Windows kernel

1/16/2019 • 291 minutes to read • Edit Online

Standard driver routines must be implemented by your driver. Driver support routines are routines that the Windows operating system provides. Drivers do not use Microsoft Win32 routines; instead, they use the driver support routines that this section describes. The driver support routines in this section are organized by kernel-mode managers and libraries.

- Standard Driver Routines Here are the required and optional routines that you must implement in your driver to respond to calls from Windows or other drivers. When these routines are called, your code must respond to the call and return the appropriate data in a timely manner.

  The following routines are required for all drivers:

  - DriverEntry
  - AddDevice
  - DispatchXxx (routines beginning with "Dispatch" such as DispatchCreate)
  - DriverUnload

    The other routines are optional, but you may need to implement them depending on your driver type and the location of your driver in the device stack.

    For more information about standard driver routines, see Introduction to Standard Driver Routines.

- Driver Support Routines

  Driver support routines are routines that the Windows operating system provides for kernel-mode drivers to use. Drivers do not use Microsoft Win32 routines; instead, they use the driver support routines that this section describes.

  The driver support routines in this section are organized by kernel-mode managers and libraries.

  The following kernel-mode managers provide support for drivers:

  - Object Manager Routines
  - Memory Manager Routines
  - Process and Thread Manager Routines
  - I/O Manager Routines
  - Power Manager Routines
  - Configuration Manager Routines
  - Kernel Transaction Manager Routines
  - Security Reference Monitor Routines

    The following kernel-mode libraries provide support for drivers:

  - Core Kernel Library Support Routines
  - Executive Library Support Routines
  - Run-Time Library (RTL) Routines
  - Safe String Library Routines
  - Safe Integer Library Routines
  - Direct Memory Access (DMA) Library Routines

- Hardware Abstraction Layer (HAL) Library Routines
- Common Log File System (CLFS) Routines
- Windows Management Instrumentation (WMI) Library Support Routines
- ZwXxx Routines
- Auxiliary Kernel-Mode Library Routines and Structures
- Processor Group Compatibility Library

Public Headers for Windows Kernel

To develop Windows kernel, you need these headers:

- aux_klib.h
- buffring.h
- evntrace.h
- hwnclx.h
- ioaccess.h
- iointex.h
- ntddk.h
- ntddsfio.h
- ntddsysenv.h
- ntimage.h
- ntintsafe.h
- ntnls.h
- ntpoapi.h
- ntstrsafe.h
- pcivirt.h
- pep_x.h
- pepevents.h
- pepfx.h
- poclass.h
- procgrp.h
- pwmutil.h
- vpci.h
- wdm.h
- wdmsec.h
- wmidata.h
- wmilib.h
- wmistr.h

For the programming guide, see Windows kernel.

Initialization and Unload

This section summarizes kernel-mode support routines that can be called by drivers from their DriverEntry, AddDevice, Reinitialize, or Unload routines.

ROUTINES FOR ...	ROUTINE

ROUTINES FOR ...	ROUTINE
Obtaining and reporting hardware configuration information about a driver's devices and the current platform.	IoGetDeviceProperty IoReportDetectedDevice IoReportResourceForDetection IoGetDmaAdapter IoGetConfigurationInformation HalExamineMBR IoReadPartitionTable IoInvalidateDeviceRelations IoInvalidateDeviceState IoRegisterPlugPlayNotification IoUnregisterPlugPlayNotification IoRequestDeviceEject IoReportTargetDeviceChange
Obtaining and reporting configuration information, and for registering interfaces in the registry.	IoGetDeviceProperty IoOpenDeviceInterfaceRegistryKey IoOpenDeviceRegistryKey IoRegisterDeviceInterface IoSetDeviceInterfaceState RtlCheckRegistryKey RtlCreateRegistryKey RtlQueryRegistryValues RtlWriteRegistryValue RtlDeleteRegistryValue InitializeObjectAttributes ZwCreateKey ZwOpenKey ZwQueryKey ZwEnumerateKey ZwEnumerateValueKey ZwQueryValueKey ZwSetValueKey ZwFlushKey ZwDeleteKey ZwClose
Setting up and freeing the objects and resources that drivers might use.	IoCreateDevice IoDeleteDevice IoGetDeviceObjectPointer

ROUTINES FOR ...	ROUTINE
	IoAttachDeviceToDeviceStack
	IoGetAttachedDeviceReference
	IoDetachDevice
	IoAllocateDriverObjectExtension
	IoGetDriverObjectExtension
	IoRegisterDeviceInterface
	IoIsWdmVersionAvailable
	IoDeleteSymbolicLink

	ExInitializePagedLookasideList
	ExInitializeResourceLite
	ExReinitializeResourceLite

ROUTINES FOR ...	ROUTINE
	ExDeleteResourceLite ObReferenceObjectByHandle ObReferenceObjectByPointer ObReferenceObject ObDereferenceObject RtlInitString RtlInitAnsiString RtlInitUnicodeString InitializeObjectAttributes ZwCreateDirectoryObject ZwCreateFile ZwCreateKey ZwDeleteKey ZwMakeTemporaryObject ZwClose PsGetVersion ObGetObjectSecurity ObReleaseObjectSecurity
Initializing driver-managed internal queues.	KeInitializeSpinLock InitializeListHead ExInitializeSListHead KeInitializeDeviceQueue IoCsqInitialize

The following routines are reserved for system use. Do not use them in your driver.

- HalAcquireDisplayOwnership
- HalAllocateAdapterChannel. Use AllocateAdapterChannel instead.
- HalAllocateCrashDumpRegisters
- HalAllocateMapRegisters
- HalGetScatterGatherList. Use GetScatterGatherList instead.
- HalMakeBeep
- HalPutDmaAdapter. Use PutDmaAdapter instead.
- HalPutScatterGatherList. Use PutScatterGatherList instead.

The following obsolete routines are exported only to support existing drivers:

OBSOLETE ROUTINE	REPLACEMENT
HalAllocateCommonBuffer	See AllocateCommonBuffer instead.

OBSOLETE ROUTINE	REPLACEMENT
HalAssignSlotResources	Drivers of PnP devices are assigned resources by the PnP manager, which passes resource lists with each IRP_MN_START_DEVICE request. Drivers that must support a legacy device that cannot be enumerated by the PnP manager should use IoReportDetectedDevice and IoReportResourceForDetection.
HalFreeCommonBuffer	See FreeCommonBuffer instead.
HalGetAdapter	See IoGetDmaAdapter instead.
HalGetBusData	Instead, use IRP_MN_QUERY_INTERFACE to query the GUID_BUS_INTERFACE_STANDARD interface. This query request returns a function pointer to GetBusData, which can be used to read from the configuration space of a given device.
HalGetBusDataByOffset	Instead, use IRP_MN_QUERY_INTERFACE to query the GUID_BUS_INTERFACE_STANDARD interface. This query request returns a function pointer to GetBusData, which can be used to read from the configuration space of a given device.
HalGetDmaAlignmentRequirement	See GetDmaAlignment instead.
HalGetInterruptVector	Drivers of PnP devices are assigned resources by the PnP manager, which passes resource lists with each IRP_MN_START_DEVICE request. Drivers that must support a legacy device that cannot be enumerated by the PnP manager should use IoReportDetectedDevice and IoReportResourceForDetection.
HalReadDmaCounter	See ReadDmaCounter instead.
HalSetBusData	Instead, use IRP_MN_QUERY_INTERFACE to query the GUID_BUS_INTERFACE_STANDARD interface. This query request returns a function pointer to SetBusData, which can be used to write to the configuration space of a given device.
HalSetBusDataByOffset	Instead, use IRP_MN_QUERY_INTERFACE to query the GUID_BUS_INTERFACE_STANDARD interface. This query request returns a function pointer to SetBusData, which can be used to write to the configuration space of a given device.
HalTranslateBusAddress	The PnP manager passes lists of raw and translated resources in its IIRP_MN_START_DEVICE request for each device. Consequently, in most cases there is no need to translate bus addresses. However, if translation is required, use IRP_MN_QUERY_INTERFACE to query the GUID_BUS_INTERFACE_STANDARD interface. The query request returns a function pointer to TranslateBusAddress, which can be used to translates addresses on the parent bus to logical addresses.

These obsolete routines are included in the Ntddk.h header file.

The following routine is not supported and should not be used:

- HalReturnToFirmware

Windows performs resource balancing of PCI bus resources to open an address region for a plugged device. The rebalance operation causes the bus data for some driver's device to move dynamically (between IRP_MN_STOP_DEVICE and IRP_MN_START_DEVICE calls). Therefore, a driver must not access the bus data directly. Instead the driver must pass it down to the lower bus driver because it knows the location of the device.

For more information, see Stopping a Device to Rebalance Resources.

Registry

Used for obtaining and reporting configuration information, and for registering interfaces in the registry.

FUNCTION	DESCRIPTION
IoGetDeviceProperty	Retrieves device setup information from the registry. Use this routine, rather than accessing the registry directly, to insulate a driver from differences across platforms and from possible changes in the registry structure.
IoOpenDeviceInterfaceRegistryKey	Returns a handle to a registry key for storing information about a particular device interface.
IoOpenDeviceRegistryKey	Returns a handle to a device-specific or a driver-specific registry key for a particular device instance.
IoRegisterDeviceInterface	Registers device functionality (a device interface) that a driver will enable for use by applications or other system components. The I/O manager creates a registry key for the device interface. Drivers can access persistent storage under this key using IoOpenDeviceInterfaceRegistryKey.
IoSetDeviceInterfaceState	Enables or disables a previously registered device interface. Applications and other system components can open only interfaces that are enabled.
RtlCheckRegistryKey	Returns STATUS_SUCCESS if a key exists in the registry along the given relative path.
RtlCreateRegistryKey	Adds a key object in the registry along the given relative path.
RtlQueryRegistryValues	Gives a driver-supplied callback read-only access to the entries for a specified value name, along a specified relative path, in the registry, after the callback routine is given control.
RtlWriteRegistryValue	Writes caller-supplied data into the registry along the specified relative path at the given value name.
RtlDeleteRegistryValue	Removes the specified value name (and the associated value entries) from the registry along the given relative path.
InitializeObjectAttributes	Sets up a parameter of type OBJECT_ATTRIBUTES for a subsequent call to a ZwCreateXxx or ZwOpenXxx routine.

FUNCTION	DESCRIPTION
ZwCreateKey	Creates a new key in the registry with the given object's attributes, allowed access, and creation options (such as whether the key is created again when the system is booted). Alternatively, opens an existing key and returns a handle for the key object.
ZwOpenKey	Returns a handle for a key in the registry given the object's attributes (which must include a name for the key) and the desired access to the object.
ZwQueryKey	Returns information about the class of a key, and the number and sizes of its subkeys. This information includes, for example, the length of subkey names and the size of value entries.
ZwEnumerateKey	Returns the specified information about the subkey, as selected by a zero-based index, of an opened key in the registry.
ZwEnumerateValueKey	Returns the specified information about the value entry of a subkey, as selected by a zero-based index, of an opened key in the registry.
ZwQueryValueKey	Returns the value entry for an opened key in the registry.
ZwSetValueKey	Replaces (or creates) a value entry for an opened key in the registry.
ZwFlushKey	Forces changes made by ZwCreateKey or ZwSetValueKey for the opened key object to be written to disk.
ZwDeleteKey	Removes a key and its value entries from the registry as soon as the key is closed.
ZwClose	Releases the handle for an opened object, causing the handle to become invalid and decrementing the reference count of the object handle.

Objects and Resources

Used for setting up and freeing the objects and resources that drivers might use.

FUNCTION	DESCRIPTION
IoCreateDevice	Initializes a device object, which represents a physical, virtual, or logical device for which the driver is being loaded into the system. Then it allocates space for the driver-defined device extension associated with the device object.
IoDeleteDevice	Removes a device object from the system when the underlying device is removed from the system.
IoGetDeviceObjectPointer	Requests access to a named device object and returns a pointer to that device object if the requested access is granted. Also returns a pointer to the file object referenced by the named device object. In effect, this routine establishes a connection between the caller and the next-lower-level driver.

FUNCTION	DESCRIPTION
IoAttachDeviceToDeviceStack	Attaches the caller's device object to the highest device object in a chain of drivers and returns a pointer to the previously highest device object. I/O requests bound for the target device are routed first to the caller.
IoGetAttachedDeviceReference	Returns a pointer to the highest level device object in a driver stack and increments the reference count on that object.
IoDetachDevice	Releases an attachment between the caller's device object and a target driver's device object.
IoAllocateDriverObjectExtension	Allocates a per-driver context area with a given unique identifier.
IoGetDriverObjectExtension	Retrieves a previously allocated per-driver context area.
IoRegisterDeviceInterface	Registers device functionality (a device interface) that a driver will enable for use by applications or other system components. The I/O manager creates a registry key for the device interface. Drivers can access persistent storage under this key by calling IoOpenDeviceInterfaceRegistryKey.
IoIsWdmVersionAvailable	Checks whether a given WDM version is supported by the operating system.
IoDeleteSymbolicLink	Releases a symbolic link between a device object name and a user-visible name.
IoAssignArcName	Sets up a symbolic link between a named device object (such as a tape, floppy, or CD-ROM) and the corresponding ARC name for the device.
IoDeassignArcName	Releases the symbolic link created by calling IoAssignArcName.
IoSetShareAccess	Sets the access allowed to a given file object that represents a device. (Only highest-level drivers can call this routine.)
IoConnectInterrupt	Registers a driver's interrupt-handling routine. Drivers should use IoConnectInterruptEx instead.
IoDisconnectInterrupt	Unregisters an interrupt-handling routine that IoConnectInterrupt registered.
IoConnectInterruptEx	Registers a driver's interrupt-handling routine. Drivers can register either an InterruptService routine for line-based interrupts or an InterruptMessageService routine for message-signaled interrupts.

FUNCTION	DESCRIPTION
IoDisconnectInterruptEx	Unregisters an interrupt-handling routine that IoConnectInterruptEx registered.
IoInitializeDpcRequest	Associates a driver-supplied DpcForIsr routine with a given device object, so that the DpcForIsr routine can complete interrupt-driven I/O operations.
IoReadPartitionTable	Returns a list of partitions on a disk with a given sector size.
IoSetPartitionInformation	Sets the partition type and number for a (disk) partition.
IoWritePartitionTable	Writes partition tables for a disk, given the device object that represents the disk, the sector size, and a pointer to a buffer containing the drive layout structure.
IoCreateController	Initializes a controller object representing a physical device controller that is shared by two or more similar devices that have the same driver, and specifies the size of the controller extension.
IoDeleteController	Removes a controller object from the system.
KeInitializeSpinLock	Initializes a variable of type KSPIN_LOCK.
KeInitializeDpc	Initializes a DPC object, setting up a driver-supplied CustomDpc routine that can be called with a given context.
KeInitializeTimer	Initializes a notification timer object to the Not-Signaled state.
KeInitializeTimerEx	Initializes a notification or synchronization timer object to the Not-Signaled state.
KeInitializeEvent	Initializes an event object as a synchronization (single waiter) or notification (multiple waiters) type event and sets up its initial state (Signaled or Not-Signaled).
ExInitializeFastMutex	Initializes a fast mutex variable that is used to synchronize mutually exclusive access to a shared resource by a set of threads.
KeInitializeMutex	Initializes a mutex object as set to the Signaled state.
KeInitializeSemaphore	Initializes a semaphore object to a given count and specifies an upper bound for the count.
IoCreateNotificationEvent	Initializes a named notification event to be used to synchronize access between two or more components. Notification events are not automatically reset.
IoCreateSynchronizationEvent	Initializes a named synchronization event to be used to serialize access to hardware between two otherwise unrelated drivers.

FUNCTION	DESCRIPTION
PsCreateSystemThread	Creates a kernel-mode thread that is associated with a given process object or with the default system process. Returns a handle for the thread.
PsTerminateSystemThread	Terminates the current thread and satisfies as many waits as possible for the current thread object.
KeSetBasePriorityThread	Sets up the run-time priority, relative to the system process, for a driver-created thread.
KeSetPriorityThread	Sets up the run-time priority for a driver-created thread with a real-time priority attribute.
MmIsThisAnNtAsSystem	Returns TRUE if the current platform is a server, indicating that more resources are likely to be necessary to process I/O requests than if the machine were a client.
MmQuerySystemSize	Returns an estimate (small, medium, or large) of the amount of memory available on the current platform.
ExInitializeNPagedLookasideList	Initializes a lookaside list of nonpaged memory. After a successful initialization, fixed-size blocks can be allocated from and freed to the lookaside list.
ExInitializePagedLookasideList	Initializes a lookaside list of paged memory. After a successful initialization, fixed-size blocks can be allocated from and freed to the lookaside list.
ExInitializeResourceLite	Initializes a resource, for which the caller provides the storage, to be used for synchronization by a set of threads.
ExReinitializeResourceLite	Reinitializes an existing resource variable.
ExDeleteResourceLite	Deletes a caller-initialized resource from the system's resource list.
ObReferenceObjectByHandle	Returns a pointer to the object body and handle information (attributes and granted access rights), given the handle for an object, the object's type, and a mask. Specifies the desired access to the object and the preferred access mode. A successful call increments the reference count for the object.
ObReferenceObjectByPointer	Increments the reference count for an object so the caller can ensure that the object is not removed from the system while the caller is using it.
ObReferenceObject	Increments the reference count for an object, given a pointer to the object.
ObDereferenceObject	Releases a reference to an object (decrements the reference count), given a pointer to the object body.
RtlInitString	Initializes a counted string in a buffer.

FUNCTION	DESCRIPTION
RtlInitAnsiString	Initializes a counted ANSI string in a buffer.
RtlInitUnicodeString	Initializes a counted Unicode string in a buffer.
InitializeObjectAttributes	Initializes a parameter of type OBJECT_ATTRIBUTES for a subsequent call to a ZwCreateXxx or ZwOpenXxx routine.
ZwCreateDirectoryObject	Creates or opens a directory object with a specified set of object attributes and requests one or more types of access for the caller. Returns a handle for the directory object.
ZwCreateFile	Creates or opens a file object that represents a physical, logical, or virtual device, a directory, a data file, or a volume. Returns a handle for the file object.
ZwCreateKey	Creates or opens a key object in the registry and returns a handle for the key object.
ZwDeleteKey	Deletes an existing, open key in the registry after the last handle for the key is closed.
ZwMakeTemporaryObject	Resets the "permanent" attribute of an opened object, so that the object and its name can be deleted when the reference count for the object becomes zero.
ZwClose	Releases the handle for an opened object, causing the handle to become invalid, and decrements the reference count of the object handle.
PsGetVersion	Indicates whether the driver is running on a free or checked build, and optionally supplies information about the operating system version and build number.
ObGetObjectSecurity	Returns a buffered security descriptor for a given object.
ObReleaseObjectSecurity	Releases the security descriptor returned by ObGetObjectSecurity.

Initializing Driver-Managed Queues

Used for initializing driver-managed internal queues.

FUNCTION	DESCRIPTION
KeInitializeSpinLock	Initializes a variable of type KSPIN_LOCK. An initialized spin lock is a required parameter to the ExXxxInterlockedList routines.
InitializeListHead	Sets up a queue header for a driver's internal queue, given a pointer to driver-supplied storage for the queue header and queue.
ExInitializeSListHead	Sets up the queue header for a sequenced, interlocked, singly linked list.

FUNCTION	DESCRIPTION
KeInitializeDeviceQueue	Initializes a device queue object to a Not Busy state, setting up an associated spin lock for multiprocessor-safe access to device queue entries.
IoCsqInitialize	Initializes the dispatch table for a driver's cancel-safe IRP queue.

I/O Manager Routines

All kernel-mode drivers except video and SCSI miniport drivers and NDIS drivers call IoXxx routines.

References for the IoXxx routines are in alphabetical order.

For an overview of the functionality of these routines, see Summary of Kernel-Mode Support Routines.

The following routine is for system use. Do not use it in your driver.

IoUpdateDiskGeometry

Power Management Routines

The Windows power management architecture provides a comprehensive approach to power management supported at the component (subdevice) level, in addition to the system level and the device level.

Kernel-mode drivers call the PoXxx routines to perform power management for the devices that they control. This section contains the reference pages for these routines. The PoXxx routines are declared in the Wdm.h header file.

For more information about power management, see Power Management for Windows Drivers.

FUNCTION	DESCRIPTION
PoCallDriver	The PoCallDriver routine passes a power IRP to the next-lower driver in the device stack. (Windows Server 2003, Windows XP, and Windows 2000 only.)
PoClearPowerRequest	The PoClearPowerRequest routine decrements the count for the specified power request type.
PoCreatePowerRequest	The PoCreatePowerRequest routine creates a power request object.
PoDeletePowerRequest	The PoDeletePowerRequest routine deletes a power request object.
PoEndDeviceBusy	The PoEndDeviceBusy routine marks the end of a period of time in which the device is busy.
PoGetSystemWake	The PoGetSystemWake routine determines whether a specified IRP has been marked as waking the system from a sleeping state.
PoQueryWatchdogTime	The PoQueryWatchdogTime routine indicates whether the power manager has enabled a watchdog time-out counter for any power IRP that is currently assigned to the device stack.

FUNCTION	DESCRIPTION
PoRegisterDeviceForIdleDetection	The PoRegisterDeviceForIdleDetection routine enables or cancels idle detection and sets idle time-out values for a device.
PoRegisterPowerSettingCallback	The PoRegisterPowerSettingCallback routine registers a power-setting callback routine to receive notifications of changes in the specified power setting.
PoRegisterSystemState	The PoRegisterSystemState routine registers the system as busy due to certain activity.
PoRequestPowerIrp	The PoRequestPowerIrp routine allocates a power IRP and sends it to the top driver in the device stack for the specified device.
PoSetDeviceBusyEx	The PoSetDeviceBusyEx routine notifies the power manager that the device associated with the specified idle counter is busy.
PoSetPowerRequest	The PoSetPowerRequest routine increments the count for the specified power request type.
PoSetPowerState	The PoSetPowerState routine notifies the system of a change in the device power state for a device.
PoSetSystemState	Drivers call the PoSetSystemState routine to indicate that the system is active.
PoSetSystemWake	The PoSetSystemWake routine marks the specified IRP as one that contributed to waking the system from a sleep state.
PoStartDeviceBusy	The PoStartDeviceBusy routine marks the start of a period of time in which the device is busy.
PoStartNextPowerIrp	The PoStartNextPowerIrp routine signals the power manager that the driver is ready to handle the next power IRP. (Windows Server 2003, Windows XP, and Windows 2000 only.)
PoUnregisterPowerSettingCallback	The PoUnregisterPowerSettingCallback routine unregisters a power-setting callback routine that a driver previously registered by calling the PoRegisterPowerSettingCallback routine.
PoUnregisterSystemState	The PoUnregisterSystemState routine cancels a system state registration created by PoRegisterSystemState.

Device Power Management

Starting with Windows 8, drivers can divide their device hardware into multiple logical components to enable fine-grained power management. A component has a set of power states that can be managed independently of the power states of other components in the same device. In the F0 state, the component is fully turned on. The component might support additional, low-power states F1, F2, and so on.

The power policy owner for a device is typically the device's function driver. To enable component-level power management, this driver registers the device with the power management framework (PoFx). By registering the

device, the driver assumes the responsibility for informing PoFx when a component is actively being used and when the component is idle. PoFx makes intelligent idle state choices for the device based on information about the component activity, latency tolerance, expected idle durations, and wake requirements. By controlling power usage at the component level, PoFx can reduce power requirements while preserving system responsiveness. For more information, see Component-Level Power Management.

Starting with Windows 8, drivers can divide their device hardware into multiple logical components to enable fine-grained power management. A component has a set of power states that can be managed independently of the power states of other components in the same device. In the F0 state, the component is fully turned on. The component might support additional, low-power states F1, F2, and so on.

The power policy owner for a device is typically the device's function driver. To enable component-level power management, this driver registers the device with the power management framework (PoFx). By registering the device, the driver assumes the responsibility for informing PoFx when a component is actively being used and when the component is idle. PoFx makes intelligent idle state choices for the device based on information about the component activity, latency tolerance, expected idle durations, and wake requirements. By controlling power usage at the component level, PoFx can reduce power requirements while preserving system responsiveness. For more information, see Component-Level Power Management.

This section describes the routines that are implemented by the power management framework (PoFx) to enable device power management. These routines are called by the driver that is the power policy owner (PPO) for a device. Typically, the function driver for a device is the PPO for this device.

FUNCTION	DESCRIPTION
PoFxActivateComponent	The PoFxActivateComponent routine increments the activation reference count on the specified component.
PoFxCompleteDevicePowerNotRequired	The PoFxCompleteDevicePowerNotRequired routine notifies the power management framework (PoFx) that the calling driver has completed its response to a call to the driver's DevicePowerNotRequiredCallback callback routine.
PoFxCompleteIdleCondition	The PoFxCompleteIdleCondition routine informs the power management framework (PoFx) that the specified component has completed a pending change to the idle condition.
PoFxCompleteIdleState	The PoFxCompleteIdleState routine informs the power management framework (PoFx) that the specified component has completed a pending change to an Fx state.
PoFxIdleComponent	The PoFxIdleComponent routine decrements the activation reference count on the specified component.
PoFxIssueComponentPerfStateChange	The PoFxIssueComponentPerfStateChange routine submits a request to place a device component in a particular performance state.
PoFxIssueComponentPerfStateChangeMultiple	The PoFxIssueComponentPerfStateChangeMultiple routine submits a request to change the performance states in multiple performance state sets simultaneously for a device component.
PoFxNotifySurprisePowerOn	The PoFxNotifySurprisePowerOn routine notifies the power management framework (PoFx) that a device was turned on as a side effect of supplying power to some other device.

FUNCTION	DESCRIPTION
PoFxPowerControl	The PoFxPowerControl routine sends a power control request to the power management framework (PoFx).
PoFxQueryCurrentComponentPerfState	The PoFxQueryCurrentComponentPerfState routine retrieves the active performance state in a component's performance state set.
PoFxRegisterComponentPerfStates	The PoFxRegisterComponentPerfStates routine registers a device component for performance state management by the power management framework (PoFx).
PoFxRegisterDevice	The PoFxRegisterDevice routine registers a device with the power management framework (PoFx).
PoFxReportDevicePoweredOn	The PoFxReportDevicePoweredOn routine notifies the power management framework (PoFx) that the device completed the requested transition to the D0 (fully on) power state.
PoFxSetComponentLatency	The PoFxSetComponentLatency routine specifies the maximum latency that can be tolerated in the transition from the idle condition to the active condition in the specified component.
PoFxSetComponentResidency	The PoFxSetComponentResidency routine sets the estimated time for how long a component is likely to remain idle after the component enters the idle condition.
PoFxSetComponentWake	The PoFxSetComponentWake routine indicates whether the driver arms the specified component to wake whenever the component enters the idle condition.
PoFxSetDeviceIdleTimeout	The PoFxSetDeviceIdleTimeout routine specifies the minimum time interval from when the last component of the device enters the idle condition to when the power management framework (PoFx) calls the driver's DevicePowerNotRequiredCallback routine.
PoFxSetTargetDripsDevicePowerState	This routine is called to notify the power manager of the device's target device power state for DRIPS. The driver can override the DRIPS constraint provided by the PEP.
PoFxStartDevicePowerManagement	The PoFxStartDevicePowerManagement routine completes the registration of a device with the power management framework (PoFx) and starts device power management.
PoFxUnregisterDevice	The PoFxUnregisterDevice routine removes the registration of a device from the power management framework (PoFx).

Device Power Management Callbacks

Device power management callbacks are the callback routines that are required by the power management framework (PoFx) to enable device power management. The driver that is the power policy owner for the device implements these callback routines. PoFx calls these routines to query and configure the power states of the components in the device.

CALLBACK	DESCRIPTION
ComponentActiveConditionCallback	The ComponentActiveConditionCallback callback routine notifies the driver that the specified component completed a transition from the idle condition to the active condition.
ComponentIdleConditionCallback	The ComponentIdleConditionCallback callback routine notifies the driver that the specified component completed a transition from the active condition to the idle condition.
ComponentIdleStateCallback	The ComponentIdleStateCallback callback routine notifies the driver of a pending change to the Fx power state of the specified component.
ComponentPerfStateCallback	The ComponentPerfStateCallback callback routine notifies the driver that its request to change the performance state of a component is complete.
DevicePowerNotRequiredCallback	The DevicePowerNotRequiredCallback callback routine notifies the device driver that the device is not required to stay in the D0 power state.
DevicePowerRequiredCallback	The DevicePowerRequiredCallback callback routine notifies the device driver that the device must enter and remain in the D0 power state.
PowerControlCallback	The PowerControlCallback callback routine performs a power control operation that is requested by the power management framework (PoFx).

Platform extension plug-in (PEP) reference

Platform extension plug-ins (PEPs) provide interfaces for platform power management including device power management (DPM), processor power management (PPM), and, starting with Windows 10, ACPI runtime methods.

The types of notifications sent to platform extension plug-ins (PEPs) include: ACPI notifications

Device power management (DPM) notifications

Processor power management (PPM) notifications

PPM power control codes

INITIALIZATION FUNCTION	DESCRIPTION
PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE	The PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_EXTENDED_ADDRESS structure.
PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE	The PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_EXTENDED_ADDRESS structure.
PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE	The PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_GPIO_RESOURCE structure.

INITIALIZATION FUNCTION	DESCRIPTION
PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE	The PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_GPIO_RESOURCE structure.
PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE	The PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_INTERRUPT_RESOURCE structure.
PEP_ACPI_INITIALIZE_IOPORT_RESOURCE	The PEP_ACPI_INITIALIZE_IOPORT_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_IO_MEMORY_RESOURCE structure.
PEP_ACPI_INITIALIZE_MEMORY_RESOURCE	The PEP_ACPI_INITIALIZE_MEMORY_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_IO_MEMORY_RESOURCE structure.
PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE	The PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_I2C_RESOURCE structure.
PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE	The PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_SPI_RESOURCE structure.
PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE	The PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_UART_RESOURCE structure.

PEP callback routines The callback routines are implemented by platform extension plug-ins, and are called by the Windows power management framework (PoFx).

CALLBACK FUNCTION	DESCRIPTION
AcceptAcpiNotification	An AcceptAcpiNotification event callback routine handles ACPI notifications from the Windows power management framework (PoFx).
AcceptDeviceNotification	An AcceptDeviceNotification event callback routine handles device power management (DPM) notifications from the Windows power management framework (PoFx).
AcceptProcessorNotification	An AcceptProcessorNotification event callback routine handles processor power management (PPM) notifications from the Windows power management framework (PoFx).
PO_ENUMERATE_INTERRUPT_SOURCE_CALLBACK	An EnumerateInterruptSource callback routine supplies a platform extension plug-in (PEP) with information about an interrupt source.
PROCESSOR_HALT_ROUTINE	A Halt callback routine transitions the processor to an idle state.
PowerOnDumpDeviceCallback	The PowerOnDumpDeviceCallback callback routine turns on the crash-dump device.

Power management framework (PoFx) routines

Some miscellaneous PoFx routines and structures will most likely end up in the power-management section of the Kernel-Mode Driver Architecture doc set.

INITIALIZATION FUNCTION	DESCRIPTION
PoFxRegisterPlugin	The PoFxRegisterPlugin routine registers a platform extension plug-in (PEP) with the Windows power management framework (PoFx).
PoFxRegisterPluginEx	The PoFxRegisterPluginEx routine registers a platform extension plug-in (PEP) with the Windows power management framework (PoFx).
PoFxRegisterCoreDevice	The PoFxRegisterCoreDevice routine registers a new core system resource with the Windows power management framework (PoFx).
PoFxRegisterCrashdumpDevice	The PoFxRegisterCrashdumpDevice routine registers a crash-dump device.
PoFxPowerOnCrashdumpDevice	The PoFxPowerOnCrashdumpDevice routine requests that a crash-dump device be turned on.

CALLBACK FUNCTION	DESCRIPTION
POFXCALLBACKENUMERATEUNMASKEDINTERRUPTS	The EnumerateUnmaskedInterrupts routine enumerates interrupt sources whose interrupts are unmasked and enabled.
POFXCALLBACKPLATFORMIDLEVETO	The PlatformIdleVeto routine increments or decrements the veto count for a veto code for a platform idle state.
POFXCALLBACKPROCESSORHALT	The ProcessorHalt routine prepares the processor to be halted.
POFXCALLBACKPROCESSORIDLEVETO	The ProcessorIdleVeto routine increments or decrements the veto count for a veto code for a processor idle state.
POFXCALLBACKREQUESTCOMMON	The RequestCommon routine is a generic request handler.
POFXCALLBACKREQUESTINTERRUPT	The RequestInterrupt routine requests that the operating system replay an edge-triggered interrupt that might have been lost while the hardware platform was in a low-power state.
POFXCALLBACKREQUESTWORKER	The RequestWorker routine is called by a platform extension plug-in (PEP) to inform the Windows power management framework (PoFx) that the platform extension plug-in (PEP) has a work request to submit on behalf of the specified device.
POFXCALLBACKCRITICALRESOURCE	The TransitionCriticalResource routine changes the active/inactive state of a core system component.
POFXCALLBACKUPDATEPLATFORMIDLESTATE	The UpdatePlatformIdleState routine is called by the platform extension plug-in (PEP) to update the properties of the specified platform idle state.

CALLBACK FUNCTION	DESCRIPTION
POFXCALLBACKUPDATEPROCESSORIDLESTATE	The UpdateProcessorIdleState routine is called by the platform extension plug-in (PEP) to update the properties of the specified processor idle state.
ComponentCriticalTransitionCallback	The ComponentCriticalTransitionCallback callback routine handles a transition of the specified component between the F0 (fully on) and low-power Fx component power states.

Configuration Manager Routines

The configuration manager routines use the CmXxx naming convention.

- CmCallbackGetKeyObjectID
- CmCallbackGetKeyObjectIDEx
- CmCallbackReleaseKeyObjectIDEx
- CmGetBoundTransaction
- CmGetCallbackVersion
- CmRegisterCallback
- CmRegisterCallbackEx
- CmSetCallbackObjectContext
- CmUnRegisterCallback

Kernel Transaction Manager (KTM) Routines

This section describes the routines, structures, and enumerations that the Kernel Transaction Manager (KTM) provides.

Transaction Manager Object Routines

This section includes the following topics:

- TmRecoverTransactionManager
- ZwCreateTransactionManager
- ZwOpenTransactionManager
- ZwQueryInformationTransactionManager
- ZwRecoverTransactionManager
- ZwRollforwardTransactionManager

Transaction Object Routines

This section includes the following topics:

- TmCommitTransaction
- TmGetTransactionId
- TmIsTransactionActive
- TmRollbackTransaction
- ZwCommitTransaction
- ZwCreateTransaction
- ZwEnumerateTransactionObject
- ZwOpenTransaction
- ZwQueryInformationTransaction
- ZwRollbackTransaction

- ZwSetInformationTransaction

Enlistment Object Routines

This section includes the following topics:

- TmCommitComplete
- TmCommitEnlistment
- TmCreateEnlistment
- TmDereferenceEnlistmentKey
- TmPrepareComplete
- TmPrePrepareComplete
- TmPrepareEnlistment
- TmPrePrepareEnlistment
- TmReadOnlyEnlistment
- TmRecoverEnlistment
- TmReferenceEnlistmentKey
- TmRequestOutcomeEnlistment
- TmRollbackComplete
- TmRollbackEnlistment
- TmSinglePhaseReject
- ZwCommitComplete
- ZwCommitEnlistment
- ZwCreateEnlistment
- ZwOpenEnlistment
- ZwPrepareComplete
- ZwPrePrepareComplete
- ZwPrepareEnlistment
- ZwPrePrepareEnlistment
- ZwQueryInformationEnlistment
- ZwReadOnlyEnlistment
- ZwRecoverEnlistment
- ZwRollbackComplete
- ZwRollbackEnlistment
- ZwSetInformationEnlistment
- ZwSinglePhaseReject

Resource Manager Object Routines

This section includes the following topics:

- ResourceManagerNotification
- TmEnableCallbacks
- TmRecoverResourceManager
- ZwCreateResourceManager
- ZwGetNotificationResourceManager
- ZwOpenResourceManager
- ZwQueryInformationResourceManager
- ZwRecoverResourceManager
- ZwSetInformationResourceManager

Security Reference Monitor Routines

Generally, higher-level drivers, particularly network drivers, call these routines.

References for the SeXxx routines are in alphabetical order.

- SeAccessCheck
- SeAssignSecurity
- SeAssignSecurityEx
- SeDeassignSecurity
- SeFreePrivileges
- ○ SeSinglePrivilegeCheck SeValidSecurityDescriptor

Core Kernel Library Support Routines

All kernel-mode drivers except video and SCSI miniport drivers and NDIS drivers are likely to call at least some KeXxx routines.

This section describes references for the KeXxx routines, in alphabetical order.

For an overview of the functionality of these routines, see Summary of Kernel-Mode Support Routines.

The following routines are reserved for system use:

- KeAcquireSpinLockRaiseToSynch
- KeBreakinBreakpoint
- KeEnterKernelDebugger
- KeFlushWriteBuffer
- KeGetBugMessageText
- KeRaiseIrqlToSynchLevel
- KeRemoveByKeyDeviceQueueIfBusy
- KeSetTimeUpdateNotifyRoutine

Executive Library Support Routines

This section describes the executive library support routines. These routines use the ExXxx naming convention and are listed in alphabetical order.

The following executive support routines are reserved for system use. Do not use them in your driver.

ROUTINE	REPLACEMENT
ExAcquireSpinLock	Use KeAcquireSpinLock instead.
ExAcquireSpinLockAtDpcLevel	Use KeAcquireSpinLockAtDpcLevel instead.
ExfInterlockedDecrementLong	Use InterlockedDecrement instead.
ExfInterlockedExchangeUlong	Use InterlockedExchange instead.
ExfInterlockedIncrementLong	Use InterlockedIncrement instead.
ExfInterlockedPopEntryList	Use ExInterlockedPopEntryList instead.

ROUTINE	REPLACEMENT
ExfInterlockedPushEntryList	Use ExInterlockedPushEntryList instead.
ExReleaseSpinLock	Use KeReleaseSpinLock instead.
ExReleaseSpinLockFromDpcLevel	Use KeReleaseSpinLockFromDpcLevel instead.
ExVerifySuite	

CLFS Library Routines

This section contains reference pages for routines implemented by the Common Log File System (CLFS). For a listing of the CLFS management routines, see CLFS Management Library Routines. For a conceptual discussion of CLFS, see Common Log File System in the design guide section of this documentation. For definitions of key terms used in the CLFS documentation, see CLFS Terminology.

CALLBACK FUNCTION	DESCRIPTION
ClfsAddLogContainer	The ClfsAddLogContainer routine adds a container to a CLFS log.
ClfsAddLogContainerSet	The ClfsAddLogContainerSet routine atomically adds a set of containers to a CLFS log.
ClfsAdvanceLogBase	The ClfsAdvanceLogBase routine sets the base LSN of a CLFS stream.
ClfsAlignReservedLog	The ClfsAlignReservedLog routine calculates the size of the space that must be reserved for a specified set of records. The size calculation includes the space required for headers and the space required for sector alignment.
ClfsAllocReservedLog	The ClfsAllocReservedLog routine reserves space in a marshalling area for a set of records.
ClfsCloseAndResetLogFile	The ClfsCloseAndResetLogFile routine releases all references to a specified log file object and marks its associated stream for reset.
ClfsCloseLogFileObject	The ClfsCloseLogFileObject routine releases all references to a log file object.
ClfsCreateLogFile	The ClfsCreateLogFile routine creates or opens a CLFS stream. If necessary, ClfsCreateLogFile also creates the underlying physical log that holds the stream's records.
ClfsCreateMarshallingArea	The ClfsCreateMarshallingArea routine creates a marshalling area for a CLFS stream and returns a pointer to an opaque context that represents the new marshalling area.
ClfsCreateScanContext	The ClfsCreateScanContext routine creates a scan context that can be used to iterate over the containers of a specified CLFS log.

CALLBACK FUNCTION	DESCRIPTION
ClfsDeleteLogByPointer	The ClfsDeleteLogByPointer routine marks a CLFS stream for deletion.
ClfsDeleteLogFile	The ClfsDeleteLogFile routine marks a CLFS stream for deletion.
ClfsDeleteMarshallingArea	The ClfsDeleteMarshallingArea routine deletes a marshalling area.
ClfsFlushBuffers	The ClfsFlushBuffers routine forces all log I/O blocks in a specified marshalling area to stable storage.
ClfsFlushToLsn	The ClfsFlushToLsn routine forces, to stable storage, all records that have an LSN less than or equal to a specified LSN.
ClfsGetContainerName	The ClfsGetContainerName routine returns the path name of a specified container.
ClfsGetIoStatistics	The ClfsGetIoStatistics routine returns I/O statistics for a specified CLFS log.
ClfsLsnBlockOffset	The ClfsLsnBlockOffset routine returns the sector-aligned block offset contained in a specified LSN.
ClfsLsnContainer	The ClfsLsnContainer routine returns the logical container identifier contained in a specified LSN.
ClfsLsnCreate	The ClfsLsnCreate routine creates a log sequence number (LSN), given a container identifier, a block offset, and a record sequence number.
ClfsLsnEqual	The ClfsLsnEqual routine determines whether two LSNs from the same stream are equal.
ClfsLsnGreater	The ClfsLsnGreater routine determines whether one LSN is greater than another LSN. The two LSNs must be from the same stream.
ClfsLsnLess	The ClfsLsnLess routine determines whether one LSN is less than another LSN. The two LSNs must be from the same stream.
ClfsLsnNull	The ClfsLsnNull routine determines whether a specified LSN is equal to the smallest possible LSN, CLFS_LSN_NULL.
ClfsLsnRecordSequence	The ClfsLsnRecordSequence routine returns the record sequence number contained in a specified LSN.
ClfsQueryLogFileInformation	The ClfsQueryLogFileInformation routine returns metadata and state information for a specified CLFS stream or its underlying physical log or both.

CALLBACK FUNCTION	DESCRIPTION
ClfsReadLogRecord	The ClfsReadLogRecord routine reads a target record in a CLFS stream and returns a read context that the caller can use to read the records preceding or following it in the stream.
ClfsReadNextLogRecord	The ClfsReadNextLogRecord routine reads the next record in a sequence, relative to the current record in a read context.
ClfsReadPreviousRestartArea	The ClfsReadPreviousRestartArea routine reads the previous restart record relative to the current record in a read context.
ClfsReadRestartArea	The ClfsReadRestartArea routine reads the restart record that was most recently written to a specified CLFS stream.
ClfsRemoveLogContainer	The ClfsRemoveLogContainer routine removes a container from a CLFS log.
ClfsRemoveLogContainerSet	The ClfsRemoveLogContainerSet routine atomically removes a set of containers from a CLFS log.
ClfsReserveAndAppendLog	The ClfsReserveAndAppendLog routine reserves space in a marshalling area or appends a record to a marshalling area or does both atomically.
ClfsReserveAndAppendLogAligned	The ClfsReserveAndAppendLogAligned routine reserves space in a marshalling area or appends a record to a marshalling area or does both atomically. The record's data is aligned on specified boundaries.
ClfsScanLogContainers	The ClfsScanLogContainers routine retrieves descriptive information for a sequence of containers that belong to a particular CLFS log.
ClfsSetArchiveTail	The ClfsSetArchiveTail routine sets the archive tail of a CLFS log to a specified LSN.
ClfsSetEndOfLog	The ClfsSetEndOfLog routine truncates a CLFS stream.
ClfsSetLogFileInformation	The ClfsSetLogFileInformation routine sets metadata and state information for a specified stream and its underlying physical log.
ClfsTerminateReadLog	The ClfsTerminateReadLog routine invalidates a specified read context after freeing resources associated with the context.
ClfsWriteRestartArea	The ClfsWriteRestartArea routine atomically appends a new restart record to a CLFS stream, flushes the restart record to stable storage, and optionally updates the base LSN of the stream.

IRPs

Microsoft Windows use I/O Request Packets (IRPs) to send messages to device drivers. An IRP is a data structure that contains specific information used to convey the status of an event. For more information about the IRP data structure, see IRP and IRP Major Function Codes.

Your driver can use System-Supplied Driver Interfaces to send IRPs to other drivers.

In addition to the Standard IRP Codes, there are three additional types of IRPs for specific technologies:

- Plug and Play IRPs, see Plug and Play Minor IRPs
- Power Management IRPs, see Power Management Minor IRPs
- Windows Management Instrumentation (WMI) IRPs, see WMI Minor IRPs

This section describes kernel-mode support routines that drivers can call:

- While processing IRPs.
- To allocate and set up IRPs for requests from higher-level drivers to lower drivers.
- To use file objects.

Processing IRPs

FUNCTION	DESCRIPTION
IoGetCurrentIrpStackLocation	Returns a pointer to the caller's I/O stack location in a given IRP.
IoGetNextIrpStackLocation	Returns a pointer to the next-lower-level driver's I/O stack location in a given IRP.
IoCopyCurrentIrpStackLocationToNext Copies the IRP stack parameters from the current stack location to the stack location of the next-lower driver and allows the current driver to set an I/O completion routine.	
IoSkipCurrentIrpStackLocation	Copies the IRP stack parameters from the current stack location to the stack location of the next-lower driver and does not allow the current driver to set an I/O completion routine.
IoGetRelatedDeviceObject	Returns a pointer to the device object represented by a given file object.
IoGetFunctionCodeFromCtlCode	Returns the value of the function field within a given IOCTL_XXX or FSCTL_XXX code.
IoValidateDeviceIoControlAccess	Verifies that the sender of an IRP_MJ_DEVICE_CONTROL or IRP_MJ_FILE_SYSTEM_CONTROL IRP has the access specified.
IoSetCompletionRoutine	Registers a driver-supplied IoCompletion routine for an IRP, so the IoCompletion routine is called when the next-lower-level driver has completed the requested operation in one or more of the following ways: successfully, with an error, or by canceling the IRP.
IoSetCompletionRoutineEx	Same as IoSetCompletionRoutine, except that it guarantees a non-Plug and Play driver is not unloaded before the IoCompletion routine exits.
IoCallDriver	Sends an IRP to a lower-level driver.
PoCallDriver	Sends an IRP with major function code IRP_MJ_POWER to the next-lower driver.

FUNCTION	DESCRIPTION
IoForwardIrpSynchronously	Sends an IRP to a lower-level driver synchronously.
IoMarkIrpPending	Marks a given IRP indicating that STATUS_PENDING was returned because further processing is required by another driver routine or by a lower-level driver.
IoStartPacket	Calls the driver's StartIo routine with the given IRP for the given device object or inserts the IRP into the device queue if the device is already busy, specifying whether the IRP is cancelable.
IoSetStartIoAttributes	Sets attributes for when the driver's StartIo routine will execute.
IoAcquireCancelSpinLock	Synchronizes cancelable state transitions for IRPs in a multiprocessor-safe manner.
IoSetCancelRoutine	Sets or clears the Cancel routine in an IRP. Setting a Cancel routine makes an IRP cancelable.
IoReleaseCancelSpinLock	Releases the cancel spin lock when the driver has changed the cancelable state of an IRP or releases the cancel spin lock from the driver's Cancel routine.
IoCancelIrp	Marks an IRP as canceled.
IoReadPartitionTable	Returns a list of partitions on a disk with a given sector size.
IoSetPartitionInformation	Sets the partition type and number for a (disk) partition.
IoWritePartitionTable	Writes partition tables for a disk, given the device object representing the disk, the sector size, and a pointer to a buffer containing the drive geometry.
IoAllocateErrorLogEntry	Allocates and initializes an error log packet; returns a pointer so that the caller can supply error-log data and call IoWriteErrorLogEntry with the packet.
IoWriteErrorLogEntry	Queues a previously allocated and filled-in error log packet to the system error logging thread.
IoIsErrorUserInduced	Returns a Boolean value indicating whether an I/O request failed due to one of the following conditions: STATUS_IO_TIMEOUT, STATUS_DEVICE_NOT_READY, STATUS_UNRECOGNIZED_MEDIA, STATUS_VERIFY_REQUIRED, STATUS_WRONG_VOLUME, STATUS_MEDIA_WRITE_PROTECTED, or STATUS_NO_MEDIA_IN_DEVICE. If the result is TRUE, a removable-media driver must call IoSetHardErrorOrVerifyDevice before completing the IRP.

FUNCTION	DESCRIPTION
IoSetHardErrorOrVerifyDevice	Supplies the device object for which the given IRP was failed due to a user-induced error, such as supplying the incorrect media for the requested operation or changing the media before the requested operation was completed. A file system driver uses the associated device object to notify the user, who can then correct the error or retry the operation.
IoRaiseHardError	Notifies the user that the given IRP was failed on the given device object for an optional VPB, so that the user can correct the error or retry the operation.
IoRaiseInformationalHardError	Notifies the user of an error, providing an I/O error status and an optional string supplying more information.
ExRaiseStatus	Raises an error status and causes a caller-supplied structured exception handler to be called. Useful only to highest-level drivers that supply exception handlers, in particular to file systems.
IoStartNextPacket	Dequeues the next IRP for a given device object, specifies whether the IRP is cancelable, and calls the driver's StartIo routine.
IoStartNextPacketByKey	Dequeues the next IRP for a device object according to a specified sort-key value, specifies whether the IRP is cancelable, and calls the driver's StartIo routine.
IoCompleteRequest	Completes an I/O request, giving a priority boost to the original caller and returning a given IRP to the I/O system for disposal: either to call any IoCompletion routines supplied by higher-level drivers, or to return status to the original requester of the operation.
IoGetCurrentProcess	Returns a pointer to the current process. Useful only to highest-level drivers.
IoGetInitialStack	Returns the initial base address of the current thread's stack. Useful only to highest-level drivers.
IoGetRemainingStackSize	Returns the amount of available stack space. Useful only to highest-level drivers.
IoGetStackLimits	Returns the boundaries of the current thread's stack frame. Useful only to highest-level drivers.
IoCsqInitialize	Initializes the dispatch table for a driver's cancel-safe IRP queue.
IoCsqInsertIrp	Inserts an IRP into a driver's cancel-safe IRP queue.
IoCsqRemoveIrp	Removes the specified IRP from a driver's cancel-safe IRP queue.
IoCsqRemoveNextIrp	Removes the next IRP from a driver's cancel-safe IRP queue.

Driver-Allocated IRPs

FUNCTION	DESCRIPTION
oBuildAsynchronousFsdRequest	Allocates and sets up an IRP that specifies a major function code (IRP_MJ_PNP, IRP_MJ_READ, IRP_MJ_WRITE, IRP_MJ_SHUTDOWN, or IRP_MJ_FLUSH_BUFFERS) with a pointer to: The lower driver's device object on which the I/O should occur. A buffer that will contain the data to be read or that contains the data to be written. The length of the buffer in bytes. The starting offset on the media. The I/O status block where the called driver can return status information and the caller's IoCompletion routine can access it. Returns a pointer to the IRP so the caller can set any necessary minor function code and set up its IoCompletion routine before sending the IRP to the target driver.
IoBuildSynchronousFsdRequest	Allocates and sets up an IRP specifying a major function code (IRP_MJ_PNP, IRP_MJ_READ, IRP_MJ_WRITE, IRP_MJ_SHUTDOWN, or IRP_MJ_FLUSH_BUFFERS) with a pointer to: The lower driver's device object on which the I/O should occur. A buffer that will contain the data to be read or that contains the data to be written. The length of the buffer in bytes. The starting offset on the media. An event object to be set to the Signaled state when the requested operation completes. The I/O status block where the called driver can return status information and the caller's IoCompletion routine can access it. Returns a pointer to the IRP so the caller can set any necessary minor function code and set up its IoCompletion routine before sending the IRP to the target driver.
IoBuildDeviceIoControlRequest	Allocates and sets up an IRP specifying a major function code (either IRP_MJ_INTERNAL_DEVICE_CONTROL or IRP_MJ_DEVICE_CONTROL) with an optional input or output buffer; a pointer to the lower driver's device object; an event to be set to the Signaled state when the requested operation completes; and an I/O status block to be set by the driver that receives the IRP. Returns a pointer to the IRP so the caller can set the appropriate IOCTL_XXX before sending the IRP to the next-lower-level driver.
PoRequestPowerIrp	Allocates and initializes an IRP with major function code IRP_MJ_POWER and then sends the IRP to the top-level driver in the device stack for the specified device object.
IoSizeOfIrp	Returns the size in bytes required for an IRP with a given count of I/O stack locations.
IoAllocateIrp	Allocates an IRP, given the number of I/O stack locations (optionally, for the caller, but at least one for each driver layered under the caller) and whether to charge quota against the caller. Returns a pointer to an IRP in nonpaged system space if successful; otherwise, returns NULL.
IoInitializeIrp	Initializes an IRP, given a pointer to an already allocated IRP, its length in bytes, and its number of I/O stack locations.

FUNCTION	DESCRIPTION
IoSetNextIrpStackLocation	Sets the current IRP stack location to the caller's location in an IRP. The stack location must have been allocated by a preceding call to IoAllocateIrp that specified a stack-size argument large enough to give the caller its own stack location.
IoAllocateMdl	Allocates an MDL large enough to map the starting address and length supplied by the caller; optionally associates the MDL with a given IRP.
IoBuildPartialMdl	Builds an MDL for the specified starting virtual address and length in bytes from a given source MDL. Drivers that split large transfer requests into a number of smaller transfers can call this routine.
IoFreeMdl	Releases a given MDL allocated by the caller.
IoMakeAssociatedIrp	Allocates and initializes an IRP to be associated with a master IRP sent to the highest-level driver, allowing the driver to "split" the original request and send associated IRPs on to lower-level drivers or to the device.
IoSetCompletionRoutine	Registers a driver-supplied IoCompletion routine with a given IRP, so that the IoCompletion routine is called when lower-level drivers have completed the request. The IoCompletion routine lets the caller release the IRP it allocated with IoAllocateIrp or IoBuildAsynchronousFsdRequest; to release any other resources it allocated to set up an IRP for lower drivers; and to perform any I/O completion processing necessary.
IoSetCompletionRoutineEx	Same as IoSetCompletionRoutine, except that it guarantees a non-Plug and Play driver is not unloaded before the IoCompletion routine exits.
IoCallDriver	Sends an IRP to a lower-level driver.
IoFreeIrp	Releases an IRP that was allocated by the caller.
IoReuseIrp	Reinitializes for reuse an IRP that was previously allocated by IoAllocateIrp.

File Objects

FUNCTION	DESCRIPTION
nitializeObjectAttributes	Initializes a parameter of type OBJECT_ATTRIBUTES for a subsequent call to a ZwCreateXxx or ZwOpenXxx routine.
ZwCreateFile	Creates or opens a file object representing a physical, logical, or virtual device, a directory, a data file, or a volume.
ZwQueryInformationFile	Returns information about the state or attributes of an open file.

FUNCTION	DESCRIPTION
IoGetFileObjectGenericMapping	Returns information about the mapping between generic access rights and specific access rights for file objects.
ZwReadFile	Returns data from an open file.
ZwSetInformationFile	Changes information about the state or attributes of an open file.
ZwWriteFile	Transfers data to an open file.
ZwClose	Releases the handle for an opened object, causing the handle to become invalid and decrementing the reference count of the object handle.

