CLOCK`

127700 The system supports the Monotonic Clock option.

127701 This option allows realtime applications to rely on a monotonically increasing clock that  
127702 does not jump backwards, and whose value does not change except for the regular ticking  
127703 of the clock.127704 `_POSIX_PRIORITY_SCHEDULING`

127705 The system provides priority-based process scheduling.

127706 Support of this option provides predictable scheduling behavior, allowing applications to  
127707 determine the order in which processes that are ready to run are granted access to a  
127708 processor. It should only be required if needed, but it should never be prohibited.127709 `_POSIX_REALTIME_SIGNALS`

127710 Support for realtime signals is mandatory in POSIX.1-2008.

127711 This facility provides prioritized, queued signals with associated data values.

127712 `_POSIX_REGEX`

127713 Support for regular expression facilities is mandatory in POSIX.1-2008.

- 127714 `_POSIX_SAVED_IDS`  
 127715 Support for this feature is mandatory in POSIX.1-2008.
- 127716 Certain classes of applications rely on it for proper operation, and there is no alternative  
 127717 short of giving the application root privileges on most implementations that did not provide  
 127718 `_POSIX_SAVED_IDS`.
- 127719 `_POSIX_SEMAPHORES`  
 127720 Support for counting semaphores is mandatory in POSIX.1-2008.
- 127721 `_POSIX_SHARED_MEMORY_OBJECTS`  
 127722 The system supports the mapping of shared memory objects into the process address space.
- 127723 Both this option and the Memory Mapped Files option provide shared access to memory  
 127724 objects in the process address space. The functions defined under this option provide the  
 127725 functionality of existing practice for shared memory objects. This functionality was deemed  
 127726 appropriate for embedded systems applications and, hence, is provided under this option.  
 127727 It should only be required if needed, but it should never be prohibited.
- 127728 `_POSIX_SHELL`  
 127729 Support for the *sh* utility command line interpreter is mandatory in POSIX.1-2008.
- 127730 `_POSIX_SPAWN`  
 127731 The system supports the spawn option.
- 127732 This option provides applications with an efficient mechanism to spawn execution of a new  
 127733 process.
- 127734 `_POSIX_SPINLOCKS`  
 127735 Support for spin locks is mandatory in POSIX.1-2008.
- 127736 This facility provides a simple and efficient synchronization mechanism for threads  
 127737 executing in multi-processor systems.
- 127738 `_POSIX_SPORADIC_SERVER`  
 127739 The system supports the sporadic server scheduling policy.
- 127740 This option provides applications with a new scheduling policy for scheduling aperiodic  
 127741 processes or threads in hard realtime applications.
- 127742 `_POSIX_SYNCHRONIZED_IO`  
 127743 The system supports guaranteed file synchronization.
- 127744 This option was created to support historical systems that did not provide the feature.  
 127745 Applications that are expecting guaranteed completion of their input and output operations  
 127746 should require this option, rather than the File Synchronization option. It should only be  
 127747 required if needed, but it should never be prohibited.
- 127748 `_POSIX_THREADS`  
 127749 Support for multiple threads of control within a single process is mandatory in  
 127750 POSIX.1-2008.
- 127751 `_POSIX_THREAD_ATTR_STACKADDR`  
 127752 The system supports specification of the stack address for a created thread.
- 127753 Applications may take advantage of support of this option for performance benefits, but  
 127754 dependence on this feature should be minimized. This option should never be prohibited.
- 127755 XSI-conformant systems support this option.