Silo DDIs

This section describes the silo DDIs. These DDIs offer the ability for kernel components to learn about the server silos that are created and destroyed on a machine. Components register to receive notifications for these events and optionally store state that is associated with each silo.

Context management

These DDIs provide the ability to assign and retrieve context structures on silo objects. This allows drivers to attach per-silo information for each silo.

- PsAllocSiloContextSlot
- PsFreeSiloContextSlot
- PsCreateSiloContext
- PsInsertSiloContext
- PsReplaceSiloContext
- PsInsertPermanentSiloContext
- PsGetPermanentSiloContext
- PsMakeSiloContextPermanent
- PsGetSiloContext
- PsRemoveSiloContext
- PsReferenceSiloContext
- PsDereferenceSiloContext
- SILO_CONTEXT_CLEANUP_CALLBACK

Threading

These DDIs provide the ability to set and retrieve the silo for the current thread.

- PsAttachSiloToCurrentThread
- PsDetachSiloFromCurrentThread
- PsGetCurrentSilo
- PsGetCurrentServerSilo

Monitoring

These DDIs provide the ability for a driver to receive notifications about silo creation and termination events.

- PsRegisterSiloMonitor

- PsUnregisterSiloMonitor
- PsStartSiloMonitor
- PsGetSiloMonitorContextSlot
- SILO_MONITOR_CREATE_CALLBACK
- SILO_MONITOR_TERMINATE_CALLBACK

Helpers

These DDIs are helpful for working with silo objects.

- PsGetJobSilo
- PsGetJobServerSilo
- PsGetEffectiveServerSilo
- PsIsHostSilo
- PsGetHostSilo
- PsTerminateServerSilo

Synchronization

This section describes the kernel-mode support routines that drivers can call to:

- Synchronize the execution of their own standard driver routines (Driver Routines and I/O Objects).
- Temporarily change the current IRQL for a call to a support routine or that return the current IRQL (IRQL).
- Synchronize access to resources with spin locks or to perform interlocked operations without spin locks (Spin Locks and Interlocks).
- Manage time-outs or determine system time (Timers).
- Use system threads or to manage synchronization within a nonarbitrary thread context (Driver Threads, Dispatcher Objects, and Resources).

Driver Routines and I/O Objects

FUNCTION	DESCRIPTION
KeSynchronizeExecution	Synchronizes the execution of a driver-supplied SynchCritSection routine with that of the ISR associated with a set of interrupt objects, given a pointer to the interrupt objects.
IoRequestDpc	Queues a driver-supplied DpcForIsr routine to complete interrupt-driven I/O processing at a lower IRQL.
KeInsertQueueDpc	Queues a DPC to be executed as soon as the IRQL of a processor drops below DISPATCH_LEVEL; returns FALSE if the DPC object is already queued.
KeRemoveQueueDpc	Removes a given DPC object from the DPC queue; returns FALSE if the object is not in the queue.
KeSetImportanceDpc	Controls how a particular DPC is queued and, to some degree, how soon the DPC routine is run.
KeSetTargetProcessorDpc	Controls on which processor a particular DPC subsequently will be queued.
KeFlushQueuedDpcs	Call this routine to wait for all queued DPCs to execute.

FUNCTION	DESCRIPTION
AllocateAdapterChannel	Connects a device object to an adapter object and calls a driver-supplied AdapterControl routine to carry out an I/O operation through the system DMA controller or a bus-master adapter as soon as the appropriate DMA channel and any necessary map registers are available. (This routine reserves exclusive access to a DMA channel and map registers for the specified device.)
FreeAdapterChannel	Releases an adapter object, representing a system DMA channel, and optionally releases map registers, if any were allocated.
FreeMapRegisters	Releases a set of map registers that were saved from a call to AllocateAdapterChannel, after the registers have been used by IoMapTransfer and the bus-master DMA transfer is complete.
IoAllocateController	Connects a device object to a controller object and calls a driver-supplied ControllerControl routine to carry out an I/O operation on the device controller as soon as the controller is not busy. (This routine reserves exclusive access to the hardware controller for the specified device.)
IoFreeController	Releases a controller object, provided that all device operations queued to the controller for the current IRP have completed.
IoStartTimer	Enables the timer for a given device object and calls the driver-supplied IoTimer routine once per second thereafter.
IoStopTimer	Disables the timer for a given device object so that the driver-supplied IoTimer routine is not called unless the driver reenables the timer.
KeSetTimer	Sets the absolute or relative interval at which a timer object will be set to the Signaled state and optionally supplies a timer DPC to be executed after the interval expires.
KeSetTimerEx	Sets the absolute or relative interval at which a timer object will be set to the Signaled state, optionally supplies a timer DPC to be executed when the interval expires, and optionally supplies a recurring interval for the timer.
KeCancelTimer	Cancels a timer object before the interval passed to KeSetTimer expires; dequeues a timer DPC before the timer interval, if any was set, expires.
KeReadStateTimer	Returns whether a given timer object is set to the Signaled state.
IoStartPacket	Calls the driver's StartIo routine with the given IRP for the given device object or inserts the IRP into the device queue if the device is already busy, specifying whether the IRP is cancelable.
IoStartNextPacket	Dequeues the next IRP for a given device object, specifying whether the IRP is cancelable, and calls the driver's StartIo routine.

FUNCTION	DESCRIPTION
IoStartNextPacketByKey	Dequeues the next IRP, according to the specified sort-key value, for a given device object. Specifies whether the IRP is cancelable and calls the driver's StartIo routine.
IoSetCompletionRoutine	Registers a driver-supplied IoCompletion routine with a given IRP, so the IoCompletion routine is called when the next-lower-level driver has completed the requested operation in one or more of the following ways: successfully, with an error, or by canceling the IRP.
IoSetCompletionRoutineEx	Same as IoSetCompletionRoutine, except that it guarantees a non-Plug and Play driver is not unloaded before the IoCompletion routine exits.
IoSetCancelRoutine	Sets or clears the Cancel routine in an IRP. Setting a Cancel routine makes an IRP cancelable.
KeStallExecutionProcessor	Stalls the caller (a device driver) for a given interval on the current processor.
ExAcquireResourceExclusiveLite	Acquires an initialized resource for exclusive access by the calling thread and optionally waits for the resource to be acquired.
ExAcquireResourceSharedLite	Acquires an initialized resource for shared access by the calling thread and optionally waits for the resource to be acquired.
ExAcquireSharedStarveExclusive	Acquires a given resource for shared access without waiting for any pending attempts to acquire exclusive access to the same resource.
ExAcquireSharedWaitForExclusive	Acquires a given resource for shared access, optionally waiting for any pending exclusive waiters to acquire and release the resource first.
ExReleaseResourceForThreadLite	Releases a given resource that was acquired by the given thread.
ZwReadFile	Reads data from an open file. If the caller opened the file object with certain parameters, the caller can wait for the file handle to be returned for completion of the I/O.
ZwWriteFile	Writes data to an open file. If the caller opened the file object with certain parameters, the caller can wait for the file handle to be returned for completion of the I/O.

IRQL

FUNCTION	DESCRIPTION
KeRaiseIrql	Raises the hardware priority to a given IRQL value, thereby masking off interrupts of equivalent or lower IRQL on the current processor.

FUNCTION	DESCRIPTION
KeRaiseIrqlToDpcLevel	aises the hardware priority to IRQL DISPATCH_LEVEL, thereby masking off interrupts of equivalent or lower IRQL on the current processor.
KeLowerIrql	Restores the IRQL on the current processor to its original value.
KeGetCurrentIrql	Returns the current hardware priority IRQL value.

Spin Locks and Interlocks

FUNCTION	DESCRIPTION
oAcquireCancelSpinLock	Synchronizes cancelable state transitions for IRPs in a multiprocessor-safe manner.
IoSetCancelRoutine	Sets or clears the Cancel routine in an IRP during a cancelable state transition. Setting a Cancel routine makes an IRP cancelable.
IoReleaseCancelSpinLock	Releases the cancel spin lock when the driver has changed the cancelable state of an IRP or releases the cancel spin lock from the driver's Cancel routine.
KeInitializeSpinLock	Initializes a variable of type KSPIN_LOCK, used to synchronize access to data shared among non-ISR routines. An initialized spin lock also is a required parameter to the ExInterlockedXxx routines.
KeAcquireSpinLock	Acquires a spin lock so the caller can synchronize access to shared data safely on multiprocessor platforms.
KeAcquireSpinLockRaiseToDpc	Acquires a spin lock so the caller can synchronize access to shared data safely on multiprocessor platforms.
KeReleaseSpinLock	Releases a spin lock that was acquired by calling KeAcquireSpinLock and restores the original IRQL at which the caller was running.
KeAcquireSpinLockAtDpcLevel	Acquires a spin lock, provided that the caller is already running at IRQL DISPATCH_LEVEL.
KeTryToAcquireSpinLockAtDpcLevel	Acquires a spin lock that is not already held, provided that the caller is already running at IRQL DISPATCH_LEVEL.
KeReleaseSpinLockFromDpcLevel	Releases a spin lock that was acquired by calling KeAcquireSpinLockAtDpcLevel.
KeAcquireInStackQueuedSpinLock	Acquires a queued spin lock so the caller can synchronize access to shared data safely on multiprocessor platforms.
KeReleaseInStackQueuedSpinLock	Releases a queued spin lock that was acquired by calling KeAcquireInStackQueuedSpinLock.

FUNCTION	DESCRIPTION
KeAcquireInStackQueuedSpinLockAtDpcLevel	Acquires a queued spin lock, provided that the caller is already running at IRQL DISPATCH_LEVEL.
KeReleaseInStackQueuedSpinLockFromDpcLevel	Releases a queued spin lock that was acquired by calling KeAcquireInStackQueuedSpinLockAtDpcLevel.
KeAcquireInterruptSpinLock	Acquires the spin lock that synchronizes access with an interrupt's ISR.
KeReleaseInterruptSpinLock	Release the spin lock that synchronized access with an interrupt's ISR.
ExInterlockedXxxList	Insert and remove IRPs in a driver-managed internal queue, which is protected by an initialized spin lock for which the driver provides the storage.
KeXxxDeviceQueue	Insert and remove IRPs in a driver-allocated and managed internal device queue object, which is protected by a built-in spin lock.
ExInterlockedAddUlong	Adds a value to a variable of type ULONG as an atomic operation, using a spin lock to ensure multiprocessor-safe access to the variable; returns the value of the variable before the call occurred.
ExInterlockedAddLargeInteger	Adds a value to a variable of type LARGE_INTEGER as an atomic operation, using a spin lock to ensure multiprocessor-safe access to the variable; returns the value of the variable before the call occurred.
InterlockedIncrement	Increments a variable of type LONG as an atomic operation. The sign of the return value is the sign of the result of the operation.
InterlockedDecrement	Decrements a variable of type LONG as an atomic operation. The sign of the return value is the sign of the result of the operation.
InterlockedExchange	Sets a variable of type LONG to a specified value as an atomic operation; returns the value of the variable before the call occurred.
InterlockedExchangeAdd	Adds a value to a given integer variable as an atomic operation; returns the value of the variable before the call occurred.
InterlockedCompareExchange	Compares the values referenced by two pointers. If the values are equal, resets one of the values to a caller-supplied value in an atomic operation.
InterlockedCompareExchangePointer	Compares the pointers referenced by two pointers. If the pointer values are equal, resets one of the values to a caller-supplied value in an atomic operation.

FUNCTION	DESCRIPTION
ExInterlockedCompareExchange64	Compares one integer variable to another and, if they are equal, resets the first variable to a caller-supplied ULONGLONG-type value as an atomic operation.
KeGetCurrentProcessorNumber	Returns the current processor number when debugging spin lock usage in SMP machines.

Timers

FUNCTION	DESCRIPTION
oInitializeTimer	Associates a timer with the given device object and registers a driver-supplied IoTimer routine for the device object.
IoStartTimer	Enables the timer for a given device object and calls the driver-supplied IoTimer routine once every second.
IoStopTimer	Disables the timer for a given device object so the driver-supplied IoTimer routine is not called unless the driver reenables the timer.
KeInitializeDpc	Initializes a DPC object and sets up a driver-supplied CustomTimerDpc routine that can be called with a given context.
KeInitializeTimer	Initializes a notification timer object to the Not-Signaled state.
KeInitializeTimerEx	Initializes a notification or synchronization timer object to the Not-Signaled state.
KeSetTimer	Sets the absolute or relative interval at which a timer object will be set to the Signaled state; optionally supplies a timer DPC to be executed when the interval expires.
KeSetTimerEx	Sets the absolute or relative interval at which a timer object will be set to the Signaled state; optionally supplies a timer DPC to be executed when the interval expires; and optionally supplies a recurring interval for the timer.
KeCancelTimer	Cancels a timer object before the interval passed to KeSetTimer expires; dequeues a timer DPC before the timer interval, if any was set, expires.
KeReadStateTimer	Returns TRUE if a given timer object is set to the Signaled state.
KeQuerySystemTime	Returns the current system time.
KeQueryRuntimeThread	Returns the accumulated kernel-mode and user-mode run time.
KeQueryTickCount	Returns the number of interval-timer interrupts that have occurred since the system was booted.

FUNCTION	DESCRIPTION
KeQueryTimeIncrement	Returns the number of 100-nanosecond units that are added to the system time at each interval-timer interrupt.
KeQueryInterruptTime	Returns the current value of the system interrupt-time count in 100-nanosecond units, with accuracy to within system clock tick.
KeQueryInterruptTimePrecise	Returns the current value of the system interrupt-time count in 100-nanosecond units, with accuracy to within a microsecond.
KeQueryPerformanceCounter	Returns the system performance counter value in hertz.

Driver Threads, Dispatcher Objects, and Resources

FUNCTION	DESCRIPTION
KeDelayExecutionThread	Puts the current thread into an alertable or nonalertable wait state for a given interval.
ExInitializeResourceLite	Initializes a resource, for which the caller provides the storage, to be used for synchronization by a set of threads (shared readers, exclusive writers).
ExReinitializeResourceLite	Reinitializes an existing resource variable.
ExAcquireResourceExclusiveLite	Acquires an initialized resource for exclusive access by the calling thread and optionally waits for the resource to be acquired.
ExAcquireResourceSharedLite	Acquires an initialized resource for shared access by the calling thread and optionally waits for the resource to be acquired.
ExAcquireSharedStarveExclusive	Acquires a given resource for shared access without waiting for any pending attempts to acquire exclusive access to the same resource.
ExAcquireSharedWaitForExclusive	Acquires a given resource for shared access, optionally waiting for any pending exclusive waiters to acquire and release the resource first.
ExIsResourceAcquiredExclusiveLite	Returns whether the calling thread has exclusive access to a given resource.
ExIsResourceAcquiredSharedLite	Returns how many times the calling thread has acquired shared access to a given resource.
ExGetExclusiveWaiterCount	Returns the number of threads currently waiting to acquire a given resource for exclusive access.
ExGetSharedWaiterCount	Returns the number of threads currently waiting to acquire a given resource for shared access.

FUNCTION	DESCRIPTION
ExConvertExclusiveToSharedLite	Converts a given resource from acquired for exclusive access to acquired for shared access.
ExGetCurrentResourceThread	Returns the thread ID of the current thread.
ExReleaseResourceForThreadLite	Releases a given resource that was acquired by the given thread.
ExDeleteResourceLite	Deletes a caller-initialized resource from the system's resource list.
IoQueueWorkItem	Queues an initialized work queue item so the driver-supplied routine will be called when a system worker thread is given control.
KeSetTimer	Sets the absolute or relative interval at which a timer object will be set to the Signaled state, and optionally supplies a timer DPC to be executed when the interval expires.
KeSetTimerEx	Sets the absolute or relative interval at which a timer object will be set to the Signaled state. Optionally supplies a timer DPC to be executed when the interval expires and a recurring interval for the timer.
KeCancelTimer	Cancels a timer object before the interval passed to KeSetTimer expires. Dequeues a timer DPC before the timer interval (if any) expires.
KeReadStateTimer	Returns TRUE if a given timer object is set to the Signaled state.
KeSetEvent	Returns the previous state of a given event object and sets the event (if not already Signaled) to the Signaled state.
KeClearEvent	Resets an event to the Not-Signaled state.
KeResetEvent	Returns the previous state of an event object and resets the event to the Not-Signaled state.
KeReadStateEvent	Returns the current state (nonzero for Signaled or zero for Not-Signaled) of a given event object.
ExAcquireFastMutex	Acquires an initialized fast mutex, possibly after putting the caller into a wait state until it is acquired, and gives the calling thread ownership with APCs disabled.
ExTryToAcquireFastMutex	Acquires the given fast mutex immediately for the caller with APCs disabled, or returns FALSE.
ExReleaseFastMutex	Releases ownership of a fast mutex that was acquired with ExAcquireFastMutex or ExTryToAcquireFastMutex.
ExAcquireFastMutexUnsafe	Acquires an initialized fast mutex, possibly after putting the caller into a wait state until it is acquired.

FUNCTION	DESCRIPTION
ExReleaseFastMutexUnsafe	Releases ownership of a fast mutex that was acquired with ExAcquireFastMutexUnsafe.
KeReleaseMutex	Releases a given mutex object, specifying whether the caller will call one of the KeWaitXxx routines as soon as KeReleaseMutex returns the previous value of the mutex state (a zero for Signaled; otherwise, Not-Signaled).
KeReadStateMutex	Returns the current state (one for Signaled or any other value for Not-Signaled) of a given mutex object.
KeReleaseSemaphore	Releases a given semaphore object. Supplies a (run-time) priority boost for waiting threads if the release sets the semaphore to the Signaled state. Augments the semaphore count by a given value and specifies whether the caller will call one of the KeWaitXxx routines as soon as KeReleaseSemaphore returns.
KeReadStateSemaphore	Returns the current state (zero for Not-Signaled or a positive value for Signaled) of a given semaphore object.
KeWaitForSingleObject	Puts the current thread into an alertable or nonalertable wait state until a given dispatcher object is set to the Signaled state or (optionally) until the wait times out.
KeWaitForMutexObject	Puts the current thread into an alertable or nonalertable wait state until a given mutex is set to the Signaled state or (optionally) until the wait times out.
KeWaitForMultipleObjects	Puts the current thread into an alertable or nonalertable wait state until any one or all of a number of dispatcher objects are set to the Signaled state or (optionally) until the wait times out.
PsGetCurrentThread	Returns a pointer to the current thread.
KeGetCurrentThread	Returns a pointer to the opaque thread object that represents the current thread.
IoGetCurrentProcess	Returns a pointer to the process of the current thread.
PsGetCurrentProcess	Returns a pointer to the process of the current thread.
KeEnterCriticalRegion	Temporarily disables the delivery of normal kernel APCs while a highest-level driver is running in the context of the user-mode thread that requested the current I/O operation. Special kernel-mode APCs are still delivered.
KeLeaveCriticalRegion	Reenables, as soon as possible, the delivery of normal kernel-mode APCs that were disabled by a preceding call to KeEnterCriticalRegion.
KeAreApcsDisabled	Returns TRUE if normal kernel-mode APCs are disabled.

FUNCTION	DESCRIPTION
KeSaveFloatingPointState	Saves the current thread's nonvolatile floating-point context so that the caller can carry out its own floating-point operations.
KeRestoreFloatingPointState	Restores the previous nonvolatile floating-point context that was saved with KeSaveFloatingPointState.
ZwSetInformationThread	Sets the priority of a given thread for which the caller has a handle.
PsGetCurrentProcessId	Returns the system-assigned identifier of the current process.
PsGetCurrentThreadId	Returns the system-assigned identifier of the current thread.
PsSetCreateProcessNotifyRoutine	Registers a highest level driver's callback routine that is subsequently executed whenever a new process is created or existing process deleted.
PsSetCreateThreadNotifyRoutine	Registers a highest level driver's callback routine that is subsequently executed whenever a new thread is created or an existing thread is deleted.
PsSetLoadImageNotifyRoutine	Registers a callback routine for a highest level system-profiling driver. The callback routine is subsequently executed whenever a new image is loaded for execution.

Memory Allocation and Buffer Management

This section describes the Windows kernel routines and macros that kernel-mode drivers call to allocate memory and manage I/O buffers.

The Windows memory manager provides a set of routines that kernel-mode drivers use to allocate and manage memory. These routines have names that begin with the prefix Mm.

This section contains reference pages for the MmXxx routines and memory-management macros. These reference pages are listed in alphabetical order.

For an overview of the functionality of these routines and macros, see Memory Allocation and Buffer Management. For an introduction to memory management support for kernel-mode drivers, see Memory Management for Windows Drivers.

The following routines are reserved for system use. Do not use them in your driver.

- MmAddPhysicalMemory
- MmAddPhysicalMemoryEx
- MmAddVerifierThunks
- MmCreateMirror
- MmGetMdlBaseVa
- MmGetPhysicalMemoryRanges
- MmGetProcedureAddress
- MmGetVirtualForPhysical
- MmIsVerifierEnabled
- MmIsIoSpaceActive

- MmMapUserAddressesToPage
- MmMapVideoDisplay
- MmMapViewInSessionSpace
- MmMapViewInSystemSpace
- MmMarkPhysicalMemoryAsBad
- MmMarkPhysicalMemoryAsGood
- MmProbeAndLockProcessPages
- MmRemovePhysicalMemory
- MmRemovePhysicalMemoryEx
- MmRotatePhysicalView
- MmUnmapVideoDisplay
- MmUnmapViewInSessionSpace
- MmUnmapViewInSystemSpace

For more information about memory allocation and buffer management, see Memory Management for Windows Drivers.

Buffer Management

The short-term buffer management routines are called by kernel-mode drivers to allocate and free temporary buffers.

FUNCTION	DESCRIPTION
ExAllocatePoolWithTag	Allocates (optionally cache-aligned) pool memory from paged or nonpaged system space. The caller-supplied tag is put into any crash dump of memory that occurs.
ExAllocatePoolWithQuotaTag	Allocates pool memory, charging quota against the original requester of the I/O operation. The caller-supplied tag is put into any crash dump of memory that occurs. Only highest-level drivers can call this routine.
ExFreePool	Releases memory to paged or nonpaged system space.
ExFreePoolWithTag	Releases memory with the specified pool tag.
ExInitializeNPagedLookasideList	Initializes a lookaside list of nonpaged memory. After successful initialization of the list, fixed-size blocks can be allocated from, and freed to, the lookaside list.
ExAllocateFromNPagedLookasideList	Removes the first entry from the specified lookaside list in nonpaged memory. If the lookaside list is empty, allocates an entry from nonpaged pool.
ExFreeToNPagedLookasideList	Returns an entry to the specified lookaside list in nonpaged memory. If the list has reached its maximum size, returns the entry to nonpaged pool.
ExDeleteNPagedLookasideList	Deletes a nonpaged lookaside list.
ExInitializePagedLookasideList	Initializes a lookaside list of paged memory. After successful initialization of the list, fixed-size blocks can be allocated from and freed to the lookaside list.

FUNCTION	DESCRIPTION
ExAllocateFromPagedLookasideList	Removes the first entry from the specified lookaside list in paged memory. If the lookaside list is empty, allocates an entry from paged pool.
ExFreeToPagedLookasideList	Returns an entry to the specified lookaside list in paged memory. If the list has reached its maximum size, returns the entry to paged pool.
ExDeletePagedLookasideList	Deletes a paged lookaside list.
MmQuerySystemSize	Returns an estimate (small, medium, or large) of the amount of memory available on the current platform.
MmIsThisAnNtAsSystem	Returns TRUE if the machine is running as a server. If this routine returns TRUE, the caller is likely to require more resources to process I/O requests, and the machine is a server so it is likely to have more resources available.

Long-Term Internal Driver Buffers

The long-term buffer management routines are called by kernel-mode drivers to allocate long-term driver-internal buffers.

FUNCTION	DESCRIPTION
MmAllocateContiguousMemory	Allocates a range of physically contiguous, cache-aligned memory in nonpaged pool.
MmFreeContiguousMemory	Releases a range of physically contiguous memory when the driver unloads.
MmAllocateNonCachedMemory	Allocates a virtual address range of noncached and cache-aligned memory in nonpaged system space (pool).
MmFreeNonCachedMemory	Releases a virtual address range of noncached memory in nonpaged system space when the driver unloads.
MmAllocateMappingAddress	Reserves a range of virtual address space that can later be mapped with MmMapLockedPagesWithReservedMapping.
MmFreeMappingAddress	Frees a reserved memory address reserved by MmAllocateMappingAddress.
AllocateCommonBuffer	Allocates and maps a logically contiguous region of memory that is simultaneously accessible both from the processor and from a device, given access to an adapter object, the requested length of the memory region to allocate, and access to variables where the starting logical and virtual addresses of the allocated region are returned. Returns TRUE if the requested length was allocated. Can be used for continuous bus-master DMA or for system DMA using the autoinitialize mode of a system DMA controller.

FUNCTION	DESCRIPTION
FreeCommonBuffer	Releases an allocated common buffer and unmaps it, given access to the adapter object, the length, and the starting logical and virtual addresses of the region to be freed when the driver unloads. Arguments must match those passed in the call to AllocateCommonBuffer.

Buffered Data and Buffer Initialization

The buffered-data and buffer-initialization routines are called by kernel-mode drivers to manage buffered data or initialize driver-allocated buffers.

FUNCTION	DESCRIPTION
RtlCompar	Memory
RtlCopyMemory	Copies the data from one caller-supplied buffer to another, given pointers to both buffers and the length in bytes to be copied.
RtlMoveMemory	Copies the data from one caller-supplied memory range to another, given pointers to the base of both ranges and the length in bytes to be copied.
RtlFillMemory	Fills a caller-supplied buffer with the specified UCHAR value, given a pointer to the buffer and the length in bytes to be filled.
RtlZeroMemory	Fills a buffer with zeros, given a pointer to the caller-supplied buffer and the length in bytes to be filled.
RtlStoreUshort	Stores a USHORT value at a given address, avoiding alignment faults.
RtlRetrieveUshort	Retrieves a USHORT value at a given address, avoiding alignment faults, and stores the value at a given address that is assumed to be aligned.
RtlStoreUlong	Stores a ULONG value at a given address, avoiding alignment faults.
RtlRetrieveUlong	Retrieves a ULONG value at a given address, avoiding alignment faults, and stores the value at a given address that is assumed to be aligned.

Address Mappings and MDLs

The address-mapping and MDL-management routines are called by kernel-mode drivers to manage address mappings and memory descriptor lists (MDLs).

FUNCTION	DESCRIPTION
oAllocateMdl	Allocates an MDL large enough to map the starting address and length supplied by the caller; optionally associates the MDL with a given IRP.

FUNCTION	DESCRIPTION
IoBuildPartialMdl	Builds an MDL for the specified starting virtual address and length in bytes from a given source MDL. Drivers that split large transfer requests into a number of smaller transfers can call this routine.
IoFreeMdl	Releases a given MDL allocated by the caller.
MmAllocatePagesForMdlEx	Allocates nonpaged, physical memory pages for an MDL.
MmBuildMdlForNonPagedPool	Fills in the corresponding physical addresses of a given MDL that specifies a range of virtual addresses in nonpaged pool.
MmCreateMdl	Obsolete. Allocates and initializes an MDL describing a buffer specified by the given virtual address and length in bytes; returns a pointer to the MDL.
MmGetMdlByteCount	Returns the length in bytes of the buffer mapped by a given MDL.
MmGetMdlByteOffset	Returns the byte offset within a page of the buffer described by a given MDL.
MmGetMdlVirtualAddress	Returns a (possibly invalid) virtual address for a buffer described by a given MDL; the returned address, used as an index to a physical address entry in the MDL, can be input to MapTransfer for drivers that use DMA.
MmGetPhysicalAddress	Returns the corresponding physical address for a given valid virtual address.
MmGetSystemAddressForMdlSafe	Returns a system-space virtual address that maps the physical pages described by a given MDL for drivers whose devices must use programmed I/O (PIO). If no virtual address exists, one is assigned.
MmInitializeMdl	Initializes a caller-created MDL to describe a buffer specified by the given virtual address and length in bytes.
MmIsAddressValid	Returns whether a page fault will occur if a read or write operation is done at the given virtual address.
MmMapIoSpace	Maps a physical address range to a cached or noncached virtual address range in nonpaged system space.
MmMapLockedPages	Obsolete. Maps already locked physical pages, described by a given MDL, to a returned virtual address range.
MmMapLockedPagesWithReservedMapping	Maps a virtual address range already reserved with MmAllocateMappingAddress.
MmPrepareMdlForReuse	Reinitializes a caller-created MDL for reuse.

FUNCTION	DESCRIPTION
MmProbeAndLockPages	Probes the pages specified in an MDL for a particular kind of access, makes the pages resident, and locks them in memory; returns the MDL updated with corresponding physical addresses. (Usually, only highest-level drivers call this routine.)
MmProtectMdlSystemAddress	Sets the protection type for the memory-address range.
MmSecureVirtualMemory	Secures a memory-address range so that it cannot be freed and its page protection cannot be made more restrictive.
MmSizeOfMdl	Returns the number of bytes required for an MDL describing the buffer specified by the given virtual address and length in bytes.
MmUnlockPages	Unlocks the previously probed and locked pages specified in an MDL.
MmUnmapIoSpace	Unmaps a virtual address range from a physical address range.
MmUnmapLockedPages	Releases a mapping set up by MmMapLockedPages.
MmUnmapReservedMapping	Unmaps a virtual address range mapped by MmMapLockedPagesWithReservedMapping.
MmUnsecureVirtualMemory Unsecures a memory-address range secured by MmSecureVirtualMemory.	

Buffer and MDL Management

The buffer- and MDL-management macros are called by kernel-mode drivers to manage buffers and memory descriptor lists (MDLs).

For more information about MDLs, see Using MDLs.

FUNCTION	DESCRIPTION
ADDRESS_A	D_SIZE_TO_SPAN_PAGES
BYTE_OFFSET	Returns the byte offset of a given virtual address within the page.
BYTES_TO_PAGES	Returns the number of pages necessary to contain a given number of bytes.
PAGE_ALIGN	Returns the page-aligned virtual address for the page that contains a given virtual address.
ROUND_TO_PAGES	Rounds a given size in bytes up to a page-size multiple.

Device Memory Access

The device-memory-access macros are called by kernel-mode drivers to access the memory-mapped hardware registers and I/O ports of their respective devices.

For the following macros, XXX_REGISTER_XXX indicates device memory that is mapped onto system memory address space, while XXX_PORT_XXX indicates device memory in I/O port address space.

FUNCTION	DESCRIPTION
EAD_PORT_UCHAR	Reads a UCHAR value from the given I/O port address.
READ_PORT_USHORT	Reads a USHORT value from the given I/O port address.
READ_PORT_ULONG	Reads a ULONG value from the given I/O port address.
READ_PORT_BUFFER_UCHAR	Reads a given count of UCHAR values from the given I/O port into a given buffer.
READ_PORT_BUFFER_USHORT	Reads a given count of USHORT values from the given I/O port into a given buffer.
READ_PORT_BUFFER_ULONG	Reads a given count of ULONG values from the given I/O port into a given buffer.
WRITE_PORT_UCHAR	Writes a given UCHAR value to the given I/O port address.
WRITE_PORT_USHORT	Writes a given USHORT value to the given I/O port address.
WRITE_PORT_ULONG	Writes a given ULONG value to the given I/O port address.
WRITE_PORT_BUFFER_UCHAR	Writes a given count of UCHAR values from a given buffer to the given I/O port.
WRITE_PORT_BUFFER_USHORT	Writes a given count of USHORT values from a given buffer to the given I/O port.
WRITE_PORT_BUFFER_ULONG	Writes a given count of ULONG values from a given buffer to the given I/O port.
READ_REGISTER_UCHAR	Reads a UCHAR value from the given register address in memory space.
READ_REGISTER_USHORT	Reads a USHORT value from the given register address in memory space.
READ_REGISTER_ULONG	Reads a ULONG value from the given register address in memory space.
READ_REGISTER_BUFFER_UCHAR	Reads a given count of UCHAR values from the given register address into the given buffer.
READ_REGISTER_BUFFER_USHORT	Reads a given count of USHORT values from the given register address into the given buffer.
READ_REGISTER_BUFFER_ULONG	Reads a given count of ULONG values from the given register address into the given buffer.
WRITE_REGISTER_UCHAR	Writes a given UCHAR value to the given register address in memory space.

FUNCTION	DESCRIPTION
WRITE_REGISTER_USHORT	Writes a given USHORT value to the given register address in memory space.
WRITE_REGISTER_ULONG	Writes a given ULONG value to the given register address in memory space.
WRITE_REGISTER_BUFFER_UCHAR	Writes a given count of UCHAR values from a given buffer to the given register address.
WRITE_REGISTER_BUFFER_USHORT	Writes a given count of USHORT values from a given buffer to the given register address.
WRITE_REGISTER_BUFFER_ULONG	Writes a given count of ULONG values from a given buffer to the given register address.

Pageable Drivers

The pageable-driver routines are called by kernel-mode drivers to lock and unlock a driver's pageable code or data sections, or make an entire driver pageable.

FUNCTION	DESCRIPTION
M	LockPagableCodeSection
MmLockPagableDataSection	Locks data marked with a special compiler directive into system space, when that data is accessed infrequently, predictably, and at an IRQL of less than DISPATCH_LEVEL.
MmLockPagableSectionByHandle	Locks a pageable section into system memory using a handle returned from MmLockPagableCodeSection or MmLockPagableDataSection.
MmUnlockPagableImageSection	Releases a section that was previously locked into system space when the driver is no longer processing IRPs, or when the contents of the section are no longer required.
MmPageEntireDriver	Lets a driver page all of its code and data regardless of the attributes of the various sections in the driver's image.
MmResetDriverPaging	Resets a driver's pageable status to that specified by the sections making up the driver's image.

Sections and Views

The section- and view-management routines are called by kernel-mode drivers to set up mapped sections and views of memory.

FUNCTION	DESCRIPTION
nitializeObjectAttributes	Sets up a parameter of type OBJECT_ATTRIBUTES for a subsequent call to a ZwCreateXxx or ZwOpenXxx routine.
ZwOpenSection	Obtains a handle for an existing section, provided that the requested access can be allowed.

FUNCTION	DESCRIPTION
ZwMapViewOfSection	Maps a view of an open section into the virtual address space of a process. Returns an offset into the section (base of the mapped view) and the size mapped.
ZwUnmapViewOfSection	Releases a mapped view in the virtual address space of a process.

Access to Structures

The structure-access macros are called by kernel-mode drivers to access parts of structures.

FUNCTION	DESCRIPTION
RGUMENT_PRESENT	Returns FALSE if an argument pointer is NULL; otherwise returns TRUE.
CONTAINING_RECORD	Returns the base address of an instance of a structure given the structure type and the address of a field within it.
FIELD_OFFSET	Returns the byte offset of a named field in a known structure type.

Plug and Play Routines

These routines are used by drivers to implement Plug and Play (PnP) support. For background and task-oriented information about supporting PnP in drivers, see Plug and Play.

The following topics summarize the routines by functionality:

Device Information Routines

FUNCTION	DESCRIPTION
oGetDeviceProperty	Retrieves information about a device such as configuration information and the name of its PDO.
IoInvalidateDeviceRelations	Notifies the PnP manager that the relations for a device have changed.
IoInvalidateDeviceState	Notifies the PnP manager that the PnP state of a device has changed. In response, the PnP manager sends an IRP_MN_QUERY_PNP_DEVICE_STATE to the device stack.
IoReportDetectedDevice	Reports a non-PnP device to the PnP manager.
IoReportResourceForDetection	Claims hardware resources in the configuration registry for a legacy device. This routine is for drivers that detect legacy hardware that cannot be enumerated by PnP.

Registry Routines

FUNCTION	DESCRIPTION

FUNCTION	DESCRIPTION
oOpenDeviceInterfaceRegistryKey	Returns a handle to a registry key for storing information about a particular device interface.
IoOpenDeviceRegistryKey	Returns a handle to a device-specific or a driver-specific registry key for a particular device instance.

Device Interface Routines

FUNCTION	DESCRIPTION
IoRegisterDeviceInterface	Registers device functionality (a device interface) that a driver will enable for use by applications or other system components.
IoSetDeviceInterfaceState	Enables or disables a previously registered device interface. Applications and other system components can open only interfaces that are enabled.
IoOpenDeviceInterfaceRegistryKey	Returns a handle to a registry key for storing information about a particular device interface.
IoGetDeviceInterfaces	Returns a list of device interfaces of a particular device interface class (such as all devices on the system that support a HID interface).
IoGetDeviceInterfaceAlias	Returns the alias device interface of the specified interface class, if the alias exists. Device interfaces are considered aliases if they are exposed by the same underlying device and have identical interface reference strings, but are of different interface classes.

PnP Notification Routines

FUNCTION	DESCRIPTION
IoRegisterPlugPlayNotification	Registers a driver callback routine to be called when the specified PnP event occurs.
IoReportTargetDeviceChange	Notifies the PnP manager that a custom event has occurred on a device. The PnP manager sends notification of the event to drivers that registered for it. Do not use this routine to report system PnP events, such as GUID_TARGET_DEVICE_REMOVE_COMPLETE.
IoReportTargetDeviceChangeAsynchronous	Notifies the PnP manager that a custom event has occurred on a device. Returns immediately and does not wait while the PnP manager sends notification of the event to drivers that registered for it. Do not use this routine to report system PnP events, such as GUID_TARGET_DEVICE_REMOVE_COMPLETE.
IoUnregisterPlugPlayNotification	Removes the registration of a driver's callback routine for a PnP event.

Remove Lock Routines

FUNCTION	DESCRIPTION
oInitializeRemoveLock	Initializes a remove lock for a device object. A driver can use the lock to track outstanding I/O on a device and to determine when the driver can delete its device object in response to an IRP_MN_REMOVE_DEVICE request.
IoAcquireRemoveLock	Increments the count for a remove lock, indicating that the associated device object should not be detached from the device stack nor deleted.
IoReleaseRemoveLock	Releases a remove lock acquired with a previous call to IoAcquireRemoveLock.
IoReleaseRemoveLockAndWait	Releases a remove lock acquired with a previous call to IoAcquireRemoveLock and waits until all acquisitions of the lock have been released. A driver typically calls this routine in its dispatch code for an IRP_MN_REMOVE_DEVICE request.

Other PnP Routines

FUNCTION	DESCRIPTION
oAdjustPagingPathCount	Increments or decrements a caller-supplied page-file counter as an atomic operation. This routine can be used to adjust other counters, such as counters for hibernation files or crash-dump files.
IoRequestDeviceEject	Notifies the PnP manager that the device eject button was pressed. Note that this routine reports a request for a device eject, not media eject.

Windows Management Instrumentation Routines

This section summarizes kernel-mode support routines that drivers can use to interact with Windows Management Instrumentation (WMI).

The categories of support routines include those that drivers can call to:

- Process IRPs that a driver receives (WMI IRP Processing Routines).

FUNCTION	DESCRIPTION
WmiCompleteRequest	If a driver uses WmiSystemControl to dispatch the WMI IRP to a callback routine, then the callback routine can use WmiCompleteRequest to complete the IRP.
WmiSystemControl Dispatches a WMI IRP to a driver-supplied callback routine.	
WmiFireEvent	The WmiFireEvent routine sends an event to WMI for delivery to data consumers that have requested notification of the event.
WmiQueryTraceInformation	The WmiQueryTraceInformation routine returns information about a WMI event trace.

FUNCTION	DESCRIPTION
WmiSystemControl	The WmiSystemControl routine is a dispatch routine for drivers that use WMI library support routines to handle WMI IRPs.
WmiTraceMessage	The WmiTraceMessage routine adds a message to the output log of a WPP software tracing session.
WmiTraceMessageVa	The WmiTraceMessageVa routine adds a message to the output log of a WPP software tracing session.

- Drivers can use these routines in processing WMI IRPs. Drivers use these routines to send WMI IRPs.

FUNCTION	DESCRIPTION
IoWMIAllocateInstanceIds	Allocates unused WMI instance IDs for a given WMI class GUID.
IoWMIDeviceObjectToInstanceName	Given a device object, determines the WMI class instance name supported by the corresponding driver. Callers can use this to determine the instance names supported by a particular driver.
IoWMIExecuteMethod	Executes the specified WMI class method.
IoWMIHandleToInstanceName	Given a file handle, determines the WMI class instance name supported by the corresponding driver. Callers can use this to determine the instance names supported by a particular driver.
IoWMIOpenBlock	Opens a WMI data block. Callers use this to submit WMI I/O requests.
IoWMIQueryAllData	Fetches the property values for every instance of the specified WMI class GUID.
IoWMIQueryAllDataMultiple	Fetches the property values for every instance of the specified set of WMI class GUIDs.
IoWMIQuerySingleInstance	Fetches the property values for a particular instance of the specified WMI class GUID.
IoWMIQuerySingleInstanceMultiple	Fetches the property values for a particular set of WMI class instances.
IoWMISetNotificationCallback	Sets a notification callback for WMI events.
IoWMISetSingleInstance	Sets the property values for a particular WMI class instance.
IoWMISetSingleItem	Sets the specified property for a particular WMI class instance.

This section describes required and optional routines that a kernel-mode WDM driver contains, if the driver handles WMI Minor IRPs by calling WmiSystemControl. For more information, see Calling WmiSystemControl to

Handle WMI IRPs.

The DpWmiXxx names that are used in the Microsoft Windows Driver Kit (WDK) documentation are placeholders. A driver's DpWmiXxx routines can have any names that the driver writer chooses.

ZwXxx / NtXxx Routines

The ZwXxx routines provide a set of system entry points that parallel some of the executive's system services. Calling a ZwXxx routine from kernel-mode code results in a call to the corresponding system service. Calling a ZwXxx routine from user mode is not supported; instead, native applications (applications that bypass the Microsoft Win32 subsystem) should call the NtXxx equivalent of the ZwXxx routine.

For a list of NtXxx routines, see NtXxx Routines.

For a call to a ZwXxx routine from a kernel-mode driver, the system does not check the caller's access rights, nor does it set the previous processor mode to UserMode. Before calling a ZwXxx routine, a kernel-mode driver must check all user-supplied parameters for validity.

For more information about the relationship between NtXxx and ZwXxx routines, see Using Nt and Zw Versions of the Native System Services Routines. For a list of the ZwXxx routines in each major functional category, see Summary of Kernel-Mode Support Routines.

The following routines are reserved for system use. Do not use them in your driver.

|Routine|Replacement| |ZwCancelTimer| Use KeCancelTimer instead.| |ZwCreateTimer| Use KeInitializeTimer or KeInitializeTimerEx instead.| |ZwOpenTimer.|| |ZwSetTimer| Use KeSetTimer instead.| |NtRenameTransactionManager| Obsolete.|

> **NOTE**
> NtRenameTransactionManager and TmRenameTransactionManager are two versions of the same routine. Kernel-mode drivers should not call NtRenameTransactionManager. They should instead call TmRenameTransactionManager.

FUNCTION	DESCRIPTION
NtRenameTransactionManager	The NtRenameTransactionManager routine changes the identity of the transaction manager object that is stored in the CLFS log file stream contained in the log file name.
NtSetInformationTransactionManager Do not call this routine from kernel-mode code.	
ZwAllocateLocallyUniqueId	The ZwAllocateLocallyUniqueId routine allocates a locally unique identifier (LUID).
ZwAllocateVirtualMemory	The ZwAllocateVirtualMemory routine reserves, commits, or both, a region of pages within the user-mode virtual address space of a specified process.
ZwClose	The ZwClose routine closes an object handle.
ZwCreateDirectoryObject	The ZwCreateDirectoryObject routine creates or opens an object-directory object.

FUNCTION	DESCRIPTION
ZwCreateEvent	The ZwCreateEvent routine creates an event object, sets the initial state of the event to the specified value, and opens a handle to the object with the specified desired access.
ZwCreateFile	The ZwCreateFile routine creates a new file or opens an existing file.
ZwCreateKey	The ZwCreateKey routine creates a new registry key or opens an existing one.
ZwCreateKeyTransacted	The ZwCreateKeyTransacted routine creates a new registry key or opens an existing one, and it associates the key with a transaction.
ZwCreateSection	The ZwCreateSection routine creates a section object.
ZwDeleteFile	The ZwDeleteFile routine deletes the specified file.
ZwDeleteKey	The ZwDeleteKey routine deletes an open key from the registry.
ZwDeleteValueKey	The ZwDeleteValueKey routine deletes a value entry matching a name from an open key in the registry. If no such entry exists, an error is returned.
ZwDeviceIoControlFile	The ZwDeviceIoControlFile routine sends a control code directly to a specified device driver, causing the corresponding driver to perform the specified operation.
ZwDuplicateToken	The ZwDuplicateToken function creates a handle to a new access token that duplicates an existing token. This function can create either a primary token or an impersonation token.
ZwEnumerateKey	The ZwEnumerateKey routine returns information about a subkey of an open registry key.
ZwEnumerateValueKey	The ZwEnumerateValueKey routine gets information about the value entries of an open key.
ZwFlushBuffersFile	The ZwFlushBuffersFile routine is called by a file system filter driver to send a flush request for the specified file to the file system.
ZwFlushBuffersFileEx	The ZwFlushBuffersFileEx routine is called by a file system filter driver to send a flush request for a given file to the file system. An optional flush operation flag can be set to control how file data is written to storage.
ZwFlushKey	The ZwFlushKey routine forces a registry key to be committed to disk.
ZwFlushVirtualMemory	The ZwFlushVirtualMemory routine flushes a range of virtual addresses within the virtual address space of a specified process which map to a data file back out to the data file if they have been modified.

FUNCTION	DESCRIPTION
ZwFreeVirtualMemory	The ZwFreeVirtualMemory routine releases, decommits, or both, a region of pages within the virtual address space of a specified process.
ZwFsControlFile	The ZwFsControlFile routine sends a control code directly to a specified file system or file system filter driver, causing the corresponding driver to perform the specified action.
ZwLoadDriver	The ZwLoadDriver routine loads a driver into the system.
ZwLockFile	The ZwLockFile routine requests a byte-range lock for the specified file.
ZwMakeTemporaryObject	The ZwMakeTemporaryObject routine changes the attributes of an object to make it temporary.
ZwMapViewOfSection	The ZwMapViewOfSection routine maps a view of a section into the virtual address space of a subject process.
ZwNotifyChangeKey	The ZwNotifyChangeKey routine allows a driver to request notification when a registry key changes.
ZwOpenEvent	The ZwOpenEvent routine opens a handle to an existing named event object with the specified desired access.
ZwOpenFile	The ZwOpenFile routine opens an existing file, directory, device, or volume.
ZwOpenKey	The ZwOpenKey routine opens an existing registry key.
ZwOpenKeyEx	The ZwOpenKeyEx routine opens an existing registry key.
ZwOpenKeyTransacted	The ZwOpenKeyTransacted routine opens an existing registry key and associates the key with a transaction.
ZwOpenKeyTransactedEx	The ZwOpenKeyTransactedEx routine opens an existing registry key and associates the key with a transaction.
ZwOpenProcess	The ZwOpenProcess routine opens a handle to a process object and sets the access rights to this object.
ZwOpenProcessTokenEx	The ZwOpenProcessTokenEx routine opens the access token associated with a process.
ZwOpenSection	The ZwOpenSection routine opens a handle for an existing section object.
ZwOpenSymbolicLinkObject	The ZwOpenSymbolicLinkObject routine opens an existing symbolic link.

FUNCTION	DESCRIPTION
ZwOpenThreadTokenEx	The ZwOpenThreadTokenEx routine opens the access token associated with a thread.
ZwPowerInformation	The ZwPowerInformation routine sets or retrieves system power information.
ZwQueryInformationThread	The ZwQueryInformationThread routine retrieves information about the specified thread, such as its page priority.
ZwQueryDirectoryFile	The ZwQueryDirectoryFile routine returns various kinds of information about files in the directory specified by a given file handle.
ZwQueryEaFile	The ZwQueryEaFile routine returns information about extended-attribute (EA) values for a file.
ZwQueryFullAttributesFile	The ZwQueryFullAttributesFile routine supplies network open information for the specified file.
ZwQueryInformationFile	The ZwQueryInformationFile routine returns various kinds of information about a file object.
ZwQueryInformationToken	The ZwQueryInformationToken routine retrieves a specified type of information about an access token. The calling process must have appropriate access rights to obtain the information.
ZwQueryKey	The ZwQueryKey routine provides information about the class of a registry key, and the number and sizes of its subkeys.
ZwQueryObjec	The ZwQueryObject routine provides information about a supplied object.
ZwQueryQuotaInformationFile	The ZwQueryQuotaInformationFile routine retrieves quota entries associated with the volume specified by the FileHandle parameter.
ZwQuerySecurityObject	The ZwQuerySecurityObject routine retrieves a copy of an object's security descriptor.
ZwQuerySymbolicLinkObject	The ZwQuerySymbolicLinkObject routine returns a Unicode string that contains the target of a symbolic link.
ZwQueryValueKey	The ZwQueryValueKey routine returns a value entry for a registry key.
ZwQueryVirtualMemory	The ZwQueryVirtualMemory routine determines the state, protection, and type of a region of pages within the virtual address space of the subject process.
ZwQueryVolumeInformationFile	The ZwQueryVolumeInformationFile routine retrieves information about the volume associated with a given file, directory, storage device, or volume.
ZwReadFile	The ZwReadFile routine reads data from an open file.

FUNCTION	DESCRIPTION
ZwSetEaFile	The ZwSetEaFile routine sets extended-attribute (EA) values for a file.
ZwSetEvent	The ZwSetEvent routine sets an event object to a Signaled state and attempts to satisfy as many waits as possible.
ZwSetInformationFile	The ZwSetInformationFile routine changes various kinds of information about a file object.
ZwSetInformationThread	The ZwSetInformationThread routine sets the priority of a thread.
ZwSetInformationToken The ZwSetInformationToken routine modifies information in a specified token. The calling process must have appropriate access rights to set the information.	
ZwSetInformationVirtualMemory	The ZwSetInformationVirtualMemory routine performs an operation on a specified list of address ranges in the user address space of a process.
ZwSetQuotaInformationFile	The ZwSetQuotaInformationFile routine changes quota entries for the volume associated with the FileHandle parameter. All of the quota entries in the specified buffer are applied to the volume.
ZwSetSecurityObject	The ZwSetSecurityObject routine sets an object's security state.
ZwSetValueKey	The ZwSetValueKey routine creates or replaces a registry key's value entry.
ZwSetVolumeInformationFile	The ZwSetVolumeInformationFile routine modifies information about the volume associated with a given file, directory, storage device, or volume.
ZwTerminateProcess	The ZwTerminateProcess routine terminates a process and all of its threads.
ZwUnloadDriver	The ZwUnloadDriver routine unloads a driver from the system. Use this routine with extreme caution. (See the following Remarks section.)
ZwUnlockFile	The ZwUnlockFile routine unlocks a byte-range lock in a file.
ZwUnmapViewOfSection	The ZwUnmapViewOfSection routine unmaps a view of a section from the virtual address space of a subject process.
ZwWaitForSingleObject	The ZwWaitForSingleObject routine waits until the specified object attains a state of Signaled. An optional time-out can also be specified.
ZwWriteFile	The ZwWriteFile routine writes data to an open file.

Auxiliary Kernel-Mode Library Routines and Structures

The Auxiliary Kernel-Mode Library enables drivers to access some system capabilities that are not available from kernel-mode subsystems.

The AuxKlibInitialize routine initializes the Auxiliary Kernel-Mode Library. Drivers that use this library must call AuxKlibInitialize before calling any of the library's other routines.

- AuxKlibEnumerateSystemFirmwareTables
- AuxKlibGetBugCheckData
- AuxKlibGetImageExportDirectory
- AuxKlibGetSystemFirmwareTable
- AuxKlibInitialize
- AuxKlibQueryModuleInformation
- AUX_MODULE_BASIC_INFO
- AUX_MODULE_EXTENDED_INFO
- KBUGCHECK_DATA

Processor Group Compatibility Library

Support is available for kernel-mode drivers that use processor groups. The Processor Group (ProcGrp) compatibility library enables a kernel-mode driver that is written to use processor groups run on earlier versions of Windows, which do not support processor groups. When this driver runs on, it can take advantage of multiple processor groups, if the hardware platform supports them. When this same driver runs on an earlier version of Windows, it is limited to a single processor group, regardless of the capabilities of the hardware platform. To use the ProcGrp library, the driver must call a library initialization routine. Additionally, the driver must be compiled for the Windows 7 environment in the WDK, and must be linked with Procgrp.lib.

The ProcGrp library is designed to meet the compatibility requirements of drivers that call the following KeXxx routines but must also run on versions of Windows that do not implement these routines:

- KeGetCurrentProcessorNumberEx
- KeGetProcessorIndexFromNumber
- KeGetProcessorNumberFromIndex
- KeQueryActiveGroupCount
- KeQueryActiveProcessorCountEx
- KeQueryGroupAffinity
- KeQueryMaximumProcessorCount
- KeQueryMaximumProcessorCountEx
- KeQueryMaximumGroupCount
- KeSetSystemAffinityThreadEx
- KeSetSystemGroupAffinityThread
- KeRevertToUserAffinityThreadEx
- KeRevertToUserGroupAffinityThread
- KeSetTargetProcessorDpcEx

The ProcGrp library implements wrapper functions for the KeXxx routines in the preceding list. If the library runs on Windows 7 or Windows Server 2008 R2, the wrapper functions simply call the corresponding KeXxx routines. The wrapper functions have the same names as these KeXxx routines, and their behavior is identical to that of the KeXxx routines that they replace.

Earlier versions of Windows do not support processor groups and do not implement the KeXxx routines in the preceding list. If the ProcGrp library is linked to a driver that runs on one of these earlier versions of Windows, the library initialization function, WdmlibProcgrpInitialize, detects that the operating system does not support

processor groups. To deal with this case, each wrapper function contains a simplified implementation of the corresponding KeXxx routine. This implementation supports only one processor group, group number 0. For example, the wrapper function for the KeQueryMaximumGroupCount routine always returns a count of one. For another example, the wrapper function for the KeGetCurrentProcessorNumberEx routine emulates this routine by calling the KeGetCurrentProcessorNumber routine. KeGetCurrentProcessorNumber is similar to KeGetCurrentProcessorNumberEx, but lacks support for processor groups, which, in this case, has the same effect as supporting just one processor group.

For more information about the support for processor groups in Windows 7, see the Supporting Systems That Have More Than 64 Processors white paper on the WHDC website.

The ProcGrp library is contained in the Windows 7 version of the WDK. The library functions are declared in the Procgrp.h header file and are implemented in the Procgrp.lib library file.

In addition to the KeXxx wrapper functions, the ProcGrp library implements the following function to initialize the library:

- WdmlibProcgrpInitialize

DMA

DMA Library Routines Drivers use the routines documented in this section to perform direct memory access (DMA) operations. The routines are accessed through pointers and cannot be called directly by name.

Drivers performing DMA operations use IoGetDmaAdapter to get a pointer to the DMA_ADAPTER structure for the device. The DmaOperations member of the structure points to a DMA_OPERATIONS structure, which is a table of pointers to the DMA routines for the physical device object of that device.

FUNCTION	DESCRIPTION
IoGetDmaAdapter	Returns a pointer to an adapter object that represents either the DMA channel to which the driver's device is connected or the driver's bus-master adapter. Also returns the maximum number of map registers the driver can specify for each DMA transfer.
MmGetMdlVirtualAddress	Returns the base virtual address of a buffer described by a given MDL. The returned address, used as an index to a physical address entry in the MDL, can be input to MapTransfer.
MmGetSystemAddressForMdlSafe	Returns a nonpaged system-space virtual address for the base of the memory area described by an MDL. It maps the physical pages described by the MDL into system space, if they are not already mapped to system space.
ADDRESS_AND_SIZE_TO_SPAN_PAGES	Returns the number of pages spanned by the virtual range defined by a virtual address and a length in bytes. A driver can use this macro to determine whether a transfer request must be split into partial transfers.
AllocateAdapterChannel	Reserves exclusive access to a DMA channel and map registers for a device. When the channel and registers are available, this routine calls a driver-supplied AdapterControl routine to carry out an I/O operation through either the system DMA controller or a bus-master adapter.

FUNCTION	DESCRIPTION
AllocateCommonBuffer	Allocates and maps a logically contiguous region of memory that is simultaneously accessible from both the processor and a device. This routine returns TRUE if the requested length was allocated.
BuildMdlFromScatterGatherList	Builds an MDL corresponding to a scatter/gather list.
BuildScatterGatherList	Prepares the system for scatter/gather DMA for a device and calls a driver-supplied routine to carry out the I/O operation. This function provides the same functionality as GetScatterGatherList, except it uses a driver-supplied buffer to hold the scatter/gather list.
CalculateScatterGatherList	Computes the buffer size needed to hold a scatter/gather list for a memory buffer.
FlushAdapterBuffers	Forces any data remaining in either a bus-master adapter's or the system DMA controller's internal buffers to be written into memory or to the device.
FreeAdapterChannel	Releases an adapter object that represents a system DMA channel, and optionally releases any allocated map registers.
FreeCommonBuffer	Releases and unmaps a previously allocated common buffer. Arguments must match those passed in an earlier call to AllocateCommonBuffer.
FreeMapRegisters	Releases a set of map registers that were saved from a call to AllocateAdapterChannel. A driver calls this routine after using the registers in one or more calls to MapTransfer, flushing the cache by calling FlushAdapterBuffers, and completing the bus-master DMA transfer.
GetDmaAlignment	Returns the buffer alignment requirements for a DMA controller or device.
GetScatterGatherList	Prepares the system for scatter/gather DMA for a device and calls a driver-supplied routine to carry out the I/O operation. For devices that support scatter/gather DMA, this routine combines the functionality of AllocateAdapterChannel and MapTransfer.
KeFlushIoBuffers	Flushes the memory region described by an MDL from all processors' caches into memory.
MapTransfer	Sets up map registers for an adapter object previously allocated by AllocateAdapterChannel to map a transfer from a locked-down buffer. Returns the logical address of the mapped region and, for bus-master devices that support scatter/gather, the number of bytes mapped.
PutDmaAdapter	Frees an adapter object previously allocated by IoGetDmaAdapter.

FUNCTION	DESCRIPTION
PutScatterGatherList	Frees map registers and scatter/gather list previously allocated by GetScatterGatherList.
ReadDmaCounter Returns the number of bytes yet to be transferred during the current system DMA operation (in autoinitialize mode).	

PIO

FUNCTION	DESCRIPTION
MmProbeAndLockPages	Probes the pages specified in an MDL for a particular kind of access, makes the pages resident, and locks them in memory; returns the MDL updated with corresponding physical addresses.
MmGetSystemAddressForMdlSafe	Returns a system-space virtual address that maps the physical pages described by a given MDL for drivers whose devices must use PIO. If no virtual address exists, one is assigned.
KeFlushIoBuffers	Flushes the memory region described by a given MDL from all processors' caches into memory.
MmUnlockPages	Unlocks the previously probed and locked pages specified in an MDL.
MmMapIoSpace	Maps a physical address range to a cached or noncached virtual address range in nonpaged system space.
MmUnmapIoSpace	Unmaps a virtual address range from a physical address range.

Interrupts

FUNCTION	DESCRIPTION
IoConnectInterrupt	Registers a driver's interrupt handling routine. Drivers should use IoConnectInterruptEx instead.
IoDisconnectInterrupt	Unregisters an interrupt handling routine that IoConnectInterrupt registered.
IoConnectInterruptEx	Registers a driver's interrupt handling routine. Drivers can register either an InterruptService routine for line-based interrupts or an InterruptMessageService routine for message-signaled interrupts.
IoDisconnectInterruptEx	Unregisters an interrupt-handling routine that IoConnectInterruptEx registered.

FUNCTION	DESCRIPTION
IoInitializeDpcRequest	Associates a driver-supplied DpcForIsr routine with a given device object, so that the DpcForIsr routine can complete interrupt-driven I/O operations.
KeSynchronizeExecution	Synchronizes the execution of a driver-supplied SynchCritSection routine with that of the ISR associated with a set of interrupt objects, given a pointer to the interrupt objects.
KeAcquireInterruptSpinLock	Acquires the spin lock that synchronizes access with an interrupt's ISR.
KeReleaseInterruptSpinLock	Releases the spin lock that synchronized access with an interrupt's ISR.
KeRegisterNmiCallback	Registers a routine to be called whenever a nonmaskable interrupt (NMI) occurs.
KeDeregisterNmiCallback	Deregisters a routine registered by KeRegisterNmiCallback.

Driver-Managed Queues

FUNCTION	DESCRIPTION
KeInitializeSpinLock	Initializes a variable of type KSPIN_LOCK. An initialized spin lock is a required parameter to the ExInterlockedXxxList routines.
InitializeListHead	Sets up a queue header for a driver's internal queue, given a pointer to driver-supplied storage for the queue header and queue. An initialized queue header is a required parameter to the ExInterlockedInsert/RemoveXxxList routines.
ExInterlockedInsertTailList	Inserts an entry at the tail of a doubly linked list, using a spin lock to ensure multiprocessor-safe access to the list and atomic modification of the list links.
ExInterlockedInsertHeadList	Inserts an entry at the head of a doubly linked list, using a spin lock to ensure multiprocessor-safe access to the list and atomic modification of the links in the list.
ExInterlockedRemoveHeadList	Removes an entry from the head of a doubly linked list, using a spin lock to ensure multiprocessor-safe access to the list and atomic modification of the links in the list.
ExInterlockedPopEntryList	Removes an entry from the head of a singly linked list as an atomic operation, using a spin lock to ensure multiprocessor-safe access to the list.
ExInterlockedPushEntryList	Inserts an entry at the head of a singly linked list as an atomic operation, using a spin lock to ensure multiprocessor-safe access to the list.

FUNCTION	DESCRIPTION
IsListEmpty	Returns TRUE if a queue is empty. (This type of doubly linked list is not protected by a spin lock, unless the caller explicitly manages synchronization to queued entries with an initialized spin lock for which the caller supplies the storage.)
InsertTailList	Queues an entry at the end of the list.
InsertHeadList	Queues an entry at the head of the list.
RemoveHeadList	Dequeues an entry at the head of the list.
RemoveTailList	Dequeues an entry at the end of the list.
RemoveEntryList	Returns whether a given entry is in the given list and dequeues the entry if it is.
PushEntryList	Inserts an entry into the queue. (This type of singly linked list is not protected by a spin lock, unless the caller explicitly manages synchronization to queued entries with an initialized spin lock for which the caller supplies the storage.)
PopEntryList	Removes an entry from the queue.
ExInterlockedPopEntrySList	Removes an entry from the head of a sequenced, singly linked list that was set up with ExInitializeSListHead.
ExInterlockedPushEntrySList	Queues an entry at the head of a sequenced, singly linked list that was set up with ExInitializeSListHead.
ExQueryDepthSList	Returns the number of entries currently queued in a sequenced, singly linked list.
ExInitializeNPagedLookasideList	Sets up a lookaside list, protected by a system-supplied spin lock, in nonpaged pool from which the driver can allocate and free blocks of a fixed size.
KeInitializeDeviceQueue	Initializes a device queue object to a not-busy state, setting up an associated spin lock for multiprocessor-safe access to device queue entries.
KeInsertDeviceQueue	Acquires the device queue spin lock and queues an entry to a device driver if the device queue is not empty; otherwise, inserts the entry at the tail of the device queue.
KeInsertByKeyDeviceQueue	Acquires the device queue spin lock and queues an entry to a device driver if the device queue is not empty; otherwise, inserts the entry into the queue according to the given sort-key value.
KeRemoveDeviceQueue	Removes an entry from the head of a given device queue.
KeRemoveByKeyDeviceQueue	Removes an entry, selected according to the specified sort-key value, from the given device queue.

FUNCTION	DESCRIPTION
KeRemoveEntryDeviceQueue	Determines whether a given entry is in the given device queue and, if so, dequeues the entry.

Driver System Processes and Threads

FUNCTION	DESCRIPTION
PsCreateSystemThread	Creates a kernel-mode thread associated with a given process object or with the default system process. Returns a handle for the thread.
PsTerminateSystemThread	Terminates the current thread and satisfies as many waits as possible for the current thread object.
PsGetCurrentThread	Returns a handle for the current thread.
KeGetCurrentThread	Returns a pointer to the opaque thread object that represents the current thread.
KeQueryPriorityThread	Returns the current priority of a given thread.
KeSetBasePriorityThread	Sets up the run-time priority, relative to the system process, for a driver-created thread.
KeSetPriorityThread	Sets up the run-time priority for a driver-created thread with a real-time priority attribute.
KeDelayExecutionThread	Puts the current thread into an alertable or nonalertable wait state for a given interval.
IoQueueWorkItem	Queues an initialized work queue item so the driver-supplied routine will be called when a system worker thread is given control.
ZwSetInformationThread	Sets the priority of a given thread for which the caller has a handle.

FUNCTION	DESCRIPTION
PsGetCurrentProcessId	The PsGetCurrentProcessId routine identifies the current thread's process.
PsGetProcessCreateTimeQuadPart	The PsGetProcessCreateTimeQuadPart routine returns a LONGLONG value that represents the time at which the process was created.
PsGetProcessId	The PsGetProcessId routine returns the process identifier (process ID) that is associated with a specified process.
PsQueryTotalCycleTimeProcess	The PsQueryTotalCycleTimeProcess routine returns the accumulated cycle time for the specified process.

FUNCTION	DESCRIPTION
PCREATE_PROCESS_NOTIFY_ROUTINE	Process-creation callback implemented by a driver to track the system-wide creation and deletion of processes against the driver's internal state.
PsSetCreateProcessNotifyRoutine	The PsSetCreateProcessNotifyRoutine routine adds a driver-supplied callback routine to, or removes it from, a list of routines to be called whenever a process is created or deleted.
PCREATE_PROCESS_NOTIFY_ROUTINE_EX	A callback routine implemented by a driver to notify the caller when a process is created or exits.
PsSetCreateProcessNotifyRoutineEx	The PsSetCreateProcessNotifyRoutineEx routine registers or removes a callback routine that notifies the caller when a process is created or exits.
PsSetCreateProcessNotifyRoutineEx2	The PsSetCreateProcessNotifyRoutineEx2 routine registers or removes a callback routine that notifies the caller when a process is created or deleted.

FUNCTION	DESCRIPTION
PLOAD_IMAGE_NOTIFY_ROUTINE	Called by the operating system to notify the driver when a driver image or a user image (for example, a DLL or EXE) is mapped into virtual memory.
PsSetLoadImageNotifyRoutine	The PsSetLoadImageNotifyRoutine routine registers a driver-supplied callback that is subsequently notified whenever an image is loaded (or mapped into memory).
PsSetLoadImageNotifyRoutineEx	The PsSetLoadImageNotifyRoutineEx routine registers a driver-supplied callback that is subsequently notified whenever an image is loaded (or mapped into memory).
PsTerminateSystemThread	The PsTerminateSystemThread routine terminates the current system thread.

Best practices for implementing process and thread-related callback functions

This set of guidelines applies to these callback routines:

- PCREATE_PROCESS_NOTIFY_ROUTINE
- PCREATE_PROCESS_NOTIFY_ROUTINE_EX
- PCREATE_THREAD_NOTIFY_ROUTINE
- PLOAD_IMAGE_NOTIFY_ROUTINE

Keep notify routines short and simple.

- Do not make calls into a user mode service to validate the process, thread, or image.
- Do not make registry calls.
- Do not make blocking and/or Interprocess Communication (IPC) function calls.
- Do not synchronize with other threads because it can lead to reentrancy deadlocks.
- Use System Worker Threads to queue work especially work involving:
    - Slow API's or API's that call into other process.

- Any blocking behavior which could interrupt threads in core services.

- Be considerate of best practices for kernel mode stack usage. For examples, see How do I keep my driver from running out of kernel-mode stack? and Key Driver Concepts and Tips.

Run-Time Library (RTL) Routines

For information about functions that copy, concatenate, and format strings in a manner that prevents buffer overrun errors, see Safe String Functions, below. Other string manipulation functions include the following:

FUNCTION	DESCRIPTION
RtlInitString	Initializes the specified string in a buffer.
RtlInitAnsiString	Initializes the specified ANSI string in a buffer.
RtlInitUnicodeString	Initializes the specified Unicode string in a buffer.
RtlAnsiStringToUnicodeSize	Returns the size in bytes required to hold a Unicode version of a given buffered ANSI string.
RtlAnsiStringToUnicodeString	Converts a buffered ANSI string to a Unicode string, given a pointer to the source-string buffer and the address of caller-supplied storage for a pointer to the destination buffer. (This routine allocates a destination buffer if the caller does not supply the storage.) You can also use the string manipulation routines provided by a compiler to convert ANSI strings to Unicode.
RtlFreeUnicodeString	Releases a buffer containing a Unicode string, given a pointer to the buffer returned by RtlAnsiStringToUnicodeString.
RtlUnicodeStringToAnsiString	Converts a buffered Unicode string to an ANSI string, given a pointer to the source-string buffer and the address of caller-supplied storage for a pointer to the destination buffer. (This routine allocates a destination buffer if the caller does not supply the storage.)
RtlFreeAnsiString	Releases a buffer containing an ANSI string, given a pointer to the buffer returned by RtlUnicodeStringToAnsiString.
RtlAppendUnicodeStringToString	Concatenates a copy of a buffered Unicode string with a buffered Unicode string, given pointers to both buffers.
RtlAppendUnicodeToString	Concatenates a given input string with a buffered Unicode string, given a pointer to the buffer.
RtlCopyString	Copies the source string to the destination, given pointers to both buffers, or sets the length of the destination string (but not the length of the destination buffer) to zero if the optional pointer to the source-string buffer is NULL.
RtlCopyUnicodeString	Copies the source string to the destination, given pointers to both buffers, or sets the length of the destination string (but not the length of the destination buffer) to zero if the optional pointer to the source-string buffer is NULL.

FUNCTION	DESCRIPTION
RtlEqualString	Returns TRUE if the given ANSI alphabetic strings are equivalent.
RtlEqualUnicodeString	Returns TRUE if the given buffered strings are equivalent.
RtlCompareString	Compares two buffered, single-byte character strings and returns a signed value indicating whether they are equivalent or which is greater.
RtlCompareUnicodeString	Compares two buffered Unicode strings and returns a signed value indicating whether they are equivalent or which is greater.
RtlUpperString	Converts a copy of a buffered string to uppercase and stores the copy in a destination buffer.
RtlUpcaseUnicodeString	Converts a copy of a buffered Unicode string to uppercase and stores the copy in a destination buffer.
RtlIntegerToUnicodeString	Converts an unsigned integer value in the specified base to one or more Unicode characters in a buffer.
RtlUnicodeStringToInteger	RtlUnicodeStringToInteger converts the Unicode string representation of an integer into its integer equivalent.

The following routines are reserved for system use. Do not use them in your driver.

ROUTINE	REPLACEMENT
RtlAssert	Use ASSERT instead.
RtlGetCallersAddress	Use the intrinsic _ReturnAddress instead.
RtlInterlockedAndBits	Use InterlockedAnd instead.
RtlInterlockedAndBitsDiscardReturn	Use InterlockedAnd instead.
RtlInterlockedClearBits	Use InterlockedAnd instead.
RtlInterlockedClearBitsDiscardReturn	Use InterlockedAnd instead.
RtlInterlockedSetBits	Use InterlockedOr instead.
RtlInterlockedSetBitsDiscardReturn	Use InterlockedOr instead.
RtlInterlockedSetClearBits	
RtlInterlockedXorBits	Use InterlockedXor instead
RtlWalkFrameChain	

Safe String Functions for Unicode and ANSI Characters

Use the functions in this section to manipulate Unicode and ANSI strings in kernel-mode drivers.

Each function is available in two versions:

A W-suffixed version that supports two-byte Unicode characters.

An A-suffixed version that supports one-byte ANSI characters.

If you use the safe string functions instead of the string manipulation functions that are provided by C-language run-time libraries, you protect your code from buffer overrun errors that can make code untrustworthy. For more information, see Using Safe String Functions.

FUNCTION	DESCRIPTION
RtlStringCbCatW	The RtlStringCbCatW and RtlStringCbCatA functions concatenate two byte-counted strings.
RtlStringCbCatExW	The RtlStringCbCatExW and RtlStringCbCatExA functions concatenate two byte-counted strings.
RtlStringCbCatNW	The RtlStringCbCatNW and RtlStringCbCatNA functions concatenate two byte-counted strings while limiting the size of the appended string.
RtlStringCbCatNExW	The RtlStringCbCatNExW and RtlStringCbCatNExA functions concatenate two byte-counted strings while limiting the size of the appended string.
RtlStringCbCopyW	The RtlStringCbCopyW and RtlStringCbCopyA functions copy a byte-counted string into a buffer.
RtlStringCbCopyExW	The RtlStringCbCopyExW and RtlStringCbCopyExA functions copy a byte-counted string into a buffer.
RtlStringCbCopyNW	The RtlStringCbCopyNW and RtlStringCbCopyNA functions copy a byte-counted string to a buffer while limiting the size of the copied string.
RtlStringCbCopyNExW	The RtlStringCbCopyNExW and RtlStringCbCopyNExA functions copy a byte-counted string to a buffer while limiting the size of the copied string.
RtlStringCbLengthW	The RtlStringCbLengthW and RtlStringCbLengthA functions determine the length, in bytes, of a supplied string.
RtlStringCbPrintfW	The RtlStringCbPrintfW and RtlStringCbPrintfA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCbPrintfExW	The RtlStringCbPrintfExW and RtlStringCbPrintfExA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCbVPrintfW	The RtlStringCbVPrintfW and RtlStringCbVPrintfA functions create a byte-counted text string, with formatting that is based on supplied formatting information.

FUNCTION	DESCRIPTION
RtlStringCbVPrintfExW	The RtlStringCbVPrintfExW and RtlStringCbVPrintfExA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchCatW	The RtlStringCchCatW and RtlStringCchCatA functions concatenate two character-counted strings.
RtlStringCchCatExW	The RtlStringCchCatExW and RtlStringCchCatExA functions concatenate two character-counted strings.
RtlStringCchCatNW	The RtlStringCchCatNW and RtlStringCchCatNA functions concatenate two character-counted strings while limiting the size of the appended string.
RtlStringCchCatNExW	The RtlStringCchCatNExW and RtlStringCchCatNExA functions concatenate two character-counted strings while limiting the size of the appended string.
RtlStringCchCopyW	The RtlStringCchCopyW and RtlStringCchCopyA functions copy a null-terminated source string into a destination buffer of specified length.
RtlStringCchCopyExW	The RtlStringCchCopyExW and RtlStringCchCopyExA functions copy a character-counted string into a buffer.
RtlStringCchCopyNW	The RtlStringCchCopyNW and RtlStringCchCopyNA functions copy a character-counted string to a buffer while limiting the size of the copied string.
RtlStringCchCopyNExW	The RtlStringCchCopyNExW and RtlStringCchCopyNExA functions copy a character-counted string to a buffer while limiting the size of the copied string.
RtlStringCchLengthW	The RtlStringCchLengthW and RtlStringCchLengthA functions determine the length, in characters, of a supplied string.
RtlStringCchPrintfW	The RtlStringCchPrintfW and RtlStringCchPrintfA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchPrintfExW	The RtlStringCchPrintfExW and RtlStringCchPrintfExA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchVPrintfW	The RtlStringCchVPrintfW and RtlStringCchVPrintfA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchVPrintfExW	The RtlStringCchVPrintfExW and RtlStringCchVPrintfExA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlUnalignedStringCbLength	The RtlUnalignedStringCbLengthW function is a version of the RtlStringCbLength function that accepts an unaligned pointer to a string of Unicode characters.

FUNCTION	DESCRIPTION
RtlUnalignedStringCchLengthW	The RtlUnalignedStringCchLengthW function is a version of the RtlStringCchLength function that accepts an unaligned pointer to a string of Unicode characters.

Safe String Functions for UNICODE_STRING Structures

Use the functions in this section to manipulate strings within UNICODE_STRING structures in kernel-mode drivers.

If you use the safe string functions instead of the string manipulation functions that C-language run-time libraries provide, you protect your code from buffer overrun errors that can make code untrustworthy. For more information about safe string functions, see Using Safe String Functions.

FUNCTION	DESCRIPTION
RtlStringCbCopyUnicodeString	The RtlStringCbCopyUnicodeString function copies the contents of a UNICODE_STRING structure to a specified destination.
RtlStringCbCopyUnicodeStringEx	The RtlStringCbCopyUnicodeStringEx function copies the contents of a UNICODE_STRING structure to a specified destination.
RtlStringCchCopyUnicodeString	The RtlStringCchCopyUnicodeString function copies the contents of a UNICODE_STRING structure to a specified destination.
RtlStringCchCopyUnicodeStringEx	The RtlStringCchCopyUnicodeStringEx function copies the contents of a UNICODE_STRING structure to a specified destination.
RtlUnicodeStringCat	The RtlUnicodeStringCat function concatenates two strings that are contained in UNICODE_STRING structures.
RtlUnicodeStringCatEx	The RtlUnicodeStringCatEx function concatenates two strings that are contained in UNICODE_STRING structures.
RtlUnicodeStringCatString	The RtlUnicodeStringCatString function concatenates two strings when the destination string is contained in a UNICODE_STRING structure.
RtlUnicodeStringCatStringEx	The RtlUnicodeStringCatStringEx function concatenates two strings when the destination string is contained in a UNICODE_STRING structure.
RtlUnicodeStringCbCatN	The RtlUnicodeStringCbCatN function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.
RtlUnicodeStringCbCatNEx	The RtlUnicodeStringCbCatNEx function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.

FUNCTION	DESCRIPTION
RtlUnicodeStringCbCatStringN	The RtlUnicodeStringCbCatStringN function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.
RtlUnicodeStringCbCatStringNEx	The RtlUnicodeStringCbCatStringNEx function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.
RtlUnicodeStringCbCopyN	The RtlUnicodeStringCbCopyN function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.
RtlUnicodeStringCbCopyNEx	The RtlUnicodeStringCbCopyNEx function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.
RtlUnicodeStringCbCopyStringN	The RtlUnicodeStringCbCopyStringN function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.
RtlUnicodeStringCbCopyStringNEx	The RtlUnicodeStringCbCopyStringNEx function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.
RtlUnicodeStringCchCatN	The RtlUnicodeStringCchCatN function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.
RtlUnicodeStringCchCatNEx	The RtlUnicodeStringCchCatNEx function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.
RtlUnicodeStringCchCatStringN	The RtlUnicodeStringCchCatStringN function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.
RtlUnicodeStringCchCatStringNEx	The RtlUnicodeStringCchCatStringNEx function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.
RtlUnicodeStringCchCopyN	The RtlUnicodeStringCchCopyN function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.
RtlUnicodeStringCchCopyNEx	The RtlUnicodeStringCchCopyNEx function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.
RtlUnicodeStringCchCopyStringN	The RtlUnicodeStringCchCopyStringN function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.

FUNCTION	DESCRIPTION
RtlUnicodeStringCchCopyStringNEx	The RtlUnicodeStringCchCopyStringNEx function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.
RtlUnicodeStringCopy	The RtlUnicodeStringCopy function copies a string from one UNICODE_STRING structure to another.
RtlUnicodeStringCopyEx	The RtlUnicodeStringCopyEx function copies a string from one UNICODE_STRING structure to another.
RtlUnicodeStringCopyString	The RtlUnicodeStringCopyString function copies a string into a UNICODE_STRING structure.
RtlUnicodeStringCopyStringEx	The RtlUnicodeStringCopyStringEx function copies a string into a UNICODE_STRING structure.
RtlUnicodeStringInit	The RtlUnicodeStringInit function initializes a UNICODE_STRING structure.
RtlUnicodeStringInitEx	The RtlUnicodeStringInitEx function initializes a UNICODE_STRING structure.
RtlUnicodeStringPrintf	The RtlUnicodeStringPrintf function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.
RtlUnicodeStringPrintfEx	The RtlUnicodeStringPrintfEx function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.
RtlUnicodeStringValidate	The RtlUnicodeStringValidate function validates the contents of a UNICODE_STRING structure.
RtlUnicodeStringValidateEx	The RtlUnicodeStringValidateEx function validates the contents of a UNICODE_STRING structure.
RtlUnicodeStringVPrintf	The RtlUnicodeStringVPrintf function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.
RtlUnicodeStringVPrintfEx	The RtlUnicodeStringVPrintfEx function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.

Safe Integer Library Routines

This section describes the safe integer functions for drivers. These functions are defined as inline functions in the Ntintsafe.h header file in the WDK. The safe integer functions are designed to help drivers to avoid arithmetic overflow errors. These functions are divided into two sets; the first converts integer values from one type to another, and the second performs math functions. For more information about these functions, see Using Safe Integer Functions.

The Intsafe.h header file in the Windows SDK defines a similar set of safe integer functions for use by applications. For more information about this version of the safe integer functions, see Intsafe.h Functions.

Data Conversions

FUNCTION	DESCRIPTION
InterlockedExchange	Sets a variable of type LONG to a given value as an atomic operation; returns the original value of the variable.
RtlConvertLongToLargeInteger	Converts a given LONG value to a LARGE_INTEGER value.
RtlConvertUlongToLargeInteger	Converts a given ULONG value to a LARGE_INTEGER value.
RtlTimeFieldsToTime	Converts information in a TIME_FIELDS structure to system time.
RtlTimeToTimeFields	Converts a system time value into a buffered TIME_FIELDS value.
ExSystemTimeToLocalTime	Adds the time-zone bias for the current locale to GMT system time, converting it to local time.
ExLocalTimeToSystemTime	Subtracts the time-zone bias from the local time, converting it to GMT system time.
RtlAnsiStringToUnicodeString	Converts a buffered ANSI string to a Unicode string, given a pointer to the source-string buffer and the address of caller-supplied storage for a pointer to the destination buffer. (This routine allocates a destination buffer if the caller does not supply the storage.)
RtlUnicodeStringToAnsiString	Converts a buffered Unicode string to an ANSI string, given a pointer to the source-string buffer and the address of caller-supplied storage for a pointer to the destination buffer. (This routine allocates a destination buffer if the caller does not supply the storage.)
RtlUpperString	Converts a copy of a buffered string to uppercase and stores the copy in a destination buffer.
RtlUpcaseUnicodeString	Converts a copy of a buffered Unicode string to uppercase and stores the copy in a destination buffer.
RtlCharToInteger	Converts a single-byte character value into an integer in the specified base.
RtlIntegerToUnicodeString	Converts an unsigned integer value in the specified base to one or more Unicode characters in the given buffer.
RtlUnicodeStringToInteger	Converts a Unicode string representation of an integer into its integer equivalent.

Access to Driver-Managed Objects

FUNCTION	DESCRIPTION
ExCreateCallback	Creates or opens a callback object.
ExNotifyCallback	Calls the callback routines registered with a previously created or opened callback object.
ExRegisterCallback	Registers a callback routine with a previously created or opened callback object, so that the caller can be notified when conditions defined for the callback routine occur.
ExUnregisterCallback	Cancels the registration of a callback routine with a callback object.
IoRegisterDeviceInterface	Registers device functionality (a device interface) that a driver can enable for use by applications or other system components.
IoSetDeviceInterfaceState	Enables or disables a previously registered device interface. Applications and other system components can open only interfaces that are enabled.
IoGetDeviceInterfaceAlias	Returns the alias device interface of the specified interface class, if the alias exists. Device interfaces are considered aliases if they are exposed by the same underlying device and have identical interface reference strings, but are of different interface classes.
IoGetDeviceInterfaces	Returns a list of device interfaces of a particular device interface class (such as all devices on the system that support a HID interface).
IoGetFileObjectGenericMapping	Returns information about the mapping between generic access rights and specific access rights for file objects.
IoSetShareAccess	Sets the access allowed to a given file object representing a device. (Only highest-level drivers can call this routine.)
IoCheckShareAccess	Checks whether a request to open a file object specifies a desired access that is compatible with the current shared access permissions for the open file object. (Only highest-level drivers can call this routine.)
IoUpdateShareAccess	Modifies the current shared access permissions on the given file object. (Only highest-level drivers can call this routine.)
IoRemoveShareAccess	Restores the shared access permissions on the given file object that were modified by a preceding call to IoUpdateShareAccess.
RtlLengthSecurityDescriptor	Returns the size in bytes of a given security descriptor.
RtlValidSecurityDescriptor	Returns whether a given security descriptor is valid.
RtlCreateSecurityDescriptor	Initializes a new security descriptor to an absolute format with default values (in effect, with no security constraints).

FUNCTION	DESCRIPTION
RtlSetDaclSecurityDescriptor	Sets the discretionary ACL information for a given security descriptor in absolute format.
SeAssignSecurity	Builds a security descriptor for a new object, given the security descriptor of its parent directory (if any) and an originally requested security for the object.
SeDeassignSecurity	Deallocates the memory associated with a security descriptor that was created with SeAssignSecurity.
SeValidSecurityDescriptor	Returns whether a given security descriptor is structurally valid.
SeAccessCheck	Returns a Boolean value indicating whether the requested access rights can be granted to an object protected by a security descriptor and, possibly, a current owner.
SeSinglePrivilegeCheck	Returns a Boolean value indicating whether the current thread has at least the given privilege level.

Error Handling

FUNCTION	DESCRIPTION
IoAllocateErrorLogEntry	Allocates and initializes an error log packet; returns a pointer so the caller can supply error log data and call IoWriteErrorLogEntry with the packet.
IoFreeErrorLogEntry	Frees an error log entry allocated by IoAllocateErrorLogEntry.
IoWriteErrorLogEntry	Queues a previously allocated error log packet, filled in by the driver, to the system error logging thread.
IoIsErrorUserInduced	Returns a Boolean value indicating whether an I/O request failed due to one of the following (user-correctable) conditions: STATUS_IO_TIMEOUT, STATUS_DEVICE_NOT_READY, STATUS_UNRECOGNIZED_MEDIA, STATUS_VERIFY_REQUIRED, STATUS_WRONG_VOLUME, STATUS_MEDIA_WRITE_PROTECTED, or STATUS_NO_MEDIA_IN_DEVICE. If the result is TRUE, a removable-media driver must call IoSetHardErrorOrVerifyDevice before completing the IRP.
IoSetHardErrorOrVerifyDevice	Supplies the device object for which the given IRP was failed due to a user-induced error, such as supplying the incorrect media for the requested operation or changing the media before the requested operation was completed. (A file system driver uses the associated device object to send a dialog box to the user; the user can then correct the error or retry the operation.)
IoSetThreadHardErrorMode	Enables or disables error reporting for the current thread using IoRaiseHardError or IoRaiseInformationalHardError.

FUNCTION	DESCRIPTION
IoRaiseHardError	Causes a dialog box to be sent to the user indicating that the given IRP was failed on the given device object for an optional VPB, so that the user can correct the error or retry the operation.
IoRaiseInformationalHardError	Causes a dialog box to be sent to the user, showing an I/O error status and optional string supplying more information.
ExRaiseStatus	Raises an error status so that a caller-supplied structured exception handler is called. (This routine is useful only to highest-level drivers that supply exception handlers, in particular to file systems.)
KeBugCheckEx	Brings down the system in a controlled manner, displaying the bug-check code and possibly more information, after the caller discovers an unrecoverable inconsistency that will corrupt the system unless it is brought down. After the system is brought down, this routine displays bug-check and possibly other information. (This routine can be called when debugging under-development drivers. Otherwise, drivers should never call this routine when they can handle an error by failing an IRP and by calling IoAllocateErrorLogEntry and IoWriteErrorLogEntry.)
KeBugCheck	Brings down the system in a controlled manner when the caller discovers an unrecoverable inconsistency that will corrupt the system if the caller continues to run. KeBugCheckEx is preferable.
KeInitializeCallbackRecord	Initializes a bug-check callback record before a device driver calls KeRegisterBugCheckCallback.
KeRegisterBugCheckCallback	Registers the device driver's bug-check callback routine, which is called if a system bug check occurs. Such a driver-supplied routine saves driver-determined state information, such as the contents of device registers, that would not otherwise be written into the system crash-dump file.
KeDeregisterBugCheckCallback	Removes a device driver's callback routine from the set of registered bug-check callback routines.

IOCTLs

TITLE	DESCRIPTION
IOCTL_SYSENV_ENUM_VARIABLES	Returns information about system environment variables using SysEnv device.
IOCTL_SYSENV_GET_VARIABLE	Gets the value of the specified system environment variables using SysEnv device.
IOCTL_SYSENV_QUERY_VARIABLE_INFO	Returns information about system environment variables using SysEnv device.

TITLE	DESCRIPTION
IOCTL_SYSENV_SET_VARIABLE	Sets the value of the specified system environment variables using SysEnv device.

Enumerations

TITLE	DESCRIPTION
BDCB_CALLBACK_TYPE	The BDCB_CALLBACK_TYPE enumeration specifies whether the callback being passed to a BOOT_DRIVER_CALLBACK_FUNCTION routine is a status update or a boot-start driver initialization notification.
BDCB_CLASSIFICATION	The BDCB_CLASSIFICATION enumeration lists different classifications of boot start images.
BDCB_STATUS_UPDATE_TYPE	The BDCB_STATUS_UPDATE_TYPE enumeration lists the types of boot-driver callback status updates.
BOUND_CALLBACK_STATUS	The BOUND_CALLBACK_STATUS enumeration indicates how a user-mode bounds exception was processed by the BoundCallback function.
BUS_DATA_TYPE	The BUS_DATA_TYPE enumeration indicates the type of bus configuration space.
BUS_DATA_TYPE	The BUS_DATA_TYPE enumeration indicates the type of bus configuration space.
CLFS_CONTEXT_MODE	The CLFS_CONTEXT_MODE enumeration indicates the type of sequence that the Common Log File System (CLFS) driver follows when it reads a set of records from a stream.
CLFS_MGMT_POLICY_TYPE	The CLFS_MGMT_POLICY_TYPE enumeration type identifies the type of a CLFS management policy.
CLS_LOG_INFORMATION_CLASS	The CLFS_LOG_INFORMATION_CLASS enumeration indicates the type of information that is requested by a call to ClfsQueryLogFileInformation.
D3COLD_LAST_TRANSITION_STATUS	The D3COLD_LAST_TRANSITION_STATUS enumeration indicates whether the most recent transition to the D3hot device power state was followed by a transition to the D3cold device power state.
DEVICE_INSTALL_STATE	The DEVICE_INSTALL_STATE enumeration describes a device's installation state.
DEVICE_POWER_STATE	The DEVICE_POWER_STATE enumeration type indicates a device power state.
DEVICE_POWER_STATE	The DEVICE_POWER_STATE enumeration type indicates a device power state.

TITLE	DESCRIPTION
DEVICE_REGISTRY_PROPERTY	The DEVICE_REGISTRY_PROPERTY enumeration identifies device properties that are stored in the registry.
DEVICE_REGISTRY_PROPERTY	The DEVICE_REGISTRY_PROPERTY enumeration identifies device properties that are stored in the registry.
DEVICE_REMOVAL_POLICY	The DEVICE_REMOVAL_POLICY enumeration describes a device's removal policy.
DEVICE_RESET_TYPE	The DEVICE_RESET_TYPE enumeration specifies the type of device reset that is being requested by a call to the DeviceReset routine of the GUID_DEVICE_RESET_INTERFACE_STANDARD interface.
DEVICE_WAKE_DEPTH	The DEVICE_WAKE_DEPTH enumeration specifies the deepest device power state from which a device can trigger a wake signal.
DMA_COMPLETION_STATUS	The DMA_COMPLETION_STATUS enumeration describes the completion status of a DMA transfer.
ENLISTMENT_INFORMATION_CLASS	The ENLISTMENT_INFORMATION_CLASS enumeration identifies the type of information that the ZwSetInformationEnlistment routine can set and that the ZwQueryInformationEnlistment routine can retrieve for an enlistment object.
GPIO_PIN_CONFIG_TYPE	The GPIO_PIN_CONFIG_TYPE enumeration describes a connection IO resource.
GPIO_PIN_CONFIG_TYPE	The GPIO_PIN_CONFIG_TYPE enumeration describes a connection IO resource.
GPIO_PIN_IORESTRICTION_TYPE	The GPIO_PIN_IORESTRICTION_TYPE enumeration describes the functions that a GPIO pin is limited to performing.
GPIO_PIN_IORESTRICTION_TYPE	The GPIO_PIN_IORESTRICTION_TYPE enumeration describes the functions that a GPIO pin is limited to performing.
HARDWARE_COUNTER_TYPE	The HARDWARE_COUNTER_TYPE enumeration specifies the type of a hardware counter.
IMAGE_POLICY_ENTRY_TYPE	This enumeration is not supported.
IMAGE_POLICY_ID	This enumeration is not supported.
INTERFACE_TYPE	The INTERFACE_TYPE enumeration indicates the bus type.
INTERFACE_TYPE	The INTERFACE_TYPE enumeration indicates the bus type.
INTERFACE_TYPE	The INTERFACE_TYPE enumeration indicates the bus type.
IO_ACCESS_MODE	Defines the types of access mode for Scheduled File I/O (SFIO).

TITLE	DESCRIPTION
IO_ACCESS_MODE	Defines the types of access mode for Scheduled File I/O (SFIO).
IO_ACCESS_TYPE	Defines the access rights for Scheduled File I/O (SFIO).
IO_ACCESS_TYPE	Defines the access rights for Scheduled File I/O (SFIO).
IO_ALLOCATION_ACTION	The IO_ALLOCATION_ACTION enumerated type is used to specify return values for AdapterControl and ControllerControl routines.
IO_CONTAINER_INFORMATION_CLASS	The IO_CONTAINER_INFORMATION_CLASS enumeration contains constants that indicate the classes of system information that a kernel-mode driver can request.
IO_CONTAINER_NOTIFICATION_CLASS	The IO_CONTAINER_NOTIFICATION_CLASS enumeration contains constants that indicate the classes of events for which a kernel-mode driver can register to receive notifications.
IO_PAGING_PRIORITY	The IO_PAGING_PRIORITY enumeration describes the priority value for a paging I/O IRP.
IO_PRIORITY_HINT	The IO_PRIORITY_HINT enumeration type specifies the priority hint for an IRP.
IO_SESSION_EVENT	The IO_SESSION_EVENT enumeration indicates the type of session event for which a driver is receiving notification.
IO_SESSION_STATE	The IO_SESSION_STATE enumeration contains constants that indicate the current state of a user session.
IRQ_DEVICE_POLICY	The IRQ_DEVICE_POLICY enumeration type indicates the policy the operating system can use to assign the interrupts from a device to different processors.
IRQ_DEVICE_POLICY	The IRQ_DEVICE_POLICY enumeration type indicates the policy the operating system can use to assign the interrupts from a device to different processors.
IRQ_PRIORITY	The IRQ_PRIORITY enumeration type indicates the priority the system should give to servicing a device's interrupts.
IRQ_PRIORITY	The IRQ_PRIORITY enumeration type indicates the priority the system should give to servicing a device's interrupts.
KBUGCHECK_CALLBACK_REASON	The KBUGCHECK_CALLBACK_REASON enumeration type specifies the situations in which a bug-check callback executes.
KBUGCHECK_DUMP_IO_TYPE	The KBUGCHECK_DUMP_IO_TYPE enumeration type identifies the type of a section of data within a crash dump file.
KEY_INFORMATION_CLASS	The KEY_INFORMATION_CLASS enumeration type represents the type of information to supply about a registry key.

TITLE	DESCRIPTION
KEY_SET_INFORMATION_CLASS	The KEY_SET_INFORMATION_CLASS enumeration type represents the type of information to set for a registry key.
KEY_VALUE_INFORMATION_CLASS	The KEY_VALUE_INFORMATION_CLASS enumeration type specifies the type of information to supply about the value of a registry key.
KINTERRUPT_MODE	The KINTERRUPT_MODE enumeration type indicates whether an interrupt is level-triggered or edge-triggered.
KINTERRUPT_MODE	The KINTERRUPT_MODE enumeration type indicates whether an interrupt is level-triggered or edge-triggered.
KINTERRUPT_MODE	The KINTERRUPT_MODE enumeration type indicates whether an interrupt is level-triggered or edge-triggered.
KINTERRUPT_POLARITY	The KINTERRUPT_POLARITY enumeration indicates how a device signals an interrupt request on an interrupt line.
KINTERRUPT_POLARITY	The KINTERRUPT_POLARITY enumeration indicates how a device signals an interrupt request on an interrupt line.
KTMOBJECT_TYPE	The KTMOBJECT_TYPE enumeration identifies the types of objects that KTM supports.
MEMORY_CACHING_TYPE	The MEMORY_CACHING_TYPE enumeration type specifies the permitted caching behavior when allocating or mapping memory.
MEMORY_CACHING_TYPE	The MEMORY_CACHING_TYPE enumeration type specifies the permitted caching behavior when allocating or mapping memory.
MEMORY_CACHING_TYPE	The MEMORY_CACHING_TYPE enumeration type specifies the permitted caching behavior when allocating or mapping memory.
MEMORY_INFORMATION_CLASS	Defines classes of memory information that can be retrieved by using the ZwQueryVirtualMemory function.
MONITOR_DISPLAY_STATE	Indicates the power state of the monitor being displayed on.
MONITOR_DISPLAY_STATE	Indicates the power state of the monitor being displayed on.
PEP_ACPI_OBJECT_TYPE	The PEP_ACPI_OBJECT_TYPE enumeration indicates the type of ACPI object.
PEP_ACPI_OBJECT_TYPE	The PEP_ACPI_OBJECT_TYPE enumeration indicates the type of ACPI object.
PEP_ACPI_RESOURCE_TYPE	The PEP_ACPI_RESOURCE_TYPE enumeration is used to identify the type of ACPI resource that is contained in the PEP_ACPI_RESOURCE union.

TITLE	DESCRIPTION
PEP_ACPI_RESOURCE_TYPE	The PEP_ACPI_RESOURCE_TYPE enumeration is used to identify the type of ACPI resource that is contained in the PEP_ACPI_RESOURCE union.
PEP_DEVICE_ACCEPTANCE_TYPE	The PEP_DEVICE_ACCEPTANCE_TYPE enumeration indicates whether a PEP accepts ownership of a device.
PEP_DEVICE_ACCEPTANCE_TYPE	The PEP_DEVICE_ACCEPTANCE_TYPE enumeration indicates whether a PEP accepts ownership of a device.
PEP_PERF_STATE_TYPE	The PEP_PERF_STATE_TYPE enumeration indicates the type of performance information that is specified for a performance state (P-state) of a component.
PEP_PERF_STATE_TYPE	The PEP_PERF_STATE_TYPE enumeration indicates the type of performance information that is specified for a performance state (P-state) of a component.
PEP_PERF_STATE_UNIT	The PEP_PERF_STATE_UNIT enumeration indicates the measurement units in which the performance state (P-state) of a component is specified.
PEP_PERF_STATE_UNIT	The PEP_PERF_STATE_UNIT enumeration indicates the measurement units in which the performance state (P-state) of a component is specified.
PEP_PROCESSOR_IDLE_CANCEL_CODE	The PEP_PROCESSOR_IDLE_CANCEL_CODE enumeration values indicate reasons why a processor cannot enter an idle state that was previously selected by the platform extension plug-in (PEP).
PEP_PROCESSOR_IDLE_TYPE	The PEP_PROCESSOR_IDLE_TYPE enumeration indicates whether idle constraints apply to just the current processor or to all processors in the hardware platform.
PEP_WORK_TYPE	The PEP_WORK_TYPE enumeration describes the type of work that the platform extension plug-in (PEP) is requesting.
PEP_WORK_TYPE	The PEP_WORK_TYPE enumeration describes the type of work that the platform extension plug-in (PEP) is requesting.
PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR_TYPE	The PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR_TYPE enumeration contains constants that indicate the type of hardware performance counter resource that is described by a PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR structure.
PO_FX_PERF_STATE_TYPE	The PO_FX_PERF_STATE_TYPE enumeration contains values that describe the type of performance states in a PO_FX_COMPONENT_PERF_SET.
PO_FX_PERF_STATE_TYPE	The PO_FX_PERF_STATE_TYPE enumeration contains values that describe the type of performance states in a PO_FX_COMPONENT_PERF_SET.

TITLE	DESCRIPTION
PO_FX_PERF_STATE_UNIT	The PO_FX_PERF_STATE_UNIT enumeration contains values that describe the type of unit that is controlled by the performance states in a PO_FX_COMPONENT_PERF_SET.
PO_FX_PERF_STATE_UNIT	The PO_FX_PERF_STATE_UNIT enumeration contains values that describe the type of unit that is controlled by the performance states in a PO_FX_COMPONENT_PERF_SET.
POOL_TYPE	The POOL_TYPE enumeration type specifies the type of system memory to allocate.
POOL_TYPE	The POOL_TYPE enumeration type specifies the type of system memory to allocate.
POWER_ACTION	The POWER_ACTION enumeration identifies the system power actions that can occur on a computer.
POWER_INFORMATION_LEVEL	Indicates power level information.
POWER_INFORMATION_LEVEL	Indicates power level information.
POWER_MONITOR_REQUEST_REASON	Defines values for power transitions reasons for a monitor.
POWER_REQUEST_TYPE	The POWER_REQUEST_TYPE enumeration indicates the power request type.
POWER_REQUEST_TYPE	The POWER_REQUEST_TYPE enumeration indicates the power request type.
POWER_STATE_TYPE	The POWER_STATE_TYPE enumeration type indicates that a power state value is a system power state or a device power state.
POWER_STATE_TYPE	The POWER_STATE_TYPE enumeration type indicates that a power state value is a system power state or a device power state.
PSCREATEPROCESSNOTIFYTYPE	Indicates the type of process notification. This enumeration is used in PsSetCreateProcessNotifyRoutineEx2 to register callback notifications.
PSCREATETHREADNOTIFYTYPE	Indicates the type of thread notification. This enumeration is used in PsSetCreateThreadNotifyRoutineEx to register callback notifications associated with thread creation or deletion.
REG_NOTIFY_CLASS	The REG_NOTIFY_CLASS enumeration type specifies the type of registry operation that the configuration manager is passing to a RegistryCallback routine.
RESOURCEMANAGER_INFORMATION_CLASS	The RESOURCEMANAGER_INFORMATION_CLASS enumeration identifies the type of information that the ZwQueryInformationResourceManager routine can retrieve for a resource manager object.

TITLE	DESCRIPTION
SUBSYSTEM_INFORMATION_TYPE	Indicates the type of subsystem for a process or thread. This enumeration is used in NtQueryInformationProcess and NtQueryInformationThread calls.
SYSTEM_POWER_STATE	The SYSTEM_POWER_STATE enumeration type is used to indicate a system power state.
SYSTEM_POWER_STATE	The SYSTEM_POWER_STATE enumeration type is used to indicate a system power state.
TRACE_INFORMATION_CLASS	The TRACE_INFORMATION_CLASS enumeration type is used to indicate types of information associated with a WMI event tracing session.
TRANSACTION_INFORMATION_CLASS	The TRANSACTION_INFORMATION_CLASS enumeration specifies the type of information that ZwSetInformationTransaction can set and ZwQueryInformationTransaction can retrieve for a transaction manager object.
TRANSACTION_OUTCOME	The TRANSACTION_OUTCOME enumeration defines the outcomes (results) that KTM can assign to a transaction.
TRANSACTION_STATE	The TRANSACTION_STATE enumeration defines the states that KTM can assign to a transaction.
TRANSACTIONMANAGER_INFORMATION_CLASS	The TRANSACTIONMANAGER_INFORMATION_CLASS enumeration specifies the type of information that the ZwQueryInformationTransactionManager routine can retrieve for a transaction manager object.
WORK_QUEUE_TYPE	The WORK_QUEUE_TYPE enumeration type indicates the type of system worker thread that handles a work item.

Functions

TITLE	DESCRIPTION
ALLOCATE_FUNCTION_EX	The LookasideListAllocateEx routine allocates the storage for a new lookaside-list entry when a client requests an entry from a lookaside list that is empty.
AppendTailList	The AppendTailList routine appends a doubly linked list of LIST_ENTRY structures to the tail of another doubly linked list of LIST_ENTRY structures.
AppendTailList	The AppendTailList routine appends a doubly linked list of LIST_ENTRY structures to the tail of another doubly linked list of LIST_ENTRY structures.
ARGUMENT_PRESENT	The ARGUMENT_PRESENT macro takes an argument pointer and returns FALSE if the pointer is NULL. Otherwise, it returns TRUE.

TITLE	DESCRIPTION
AuxKlibEnumerateSystemFirmwareTables	The AuxKlibEnumerateSystemFirmwareTables routine enumerates all system firmware tables of the specified type.
AuxKlibGetBugCheckData	The AuxKlibGetBugCheckData routine retrieves information about a bug check that has just occurred.
AuxKlibGetImageExportDirectory	The AuxKlibGetImageExportDirectory routine returns an image module's export directory.
AuxKlibGetSystemFirmwareTable	The AuxKlibGetSystemFirmwareTable routine retrieves the specified firmware table from the firmware table provider.
AuxKlibInitialize	The AuxKlibInitialize routine initializes the Auxiliary Kernel-Mode Library.
AuxKlibQueryModuleInformation	The AuxKlibQueryModuleInformation routine retrieves information about the image modules that the operating system has loaded.
BOUND_CALLBACK	The BoundCallback routine is executed whenever the system issues a bounds exception for a user-mode thread.
ClfsAddLogContainer	The ClfsAddLogContainer routine adds a container to a CLFS log.
ClfsAddLogContainerSet	The ClfsAddLogContainerSet routine atomically adds a set of containers to a CLFS log.
ClfsAdvanceLogBase	The ClfsAdvanceLogBase routine sets the base LSN of a CLFS stream.
ClfsAlignReservedLog	The ClfsAlignReservedLog routine calculates the size of the space that must be reserved for a specified set of records. The size calculation includes the space required for headers and the space required for sector alignment.
ClfsAllocReservedLog	The ClfsAllocReservedLog routine reserves space in a marshalling area for a set of records.
ClfsCloseAndResetLogFile	The ClfsCloseAndResetLogFile routine releases all references to a specified log file object and marks its associated stream for reset.
ClfsCloseLogFileObject	The ClfsCloseLogFileObject routine releases all references to a log file object.
ClfsCreateLogFile	The ClfsCreateLogFile routine creates or opens a CLFS stream. If necessary, ClfsCreateLogFile also creates the underlying physical log that holds the stream's records.
ClfsCreateMarshallingArea	The ClfsCreateMarshallingArea routine creates a marshalling area for a CLFS stream and returns a pointer to an opaque context that represents the new marshalling area.

TITLE	DESCRIPTION
ClfsCreateScanContext	The ClfsCreateScanContext routine creates a scan context that can be used to iterate over the containers of a specified CLFS log.
ClfsDeleteLogByPointer	The ClfsDeleteLogByPointer routine marks a CLFS stream for deletion.
ClfsDeleteLogFile	The ClfsDeleteLogFile routine marks a CLFS stream for deletion.
ClfsDeleteMarshallingArea	The ClfsDeleteMarshallingArea routine deletes a marshalling area.
ClfsFlushBuffers	The ClfsFlushBuffers routine forces all log I/O blocks in a specified marshalling area to stable storage.
ClfsFlushToLsn	The ClfsFlushToLsn routine forces, to stable storage, all records that have an LSN less than or equal to a specified LSN.
ClfsGetContainerName	The ClfsGetContainerName routine returns the path name of a specified container.
ClfsGetIoStatistics	The ClfsGetIoStatistics routine returns I/O statistics for a specified CLFS log.
ClfsLsnBlockOffset	The ClfsLsnBlockOffset routine returns the sector-aligned block offset contained in a specified LSN.
ClfsLsnContainer	The ClfsLsnContainer routine returns the logical container identifier contained in a specified LSN.
ClfsLsnCreate	The ClfsLsnCreate routine creates a log sequence number (LSN), given a container identifier, a block offset, and a record sequence number.
ClfsLsnEqual	The ClfsLsnEqual routine determines whether two LSNs from the same stream are equal.
ClfsLsnGreater	The ClfsLsnGreater routine determines whether one LSN is greater than another LSN. The two LSNs must be from the same stream.
ClfsLsnLess	The ClfsLsnLess routine determines whether one LSN is less than another LSN. The two LSNs must be from the same stream.
ClfsLsnNull	The ClfsLsnNull routine determines whether a specified LSN is equal to the smallest possible LSN, CLFS_LSN_NULL.
ClfsLsnRecordSequence	The ClfsLsnRecordSequence routine returns the record sequence number contained in a specified LSN.

TITLE	DESCRIPTION
ClfsMgmtDeregisterManagedClient	The ClfsMgmtDeregisterManagedClient routine removes the connection between a client and a log, so that the client no longer manages the log.
ClfsMgmtHandleLogFileFull	The ClfsMgmtHandleLogFileFull routine attempts to make more space available in a log. It might make more space available by adding containers to the log, or it might ask clients to move their log tails.
ClfsMgmtInstallPolicy	The ClfsMgmtInstallPolicy routine adds a CLFS_MGMT_POLICY structure to a physical log.
ClfsMgmtQueryPolicy	The ClfsMgmtQueryPolicy routine retrieves a specific CLFS_MGMT_POLICY structure for a log.
ClfsMgmtRegisterManagedClient	The ClfsMgmtRegisterManagedClient routine creates a client that will manage a CLFS log.
ClfsMgmtRemovePolicy	The ClfsMgmtRemovePolicy routine resets a log's CLFS_MGMT_POLICY structure to its default value.
ClfsMgmtSetLogFileSize	The ClfsMgmtSetLogFileSize routine adds containers to a log or deletes containers from a log.
ClfsMgmtSetLogFileSizeAsClient	The ClfsMgmtSetLogFileSizeAsClient routine sets the log file size by adding containers to a client log or deleting containers from a client log.
ClfsMgmtTailAdvanceFailure	The ClfsMgmtTailAdvanceFailure routine notifies CLFS management that the client could not advance the log's tail.
ClfsQueryLogFileInformation	The ClfsQueryLogFileInformation routine returns metadata and state information for a specified CLFS stream or its underlying physical log or both.
ClfsReadLogRecord	The ClfsReadLogRecord routine reads a target record in a CLFS stream and returns a read context that the caller can use to read the records preceding or following it in the stream.
ClfsReadNextLogRecord	The ClfsReadNextLogRecord routine reads the next record in a sequence, relative to the current record in a read context.
ClfsReadPreviousRestartArea	The ClfsReadPreviousRestartArea routine reads the previous restart record relative to the current record in a read context.
ClfsReadRestartArea	The ClfsReadRestartArea routine reads the restart record that was most recently written to a specified CLFS stream.
ClfsRemoveLogContainer	The ClfsRemoveLogContainer routine removes a container from a CLFS log.
ClfsRemoveLogContainerSet	The ClfsRemoveLogContainerSet routine atomically removes a set of containers from a CLFS log.