|        |                                                                                               |
|--------|-----------------------------------------------------------------------------------------------|
| 127756 | <code>_POSIX_THREAD_ATTR_STACKSIZE</code>                                                     |
| 127757 | The system supports specification of the stack size for a created thread.                     |
| 127758 | Applications may require this option in order to ensure proper execution, but such usage      |
| 127759 | limits portability and dependence on this feature should be minimized. It should only be      |
| 127760 | required if needed, but it should never be prohibited.                                        |
| 127761 | XSI-conformant systems support this option.                                                   |
| 127762 | <code>_POSIX_THREAD_PRIORITY_SCHEDULING</code>                                                |
| 127763 | The system provides priority-based thread scheduling.                                         |
| 127764 | Support of this option provides predictable scheduling behavior, allowing applications to     |
| 127765 | determine the order in which threads that are ready to run are granted access to a processor. |
| 127766 | It should only be required if needed, but it should never be prohibited.                      |
| 127767 | <code>_POSIX_THREAD_PRIO_INHERIT</code>                                                       |
| 127768 | The system provides mutual-exclusion operations with priority inheritance.                    |
| 127769 | Support of this option provides predictable scheduling behavior, allowing applications to     |
| 127770 | determine the order in which threads that are ready to run are granted access to a processor. |
| 127771 | It should only be required if needed, but it should never be prohibited.                      |
| 127772 | <code>_POSIX_THREAD_PRIO_PROTECT</code>                                                       |
| 127773 | The system supports a priority ceiling emulation protocol for mutual-exclusion operations.    |
| 127774 | Support of this option provides predictable scheduling behavior, allowing applications to     |
| 127775 | determine the order in which threads that are ready to run are granted access to a processor. |
| 127776 | It should only be required if needed, but it should never be prohibited.                      |
| 127777 | <code>_POSIX_THREAD_PROCESS_SHARED</code>                                                     |
| 127778 | The system provides shared access among multiple processes to synchronization objects.        |
| 127779 | This option was created to support historical systems that did not provide the feature. It    |
| 127780 | should only be required if needed, but it should never be prohibited.                         |
| 127781 | XSI-conformant systems support this option.                                                   |
| 127782 | <code>_POSIX_THREAD_SAFE_FUNCTIONS</code>                                                     |
| 127783 | Support for thread-safe functions is mandatory in POSIX.1-2008.                               |
| 127784 | <code>_POSIX_THREAD_SPORADIC_SERVER</code>                                                    |
| 127785 | The system supports the thread sporadic server scheduling policy.                             |
| 127786 | Support for this option provides applications with a new scheduling policy for scheduling     |
| 127787 | aperiodic threads in hard realtime applications.                                              |
| 127788 | <code>_POSIX_TIMEOUTS</code>                                                                  |
| 127789 | Support for timeouts for some blocking services is mandatory in POSIX.1-2008.                 |
| 127790 | <code>_POSIX_TIMERS</code>                                                                    |
| 127791 | Support for higher resolution clocks with multiple timers per process is mandatory in         |
| 127792 | POSIX.1-2008.                                                                                 |
| 127793 | This facility is appropriate for applications requiring higher resolution timestamps or       |
| 127794 | needing to control the timing of multiple activities.                                         |
| 127795 | <code>_POSIX_TRACE</code>                                                                     |
| 127796 | The system supports the Trace option.                                                         |
| 127797 | This option was created to allow applications to perform tracing.                             |

127798 `_POSIX_TRACE_EVENT_FILTER`  
 127799 The system supports the Trace Event Filter option.  
 127800 This option is dependent on support of the Trace option.  
 127801 `_POSIX_TRACE_INHERIT`  
 127802 The system supports the Trace Inherit option.  
 127803 This option is dependent on support of the Trace option.  
 127804 `_POSIX_TRACE_LOG`  
 127805 The system supports the Trace Log option.  
 127806 This option is dependent on support of the Trace option.  
 127807 `_POSIX_TYPED_MEMORY_OBJECTS`  
 127808 The system supports the Typed Memory Objects option.  
 127809 This option was created to allow realtime applications to access different kinds of physical  
 127810 memory, and allow processes in these applications to share portions of this memory.

### 127811 **D.3.5 Configurable Limits**

127812 In general, the configurable limits in the `<limits.h>` header defined in the Base Definitions  
 127813 volume of POSIX.1-2008 have been set to minimal values; many applications or implementations  
 127814 may require larger values. No profile can cite lower values.

127815 `{AIO_LISTIO_MAX}`  
 127816 The current minimum is likely to be inadequate for most applications. It is expected that  
 127817 this value will be increased by profiles requiring support for list input and output  
 127818 operations.

127819 `{AIO_MAX}`  
 127820 The current minimum is likely to be inadequate for most applications. It is expected that  
 127821 this value will be increased by profiles requiring support for asynchronous input and  
 127822 output operations.

127823 `{AIO_PRIO_DELTA_MAX}`  
 127824 The functionality associated with this limit is needed only by sophisticated applications. It  
 127825 is not expected that this limit would need to be increased under a general-purpose profile.