TITLE	DESCRIPTION
ClfsReserveAndAppendLog	The ClfsReserveAndAppendLog routine reserves space in a marshalling area or appends a record to a marshalling area or does both atomically.
ClfsReserveAndAppendLogAligned	The ClfsReserveAndAppendLogAligned routine reserves space in a marshalling area or appends a record to a marshalling area or does both atomically. The record's data is aligned on specified boundaries.
ClfsScanLogContainers	The ClfsScanLogContainers routine retrieves descriptive information for a sequence of containers that belong to a particular CLFS log.
ClfsSetArchiveTail	The ClfsSetArchiveTail routine sets the archive tail of a CLFS log to a specified LSN.
ClfsSetEndOfLog	The ClfsSetEndOfLog routine truncates a CLFS stream.
ClfsSetLogFileInformation	The ClfsSetLogFileInformation routine sets metadata and state information for a specified stream and its underlying physical log.
ClfsTerminateReadLog	The ClfsTerminateReadLog routine invalidates a specified read context after freeing resources associated with the context.
ClfsWriteRestartArea	The ClfsWriteRestartArea routine atomically appends a new restart record to a CLFS stream, flushes the restart record to stable storage, and optionally updates the base LSN of the stream.
CmCallbackGetKeyObjectID	The CmCallbackGetKeyObjectID routine retrieves the unique identifier and object name that are associated with a specified registry key object.
CmCallbackGetKeyObjectIDEx	The CmCallbackGetKeyObjectIDEx routine retrieves the unique identifier and object name that are associated with a specified registry key object.
CmCallbackReleaseKeyObjectIDEx	The CmCallbackReleaseKeyObjectIDEx routine frees an object name string obtained from the CmCallbackGetKeyObjectIDEx routine.
CmGetBoundTransaction	The CmGetBoundTransaction routine returns a pointer to the transaction object that represents the transaction, if any, that is associated with a specified registry key object.
CmGetCallbackVersion	The CmGetCallbackVersion routine retrieves the major and minor version numbers for the current version of the configuration manager's registry callback feature.
CmRegisterCallback	The CmRegisterCallback routine is obsolete for Windows Vista and later operating system versions. Use CmRegisterCallbackEx instead.The CmRegisterCallback routine registers a RegistryCallback routine.

TITLE	DESCRIPTION
CmRegisterCallbackEx	The CmRegisterCallbackEx routine registers a RegistryCallback routine.
CmSetCallbackObjectContext	The CmSetCallbackObjectContext routine associates specified context information with a specified registry object.
CmUnRegisterCallback	The CmUnRegisterCallback routine unregisters a RegistryCallback routine that a CmRegisterCallback or CmRegisterCallbackEx routine previously registered.
DMA_COMPLETION_ROUTINE	The DmaCompletionRoutine callback routine notifies the driver that previously requested a system DMA transfer that this transfer is complete.
DRIVER_ADD_DEVICE	The AddDevice routine is responsible for creating functional device objects (FDO) or filter device objects (filter DO) for devices enumerated by the Plug and Play (PnP) manager.
DRIVER_CANCEL	The Cancel routine cancels an I/O operation.
DRIVER_CONTROL	This routine starts a DMA data-transfer or a data transfer operation.
DRIVER_DISPATCH	The callback routine services various IRPs. For a list of function codes, see Remarks.
DRIVER_INITIALIZE	DriverEntry is the first routine called after a driver is loaded, and is responsible for initializing the driver.
DRIVER_INITIALIZE	DriverEntry is the first routine called after a driver is loaded, and is responsible for initializing the driver.
DRIVER_LIST_CONTROL	The AdapterListControl routine starts a direct memory access (DMA) scatter/gather operation.
DRIVER_REINITIALIZE	The Reinitialize routine continues driver and device initialization after the driver's DriverEntry routine returns.
DRIVER_STARTIO	The StartIo routine starts the I/O operation described by an IRP.
DRIVER_UNLOAD	The Unload routine performs any operations that are necessary before the system unloads the driver.
EX_CALLBACK_FUNCTION	A filter driver's RegistryCallback routine can monitor, block, or modify a registry operation.
ExAcquireResourceExclusiveLite	The ExAcquireResourceExclusiveLite routine acquires the given resource for exclusive access by the calling thread.
ExAcquireResourceSharedLite	The ExAcquireResourceSharedLite routine acquires the given resource for shared access by the calling thread.

TITLE	DESCRIPTION
ExAcquireRundownProtection	The ExAcquireRundownProtection routine tries to acquire run-down protection on a shared object so the caller can safely access the object.
ExAcquireRundownProtectionEx	The ExAcquireRundownProtectionEx routine tries to acquire run-down protection on a shared object so the caller can safely access the object.
ExAcquireSharedStarveExclusive	The ExAcquireSharedStarveExclusive routine acquires a given resource for shared access without waiting for any pending attempts to acquire exclusive access to the same resource.
ExAcquireSharedWaitForExclusive	The ExAcquireSharedWaitForExclusive routine acquires the given resource for shared access if shared access can be granted and there are no exclusive waiters.
ExAllocateFromLookasideListEx	The ExAllocateFromLookasideListEx routine removes the first entry from the specified lookaside list, or, if the list is empty, dynamically allocates the storage for a new entry.
ExAllocateFromNPagedLookasideList	The ExAllocateFromNPagedLookasideList routine returns a pointer to a nonpaged entry from the given lookaside list, or it returns a pointer to a newly allocated nonpaged entry.
ExAllocateFromPagedLookasideList	The ExAllocateFromPagedLookasideList routine returns a pointer to a paged entry from the given lookaside list, or it returns a pointer to a newly allocated paged entry.
ExAllocatePool	The ExAllocatePool routine is obsolete, and is exported only for existing binaries. Use ExAllocatePoolWithTag instead.ExAllocatePool allocates pool memory of the specified type and returns a pointer to the allocated block.
ExAllocatePoolWithQuota	The ExAllocatePoolWithQuota routine is obsolete, and is exported only for existing driver binaries. Use ExAllocatePoolWithQuotaTag instead.ExAllocatePoolWithQuota allocates pool memory, charging quota against the current process.
ExAllocatePoolWithQuotaTag	The ExAllocatePoolWithQuotaTag routine allocates pool memory, charging the quota against the current process.
ExAllocatePoolWithTag	The ExAllocatePoolWithTag routine allocates pool memory of the specified type and returns a pointer to the allocated block.
ExAllocatePoolWithTagPriority	The ExAllocatePoolWithTagPriority routine allocates pool memory of the specified type.
ExAllocateTimer	The ExAllocateTimer routine allocates and initializes a timer object.
ExCancelTimer	The ExCancelTimer routine cancels a timer that was set by a previous call to the ExSetTimer routine.

TITLE	DESCRIPTION
ExConvertExclusiveToSharedLite	The ExConvertExclusiveToSharedLite routine converts a given resource from acquired for exclusive access to acquired for shared access.
ExCreateCallback	The ExCreateCallback routine either creates a new callback object or opens an existing callback object on behalf of the caller.
ExDeleteLookasideListEx	The ExDeleteLookasideListEx routine deletes a lookaside list.
ExDeleteNPagedLookasideList	The ExDeleteNPagedLookasideList routine destroys a nonpaged lookaside list.
ExDeletePagedLookasideList	The ExDeletePagedLookasideList routine destroys a paged lookaside list.
ExDeleteResourceLite	The ExDeleteResourceLite routine deletes a given resource from the system's resource list.
ExDeleteTimer	The ExDeleteTimer routine deletes a timer object that was previously allocated by the ExAllocateTimer routine.
ExFlushLookasideListEx	The ExFlushLookasideListEx routine flushes all entries from the specified lookaside list and frees the allocated storage for each entry.
ExFreePool	The ExFreePool routine deallocates a block of pool memory.
ExFreePool	The ExFreePool routine deallocates a block of pool memory.
ExFreePoolWithTag	The ExFreePoolWithTag routine deallocates a block of pool memory allocated with the specified tag.
ExFreeToLookasideListEx	The ExFreeToLookasideListEx routine inserts an entry into a lookaside list, or, if the list is full, frees the allocated storage for the entry.
ExFreeToNPagedLookasideList	The ExFreeToNPagedLookasideList routine returns a nonpaged entry to the given lookaside list or to nonpaged pool.
ExFreeToPagedLookasideList	The ExFreeToPagedLookasideList routine returns a pageable entry to the given lookaside list or to paged pool.
ExGetExclusiveWaiterCount	The ExGetExclusiveWaiterCount routine returns the number of waiters on exclusive access to a given resource.
ExGetFirmwareEnvironmentVariable	The ExGetFirmwareEnvironmentVariable routine gets the value of the specified system firmware environment variable.
ExGetFirmwareType	Returns the system firmware type.
ExGetPreviousMode	The ExGetPreviousMode routine returns the previous processor mode for the current thread.

TITLE	DESCRIPTION
ExGetSharedWaiterCount	The ExGetSharedWaiterCount routine returns the number of waiters on shared access to a given resource.
ExInitializeDeleteTimerParameters	The ExInitializeDeleteTimerParameters routine initializes an EXT_DELETE_PARAMETERS structure.
ExInitializeFastMutex	The ExInitializeFastMutex routine initializes a fast mutex variable, used to synchronize mutually exclusive access by a set of threads to a shared resource.
ExInitializeLookasideListEx	The ExInitializeLookasideListEx routine initializes a lookaside list.
ExInitializeNPagedLookasideList	The ExInitializeNPagedLookasideList routine initializes a lookaside list for nonpaged entries of the specified size.
ExInitializePagedLookasideList	The ExInitializePagedLookasideList routine initializes a lookaside list for pageable entries of the specified size.
ExInitializeResourceLite	The ExInitializeResourceLite routine initializes a resource variable.
ExInitializeRundownProtection	The ExInitializeRundownProtection routine initializes run-down protection on a shared object.
ExInitializeSetTimerParameters	The ExInitializeSetTimerParameters routine initializes an EXT_SET_PARAMETERS structure.
ExInterlockedAddLargeInteger	The ExInterlockedAddLargeInteger routine adds a large integer value to the specified variable as an atomic operation.
ExInterlockedAddLargeStatistic	The ExInterlockedAddLargeStatistic routine performs an interlocked addition of a ULONG increment value to a LARGE_INTEGER variable.
ExInterlockedAddUlong	The ExInterlockedAddUlong routine adds an unsigned long value to a given unsigned integer as an atomic operation.
ExInterlockedCompareExchange64	The ExInterlockedCompareExchange64 routine compares one integer variable to another and, if they are equal, sets the first variable to a caller-supplied value.
ExInterlockedFlushSList	The ExInterlockedFlushSList routine atomically removes all entries from a sequenced singly linked list.
ExInterlockedInsertHeadList	The ExInterlockedInsertHeadList routine atomically inserts an entry at the beginning of a doubly linked list of LIST_ENTRY structures.
ExInterlockedInsertTailList	The ExInterlockedInsertTailList routine atomically inserts an entry at the end of a doubly linked list of LIST_ENTRY structures.

TITLE	DESCRIPTION
ExInterlockedPopEntryList	The ExInterlockedPopEntryList routine atomically removes an entry from the beginning of a singly linked list of SINGLE_LIST_ENTRY structures.
ExInterlockedPopEntrySList	The ExInterlockedPopEntrySList routine atomically removes the first entry from a sequenced singly linked list.
ExInterlockedPushEntryList	The ExInterlockedPushEntryList routine atomically inserts an entry at the beginning of a singly linked list of SINGLE_LIST_ENTRY structures.
ExInterlockedPushEntrySList	The ExInterlockedPushEntrySList routine atomically inserts an entry at the beginning of a sequenced singly linked list.
ExInterlockedRemoveHeadList	The ExInterlockedRemoveHeadList routine removes an entry from the beginning of a doubly linked list of LIST_ENTRY structures.
ExIsProcessorFeaturePresent	The ExIsProcessorFeaturePresent routine queries for the existence of a specified processor feature.
ExIsResourceAcquiredExclusiveLite	The ExIsResourceAcquiredExclusiveLite routine returns whether the current thread has exclusive access to a given resource.
ExIsResourceAcquiredSharedLite	The ExIsResourceAcquiredSharedLite routine returns whether the current thread has access (either shared or exclusive) to a given resource.
ExIsSoftBoot	Determines whether the system has gone through a soft restart.
ExLocalTimeToSystemTime	The ExLocalTimeToSystemTime routine converts a system time value for the current time zone to an unbiased, GreenGMT value.
ExNotifyCallback	The ExNotifyCallback routine causes all callback routines registered for the given object to be called.
EXPAND_STACK_CALLOUT	The ExpandedStackCall routine executes with a guaranteed stack size.
ExQueryDepthSList	The ExQueryDepthSList routine returns the number of entries currently in a given sequenced singly linked list.
ExQueryTimerResolution	The ExQueryTimerResolution routine reports the range of timer resolutions that are supported by the system clock.
ExRaiseAccessViolation	The ExRaiseAccessViolation routine can be used with structured exception handling to throw a driver-determined exception for a memory access violation that occurs when a driver processes I/O requests.

TITLE	DESCRIPTION
ExRaiseDatatypeMisalignment	The ExRaiseDatatypeMisalignment routine can be used with structured exception handling to throw a driver-determined exception for a misaligned data type that occurs when a driver processes I/O requests.
ExRaiseStatus	The ExRaiseStatus routine is called by drivers that supply structured exception handlers to handle particular errors that occur while they are processing I/O requests.
ExRegisterCallback	The ExRegisterCallback routine registers a given callback routine with a given callback object.
ExReinitializeResourceLite	The ExReinitializeResourceLite routine reinitializes an existing resource variable.
ExReInitializeRundownProtection	The ExReInitializeRundownProtection routine reinitializes an EX_RUNDOWN_REF structure after the associated object is run down.
ExReleaseResourceForThreadLite	The ExReleaseResourceForThreadLite routine releases the input resource of the indicated thread.
ExReleaseResourceLite	The ExReleaseResourceLite routine releases a specified executive resource owned by the current thread.
ExReleaseRundownProtection	The ExReleaseRundownProtection routine releases run-down protection that the caller previously acquired by calling the ExAcquireRundownProtection routine.
ExReleaseRundownProtectionEx	The ExReleaseRundownProtectionEx routine releases run-down protection that the caller previously acquired by calling the ExAcquireRundownProtectionEx routine.
ExReleaseSpinLockExclusive	The ExReleaseSpinLockExclusive routine releases a spin lock that the caller previously acquired for exclusive access, and restores the IRQL to its original value.
ExReleaseSpinLockShared	The ExReleaseSpinLockShared routine releases ownership of a spin lock that the caller previously acquired for shared access, and restores the IRQL to its original value.
ExRundownCompleted	The ExRundownCompleted routine updates the run-down status of a shared object to indicate that the run down of the object has completed.
ExSetFirmwareEnvironmentVariable	The ExSetFirmwareEnvironmentVariable routine sets the value of the specified system firmware environment variable.
ExSetResourceOwnerPointer	The ExSetResourceOwnerPointer routine sets the owner thread pointer for an executive resource.
ExSetResourceOwnerPointerEx	The ExSetResourceOwnerPointerEx routine transfers the ownership of an executive resource from the calling thread to an owner pointer, which is a system address that identifies the resource owner.

TITLE	DESCRIPTION
ExSetTimer	The ExSetTimer routine starts a timer operation and sets the timer to expire at the specified due time.
ExSetTimerResolution	The ExSetTimerResolution routine modifies the frequency at which the system clock interrupts. Use this routine with extreme caution (see the following Remarks section).
ExSystemTimeToLocalTime	The ExSystemTimeToLocalTime routine converts a GMT system time value to the local system time for the current time zone.
EXT_CALLBACK	An ExTimerCallback callback routine runs after an EX_TIMER timer object's time interval expires.
EXT_DELETE_CALLBACK	An ExTimerDeleteCallback callback routine runs when the operating system deletes an EX_TIMER timer object.
ExTryConvertSharedSpinLockExclusive	The ExTryConvertSharedSpinLockExclusive routine attempts to convert the access state of a spin lock from acquired for shared access to exclusive access.
ExUnregisterCallback	The ExUnregisterCallback routine removes a callback routine previously registered with a callback object from the list of routines to be called during the notification process.
ExUuidCreate	The ExUuidCreate routine initializes a UUID (GUID) structure to a newly generated value.
ExWaitForRundownProtectionRelease	The ExWaitForRundownProtectionRelease routine waits until all drivers that have already been granted run-down protection complete their accesses of the shared object.
FIELD_OFFSET	The FIELD_OFFSET macro returns the byte offset of a named field in a known structure type.
FIELD_OFFSET	The FIELD_OFFSET macro returns the byte offset of a named field in a known structure type.
FirstEntrySList	The FirstEntrySList routine returns the first entry in a sequenced singly linked list.
FREE_FUNCTION_EX	The LookasideListFreeEx routine frees the storage for a lookaside-list entry when a client tries to insert the entry into a lookaside list that is full.
GET_D3COLD_CAPABILITY	The GetBusDriverD3ColdSupport routine enables the driver for a device to query whether the enumerating bus driver supports the D3cold device power state.
GET_D3COLD_LAST_TRANSITION_STATUS	The GetLastTransitionStatus routine enables the driver for a device to query whether the most recent transition to the D3hot substate was followed by a transition to the D3cold substate.
GET_DMA_ADAPTER	The GetDmaAdapter routine returns a DMA_ADAPTER structure for the target device.

TITLE	DESCRIPTION
GET_IDLE_WAKE_INFO	The GetIdleWakeInfo routine enables the driver for a device to discover the device power states from which the device can signal a wake event.
GET_SDEV_IDENTIFIER	This material is not yet available. This placeholder topic is provided as an example of documentation that may be included in a later release.
GET_SET_DEVICE_DATA	The GetBusData routine reads data from the device's configuration space.
HalAllocateHardwareCounters	The HalAllocateHardwareCounters routine allocates a set of hardware performance counters.
HalExamineMBR	The HalExamineMBR routine reads the master boot record (MBR) of a disk and returns data from the MBR if the MBR is of the type specified by the caller.
HalFreeHardwareCounters	The HalFreeHardwareCounters routine frees a set of hardware performance counters that was acquired in a previous call to HalAllocateHardwareCounters routine.
InitializeListHead	The InitializeListHead routine initializes a LIST_ENTRY structure that represents the head of a doubly linked list.
InitializeListHead	The InitializeListHead routine initializes a LIST_ENTRY structure that represents the head of a doubly linked list.
InitializeObjectAttributes	The InitializeObjectAttributes macro initializes the opaque OBJECT_ATTRIBUTES structure, which specifies the properties of an object handle to routines that open handles.
InitializeSListHead	The InitializeSListHead routine (or ExInitializeSListHead) initializes an SLIST_HEADER structure that represents the head of a sequenced singly linked list.
InsertHeadList	The InsertHeadList routine inserts an entry at the head of a doubly linked list of LIST_ENTRY structures.
InsertHeadList	The InsertHeadList routine inserts an entry at the head of a doubly linked list of LIST_ENTRY structures.
InsertTailList	The InsertTailList routine inserts an entry at the tail of a doubly linked list of LIST_ENTRY structures.
InsertTailList	The InsertTailList routine inserts an entry at the tail of a doubly linked list of LIST_ENTRY structures.
InterlockedAnd	The InterlockedAnd macro atomically computes a bitwise AND operation.

TITLE	DESCRIPTION
InterlockedAnd	The InterlockedAnd macro atomically computes a bitwise AND operation.
InterlockedCompareExchange	The InterlockedCompareExchange routine performs an atomic operation that compares the input value pointed to by Destination with the value of Comparand.
InterlockedCompareExchange	The InterlockedCompareExchange routine performs an atomic operation that compares the input value pointed to by Destination with the value of Comperand.
InterlockedCompareExchangePointer	The InterlockedCompareExchangePointer routine performs an atomic operation that compares the input pointer value pointed to by Destination with the pointer value Comparand.
InterlockedCompareExchangePointer	The InterlockedCompareExchangePointer routine performs an atomic operation that compares the input pointer value pointed to by Destination with the pointer value Comperand.
InterlockedDecrement	The InterlockedDecrement routine decrements a caller-supplied variable of type LONG as an atomic operation.
InterlockedDecrement	The InterlockedDecrement routine decrements a caller-supplied variable of type LONG as an atomic operation.
InterlockedExchange	The InterlockedExchange routine sets an integer variable to a given value as an atomic operation.
InterlockedExchange	The InterlockedExchange routine sets an integer variable to a given value as an atomic operation.
InterlockedExchangeAdd	The InterlockedExchangeAdd routine adds a value to a given integer as an atomic operation and returns the original value of the given integer.
InterlockedExchangeAdd	The InterlockedExchangeAdd routine adds a value to a given integer as an atomic operation and returns the original value of the given integer.
InterlockedExchangePointer	The InterlockedExchangePointer routine performs an atomic operation that sets a pointer to a new value.
InterlockedExchangePointer	The InterlockedExchangePointer routine performs an atomic operation that sets a pointer to a new value.
InterlockedIncrement	The InterlockedIncrement routine increments a caller-supplied variable as an atomic operation.
InterlockedIncrement	The InterlockedIncrement routine increments a caller-supplied variable as an atomic operation.
InterlockedOr	The InterlockedOr routine atomically computes a bitwise OR operation.

TITLE	DESCRIPTION
InterlockedOr	The InterlockedOr routine atomically computes a bitwise OR operation.
InterlockedXor	The InterlockedOr routine atomically computes a bitwise exclusive OR operation.
InterlockedXor	The InterlockedOr routine atomically computes a bitwise exclusive OR operation.
IO_COMPLETION_ROUTINE	The IoCompletion routine completes the processing of I/O operations.
IO_CSQ_ACQUIRE_LOCK	The CsqAcquireLock routine is used by the system to acquire the lock for a driver-implemented, cancel-safe IRP queue.
IO_CSQ_COMPLETE_CANCELED_IRP	The CsqCompleteCanceledIrp routine is used by the system to signal to the driver that it can complete a canceled IRP.
IO_CSQ_INSERT_IRP	The CsqInsertIrp routine is used by the system to insert an IRP into a driver-implemented, cancel-safe IRP queue.
IO_CSQ_INSERT_IRP_EX	The CsqInsertIrpEx routine is used by the system to insert an IRP into a driver-implemented, cancel-safe IRP queue.
IO_CSQ_PEEK_NEXT_IRP	The CsqPeekNextIrp routine is used by the system to find the next matching IRP in a driver-implemented, cancel-safe IRP queue.
IO_CSQ_RELEASE_LOCK	The CsqReleaseLock routine is used by the system to release the lock that was acquired using CsqAcquireLock.
IO_CSQ_REMOVE_IRP	The CsqRemoveIrp routine is used by the system to remove the specified IRP from a driver-implemented, cancel-safe IRP queue.
IO_DPC_ROUTINE	The DpcForIsr routine finishes the servicing of an I/O operation, after an InterruptService routine returns.
IO_SESSION_NOTIFICATION_FUNCTION	The IO_SESSION_NOTIFICATION_FUNCTION function type defines a callback routine through which a driver receives notifications of changes in the state of user sessions that the driver is interested in.
IO_TIMER_ROUTINE	The IoTimer routine is a DPC that, if registered, is called once per second.
IO_WORKITEM_ROUTINE	A WorkItem routine performs the processing for a work item that was queued by the IoQueueWorkItem routine.
IO_WORKITEM_ROUTINE_EX	A WorkItemEx routine performs the processing for a work item that was queued by the IoQueueWorkItemEx or IoTryQueueWorkItem routine.

TITLE	DESCRIPTION
IoAcquireRemoveLock	The IoAcquireRemoveLock routine increments the count for a remove lock, indicating that the associated device object should not be detached from the device stack or deleted.
IoAdjustPagingPathCount	The IoAdjustPagingPathCount routine increments or decrements a caller-supplied page-file counter as an atomic operation.
IoAllocateController	The IoAllocateController routine sets up the call to a driver-supplied ControllerControl routine as soon as the device controller, represented by the given controller object, is available to carry out an I/O operation for the target device, represented by the given device object.
IoAllocateDriverObjectExtension	The IoAllocateDriverObjectExtension routine allocates a per-driver context area, called a driver object extension, and assigns a unique identifier to it.
IoAllocateErrorLogEntry	The IoAllocateErrorLogEntry routine allocates an error log entry, and returns a pointer to the packet that the caller uses to supply information about an I/O error.
IoAllocateIrp	The IoAllocateIrp routine allocates an IRP, given the number of I/O stack locations for each driver layered under the caller, and, optionally, for the caller.
IoAllocateMdl	The IoAllocateMdl routine allocates a memory descriptor list (MDL) large enough to map a buffer, given the buffer's starting address and length. Optionally, this routine associates the MDL with an IRP.
IoAllocateWorkItem	The IoAllocateWorkItem routine allocates a work item.
IoAssignArcName	The IoAssignArcName routine creates a symbolic link between the ARC name of a physical device and the name of the corresponding device object when it has been created.
IoAttachDevice	The IoAttachDevice routine attaches the caller's device object to a named target device object, so that I/O requests bound for the target device are routed first to the caller.
IoAttachDeviceToDeviceStack	The IoAttachDeviceToDeviceStack routine attaches the caller's device object to the highest device object in the chain and returns a pointer to the previously highest device object.
IoBuildAsynchronousFsdRequest	The IoBuildAsynchronousFsdRequest routine allocates and sets up an IRP to be sent to lower-level drivers.
IoBuildDeviceIoControlRequest	The IoBuildDeviceIoControlRequest routine allocates and sets up an IRP for a synchronously processed device control request.
IoBuildPartialMdl	The IoBuildPartialMdl routine builds a new memory descriptor list (MDL) that represents part of a buffer that is described by an existing MDL.

TITLE	DESCRIPTION
IoBuildSynchronousFsdRequest	The IoBuildSynchronousFsdRequest routine allocates and sets up an IRP for a synchronously processed I/O request.
IoCallDriver	The IoCallDriver routine sends an IRP to the driver associated with a specified device object.
IoCancelIrp	The IoCancelIrp routine sets the cancel bit in a given IRP and calls the cancel routine for the IRP if there is one.
IoCheckLinkShareAccess	The IoCheckLinkShareAccess routine is called by file system drivers (FSDs) or other highest-level drivers to check whether link shared access to a file object is permitted.
IoCheckShareAccess	The IoCheckShareAccess routine is called by file system drivers (FSDs) or other highest-level drivers to check whether shared access to a file object is permitted.
IoCheckShareAccessEx	The IoCheckShareAccessEx routine is called by file system drivers (FSDs) or other highest-level drivers to check whether shared access to a file object is permitted.
IoClearActivityIdThread	The IoClearActivityIdThread routine clears the activity ID of the current thread.
IoCompleteRequest	The IoCompleteRequest routine indicates that the caller has completed all processing for a given I/O request and is returning the given IRP to the I/O manager.
IoConnectInterrupt	The IoConnectInterrupt routine registers a device driver's InterruptService routine (ISR), so that it will be called when a device interrupts on any of a specified set of processors.
IoConnectInterruptEx	For more information, see the WdmlibIoConnectInterruptEx function.#define IoConnectInterruptEx WdmlibIoConnectInterruptEx
IoCopyCurrentIrpStackLocationToNext	The IoCopyCurrentIrpStackLocationToNext routine copies the IRP stack parameters from the current I/O stack location to the stack location of the next-lower driver.
IoCreateController	The IoCreateController routine allocates memory for and initializes a controller object with a controller extension of a driver-determined size.
IoCreateDevice	The IoCreateDevice routine creates a device object for use by a driver.
IoCreateFile	The IoCreateFile routine either causes a new file or directory to be created, or it opens an existing file, device, directory, or volume, giving the caller a handle for the file object.
IoCreateNotificationEvent	The IoCreateNotificationEvent routine creates or opens a named notification event used to notify one or more threads of execution that an event has occurred.

TITLE	DESCRIPTION
IoCreateSymbolicLink	The IoCreateSymbolicLink routine sets up a symbolic link between a device object name and a user-visible name for the device.
IoCreateSynchronizationEvent	The IoCreateSynchronizationEvent routine creates or opens a named synchronization event for use in serialization of access to hardware between two otherwise unrelated drivers.
IoCreateSystemThread	The IoCreateSystemThread routine creates a system thread that executes in kernel mode, and supplies a handle for the thread.
IoCreateUnprotectedSymbolicLink	The IoCreateUnprotectedSymbolicLink routine sets up an unprotected symbolic link between a device object name and a corresponding Win32-visible name.
IoCsqInitialize	The IoCsqInitialize routine initializes the driver's cancel-safe IRP queue dispatch table.
IoCsqInitializeEx	The IoCsqInitializeEx routine initializes the dispatch table for a cancel-safe IRP queue.
IoCsqInsertIrp	The IoCsqInsertIrp routine inserts an IRP in the driver's cancel-safe IRP queue.
IoCsqInsertIrpEx	The IoCsqInsertIrpEx routine inserts an IRP into the driver's cancel-safe IRP queue.
IoCsqRemoveIrp	The IoCsqRemoveIrp routine removes a particular IRP from the queue.
IoCsqRemoveNextIrp	The IoCsqRemoveNextIrp routine removes the next matching IRP in the queue.
IoDeassignArcName	The IoDeassignArcName routine removes a symbolic link between the ARC name for a device and the named device object.
IoDecrementKeepAliveCount	The IoDecrementKeepAliveCount routine decrements a reference count associated with an Windows app on a specific device.
IoDeleteController	The IoDeleteController routine removes a given controller object from the system, for example, when the driver that created it is being unloaded.
IoDeleteDevice	The IoDeleteDevice routine removes a device object from the system, for example, when the underlying device is removed from the system.
IoDeleteSymbolicLink	The IoDeleteSymbolicLink routine removes a symbolic link from the system.
IoDetachDevice	The IoDetachDevice routine releases an attachment between the caller's device object and a lower driver's device object.

TITLE	DESCRIPTION
IoDisconnectInterrupt	The IoDisconnectInterrupt routine releases a device driver's set of interrupt object(s) when the device is paused or removed, or when the driver is being unloaded.
IoDisconnectInterruptEx	For more information, see the WdmlibIoDisconnectInterruptEx function.#define IoDisconnectInterruptEx WdmlibIoDisconnectInterruptEx
IoForwardIrpSynchronously	The IoForwardIrpSynchronously routine sends an IRP to a specified driver and waits for that driver to complete the IRP.
IoFreeController	The IoFreeController routine releases a previously allocated controller object when the driver has completed an I/O request.
IoFreeErrorLogEntry	The IoFreeErrorLogEntry routine frees an unused error log entry.
IoFreeIrp	The IoFreeIrp routine releases a caller-allocated IRP from the caller's IoCompletion routine.
IoFreeMdl	The IoFreeMdl routine releases a caller-allocated memory descriptor list (MDL).
IoFreeWorkItem	The IoFreeWorkItem routine frees a work item that was allocated by IoAllocateWorkItem.
IoGetActivityIdIrp	The IoGetActivityIdIrp routine retrieves the current activity ID associated with an IRP.
IoGetActivityIdThread	The IoGetActivityIdThread routine returns the activity ID associated with the current thread.
IoGetAffinityInterrupt	For more information, see the WdmlibIoGetAffinityInterrupt function.#define IoGetAffinityInterrupt WdmlibIoGetAffinityInterrupt
IoGetAttachedDeviceReference	The IoGetAttachedDeviceReference routine returns a pointer to the highest level device object in a driver stack and increments the reference count on that object.
IoGetAttachedDeviceReference	The IoGetAttachedDeviceReference routine returns a pointer to the highest level device object in a driver stack and increments the reference count on that object.
IoGetBootDiskInformation	The IoGetBootDiskInformation routine returns information describing the boot and system disks.

TITLE	DESCRIPTION
IoGetConfigurationInformation	The IoGetConfigurationInformation routine returns a pointer to the I/O manager's global configuration information structure, which contains the current values for how many physical disk, floppy, CD-ROM, tape, SCSI HBA, serial, and parallel devices have device objects created to represent them by drivers as they are loaded.
IoGetConfigurationInformation	The IoGetConfigurationInformation routine returns a pointer to the I/O manager's global configuration information structure, which contains the current values for how many physical disk, floppy, CD-ROM, tape, SCSI HBA, serial, and parallel devices have device objects created to represent them by drivers as they are loaded.
IoGetContainerInformation	The IoGetContainerInformation routine provides information about the current state of a user session.
IoGetCurrentIrpStackLocation	The IoGetCurrentIrpStackLocation routine returns a pointer to the caller's I/O stack location in the specified IRP.
IoGetCurrentProcess	The IoGetCurrentProcess routine returns a pointer to the current process.
IoGetDeviceInterfaceAlias	The IoGetDeviceInterfaceAlias routine returns the alias device interface of the specified device interface instance, if the alias exists.
IoGetDeviceInterfacePropertyData	The IoGetDeviceInterfacePropertyData routine retrieves the current value of a device interface property.
IoGetDeviceInterfaces	The IoGetDeviceInterfaces routine returns a list of device interface instances of a particular device interface class (such as all devices on the system that support a HID interface).
IoGetDeviceNumaNode	The IoGetDeviceNumaNode routine gets the node number of a device.
IoGetDeviceObjectPointer	The IoGetDeviceObjectPointer routine returns a pointer to the top object in the named device object's stack and a pointer to the corresponding file object, if the requested access to the objects can be granted.
IoGetDeviceProperty	The IoGetDeviceProperty routine retrieves information about a device such as configuration information and the name of its PDO.
IoGetDevicePropertyData	The IoGetDevicePropertyData routine retrieves the current setting for a device property.
IoGetDmaAdapter	The IoGetDmaAdapter routine returns a pointer to the DMA adapter structure for a physical device object.
IoGetDriverObjectExtension	The IoGetDriverObjectExtension routine retrieves a previously allocated per-driver context area.

TITLE	DESCRIPTION
IoGetFileObjectGenericMapping	The IoGetFileObjectGenericMapping routine returns information about the mapping between each generic access right and the set of specific access rights for file objects.
IoGetFunctionCodeFromCtlCode	The IoGetFunctionCodeFromCtlCode macro returns the value of the function code contained in an I/O control code.
IoGetInitialStack	The IoGetInitialStack routine returns the base address of the current thread's stack.
IoGetInitiatorProcess	The IoGetInitiatorProcess routine retrieves the process which initiated the creation of a file object if different than the process which is issuing the create.
IoGetIoPriorityHint	The IoGetIoPriorityHint routine gets the priority hint value from an IRP.
IoGetNextIrpStackLocation	The IoGetNextIrpStackLocation routine gives a higher level driver access to the next-lower driver's I/O stack location in an IRP so the caller can set it up for the lower driver.
IoGetPagingIoPriority	The IoGetPagingIoPriority routine indicates the priority level of a paging I/O request.
IoGetRelatedDeviceObject	Given a file object, the IoGetRelatedDeviceObject routine returns a pointer to the corresponding device object.
IoGetRemainingStackSize	The IoGetRemainingStackSize routine returns the current amount of available kernel-mode stack space.
IoGetStackLimits	The IoGetStackLimits routine returns the boundaries of the current thread's stack frame.
IoIncrementKeepAliveCount	The IoIncrementKeepAliveCount routine increments a reference count associated with an Windows app process on a specific device.
IoInitializeDpcRequest	The IoInitializeDpcRequest routine registers a driver-supplied DpcForIsr routine.
IoInitializeIrp	The IoInitializeIrp routine initializes a given IRP that was allocated by the caller.
IoInitializeRemoveLock	The IoInitializeRemoveLock routine initializes a remove lock for a device object.
IoInitializeTimer	The IoInitializeTimer routine sets up a driver-supplied IoTimer routine associated with a given device object.
IoInitializeWorkItem	The IoInitializeWorkItem routine initializes a work item that the caller has already allocated.

TITLE	DESCRIPTION
IoInvalidateDeviceRelations	The IoInvalidateDeviceRelations routine notifies the PnP manager that the relations for a device (such as bus relations, ejection relations, removal relations, and the target device relation) have changed.
IoInvalidateDeviceState	The IoInvalidateDeviceState routine notifies the PnP manager that some aspect of the PnP state of a device has changed.
IoIs32bitProcess	The IoIs32bitProcess routine checks whether the originator of the current I/O request is a 32-bit user-mode application.
IoIsErrorUserInduced	The IoIsErrorUserInduced routine determines whether an I/O error encountered while processing a request to a removable-media device was caused by the user.
IoIsValidIrpStatus	The IoIsValidIrpStatus routine validates the specified NTSTATUS status code value.
IoIsWdmVersionAvailable	The IoIsWdmVersionAvailable routine checks whether a given WDM version is supported by the operating system.
IoMakeAssociatedIrp	This routine is reserved for use by file systems and file system filter drivers.
IoMarkIrpPending	The IoMarkIrpPending routine marks the specified IRP, indicating that a driver's dispatch routine subsequently returned STATUS_PENDING because further processing is required by other driver routines.
IoOpenDeviceInterfaceRegistryKey	The IoOpenDeviceInterfaceRegistryKey routine returns a handle to a registry key for storing information about a particular device interface instance.
IoOpenDeviceRegistryKey	The IoOpenDeviceRegistryKey routine returns a handle to a device-specific or a driver-specific registry key for a particular device instance.
IoPropagateActivityIdToThread	The IoPropagateActivityIdToThread routine associates the activity ID from an IRP with the current thread.
IoQueryFullDriverPath	The IoQueryFullDriverPath routine retrieves the full path name of the binary file that is loaded for the specified driver object.
IoQueueWorkItem	The IoQueueWorkItem routine associates a WorkItem routine with a work item, and it inserts the work item into a queue for later processing by a system worker thread.
IoQueueWorkItemEx	The IoQueueWorkItemEx routine associates a WorkItemEx routine with a work item, and it inserts the work item into a queue for later processing by a system worker thread.
IoRaiseHardError	The IoRaiseHardError routine causes a dialog box to appears that warns the user that a device I/O error has occurred, which might indicate that a physical device is failing.

TITLE	DESCRIPTION
IoRaiseInformationalHardError	The IoRaiseInformationalHardError routine sends a dialog box to the user, warning about a device I/O error that indicates why a user I/O request failed.
IoRegisterBootDriverCallback	The IoRegisterBootDriverCallback routine registers a BOOT_DRIVER_CALLBACK_FUNCTION routine to be called during the initialization of a boot-start driver and its dependent DLLs.
IoRegisterBootDriverReinitialization	The IoRegisterBootDriverReinitialization routine is called by a boot driver to register the driver's reinitialization routine with the I/O manager to be called after all devices have been enumerated and started.
IoRegisterContainerNotification	The IoRegisterContainerNotification routine registers a kernel-mode driver to receive notifications about a specified class of events.
IoRegisterDeviceInterface	The IoRegisterDeviceInterface routine registers a device interface class, if it has not been previously registered, and creates a new instance of the interface class, which a driver can subsequently enable for use by applications or other system components.
IoRegisterDriverReinitialization	The IoRegisterDriverReinitialization routine is called by a driver during its initialization or reinitialization to register its Reinitialize routine to be called again before the driver's and, possibly the system's, initialization is complete.
IoRegisterLastChanceShutdownNotification	The IoRegisterLastChanceShutdownNotification routine registers a driver to receive an IRP_MJ_SHUTDOWN IRP when the system is shut down, after all file systems have been flushed.
IoRegisterPlugPlayNotification	The IoRegisterPlugPlayNotification routine registers a Plug and Play (PnP) notification callback routine to be called when a PnP event of the specified category occurs.
IoRegisterShutdownNotification	The IoRegisterShutdownNotification routine registers the driver to receive an IRP_MJ_SHUTDOWN IRP when the system is shut down.
IoReleaseRemoveLock	The IoReleaseRemoveLock routine releases a remove lock acquired with a previous call to IoAcquireRemoveLock.
IoReleaseRemoveLockAndWait	The IoReleaseRemoveLockAndWait routine releases a remove lock that the driver acquired in a previous call to IoAcquireRemoveLock, and waits until all acquisitions of the lock have been released.
IoRemoveLinkShareAccess	The IoRemoveLinkShareAccess routine removes the access and link share-access information for a given open instance of a file object.

TITLE	DESCRIPTION
IoRemoveShareAccess	The IoRemoveShareAccess routine removes the access and share-access information for a given open instance of a file object.
IoReportDetectedDevice	The IoReportDetectedDevice routine reports a non-PnP device to the PnP manager.
IoReportInterruptActive	The IoReportInterruptActive routine informs the operating system that a registered interrupt service routine (ISR) is active and ready to handle interrupt requests.
IoReportInterruptInactive	The IoReportInterruptInactive routine informs the operating system that a registered interrupt service routine (ISR) is inactive and is not expecting interrupt requests.
IoReportResourceForDetection	The IoReportResourceForDetection routine claims hardware resources in the configuration registry for a legacy device.
IoReportRootDevice	The IoReportRootDevice routine reports a device that cannot be detected by a PnP bus driver to the PnP Manager. IoReportRootDevice allows only one device per driver to be created.
IoReportTargetDeviceChange	The IoReportTargetDeviceChange routine notifies the PnP manager that a custom event has occurred on a device.
IoReportTargetDeviceChangeAsynchronous	The IoReportTargetDeviceChangeAsynchronous routine notifies the PnP manager that a custom event has occurred on a device.
IoRequestDeviceEject	The IoRequestDeviceEject routine notifies the PnP manager that the device eject button was pressed.
IoRequestDpc	The IoRequestDpc routine queues a driver-supplied DpcForIsr routine to complete interrupt-driven I/O processing at a lower IRQL.
IoReuseIrp	The IoReuseIrp routine reinitializes an IRP so that it can be reused.
IoSetActivityIdIrp	The IoSetActivityIdIrp routine associates an activity ID with an IRP.
IoSetActivityIdThread	The IoSetActivityIdThread routine associates an activity ID with the current thread. Drivers should use this routine when they are tracing aware and are issuing I/O on a worker thread.
IoSetCancelRoutine	The IoSetCancelRoutine routine sets up a driver-supplied Cancel routine to be called if a given IRP is canceled.
IoSetCompletionRoutine	The IoSetCompletionRoutine routine registers an IoCompletion routine, which will be called when the next-lower-level driver has completed the requested operation for the given IRP.

TITLE	DESCRIPTION
IoSetCompletionRoutineEx	The IoSetCompletionRoutineEx routine registers an IoCompletion routine, which is called when the next-lower-level driver has completed the requested operation for the given IRP.
IoSetDeviceInterfacePropertyData	The IoSetDeviceInterfacePropertyData routine modifies the current value of a device interface property.
IoSetDeviceInterfaceState	The IoSetDeviceInterfaceState routine enables or disables an instance of a previously registered device interface class.
IoSetDevicePropertyData	The IoSetDevicePropertyData routine modifies the current setting for a device property.
IoSetHardErrorOrVerifyDevice	Lower-level drivers call the IoSetHardErrorOrVerifyDevice routine to identify a removable media device that has encountered an error, so that a file system driver can prompt the user to verify that the medium is valid.
IoSetIoPriorityHint	The IoSetIoPriorityHint routine sets the priority hint value for an IRP.
IoSetLinkShareAccess	The IoSetLinkShareAccess routine sets the access rights for link sharing the specified file object.
IoSetMasterIrpStatus	The IoSetMasterIrpStatus routine conditionally replaces the Status value in an IRP with the specified NTSTATUS value.
IoSetNextIrpStackLocation	The IoSetNextIrpStackLocation routine sets the IRP stack location in a driver-allocated IRP to that of the caller.
IoSetShareAccess	The IoSetShareAccess routine sets the access rights for sharing the given file object.
IoSetShareAccessEx	The IoSetShareAccessEx routine sets the access rights for sharing the specified file object.
IoSetStartIoAttributes	The IoSetStartIoAttributes routine sets attributes for the driver's StartIo routine.
IoSetStartIoAttributes	The IoSetStartIoAttributes routine sets attributes for the driver's StartIo routine.
IoSetSystemPartition	The IoSetSystemPartition routine sets the boot partition for the system.
IoSetThreadHardErrorMode	The IoSetThreadHardErrorMode routine enables or disables hard error reporting for the current thread.
IoSizeOfIrp	The IoSizeOfIrp routine determines the size in bytes for an IRP, given the number of stack locations in the IRP.
IoSizeOfIrp	The IoSizeOfIrp routine determines the size in bytes for an IRP, given the number of stack locations in the IRP.

TITLE	DESCRIPTION
IoSizeofWorkItem	The IoSizeofWorkItem routine returns the size, in bytes, of an IO_WORKITEM structure.
IoStartNextPacket	The IoStartNextPacket routine dequeues the next IRP, if any, from the given device object's associated device queue and calls the driver's StartIo routine.
IoStartNextPacket	The IoStartNextPacket routine dequeues the next IRP, if any, from the given device object's associated device queue and calls the driver's StartIo routine.
IoStartNextPacketByKey	The IoStartNextPacketByKey routine dequeues the next I/O request packet from the specified device object's associated device queue according to a specified sort-key value and calls the driver's StartIo routine with that IRP.
IoStartNextPacketByKey	The IoStartNextPacketByKey routine dequeues the next I/O request packet from the specified device object's associated device queue according to a specified sort-key value and calls the driver's StartIo routine with that IRP.
IoStartPacket	The IoStartPacket routine calls the driver's StartIo routine with the given IRP or inserts the IRP into the device queue associated with the given device object if the device is already busy.
IoStartPacket	The IoStartPacket routine calls the driver's StartIo routine with the given IRP or inserts the IRP into the device queue associated with the given device object if the device is already busy.
IoStartTimer	The IoStartTimer routine enables the timer associated with a given device object so the driver-supplied IoTimer routine is called once per second.
IoStartTimer	The IoStartTimer routine enables the timer associated with a given device object so the driver-supplied IoTimer routine is called once per second.
IoStopTimer	The IoStopTimer routine disables the timer for a specified device object so the driver-supplied IoTimer routine is not called.
IoStopTimer	The IoStopTimer routine disables the timer for a specified device object so the driver-supplied IoTimer routine is not called.
IoTransferActivityId	The IoTransferActivityId routine logs an ETW transfer event using the I/O tracing provider on behalf of the caller. This allows a driver to associate two related activity IDs without requiring a specific provider to be enabled.
IoUninitializeWorkItem	The IoUninitializeWorkItem routine uninitializes a work item that was initialized by IoInitializeWorkItem.

TITLE	DESCRIPTION
IoUnregisterBootDriverCallback	The IoUnRegisterBootDriverCallback routine unregisters a previously registered BOOT_DRIVER_CALLBACK_FUNCTION routine.
IoUnregisterContainerNotification	The IoUnregisterContainerNotification routine cancels a container notification registration that was previously created by the IoRegisterContainerNotification routine.
IoUnregisterPlugPlayNotification	This routine is obsolete in Windows 7 and later versions of Windows. For more information, see the following Remarks section.The IoUnregisterPlugPlayNotification routine removes the registration of a driver's callback routine for a PnP event.
IoUnregisterPlugPlayNotificationEx	The IoUnregisterPlugPlayNotificationEx routine cancels the registration of a driver's callback routine for notifications of Plug and Play (PnP) events.
IoUnregisterShutdownNotification	The IoUnregisterShutdownNotification routine removes a registered driver from the shutdown notification queue.
IoUpdateLinkShareAccess	The IoUpdateLinkShareAccess routine updates the share access for the given file object, usually when the file is being opened.
IoUpdateShareAccess	The IoUpdateShareAccess routine updates the share access for the given file object, usually when the file is being opened.
IoValidateDeviceIoControlAccess	For more information, see the WdmlibIoValidateDeviceIoControlAccess function.
IoVerifyPartitionTable	The IoVerifyPartitionTable routine checks the validity of the partition table for a disk.
IoVolumeDeviceToDosName	The IoVolumeDeviceToDosName routine returns the MS-DOS path for a specified device object that represents a file system volume.
IoWithinStackLimits	The IoWithinStackLimits routine determines whether a region of memory is within the stack limit of the current thread.
IoWMIAllocateInstanceIds	The IoWMIAllocateInstanceIds routine allocates one or more instance IDs that are unique to the GUID.
IoWMIDeviceObjectToInstanceName	The IoWMIDeviceObjectToInstanceName routine determines the instance name for the WMI class instance implemented by the driver that is specified by a device object.
IoWMIDeviceObjectToProviderId	The IoWMIDeviceObjectToProviderId routine translates the specified device object into the corresponding WMI Provider ID.
IoWMIExecuteMethod	The IoWMIExecuteMethod routine runs a WMI class method on the specified WMI data block instance.

TITLE	DESCRIPTION
IoWMIHandleToInstanceName	The IoWMIHandleToInstanceName routine determines the instance name for the WMI class instance implemented by the driver that is specified by a file handle.
IoWMIOpenBlock	The IoWMIOpenBlock routine opens the WMI data block object for the specified WMI class.
IoWMIQueryAllData	The IoWMIQueryAllData routine returns all WMI data blocks that implement a given WMI class.
IoWMIQueryAllDataMultiple	The IoWMIQueryAllDataMultiple routine returns all WMI data blocks that implement one of a set of WMI classes.
IoWMIQuerySingleInstance	The IoWMIQuerySingleInstance routine returns the specified instance of a WMI data block.
IoWMIQuerySingleInstanceMultiple	The IoWMIQuerySingleInstanceMultiple routine returns all WMI data block instances that implement the specified WMI classes with the specified instance names.
IoWMIRegistrationControl	The IoWMIRegistrationControl routine registers or unregisters the caller as a WMI data provider for a specified device object.
IoWMISetNotificationCallback	The IoWMISetNotificationCallback routine registers a notification callback for a WMI event.
IoWMISetSingleInstance	The IoWMISetSingleInstance routine sets the values for properties within the data block instance that matches the specified WMI class and instance name.
IoWMISetSingleItem	The IoWMISetSingleItem routine sets a single property in the data block instance that matches the specified WMI class and instance name.
IoWMISuggestInstanceName	The IoWMISuggestInstanceName routine is used to request that WMI suggest a base name which a driver can use to build WMI instance names for the device.
IoWMIWriteEvent	The IoWMIWriteEvent routine delivers a given event to the user-mode WMI components for notification.
IoWriteErrorLogEntry	The IoWriteErrorLogEntry routine queues a given error log packet to the system error logging thread.
IoWriteErrorLogEntry	The IoWriteErrorLogEntry routine queues a given error log packet to the system error logging thread.
IsListEmpty	The IsListEmpty routine indicates whether a doubly linked list of LIST_ENTRY structures is empty.
IsListEmpty	The IsListEmpty routine indicates whether a doubly linked list of LIST_ENTRY structures is empty.

TITLE	DESCRIPTION
KBUGCHECK_CALLBACK_ROUTINE	The BugCheckCallback routine is executed whenever the system issues a bug check.
KBUGCHECK_REASON_CALLBACK_ROUTINE	Driver-implemented callback functions that the system executes when it issues a bug check.
KDEFERRED_ROUTINE	The callback routine performs actions, after an InterruptService returns, of a threaded DPC, The CustomDpc routine finishes the servicing of an I/O operation, after an InterruptService routine returns.The CustomThreadedDpc routine performs the action of a threaded DPC. The system executes this routine when the threaded DPC runs.The CustomTimerDpc routine executes after a timer object's time interval expires.
KeAcquireSpinLock	The KeAcquireSpinLock routine acquires a spin lock so the caller can synchronize access to shared data in a multiprocessor-safe way by raising IRQL.
KeAcquireSpinLockAtDpcLevel	The KeAcquireSpinLockAtDpcLevel routine acquires a spin lock when the caller is already running at IRQL >= DISPATCH_LEVEL.
KeAreAllApcsDisabled	The KeAreAllApcsDisabled routine indicates whether the calling thread is inside a guarded region or running at IRQL >= APC_LEVEL, which disables all APC delivery.
KeAreApcsDisabled	The KeAreApcsDisabled routine returns whether the calling thread is within a critical region or a guarded region, which disables normal kernel APC delivery.
KeAreApcsDisabled	The KeAreApcsDisabled routine returns whether the calling thread is within a critical region or a guarded region, which disables normal kernel APC delivery.
KeBugCheck	The KeBugCheck routine brings down the system in a controlled manner when the caller discovers an unrecoverable inconsistency that would corrupt the system if the caller continued to run.
KeBugCheckEx	The KeBugCheckEx routine brings down the system in a controlled manner when the caller discovers an unrecoverable inconsistency that would corrupt the system if the caller continued to run.
KeCancelTimer	The KeCancelTimer routine dequeues a timer object before the timer interval, if any was set, expires.
KeClearEvent	The KeClearEvent routine sets an event to a not-signaled state.
KeConvertAuxiliaryCounterToPerformanceCounter	The KeConvertAuxiliaryCounterToPerformanceCounter routine converts the specified auxiliary counter value into a performance counter value.

TITLE	DESCRIPTION
KeConvertPerformanceCounterToAuxiliaryCounter	The KeConvertPerformanceCounterToAuxiliaryCounter routine converts the specified performance counter value into an auxiliary counter value.
KeDelayExecutionThread	The KeDelayExecutionThread routine puts the current thread into an alertable or nonalertable wait state for a specified interval.
KeDeregisterBoundCallback	The KeDeregisterBoundCallback routine deregisters a user-mode bound exception callback registered by KeRegisterBoundCallback.
KeDeregisterBugCheckCallback	The KeDeregisterBugCheckCallback routine removes a callback routine that was registered by KeRegisterBugCheckCallback.
KeDeregisterBugCheckReasonCallback	The KeDeregisterBugCheckReasonCallback routine removes a callback routine that was registered by KeRegisterBugCheckReasonCallback.
KeDeregisterNmiCallback	The KeDeregisterNmiCallback routine deregisters a nonmaskable interrupt (NMI) callback registered by KeRegisterNmiCallback.
KeDeregisterProcessorChangeCallback	The KeDeregisterProcessorChangeCallback routine unregisters a callback function that was previously registered with the operating system by calling the KeRegisterProcessorChangeCallback routine.
KeEnterCriticalRegion	The KeEnterCriticalRegion routine temporarily disables the execution of normal kernel APCs, but does not prevent special kernel APCs from running.
KeEnterCriticalRegion	The KeEnterCriticalRegion routine temporarily disables the execution of normal kernel APCs, but does not prevent special kernel APCs from running.
KeEnterGuardedRegion	The KeEnterGuardedRegion routine enters a guarded region, which disables all kernel-mode APC delivery to the current thread.
KeEnterGuardedRegion	The KeEnterGuardedRegion routine enters a guarded region, which disables all kernel-mode APC delivery to the current thread.
KeExpandKernelStackAndCallout	The KeExpandKernelStackAndCallout routine calls a routine with a guaranteed amount of stack space.
KeFlushIoBuffers	The KeFlushIoBuffers routine flushes the memory region described by an MDL from caches of all processors.
KeFlushQueuedDpcs	The KeFlushQueuedDpcs routine returns after all queued DPCs on all processors have executed.
KefReleaseSpinLockFromDpcLevel	The KeReleaseSpinLockFromDpcLevel routine releases an executive spin lock without changing the IRQL.

TITLE	DESCRIPTION
KeGetCurrentIrql	The KeGetCurrentIrql routine returns the current IRQL.
KeGetCurrentNodeNumber	The KeGetCurrentNodeNumber routine gets the NUMA node number for the logical processor that the caller is running on.
KeGetCurrentNodeNumber	The KeGetCurrentNodeNumber routine gets the NUMA node number for the logical processor that the caller is running on.
KeGetCurrentProcessorNumber	The KeGetCurrentProcessorNumber routine returns the system-assigned number of the current processor on which the caller is running.
KeGetCurrentProcessorNumberEx	The KeGetCurrentProcessorNumberEx routine gets the processor number of the logical processor that the caller is running on.
KeGetCurrentProcessorNumberEx	The KeGetCurrentProcessorNumberEx routine gets the processor number of the logical processor that the caller is running on.
KeGetCurrentThread	The KeGetCurrentThread routine identifies the current thread.
KeGetProcessorIndexFromNumber	The KeGetProcessorIndexFromNumber routine converts a group number and a group-relative processor number to a systemwide processor index.
KeGetProcessorIndexFromNumber	The KeGetProcessorIndexFromNumber routine converts a group number and a group-relative processor number to a systemwide processor index.
KeGetProcessorNumberFromIndex	The KeGetProcessorNumberFromIndex routine converts a systemwide processor index to a group number and a group-relative processor number.
KeGetProcessorNumberFromIndex	The KeGetProcessorNumberFromIndex routine converts a systemwide processor index to a group number and a group-relative processor number.
KeGetRecommendedSharedDataAlignment	The KeGetRecommendedSharedDataAlignment routine returns the preferred alignment for memory structures that can be accessed by more than one processor.
KeInitializeCrashDumpHeader	The KeInitializeCrashDumpHeader routine supplies the header information the system requires for a crash dump file.
KeInitializeCrashDumpHeader	The KeInitializeCrashDumpHeader routine supplies the header information the system requires for a crash dump file.
KeInitializeDeviceQueue	The KeInitializeDeviceQueue routine initializes a device queue object to a not-busy state.
KeInitializeDpc	The KeInitializeDpc routine initializes a DPC object, and registers a CustomDpc routine for that object.

TITLE	DESCRIPTION
KeInitializeEvent	The KeInitializeEvent routine initializes an event object as a synchronization (single waiter) or notification type event and sets it to a signaled or not-signaled state.
KeInitializeGuardedMutex	The KeInitializeGuardedMutex routine initializes a guarded mutex.
KeInitializeMutex	The KeInitializeMutex routine initializes a mutex object, setting it to a signaled state.
KeInitializeSemaphore	The KeInitializeSemaphore routine initializes a semaphore object with a specified count and specifies an upper limit that the count can attain.
KeInitializeSpinLock	The KeInitializeSpinLock routine initializes a variable of type KSPIN_LOCK.
KeInitializeThreadedDpc	The KeInitializeThreadedDpc routine initializes a threaded DPC object, and registers a CustomThreadedDpc routine for that object.
KeInitializeTimer	The KeInitializeTimer routine initializes a timer object.
KeInitializeTimerEx	The KeInitializeTimerEx routine initializes an extended kernel timer object.
KeInsertByKeyDeviceQueue	The KeInsertByKeyDeviceQueue routine acquires the spin lock for the specified DeviceQueue and queues an entry according to the specified sort-key value if the device queue is set to a busy state.
KeInsertDeviceQueue	The KeInsertDeviceQueue routine acquires the spin lock for the specified device queue object and, if the device queue is set to a busy state, queues the specified entry.
KeInsertQueueDpc	The KeInsertQueueDpc routine queues a DPC for execution.
KeInvalidateAllCaches	The KeInvalidateAllCaches routine flushes all processor caches.
KeIpiGenericCall	The KeIpiGenericCall routine causes the specified routine to run on all processors simultaneously.
KeLeaveCriticalRegion	The KeLeaveCriticalRegion routine reenables the delivery of normal kernel-mode APCs that were disabled by a preceding call to KeEnterCriticalRegion.
KeLeaveCriticalRegion	The KeLeaveCriticalRegion routine reenables the delivery of normal kernel-mode APCs that were disabled by a preceding call to KeEnterCriticalRegion.
KeLeaveGuardedRegion	The KeLeaveGuardedRegion routine exits a guarded region entered by KeEnterGuardedRegion.

TITLE	DESCRIPTION
KeLeaveGuardedRegion	The KeLeaveGuardedRegion routine exits a guarded region entered by KeEnterGuardedRegion.
KeLowerIrql	The KeLowerIrql routine restores the IRQL on the current processor to its original value.
KeMemoryBarrier	The KeMemoryBarrier routine creates a barrier at its position in the code—across which the compiler and the processor cannot move any operations.
KePulseEvent	The KePulseEvent routine atomically sets an event object to a signaled state, attempts to satisfy as many waits as possible, and then resets the event object to a not-signaled state.
KeQueryActiveGroupCount	The KeQueryActiveGroupCount routine returns the number of active processor groups in a multiprocessor system.
KeQueryActiveGroupCount	The KeQueryActiveGroupCount routine returns the number of active processor groups in a multiprocessor system.
KeQueryActiveProcessorCount	The KeQueryActiveProcessorCount routine returns the number of currently active processors.
KeQueryActiveProcessorCount	The KeQueryActiveProcessorCount routine returns the number of currently active processors.
KeQueryActiveProcessorCountEx	The KeQueryActiveProcessorCountEx routine returns the number of active logical processors in a specified group in a multiprocessor system or in the entire system.
KeQueryActiveProcessorCountEx	The KeQueryActiveProcessorCountEx routine returns the number of active logical processors in a specified group in a multiprocessor system or in the entire system.
KeQueryActiveProcessors	The KeQueryActiveProcessors routine returns a bitmask of the currently active processors.
KeQueryActiveProcessors	The KeQueryActiveProcessors routine returns a bitmask of the currently active processors.
KeQueryAuxiliaryCounterFrequency	The KeQueryAuxiliaryCounterFrequency routine returns frequency of the auxiliary counter in units of Hz.
KeQueryDpcWatchdogInformation	The KeQueryDpcWatchdogInformation routine returns the deferred procedure call (DPC) watchdog timer values for the current processor.
KeQueryGroupAffinity	The KeQueryGroupAffinity routine returns an affinity mask that identifies the active logical processors in a specified group in a multiprocessor system.
KeQueryGroupAffinity	The KeQueryGroupAffinity routine returns an affinity mask that identifies the active logical processors in a specified group in a multiprocessor system.

TITLE	DESCRIPTION
KeQueryHardwareCounterConfiguration	The KeQueryHardwareCounterConfiguration routine queries the operating system for the list of hardware counters to use for thread profiling.
KeQueryHighestNodeNumber	The KeQueryHighestNodeNumber routine returns the highest node number in a multiprocessor system that has a non-uniform memory access (NUMA) architecture.
KeQueryHighestNodeNumber	The KeQueryHighestNodeNumber routine returns the highest node number in a multiprocessor system that has a non-uniform memory access (NUMA) architecture.
KeQueryInterruptTime	The KeQueryInterruptTime routine returns the current value of the system interrupt time count, with accuracy to within system clock tick.
KeQueryInterruptTimePrecise	The KeQueryInterruptTimePrecise routine returns the current value of the system interrupt time count, with accuracy to within a microsecond.
KeQueryLogicalProcessorRelationship	The KeQueryLogicalProcessorRelationship routine gets information about the relationships of one or more processors to the other processors in a multiprocessor system.
KeQueryLogicalProcessorRelationship	The KeQueryLogicalProcessorRelationship routine gets information about the relationships of one or more processors to the other processors in a multiprocessor system.
KeQueryMaximumGroupCount	The KeQueryMaximumGroupCount routine returns the maximum number of groups in a multiprocessor system.
KeQueryMaximumGroupCount	The KeQueryMaximumGroupCount routine returns the maximum number of groups in a multiprocessor system.
KeQueryMaximumProcessorCount	The KeQueryMaximumProcessorCount routine returns the maximum number of processors.
KeQueryMaximumProcessorCount	The KeQueryMaximumProcessorCount routine returns the maximum number of processors.
KeQueryMaximumProcessorCountEx	The KeQueryMaximumProcessorCountEx routine returns the maximum number of logical processors in a specified group in a multiprocessor system.
KeQueryMaximumProcessorCountEx	The KeQueryMaximumProcessorCountEx routine returns the maximum number of logical processors in a specified group in a multiprocessor system.
KeQueryNodeActiveAffinity	The KeQueryNodeActiveAffinity routine gets the current processor affinity of a specified node in a multiprocessor system that has a non-uniform memory access (NUMA) architecture.

TITLE	DESCRIPTION
KeQueryNodeActiveAffinity	The KeQueryNodeActiveAffinity routine gets the current processor affinity of a specified node in a multiprocessor system that has a non-uniform memory access (NUMA) architecture.
KeQueryNodeMaximumProcessorCount	The KeQueryNodeMaximumProcessorCount routine returns the maximum number of logical processors that a specified node in a non-uniform memory access (NUMA) multiprocessor system can contain.
KeQueryNodeMaximumProcessorCount	The KeQueryNodeMaximumProcessorCount routine returns the maximum number of logical processors that a specified node in a non-uniform memory access (NUMA) multiprocessor system can contain.
KeQueryPerformanceCounter	The KeQueryPerformanceCounter routine retrieves the current value and frequency of the performance counter.Use KeQueryPerformanceCounter to acquire high resolution (<1us) time stamps for time interval measurements.
KeQueryPerformanceCounter	The KeQueryPerformanceCounter routine retrieves the current value and frequency of the performance counter.Use KeQueryPerformanceCounter to acquire high resolution (<1us) time stamps for time interval measurements.
KeQueryPriorityThread	The KeQueryPriorityThread routine returns the current priority of a particular thread.
KeQueryRuntimeThread	The KeQueryRuntimeThread routine reports the accumulated kernel-mode and user-mode run time of a thread, in clock ticks.
KeQuerySystemTime	The KeQuerySystemTime routine obtains the current system time.
KeQuerySystemTimePrecise	The KeQuerySystemTimePrecise routine retrieves the current system time, and is more precise than the KeQuerySystemTime routine.
KeQueryTickCount	The KeQueryTickCount routine maintains a count of the interval timer interrupts that have occurred since the system was booted.
KeQueryTickCount	The KeQueryTickCount routine maintains a count of the interval timer interrupts that have occurred since the system was booted.
KeQueryTimeIncrement	The KeQueryTimeIncrement routine returns the number of 100-nanosecond units that are added to the system time each time the interval clock interrupts.
KeQueryTotalCycleTimeThread	The KeQueryTotalCycleTimeThread routine returns the accumulated cycle time for the specified thread.

TITLE	DESCRIPTION
KeQueryUnbiasedInterruptTime	The KeQueryUnbiasedInterruptTime routine returns the current value of the system interrupt time count.
KeRaiseIrql	The KeRaiseIrql routine raises the hardware priority to the specified IRQL value, thereby masking off interrupts of equivalent or lower IRQL on the current processor.
KeRaiseIrqlToDpcLevel	The KeRaiseIrqlToDpcLevel routine raises the hardware priority to IRQL = DISPATCH_LEVEL, thereby masking off interrupts of equivalent or lower IRQL on the current processor.
KeRaiseIrqlToDpcLevel	The KeRaiseIrqlToDpcLevel routine raises the hardware priority to IRQL = DISPATCH_LEVEL, thereby masking off interrupts of equivalent or lower IRQL on the current processor.
KeReadStateEvent	The KeReadStateEvent routine returns the current state, signaled or not-signaled, of an event object.
KeReadStateMutex	The KeReadStateMutex routine returns the current state, signaled or not-signaled, of the specified mutex object.
KeReadStateSemaphore	The KeReadStateSemaphore routine returns the current state, signaled or not-signaled, of the specified semaphore object.
KeReadStateTimer	The KeReadStateTimer routine reads the current state of a timer object.
KeRegisterBoundCallback	The KeRegisterBoundCallback routine registers a routine to be called whenever a user-mode bound exception occurs.
KeRegisterBugCheckCallback	The KeRegisterBugCheckCallback routine registers a BugCheckCallback routine, which executes when the operating system issues a bug check.
KeRegisterBugCheckReasonCallback	The KeRegisterBugCheckReasonCallback routine registers a BugCheckDumpIoCallback, BugCheckSecondaryDumpDataCallback, or BugCheckAddPagesCallback routine, which executes when the operating system issues a bug check.
KeRegisterNmiCallback	The KeRegisterNmiCallback routine registers a routine to be called whenever a nonmaskable interrupt (NMI) occurs.
KeRegisterProcessorChangeCallback	The KeRegisterProcessorChangeCallback routine registers a callback function with the operating system so that the operating system will notify the driver when a new processor is added to the hardware partition.
KeReleaseGuardedMutex	The KeReleaseGuardedMutex routine releases a guarded mutex acquired with KeAcquireGuardedMutex or KeTryToAcquireGuardedMutex.
KeReleaseGuardedMutexUnsafe	The KeReleaseGuardedMutexUnsafe routine releases a guarded mutex acquired by KeAcquireGuardedMutexUnsafe.

TITLE	DESCRIPTION
KeReleaseInStackQueuedSpinLock	The KeReleaseInStackQueuedSpinLock routine releases a queued spin lock acquired by KeAcquireInStackQueuedSpinLock.
KeReleaseInStackQueuedSpinLockForDpc	The KeReleaseInStackQueuedSpinLockForDpc routine releases a queued spin lock that was acquired by calling KeAcquireInStackQueuedSpinLockForDpc.
KeReleaseInStackQueuedSpinLockFromDpcLevel	The KeReleaseInStackQueuedSpinLockFromDpcLevel routine releases a queued spin lock acquired by KeAcquireInStackQueuedSpinLockAtDpcLevel.
KeReleaseInterruptSpinLock	The KeReleaseInterruptSpinLock routine releases an interrupt spin lock acquired by KeAcquireInterruptSpinLock.
KeReleaseMutex	The KeReleaseMutex routine releases a mutex object, and specifies whether the caller is to call one of the KeWaitXxx routines as soon as KeReleaseMutex returns control.
KeReleaseSemaphore	The KeReleaseSemaphore routine releases the specified semaphore object.
KeReleaseSpinLock	The KeReleaseSpinLock routine releases a spin lock and restores the original IRQL at which the caller was running.
KeReleaseSpinLockForDpc	The KeReleaseSpinLockForDpc routine releases a spin lock that was acquired by calling KeAcquireSpinLockForDpc.
KeReleaseSpinLockFromDpcLevel	The KeReleaseSpinLockFromDpcLevel routine releases an executive spin lock without changing the IRQL.
KeRemoveByKeyDeviceQueue	The KeRemoveByKeyDeviceQueue routine removes an entry, selected according to a sort key value, from the specified device queue.
KeRemoveDeviceQueue	The KeRemoveDeviceQueue routine removes an entry from the head of a specified device queue.
KeRemoveEntryDeviceQueue	The KeRemoveEntryDeviceQueue routine returns whether the specified entry is in the device queue and removes it, if it was queued, from the device queue.
KeRemoveQueueDpc	The KeRemoveQueueDpc routine removes the specified DPC object from the system DPC queue.
KeResetEvent	The KeResetEvent routine resets a specified event object to a not-signaled state and returns the previous state of that event object.
KeRestoreExtendedProcessorState	The KeRestoreExtendedProcessorState routine restores extended processor state information that was previously saved.

TITLE	DESCRIPTION
KeRestoreFloatingPointState	The KeRestoreFloatingPointState routine restores the nonvolatile floating-point context saved by the preceding call to KeSaveFloatingPointState.
KeRevertToUserAffinityThreadEx	The KeRevertToUserAffinityThreadEx routine restores the previous affinity of the current thread.
KeRevertToUserGroupAffinityThread	The KeRevertToUserGroupAffinityThread routine restores the group affinity of the calling thread to its original value at the time that the thread was created.
KeSaveExtendedProcessorState	The KeSaveExtendedProcessorState routine saves extended processor state information.
KeSaveFloatingPointState	The KeSaveFloatingPointState routine saves the nonvolatile floating-point context so the caller can carry out floating-point operations.
KeSetBasePriorityThread	The KeSetBasePriorityThread routine sets the run-time priority, relative to the current process, for a given thread.
KeSetCoalescableTimer	The KeSetCoalescableTimer routine sets the initial expiration time and period of a timer object and specifies how much delay can be tolerated in the expiration times.
KeSetEvent	The KeSetEvent routine sets an event object to a signaled state if the event was not already signaled, and returns the previous state of the event object.
KeSetHardwareCounterConfiguration	The KeSetHardwareCounterConfiguration routine specifies a list of hardware counters to use for thread profiling.
KeSetImportanceDpc	The KeSetImportanceDpc routine specifies how soon the DPC routine is run.
KeSetImportanceDpc	The KeSetImportanceDpc routine specifies how soon the DPC routine is run.
KeSetKernelStackSwapEnable	The KeSetKernelStackSwapEnable routine enables and disables swapping of the caller's stack to disk.
KeSetPriorityThread	The KeSetPriorityThread routine sets the run-time priority of a driver-created thread.
KeSetSystemAffinityThread	The KeSetSystemAffinityThread routine sets the system affinity of the current thread.
KeSetSystemAffinityThreadEx	The KeSetSystemAffinityThreadEx routine sets the system affinity of the current thread.
KeSetSystemGroupAffinityThread	The KeSetSystemGroupAffinityThread routine changes the group number and affinity mask of the calling thread.

TITLE	DESCRIPTION
KeSetTargetProcessorDpc	The KeSetTargetProcessorDpc routine specifies the processor that a DPC routine will be run on.
KeSetTargetProcessorDpc	The KeSetTargetProcessorDpc routine specifies the processor that a DPC routine will be run on.
KeSetTargetProcessorDpcEx	The KeSetTargetProcessorDpcEx routine specifies the processor that a DPC routine will run on.
KeSetTimer	The KeSetTimer routine sets the absolute or relative interval at which a timer object is to be set to a signaled state and, optionally, supplies a CustomTimerDpc routine to be executed when that interval expires.
KeSetTimerEx	The KeSetTimerEx routine sets the absolute or relative interval at which a timer object is to be set to a signaled state, optionally supplies a CustomTimerDpc routine to be executed when that interval expires, and optionally supplies a recurring interval for the timer.
KeStallExecutionProcessor	The KeStallExecutionProcessor routine stalls the caller on the current processor for a specified time interval.
KeStallExecutionProcessor	The KeStallExecutionProcessor routine stalls the caller on the current processor for a specified time interval.
KeSynchronizeExecution	The KeSynchronizeExecution routine synchronizes the execution of the specified routine with the interrupt service routine (ISR) that is assigned to a set of one or more interrupt objects.
KeTestSpinLock	The KeTestSpinLock routine tests for the availability of a spin lock.
KeTryToAcquireSpinLockAtDpcLevel	The KeTryToAcquireSpinLockAtDpcLevel routine attempts to acquire a spin lock at DISPATCH_LEVEL.
KeWaitForMultipleObjects	The KeWaitForMultipleObjects routine puts the current thread into an alertable or nonalertable wait state until any or all of a number of dispatcher objects are set to a signaled state or (optionally) until the wait times out.
KeWaitForSingleObject	The KeWaitForSingleObject routine puts the current thread into a wait state until the given dispatcher object is set to a signaled state or (optionally) until the wait times out.
KIPI_BROADCAST_WORKER	The IpiGenericCall routine runs simultaneously on all processors.
KMESSAGE_SERVICE_ROUTINE	An InterruptMessageService routine services a message-signaled interrupt.
KSERVICE_ROUTINE	The InterruptService routine (ISR) quickly services a device interrupt and schedules post-interrupt processing of received data, if necessary.

TITLE	DESCRIPTION
KSTART_ROUTINE	The ThreadStart routine provides an entry point for a driver-created system thread.
KSYNCHRONIZE_ROUTINE	The SynchCritSection routine is used to access hardware resources or driver data that are shared with a driver's InterruptService routine.
MM_MDL_ROUTINE	A driver-supplied callback routine that is invoked after a memory descriptor list (MDL) is mapped by calling the MmMapMdl function.
MmAdvanceMdl	The MmAdvanceMdl routine advances the beginning of an MDL's virtual memory range by the specified number of bytes.
MmAllocateContiguousMemory	The MmAllocateContiguousMemory routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateContiguousMemory	The MmAllocateContiguousMemory routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateContiguousMemorySpecifyCache	The MmAllocateContiguousMemorySpecifyCache routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateContiguousMemorySpecifyCache	The MmAllocateContiguousMemorySpecifyCache routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateContiguousMemorySpecifyCacheNode	The MmAllocateContiguousMemorySpecifyCacheNode routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateContiguousMemorySpecifyCacheNode	The MmAllocateContiguousMemorySpecifyCacheNode routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateContiguousNodeMemory	The MmAllocateContiguousNodeMemory routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateContiguousNodeMemory	The MmAllocateContiguousNodeMemory routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateMappingAddress	The MmAllocateMappingAddress routine reserves a range of system virtual address space of the specified size.
MmAllocateMdlForIoSpace	The MmAllocateMdlForIoSpace routine allocates an MDL and initializes this MDL to describe a set of physical address ranges in I/O address space.

TITLE	DESCRIPTION
MmAllocateNodePagesForMdlEx	The MmAllocateNodePagesForMdlEx routine allocates nonpaged physical memory from an ideal node, and allocates an MDL structure to describe this memory.
MmAllocateNonCachedMemory	The MmAllocateNonCachedMemory routine allocates a virtual address range of noncached and cache-aligned memory.
MmAllocatePagesForMdl	The MmAllocatePagesForMdl routine allocates zero-filled, nonpaged, physical memory pages to an MDL.
MmAllocatePagesForMdlEx	The MmAllocatePagesForMdlEx routine allocates nonpaged, physical memory pages to an MDL.
MmBuildMdlForNonPagedPool	The MmBuildMdlForNonPagedPool routine receives an MDL that specifies a nonpaged virtual memory buffer, and updates it to describe the underlying physical pages.
MmCopyMemory	The MmCopyMemory routine copies the specified range of virtual or physical memory into the caller-supplied buffer.
MmFreeContiguousMemory	The MmFreeContiguousMemory routine releases a range of physically contiguous memory that was allocated by an MmAllocateContiguousMemoryXxx routine.
MmFreeContiguousMemory	The MmFreeContiguousMemory routine releases a range of physically contiguous memory that was allocated by an MmAllocateContiguousMemoryXxx routine.
MmFreeContiguousMemorySpecifyCache	The MmFreeContiguousMemorySpecifyCache routine frees a buffer that was allocated by an MmAllocateContiguousMemorySpecifyCacheXxx routine.
MmFreeContiguousMemorySpecifyCache	The MmFreeContiguousMemorySpecifyCache routine frees a buffer that was allocated by an MmAllocateContiguousMemorySpecifyCacheXxx routine.
MmFreeMappingAddress	The MmFreeMappingAddress routine frees a range of virtual memory reserved by the MmAllocateMappingAddress routine.
MmFreeNonCachedMemory	The MmFreeNonCachedMemory routine releases a range of noncached memory that was allocated by the MmAllocateNonCachedMemory routine.
MmFreePagesFromMdl	The MmFreePagesFromMdl routine frees all the physical pages that are described by an MDL that was created by the MmAllocatePagesForMdl routine.
MmGetPhysicalAddress	The MmGetPhysicalAddress routine returns the physical address corresponding to a valid nonpaged virtual address.
MmGetSystemAddressForMdl	The MmGetSystemAddressForMdl routine is obsolete for Windows 2000 and later versions of Windows, and for Windows Me.

TITLE	DESCRIPTION
MmGetSystemRoutineAddress	The MmGetSystemRoutineAddress routine returns a pointer to a function specified by SystemRoutineName.
MmIsAddressValid	The MmIsAddressValid routine checks whether a page fault will occur for a read or write operation at a given virtual address.Warning We do not recommend using this function.
MmIsDriverSuspectForVerifier	The MmIsDriverSuspectForVerifier routine indicates whether the driver represented by the specified driver object is in the list of drivers that are selected to be verified by Driver Verifier.
MmIsDriverVerifying	The MmIsDriverVerifying routine indicates whether the kernel-mode driver that is identified by the specified driver object is being verified or calls a driver that is being verified by Driver Verifier.
MmIsDriverVerifyingByAddress	The MmIsDriverVerifyingByAddress routine checks whether the kernel-mode driver that is identified by the specified image address is being verified or calls a driver that is being verified by Driver Verifier.
MmIsThisAnNtAsSystem	The MmIsThisAnNtAsSystem routine is obsolete for Windows XP and later versions of Windows. Use RtlGetVersion or RtlVerifyVersionInfo instead.
MmLockPagableCodeSection	The MmLockPagableCodeSection routine locks a section of driver code, containing a set of driver routines marked with a special compiler directive, into system space.
MmLockPagableDataSection	The MmLockPagableDataSection routine locks an entire section of driver data into system space.
MmLockPagableSectionByHandle	The MmLockPagableSectionByHandle routine locks a pageable code or data section into system memory by incrementing the reference count on the handle to the section.
MmMapIoSpace	The MmMapIoSpace routine maps the given physical address range to nonpaged system space.
MmMapIoSpaceEx	The MmMapIoSpaceEx routine maps the given physical address range to non-paged system space using the specified page protection.
MmMapLockedPages	The MmMapLockedPages routine is obsolete for Windows 2000 and later versions of Windows, and for Windows Me.
MmMapLockedPagesSpecifyCache	The MmMapLockedPagesSpecifyCache routine maps the physical pages that are described by an MDL to a virtual address, and enables the caller to specify the cache attribute that is used to create the mapping.
MmMapLockedPagesWithReservedMapping	The MmMapLockedPagesWithReservedMapping routine maps all or part of an address range that was previously reserved by the MmAllocateMappingAddress routine.

TITLE	DESCRIPTION
MmMapMdl	This function maps physical pages described by a memory descriptor list (MDL) into the system virtual address space.
MmPageEntireDriver	The MmPageEntireDriver routine causes all of a driver's code and data to be made pageable, overriding the attributes of the various sections that make up the driver's image.
MmProbeAndLockPages	The MmProbeAndLockPages routine probes the specified virtual memory pages, makes them resident, and locks them in memory.
MmProbeAndLockSelectedPages	The MmProbeAndLockSelectedPages routine probes the selected virtual memory pages, makes them resident, and locks them in memory.
MmProtectMdlSystemAddress	The MmProtectMdlSystemAddress routine sets the protection type for a memory address range.
MmQuerySystemSize	The MmQuerySystemSize routine returns an estimate of the amount of memory in the system.
MmResetDriverPaging	The MmResetDriverPaging routine resets the pageable status of a driver's sections to that specified when the driver was compiled.
MmSecureVirtualMemory	The MmSecureVirtualMemory routine secures a user-space memory address range so that it cannot be freed and its protection type cannot be made more restrictive.
MmSizeOfMdl	The MmSizeOfMdl routine returns the number of bytes to allocate for an MDL describing a given address range.
MmUnlockPagableImageSection	The MmUnlockPagableImageSection routine releases a section of driver code or driver data, previously locked into system space with MmLockPagableCodeSection, MmLockPagableDataSection or MmLockPagableSectionByHandle, so the section can be paged out again.
MmUnlockPages	The MmUnlockPages routine unlocks the physical pages that are described by the specified memory descriptor list (MDL).
MmUnmapIoSpace	The MmUnmapIoSpace routine unmaps a specified range of physical addresses previously mapped by MmMapIoSpace.
MmUnmapLockedPages	The MmUnmapLockedPages routine releases a mapping that was set up by a preceding call to the MmMapLockedPages or MmMapLockedPagesSpecifyCache routine.
MmUnmapReservedMapping	The MmUnmapReservedMapping routine unmaps a memory buffer that was mapped by the MmMapLockedPagesWithReservedMapping routine.

TITLE	DESCRIPTION
MmUnsecureVirtualMemory	The MmUnsecureVirtualMemory routine unsecures a memory address range secured by the MmSecureVirtualMemory routine.
NtAllocateVirtualMemory	The ZwAllocateVirtualMemory routine reserves, commits, or both, a region of pages within the user-mode virtual address space of a specified process.
NtClose	The ZwClose routine closes an object handle.
NtCommitComplete	The ZwCommitComplete routine notifies KTM that the calling resource manager has finished committing a transaction's data.
NtCommitEnlistment	The ZwCommitEnlistment routine initiates the commit operation for a specified enlistment's transaction.
NtCommitTransaction	The ZwCommitTransaction routine initiates a commit operation for a specified transaction.
NtCreateEnlistment	The ZwCreateEnlistment routine creates a new enlistment object for a transaction.
NtCreateFile	The ZwCreateFile routine creates a new file or opens an existing file.
NtCreateResourceManager	The ZwCreateResourceManager routine creates a resource manager object.
NtCreateSection	The ZwCreateSection routine creates a section object.
NtCreateTransaction	The ZwCreateTransaction routine creates a transaction object.
NtCreateTransactionManager	The ZwCreateTransactionManager routine creates a new transaction manager object.
NtDeviceIoControlFile	The ZwDeviceIoControlFile routine sends a control code directly to a specified device driver, causing the corresponding driver to perform the specified operation.
NtDuplicateToken	The ZwDuplicateToken function creates a handle to a new access token that duplicates an existing token. This function can create either a primary token or an impersonation token.
NtEnumerateTransactionObject	The ZwEnumerateTransactionObject routine enumerates the KTM objects on a computer.
NtFlushBuffersFileEx	The ZwFlushBuffersFileEx routine is called by a file system filter driver to send a flush request for a given file to the file system. An optional flush operation flag can be set to control how file data is written to storage.

TITLE	DESCRIPTION
NtFreeVirtualMemory	The ZwFreeVirtualMemory routine releases, decommits, or both, a region of pages within the virtual address space of a specified process.
NtFsControlFile	The ZwFsControlFile routine sends a control code directly to a specified file system or file system filter driver, causing the corresponding driver to perform the specified action.
NtGetNotificationResourceManager	The ZwGetNotificationResourceManager routine retrieves the next transaction notification from a specified resource manager's notification queue.
NtLockFile	The NtLockFile routine requests a byte-range lock for the specified file.
NtOpenEnlistment	The ZwOpenEnlistment routine obtains a handle to an existing enlistment object.
NtOpenFile	The ZwOpenFile routine opens an existing file, directory, device, or volume.
NtOpenProcess	The ZwOpenProcess routine opens a handle to a process object and sets the access rights to this object.
NtOpenProcessTokenEx	The ZwOpenProcessTokenEx routine opens the access token associated with a process.
NtOpenResourceManager	The ZwOpenResourceManager routine returns a handle to an existing resource manager object.
NtOpenThreadTokenEx	The ZwOpenThreadTokenEx routine opens the access token associated with a thread.
NtOpenTransaction	The ZwOpenTransaction routine obtains a handle to an existing transaction object.
NtOpenTransactionManager	The ZwOpenTransactionManager routine obtains a handle to an existing transaction manager object.
NtPowerInformation	The ZwPowerInformation routine sets or retrieves system power information.
NtPowerInformation	The ZwPowerInformation routine sets or retrieves system power information.
NtPrepareComplete	The ZwPrepareComplete routine notifies KTM that the calling resource manager has finished preparing a transaction's data.
NtPrepareEnlistment	The ZwPrepareEnlistment routine initiates the prepare operation for a specified enlistment's transaction.
NtPrePrepareComplete	The ZwPrePrepareComplete routine notifies KTM that the calling resource manager has finished preliminary preparation of a transaction's data.

TITLE	DESCRIPTION
NtPrePrepareEnlistment	The ZwPrePrepareEnlistment routine initiates the pre-prepare operation for a specified enlistment's transaction.
NtQueryDirectoryFile	The ZwQueryDirectoryFile routine returns various kinds of information about files in the directory specified by a given file handle.
NtQueryInformationEnlistment	The ZwQueryInformationEnlistment routine retrieves information about a specified enlistment object.
NtQueryInformationFile	The ZwQueryInformationFile routine returns various kinds of information about a file object.
NtQueryInformationResourceManager	The ZwQueryInformationResourceManager routine retrieves information about a specified resource manager object.
NtQueryInformationToken	The ZwQueryInformationToken routine retrieves a specified type of information about an access token. The calling process must have appropriate access rights to obtain the information.
NtQueryInformationTransaction	The ZwQueryInformationTransaction routine retrieves information about a specified transaction.
NtQueryInformationTransactionManager	The ZwQueryInformationTransactionManager routine retrieves information about a specified transaction manager object.
NtQueryObject	The ZwQueryObject routine provides information about a supplied object.
NtQueryQuotaInformationFile	The ZwQueryQuotaInformationFile routine retrieves quota entries associated with the volume specified by the FileHandle parameter.
NtQuerySecurityObject	The ZwQuerySecurityObject routine retrieves a copy of an object's security descriptor.
NtQueryVirtualMemory	The ZwQueryVirtualMemory routine determines the state, protection, and type of a region of pages within the virtual address space of the subject process.
NtQueryVolumeInformationFile	The ZwQueryVolumeInformationFile routine retrieves information about the volume associated with a given file, directory, storage device, or volume.
NtReadFile	The ZwReadFile routine reads data from an open file.
NtReadOnlyEnlistment	The ZwReadOnlyEnlistment routine sets a specified enlistment to be read-only.
NtRecoverEnlistment	The ZwRecoverEnlistment routine initiates a recovery operation for the transaction that is associated with a specified enlistment.

TITLE	DESCRIPTION
NtRecoverResourceManager	The ZwRecoverResourceManager routine tries to recover the transaction that is associated with each enlistment of a specified resource manager object.
NtRecoverTransactionManager	The ZwRecoverTransactionManager routine reconstructs the state of the transaction manager object (including all transactions, enlistments, and resource managers) from the recovery information that is in the log stream.
NtRenameTransactionManager	The NtRenameTransactionManager routine changes the identity of the transaction manager object that is stored in the CLFS log file stream contained in the log file name.
NtRollbackComplete	The ZwRollbackComplete routine notifies KTM that the calling resource manager has finished rolling back a transaction's data.
NtRollbackEnlistment	The ZwRollbackEnlistment routine rolls back the transaction that is associated with a specified enlistment.
NtRollbackTransaction	The ZwRollbackTransaction routine initiates a rollback operation for a specified transaction.
NtRollforwardTransactionManager	The ZwRollforwardTransactionManager routine initiates recovery operations for all of the in-progress transactions that are assigned to a specified transaction manager.
NtSetInformationEnlistment	The ZwSetInformationEnlistment routine sets information for a specified enlistment object.
NtSetInformationFile	The ZwSetInformationFile routine changes various kinds of information about a file object.
NtSetInformationResourceManager	The ZwSetInformationResourceManager routine is not used.
NtSetInformationThread	The ZwSetInformationThread routine sets the priority of a thread.
NtSetInformationToken	The ZwSetInformationToken routine modifies information in a specified token. The calling process must have appropriate access rights to set the information.
NtSetInformationTransaction	The ZwSetInformationTransaction routine sets information for a specified transaction.
NtSetInformationTransactionManager	Do not call this routine from kernel-mode code.
NtSetQuotaInformationFile	The ZwSetQuotaInformationFile routine changes quota entries for the volume associated with the FileHandle parameter. All of the quota entries in the specified buffer are applied to the volume.
NtSetSecurityObject	The ZwSetSecurityObject routine sets an object's security state.

TITLE	DESCRIPTION
NtSinglePhaseReject	The ZwSinglePhaseReject routine informs KTM that the calling resource manager will not support single-phase commit operations for a specified enlistment.
NtUnlockFile	The ZwUnlockFile routine unlocks a byte-range lock in a file.
NtWriteFile	The ZwWriteFile routine writes data to an open file.
ObCloseHandle	The ObCloseHandle routine closes an object handle.
ObDereferenceObject	The ObDereferenceObject routine decrements the given object's reference count and performs retention checks.
ObDereferenceObjectDeferDelete	The ObDereferenceObjectDeferDelete routine decrements the reference count for the given object, checks for object retention, and avoids deadlocks.
ObDereferenceObjectDeferDeleteWithTag	The ObDereferenceObjectDeferDeleteWithTag routine decrements the reference count for the specified object, defers deletion of the object to avoid deadlocks, and writes a four-byte tag value to the object to support object reference tracing.
ObDereferenceObjectWithTag	The ObDereferenceObjectWithTag routine decrements the reference count of the specified object, and writes a four-byte tag value to the object to support object reference tracing.
ObfReferenceObject	The ObReferenceObject routine increments the reference count to the given object.
ObGetObjectSecurity	The ObGetObjectSecurity routine gets the security descriptor for a given object.
ObReferenceObject	The ObReferenceObject routine increments the reference count to the given object.
ObReferenceObjectByHandle	The ObReferenceObjectByHandle routine provides access validation on the object handle, and, if access can be granted, returns the corresponding pointer to the object's body.
ObReferenceObjectByHandleWithTag	The ObReferenceObjectByHandleWithTag routine increments the reference count of the object that is identified by the specified handle, and writes a four-byte tag value to the object to support object reference tracing.
ObReferenceObjectByPointer	The ObReferenceObjectByPointer routine increments the pointer reference count for a given object.
ObReferenceObjectByPointerWithTag	The ObReferenceObjectByPointerWithTag routine increments the reference count of the specified object, and writes a four-byte tag value to the object to support object reference tracing.

TITLE	DESCRIPTION
ObReferenceObjectWithTag	The ObReferenceObjectWithTag routine increments the reference count of the specified object, and writes a four-byte tag value to the object to support object reference tracing.
ObRegisterCallbacks	The ObRegisterCallbacks routine registers a list of callback routines for thread, process, and desktop handle operations.
ObReleaseObjectSecurity	The ObReleaseObjectSecurity routine is the reciprocal to ObGetObjectSecurity.
ObUnRegisterCallbacks	The ObUnRegisterCallbacks routine unregisters a set of callback routines that were registered with the ObRegisterCallbacks routine.
PALLOCATE_ADAPTER_CHANNEL	The AllocateAdapterChannel routine prepares the system for a DMA operation on behalf of the target device object, and then calls the driver-supplied AdapterControl routine to carry out the DMA operation.
PALLOCATE_ADAPTER_CHANNEL_EX	The AllocateAdapterChannelEx routine allocates the resources that are needed to perform a DMA transfer, and then calls the driver-supplied AdapterControl routine to initiate the DMA transfer.
PALLOCATE_COMMON_BUFFER	The AllocateCommonBuffer routine allocates memory and maps it so that it is simultaneously accessible from both the processor and a device for DMA operations.
PALLOCATE_COMMON_BUFFER_EX	The AllocateCommonBufferEx routine allocates memory for a common buffer and maps this memory so that it can be accessed both by the processor and by a device that performs DMA operations.
PBUILD_MDL_FROM_SCATTER_GATHER_LIST	The BuildMdlFromScatterGatherList routine builds an MDL from a scatter/gather list allocated by the system.Note This routine is reserved for system use.
PBUILD_SCATTER_GATHER_LIST	The BuildScatterGatherList routine prepares the system for a DMA operation, using a driver-supplied buffer to build the scatter/gather list.
PBUILD_SCATTER_GATHER_LIST_EX	The BuildScatterGatherListEx routine allocates the resources that are required for a DMA transfer, builds a scatter/gather list, and calls the driver-supplied AdapterListControl routine to initiate the DMA transfer.
PCALCULATE_SCATTER_GATHER_LIST_SIZE	The CalculateScatterGatherList routine calculates the size, in bytes, of scatter/gather list necessary to hold a given buffer.
PCANCEL_ADAPTER_CHANNEL	The CancelAdapterChannel routine tries to cancel a pending request to allocate a DMA channel.
PCANCEL_MAPPED_TRANSFER	The CancelMappedTransfer routine cancels a system DMA transfer that is currently mapped to an adapter.

TITLE	DESCRIPTION
PCI_MSIX_MASKUNMASK_ENTRY	The MaskTableEntry routine masks an interrupt in the MSI-X hardware interrupt table.
PCI_MSIX_SET_ENTRY	The SetTableEntry routine sets the message ID for a table entry in the MSI-X hardware interrupt table.
PCLFS_CLIENT_ADVANCE_TAIL_CALLBACK	The ClfsAdvanceTailCallback function advances the base log sequence number (LSN) of the client's log.
PCLFS_CLIENT_LFF_HANDLER_COMPLETE_CALLBACK	The ClfsLogGrowthCompleteCallback function implements the actions that the client will take when space is freed in a log that had previously been full.
PCLFS_CLIENT_LOG_UNPINNED_CALLBACK	The ClfsLogUnpinnedCallback function implements any actions that the client will take when a log that had previously been pinned becomes unpinned.
PCONFIGURE_ADAPTER_CHANNEL	The ConfigureAdapterChannel routine invokes a custom function that is implemented by the DMA controller represented by an adapter object.
PCREATE_PROCESS_NOTIFY_ROUTINE	Process-creation callback implemented by a driver to track the system-wide creation and deletion of processes against the driver's internal state.
PCREATE_PROCESS_NOTIFY_ROUTINE_EX	A callback routine implemented by a driver to notify the caller when a process is created or exits.
PCREATE_THREAD_NOTIFY_ROUTINE	A callback routine implemented by a driver to notify the caller when a thread is created or deleted.
PDEVICE_RESET_HANDLER	The DeviceReset routine is used to reset and recover a malfunctioning device.
PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE	The PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_EXTENDED_ADDRESS structure.
PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE	The PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_EXTENDED_ADDRESS structure.
PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE	The PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_EXTENDED_ADDRESS structure.
PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE	The PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_EXTENDED_ADDRESS structure.
PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE	The PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_GPIO_RESOURCE structure.

TITLE	DESCRIPTION
PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE	The PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_GPIO_RESOURCE structure.
PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE	The PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_GPIO_RESOURCE structure.
PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE	The PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_GPIO_RESOURCE structure.
PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE	The PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_INTERRUPT_RESOURCE structure.
PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE	The PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_INTERRUPT_RESOURCE structure.
PEP_ACPI_INITIALIZE_IOPORT_RESOURCE	The PEP_ACPI_INITIALIZE_IOPORT_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_IO_MEMORY_RESOURCE structure.
PEP_ACPI_INITIALIZE_IOPORT_RESOURCE	The PEP_ACPI_INITIALIZE_IOPORT_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_IO_MEMORY_RESOURCE structure.
PEP_ACPI_INITIALIZE_MEMORY_RESOURCE	The PEP_ACPI_INITIALIZE_MEMORY_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_IO_MEMORY_RESOURCE structure.
PEP_ACPI_INITIALIZE_MEMORY_RESOURCE	The PEP_ACPI_INITIALIZE_MEMORY_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_IO_MEMORY_RESOURCE structure.
PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE	The PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_I2C_RESOURCE structure.
PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE	The PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_I2C_RESOURCE structure.
PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE	The PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_SPI_RESOURCE structure.
PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE	The PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_SPI_RESOURCE structure.
PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE	The PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_UART_RESOURCE structure.

TITLE	DESCRIPTION
PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE	The PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_UART_RESOURCE structure.
PEPCALLBACKNOTIFYACPI	An AcceptAcpiNotification event callback routine handles ACPI notifications from the Windows power management framework (PoFx).
PEPCALLBACKNOTIFYACPI	An AcceptAcpiNotification event callback routine handles ACPI notifications from the Windows power management framework (PoFx).
PEPCALLBACKNOTIFYDPM	An AcceptDeviceNotification event callback routine handles device power management (DPM) notifications from the Windows power management framework (PoFx).
PEPCALLBACKNOTIFYDPM	An AcceptDeviceNotification event callback routine handles device power management (DPM) notifications from the Windows power management framework (PoFx).
PEPCALLBACKNOTIFYPPM	An AcceptProcessorNotification event callback routine handles processor power management (PPM) notifications from the Windows power management framework (PoFx).
PEPCALLBACKNOTIFYPPM	An AcceptProcessorNotification event callback routine handles processor power management (PPM) notifications from the Windows power management framework (PoFx).
PEPCALLBACKPOWERONCRASHDUMPDEVICE	The PowerOnDumpDeviceCallback callback routine turns on the crash-dump device.
PEPCALLBACKPOWERONCRASHDUMPDEVICE	The PowerOnDumpDeviceCallback callback routine turns on the crash-dump device.
PFLUSH_ADAPTER_BUFFERS	The FlushAdapterBuffers routine flushes any data remaining in the system DMA controller's internal cache or in a bus-master adapter's internal cache at the end of a DMA transfer operation.
PFLUSH_ADAPTER_BUFFERS_EX	The FlushAdapterBuffersEx routine flushes any data that remains in the data cache at the end of a DMA transfer operation performed by a system DMA controller or bus-master device.
PFREE_ADAPTER_CHANNEL	The FreeAdapterChannel routine releases the system DMA controller when a driver has completed all DMA operations necessary to satisfy the current IRP.
PFREE_ADAPTER_OBJECT	The FreeAdapterObject routine releases the specified adapter object after a driver has completed all DMA operations.
PFREE_COMMON_BUFFER	The FreeCommonBuffer routine frees a common buffer allocated by AllocateCommonBuffer, along with all resources the buffer uses.

TITLE	DESCRIPTION
PFREE_MAP_REGISTERS	The FreeMapRegisters routine releases a set of map registers that were saved from a call to AllocateAdapterChannel.
PGET_DMA_ADAPTER_INFO	The GetDmaAdapterInfo routine retrieves information about the hardware capabilities of a system DMA channel.
PGET_DMA_ALIGNMENT	The GetDmaAlignment routine returns the alignment requirements of the DMA system.
PGET_DMA_TRANSFER_INFO	The GetDmaTransferInfo routine calculates the allocation requirements for a scatter/gather DMA transfer.
PGET_LOCATION_STRING	The PnpGetLocationString routine provides the device-specific part of the device's SPDRP_LOCATION_PATHS property.
PGET_SCATTER_GATHER_LIST	The GetScatterGatherList routine prepares the system for a DMA scatter/gather operation on behalf of the target device object, through either the system DMA controller or a bus-master adapter.
PGET_SCATTER_GATHER_LIST_EX	The GetScatterGatherListEx routine allocates the resources that are required for a DMA transfer, builds a scatter/gather list, and calls the driver-supplied AdapterListControl routine to initiate the DMA transfer.
pHalExamineMBR	The HalExamineMBR routine reads the master boot record (MBR) of a disk and returns data from the MBR if the MBR is of the type specified by the caller.
PINITIALIZE_DMA_TRANSFER_CONTEXT	The InitializeDmaTransferContext routine initializes an opaque DMA transfer context that is used to track pending allocations of DMA resources.
PINTERFACE_DEREFERENCE	The InterfaceDereference routine decrements the reference count on a driver-defined interface.
PINTERFACE_DEREFERENCE	The InterfaceDereference routine decrements the reference count on a driver-defined interface.
PINTERFACE_DEREFERENCE	The InterfaceDereference routine decrements the reference count on a driver-defined interface.
PINTERFACE_REFERENCE	The InterfaceReference routine increments the reference count on a driver-defined interface.
PINTERFACE_REFERENCE	The InterfaceReference routine increments the reference count on a driver-defined interface.
PINTERFACE_REFERENCE	The InterfaceReference routine increments the reference count on a driver-defined interface.
PLOAD_IMAGE_NOTIFY_ROUTINE	Called by the operating system to notify the driver when a driver image or a user image (for example, a DLL or EXE) is mapped into virtual memory.

TITLE	DESCRIPTION
PMAP_TRANSFER	The MapTransfer routine sets up map registers for an adapter object to map a DMA transfer from a locked-down buffer.
PMAP_TRANSFER_EX	The MapTransferEx routine sets up map registers to map the physical addresses in a scatter/gather list to the logical addresses that are required to do a DMA transfer.
PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK	The ComponentActiveConditionCallback callback routine notifies the driver that the specified component completed a transition from the idle condition to the active condition.
PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK	The ComponentActiveConditionCallback callback routine notifies the driver that the specified component completed a transition from the idle condition to the active condition.
PO_FX_COMPONENT_CRITICAL_TRANSITION_CALLBACK	The ComponentCriticalTransitionCallback callback routine handles a transition of the specified component between the F0 (fully on) and low-power Fx component power states.
PO_FX_COMPONENT_CRITICAL_TRANSITION_CALLBACK	The ComponentCriticalTransitionCallback callback routine handles a transition of the specified component between the F0 (fully on) and low-power Fx component power states.
PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK	The ComponentIdleConditionCallback callback routine notifies the driver that the specified component completed a transition from the active condition to the idle condition.
PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK	The ComponentIdleConditionCallback callback routine notifies the driver that the specified component completed a transition from the active condition to the idle condition.
PO_FX_COMPONENT_IDLE_STATE_CALLBACK	The ComponentIdleStateCallback callback routine notifies the driver of a pending change to the Fx power state of the specified component.
PO_FX_COMPONENT_IDLE_STATE_CALLBACK	The ComponentIdleStateCallback callback routine notifies the driver of a pending change to the Fx power state of the specified component.
PO_FX_COMPONENT_PERF_STATE_CALLBACK	The ComponentPerfStateCallback callback routine notifies the driver that its request to change the performance state of a component is complete.
PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK	The DevicePowerNotRequiredCallback callback routine notifies the device driver that the device is not required to stay in the D0 power state.
PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK	The DevicePowerNotRequiredCallback callback routine notifies the device driver that the device is not required to stay in the D0 power state.
PO_FX_DEVICE_POWER_REQUIRED_CALLBACK	The DevicePowerRequiredCallback callback routine notifies the device driver that the device must enter and remain in the D0 power state.

TITLE	DESCRIPTION
PO_FX_DEVICE_POWER_REQUIRED_CALLBACK	The DevicePowerRequiredCallback callback routine notifies the device driver that the device must enter and remain in the D0 power state.
PO_FX_POWER_CONTROL_CALLBACK	The PowerControlCallback callback routine performs a power control operation that is requested by the power management framework (PoFx).
PO_FX_POWER_CONTROL_CALLBACK	The PowerControlCallback callback routine performs a power control operation that is requested by the power management framework (PoFx).
POB_POST_OPERATION_CALLBACK	The ObjectPostCallback routine is called by the operating system after a process or thread handle operation occurs.
POB_PRE_OPERATION_CALLBACK	The ObjectPreCallback routine is called by the operating system when a process or thread handle operation occurs.
PoCallDriver	The PoCallDriver routine passes a power IRP to the next-lower driver in the device stack. (Windows Server 2003, Windows XP, and Windows 2000 only.).
PoCallDriver	The PoCallDriver routine passes a power IRP to the next-lower driver in the device stack. (Windows Server 2003, Windows XP, and Windows 2000 only.).
PoClearPowerRequest	The PoClearPowerRequest routine decrements the count for the specified power request type.
PoClearPowerRequest	The PoClearPowerRequest routine decrements the count for the specified power request type.
PoCreatePowerRequest	The PoCreatePowerRequest routine creates a power request object.
PoCreatePowerRequest	The PoCreatePowerRequest routine creates a power request object.
PoDeletePowerRequest	The PoDeletePowerRequest routine deletes a power request object.
PoDeletePowerRequest	The PoDeletePowerRequest routine deletes a power request object.
PoEndDeviceBusy	The PoEndDeviceBusy routine marks the end of a period of time in which the device is busy.
PoEndDeviceBusy	The PoEndDeviceBusy routine marks the end of a period of time in which the device is busy.
PoFxActivateComponent	The PoFxActivateComponent routine increments the activation reference count on the specified component.

TITLE	DESCRIPTION
POFXCALLBACKCRITICALRESOURCE	The TransitionCriticalResource routine changes the active/inactive state of a core system component.
POFXCALLBACKCRITICALRESOURCE	The TransitionCriticalResource routine changes the active/inactive state of a core system component.
POFXCALLBACKENUMERATEUNMASKEDINTERRUPTS	The EnumerateUnmaskedInterrupts routine enumerates interrupt sources whose interrupts are unmasked and enabled.
POFXCALLBACKENUMERATEUNMASKEDINTERRUPTS	The EnumerateUnmaskedInterrupts routine enumerates interrupt sources whose interrupts are unmasked and enabled.
POFXCALLBACKPLATFORMIDLEVETO	The PlatformIdleVeto routine increments or decrements the veto count for a veto code for a platform idle state.
POFXCALLBACKPLATFORMIDLEVETO	The PlatformIdleVeto routine increments or decrements the veto count for a veto code for a platform idle state.
POFXCALLBACKPROCESSORHALT	The ProcessorHalt routine prepares the processor to be halted.
POFXCALLBACKPROCESSORHALT	The ProcessorHalt routine prepares the processor to be halted.
POFXCALLBACKPROCESSORIDLEVETO	The ProcessorIdleVeto routine increments or decrements the veto count for a veto code for a processor idle state.
POFXCALLBACKPROCESSORIDLEVETO	The ProcessorIdleVeto routine increments or decrements the veto count for a veto code for a processor idle state.
POFXCALLBACKREQUESTCOMMON	The RequestCommon routine is a generic request handler.
POFXCALLBACKREQUESTCOMMON	The RequestCommon routine is a generic request handler.
POFXCALLBACKREQUESTINTERRUPT	The RequestInterrupt routine requests that the operating system replay an edge-triggered interrupt that might have been lost while the hardware platform was in a low-power state.
POFXCALLBACKREQUESTINTERRUPT	The RequestInterrupt routine requests that the operating system replay an edge-triggered interrupt that might have been lost while the hardware platform was in a low-power state.
POFXCALLBACKREQUESTWORKER	The RequestWorker routine is called by a platform extension plug-in (PEP) to inform the Windows power management framework (PoFx) that the platform extension plug-in (PEP) has a work request to submit on behalf of the specified device.
POFXCALLBACKREQUESTWORKER	The RequestWorker routine is called by a platform extension plug-in (PEP) to inform the Windows power management framework (PoFx) that the platform extension plug-in (PEP) has a work request to submit on behalf of the specified device.

TITLE	DESCRIPTION
POFXCALLBACKUPDATEPLATFORMIDLESTATE	The UpdatePlatformIdleState routine is called by the platform extension plug-in (PEP) to update the properties of the specified platform idle state.
POFXCALLBACKUPDATEPLATFORMIDLESTATE	The UpdatePlatformIdleState routine is called by the platform extension plug-in (PEP) to update the properties of the specified platform idle state.
POFXCALLBACKUPDATEPROCESSORIDLESTATE	The UpdateProcessorIdleState routine is called by the platform extension plug-in (PEP) to update the properties of the specified processor idle state.
POFXCALLBACKUPDATEPROCESSORIDLESTATE	The UpdateProcessorIdleState routine is called by the platform extension plug-in (PEP) to update the properties of the specified processor idle state.
PoFxCompleteDevicePowerNotRequired	The PoFxCompleteDevicePowerNotRequired routine notifies the power management framework (PoFx) that the calling driver has completed its response to a call to the driver's DevicePowerNotRequiredCallback callback routine.
PoFxCompleteIdleCondition	The PoFxCompleteIdleCondition routine informs the power management framework (PoFx) that the specified component has completed a pending change to the idle condition.
PoFxCompleteIdleState	The PoFxCompleteIdleState routine informs the power management framework (PoFx) that the specified component has completed a pending change to an Fx state.
PoFxIdleComponent	The PoFxIdleComponent routine decrements the activation reference count on the specified component.
PoFxIssueComponentPerfStateChange	The PoFxIssueComponentPerfStateChange routine submits a request to place a device component in a particular performance state.
PoFxIssueComponentPerfStateChangeMultiple	The PoFxIssueComponentPerfStateChangeMultiple routine submits a request to change the performance states in multiple performance state sets simultaneously for a device component.
PoFxNotifySurprisePowerOn	The PoFxNotifySurprisePowerOn routine notifies the power management framework (PoFx) that a device was turned on as a side effect of supplying power to some other device.
PoFxPowerControl	The PoFxPowerControl routine sends a power control request to the power management framework (PoFx).
PoFxPowerOnCrashdumpDevice	The PoFxPowerOnCrashdumpDevice routine requests that a crash-dump device be turned on.
PoFxQueryCurrentComponentPerfState	The PoFxQueryCurrentComponentPerfState routine retrieves the active performance state in a component's performance state set.