127826 `{ARG_MAX}`  
 127827 The current minimum is likely to need to be increased for profiles, particularly as larger  
 127828 amounts of information are passed through the environment. Many implementations are  
 127829 believed to support larger values.

127830 `{CHILD_MAX}`  
 127831 The current minimum is suitable only for systems where a single user is not running  
 127832 applications in parallel. It is significantly too low for any system also requiring windows,  
 127833 and if `_POSIX_JOB_CONTROL` is specified, it should be raised.

127834 `{CLOCKRES_MIN}`  
 127835 It is expected that profiles will require a finer granularity clock, perhaps as fine as 1  $\mu$ s,  
 127836 represented by a value of 1 000 for this limit.

127837 `{DELAYTIMER_MAX}`  
 127838 It is believed that most implementations will provide larger values.

|        |                                                                                                 |
|--------|-------------------------------------------------------------------------------------------------|
| 127839 | {LINK_MAX}                                                                                      |
| 127840 | For most applications and usage, the current minimum is adequate. Many implementations          |
| 127841 | have a much larger value, but this should not be used as a basis for raising the value unless   |
| 127842 | the applications to be used require it.                                                         |
| 127843 | {LOGIN_NAME_MAX}                                                                                |
| 127844 | This is not actually a limit, but an implementation parameter. No profile should impose a       |
| 127845 | requirement on this value.                                                                      |
| 127846 | {MAX_CANON}                                                                                     |
| 127847 | For most purposes, the current minimum is adequate. Unless high-speed burst serial              |
| 127848 | devices are used, it should be left as is.                                                      |
| 127849 | {MAX_INPUT}                                                                                     |
| 127850 | See {MAX_CANON}.                                                                                |
| 127851 | {MQ_OPEN_MAX}                                                                                   |
| 127852 | The current minimum should be adequate for most profiles.                                       |
| 127853 | {MQ_PRIO_MAX}                                                                                   |
| 127854 | The current minimum corresponds to the required number of process scheduling priorities.        |
| 127855 | Many realtime practitioners believe that the number of message priority levels ought to be      |
| 127856 | the same as the number of execution scheduling priorities.                                      |
| 127857 | {NAME_MAX}                                                                                      |
| 127858 | Many implementations now support larger values, and many applications and users                 |
| 127859 | assume that larger names can be used. Many existing profiles also specify a larger value.       |
| 127860 | Specifying this value will reduce the number of conforming implementations, although this       |
| 127861 | might not be a significant consideration over time. Values greater than 255 should not be       |
| 127862 | required.                                                                                       |
| 127863 | {NGROUPS_MAX}                                                                                   |
| 127864 | The value selected will typically be 8 or larger.                                               |
| 127865 | {OPEN_MAX}                                                                                      |
| 127866 | The historically common value for this has been 20. Many implementations support larger         |
| 127867 | values. If applications that use larger values are anticipated, an appropriate value should be  |
| 127868 | specified.                                                                                      |
| 127869 | {PAGESIZE}                                                                                      |
| 127870 | This is not actually a limit, but an implementation parameter. No profile should impose a       |
| 127871 | requirement on this value.                                                                      |
| 127872 | {PATH_MAX}                                                                                      |
| 127873 | Historically, the minimum has been either 1024 or indefinite, depending on the                  |
| 127874 | implementation. Few applications actually require values larger than 256, but some users        |
| 127875 | may create file hierarchies that must be accessed with longer paths. This value should only     |
| 127876 | be changed if there is a clear requirement.                                                     |
| 127877 | {PIPE_BUF}                                                                                      |
| 127878 | The current minimum is adequate for most applications. Historically, it has been larger. If     |
| 127879 | applications that write single transactions larger than this are anticipated, it should be      |
| 127880 | increased. Applications that write lines of text larger than this probably do not need it       |
| 127881 | increased, as the text line is delimited by a <newline>.                                        |
| 127882 | {POSIX_VERSION}                                                                                 |
| 127883 | This is actually not a limit, but a standard version stamp. Generally, a profile should specify |
| 127884 | POSIX.1-2008 by a name in the normative references section, not this value.                     |