TITLE	DESCRIPTION
PoFxRegisterComponentPerfStates	The PoFxRegisterComponentPerfStates routine registers a device component for performance state management by the power management framework (PoFx).
PoFxRegisterCoreDevice	The PoFxRegisterCoreDevice routine registers a new core system resource with the Windows power management framework (PoFx).
PoFxRegisterCoreDevice	The PoFxRegisterCoreDevice routine registers a new core system resource with the Windows power management framework (PoFx).
PoFxRegisterCrashdumpDevice	The PoFxRegisterCrashdumpDevice routine registers a crash-dump device.
PoFxRegisterDevice	The PoFxRegisterDevice routine registers a device with the power management framework (PoFx).
PoFxRegisterPlugin	The PoFxRegisterPlugin routine registers a platform extension plug-in (PEP) with the Windows power management framework (PoFx).
PoFxRegisterPlugin	The PoFxRegisterPlugin routine registers a platform extension plug-in (PEP) with the Windows power management framework (PoFx).
PoFxRegisterPluginEx	The PoFxRegisterPluginEx routine registers a platform extension plug-in (PEP) with the Windows power management framework (PoFx).
PoFxRegisterPluginEx	The PoFxRegisterPluginEx routine registers a platform extension plug-in (PEP) with the Windows power management framework (PoFx).
PoFxReportDevicePoweredOn	The PoFxReportDevicePoweredOn routine notifies the power management framework (PoFx) that the device completed the requested transition to the D0 (fully on) power state.
PoFxSetComponentLatency	The PoFxSetComponentLatency routine specifies the maximum latency that can be tolerated in the transition from the idle condition to the active condition in the specified component.
PoFxSetComponentResidency	The PoFxSetComponentResidency routine sets the estimated time for how long a component is likely to remain idle after the component enters the idle condition.
PoFxSetComponentWake	The PoFxSetComponentWake routine indicates whether the driver arms the specified component to wake whenever the component enters the idle condition.

TITLE	DESCRIPTION
PoFxSetDeviceIdleTimeout	The PoFxSetDeviceIdleTimeout routine specifies the minimum time interval from when the last component of the device enters the idle condition to when the power management framework (PoFx) calls the driver's DevicePowerNotRequiredCallback routine.
PoFxSetTargetDripsDevicePowerState	This routine is called to notify the power manager of the device's target device power state for DRIPS. The driver can override the DRIPS constraint provided by the PEP.
PoFxStartDevicePowerManagement	The PoFxStartDevicePowerManagement routine completes the registration of a device with the power management framework (PoFx) and starts device power management.
PoFxUnregisterDevice	The PoFxUnregisterDevice routine removes the registration of a device from the power management framework (PoFx).
PoGetSystemWake	The PoGetSystemWake routine determines whether a specified IRP has been marked as waking the system from a sleeping state.
PopEntryList	The PopEntryList routine removes the first entry from a singly linked list of SINGLE_LIST_ENTRY structures.
PopEntryList	The PopEntryList routine removes the first entry from a singly linked list of SINGLE_LIST_ENTRY structures.
PoQueryWatchdogTime	The PoQueryWatchdogTime routine indicates whether the power manager has enabled a watchdog time-out counter for any power IRP that is currently assigned to the device stack.
PoQueryWatchdogTime	The PoQueryWatchdogTime routine indicates whether the power manager has enabled a watchdog time-out counter for any power IRP that is currently assigned to the device stack.
PoRegisterDeviceForIdleDetection	The PoRegisterDeviceForIdleDetection routine enables or cancels idle detection and sets idle time-out values for a device.
PoRegisterDeviceForIdleDetection	The PoRegisterDeviceForIdleDetection routine enables or cancels idle detection and sets idle time-out values for a device.
PoRegisterPowerSettingCallback	The PoRegisterPowerSettingCallback routine registers a power-setting callback routine to receive notifications of changes in the specified power setting.
PoRegisterPowerSettingCallback	The PoRegisterPowerSettingCallback routine registers a power-setting callback routine to receive notifications of changes in the specified power setting.
PoRegisterSystemState	The PoRegisterSystemState routine registers the system as busy due to certain activity.

TITLE	DESCRIPTION
PoRegisterSystemState	The PoRegisterSystemState routine registers the system as busy due to certain activity.
PoRequestPowerIrp	The PoRequestPowerIrp routine allocates a power IRP and sends it to the top driver in the device stack for the specified device.
PoSetDeviceBusyEx	The PoSetDeviceBusyEx routine notifies the power manager that the device associated with the specified idle counter is busy.
PoSetDeviceBusyEx	The PoSetDeviceBusyEx routine notifies the power manager that the device associated with the specified idle counter is busy.
PoSetPowerRequest	The PoSetPowerRequest routine increments the count for the specified power request type.
PoSetPowerRequest	The PoSetPowerRequest routine increments the count for the specified power request type.
PoSetPowerState	The PoSetPowerState routine notifies the system of a change in the device power state for a device.
PoSetPowerState	The PoSetPowerState routine notifies the system of a change in the device power state for a device.
PoSetSystemState	Drivers call the PoSetSystemState routine to indicate that the system is active.
PoSetSystemWake	The PoSetSystemWake routine marks the specified IRP as one that contributed to waking the system from a sleep state.
PoStartDeviceBusy	The PoStartDeviceBusy routine marks the start of a period of time in which the device is busy.
PoStartDeviceBusy	The PoStartDeviceBusy routine marks the start of a period of time in which the device is busy.
PoStartNextPowerIrp	The PoStartNextPowerIrp routine signals the power manager that the driver is ready to handle the next power IRP. (Windows Server 2003, Windows XP, and Windows 2000 only.).
PoStartNextPowerIrp	The PoStartNextPowerIrp routine signals the power manager that the driver is ready to handle the next power IRP. (Windows Server 2003, Windows XP, and Windows 2000 only.).
PoUnregisterPowerSettingCallback	The PoUnregisterPowerSettingCallback routine unregisters a power-setting callback routine that a driver previously registered by calling the PoRegisterPowerSettingCallback routine.

TITLE	DESCRIPTION
PoUnregisterPowerSettingCallback	The PoUnregisterPowerSettingCallback routine unregisters a power-setting callback routine that a driver previously registered by calling the PoRegisterPowerSettingCallback routine.
PoUnregisterSystemState	The PoUnregisterSystemState routine cancels a system state registration created by PoRegisterSystemState.
PoUnregisterSystemState	The PoUnregisterSystemState routine cancels a system state registration created by PoRegisterSystemState.
PPO_ENUMERATE_INTERRUPT_SOURCE_CALLBACK	An EnumerateInterruptSource callback routine supplies a platform extension plug-in (PEP) with information about an interrupt source.
PPO_ENUMERATE_INTERRUPT_SOURCE_CALLBACK	An EnumerateInterruptSource callback routine supplies a platform extension plug-in (PEP) with information about an interrupt source.
PPUT_DMA_ADAPTER	The PutDmaAdapter routine frees a DMA_ADAPTER structure previously allocated by IoGetDmaAdapter.
PPUT_SCATTER_GATHER_LIST	The PutScatterGatherList routine frees the previously allocated map registers and scatter/gather list used in scatter/gather DMA.
PREAD_DMA_COUNTER	The ReadDmaCounter routine returns the number of bytes remaining to be transferred during the current subordinate DMA operation.
PREENUMERATE_SELF	A ReenumerateSelf routine requests that a bus driver reenumerate a child device.
ProbeForRead	The ProbeForRead routine checks that a user-mode buffer actually resides in the user portion of the address space, and is correctly aligned.
ProbeForWrite	The ProbeForWrite routine checks that a user-mode buffer actually resides in the user-mode portion of the address space, is writable, and is correctly aligned.
PROCESSOR_HALT_ROUTINE	A Halt callback routine transitions the processor to an idle state.
PsAllocSiloContextSlot	This routine allocates a slot that can be used to insert, retrieve, and delete an object in all silos. .
PsAttachSiloToCurrentThread	This routine places a thread temporarily into the specified Silo.
PsCreateSiloContext	This routine creates an object that will be inserted in a Silo.
PsCreateSystemThread	The PsCreateSystemThread routine creates a system thread that executes in kernel mode and returns a handle for the thread.

TITLE	DESCRIPTION
PsDereferenceSiloContext	This routine decrements the reference count on the object.
PsDetachSiloFromCurrentThread	This routine removes a thread from a silo which was added by an attach. For more info about attaching, see the PsAttachSiloToCurrentThread routine.
PsFreeSiloContextSlot	This routine frees the specified slot and makes it available in the system. It undoes the effects of the PsAllocSiloContextSlot routine.
PsGetCurrentProcessId	The PsGetCurrentProcessId routine identifies the current thread's process.
PsGetCurrentServerSilo	This routine returns the effective server silo for the thread.
PsGetCurrentSilo	This routine returns the current silo for the calling thread. First the thread is checked to see if it has been attached to a silo. If not, then the thread is checked to see if it is in a silo.
PsGetCurrentThread	The PsGetCurrentThread routine identifies the current thread.
PsGetCurrentThread	The PsGetCurrentThread routine identifies the current thread.
PsGetCurrentThread	The PsGetCurrentThread routine identifies the current thread.
PsGetCurrentThreadId	The PsGetCurrentThreadId routine identifies the current thread.
PsGetCurrentThreadTeb	The PsGetCurrentThreadTeb routine returns the Thread Environment Block (TEB) of the current thread. The call must be made in kernel-mode.
PsGetEffectiveServerSilo	This routine traverses the parent chain of the Silo until finding the effective server silo or host silo.
PsGetHostSilo	This routine returns the host silo.
PsGetJobServerSilo	This routine returns the effective ServerSilo for the job. The returned pointer is valid as long as the supplied Job object remains referenced.
PsGetJobSilo	This routine returns the first job in the hierarchy that is a Silo. The returned pointer is valid as long as the supplied Job object remains referenced.
PsGetParentSilo	Retrieves the most immediate parent silo in the hierarchy for a given job object.
PsGetPermanentSiloContext	This routine retrieves an object that was inserted in the Silo without incrementing the reference count.
PsGetProcessCreateTimeQuadPart	The PsGetProcessCreateTimeQuadPart routine returns a LONGLONG value that represents the time at which the process was created.

TITLE	DESCRIPTION
PsGetProcessId	The PsGetProcessId routine returns the process identifier (process ID) that is associated with a specified process.
PsGetServerSiloActiveConsoleId	Gets the active console for the current server silo context for the supplied thread.
PsGetSiloContext	This routine retrieves the silo context from the specified silo and slot.
PsGetSiloMonitorContextSlot	This routine returns the silo context slot that was allocated by the monitor during the registration.
PsGetVersion	This function is obsolete in Windows XP and later versions of the Windows operating system. Use RtlGetVersion instead.PsGetVersion returns caller-selected information about the current version of the NT-based operating system.
PsInsertPermanentSiloContext	This routine inserts an object in an empty slot in a Silo.
PsInsertSiloContext	This routine inserts an object in an empty slot in a Silo.
PsIsHostSilo	This routine will check if the supplied Silo is the host silo.
PsIsSystemThread	The PsIsSystemThread routine checks whether a given thread is a system thread.
PsMakeSiloContextPermanent	This routine makes the slot in a silo instance read-only, allowing the object in the slot to be retrieved without affecting the reference count on that object.
PsQueryTotalCycleTimeProcess	The PsQueryTotalCycleTimeProcess routine returns the accumulated cycle time for the specified process.
PsReferenceSiloContext	This routine increments the reference count on the object.
PsRegisterSiloMonitor	This routine registers a server silo monitor that can receive notifications about server silo events.
PsRemoveCreateThreadNotifyRoutine	The PsRemoveCreateThreadNotifyRoutine routine removes a callback routine that was registered by the PsSetCreateThreadNotifyRoutine routine.
PsRemoveLoadImageNotifyRoutine	The PsRemoveLoadImageNotifyRoutine routine removes a callback routine that was registered by the PsSetLoadImageNotifyRoutine routine.
PsRemoveSiloContext	This routine removes an object that was inserted in the Silo.
PsReplaceSiloContext	This routine inserts an object in a Silo.
PsSetCreateProcessNotifyRoutine	The PsSetCreateProcessNotifyRoutine routine adds a driver-supplied callback routine to, or removes it from, a list of routines to be called whenever a process is created or deleted.

TITLE	DESCRIPTION
PsSetCreateProcessNotifyRoutineEx	The PsSetCreateProcessNotifyRoutineEx routine registers or removes a callback routine that notifies the caller when a process is created or exits.
PsSetCreateProcessNotifyRoutineEx2	The PsSetCreateProcessNotifyRoutineEx2 routine registers or removes a callback routine that notifies the caller when a process is created or deleted.
PsSetCreateThreadNotifyRoutine	The PsSetCreateThreadNotifyRoutine routine registers a driver-supplied callback that is subsequently notified when a new thread is created and when such a thread is deleted.
PsSetCreateThreadNotifyRoutineEx	The PsSetCreateThreadNotifyRoutineEx routine registers a driver-supplied callback that is subsequently notified when a new thread is created and when such a thread is deleted.
PsSetLoadImageNotifyRoutine	The PsSetLoadImageNotifyRoutine routine registers a driver-supplied callback that is subsequently notified whenever an image is loaded (or mapped into memory).
PsSetLoadImageNotifyRoutineEx	The PsSetLoadImageNotifyRoutineEx routine registers a driver-supplied callback that is subsequently notified whenever an image is loaded (or mapped into memory).
PsStartSiloMonitor	This routine tries to start the server silo monitor.
PsTerminateServerSilo	This routine terminates the specified silo.
PsTerminateSystemThread	The PsTerminateSystemThread routine terminates the current system thread.
PsUnregisterSiloMonitor	This routine unregisters a server silo monitor.
PTM_RM_NOTIFICATION	A resource manager's ResourceManagerNotification callback routine receives and handles transaction notifications.
PushEntryList	The PushEntryList routine inserts an entry at the beginning of a singly linked list of SINGLE_LIST_ENTRY structures.
PushEntryList	The PushEntryList routine inserts an entry at the beginning of a singly linked list of SINGLE_LIST_ENTRY structures.
READ_PORT_BUFFER_UCHAR	The READ_PORT_BUFFER_UCHAR routine reads a number of bytes from the specified port address into a buffer.
READ_PORT_BUFFER_UCHAR	The READ_PORT_BUFFER_UCHAR routine reads a number of bytes from the specified port address into a buffer.
READ_PORT_BUFFER_ULONG	The READ_PORT_BUFFER_ULONG routine reads a number of ULONG values from the specified port address into a buffer.
READ_PORT_BUFFER_ULONG	The READ_PORT_BUFFER_ULONG routine reads a number of ULONG values from the specified port address into a buffer.

TITLE	DESCRIPTION
READ_PORT_BUFFER_USHORT	The READ_PORT_BUFFER_USHORT routine reads a number of USHORT values from the specified port address into a buffer.
READ_PORT_BUFFER_USHORT	The READ_PORT_BUFFER_USHORT routine reads a number of USHORT values from the specified port address into a buffer.
READ_PORT_UCHAR	The READ_PORT_UCHAR routine reads a byte from the specified port address.
READ_PORT_UCHAR	The READ_PORT_UCHAR routine reads a byte from the specified port address.
READ_PORT_UCHAR	The READ_PORT_UCHAR routine reads a byte from the specified port address.
READ_PORT_ULONG	The READ_PORT_ULONG routine reads a ULONG value from the specified port address.
READ_PORT_ULONG	The READ_PORT_ULONG routine reads a ULONG value from the specified port address.
READ_PORT_ULONG	The READ_PORT_ULONG routine reads a ULONG value from the specified port address.
READ_PORT_USHORT	The READ_PORT_USHORT routine reads a USHORT value from the specified port address.
READ_PORT_USHORT	The READ_PORT_USHORT routine reads a USHORT value from the specified port address.
READ_PORT_USHORT	The READ_PORT_USHORT routine reads a USHORT value from the specified port address.
READ_REGISTER_BUFFER_UCHAR	The READ_REGISTER_BUFFER_UCHAR routine reads a number of bytes from the specified register address into a buffer.
READ_REGISTER_BUFFER_UCHAR	The READ_REGISTER_BUFFER_UCHAR routine reads a number of bytes from the specified register address into a buffer.
READ_REGISTER_BUFFER_UCHAR	The READ_REGISTER_BUFFER_UCHAR routine reads a number of bytes from the specified register address into a buffer.
READ_REGISTER_BUFFER_ULONG	The READ_REGISTER_BUFFER_ULONG routine reads a number of ULONG values from the specified register address into a buffer.
READ_REGISTER_BUFFER_ULONG	The READ_REGISTER_BUFFER_ULONG routine reads a number of ULONG values from the specified register address into a buffer.
READ_REGISTER_BUFFER_ULONG	The READ_REGISTER_BUFFER_ULONG routine reads a number of ULONG values from the specified register address into a buffer.

TITLE	DESCRIPTION
READ_REGISTER_BUFFER_USHORT	The READ_REGISTER_BUFFER_USHORT routine reads a number of USHORT values from the specified register address into a buffer.
READ_REGISTER_BUFFER_USHORT	The READ_REGISTER_BUFFER_USHORT routine reads a number of USHORT values from the specified register address into a buffer.
READ_REGISTER_BUFFER_USHORT	The READ_REGISTER_BUFFER_USHORT routine reads a number of USHORT values from the specified register address into a buffer.
READ_REGISTER_UCHAR	The READ_REGISTER_UCHAR routine reads a byte from the specified register address.
READ_REGISTER_UCHAR	The READ_REGISTER_UCHAR routine reads a byte from the specified register address.
READ_REGISTER_UCHAR	The READ_REGISTER_UCHAR routine reads a byte from the specified register address.
READ_REGISTER_UCHAR	The READ_REGISTER_UCHAR routine reads a byte from the specified register address.
READ_REGISTER_ULONG	The READ_REGISTER_ULONG routine reads a ULONG value from the specified register address.
READ_REGISTER_ULONG	The READ_REGISTER_ULONG routine reads a ULONG value from the specified register address.
READ_REGISTER_ULONG	The READ_REGISTER_ULONG routine reads a ULONG value from the specified register address.
READ_REGISTER_ULONG	The READ_REGISTER_ULONG routine reads a ULONG value from the specified register address.
READ_REGISTER_USHORT	The READ_REGISTER_USHORT routine reads a USHORT value from the specified register address.
READ_REGISTER_USHORT	The READ_REGISTER_USHORT routine reads a USHORT value from the specified register address.
READ_REGISTER_USHORT	The READ_REGISTER_USHORT routine reads a USHORT value from the specified register address.
READ_REGISTER_USHORT	The READ_REGISTER_USHORT routine reads a USHORT value from the specified register address.
RemoveEntryList	The RemoveEntryList routine removes an entry from a doubly linked list of LIST_ENTRY structures.
RemoveEntryList	The RemoveEntryList routine removes an entry from a doubly linked list of LIST_ENTRY structures.

TITLE	DESCRIPTION
RemoveHeadList	The RemoveHeadList routine removes an entry from the beginning of a doubly linked list of LIST_ENTRY structures.
RemoveHeadList	The RemoveHeadList routine removes an entry from the beginning of a doubly linked list of LIST_ENTRY structures.
RemoveTailList	The RemoveTailList routine removes an entry from the end of a doubly linked list of LIST_ENTRY structures.
RemoveTailList	The RemoveTailList routine removes an entry from the end of a doubly linked list of LIST_ENTRY structures.
REQUEST_POWER_COMPLETE	The PowerCompletion callback routine completes the processing of a power IRP.
RTL_QUERY_REGISTRY_ROUTINE	The QueryRoutine routine provides information about a registry value that was requested in a preceding call to the RtlQueryRegistryValues routine.
RTL_RUN_ONCE_INIT_FN	The RunOnceInitialization routine performs a one-time initialization operation.
RtlAnsiStringToUnicodeSize	The RtlAnsiStringToUnicodeSize routine returns the number of bytes required to hold an ANSI string converted into a Unicode string.
RtlAnsiStringToUnicodeString	RtlAnsiStringToUnicodeString converts the given ANSI source string into a Unicode string.
RtlAppendUnicodeStringToString	The RtlAppendUnicodeStringToString routine concatenates two Unicode strings.
RtlAppendUnicodeStringToString	The RtlAppendUnicodeStringToString routine concatenates two Unicode strings.
RtlAppendUnicodeToString	The RtlAppendUnicodeToString routine concatenates the supplied Unicode string to a buffered Unicode string.
RtlAppendUnicodeToString	The RtlAppendUnicodeToString routine concatenates the supplied Unicode string to a buffered Unicode string.
RtlAreBitsClear	The RtlAreBitsClear routine determines whether a given range of bits within a bitmap variable is clear.
RtlAreBitsSet	The RtlAreBitsSet routine determines whether a given range of bits within a bitmap variable is set.
RtlByteToChar	Converts a value of type BYTE to a value of type CHAR.
RtlByteToInt8	Converts a value of type BYTE to a value of type INT8.
RtlCharToInteger	The RtlCharToInteger routine converts a single-byte character string to an integer value in the specified base.

TITLE	DESCRIPTION
RtlCheckBit	The RtlCheckBit routine determines whether a particular bit in a given bitmap variable is clear or set.
RtlCheckRegistryKey	The RtlCheckRegistryKey routine checks for the existence of a given named key in the registry.
RtlClearAllBits	The RtlClearAllBits routine sets all bits in a given bitmap variable to zero.
RtlClearBit	The RtlClearBit routine sets the specified bit in a bitmap to zero.
RtlClearBits	The RtlClearBits routine sets all bits in the specified range of bits in the bitmap to zero.
RtlCmDecodeMemIoResource	The RtlCmDecodeMemIoResource routine provides the starting address and length of a CM_PARTIAL_RESOURCE_DESCRIPTOR structure that describes a range of memory or I/O port addresses.
RtlCmEncodeMemIoResource	The RtlCmEncodeMemIoResource routine updates a CM_PARTIAL_RESOURCE_DESCRIPTOR structure to describe a range of memory or I/O port addresses.
RtlCompareMemory	The RtlCompareMemory routine compares two blocks of memory and returns the number of bytes that match.
RtlCompareString	The RtlCompareString routine compares two counted strings.
RtlCompareUnicodeString	The RtlCompareUnicodeString routine compares two Unicode strings.
RtlCompareUnicodeString	The RtlCompareUnicodeString routine compares two Unicode strings.
RtlConvertLongToLargeInteger	The RtlConvertLongToLargeInteger routine converts the input signed integer to a signed large integer.
RtlConvertLongToLuid	The RtlConvertLongToLuid routine converts a long integer to a locally unique identifier (LUID), which is used by the system to represent a security privilege.
RtlConvertUlongToLargeInteger	The RtlConvertUlongToLargeInteger routine converts the input unsigned integer to a signed large integer. For Windows XP and later versions of Windows, do not use this routine; use the native support for __int64.
RtlConvertUlongToLuid	The RtlConvertUlongToLuid routine converts an unsigned long integer to a locally unique identifier (LUID), which is used by the system to represent a security privilege.
RtlCopyMemory	The RtlCopyMemory routine copies the contents of a source memory block to a destination memory block.

TITLE	DESCRIPTION
RtlCopyString	The RtlCopyString routine copies a source string to a destination string.
RtlCopyUnicodeString	The RtlCopyUnicodeString routine copies a source string to a destination string.
RtlCopyUnicodeString	The RtlCopyUnicodeString routine copies a source string to a destination string.
RtlCreateRegistryKey	The RtlCreateRegistryKey routine adds a key object in the registry along a given relative path.
RtlCreateSecurityDescriptor	The RtlCreateSecurityDescriptor routine initializes a new absolute-format security descriptor. On return, the security descriptor is initialized with no system ACL, no discretionary ACL, no owner, no primary group, and all control flags set to zero.
RtlDeleteRegistryValue	The RtlDeleteRegistryValue routine removes the specified entry name and the associated values from the registry along the given relative path.
RtlDowncaseUnicodeChar	The RtlDowncaseUnicodeChar routine converts the specified Unicode character to lowercase.
RtlDWordPtrAdd	Adds two values of type DWORD_PTR.
RtlDWordPtrMult	Multiplies one value of type DWORD_PTR by another.
RtlDWordPtrSub	Subtracts one value of type DWORD_PTR from another.
RtlEqualMemory	The RtlEqualMemory routine compares two blocks of memory to determine whether the specified number of bytes are identical.
RtlEqualString	The RtlEqualString routine compares two counted strings to determine whether they are equal.
RtlEqualUnicodeString	The RtlEqualUnicodeString routine compares two Unicode strings to determine whether they are equal.
RtlEqualUnicodeString	The RtlEqualUnicodeString routine compares two Unicode strings to determine whether they are equal.
RtlExtendCorrelationVector	This routine extends the supplied correlation vector. For a correlation vector of the form X.i, the extended value is X.i.0.
RtlFillMemory	The RtlFillMemory routine fills a block of memory with the specified fill value.
RtlFindClearBits	The RtlFindClearBits routine searches for a range of clear bits of a requested size within a bitmap.

TITLE	DESCRIPTION
RtlFindClearBitsAndSet	The RtlFindClearBitsAndSet routine searches for a range of clear bits of a requested size within a bitmap and sets all bits in the range when it has been located.
RtlFindClearRuns	The RtlFindClearRuns routine finds the specified number of runs of clear bits within a given bitmap.
RtlFindFirstRunClear	The RtlFindFirstRunClear routine searches for the initial contiguous range of clear bits within a given bitmap.
RtlFindLastBackwardRunClear	The RtlFindLastBackwardRunClear routine searches a given bitmap for the preceding clear run of bits, starting from the specified index position.
RtlFindLeastSignificantBit	The RtlFindLeastSignificantBit routine returns the zero-based position of the least significant nonzero bit in its parameter.
RtlFindLongestRunClear	The RtlFindLongestRunClear routine searches for the largest contiguous range of clear bits within a given bitmap.
RtlFindMostSignificantBit	The RtlFindMostSignificantBit routine returns the zero-based position of the most significant nonzero bit in its parameter.
RtlFindNextForwardRunClear	The RtlFindNextForwardRunClear routine searches a given bitmap variable for the next clear run of bits, starting from the specified index position.
RtlFindSetBits	The RtlFindSetBits routine searches for a range of set bits of a requested size within a bitmap.
RtlFindSetBitsAndClear	The RtlFindSetBitsAndClear routine searches for a range of set bits of a requested size within a bitmap and clears all bits in the range when it has been located.
RtlFreeAnsiString	The RtlFreeAnsiString routine releases storage that was allocated by RtlUnicodeStringToAnsiString.
RtlFreeUnicodeString	The RtlFreeUnicodeString routine releases storage that was allocated by RtlAnsiStringToUnicodeString or RtlUpcaseUnicodeString.
RtlFreeUnicodeString	The RtlFreeUnicodeString routine releases storage that was allocated by RtlAnsiStringToUnicodeString or RtlUpcaseUnicodeString.
RtlGetEnabledExtendedFeatures	The RtlGetEnabledExtendedFeatures routine returns a mask of extended processor features that are enabled by the system.
RtlGetVersion	The RtlGetVersion routine returns version information about the currently running operating system.
RtlGUIDFromString	The RtlGUIDFromString routine converts the given Unicode string to a GUID in binary format.

TITLE	DESCRIPTION
RtlHashUnicodeString	The RtlHashUnicodeString routine creates a hash value from a given Unicode string and hash algorithm.
RtlIncrementCorrelationVector	Increments the specified correlation vector. For a correlation vector of the form X.i, the incremented value is be X.(i+1).
RtlInitAnsiString	The RtlInitAnsiString routine initializes a counted string of ANSI characters.
RtlInitializeBitMap	The RtlInitializeBitMap routine initializes the header of a bitmap variable.
RtlInitializeCorrelationVector	Initializes the specified correlation vector with the supplied GUID.
RtlInitString	The RtlInitString routine initializes a counted string of 8-bit characters.
RtlInitStringEx	The RtlInitStringEx routine initializes a counted string of 8-bit characters.
RtlInitStringEx	The RtlInitStringEx routine initializes a counted string of 8-bit characters.
RtlInitUnicodeString	For more information, see the WdmlibRtlInitUnicodeStringEx function.
RtlInitUnicodeString	For more information, see the WdmlibRtlInitUnicodeStringEx function.
RtlInt64ToUnicodeString	The RtlInt64ToUnicodeString routine converts a specified unsigned 64-bit integer value to a Unicode string that represents the value in a specified base.
RtlInt64ToUnicodeString	The RtlInt64ToUnicodeString routine converts a specified unsigned 64-bit integer value to a Unicode string that represents the value in a specified base.
RtlInt8Add	Adds two values of type INT8.
RtlInt8Mult	Multiplies one value of type INT8 by another.
RtlInt8Sub	Subtracts one value of type INT8 from another.
RtlInt8ToUChar	Converts a value of type INT8 to a value of type UCHAR.
RtlInt8ToUInt	Converts a value of type INT8 to a value of type UINT.
RtlInt8ToUInt8	Converts a value of type INT8 to a value of type UINT8.
RtlInt8ToUIntPtr	Converts a value of type INT8 to a value of type UINT_PTR.
RtlInt8ToULong	Converts a value of type INT8 to a value of type ULONG.

TITLE	DESCRIPTION
RtlInt8ToULongLong	Converts a value of type INT8 to a value of type ULONGLONG.
RtlInt8ToULongPtr	Converts a value of type INT8 to a value of type ULONG_PTR.
RtlInt8ToUShort	Converts a value of type INT8 to a value of type USHORT.
RtlIntAdd	Adds two values of type INT.
RtlIntegerToUnicodeString	The RtlIntegerToUnicodeString routine converts an unsigned integer value to a null-terminated string of one or more Unicode characters in the specified base.
RtlIntegerToUnicodeString	The RtlIntegerToUnicodeString routine converts an unsigned integer value to a null-terminated string of one or more Unicode characters in the specified base.
RtlIntMult	Multiplies one value of type INT by another.
RtlIntPtrAdd	Adds two values of type INT_PTR.
RtlIntPtrMult	Multiplies one value of type INT_PTR by another.
RtlIntPtrSub	Subtracts one value of type INT_PTR from another.
RtlIntPtrToChar	Converts a value of type INT_PTR to a value of type CHAR.
RtlIntPtrToInt	Converts a value of type INT_PTR to a value of type INT.
RtlIntPtrToInt8	Converts a value of type INT_PTR to a value of type INT8.
RtlIntPtrToLong	Converts a value of type INT_PTR to a value of type LONG.
RtlIntPtrToLongPtr	Converts a value of type INT_PTR to a value of type LONG_PTR.
RtlIntPtrToShort	Converts a value of type INT_PTR to a value of type SHORT.
RtlIntPtrToUChar	Converts a value of type INT_PTR to a value of type UCHAR.
RtlIntPtrToUInt	Converts a value of type INT_PTR to a value of type UINT.
RtlIntPtrToUInt8	Converts a value of type INT_PTR to a value of type UINT8.
RtlIntPtrToUIntPtr	Converts a value of type INT_PTR to a value of type UINT_PTR.
RtlIntPtrToULong	Converts a value of type INT_PTR to a value of type ULONG.
RtlIntPtrToULongLong	Converts a value of type INT_PTR to a value of type ULONGLONG.

TITLE	DESCRIPTION
RtlIntPtrToULongPtr	Converts a value of type INT_PTR to a value of type ULONG_PTR.
RtlIntPtrToUnicodeString	The RtlIntPtrToUnicodeString routine converts a specified ULONG_PTR value to a Unicode string that represents the value in a specified base.
RtlIntPtrToUnicodeString	The RtlIntPtrToUnicodeString routine converts a specified ULONG_PTR value to a Unicode string that represents the value in a specified base.
RtlIntPtrToUShort	Converts a value of type INT_PTR to a value of type USHORT.
RtlIntSub	Subtracts one value of type INT from another.
RtlIntToChar	Converts a value of type INT to a value of type CHAR.
RtlIntToInt8	Converts a value of type INT to a value of type INT8.
RtlIntToShort	Converts a value of type INT to a value of type SHORT.
RtlIntToUChar	Converts a value of type INT to a value of type UCHAR.
RtlIntToUInt	Converts a value of type INT to a value of type UINT.
RtlIntToUInt8	Converts a value of type INT to a value of type UINT8.
RtlIntToULong	Converts a value of type INT to a value of type ULONG.
RtlIntToULongLong	Converts a value of type INT to a value of type ULONGLONG.
RtlIntToUShort	Converts a value of type INT to a value of type USHORT.
RtlIoDecodeMemIoResource	The RtlIoDecodeMemIoResource routine provides the address information that is contained in an IO_RESOURCE_DESCRIPTOR structure that describes a range of memory or I/O port addresses.
RtlIoEncodeMemIoResource	The RtlIoEncodeMemIoResource routine updates an IO_RESOURCE_DESCRIPTOR structure to describe a range of memory or I/O port addresses.
RtlIsNtDdiVersionAvailable	The RtlIsNtDdiVersionAvailable routine determines if a specified version of the Microsoft Windows device driver interface (DDI) is available.
RtlIsServicePackVersionInstalled	The RtlIsServicePackVersionInstalled routine determines if a specified service pack version of the Microsoft Windows device driver interface (DDI) is installed.
RtlIsStateSeparationEnabled	Checks if the SKU for the current context supports multiple sessions.

TITLE	DESCRIPTION
RtlLengthSecurityDescriptor	The RtlLengthSecurityDescriptor routine returns the size of a given security descriptor.
RtlLongAdd	Adds two values of type LONG.
RtlLongLongAdd	Adds two values of type LONGLONG.
RtlLongLongMult	Multiplies one value of type LONGLONG by another.
RtlLongLongSub	Subtracts one value of type LONGLONG from another.
RtlLongLongToChar	Converts a value of type LONGLONG to a value of type CHAR.
RtlLongLongToInt	Converts a value of type LONGLONG to a value of type INT.
RtlLongLongToInt8	Converts a value of type LONGLONG to a value of type INT8.
RtlLongLongToIntPtr	Converts a value of type LONGLONG to a value of type INT_PTR.
RtlLongLongToLong	Converts a value of type LONGLONG to a value of type LONG.
RtlLongLongToLongPtr	Converts a value of type LONGLONG to a value of type LONG_PTR.
RtlLongLongToShort	Converts a value of type LONGLONG to a value of type SHORT.
RtlLongLongToUChar	Converts a value of type LONGLONG to a value of type UCHAR.
RtlLongLongToUInt	Converts a value of type LONGLONG to a value of type UINT.
RtlLongLongToUInt8	Converts a value of type LONGLONG to a value of type UNIT8.
RtlLongLongToULong	Converts a value of type LONGLONG to a value of type ULONG.
RtlLongLongToULongLong	Converts a value of type LONGLONG to a value of type LONGLONG.
RtlLongLongToUShort	Converts a value of type LONGLONG to a value of type USHORT.
RtlLongMult	Multiplies one value of type LONG by another.
RtlLongPtrAdd	Adds two values of type LONG_PTR.
RtlLongPtrMult	Multiplies one value of type LONG_PTR by another.

TITLE	DESCRIPTION
RtlLongPtrSub	Subtracts one value of type LONG_PTR from another.
RtlLongPtrToChar	Converts a value of type LONG_PTR to a value of type CHAR.
RtlLongPtrToInt	Converts a value of type LONG_PTR to a value of type INT.
RtlLongPtrToInt8	Converts a value of type LONG_PTR to a value of type INT8.
RtlLongPtrToIntPtr	Converts a value of type LONG_PTR to a value of type INT_PTR.
RtlLongPtrToLong	Converts a value of type LONG_PTR to a value of type LONG.
RtlLongPtrToShort	Converts a value of type LONG_PTR to a value of type SHORT.
RtlLongPtrToUChar	Converts a value of type LONG_PTR to a value of type UCHAR.
RtlLongPtrToUInt	Converts a value of type LONG_PTR to a value of type UINT.
RtlLongPtrToUInt8	Converts a value of type LONG_PTR to a value of type UINT8.
RtlLongPtrToUIntPtr	Converts a value of type LONG_PTR to a value of type UINT_PTR.
RtlLongPtrToULong	Converts a value of type LONG_PTR to a value of type ULONG.
RtlLongPtrToULongLong	Converts a value of type LONG_PTR to a value of type ULONGLONG.
RtlLongPtrToULongPtr	Converts a value of type LONG_PTR to a value of type ULONG_PTR.
RtlLongPtrToUShort	Converts a value of type LONG_PTR to a value of type USHORT.
RtlLongSub	Subtracts one value of type LONG from another.
RtlLongToChar	Converts a value of type LONG to a value of type CHAR.
RtlLongToInt	Converts a value of type LONG to a value of type INT.
RtlLongToInt8	Converts a value of type LONG to a value of type INT8.
RtlLongToIntPtr	Converts a value of type LONG to a value of type INT_PTR.
RtlLongToShort	Converts a value of type LONG to a value of type SHORT.
RtlLongToUChar	Converts a value of type LONG to a value of type UCHAR.

TITLE	DESCRIPTION
RtlLongToUInt	Converts a value of type LONG to a value of type UINT.
RtlLongToUInt8	Converts a value of type LONG to a value of type UINT8.
RtlLongToUIntPtr	Converts a value of type LONG to a value of type UINT_PTR.
RtlLongToULong	Converts a value of type LONG to a value of type ULONG.
RtlLongToULongLong	Converts a value of type LONG to a value of type ULONGLONG.
RtlLongToULongPtr	Converts a value of type LONG to a value of type ULONG_PTR.
RtlLongToUShort	Converts a value of type LONG to a value of type USHORT.
RtlMapGenericMask	The RtlMapGenericMask routine determines the nongeneric access rights specified by an ACCESS_MASK.
RtlMoveMemory	The RtlMoveMemory routine copies the contents of a source memory block to a destination memory block, and supports overlapping source and destination memory blocks.
RtlNumberOfClearBits	The RtlNumberOfClearBits routine returns a count of the clear bits in a given bitmap variable.
RtlNumberOfSetBits	The RtlNumberOfSetBits routine returns a count of the set bits in a given bitmap variable.
RtlNumberOfSetBitsUlongPtr	The RtlNumberOfSetBitsUlongPtr routine returns the number of bits in the specified ULONG_PTR integer value that are set to one.
RtlPrefetchMemoryNonTemporal	The RtlPrefetchMemoryNonTemporal routine provides a hint to the processor that a buffer should be temporarily moved into the processor cache.
RtlPrefixUnicodeString	The RtlPrefixUnicodeString routine compares two Unicode strings to determine whether one string is a prefix of the other.
RtlPtrdiffTAdd	Adds two values of type PTRDIFF_T.
RtlPtrdiffTMult	Multiplies one value of type PTRDIFF_T by another.
RtlPtrdiffTSub	Subtracts one value of type PTRDIFF_T from another.
RtlQueryRegistryValues	The RtlQueryRegistryValues routine allows the caller to query several values from the registry subtree with a single call.
RtlQueryRegistryValueWithFallback	Retrieves a value entry for a registry key by using, a primary handle; if not found, uses the fallback handle.

TITLE	DESCRIPTION
RtlRunOnceBeginInitialize	The RtlRunOnceBeginInitialize routine begins a one-time initialization.
RtlRunOnceComplete	The RtlRunOnceComplete routine completes the one-time initialization began by RtlRunOnceBeginInitialize.
RtlRunOnceExecuteOnce	The RtlRunOnceExecuteOnce performs a one-time initialization.
RtlRunOnceInitialize	The RtlRunOnceInitialize routine initializes a RTL_RUN_ONCE structure.
RtlSecureZeroMemory	The RtlSecureZeroMemory routine fills a block of memory with zeros in a way that is guaranteed to be secure.
RtlSetAllBits	The RtlSetAllBits routine sets all bits in a given bitmap variable.
RtlSetBit	The RtlSetBit routine sets the specified bit in a bitmap to one.
RtlSetBits	The RtlSetBits routine sets all bits in a given range of a given bitmap variable.
RtlSetDaclSecurityDescriptor	The RtlSetDaclSecurityDescriptor routine sets the DACL information of an absolute-format security descriptor, or if there is already a DACL present in the security descriptor, it is superseded.
RtlShortAdd	Adds two values of type SHORT.
RtlShortMult	Multiplies one value of type SHORT by another.
RtlShortSub	Subtracts one value of type SHORT from another.
RtlShortToChar	Converts a value of type SHORT to a value of type CHAR.
RtlShortToDWordPtr	Converts a value of type SHORT to a value of type DWORD_PTR.
RtlShortToInt8	Converts a value of type SHORT to a value of type INT8.
RtlShortToUChar	Converts a value of type SHORT to a value of type UCHAR.
RtlShortToUInt	Converts a value of type SHORT to a value of type UINT.
RtlShortToUInt8	Converts a value of type SHORT to a value of type UINT8.
RtlShortToUIntPtr	Converts a value of type SHORT to a value of type UINT_PTR.
RtlShortToULong	Converts a value of type SHORT to a value of type ULONG.
RtlShortToULongLong	Converts a value of type SHORT to a value of type ULONGLONG.

TITLE	DESCRIPTION
RtlShortToULongPtr	Converts a value of type SHORT to a value of type ULONG_PTR.
RtlShortToUShort	Converts a value of type SHORT to a value of type USHORT.
RtlSizeTAdd	Adds two values of type SIZE_T.
RtlSizeTMult	Multiplies one value of type SIZE_T by another.
RtlSizeTSub	Subtracts one value of type SIZE_T from another.
RtlSSIZETAdd	Adds two values of type SSIZE_T.
RtlSSIZETMult	Multiplies one value of type SSIZE_T by another.
RtlSSIZETSub	Subtracts one value of type SSIZE_T from another.
RtlStringCbCatA	The RtlStringCbCatW and RtlStringCbCatA functions concatenate two byte-counted strings.
RtlStringCbCatExA	The RtlStringCbCatExW and RtlStringCbCatExA functions concatenate two byte-counted strings.
RtlStringCbCatExW	The RtlStringCbCatExW and RtlStringCbCatExA functions concatenate two byte-counted strings.
RtlStringCbCatNA	The RtlStringCbCatNW and RtlStringCbCatNA functions concatenate two byte-counted strings while limiting the size of the appended string.
RtlStringCbCatNExA	The RtlStringCbCatNExW and RtlStringCbCatNExA functions concatenate two byte-counted strings while limiting the size of the appended string.
RtlStringCbCatNExW	The RtlStringCbCatNExW and RtlStringCbCatNExA functions concatenate two byte-counted strings while limiting the size of the appended string.
RtlStringCbCatNW	The RtlStringCbCatNW and RtlStringCbCatNA functions concatenate two byte-counted strings while limiting the size of the appended string.
RtlStringCbCatW	The RtlStringCbCatW and RtlStringCbCatA functions concatenate two byte-counted strings.
RtlStringCbCopyA	The RtlStringCbCopyW and RtlStringCbCopyA functions copy a byte-counted string into a buffer.
RtlStringCbCopyExA	The RtlStringCbCopyExW and RtlStringCbCopyExA functions copy a byte-counted string into a buffer.
RtlStringCbCopyExW	The RtlStringCbCopyExW and RtlStringCbCopyExA functions copy a byte-counted string into a buffer.

TITLE	DESCRIPTION
RtlStringCbCopyNA	The RtlStringCbCopyNW and RtlStringCbCopyNA functions copy a byte-counted string to a buffer while limiting the size of the copied string.
RtlStringCbCopyNExA	The RtlStringCbCopyNExW and RtlStringCbCopyNExA functions copy a byte-counted string to a buffer while limiting the size of the copied string.
RtlStringCbCopyNExW	The RtlStringCbCopyNExW and RtlStringCbCopyNExA functions copy a byte-counted string to a buffer while limiting the size of the copied string.
RtlStringCbCopyNW	The RtlStringCbCopyNW and RtlStringCbCopyNA functions copy a byte-counted string to a buffer while limiting the size of the copied string.
RtlStringCbCopyUnicodeString	The RtlStringCbCopyUnicodeString function copies the contents of a UNICODE_STRING structure to a specified destination.
RtlStringCbCopyUnicodeStringEx	The RtlStringCbCopyUnicodeStringEx function copies the contents of a UNICODE_STRING structure to a specified destination.
RtlStringCbCopyW	The RtlStringCbCopyW and RtlStringCbCopyA functions copy a byte-counted string into a buffer.
RtlStringCbLengthA	The RtlStringCbLengthW and RtlStringCbLengthA functions determine the length, in bytes, of a supplied string.
RtlStringCbLengthW	The RtlStringCbLengthW and RtlStringCbLengthA functions determine the length, in bytes, of a supplied string.
RtlStringCbPrintfA	The RtlStringCbPrintfW and RtlStringCbPrintfA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCbPrintfExA	The RtlStringCbPrintfExW and RtlStringCbPrintfExA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCbPrintfExW	The RtlStringCbPrintfExW and RtlStringCbPrintfExA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCbPrintfW	The RtlStringCbPrintfW and RtlStringCbPrintfA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCbVPrintfA	The RtlStringCbVPrintfW and RtlStringCbVPrintfA functions create a byte-counted text string, with formatting that is based on supplied formatting information.

TITLE	DESCRIPTION
RtlStringCbVPrintfExA	The RtlStringCbVPrintfExW and RtlStringCbVPrintfExA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCbVPrintfExW	The RtlStringCbVPrintfExW and RtlStringCbVPrintfExA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCbVPrintfW	The RtlStringCbVPrintfW and RtlStringCbVPrintfA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchCatA	The RtlStringCchCatW and RtlStringCchCatA functions concatenate two character-counted strings.
RtlStringCchCatExA	The RtlStringCchCatExW and RtlStringCchCatExA functions concatenate two character-counted strings.
RtlStringCchCatExW	The RtlStringCchCatExW and RtlStringCchCatExA functions concatenate two character-counted strings.
RtlStringCchCatNA	The RtlStringCchCatNW and RtlStringCchCatNA functions concatenate two character-counted strings while limiting the size of the appended string.
RtlStringCchCatNExA	The RtlStringCchCatNExW and RtlStringCchCatNExA functions concatenate two character-counted strings while limiting the size of the appended string.
RtlStringCchCatNExW	The RtlStringCchCatNExW and RtlStringCchCatNExA functions concatenate two character-counted strings while limiting the size of the appended string.
RtlStringCchCatNW	The RtlStringCchCatNW and RtlStringCchCatNA functions concatenate two character-counted strings while limiting the size of the appended string.
RtlStringCchCatW	The RtlStringCchCatW and RtlStringCchCatA functions concatenate two character-counted strings.
RtlStringCchCopyA	The RtlStringCchCopyW and RtlStringCchCopyA functions copy a null-terminated source string into a destination buffer of specified length.
RtlStringCchCopyExA	The RtlStringCchCopyExW and RtlStringCchCopyExA functions copy a character-counted string into a buffer.
RtlStringCchCopyExW	The RtlStringCchCopyExW and RtlStringCchCopyExA functions copy a character-counted string into a buffer.
RtlStringCchCopyNA	The RtlStringCchCopyNW and RtlStringCchCopyNA functions copy a character-counted string to a buffer while limiting the size of the copied string.

TITLE	DESCRIPTION
RtlStringCchCopyNExA	The RtlStringCchCopyNExW and RtlStringCchCopyNExA functions copy a character-counted string to a buffer while limiting the size of the copied string.
RtlStringCchCopyNExW	The RtlStringCchCopyNExW and RtlStringCchCopyNExA functions copy a character-counted string to a buffer while limiting the size of the copied string.
RtlStringCchCopyNW	The RtlStringCchCopyNW and RtlStringCchCopyNA functions copy a character-counted string to a buffer while limiting the size of the copied string.
RtlStringCchCopyUnicodeString	The RtlStringCchCopyUnicodeString function copies the contents of a UNICODE_STRING structure to a specified destination.
RtlStringCchCopyUnicodeStringEx	The RtlStringCchCopyUnicodeStringEx function copies the contents of a UNICODE_STRING structure to a specified destination.
RtlStringCchCopyW	The RtlStringCchCopyW and RtlStringCchCopyA functions copy a null-terminated source string into a destination buffer of specified length.
RtlStringCchLengthA	The RtlStringCchLengthW and RtlStringCchLengthA functions determine the length, in characters, of a supplied string.
RtlStringCchLengthW	The RtlStringCchLengthW and RtlStringCchLengthA functions determine the length, in characters, of a supplied string.
RtlStringCchPrintfA	The RtlStringCchPrintfW and RtlStringCchPrintfA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchPrintfExA	The RtlStringCchPrintfExW and RtlStringCchPrintfExA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchPrintfExW	The RtlStringCchPrintfExW and RtlStringCchPrintfExA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchPrintfW	The RtlStringCchPrintfW and RtlStringCchPrintfA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchVPrintfA	The RtlStringCchVPrintfW and RtlStringCchVPrintfA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchVPrintfExA	The RtlStringCchVPrintfExW and RtlStringCchVPrintfExA functions create a character-counted text string, with formatting that is based on supplied formatting information.

TITLE	DESCRIPTION
RtlStringCchVPrintfExW	The RtlStringCchVPrintfExW and RtlStringCchVPrintfExA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchVPrintfW	The RtlStringCchVPrintfW and RtlStringCchVPrintfA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringFromGUID	The RtlStringFromGUID routine converts a given GUID from binary format into a Unicode string.
RtlTestBit	The RtlTestBit routine returns the value of a bit in a bitmap.
RtlTimeFieldsToTime	The RtlTimeFieldsToTime routine converts TIME_FIELDS information to a system time value.
RtlTimeToTimeFields	The RtlTimeToTimeFields routine converts system time into a TIME_FIELDS structure.
RtlUInt8Add	Adds two values of type UINT8.
RtlUInt8Mult	Multiplies one value of type UINT8 by another.
RtlUInt8Sub	The RtlUInt8Sub routine subtracts one value of type UINT8 from another.
RtlUInt8ToChar	Converts a value of type UINT8 to a value of type CHAR.
RtlUInt8ToInt8	Converts a value of type UINT8 to a value of type INT8.
RtlUIntAdd	Adds two values of type UINT.
RtlUIntMult	Multiplies one value of type UINT by another.
RtlUIntPtrAdd	Adds two values of type UINT_PTR.
RtlUIntPtrMult	Multiplies one value of type UINT_PTR by another.
RtlUIntPtrSub	Subtracts one value of type UINT_PTR from another.
RtlUIntPtrToChar	Converts a value of type UINT_PTR to a value of type CHAR.
RtlUIntPtrToInt	Converts a value of type UINT_PTR to a value of type INT.
RtlUIntPtrToInt16	Converts a value of type UINT_PTR to a value of type INT16.
RtlUIntPtrToInt8	Converts a value of type UINT_PTR to a value of type INT8.
RtlUIntPtrToIntPtr	Converts a value of type UINT_PTR to a value of type INT_PTR.
RtlUIntPtrToLong	Converts a value of type UINT_PTR to a value of type LONG.

TITLE	DESCRIPTION
RtlUIntPtrToLongLong	Converts a value of type UINT_PTR to a value of type LONGLONG.
RtlUIntPtrToLongPtr	Converts a value of type UINT_PTR to a value of type LONG_PTR.
RtlUIntPtrToShort	Converts a value of type UINT_PTR to a value of type SHORT.
RtlUIntPtrToUChar	Converts a value of type UINT_PTR to a value of type UCHAR.
RtlUIntPtrToUInt	Converts a value of type UINT_PTR to a value of type UINT.
RtlUIntPtrToUInt16	Converts a value of type UINT_PTR to a value of type UINT16.
RtlUIntPtrToUInt8	Converts a value of type UINT_PTR to a value of type UINT8.
RtlUIntPtrToULong	Converts a value of type UINT_PTR to a value of type LONG.
RtlUIntPtrToUShort	Converts a value of type UINT_PTR to a value of type USHORT.
RtlUIntSub	Subtracts one value of type UINT from another.
RtlUIntToChar	Converts a value of type UINT to a value of type CHAR.
RtlUIntToInt	Converts a value of type UINT to a value of type INT.
RtlUIntToInt8	Converts a value of type UINT to a value of type INT8.
RtlUIntToIntPtr	Converts a value of type UINT to a value of type INT_PTR.
RtlUIntToLong	Converts a value of type UINT to a value of type LONG.
RtlUIntToLongPtr	Converts a value of type UINT to a value of type LONG_PTR.
RtlUIntToShort	Converts a value of type UINT to a value of type SHORT.
RtlUIntToUChar	Converts a value of type UINT to a value of type UCHAR.
RtlUIntToUInt8	Converts a value of type UINT to a value of type UINT8.
RtlUIntToUShort	Converts a value of type UINT to a value of type USHORT.
RtlULongAdd	Adds two values of type ULONG.
RtlUlongByteSwap	The RtlUlongByteSwap routine reverses the ordering of the four bytes in a 32-bit unsigned integer value.
RtlULongLongAdd	Adds two values of type ULONGLONG.

TITLE	DESCRIPTION
RtlUlonglongByteSwap	The RtlUlonglongByteSwap routine reverses the ordering of the eight bytes in a 64-bit unsigned integer value.
RtlULongLongMult	Multiplies one value of type ULONGLONG by another.
RtlULongLongSub	Subtracts one value of type ULONGLONG from another.
RtlULongLongToChar	Converts a value of type ULONGLONG to a value of type CHAR.
RtlULongLongToInt	Converts a value of type ULONGLONG to a value of type INT.
RtlULongLongToInt8	Converts a value of type ULONGLONG to a value of type INT8.
RtlULongLongToLong	Converts a value of type ULONGLONG to a value of type LONG.
RtlULongLongToLongLong	Converts a value of type ULONGLONG to a value of type LONGLONG.
RtlULongLongToLongPtr	Converts a value of type ULONGLONG to a value of type LONG_PTR.
RtlULongLongToShort	Converts a value of type ULONGLONG to a value of type SHORT.
RtlULongLongToUChar	Converts a value of type ULONGLONG to a value of type UCHAR.
RtlULongLongToUInt	Converts a value of type ULONGLONG to a value of type UINT.
RtlULongLongToUInt8	Converts a value of type ULONGLONG to a value of type UINT8.
RtlULongLongToUIntPtr	Converts a value of type ULONGLONG to a value of type UINT_PTR.
RtlULongLongToULong	Converts a value of type ULONGLONG to a value of type ULONG.
RtlULongLongToULongPtr	Converts a value of type ULONGLONG to a value of type ULONG_PTR.
RtlULongLongToUShort	Converts a value of type ULONGLONG to a value of type USHORT.
RtlULongMult	Multiplies one value of type ULONG by another.
RtlULongPtrAdd	Adds two values of type ULONG_PTR.
RtlULongPtrMult	Multiplies one value of type ULONG_PTR by another.

TITLE	DESCRIPTION
RtlULongPtrSub	Subtracts one value of type ULONG_PTR from another.
RtlULongPtrToChar	Converts a value of type ULONG_PTR to a value of type CHAR.
RtlULongPtrToInt	Converts a value of type ULONG_PTR to a value of type INT.
RtlULongPtrToInt8	Converts a value of type ULONG_PTR to a value of type INT8.
RtlULongPtrToIntPtr	Converts a value of type ULONG_PTR to a value of type INT_PTR.
RtlULongPtrToLong	Converts a value of type ULONG_PTR to a value of type LONG.
RtlULongPtrToLongLong	Converts a value of type ULONG_PTR to a value of type LONGLONG.
RtlULongPtrToLongPtr	Converts a value of type ULONG_PTR to a value of type LONG_PTR.
RtlULongPtrToShort	Converts a value of type ULONG_PTR to a value of type SHORT.
RtlULongPtrToUChar	Converts a value of type ULONG_PTR to a value of type UCHAR.
RtlULongPtrToUInt	Converts a value of type ULONG_PTR to a value of type UINT.
RtlULongPtrToUInt8	Converts a value of type ULONG_PTR to a value of type UINT8.
RtlULongPtrToUIntPtr	Converts a value of type ULONG_PTR to a value of type UINT_PTR.
RtlULongPtrToULong	Converts a value of type ULONG_PTR to a value of type ULONG.
RtlULongPtrToUShort	Converts a value of type ULONG_PTR to a value of type USHORT.
RtlULongSub	Subtracts one value of type ULONG from another.
RtlULongToChar	Converts a value of type ULONG to a value of type CHAR.
RtlULongToInt	Converts a value of type ULONG to a value of type INT.
RtlULongToInt8	Converts a value of type ULONG to a value of type INT8.
RtlULongToIntPtr	Converts a value of type ULONG to a value of type INT_PTR.
RtlULongToLong	Converts a value of type ULONG to a value of type LONG.

TITLE	DESCRIPTION
RtlULongToLongPtr	Converts a value of type ULONG to a value of type LONG_PTR.
RtlULongToShort	Converts a value of type ULONG to a value of type SHORT.
RtlULongToUChar	Converts a value of type ULONG to a value of type UCHAR.
RtlULongToUInt	Converts a value of type ULONG to a value of type UINT.
RtlULongToUInt8	Converts a value of type ULONG_PTR to a value of type UINT8.
RtlULongToUIntPtr	Converts a value of type ULONG_PTR to a value of type UINT_PTR.
RtlULongToUShort	Converts a value of type ULONG to a value of type USHORT.
RtlUnalignedStringCbLengthW	The RtlUnalignedStringCbLengthW function is a version of the RtlStringCbLength function that accepts an unaligned pointer to a string of Unicode characters.
RtlUnalignedStringCchLengthW	The RtlUnalignedStringCchLengthW function is a version of the RtlStringCchLength function that accepts an unaligned pointer to a string of Unicode characters.
RtlUnicodeStringCat	The RtlUnicodeStringCat function concatenates two strings that are contained in UNICODE_STRING structures.
RtlUnicodeStringCatEx	The RtlUnicodeStringCatEx function concatenates two strings that are contained in UNICODE_STRING structures.
RtlUnicodeStringCatString	The RtlUnicodeStringCatString function concatenates two strings when the destination string is contained in a UNICODE_STRING structure.
RtlUnicodeStringCatStringEx	The RtlUnicodeStringCatStringEx function concatenates two strings when the destination string is contained in a UNICODE_STRING structure.
RtlUnicodeStringCbCatN	The RtlUnicodeStringCbCatN function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.
RtlUnicodeStringCbCatNEx	The RtlUnicodeStringCbCatNEx function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.
RtlUnicodeStringCbCatStringN	The RtlUnicodeStringCbCatStringN function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.

TITLE	DESCRIPTION
RtlUnicodeStringCbCatStringNEx	The RtlUnicodeStringCbCatStringNEx function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.
RtlUnicodeStringCbCopyN	The RtlUnicodeStringCbCopyN function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.
RtlUnicodeStringCbCopyNEx	The RtlUnicodeStringCbCopyNEx function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.
RtlUnicodeStringCbCopyStringN	The RtlUnicodeStringCbCopyStringN function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.
RtlUnicodeStringCbCopyStringNEx	The RtlUnicodeStringCbCopyStringNEx function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.
RtlUnicodeStringCchCatN	The RtlUnicodeStringCchCatN function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.
RtlUnicodeStringCchCatNEx	The RtlUnicodeStringCchCatNEx function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.
RtlUnicodeStringCchCatStringN	The RtlUnicodeStringCchCatStringN function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.
RtlUnicodeStringCchCatStringNEx	The RtlUnicodeStringCchCatStringNEx function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.
RtlUnicodeStringCchCopyN	The RtlUnicodeStringCchCopyN function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.
RtlUnicodeStringCchCopyNEx	The RtlUnicodeStringCchCopyNEx function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.
RtlUnicodeStringCchCopyStringN	The RtlUnicodeStringCchCopyStringN function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.
RtlUnicodeStringCchCopyStringNEx	The RtlUnicodeStringCchCopyStringNEx function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.

TITLE	DESCRIPTION
RtlUnicodeStringCopy	The RtlUnicodeStringCopy function copies a string from one UNICODE_STRING structure to another.
RtlUnicodeStringCopyEx	The RtlUnicodeStringCopyEx function copies a string from one UNICODE_STRING structure to another.
RtlUnicodeStringCopyString	The RtlUnicodeStringCopyString function copies a string into a UNICODE_STRING structure.
RtlUnicodeStringCopyStringEx	The RtlUnicodeStringCopyStringEx function copies a string into a UNICODE_STRING structure.
RtlUnicodeStringInit	The RtlUnicodeStringInit function initializes a UNICODE_STRING structure.
RtlUnicodeStringInitEx	The RtlUnicodeStringInitEx function initializes a UNICODE_STRING structure.
RtlUnicodeStringPrintf	The RtlUnicodeStringPrintf function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.
RtlUnicodeStringPrintfEx	The RtlUnicodeStringPrintfEx function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.
RtlUnicodeStringToAnsiSize	The RtlUnicodeStringToAnsiSize routine returns the number of bytes required for a null-terminated ANSI string that is equivalent to a specified Unicode string.
RtlUnicodeStringToAnsiString	The RtlUnicodeStringToAnsiString routine converts a given Unicode string into an ANSI string.
RtlUnicodeStringToInteger	The RtlUnicodeStringToInteger routine converts a Unicode string representation of a number to the equivalent integer value.
RtlUnicodeStringToInteger	The RtlUnicodeStringToInteger routine converts a Unicode string representation of a number to the equivalent integer value.
RtlUnicodeStringValidate	The RtlUnicodeStringValidate function validates the contents of a UNICODE_STRING structure.
RtlUnicodeStringValidateEx	The RtlUnicodeStringValidateEx function validates the contents of a UNICODE_STRING structure.
RtlUnicodeStringVPrintf	The RtlUnicodeStringVPrintf function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.

TITLE	DESCRIPTION
RtlUnicodeStringVPrintfEx	The RtlUnicodeStringVPrintfEx function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.
RtlUnicodeToUTF8N	The RtlUnicodeToUTF8N routine converts a Unicode string to a UTF-8 string.
RtlUnicodeToUTF8N	The RtlUnicodeToUTF8N routine converts a Unicode string to a UTF-8 string.
RtlUpcaseUnicodeChar	The RtlUpcaseUnicodeChar routine converts the specified Unicode character to uppercase.
RtlUpcaseUnicodeString	The RtlUpcaseUnicodeString routine converts a copy of the source string to uppercase and writes the converted string in the destination buffer.
RtlUpperChar	The RtlUpperChar routine converts the specified character to uppercase.
RtlUpperString	The RtlUpperString routine copies the given SourceString to the DestinationString buffer, converting it to uppercase.
RtlUShortAdd	Adds two values of type USHORT.
RtlUshortByteSwap	The RtlUshortByteSwap routine reverses the ordering of the two bytes in a 16-bit unsigned integer value.
RtlUShortMult	Multiplies one value of type USHORT by another.
RtlUShortSub	Subtracts one value of type USHORT from another.
RtlUShortToChar	Converts a value of type USHORT to a value of type CHAR.
RtlUShortToInt8	Converts a value of type USHORT to a value of type INT8.
RtlUShortToShort	Converts a value of type USHORT to a value of type SHORT.
RtlUShortToUChar	Converts a value of type USHORT to a value of type UCHAR.
RtlUShortToUInt8	Converts a value of type USHORT to a value of type UINT8.
RtlUTF8ToUnicodeN	The RtlUTF8ToUnicodeN routine converts a UTF-8 string to a Unicode string.
RtlUTF8ToUnicodeN	The RtlUTF8ToUnicodeN routine converts a UTF-8 string to a Unicode string.
RtlValidateCorrelationVector	Validates the specified correlation vector to check whether it conforms to the Correlation Vector Specification (v2).

TITLE	DESCRIPTION
RtlValidRelativeSecurityDescriptor	The RtlValidRelativeSecurityDescriptor routine checks the validity of a self-relative security descriptor.
RtlValidSecurityDescriptor	The RtlValidSecurityDescriptor routine checks a given security descriptor's validity.
RtlVerifyVersionInfo	The RtlVerifyVersionInfo routine compares a specified set of operating system version requirements to the corresponding attributes of the currently running version of the operating system.
RtlVolumeDeviceToDosName	The RtlVolumeDeviceToDosName routine is obsolete for Windows XP and later versions of Windows. Use IoVolumeDeviceToDosName instead.RtlVolumeDeviceToDosName returns the MS-DOS path for a specified device object that represents a file system volume.
RtlWriteRegistryValue	The RtlWriteRegistryValue routine writes caller-supplied data into the registry along the specified relative path at the given value name.
RtlxAnsiStringToUnicodeSize	The RtlxAnsiStringToUnicodeSize routine returns the number of bytes that are required for a null-terminated Unicode string that is equivalent to a specified ANSI string.
RtlxUnicodeStringToAnsiSize	The RtlxUnicodeStringToAnsiSize routine returns the number of bytes required for a null-terminated ANSI string that is equivalent to a specified Unicode string.
RtlZeroMemory	The RtlZeroMemory routine fills a block of memory with zeros, given a pointer to the block and the length, in bytes, to be filled.
SeAccessCheck	The SeAccessCheck routine determines whether the requested access rights can be granted to an object protected by a security descriptor and an object owner.
SeAssignSecurity	The SeAssignSecurity routine builds a self-relative security descriptor for a new object, given the security descriptor of its parent directory and any originally requested security for the object.
SeAssignSecurityEx	The SeAssignSecurityEx routine builds a self-relative security descriptor for a new object given the following optional parameters:_a security descriptor of the object's parent directory, an explicit security descriptor for the object, and the object type.
SeDeassignSecurity	The SeDeassignSecurity routine deallocates the memory associated with a security descriptor that was assigned using SeAssignSecurity.
SeFreePrivileges	The SeFreePrivileges routine frees a privilege set returned by SeAccessCheck.

TITLE	DESCRIPTION
SeSinglePrivilegeCheck	The SeSinglePrivilegeCheck routine checks for the passed privilege value in the context of the current thread.
SET_D3COLD_SUPPORT	The SetD3ColdSupport routine enables or disables transitions to the D3cold device power state.
SeValidSecurityDescriptor	The SeValidSecurityDescriptor routine returns whether a given security descriptor is structurally valid.
SILO_CONTEXT_CLEANUP_CALLBACK	This callback is invoked when the context object reaches a reference count of zero.
SILO_MONITOR_CREATE_CALLBACK	This is callback is invoked when a new silo is created.
SILO_MONITOR_TERMINATE_CALLBACK	This callback is invoked when a silo is terminated.
TmCommitComplete	The TmCommitComplete routine notifies KTM that the calling resource manager has finished committing a transaction.
TmCommitEnlistment	The TmCommitEnlistment routine initiates the commit operation for a specified enlistment's transaction.
TmCommitTransaction	The TmCommitTransaction routine initiates a commit operation for a specified transaction.
TmCreateEnlistment	The TmCreateEnlistment routine creates a new enlistment object for a transaction.
TmDereferenceEnlistmentKey	The TmDereferenceEnlistmentKey routine decrements the reference count for the key of a specified enlistment object.
TmEnableCallbacks	The TmEnableCallbacks routine enables a callback routine that receives transaction notifications.
TmGetTransactionId	The TmGetTransactionId routine retrieves a transaction object's unit of work (UOW) identifier.
TmInitializeTransactionManager	The TmInitializeTransactionManager routine initializes a transaction manager object.
TmIsTransactionActive	The TmIsTransactionActive routine indicates whether a specified transaction is in its active state.
TmPrepareComplete	The TmPrepareComplete routine notifies KTM that the calling resource manager has finished preparing a transaction's data.
TmPrepareEnlistment	The TmPrepareEnlistment routine initiates the prepare operation for a specified enlistment's transaction.
TmPrePrepareComplete	The TmPrePrepareComplete routine notifies KTM that the calling resource manager has finished preliminary preparation of a transaction's data.

TITLE	DESCRIPTION
TmPrePrepareEnlistment	The TmPrePrepareEnlistment routine initiates the pre-prepare operation for a specified enlistment's transaction.
TmReadOnlyEnlistment	The TmReadOnlyEnlistment routine sets a specified enlistment to be read-only.
TmRecoverEnlistment	The TmRecoverEnlistment routine initiates a recovery operation for the transaction that is associated with a specified enlistment.
TmRecoverResourceManager	The TmRecoverResourceManager routine tries to recover the transaction that is associated with each enlistment of a specified resource manager object.
TmRecoverTransactionManager	The TmRecoverTransactionManager routine reconstructs the state of the transaction manager object (including all transactions, enlistments, and resource managers) from the recovery information that is in the log stream.
TmReferenceEnlistmentKey	The TmReferenceEnlistmentKey routine increments the reference count for the key of a specified enlistment object and retrieves the key.
TmRenameTransactionManager	The TmRenameTransactionManager routine changes the identity of the transaction manager object that is stored in the CLFS log file stream contained in the log file name.
TmRequestOutcomeEnlistment	The TmRequestOutcomeEnlistment routine asks KTM to try to provide an immediate outcome (commit or rollback) for the transaction that is associated with a specified enlistment.
TmRollbackComplete	The TmRollbackComplete routine notifies KTM that the calling resource manager has finished rolling back a transaction's data.
TmRollbackEnlistment	The TmRollbackEnlistment routine rolls back a specified enlistment.
TmRollbackTransaction	The TmRollbackTransaction routine initiates a rollback operation for a specified transaction.
TmSinglePhaseReject	The TmSinglePhaseReject routine informs KTM that the calling resource manager will not support a single-phase commit operation for a specified enlistment.
TRANSLATE_BUS_ADDRESS	The TranslateBusAddress routine translates addresses on the parent bus to logical addresses.
VslCreateSecureSection	This material is not yet available. This placeholder topic is provided as an example of documentation that may be included in a later release.
VslDeleteSecureSection	This material is not yet available. This placeholder topic is provided as an example of documentation that may be included in a later release.

TITLE	DESCRIPTION
WdmlibIoConnectInterruptEx	The WdmlibIoConnectInterruptEx function registers an interrupt-handling routine for a device's interrupts.
WdmlibIoCreateDeviceSecure	The WdmlibIoCreateDeviceSecure function (or IoCreateDeviceSecure) creates a named device object and applies the specified security settings.
WdmlibIoDisconnectInterruptEx	The WdmlibIoDisconnectInterruptEx function unregisters an interrupt service routine (ISR) that was registered by a previous call to the WdmlibIoConnectInterruptEx function.
WdmlibIoGetAffinityInterrupt	The WdmlibIoGetAffinityInterrupt function gets the group affinity of an interrupt object.
WdmlibIoValidateDeviceIoControlAccess	The WdmlibIoValidateDeviceIoControlAccess function verifies that the sender of an IRP_MJ_DEVICE_CONTROL or IRP_MJ_FILE_SYSTEM_CONTROL IRP has the specified access to the device object.
WdmlibProcgrpInitialize	The WdmlibProcgrpInitialize function initializes the Processor Group (ProcGrp) compatibility library.
WdmlibRtlInitUnicodeStringEx	The WdmlibRtlInitUnicodeStringEx function initializes a counted string of Unicode characters.
WMI_EXECUTE_METHOD_CALLBACK	The DpWmiExecuteMethod routine executes a method associated with a data block. This routine is optional.
WMI_FUNCTION_CONTROL_CALLBACK	The DpWmiFunctionControl routine enables or disables notification of events, and enables or disables data collection for data blocks that the driver registered as expensive to collect. This routine is optional.
WMI_QUERY_DATABLOCK_CALLBACK	The DpWmiQueryDataBlock routine returns either a single instance or all instances of a data block. This routine is required.
WMI_QUERY_REGINFO_CALLBACK	The DpWmiQueryReginfo routine provides information about the data blocks and event blocks to be registered by a driver. This routine is required.
WMI_SET_DATABLOCK_CALLBACK	The DpWmiSetDataBlock routine changes all data items in a single instance of a data block. This routine is optional.
WMI_SET_DATAITEM_CALLBACK	The DpWmiSetDataItem routine changes a single data item in an instance of a data block. This routine is optional.
WmiCompleteRequest	The WmiCompleteRequest routine indicates that a driver has finished processing a WMI request in a DpWmiXxx routine.
WmiFireEvent	The WmiFireEvent routine sends an event to WMI for delivery to data consumers that have requested notification of the event.

TITLE	DESCRIPTION
WmiQueryTraceInformation	The WmiQueryTraceInformation routine returns information about a WMI event trace.
WmiSystemControl	The WmiSystemControl routine is a dispatch routine for drivers that use WMI library support routines to handle WMI IRPs.
WmiTraceMessage	The WmiTraceMessage routine adds a message to the output log of a WPP software tracing session.
WmiTraceMessageVa	The WmiTraceMessageVa routine adds a message to the output log of a WPP software tracing session.
WRITE_PORT_BUFFER_UCHAR	The WRITE_PORT_BUFFER_UCHAR routine writes a number of bytes from a buffer to the specified port.
WRITE_PORT_BUFFER_UCHAR	The WRITE_PORT_BUFFER_UCHAR routine writes a number of bytes from a buffer to the specified port.
WRITE_PORT_BUFFER_ULONG	The WRITE_PORT_BUFFER_ULONG routine writes a number of ULONG values from a buffer to the specified port address.
WRITE_PORT_BUFFER_ULONG	The WRITE_PORT_BUFFER_ULONG routine writes a number of ULONG values from a buffer to the specified port address.
WRITE_PORT_BUFFER_USHORT	The WRITE_PORT_BUFFER_USHORT routine writes a number of USHORT values from a buffer to the specified port address.
WRITE_PORT_BUFFER_USHORT	The WRITE_PORT_BUFFER_USHORT routine writes a number of USHORT values from a buffer to the specified port address.
WRITE_PORT_UCHAR	The WRITE_PORT_UCHAR routine writes a byte to the specified port address.
WRITE_PORT_UCHAR	The WRITE_PORT_UCHAR routine writes a byte to the specified port address.
WRITE_PORT_UCHAR	The WRITE_PORT_UCHAR routine writes a byte to the specified port address.
WRITE_PORT_ULONG	The WRITE_PORT_ULONG routine writes a ULONG value to the specified port address.
WRITE_PORT_ULONG	The WRITE_PORT_ULONG routine writes a ULONG value to the specified port address.
WRITE_PORT_ULONG	The WRITE_PORT_ULONG routine writes a ULONG value to the specified port address.
WRITE_PORT_USHORT	The WRITE_PORT_USHORT routine writes a USHORT value to the specified port address.
WRITE_PORT_USHORT	The WRITE_PORT_USHORT routine writes a USHORT value to the specified port address.

TITLE	DESCRIPTION
WRITE_PORT_USHORT	The WRITE_PORT_USHORT routine writes a USHORT value to the specified port address.
WRITE_REGISTER_BUFFER_UCHAR	The WRITE_REGISTER_BUFFER_UCHAR routine writes a number of bytes from a buffer to the specified register.
WRITE_REGISTER_BUFFER_UCHAR	The WRITE_REGISTER_BUFFER_UCHAR routine writes a number of bytes from a buffer to the specified register.
WRITE_REGISTER_BUFFER_UCHAR	The WRITE_REGISTER_BUFFER_UCHAR routine writes a number of bytes from a buffer to the specified register.
WRITE_REGISTER_BUFFER_ULONG	The WRITE_REGISTER_BUFFER_ULONG routine writes a number of ULONG values from a buffer to the specified register.
WRITE_REGISTER_BUFFER_ULONG	The WRITE_REGISTER_BUFFER_ULONG routine writes a number of ULONG values from a buffer to the specified register.
WRITE_REGISTER_BUFFER_ULONG	The WRITE_REGISTER_BUFFER_ULONG routine writes a number of ULONG values from a buffer to the specified register.
WRITE_REGISTER_BUFFER_ULONG64	The WRITE_REGISTER_BUFFER_ULONG64 function writes a number of ULONG64 values from a buffer to the specified register.
WRITE_REGISTER_BUFFER_USHORT	The WRITE_REGISTER_BUFFER_USHORT routine writes a number of USHORT values from a buffer to the specified register.
WRITE_REGISTER_BUFFER_USHORT	The WRITE_REGISTER_BUFFER_USHORT routine writes a number of USHORT values from a buffer to the specified register.
WRITE_REGISTER_BUFFER_USHORT	The WRITE_REGISTER_BUFFER_USHORT routine writes a number of USHORT values from a buffer to the specified register.
WRITE_REGISTER_UCHAR	The WRITE_REGISTER_UCHAR routine writes a byte to the specified address.
WRITE_REGISTER_UCHAR	The WRITE_REGISTER_UCHAR routine writes a byte to the specified address.
WRITE_REGISTER_UCHAR	The WRITE_REGISTER_UCHAR routine writes a byte to the specified address.
WRITE_REGISTER_UCHAR	The WRITE_REGISTER_UCHAR routine writes a byte to the specified address.
WRITE_REGISTER_ULONG	The WRITE_REGISTER_ULONG routine writes a ULONG value to the specified address.

TITLE	DESCRIPTION
WRITE_REGISTER_ULONG	The WRITE_REGISTER_ULONG routine writes a ULONG value to the specified address.
WRITE_REGISTER_ULONG	The WRITE_REGISTER_ULONG routine writes a ULONG value to the specified address.
WRITE_REGISTER_ULONG	The WRITE_REGISTER_ULONG routine writes a ULONG value to the specified address.
WRITE_REGISTER_USHORT	The WRITE_REGISTER_USHORT routine writes a USHORT value to the specified address.
WRITE_REGISTER_USHORT	The WRITE_REGISTER_USHORT routine writes a USHORT value to the specified address.
WRITE_REGISTER_USHORT	The WRITE_REGISTER_USHORT routine writes a USHORT value to the specified address.
WRITE_REGISTER_USHORT	The WRITE_REGISTER_USHORT routine writes a USHORT value to the specified address.
ZwAllocateLocallyUniqueId	The ZwAllocateLocallyUniqueId routine allocates a locally unique identifier (LUID).
ZwClose	The ZwClose routine closes an object handle.
ZwCommitComplete	The ZwCommitComplete routine notifies KTM that the calling resource manager has finished committing a transaction's data.
ZwCommitEnlistment	The ZwCommitEnlistment routine initiates the commit operation for a specified enlistment's transaction.
ZwCommitTransaction	The ZwCommitTransaction routine initiates a commit operation for a specified transaction.
ZwCreateDirectoryObject	The ZwCreateDirectoryObject routine creates or opens an object-directory object.
ZwCreateEnlistment	The ZwCreateEnlistment routine creates a new enlistment object for a transaction.
ZwCreateFile	The ZwCreateFile routine creates a new file or opens an existing file.
ZwCreateKey	The ZwCreateKey routine creates a new registry key or opens an existing one.
ZwCreateKeyTransacted	The ZwCreateKeyTransacted routine creates a new registry key or opens an existing one, and it associates the key with a transaction.
ZwCreateResourceManager	The ZwCreateResourceManager routine creates a resource manager object.

TITLE	DESCRIPTION
ZwCreateSection	The ZwCreateSection routine creates a section object.
ZwCreateTransaction	The ZwCreateTransaction routine creates a transaction object.
ZwCreateTransactionManager	The ZwCreateTransactionManager routine creates a new transaction manager object.
ZwDeleteKey	The ZwDeleteKey routine deletes an open key from the registry.
ZwDeleteValueKey	The ZwDeleteValueKey routine deletes a value entry matching a name from an open key in the registry. If no such entry exists, an error is returned.
ZwDeviceIoControlFile	The ZwDeviceIoControlFile routine sends a control code directly to a specified device driver, causing the corresponding driver to perform the specified operation.
ZwEnumerateKey	The ZwEnumerateKey routine returns information about a subkey of an open registry key.
ZwEnumerateTransactionObject	The ZwEnumerateTransactionObject routine enumerates the KTM objects on a computer.
ZwEnumerateValueKey	The ZwEnumerateValueKey routine gets information about the value entries of an open key.
ZwFlushKey	The ZwFlushKey routine forces a registry key to be committed to disk.
ZwGetNotificationResourceManager	The ZwGetNotificationResourceManager routine retrieves the next transaction notification from a specified resource manager's notification queue.
ZwLoadDriver	The ZwLoadDriver routine loads a driver into the system.
ZwMakeTemporaryObject	The ZwMakeTemporaryObject routine changes the attributes of an object to make it temporary.
ZwMapViewOfSection	The ZwMapViewOfSection routine maps a view of a section into the virtual address space of a subject process.
ZwOpenEnlistment	The ZwOpenEnlistment routine obtains a handle to an existing enlistment object.
ZwOpenEvent	The ZwOpenEvent routine opens a handle to an existing named event object with the specified desired access.
ZwOpenFile	The ZwOpenFile routine opens an existing file, directory, device, or volume.
ZwOpenKey	The ZwOpenKey routine opens an existing registry key.

TITLE	DESCRIPTION
ZwOpenKeyEx	The ZwOpenKeyEx routine opens an existing registry key.
ZwOpenKeyTransacted	The ZwOpenKeyTransacted routine opens an existing registry key and associates the key with a transaction.
ZwOpenKeyTransactedEx	The ZwOpenKeyTransactedEx routine opens an existing registry key and associates the key with a transaction.
ZwOpenProcess	The ZwOpenProcess routine opens a handle to a process object and sets the access rights to this object.
ZwOpenResourceManager	The ZwOpenResourceManager routine returns a handle to an existing resource manager object.
ZwOpenSection	The ZwOpenSection routine opens a handle for an existing section object.
ZwOpenSymbolicLinkObject	The ZwOpenSymbolicLinkObject routine opens an existing symbolic link.
ZwOpenTransaction	The ZwOpenTransaction routine obtains a handle to an existing transaction object.
ZwOpenTransactionManager	The ZwOpenTransactionManager routine obtains a handle to an existing transaction manager object.
ZwPowerInformation	The ZwPowerInformation routine sets or retrieves system power information.
ZwPrepareComplete	The ZwPrepareComplete routine notifies KTM that the calling resource manager has finished preparing a transaction's data.
ZwPrepareEnlistment	The ZwPrepareEnlistment routine initiates the prepare operation for a specified enlistment's transaction.
ZwPrePrepareComplete	The ZwPrePrepareComplete routine notifies KTM that the calling resource manager has finished preliminary preparation of a transaction's data.
ZwPrePrepareEnlistment	The ZwPrePrepareEnlistment routine initiates the pre-prepare operation for a specified enlistment's transaction.
ZwQueryFullAttributesFile	The ZwQueryFullAttributesFile routine supplies network open information for the specified file.
ZwQueryInformationEnlistment	The ZwQueryInformationEnlistment routine retrieves information about a specified enlistment object.
ZwQueryInformationFile	The ZwQueryInformationFile routine returns various kinds of information about a file object.
ZwQueryInformationResourceManager	The ZwQueryInformationResourceManager routine retrieves information about a specified resource manager object.

TITLE	DESCRIPTION
ZwQueryInformationTransaction	The ZwQueryInformationTransaction routine retrieves information about a specified transaction.
ZwQueryInformationTransactionManager	The ZwQueryInformationTransactionManager routine retrieves information about a specified transaction manager object.
ZwQueryKey	The ZwQueryKey routine provides information about the class of a registry key, and the number and sizes of its subkeys.
ZwQuerySymbolicLinkObject	The ZwQuerySymbolicLinkObject routine returns a Unicode string that contains the target of a symbolic link.
ZwQueryValueKey	The ZwQueryValueKey routine returns a value entry for a registry key.
ZwQueryVolumeInformationFile	The ZwQueryVolumeInformationFile routine retrieves information about the volume associated with a given file, directory, storage device, or volume.
ZwReadFile	The ZwReadFile routine reads data from an open file.
ZwReadOnlyEnlistment	The ZwReadOnlyEnlistment routine sets a specified enlistment to be read-only.
ZwRecoverEnlistment	The ZwRecoverEnlistment routine initiates a recovery operation for the transaction that is associated with a specified enlistment.
ZwRecoverResourceManager	The ZwRecoverResourceManager routine tries to recover the transaction that is associated with each enlistment of a specified resource manager object.
ZwRecoverTransactionManager	The ZwRecoverTransactionManager routine reconstructs the state of the transaction manager object (including all transactions, enlistments, and resource managers) from the recovery information that is in the log stream.
ZwRollbackComplete	The ZwRollbackComplete routine notifies KTM that the calling resource manager has finished rolling back a transaction's data.
ZwRollbackEnlistment	The ZwRollbackEnlistment routine rolls back the transaction that is associated with a specified enlistment.
ZwRollbackTransaction	The ZwRollbackTransaction routine initiates a rollback operation for a specified transaction.
ZwRollforwardTransactionManager	The ZwRollforwardTransactionManager routine initiates recovery operations for all of the in-progress transactions that are assigned to a specified transaction manager.
ZwSetInformationEnlistment	The ZwSetInformationEnlistment routine sets information for a specified enlistment object.

TITLE	DESCRIPTION
ZwSetInformationFile	The ZwSetInformationFile routine changes various kinds of information about a file object.
ZwSetInformationResourceManager	The ZwSetInformationResourceManager routine is not used.
ZwSetInformationThread	The ZwSetInformationThread routine sets the priority of a thread.
ZwSetInformationTransaction	The ZwSetInformationTransaction routine sets information for a specified transaction.
ZwSetValueKey	The ZwSetValueKey routine creates or replaces a registry key's value entry.
ZwSinglePhaseReject	The ZwSinglePhaseReject routine informs KTM that the calling resource manager will not support single-phase commit operations for a specified enlistment.
ZwTerminateProcess	The ZwTerminateProcess routine terminates a process and all of its threads.
ZwUnloadDriver	The ZwUnloadDriver routine unloads a driver from the system.
ZwUnmapViewOfSection	The ZwUnmapViewOfSection routine unmaps a view of a section from the virtual address space of a subject process.
ZwWriteFile	The ZwWriteFile routine writes data to an open file.

Structures

TITLE	DESCRIPTION
DMA_ADAPTER	The DMA_ADAPTER structure describes a system-defined interface to a DMA controller for a given device. A driver calls IoGetDmaAdapter to obtain this structure.
DMA_OPERATIONS	The DMA_OPERATIONS structure provides a table of pointers to functions that control the operation of a DMA controller.
IO_STATUS_BLOCK	A driver sets an IRP's I/O status block to indicate the final status of an I/O request, before calling IoCompleteRequest for the IRP.
AUX_MODULE_BASIC_INFO	The AUX_MODULE_BASIC_INFO structure contains basic information about a loaded image module.
AUX_MODULE_EXTENDED_INFO	The AUX_MODULE_EXTENDED_INFO structure contains extended information about a loaded image module.
BDCB_IMAGE_INFORMATION	The BDCB_IMAGE_INFORMATION structure describes information about a boot-start driver that is about to be initialized, provided by Windows to a boot-start driver's BOOT_DRIVER_CALLBACK_FUNCTION routine.

TITLE	DESCRIPTION
BDCB_STATUS_UPDATE_CONTEXT	The BDCB_STATUS_UPDATE_CONTEXT structure describes a status update provided by Windows to a boot-start driver's BOOT_DRIVER_CALLBACK_FUNCTION routine.
BOOTDISK_INFORMATION	The BOOTDISK_INFORMATION structure contains basic information describing the boot and system disks.
BOOTDISK_INFORMATION_EX	The BOOTDISK_INFORMATION_EX structure contains extended information describing the boot and system disks.
BUS_INTERFACE_STANDARD	The BUS_INTERFACE_STANDARD interface structure enables device drivers to make direct calls to parent bus driver routines. This structure defines the GUID_BUS_INTERFACE_STANDARD interface.
CLFS_LOG_NAME_INFORMATION	The CLFS_LOG_NAME_INFORMATION structure holds the name of a Common Log File System (CLFS) stream or log.
CLFS_MGMT_CLIENT_REGISTRATION	The CLFS_MGMT_CLIENT_REGISTRATION structure is given to CLFS management by clients who manage their own logs.
CLFS_MGMT_POLICY	The CLFS_MGMT_POLICY structure holds a description of a policy for managing a CLFS log.
CLFS_STREAM_ID_INFORMATION	The CLFS_STREAM_ID_INFORMATION structure holds a value that identifies a stream in a Common Log File System (CLFS) log.
CLS_CONTAINER_INFORMATION	The CLFS_CONTAINER_INFORMATION structure holds descriptive information for an individual container in a Common Log File System (CLFS) log.
CLS_INFORMATION	The CLFS_INFORMATION structure holds metadata and state information for a Common Log File System (CLFS) stream and/or its underlying physical log.
CLS_IO_STATISTICS	The CLFS_IO_STATISTICS structure holds I/O statistics data for a Common Log File System (CLFS) log.
CLS_IO_STATISTICS_HEADER	The CLFS_IO_STATISTICS_HEADER structure holds the header portion of a CLFS_IO_STATISTICS structure.
CLS_LSN	The CLFS_LSN structure identifies an individual record in a Common Log File System (CLFS) stream.
CLS_SCAN_CONTEXT	The CLFS_SCAN_CONTEXT structure holds context information to support a scan of the containers in a Common Log File System (CLFS) log.
CLS_WRITE_ENTRY	The CLFS_WRITE_ENTRY structure holds the address and size of a buffer that contains one unit of data to be written to a Common Log File System (CLFS) stream.

TITLE	DESCRIPTION
CM_EISA_FUNCTION_INFORMATION	The CM_EISA_FUNCTION_INFORMATION structure defines detailed EISA configuration information returned by HalGetBusData for the input BusDataType EisaConfiguration, or by HalGetBusDataByOffset for the input BusDataType EisaConfiguration and the Offset zero, assuming the caller-allocated Buffer is of sufficient Length.
CM_EISA_FUNCTION_INFORMATION	The CM_EISA_FUNCTION_INFORMATION structure defines detailed EISA configuration information returned by HalGetBusData for the input BusDataType EisaConfiguration, or by HalGetBusDataByOffset for the input BusDataType EisaConfiguration and the Offset zero, assuming the caller-allocated Buffer is of sufficient Length.
CM_EISA_SLOT_INFORMATION	The CM_EISA_SLOT_INFORMATION structure defines EISA configuration header information returned by HalGetBusData for the input BusDataType = EisaConfiguration, or by HalGetBusDataByOffset for the inputs BusDataType = EisaConfiguration and Offset = 0, assuming the caller-allocated Buffer is of sufficient Length.
CM_EISA_SLOT_INFORMATION	The CM_EISA_SLOT_INFORMATION structure defines EISA configuration header information returned by HalGetBusData for the input BusDataType = EisaConfiguration, or by HalGetBusDataByOffset for the inputs BusDataType = EisaConfiguration and Offset = 0, assuming the caller-allocated Buffer is of sufficient Length.
CM_FLOPPY_DEVICE_DATA	The CM_FLOPPY_DEVICE_DATA structure defines a device-type-specific data record that is stored in the \Registry\Machine\Hardware\Description tree for a floppy controller if the system can collect this information during the boot process.
CM_FULL_RESOURCE_DESCRIPTOR	The CM_FULL_RESOURCE_DESCRIPTOR structure specifies a set of system hardware resources of various types, assigned to a device that is connected to a specific bus. This structure is contained within a CM_RESOURCE_LIST structure.
CM_FULL_RESOURCE_DESCRIPTOR	The CM_FULL_RESOURCE_DESCRIPTOR structure specifies a set of system hardware resources of various types, assigned to a device that is connected to a specific bus. This structure is contained within a CM_RESOURCE_LIST structure.
CM_INT13_DRIVE_PARAMETER	The CM_INT13_DRIVE_PARAMETER structure defines a device-type-specific data record that is stored in the \Registry\Machine\Hardware\Description tree for a disk controller if the system can collect this information during the boot process.
CM_KEYBOARD_DEVICE_DATA	The CM_KEYBOARD_DEVICE_DATA structure defines a device-type-specific data record that is stored in the \Registry\Machine\Hardware\Description tree for a keyboard peripheral if the system can collect this information during the boot process.

TITLE	DESCRIPTION
CM_MCA_POS_DATA	The CM_MCA_POS_DATA structure is obsolete. It defines IBM-compatible MCA POS configuration information for a slot.
CM_MCA_POS_DATA	The CM_MCA_POS_DATA structure is obsolete. It defines IBM-compatible MCA POS configuration information for a slot.
CM_PARTIAL_RESOURCE_DESCRIPTOR	The CM_PARTIAL_RESOURCE_DESCRIPTOR structure specifies one or more system hardware resources, of a single type, assigned to a device.
CM_PARTIAL_RESOURCE_DESCRIPTOR	The CM_PARTIAL_RESOURCE_DESCRIPTOR structure specifies one or more system hardware resources, of a single type, assigned to a device.
CM_PARTIAL_RESOURCE_LIST	The CM_PARTIAL_RESOURCE_LIST structure specifies a set of system hardware resources, of various types, assigned to a device. This structure is contained within a CM_FULL_RESOURCE_DESCRIPTOR structure.
CM_PARTIAL_RESOURCE_LIST	The CM_PARTIAL_RESOURCE_LIST structure specifies a set of system hardware resources, of various types, assigned to a device. This structure is contained within a CM_FULL_RESOURCE_DESCRIPTOR structure.
CM_POWER_DATA	The CM_POWER_DATA structure contains information about a device's power management state and capabilities.
CM_POWER_DATA	The CM_POWER_DATA structure contains information about a device's power management state and capabilities.
CM_RESOURCE_LIST	The CM_RESOURCE_LIST structure specifies all of the system hardware resources assigned to a device.
CM_RESOURCE_LIST	The CM_RESOURCE_LIST structure specifies all of the system hardware resources assigned to a device.
CM_SCSI_DEVICE_DATA	The CM_SCSI_DEVICE_DATA structure defines a device-type-specific data record that is stored in the \Registry\Machine\Hardware\Description tree for a SCSI HBA if the system can collect this information during the boot process.
CM_SERIAL_DEVICE_DATA	The CM_SERIAL_DEVICE_DATA structure defines a device-type-specific data record that is stored in the \Registry\Machine\Hardware\Description tree for a serial controller if the system can collect this information during the boot process.
CONTROLLER_OBJECT	A controller object represents a hardware adapter or controller with homogenous devices that are the actual targets for I/O requests.
CORRELATION_VECTOR	Store the correlation vector that is used to reference events and the generated logs for diagnostic purposes.

TITLE	DESCRIPTION
COUNTED_REASON_CONTEXT	The COUNTED_REASON_CONTEXT structure contains one or more strings that give reasons for a power request.
COUNTED_REASON_CONTEXT	The COUNTED_REASON_CONTEXT structure contains one or more strings that give reasons for a power request.
D3COLD_SUPPORT_INTERFACE	The D3COLD_SUPPORT_INTERFACE interface structure contains pointers to the routines in the GUID_D3COLD_SUPPORT_INTERFACE driver interface.
DEVICE_CAPABILITIES	A DEVICE_CAPABILITIES structure describes PnP and power capabilities of a device. This structure is returned in response to an IRP_MN_QUERY_CAPABILITIES IRP.
DEVICE_DESCRIPTION	The DEVICE_DESCRIPTION structure describes the attributes of the physical device for which a driver is requesting a DMA adapter.
DEVICE_INTERFACE_CHANGE_NOTIFICATION	The DEVICE_INTERFACE_CHANGE_NOTIFICATION structure describes a device interface that has been enabled (arrived) or disabled (removed).
DEVICE_OBJECT	A device object represents a logical, virtual, or physical device for which a driver handles I/O requests.
DEVICE_RESET_INTERFACE_STANDARD	The DEVICE_RESET_INTERFACE_STANDARD structure enables function drivers to reset and recover malfunctioning devices. This structure describes the GUID_DEVICE_RESET_INTERFACE_STANDARD interface.
DMA_ADAPTER_INFO	The DMA_ADAPTER_INFO structure is a container for a DMA_ADAPTER_INFO_XXX structure that describes the capabilities of a system DMA controller.
DMA_ADAPTER_INFO_V1	The DMA_ADAPTER_INFO_V1 structure describes the capabilities of the system DMA controller that is represented by an adapter object.
DMA_TRANSFER_INFO	The DMA_TRANSFER_INFO structure is a container for a DMA_TRANSFER_INFO_XXX structure that describes the allocation requirements for a scatter/gather list.
DMA_TRANSFER_INFO_V1	The DMA_TRANSFER_INFO_V1 structure contains the allocation requirements for a scatter/gather list that describes the I/O data buffer for a DMA transfer.
DRIVER_OBJECT	Each driver object represents the image of a loaded kernel-mode driver.
ENLISTMENT_BASIC_INFORMATION	The ENLISTMENT_BASIC_INFORMATION structure contains information about an enlistment object.
EXT_DELETE_PARAMETERS	The EXT_DELETE_PARAMETERS structure contains an extended set of parameters for the ExDeleteTimer routine.

TITLE	DESCRIPTION
EXT_SET_PARAMETERS	The EXT_SET_PARAMETERS structure contains an extended set of parameters for the ExSetTimer routine.
FILE_ACCESS_INFORMATION	The FILE_ACCESS_INFORMATION structure is used to query for or set the access rights of a file.
FILE_ALIGNMENT_INFORMATION	The FILE_ALIGNMENT_INFORMATION structure is used as an argument to the ZwQueryInformationFile routine.
FILE_ALL_INFORMATION	The FILE_ALL_INFORMATION structure is a container for several FILE_XXX_INFORMATION structures.
FILE_ATTRIBUTE_TAG_INFORMATION	The FILE_ATTRIBUTE_TAG_INFORMATION structure is used as an argument to ZwQueryInformationFile.
FILE_BASIC_INFORMATION	The FILE_BASIC_INFORMATION structure is used as an argument to routines that query or set file information.
FILE_DISPOSITION_INFORMATION	The FILE_DISPOSITION_INFORMATION structure is used as an argument to the ZwSetInformationFile routine.
FILE_EA_INFORMATION	The FILE_EA_INFORMATION structure is used to query for the size of the extended attributes (EA) for a file.
FILE_END_OF_FILE_INFORMATION	The FILE_END_OF_FILE_INFORMATION structure is used as an argument to the ZwSetInformationFile routine.
FILE_FS_DEVICE_INFORMATION	The FILE_FS_DEVICE_INFORMATION structure provides file system device information about the type of device object associated with a file object.
FILE_FULL_EA_INFORMATION	The FILE_FULL_EA_INFORMATION structure provides extended attribute (EA) information. This structure is used primarily by network drivers.
FILE_IO_PRIORITY_HINT_INFORMATION	The FILE_IO_PRIORITY_HINT_INFORMATION structure is used by the ZwQueryInformationFile and ZwSetInformationFile routines to query and set the default IRP priority hint for requests on the specified file handle.
FILE_IS_REMOTE_DEVICE_INFORMATION	The FILE_IS_REMOTE_DEVICE_INFORMATION structure is used as an argument to the ZwQueryInformationFile routine.
FILE_MODE_INFORMATION	The FILE_MODE_INFORMATION structure is used to query or set the access mode of a file.
FILE_NAME_INFORMATION	The FILE_NAME_INFORMATION structure is used as argument to the ZwQueryInformationFile and ZwSetInformationFile routines.
FILE_NETWORK_OPEN_INFORMATION	The FILE_NETWORK_OPEN_INFORMATION structure is used as an argument to ZwQueryInformationFile.

TITLE	DESCRIPTION
FILE_OBJECT	The FILE_OBJECT structure is used by the system to represent a file object.
FILE_POSITION_INFORMATION	The FILE_POSITION_INFORMATION structure is used as an argument to routines that query or set file information.
FILE_STANDARD_INFORMATION	The FILE_STANDARD_INFORMATION structure is used as an argument to routines that query or set file information.
FILE_STANDARD_INFORMATION_EX	The FILE_STANDARD_INFORMATION_EX structure is used as an argument to routines that query or set file information.
FILE_VALID_DATA_LENGTH_INFORMATION	The FILE_VALID_DATA_LENGTH_INFORMATION structure is used as an argument to ZwSetInformationFile.
FUNCTION_LEVEL_DEVICE_RESET_PARAMETERS	The FUNCTION_LEVEL_DEVICE_RESET_PARAMETER structure is used as an argument to the DeviceReset routine of the GUID_DEVICE_RESET_INTERFACE_STANDARD interface.
GENERIC_MAPPING	The GENERIC_MAPPING structure describes the ACCESS_MASK value of specific access rights associated with each type of generic access right.
GROUP_AFFINITY	The GROUP_AFFINITY structure specifies a group number and the processor affinity within that group.
HARDWARE_COUNTER	The HARDWARE_COUNTER structure contains information about a hardware counter.
HWPROFILE_CHANGE_NOTIFICATION	The HWPROFILE_CHANGE_NOTIFICATION structure describes an event related to a hardware profile configuration change.
IMAGE_INFO	Used by driver's load-image routine (PLOAD_IMAGE_NOTIFY_ROUTINE) to specify image information.
IMAGE_INFO_EX	Extended version of the image information structure (see IMAGE_INFO).
IMAGE_POLICY_ENTRY	This structure is not supported.
IMAGE_POLICY_METADATA	This structure is not supported.
INTERFACE	The INTERFACE structure describes an interface that is exported by a driver for use by other drivers.
INTERFACE	The INTERFACE structure describes an interface that is exported by a driver for use by other drivers.
IO_CONNECT_INTERRUPT_PARAMETERS	The IO_CONNECT_INTERRUPT_PARAMETERS structure contains the parameters that a driver supplies to the IoConnectInterruptEx routine to register an interrupt service routine (ISR).

TITLE	DESCRIPTION
IO_DISCONNECT_INTERRUPT_PARAMETERS	The IO_DISCONNECT_INTERRUPT_PARAMETERS structure describes the parameters when unregistering an interrupt-handling routine with IoDisconnectInterruptEx.
IO_ERROR_LOG_PACKET	The IO_ERROR_LOG_PACKET structure serves as the header for an error log entry.
IO_INTERRUPT_MESSAGE_INFO	The IO_INTERRUPT_MESSAGE_INFO structure describes the driver's message-signaled interrupts.
IO_INTERRUPT_MESSAGE_INFO_ENTRY	The IO_INTERRUPT_MESSAGE_INFO_ENTRY structure describes the properties of a single message-signaled interrupt.
IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS	The IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS structure contains the connection context for a registered interrupt service routine (ISR) that was connected to an interrupt or interrupts by a previous call to the IoConnectInterruptEx routine.
IO_RESOURCE_DESCRIPTOR	The IO_RESOURCE_DESCRIPTOR structure describes a range of raw hardware resources, of one type, that can be used by a device. An array of IO_RESOURCE_DESCRIPTOR structures is contained within each IO_RESOURCE_LIST structure.
IO_RESOURCE_DESCRIPTOR	The IO_RESOURCE_DESCRIPTOR structure describes a range of raw hardware resources, of one type, that can be used by a device. An array of IO_RESOURCE_DESCRIPTOR structures is contained within each IO_RESOURCE_LIST structure.
IO_RESOURCE_LIST	The IO_RESOURCE_LIST structure describes a range of raw hardware resources, of various types, that can be used by a device.
IO_RESOURCE_LIST	The IO_RESOURCE_LIST structure describes a range of raw hardware resources, of various types, that can be used by a device.
IO_RESOURCE_REQUIREMENTS_LIST	The IO_RESOURCE_REQUIREMENTS_LIST structure describes sets of resource configurations that can be used by a device. Each configuration represents a range of raw resources, of various types, that can be used by a device.
IO_RESOURCE_REQUIREMENTS_LIST	The IO_RESOURCE_REQUIREMENTS_LIST structure describes sets of resource configurations that can be used by a device. Each configuration represents a range of raw resources, of various types, that can be used by a device.
IO_SECURITY_CONTEXT	The IO_SECURITY_CONTEXT structure represents the security context of an IRP_MJ_CREATE request.
IO_SESSION_CONNECT_INFO	The IO_SESSION_CONNECT_INFO structure provides information about a user session.

TITLE	DESCRIPTION
IO_SESSION_STATE_INFORMATION	The IO_SESSION_STATE_INFORMATION structure contains information about the state of a user session.
IO_SESSION_STATE_NOTIFICATION	The IO_SESSION_STATE_NOTIFICATION structure contains information that a kernel-mode driver supplies to the IoRegisterContainerNotification routine when the driver registers to receive notifications of session events.
IO_STACK_LOCATION	The IO_STACK_LOCATION structure defines an I/O stack location, which is an entry in the I/O stack that is associated with each IRP.
IO_STATUS_BLOCK	A driver sets an IRP's I/O status block to indicate the final status of an I/O request, before calling IoCompleteRequest for the IRP.
IRP	The IRP structure is a partially opaque structure that represents an I/O request packet. Drivers can use the following members of the IRP structure.
KBUGCHECK_ADD_PAGES	The KBUGCHECK_ADD_PAGES structure describes one or more pages of driver-supplied data to be written by a BugCheckAddPagesCallback callback routine to the crash dump file.
KBUGCHECK_DATA	The KBUGCHECK_DATA structure contains bug check parameters.
KBUGCHECK_DUMP_IO	The KBUGCHECK_DUMP_IO structure describes an I/O operation on the crash dump file.
KBUGCHECK_SECONDARY_DUMP_DATA	The KBUGCHECK_SECONDARY_DUMP_DATA structure describes a section of driver-supplied data to be written by BugCheckSecondaryDumpDataCallback to the crash dump file.
KDPC_WATCHDOG_INFORMATION	The KDPC_WATCHDOG_INFORMATION structure holds time-out information about the current deferred procedure call (DPC).
KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT	The KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT structure describes the notification context that is passed to a registered callback function when a new processor is dynamically added to a hardware partition.
KEY_BASIC_INFORMATION	The KEY_BASIC_INFORMATION structure defines a subset of the full information that is available for a registry key.
KEY_CACHED_INFORMATION	The KEY_CACHED_INFORMATION structure holds the cached information available for a registry key or subkey.
KEY_FULL_INFORMATION	The KEY_FULL_INFORMATION structure defines the information available for a registry key, including information about its subkeys and the maximum length for their names and value entries.

TITLE	DESCRIPTION
KEY_NAME_INFORMATION	The KEY_NAME_INFORMATION structure holds the name and name length of the key.
KEY_NODE_INFORMATION	The KEY_NODE_INFORMATION structure defines the basic information available for a registry (sub)key.
KEY_VALUE_BASIC_INFORMATION	The KEY_VALUE_BASIC_INFORMATION structure defines a subset of the full information available for a value entry of a registry key.
KEY_VALUE_ENTRY	The KEY_VALUE_ENTRY structure is used by the REG_QUERY_MULTIPLE_VALUE_KEY_INFORMATION structure to describe a single value entry for a registry key.
KEY_VALUE_FULL_INFORMATION	The KEY_VALUE_FULL_INFORMATION structure defines information available for a value entry of a registry key.
KEY_VALUE_PARTIAL_INFORMATION	The KEY_VALUE_PARTIAL_INFORMATION structure defines a subset of the value information available for a value entry of a registry key.
KEY_VIRTUALIZATION_INFORMATION	The KEY_VIRTUALIZATION_INFORMATION structure defines the basic information that is available for a registry key or subkey.
KEY_WRITE_TIME_INFORMATION	The KEY_WRITE_TIME_INFORMATION structure is used by the system to set the last write time for a registry key.
KTMOBJECT_CURSOR	The KTMOBJECT_CURSOR structure receives enumeration information about KTM objects when a component calls ZwEnumerateTransactionObject.
LINK_SHARE_ACCESS	The share access structure used by file systems for only link files.
MDL	An MDL structure is a partially opaque structure that represents a memory descriptor list (MDL).
MEMORY_BASIC_INFORMATION	Contains information about a range of pages in the virtual address space of a process.
MM_COPY_ADDRESS	The MM_COPY_ADDRESS structure contains either a virtual memory address or a physical memory address.
MM_PHYSICAL_ADDRESS_LIST	The MM_PHYSICAL_ADDRESS_LIST structure specifies a range of physical addresses.
OB_CALLBACK_REGISTRATION	The OB_CALLBACK_REGISTRATION structure specifies the parameters when the ObRegisterCallbacks routine registers ObjectPreCallback and ObjectPostCallback callback routines.
OB_OPERATION_REGISTRATION	The OB_OPERATION_REGISTRATION structure specifies ObjectPreCallback and ObjectPostCallback callback routines and the types of operations that the routines are called for.

TITLE	DESCRIPTION
OB_POST_CREATE_HANDLE_INFORMATION	The OB_POST_CREATE_HANDLE_INFORMATION structure provides information to a ObjectPostCallback routine about a thread or process handle that has been opened.
OB_POST_DUPLICATE_HANDLE_INFORMATION	The OB_POST_DUPLICATE_HANDLE_INFORMATION structure provides information to an ObjectPostCallback routine about a thread or process handle that has been duplicated.
OB_POST_OPERATION_INFORMATION	The OB_POST_OPERATION_INFORMATION structure provides information about a process or thread handle operation to an ObjectPostCallback routine.
OB_POST_OPERATION_PARAMETERS	The OB_POST_OPERATION_PARAMETERS union describes the operation-specific parameters for an ObjectPostCallback routine.
OB_PRE_CREATE_HANDLE_INFORMATION	The OB_PRE_CREATE_HANDLE_INFORMATION structure provides information to an ObjectPreCallback routine about a thread or process handle that is being opened.
OB_PRE_DUPLICATE_HANDLE_INFORMATION	The OB_PRE_DUPLICATE_HANDLE_INFORMATION structure provides information to an ObjectPreCallback routine about a thread or process handle that is being duplicated.
OB_PRE_OPERATION_INFORMATION	The OB_PRE_OPERATION_INFORMATION structure provides information about a process or thread handle operation to an ObjectPreCallback routine.
OB_PRE_OPERATION_PARAMETERS	The OB_PRE_OPERATION_PARAMETERS union describes the operation-specific parameters for an ObjectPreCallback routine.
OBJECT_ATTRIBUTES	The OBJECT_ATTRIBUTES structure specifies attributes that can be applied to objects or object handles by routines that create objects and/or return handles to objects.
OSVERSIONINFOEXW	The RTL_OSVERSIONINFOEXW structure contains operating system version information.
OSVERSIONINFOW	The RTL_OSVERSIONINFOW structure contains operating system version information.
PCI_COMMON_CONFIG	The PCI_COMMON_CONFIG structure is obsolete.
PCI_COMMON_CONFIG	The PCI_COMMON_CONFIG structure is obsolete.
PCI_MSIX_TABLE_CONFIG_INTERFACE	The PCI_MSIX_TABLE_CONFIG_INTERFACE structure enables device drivers to modify their MSI-X interrupt settings. This structure describes the GUID_MSIX_TABLE_CONFIG_INTERFACE interface.
PCI_SLOT_NUMBER	The PCI_SLOT_NUMBER structure is obsolete.
PCI_SLOT_NUMBER	The PCI_SLOT_NUMBER structure is obsolete.