|        |                                                                                               |
|--------|-----------------------------------------------------------------------------------------------|
| 127885 | {PTHREAD_DESTRUCTOR_ITERATIONS}                                                               |
| 127886 | It is unlikely that applications will need larger values to avoid loss of memory resources.   |
| 127887 | {PTHREAD_KEYS_MAX}                                                                            |
| 127888 | The current value should be adequate for most profiles.                                       |
| 127889 | {PTHREAD_STACK_MIN}                                                                           |
| 127890 | This should not be treated as an actual limit, but as an implementation parameter. No         |
| 127891 | profile should impose a requirement on this value.                                            |
| 127892 | {PTHREAD_THREADS_MAX}                                                                         |
| 127893 | It is believed that most implementations will provide larger values.                          |
| 127894 | {RTSIG_MAX}                                                                                   |
| 127895 | The current limit was chosen so that the set of POSIX.1 signal numbers can fit within a       |
| 127896 | 32-bit field. It is recognized that most existing implementations define many more signals    |
| 127897 | than are specified in POSIX.1 and, in fact, many implementations have already exceeded 32     |
| 127898 | signals (including the “null signal”). Support of {_POSIX_RTSIG_MAX} additional signals       |
| 127899 | may push some implementations over the single 32-bit word line, but is unlikely to push       |
| 127900 | any implementations that are already over that line beyond the 64 signal line.                |
| 127901 | {SEM_NSEMS_MAX}                                                                               |
| 127902 | The current value should be adequate for most profiles.                                       |
| 127903 | {SEM_VALUE_MAX}                                                                               |
| 127904 | The current value should be adequate for most profiles.                                       |
| 127905 | {SSIZE_MAX}                                                                                   |
| 127906 | This limit reflects fundamental hardware characteristics (the size of an integer), and should |
| 127907 | not be specified unless it is clearly required. Extreme care should be taken to assure that   |
| 127908 | any value that might be specified does not unnecessarily eliminate implementations            |
| 127909 | because of accidents of hardware design.                                                      |
| 127910 | {STREAM_MAX}                                                                                  |
| 127911 | This limit is very closely related to {OPEN_MAX}. It should never be larger than              |
| 127912 | {OPEN_MAX}, but could reasonably be smaller for application areas where most files are        |
| 127913 | not accessed through <i>stdio</i> . Some implementations may limit {STREAM_MAX} to 20 but     |
| 127914 | allow {OPEN_MAX} to be considerably larger. Such implementations should be allowed for        |
| 127915 | if the applications permit.                                                                   |
| 127916 | {TIMER_MAX}                                                                                   |
| 127917 | The current limit should be adequate for most profiles, but it may need to be larger for      |
| 127918 | applications with a large number of asynchronous operations.                                  |
| 127919 | {TTY_NAME_MAX}                                                                                |
| 127920 | This is not actually a limit, but an implementation parameter. No profile should impose a     |
| 127921 | requirement on this value.                                                                    |
| 127922 | {TZNAME_MAX}                                                                                  |
| 127923 | The minimum has been historically adequate, but if longer timezone names are anticipated      |
| 127924 | (particularly such values as UTC−1), this should be increased.                                |

**D.3.6 Optional Behavior**

127925  
127926  
127927  
127928  
127929  
127930  
127931  
127932

In POSIX.1-2008, there are no instances of the terms unspecified, undefined, implementation-defined, or with the verbs “may” or “need not”, that the standard developers anticipate or sanction as suitable for profile or test method citation. All of these are merely warnings to conforming applications to avoid certain areas that can vary from system to system, and even over time on the same system. In many cases, these terms are used explicitly to support extensions, but profiles should not anticipate and require such extensions; future versions of this standard may do so.

## Subprofiling Considerations (Informative)

127940  
127941  
127942  
127943

This section contains further information to satisfy the requirement that the project scope enable subprofiling of POSIX.1-2008. The approach taken is to include a general requirement in normative text regarding subprofiling and to include an informative section (here) containing a proposed set of subprofiling options.

### 127944 E.1 Subprofiling Option Groups

127945  
127946  
127947  
127948

The following Option Groups<sup>11</sup> are defined to support profiling. Systems claiming support to POSIX.1-2008 need not implement these options apart from the requirements stated in XBD [Section 2.1.3](#) (on page 16). These Option Groups allow profiles to subset the System Interfaces volume of POSIX.1-2008 by collecting sets of related functions.