TITLE	DESCRIPTION
PEP_ABANDON_DEVICE	The PEP_ABANDON_DEVICE structure identifies a device that has been abandoned and will no longer be used by the operating system.
PEP_ABANDON_DEVICE	The PEP_ABANDON_DEVICE structure identifies a device that has been abandoned and will no longer be used by the operating system.
PEP_ACPI_ABANDON_DEVICE	The PEP_ACPI_ABANDON_DEVICE structure indicates whether the platform extension plug-in (PEP) accepts ownership of an abandoned device.
PEP_ACPI_ABANDON_DEVICE	The PEP_ACPI_ABANDON_DEVICE structure indicates whether the platform extension plug-in (PEP) accepts ownership of an abandoned device.
PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE	The PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE structure contains an enumeration of the objects in the namespace of the device.
PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE	The PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE structure contains an enumeration of the objects in the namespace of the device.
PEP_ACPI_EVALUATE_CONTROL_METHOD	The PEP_ACPI_EVALUATE_CONTROL_METHOD structure specifies an ACPI control method to evaluate, an input argument to supply to this method, and an output buffer for the result of the evaluation.
PEP_ACPI_EVALUATE_CONTROL_METHOD	The PEP_ACPI_EVALUATE_CONTROL_METHOD structure specifies an ACPI control method to evaluate, an input argument to supply to this method, and an output buffer for the result of the evaluation.
PEP_ACPI_EXTENDED_ADDRESS	The PEP_ACPI_EXTENDED_ADDRESS structure is used to report resource usage in the address space such as memory and IO.
PEP_ACPI_EXTENDED_ADDRESS	The PEP_ACPI_EXTENDED_ADDRESS structure is used to report resource usage in the address space such as memory and IO.
PEP_ACPI_GPIO_RESOURCE	The PEP_ACPI_GPIO_RESOURCE structure describes the ACPI configuration for a general purpose input/output (GPIO) resource.
PEP_ACPI_GPIO_RESOURCE	The PEP_ACPI_GPIO_RESOURCE structure describes the ACPI configuration for a general purpose input/output (GPIO) resource.
PEP_ACPI_INTERRUPT_RESOURCE	The PEP_ACPI_INTERRUPT_RESOURCE structure describes an ACPI interrupt resource.
PEP_ACPI_INTERRUPT_RESOURCE	The PEP_ACPI_INTERRUPT_RESOURCE structure describes an ACPI interrupt resource.

TITLE	DESCRIPTION
PEP_ACPI_IO_MEMORY_RESOURCE	The PEP_ACPI_IO_MEMORY_RESOURCE structure describes an ACPI IO port descriptor resource.
PEP_ACPI_IO_MEMORY_RESOURCE	The PEP_ACPI_IO_MEMORY_RESOURCE structure describes an ACPI IO port descriptor resource.
PEP_ACPI_OBJECT_NAME	The PEP_ACPI_OBJECT_NAME union contains the four-character name of an ACPI object.
PEP_ACPI_OBJECT_NAME	The PEP_ACPI_OBJECT_NAME union contains the four-character name of an ACPI object.
PEP_ACPI_OBJECT_NAME_WITH_TYPE	The PEP_ACPI_OBJECT_NAME_WITH_TYPE structure that specifies both the path-relative name of an ACPI object and the type of this object.
PEP_ACPI_OBJECT_NAME_WITH_TYPE	The PEP_ACPI_OBJECT_NAME_WITH_TYPE structure that specifies both the path-relative name of an ACPI object and the type of this object.
PEP_ACPI_PREPARE_DEVICE	The PEP_ACPI_PREPARE_DEVICE structure indicates whether a platform extension plug-in (PEP) is prepared to provide ACPI services for the specified device.
PEP_ACPI_PREPARE_DEVICE	The PEP_ACPI_PREPARE_DEVICE structure indicates whether a platform extension plug-in (PEP) is prepared to provide ACPI services for the specified device.
PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES	The PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES structure contains a list of raw resources that are needed to control power to the device.
PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES	The PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES structure contains a list of raw resources that are needed to control power to the device.
PEP_ACPI_QUERY_OBJECT_INFORMATION	The PEP_ACPI_QUERY_OBJECT_INFORMATION structure contains information about an ACPI object.
PEP_ACPI_QUERY_OBJECT_INFORMATION	The PEP_ACPI_QUERY_OBJECT_INFORMATION structure contains information about an ACPI object.
PEP_ACPI_REGISTER_DEVICE	The PEP_ACPI_REGISTER_DEVICE structure contains registration information about a device for which the platform extension plug-in (PEP) is to provide ACPI services.
PEP_ACPI_REGISTER_DEVICE	The PEP_ACPI_REGISTER_DEVICE structure contains registration information about a device for which the platform extension plug-in (PEP) is to provide ACPI services.
PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES	The PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES structure is used in the process of converting ACPI resources to BIOS resources by one of the PEP initialization functions.

TITLE	DESCRIPTION
PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES	The PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES structure is used in the process of converting ACPI resources to BIOS resources by one of the PEP initialization functions.
PEP_ACPI_RESOURCE	The PEP_ACPI_RESOURCE structure contains hardware details for a specific ACPI resource.
PEP_ACPI_RESOURCE	The PEP_ACPI_RESOURCE structure contains hardware details for a specific ACPI resource.
PEP_ACPI_RESOURCE_FLAGS	The PEP_ACPI_RESOURCE_FLAGS structure contains flags describing an ACPI resource.
PEP_ACPI_RESOURCE_FLAGS	The PEP_ACPI_RESOURCE_FLAGS structure contains flags describing an ACPI resource.
PEP_ACPI_SPB_I2C_RESOURCE	The PEP_ACPI_SPB_I2C_RESOURCE structure describes an ACPI I2C serial bus resource.
PEP_ACPI_SPB_I2C_RESOURCE	The PEP_ACPI_SPB_I2C_RESOURCE structure describes an ACPI I2C serial bus resource.
PEP_ACPI_SPB_RESOURCE	The PEP_ACPI_SPB_RESOURCE structure describes an ACPI serial bus connection resource.
PEP_ACPI_SPB_RESOURCE	The PEP_ACPI_SPB_RESOURCE structure describes an ACPI serial bus connection resource.
PEP_ACPI_SPB_SPI_RESOURCE	The PEP_ACPI_SPB_SPI_RESOURCE structure describes an ACPI SPI serial bus resource.
PEP_ACPI_SPB_SPI_RESOURCE	The PEP_ACPI_SPB_SPI_RESOURCE structure describes an ACPI SPI serial bus resource.
PEP_ACPI_SPB_UART_RESOURCE	The PEP_ACPI_SPB_UART_RESOURCE structure describes an ACPI UART serial bus resource.
PEP_ACPI_SPB_UART_RESOURCE	The PEP_ACPI_SPB_UART_RESOURCE structure describes an ACPI UART serial bus resource.
PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES	The PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES structure contains a list of translated power-control resources for the platform extension plug-in (PEP) to use.
PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES	The PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES structure contains a list of translated power-control resources for the platform extension plug-in (PEP) to use.
PEP_ACPI_UNREGISTER_DEVICE	The PEP_ACPI_UNREGISTER_DEVICE structure contains information about a device that has been unregistered from ACPI services.

TITLE	DESCRIPTION
PEP_ACPI_UNREGISTER_DEVICE	The PEP_ACPI_UNREGISTER_DEVICE structure contains information about a device that has been unregistered from ACPI services.
PEP_COMPONENT_ACTIVE	The PEP_COMPONENT_ACTIVE structure identifies a component that is making a transition between the idle condition and the active condition.
PEP_COMPONENT_PERF_INFO	The PEP_COMPONENT_PERF_INFO structure describes the performance states (P-states) of a component.
PEP_COMPONENT_PERF_INFO	The PEP_COMPONENT_PERF_INFO structure describes the performance states (P-states) of a component.
PEP_COMPONENT_PERF_SET	The PEP_COMPONENT_PERF_SET structure describes the performance states (P-states) in a P-state set.
PEP_COMPONENT_PERF_SET	The PEP_COMPONENT_PERF_SET structure describes the performance states (P-states) in a P-state set.
PEP_COMPONENT_PERF_STATE_REQUEST	The PEP_COMPONENT_PERF_STATE_REQUEST structure specifies a performance state (P-state) set and a new performance level to assign to this set.
PEP_COMPONENT_PERF_STATE_REQUEST	The PEP_COMPONENT_PERF_STATE_REQUEST structure specifies a performance state (P-state) set and a new performance level to assign to this set.
PEP_COMPONENT_PLATFORM_CONSTRAINTS	The PEP_COMPONENT_PLATFORM_CONSTRAINTS structure describes the lowest-powered Fx state of that a component can be in when the platform is in a particular idle state.
PEP_COMPONENT_PLATFORM_CONSTRAINTS	The PEP_COMPONENT_PLATFORM_CONSTRAINTS structure describes the lowest-powered Fx state of that a component can be in when the platform is in a particular idle state.
PEP_COMPONENT_V2	The PEP_COMPONENT_V2 structure specifies the power state attributes of a component in the device.
PEP_COMPONENT_V2	The PEP_COMPONENT_V2 structure specifies the power state attributes of a component in the device.
PEP_COORDINATED_DEPENDENCY_OPTION	The PEP_COORIDNATED_DEPENDENCY_OPTION structure describes a coordinated idle state's dependency to the OS.
PEP_COORDINATED_DEPENDENCY_OPTION	The PEP_COORIDNATED_DEPENDENCY_OPTION structure describes a coordinated idle state's dependency to the OS.
PEP_COORDINATED_IDLE_STATE	The PEP_COORIDNATED_IDLE_STATE structure describes a coordinated idle state to the OS.
PEP_COORDINATED_IDLE_STATE	The PEP_COORIDNATED_IDLE_STATE structure describes a coordinated idle state to the OS.

TITLE	DESCRIPTION
PEP_CRASHDUMP_INFORMATION	The PEP_CRASHDUMP_INFORMATION structure contains information about a crash-dump device.
PEP_CRASHDUMP_INFORMATION	The PEP_CRASHDUMP_INFORMATION structure contains information about a crash-dump device.
PEP_DEBUGGER_TRANSITION_REQUIREMENTS	The PEP_DEBUGGER_TRANSITION_REQUIREMENTS structure indicates the platform idle states for which the debugger device must be turned on.
PEP_DEBUGGER_TRANSITION_REQUIREMENTS	The PEP_DEBUGGER_TRANSITION_REQUIREMENTS structure indicates the platform idle states for which the debugger device must be turned on.
PEP_DEVICE_PLATFORM_CONSTRAINTS	The PEP_DEVICE_PLATFORM_CONSTRAINTS structure specifies the constraints for entry to the various Dx power states that are supported by a device.
PEP_DEVICE_PLATFORM_CONSTRAINTS	The PEP_DEVICE_PLATFORM_CONSTRAINTS structure specifies the constraints for entry to the various Dx power states that are supported by a device.
PEP_DEVICE_POWER_STATE	The PEP_DEVICE_POWER_STATE structure indicates the status of a transition to a new Dx (device power) state.
PEP_DEVICE_POWER_STATE	The PEP_DEVICE_POWER_STATE structure indicates the status of a transition to a new Dx (device power) state.
PEP_DEVICE_REGISTER_V2	The PEP_DEVICE_REGISTER structure describes all the components in a particular device.
PEP_DEVICE_REGISTER_V2	The PEP_DEVICE_REGISTER structure describes all the components in a particular device.
PEP_DEVICE_STARTED	The PEP_DEVICE_STARTED structure identifies a device whose driver has completed its registration with the Windows power management framework (PoFx).
PEP_DEVICE_STARTED	The PEP_DEVICE_STARTED structure identifies a device whose driver has completed its registration with the Windows power management framework (PoFx).
PEP_INFORMATION	The PEP_INFORMATION structure specifies the interface that the platform extension plug-in (PEP) uses to receive notifications from the Windows power management framework (PoFx).
PEP_INFORMATION	The PEP_INFORMATION structure specifies the interface that the platform extension plug-in (PEP) uses to receive notifications from the Windows power management framework (PoFx).

TITLE	DESCRIPTION
PEP_KERNEL_INFORMATION_STRUCT_V1	The PEP_KERNEL_INFORMATION structure specifies the interface that the power extension plug-in (PEP) uses to request services from the Windows power management framework (PoFx).
PEP_KERNEL_INFORMATION_STRUCT_V2	The PEP_KERNEL_INFORMATION structure specifies the interface that the power extension plug-in (PEP) uses to request services from the Windows power management framework (PoFx).
PEP_KERNEL_INFORMATION_STRUCT_V3	The PEP_KERNEL_INFORMATION structure specifies the interface that the power extension plug-in (PEP) uses to request services from the Windows power management framework (PoFx).
PEP_KERNEL_INFORMATION_STRUCT_V3	The PEP_KERNEL_INFORMATION_STRUCT_V3 structure specifies the interface that the power extension plug-in (PEP) uses to request services from the Windows power management framework (PoFx).
PEP_LOW_POWER_EPOCH	The PEP_LOW_POWER_EPOCH structure is used to provide data for a PEP_DPM_LOW_POWER_EPOCH notification (deprecated).
PEP_LOW_POWER_EPOCH	The PEP_LOW_POWER_EPOCH structure is used to provide data for a PEP_DPM_LOW_POWER_EPOCH notification (deprecated).
PEP_NOTIFY_COMPONENT_IDLE_STATE	The PEP_NOTIFY_COMPONENT_IDLE_STATE structure contains status information about a component's pending transition to a new Fx power state.
PEP_NOTIFY_COMPONENT_IDLE_STATE	The PEP_NOTIFY_COMPONENT_IDLE_STATE structure contains status information about a component's pending transition to a new Fx power state.
PEP_PERF_STATE	The PEP_PERF_STATE structure describes a performance state (P-state) in a P-state set in which the P-states are specified as a list of one or more discrete values.
PEP_PERF_STATE	The PEP_PERF_STATE structure describes a performance state (P-state) in a P-state set in which the P-states are specified as a list of one or more discrete values.
PEP_PLATFORM_IDLE_STATE	The PEP_PLATFORM_IDLE_STATE structure specifies the properties of a platform idle state.
PEP_PLATFORM_IDLE_STATE	The PEP_PLATFORM_IDLE_STATE structure specifies the properties of a platform idle state.
PEP_PLATFORM_IDLE_STATE_UPDATE	The PEP_PLATFORM_IDLE_STATE_UPDATE structure contains the updated properties of a platform idle state.
PEP_PLATFORM_IDLE_STATE_UPDATE	The PEP_PLATFORM_IDLE_STATE_UPDATE structure contains the updated properties of a platform idle state.

TITLE	DESCRIPTION
PEP_POWER_CONTROL_COMPLETE	The PEP_POWER_CONTROL_COMPLETE structure contains status information for a power control operation that the PEP previously requested and that the device driver has completed.
PEP_POWER_CONTROL_COMPLETE	The PEP_POWER_CONTROL_COMPLETE structure contains status information for a power control operation that the PEP previously requested and that the device driver has completed.
PEP_POWER_CONTROL_REQUEST	The PEP_POWER_CONTROL_REQUEST structure contains a request from a driver for a power control operation.
PEP_POWER_CONTROL_REQUEST	The PEP_POWER_CONTROL_REQUEST structure contains a request from a driver for a power control operation.
PEP_PPM_CONTEXT_QUERY_PARKING_PAGE	The PEP_PPM_CONTEXT_QUERY_PARKING_PAGE structure describes the parking page for a processor.
PEP_PPM_CONTEXT_QUERY_PARKING_PAGE	The PEP_PPM_CONTEXT_QUERY_PARKING_PAGE structure describes the parking page for a processor.
PEP_PPM_CST_STATE	The PEP_PPM_CST_STATE structure specifies the properties of a C state (ACPI processor power state).
PEP_PPM_CST_STATE	The PEP_PPM_CST_STATE structure specifies the properties of a C state (ACPI processor power state).
PEP_PPM_CST_STATES	The PEP_PPM_CST_STATES structure specifies the properties of the C states (ACPI processor power states) that are supported for a processor.
PEP_PPM_CST_STATES	The PEP_PPM_CST_STATES structure specifies the properties of the C states (ACPI processor power states) that are supported for a processor.
PEP_PPM_ENTER_SYSTEM_STATE	Used in the PEP_NOTIFY_PPM_ENTER_SYSTEM_STATE notification to notify PEP that the system is about to enter a system power state. .
PEP_PPM_ENTER_SYSTEM_STATE	Used in the PEP_NOTIFY_PPM_ENTER_SYSTEM_STATE notification to notify PEP that the system is about to enter a system power state. .
PEP_PPM_FEEDBACK_READ	The PEP_PPM_FEEDBACK_READ structure contains the value read from a processor performance feedback counter.
PEP_PPM_FEEDBACK_READ	The PEP_PPM_FEEDBACK_READ structure contains the value read from a processor performance feedback counter.
PEP_PPM_IDLE_CANCEL	The PEP_PPM_IDLE_CANCEL structure indicates why the processor could not enter the previously selected idle state.

TITLE	DESCRIPTION
PEP_PPM_IDLE_COMPLETE	The PEP_PPM_IDLE_COMPLETE structure describe the idle states from which the processor and hardware platform are waking.
PEP_PPM_IDLE_COMPLETE	The PEP_PPM_IDLE_COMPLETE structure describe the idle states from which the processor and hardware platform are waking.
PEP_PPM_IDLE_COMPLETE_V2	The PEP_PPM_IDLE_COMPLETE_V2 structure describe the idle states from which the processor and hardware platform are waking.
PEP_PPM_IDLE_COMPLETE_V2	The PEP_PPM_IDLE_COMPLETE_V2 structure describe the idle states from which the processor and hardware platform are waking.
PEP_PPM_IDLE_EXECUTE	The PEP_PPM_IDLE_EXECUTE structure specifies the idle state that the processor is to enter.
PEP_PPM_IDLE_EXECUTE	The PEP_PPM_IDLE_EXECUTE structure specifies the idle state that the processor is to enter.
PEP_PPM_IDLE_EXECUTE_V2	The PEP_PPM_IDLE_EXECUTE_V2 structure specifies the idle state that the processor is to enter.
PEP_PPM_IDLE_EXECUTE_V2	The PEP_PPM_IDLE_EXECUTE_V2 structure specifies the idle state that the processor is to enter.
PEP_PPM_IDLE_SELECT	The PEP_PPM_IDLE_SELECT structure describes the most energy-efficient idle state that the processor can enter and still satisfy the constraints specified by the operating system.
PEP_PPM_INITIATE_WAKE	The PEP_PPM_INITIATE_WAKE structure indicates whether a processor requires an interrupt to wake up from an idle state.
PEP_PPM_INITIATE_WAKE	The PEP_PPM_INITIATE_WAKE structure indicates whether a processor requires an interrupt to wake up from an idle state.
PEP_PPM_IS_PROCESSOR_HALTED	The PEP_PPM_IS_PROCESSOR_HALTED structure indicates whether the processor is currently halted in its selected idle state.
PEP_PPM_IS_PROCESSOR_HALTED	The PEP_PPM_IS_PROCESSOR_HALTED structure indicates whether the processor is currently halted in its selected idle state.
PEP_PPM_LPI_COMPLETE	The PEP_PPM_QUERY_FEEDBACK_COUNTERS structure describes all the processor performance counters that the platform extension plug-in (PEP) supports for a particular processor.
PEP_PPM_PARK_MASK	The PEP_PROCESSOR_PARK_MASK structure contains the current core parking mask.

TITLE	DESCRIPTION
PEP_PPM_PARK_MASK	The PEP_PROCESSOR_PARK_MASK structure contains the current core parking mask.
PEP_PPM_PARK_SELECTION	The PEP_PPM_PARK_SELECTION structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding which processors in the platform should be parked to reduce power consumption.
PEP_PPM_PARK_SELECTION	The PEP_PPM_PARK_SELECTION structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding which processors in the platform should be parked to reduce power consumption.
PEP_PPM_PARK_SELECTION_V2	The PEP_PPM_PARK_SELECTION_V2 structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding which processors in the platform should be parked to reduce power consumption.
PEP_PPM_PARK_SELECTION_V2	The PEP_PPM_PARK_SELECTION_V2 structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding which processors in the platform should be parked to reduce power consumption.
PEP_PPM_PERF_CHECK_COMPLETE	The PEP_PPM_PERF_CHECK_COMPLETE structure is used to inform the PEP of details regarding the completion of a periodic performance check evaluation.
PEP_PPM_PERF_CHECK_COMPLETE	The PEP_PPM_PERF_CHECK_COMPLETE structure is used to inform the PEP of details regarding the completion of a periodic performance check evaluation.
PEP_PPM_PERF_CONSTRAINTS	The PEP_PPM_PERF_CONSTRAINTS structure describes the performance limits to apply to the processor.
PEP_PPM_PERF_CONSTRAINTS	The PEP_PPM_PERF_CONSTRAINTS structure describes the performance limits to apply to the processor.
PEP_PPM_PERF_SET	The PEP_PPM_PERF_SET structure specifies the new performance level that the operating system is requesting for the processor.
PEP_PPM_PERF_SET	The PEP_PPM_PERF_SET structure specifies the new performance level that the operating system is requesting for the processor.
PEP_PPM_PERF_SET_STATE	Used in the PEP_NOTIFY_PPM_PERF_SET notification at runtime to set the current operating performance of the processor. .
PEP_PPM_PERF_SET_STATE	Used in the PEP_NOTIFY_PPM_PERF_SET notification at runtime to set the current operating performance of the processor. .

TITLE	DESCRIPTION
PEP_PPM_PLATFORM_STATE_RESIDENCIES	The PEP_PPM_PLATFORM_STATE_RESIDENCIES structure contains the accumulated residency times and transition counts for the idle states that are supported by the hardware platform.
PEP_PPM_PLATFORM_STATE_RESIDENCIES	The PEP_PPM_PLATFORM_STATE_RESIDENCIES structure contains the accumulated residency times and transition counts for the idle states that are supported by the hardware platform.
PEP_PPM_PLATFORM_STATE_RESIDENCY	The PEP_PPM_PLATFORM_STATE_RESIDENCY structure specifies the accumulated residency time and transition count for a particular platform idle state.
PEP_PPM_PLATFORM_STATE_RESIDENCY	The PEP_PPM_PLATFORM_STATE_RESIDENCY structure specifies the accumulated residency time and transition count for a particular platform idle state.
PEP_PPM_QUERY_CAPABILITIES	The PEP_PPM_QUERY_CAPABILITIES structure contains information about the processor power management (PPM) capabilities of the platform extension plug-in (PEP).
PEP_PPM_QUERY_CAPABILITIES	The PEP_PPM_QUERY_CAPABILITIES structure contains information about the processor power management (PPM) capabilities of the platform extension plug-in (PEP).
PEP_PPM_QUERY_COORDINATED_DEPENDENCY	The PEP_PPM_QUERY_COORDINATED_DEPENDENCY structure describes dependencies for coordinated idle states.
PEP_PPM_QUERY_COORDINATED_DEPENDENCY	The PEP_PPM_QUERY_COORDINATED_DEPENDENCY structure describes dependencies for coordinated idle states.
PEP_PPM_QUERY_COORDINATED_STATES	The PEP_PPM_QUERY_COORDINATED_STATES structure contains information about each coordinated idle state that the platform extension plug-in (PEP) supports.
PEP_PPM_QUERY_COORDINATED_STATES	The PEP_PPM_QUERY_COORDINATED_STATES structure contains information about each coordinated idle state that the platform extension plug-in (PEP) supports.
PEP_PPM_QUERY_DISCRETE_PERF_STATES	Used in the PEP_NOTIFY_PPM_QUERY_DISCRETE_PERF_STATES notification that stores the list of discrete performance states that PEP supports, if the PEP_NOTIFY_PPM_QUERY_CAPABILITIES notification indicates support for discrete performance states. .
PEP_PPM_QUERY_DISCRETE_PERF_STATES	Used in the PEP_NOTIFY_PPM_QUERY_DISCRETE_PERF_STATES notification that stores the list of discrete performance states that PEP supports, if the PEP_NOTIFY_PPM_QUERY_CAPABILITIES notification indicates support for discrete performance states. .
PEP_PPM_QUERY_DOMAIN_INFO	Used in the PEP_NOTIFY_PPM_QUERY_DOMAIN_INFO notification that queries for information about a performance domain. .

TITLE	DESCRIPTION
PEP_PPM_QUERY_DOMAIN_INFO	Used in the PEP_NOTIFY_PPM_QUERY_DOMAIN_INFO notification that queries for information about a performance domain. .
PEP_PPM_QUERY_FEEDBACK_COUNTERS	The PEP_PPM_QUERY_FEEDBACK_COUNTERS structure describes all the processor performance counters that the platform extension plug-in (PEP) supports for a particular processor.
PEP_PPM_QUERY_FEEDBACK_COUNTERS	The PEP_PPM_QUERY_FEEDBACK_COUNTERS structure describes all the processor performance counters that the platform extension plug-in (PEP) supports for a particular processor.
PEP_PPM_QUERY_IDLE_STATES	The PEP_PPM_QUERY_IDLE_STATES structure describes the idle states of a particular processor.
PEP_PPM_QUERY_IDLE_STATES_V2	The PEP_PPM_QUERY_IDLE_STATES_V2 structure is used during processor initialization to query the platform extension plug-in (PEP) for a list of processor idle states that the processor supports.
PEP_PPM_QUERY_IDLE_STATES_V2	The PEP_PPM_QUERY_IDLE_STATES_V2 structure is used during processor initialization to query the platform extension plug-in (PEP) for a list of processor idle states that the processor supports.
PEP_PPM_QUERY_LP_SETTINGS	The PEP_PPM_QUERY_LP_SETTINGS structure contains a kernel handle to the registry key that contains the power optimization settings that the platform extension plug-in (PEP) has defined for each power scenario.
PEP_PPM_QUERY_PERF_CAPABILITIES	The PEP_PPM_QUERY_PERF_CAPABILITIES structure describes the performance capabilities of the processors in the specified processor performance domain.
PEP_PPM_QUERY_PERF_CAPABILITIES	The PEP_PPM_QUERY_PERF_CAPABILITIES structure describes the performance capabilities of the processors in the specified processor performance domain.
PEP_PPM_QUERY_PLATFORM_STATE	The PEP_PPM_QUERY_PLATFORM_STATE structure contains information about a platform idle state.
PEP_PPM_QUERY_PLATFORM_STATE	The PEP_PPM_QUERY_PLATFORM_STATE structure contains information about a platform idle state.
PEP_PPM_QUERY_PLATFORM_STATES	The PEP_PPM_QUERY_PLATFORM_STATES structure specifies the number of platform idle states the hardware platform supports.
PEP_PPM_QUERY_PLATFORM_STATES	The PEP_PPM_QUERY_PLATFORM_STATES structure specifies the number of platform idle states the hardware platform supports.

TITLE	DESCRIPTION
PEP_PPM_QUERY_STATE_NAME	The PEP_PPM_QUERY_STATE_NAME structure contains information about a specific coordinated or platform idle state.
PEP_PPM_QUERY_STATE_NAME	The PEP_PPM_QUERY_STATE_NAME structure contains information about a specific coordinated or platform idle state.
PEP_PPM_QUERY_VETO_REASON	The PEP_PPM_QUERY_VETO_REASON structure supplies a wide-character, null-terminated string that contains a descriptive, human-readable name for a veto reason.
PEP_PPM_QUERY_VETO_REASON	The PEP_PPM_QUERY_VETO_REASON structure supplies a wide-character, null-terminated string that contains a descriptive, human-readable name for a veto reason.
PEP_PPM_QUERY_VETO_REASONS	The PEP_PPM_QUERY_VETO_REASONS structure specifies the total number of veto reasons that the PEP uses in calls to the ProcessorIdleVeto and PlatformIdleVeto routines.
PEP_PPM_QUERY_VETO_REASONS	The PEP_PPM_QUERY_VETO_REASONS structure specifies the total number of veto reasons that the PEP uses in calls to the ProcessorIdleVeto and PlatformIdleVeto routines.
PEP_PPM_RESUME_FROM_SYSTEM_STATE	Used by the PEP_NOTIFY_PPM_RESUME_FROM_SYSTEM_STATE notification that notifies the PEP that the system has just resumed from a system power state.
PEP_PPM_RESUME_FROM_SYSTEM_STATE	Used by the PEP_NOTIFY_PPM_RESUME_FROM_SYSTEM_STATE notification that notifies the PEP that the system has just resumed from a system power state.
PEP_PPM_TEST_IDLE_STATE	The PEP_PPM_TEST_IDLE_STATE structure contains information about whether the processor can immediately enter a processor idle state.
PEP_PPM_TEST_IDLE_STATE	The PEP_PPM_TEST_IDLE_STATE structure contains information about whether the processor can immediately enter a processor idle state.
PEP_PREPARE_DEVICE	The PEP_PREPARE_DEVICE structure identifies a device that must be started up in preparation for its use by the operating system.
PEP_PREPARE_DEVICE	The PEP_PREPARE_DEVICE structure identifies a device that must be started up in preparation for its use by the operating system.
PEP_PROCESSOR_FEEDBACK_COUNTER	The PEP_PROCESSOR_FEEDBACK_COUNTER structure describes a feedback counter to the operating system.
PEP_PROCESSOR_FEEDBACK_COUNTER	The PEP_PROCESSOR_FEEDBACK_COUNTER structure describes a feedback counter to the operating system.

TITLE	DESCRIPTION
PEP_PROCESSOR_IDLE_CONSTRAINTS	The PEP_PROCESSOR_IDLE_CONSTRAINTS structure specifies a set of constraints that the PEP uses to select a processor idle state.
PEP_PROCESSOR_IDLE_DEPENDENCY	The PEP_PROCESSOR_IDLE_DEPENDENCY structure specifies the dependencies of a platform idle state on the specified processor.
PEP_PROCESSOR_IDLE_DEPENDENCY	The PEP_PROCESSOR_IDLE_DEPENDENCY structure specifies the dependencies of a platform idle state on the specified processor.
PEP_PROCESSOR_IDLE_STATE	The PEP_PROCESSOR_IDLE_STATE structure describes the capabilities of a processor idle state.
PEP_PROCESSOR_IDLE_STATE_UPDATE	The PEP_PROCESSOR_IDLE_STATE_UPDATE structure contains the updated properties of a processor idle state.
PEP_PROCESSOR_IDLE_STATE_UPDATE	The PEP_PROCESSOR_IDLE_STATE_UPDATE structure contains the updated properties of a processor idle state.
PEP_PROCESSOR_IDLE_STATE_V2	The PEP_PROCESSOR_IDLE_STATE_V2 structure describes a processor idle state that the platform extension plug-in (PEP) supports.
PEP_PROCESSOR_IDLE_STATE_V2	The PEP_PROCESSOR_IDLE_STATE_V2 structure describes a processor idle state that the platform extension plug-in (PEP) supports.
PEP_PROCESSOR_PARK_PREFERENCE	The PEP_PROCESSOR_PARK_PREFERENCE structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding whether the specified processor should be parked to reduce power consumption.
PEP_PROCESSOR_PARK_PREFERENCE	The PEP_PROCESSOR_PARK_PREFERENCE structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding whether the specified processor should be parked to reduce power consumption.
PEP_PROCESSOR_PARK_STATE	The PEP_PROCESSOR_PARK_STATE structure describes the parking state for a single processor.
PEP_PROCESSOR_PARK_STATE	The PEP_PROCESSOR_PARK_STATE structure describes the parking state for a single processor.
PEP_PROCESSOR_PERF_STATE	Use in the PEP_NOTIFY_PPM_QUERY_DISCRETE_PERF_STATES notification. This structure describes the properties of a single performance state. .
PEP_PROCESSOR_PERF_STATE	Use in the PEP_NOTIFY_PPM_QUERY_DISCRETE_PERF_STATES notification. This structure describes the properties of a single performance state. .

TITLE	DESCRIPTION
PEP_QUERY_COMPONENT_PERF_CAPABILITIES	The PEP_QUERY_COMPONENT_PERF_CAPABILITIES structure specifies the number of performance state (P-state) sets that are defined for a component.
PEP_QUERY_COMPONENT_PERF_CAPABILITIES	The PEP_QUERY_COMPONENT_PERF_CAPABILITIES structure specifies the number of performance state (P-state) sets that are defined for a component.
PEP_QUERY_COMPONENT_PERF_SET	The PEP_QUERY_COMPONENT_PERF_SET structure contains query information about a set of performance state values (P-state set) for a component.
PEP_QUERY_COMPONENT_PERF_SET	The PEP_QUERY_COMPONENT_PERF_SET structure contains query information about a set of performance state values (P-state set) for a component.
PEP_QUERY_COMPONENT_PERF_SET_NAME	The PEP_QUERY_COMPONENT_PERF_SET_NAME structure contains query information about a set of performance state values (P-state set) for a component.
PEP_QUERY_COMPONENT_PERF_SET_NAME	The PEP_QUERY_COMPONENT_PERF_SET_NAME structure contains query information about a set of performance state values (P-state set) for a component.
PEP_QUERY_COMPONENT_PERF_STATES	The PEP_QUERY_COMPONENT_PERF_STATES structure contains a list of discrete performance state (P-state) values for the specified P-state set.
PEP_QUERY_COMPONENT_PERF_STATES	The PEP_QUERY_COMPONENT_PERF_STATES structure contains a list of discrete performance state (P-state) values for the specified P-state set.
PEP_QUERY_CURRENT_COMPONENT_PERF_STATE	The PEP_QUERY_CURRENT_COMPONENT_PERF_STATE structure contains information about the current P-state in the specified P-state set.
PEP_QUERY_CURRENT_COMPONENT_PERF_STATE	The PEP_QUERY_CURRENT_COMPONENT_PERF_STATE structure contains information about the current P-state in the specified P-state set.
PEP_QUERY_SOC_SUBSYSTEM	The PEP_QUERY_SOC_SUBSYSTEM structure is used by the PEP_DPM_QUERY_SOC_SUBSYSTEM notification to gather basic information about a particular system on a chip (SoC) subsystem.
PEP_QUERY_SOC_SUBSYSTEM	The PEP_QUERY_SOC_SUBSYSTEM structure is used by the PEP_DPM_QUERY_SOC_SUBSYSTEM notification to gather basic information about a particular system on a chip (SoC) subsystem.
PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME	The PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME structure is used by the PEP_DPM_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME notification to collect details about the blocking duration for a particular system on a chip (SoC) subsystem.

TITLE	DESCRIPTION
PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME	The PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME structure is used by the PEP_DPM_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME notification to collect details about the blocking duration for a particular system on a chip (SoC) subsystem.
PEP_QUERY_SOC_SUBSYSTEM_COUNT	The PEP_QUERY_SOC_SUBSYSTEM_COUNT structure is used to tell the OS whether the PEP supports system on a chip (SoC) subsystem accounting for a given platform idle state.
PEP_QUERY_SOC_SUBSYSTEM_COUNT	The PEP_QUERY_SOC_SUBSYSTEM_COUNT structure is used to tell the OS whether the PEP supports system on a chip (SoC) subsystem accounting for a given platform idle state.
PEP_QUERY_SOC_SUBSYSTEM_METADATA	The PEP_QUERY_SOC_SUBSYSTEM_METADATA structure is used with the PEP_DPM_QUERY_SOC_SUBSYSTEM_METADATA notification to collect optional metadata about the system on a chip (SoC) subsystem whose blocking time has just been queried.
PEP_QUERY_SOC_SUBSYSTEM_METADATA	The PEP_QUERY_SOC_SUBSYSTEM_METADATA structure is used with the PEP_DPM_QUERY_SOC_SUBSYSTEM_METADATA notification to collect optional metadata about the system on a chip (SoC) subsystem whose blocking time has just been queried.
PEP_REGISTER_COMPONENT_PERF_STATES	The PEP_REGISTER_COMPONENT_PERF_STATES structure describes the performance states (P-states) of the specified component.
PEP_REGISTER_COMPONENT_PERF_STATES	The PEP_REGISTER_COMPONENT_PERF_STATES structure describes the performance states (P-states) of the specified component.
PEP_REGISTER_CRASHDUMP_DEVICE	The PEP_REGISTER_CRASHDUMP_DEVICE structure provides a callback routine to turn on a crash-dump device.
PEP_REGISTER_CRASHDUMP_DEVICE	The PEP_REGISTER_CRASHDUMP_DEVICE structure provides a callback routine to turn on a crash-dump device.
PEP_REGISTER_DEBUGGER	The PEP_REGISTER_DEBUGGER structure identifies a registered device that is a core system resource that provides debugger transport.
PEP_REGISTER_DEBUGGER	The PEP_REGISTER_DEBUGGER structure identifies a registered device that is a core system resource that provides debugger transport.
PEP_REGISTER_DEVICE_V2	The PEP_REGISTER_DEVICE_V2 structure describes a device whose driver stack has just registered with the Windows power management framework (PoFx).
PEP_REGISTER_DEVICE_V2	The PEP_REGISTER_DEVICE_V2 structure describes a device whose driver stack has just registered with the Windows power management framework (PoFx).

TITLE	DESCRIPTION
PEP_REQUEST_COMPONENT_PERF_STATE	The PEP_REQUEST_COMPONENT_PERF_STATE structure contains a list of performance state (P-state) changes requested by the Windows power management framework (PoFx), plus status information about the handling of these requests by the platform extension plug-in (PEP).
PEP_REQUEST_COMPONENT_PERF_STATE	The PEP_REQUEST_COMPONENT_PERF_STATE structure contains a list of performance state (P-state) changes requested by the Windows power management framework (PoFx), plus status information about the handling of these requests by the platform extension plug-in (PEP).
PEP_RESET_SOC_SUBSYSTEM_ACCOUNTING	The PEP_RESET_SOC_SUBSYSTEM_ACCOUNTING structure is provided to the platform extension plug-in (PEP) as part of a PEP_DPM_RESET_SOC_SUBSYSTEM_ACCOUNTING notification.
PEP_RESET_SOC_SUBSYSTEM_ACCOUNTING	The PEP_RESET_SOC_SUBSYSTEM_ACCOUNTING structure is provided to the platform extension plug-in (PEP) as part of a PEP_DPM_RESET_SOC_SUBSYSTEM_ACCOUNTING notification.
PEP_SOC_SUBSYSTEM_METADATA	The PEP_SOC_SUBSYSTEM_METADATA structure contains key-value pairs that contain metadata for a system on a chip (SoC) subsystem. It is used in the context of a PEP_DPM_QUERY_SOC_SUBSYSTEM_METADATA notification sent to a platform extension plug-in (PEP).
PEP_SOC_SUBSYSTEM_METADATA	The PEP_SOC_SUBSYSTEM_METADATA structure contains key-value pairs that contain metadata for a system on a chip (SoC) subsystem. It is used in the context of a PEP_DPM_QUERY_SOC_SUBSYSTEM_METADATA notification sent to a platform extension plug-in (PEP).
PEP_SYSTEM_LATENCY	The PEP_SYSTEM_LATENCY structure specifies the new value for the system latency tolerance.
PEP_SYSTEM_LATENCY	The PEP_SYSTEM_LATENCY structure specifies the new value for the system latency tolerance.
PEP_UNMASKED_INTERRUPT_FLAGS	The PEP_UNMASKED_INTERRUPT_FLAGS union indicates whether an unmasked interrupt source is a primary interrupt or a secondary interrupt.
PEP_UNMASKED_INTERRUPT_FLAGS	The PEP_UNMASKED_INTERRUPT_FLAGS union indicates whether an unmasked interrupt source is a primary interrupt or a secondary interrupt.
PEP_UNMASKED_INTERRUPT_INFORMATION	The PEP_UNMASKED_INTERRUPT_INFORMATION structure contains information about an interrupt source.
PEP_UNMASKED_INTERRUPT_INFORMATION	The PEP_UNMASKED_INTERRUPT_INFORMATION structure contains information about an interrupt source.

TITLE	DESCRIPTION
PEP_UNREGISTER_DEVICE	The PEP_UNREGISTER_DEVICE structure identifies a device whose registration is being removed from the Windows power management framework (PoFx).
PEP_UNREGISTER_DEVICE	The PEP_UNREGISTER_DEVICE structure identifies a device whose registration is being removed from the Windows power management framework (PoFx).
PEP_WORK	The PEP_WORK structure indicates whether the PEP has a work request to submit to the Windows power management framework (PoFx).
PEP_WORK	The PEP_WORK structure indicates whether the PEP has a work request to submit to the Windows power management framework (PoFx).
PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE	The PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE structure contains the results of an ACPI control method that was asynchronously evaluated by the platform extension plug-in (PEP).
PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE	The PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE structure contains the results of an ACPI control method that was asynchronously evaluated by the platform extension plug-in (PEP).
PEP_WORK_ACPI_NOTIFY	The PEP_WORK_ACPI_NOTIFY structure contains the ACPI Notify code for a device that has generated a hardware event.
PEP_WORK_ACPI_NOTIFY	The PEP_WORK_ACPI_NOTIFY structure contains the ACPI Notify code for a device that has generated a hardware event.
PEP_WORK_ACTIVE_COMPLETE	The PEP_WORK_ACTIVE_COMPLETE structure identifies a component that is now in the active condition.
PEP_WORK_COMPLETE_IDLE_STATE	The PEP_WORK_COMPLETE_IDLE_STATE structure identifies a component that the platform extension plug-in (PEP) has prepared for a transition to a new Fx power state.
PEP_WORK_COMPLETE_IDLE_STATE	The PEP_WORK_COMPLETE_IDLE_STATE structure identifies a component that the platform extension plug-in (PEP) has prepared for a transition to a new Fx power state.
PEP_WORK_COMPLETE_PERF_STATE	The PEP_WORK_COMPLETE_PERF_STATE structure describes the completion status of a previously requested update to the performance values assigned to a list of performance state (P-state) sets.
PEP_WORK_COMPLETE_PERF_STATE	The PEP_WORK_COMPLETE_PERF_STATE structure describes the completion status of a previously requested update to the performance values assigned to a list of performance state (P-state) sets.

TITLE	DESCRIPTION
PEP_WORK_DEVICE_IDLE	The PEP_WORK_DEVICE_IDLE structure indicates whether to ignore the idle time-out for the specified device.
PEP_WORK_DEVICE_POWER	The PEP_WORK_DEVICE_POWER structure describes the new power requirements for the specified device.
PEP_WORK_IDLE_STATE	The PEP_WORK_IDLE_STATE structure contains a request to transition a component to an Fx power state.
PEP_WORK_INFORMATION	The PEP_WORK_INFORMATION structure describes a work item that the PEP is submitting to the Windows power management framework (PoFx).
PEP_WORK_INFORMATION	The PEP_WORK_INFORMATION structure describes a work item that the PEP is submitting to the Windows power management framework (PoFx).
PEP_WORK_POWER_CONTROL	The PEP_WORK_POWER_CONTROL structure contains the parameters for a power control request that the platform extension plug-in (PEP) sends directly to a processor driver.
PEP_WORK_POWER_CONTROL	The PEP_WORK_POWER_CONTROL structure contains the parameters for a power control request that the platform extension plug-in (PEP) sends directly to a processor driver.
PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR	The PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR structure describes the counter resources available on the platform.
PHYSICAL_COUNTER_RESOURCE_LIST	The PHYSICAL_COUNTER_RESOURCE_LIST structure describes an array of PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR structures.
PLUGPLAY_NOTIFICATION_HEADER	A PLUGPLAY_NOTIFICATION_HEADER structure is included at the beginning of each PnP notification structure, such as a DEVICE_INTERFACE_CHANGE_NOTIFICATION structure.
PNP_BUS_INFORMATION	The PNP_BUS_INFORMATION structure describes a bus.
PNP_LOCATION_INTERFACE	The PNP_LOCATION_INTERFACE structure describes the GUID_PNP_LOCATION_INTERFACE interface.
PO_FX_COMPONENT_IDLE_STATE	The PO_FX_COMPONENT_IDLE_STATE structure specifies the attributes of an Fx power state of a component in a device.
PO_FX_COMPONENT_IDLE_STATE	The PO_FX_COMPONENT_IDLE_STATE structure specifies the attributes of an Fx power state of a component in a device.
PO_FX_COMPONENT_PERF_INFO	The PO_FX_COMPONENT_PERF_INFO structure describes all the sets of performance states for a single component within a device.
PO_FX_COMPONENT_PERF_INFO	The PO_FX_COMPONENT_PERF_INFO structure describes all the sets of performance states for a single component within a device.

TITLE	DESCRIPTION
PO_FX_COMPONENT_PERF_SET	The PO_FX_COMPONENT_PERF_SET structure represents a set of performance states for a single component within a device.
PO_FX_COMPONENT_PERF_SET	The PO_FX_COMPONENT_PERF_SET structure represents a set of performance states for a single component within a device.
PO_FX_COMPONENT_V1	The PO_FX_COMPONENT structure describes the power state attributes of a component in a device.
PO_FX_COMPONENT_V1	The PO_FX_COMPONENT structure describes the power state attributes of a component in a device.
PO_FX_COMPONENT_V2	The PO_FX_COMPONENT structure describes the power state attributes of a component in a device.
PO_FX_COMPONENT_V2	The PO_FX_COMPONENT structure describes the power state attributes of a component in a device.
PO_FX_CORE_DEVICE	The PO_FX_CORE_DEVICE structure contains information about the power-state attributes of the components in a core system resource, and provides a software interface for power-managing these components.
PO_FX_CORE_DEVICE	The PO_FX_CORE_DEVICE structure contains information about the power-state attributes of the components in a core system resource, and provides a software interface for power-managing these components.
PO_FX_DEVICE_V1	The PO_FX_DEVICE structure describes the power attributes of a device to the power management framework (PoFx).
PO_FX_DEVICE_V1	The PO_FX_DEVICE structure describes the power attributes of a device to the power management framework (PoFx).
PO_FX_DEVICE_V2	The PO_FX_DEVICE structure describes the power attributes of a device to the power management framework (PoFx).
PO_FX_DEVICE_V2	The PO_FX_DEVICE structure describes the power attributes of a device to the power management framework (PoFx).
PO_FX_PERF_STATE	The PO_FX_PERF_STATE structure represents a performance state for a single component within a device.
PO_FX_PERF_STATE	The PO_FX_PERF_STATE structure represents a performance state for a single component within a device.
PO_FX_PERF_STATE_CHANGE	The PO_FX_PERF_STATE_CHANGE structure contains information about a change to a performance state that is being requested by calling the PoFxIssueComponentPerfStateChange or PoFxIssueComponentPerfStateChangeMultiple routine.

TITLE	DESCRIPTION
PO_FX_PERF_STATE_CHANGE	The PO_FX_PERF_STATE_CHANGE structure contains information about a change to a performance state that is being requested by calling the PoFxIssueComponentPerfStateChange or PoFxIssueComponentPerfStateChangeMultiple routine.
PO_SPR_ACTIVE_SESSION_DATA	Allow drivers to register/unregister for SPR Active session start and end notifications.
POWER_PLATFORM_INFORMATION	The POWER_PLATFORM_INFORMATION structure contains information about the power capabilities of the system.
POWER_PLATFORM_INFORMATION	The POWER_PLATFORM_INFORMATION structure contains information about the power capabilities of the system.
POWER_STATE	The POWER_STATE union specifies a system power state value or a device power state value.
POWER_STATE	The POWER_STATE union specifies a system power state value or a device power state value.
POWER_THROTTLING_PROCESS_STATE	Stores the throttling policies and how to apply them to a target process when that process is subject to power management.
POWER_THROTTLING_THREAD_STATE	Stores the throttling policies and how to apply them to a target thread when that thread is subject to power management.
PRIVILEGE_SET	The PRIVILEGE_SET structure specifies a set of security privileges. For more information, see the reference page for PRIVILEGE_SET in the Microsoft Windows SDK documentation.
PROCESS_MITIGATION_CHILD_PROCESS_POLICY	Stores policy information about creating child processes.
PROCESS_MITIGATION_PAYLOAD_RESTRICTION_POLICY	Stores information about process mitigation policy.
PROCESS_MITIGATION_SYSTEM_CALL_FILTER_POLICY	This structure is not supported.
PROCESSOR_NUMBER	The PROCESSOR_NUMBER structure identifies a processor by its group number and group-relative processor number.
PS_CREATE_NOTIFY_INFO	The PS_CREATE_NOTIFY_INFO structure provides information about a newly created process.
REENUMERATE_SELF_INTERFACE_STANDARD	The REENUMERATE_SELF_INTERFACE_STANDARD interface structure enables a driver to request that its parent bus driver reenumerate the driver's device. This structure defines the GUID_REENUMERATE_SELF_INTERFACE_STANDARD interface.
REG_CALLBACK_CONTEXT_CLEANUP_INFORMATION	The REG_CALLBACK_CONTEXT_CLEANUP_INFORMATION structure contains information that a driver's RegistryCallback routine can use to free resources that the driver previously allocated for the context that is associated with a registry object.

TITLE	DESCRIPTION
REG_CREATE_KEY_INFORMATION	The REG_CREATE_KEY_INFORMATION structure contains information that a driver's RegistryCallback routine can use when a registry key that is being created.
REG_CREATE_KEY_INFORMATION_V1	The REG_CREATE_KEY_INFORMATION_V1 structure contains information that a filter driver's RegistryCallback routine can use when a registry key is being created.
REG_DELETE_KEY_INFORMATION	The REG_DELETE_KEY_INFORMATION structure contains information that a driver's RegistryCallback routine can use when a registry key is being deleted.
REG_DELETE_VALUE_KEY_INFORMATION	The REG_DELETE_VALUE_KEY_INFORMATION structure contains information that a driver's RegistryCallback routine can use when a registry key's value is being deleted.
REG_ENUMERATE_KEY_INFORMATION	The REG_ENUMERATE_KEY_INFORMATION structure describes one subkey of a key whose subkeys are being enumerated.
REG_ENUMERATE_VALUE_KEY_INFORMATION	The REG_ENUMERATE_VALUE_KEY_INFORMATION structure describes one value entry of a key whose value entries are being enumerated.
REG_KEY_HANDLE_CLOSE_INFORMATION	The REG_KEY_HANDLE_CLOSE_INFORMATION structure contains information about a registry key whose handle is about to be closed.
REG_LOAD_KEY_INFORMATION	The REG_LOAD_KEY_INFORMATION structure contains information about a registry hive that is being loaded.
REG_POST_CREATE_KEY_INFORMATION	The REG_POST_CREATE_KEY_INFORMATION structure contains the result of an attempt to create a registry key.
REG_POST_OPERATION_INFORMATION	The REG_POST_OPERATION_INFORMATION structure contains information about a completed registry operation that a RegistryCallback routine can use.
REG_PRE_CREATE_KEY_INFORMATION	The REG_PRE_OPEN_KEY_INFORMATION structure contains the name of a registry key that is about to be opened.
REG_QUERY_KEY_INFORMATION	The REG_QUERY_KEY_INFORMATION structure describes the metadata that is about to be queried for a key.
REG_QUERY_KEY_NAME	The REG_QUERY_KEY_NAME structure describes the full registry key name of an object being queried.
REG_QUERY_KEY_SECURITY_INFORMATION	The REG_QUERY_KEY_SECURITY_INFORMATION structure receives security information for a registry key object.

TITLE	DESCRIPTION
REG_QUERY_MULTIPLE_VALUE_KEY_INFORMATION	The REG_QUERY_MULTIPLE_VALUE_KEY_INFORMATION structure describes the multiple value entries that are being retrieved for a key.
REG_QUERY_VALUE_KEY_INFORMATION	The REG_QUERY_VALUE_KEY_INFORMATION structure contains information about a registry key's value entry that is being queried.
REG_RENAME_KEY_INFORMATION	The REG_RENAME_KEY_INFORMATION structure contains the new name for a registry key whose name is about to be changed.
REG_REPLACE_KEY_INFORMATION	The REG_REPLACE_KEY_INFORMATION structure describes the metadata that is about to be replaced for a key.
REG_RESTORE_KEY_INFORMATION	The REG_RESTORE_KEY_INFORMATION structure contains the information for a registry key that is about to be restored.
REG_SAVE_KEY_INFORMATION	The REG_SAVE_KEY_INFORMATION structure contains the information for a registry key that is about to be saved.
REG_SET_INFORMATION_KEY_INFORMATION	The REG_SET_INFORMATION_KEY_INFORMATION structure describes a new setting for a key's metadata.
REG_SET_KEY_SECURITY_INFORMATION	The REG_SET_KEY_SECURITY_INFORMATION structure specifies security information for a registry key object.
REG_SET_VALUE_KEY_INFORMATION	The REG_SET_VALUE_INFORMATION structure describes a new setting for a registry key's value entry.
REG_UNLOAD_KEY_INFORMATION	The REG_UNLOAD_KEY_INFORMATION structure contains information that a driver's RegistryCallback routine can use when a registry hive is unloaded.
RESOURCEMANAGER_BASIC_INFORMATION	The RESOURCEMANAGER_BASIC INFORMATION structure contains information about a resource manager object.
RESOURCEMANAGER_COMPLETION_INFORMATION	The RESOURCEMANAGER_COMPLETION_INFORMATION structure is not used.
SCATTER_GATHER_LIST	The SCATTER_GATHER_LIST structure describes the scatter/gather list for a DMA operation.
SDEV_IDENTIFIER_INTERFACE	This material is not yet available. This placeholder topic is provided as an example of documentation that may be included in a later release.
SECTION_OBJECT_POINTERS	The SECTION_OBJECT_POINTERS structure, allocated by a file system or a redirector driver, is used by the memory manager and cache manager to store file-mapping and cache-related information for a file stream.
SILO_MONITOR_REGISTRATION	This structure specifies a server silo monitor that can receive notifications about server silo events.

TITLE	DESCRIPTION
SLIST_ENTRY	An SLIST_ENTRY structure describes an entry in a sequenced singly linked list.
SYSENV_VALUE	Stores the value of a system environment variable using SysEnv device. This structure is used in the IOCTL_SYSENV_GET_VARIABLE request.
SYSENV_VARIABLE	Stores the name a system environment variable using SysEnv device. This structure is used in the IOCTL_SYSENV_GET_VARIABLE request.
SYSENV_VARIABLE_INFO	Stores the information about a system environment variable using SysEnv device. This structure is used in the IOCTL_SYSENV_QUERY_VARIABLE_INFO request.
SYSTEM_POWER_STATE_CONTEXT	The SYSTEM_POWER_STATE_CONTEXT structure is a partially opaque system structure that contains information about the previous system power states of a computer.
SYSTEM_POWER_STATE_CONTEXT	The SYSTEM_POWER_STATE_CONTEXT structure is a partially opaque system structure that contains information about the previous system power states of a computer.
TARGET_DEVICE_CUSTOM_NOTIFICATION	The TARGET_DEVICE_CUSTOM_NOTIFICATION structure describes a custom device event.
TARGET_DEVICE_REMOVAL_NOTIFICATION	The TARGET_DEVICE_REMOVAL_NOTIFICATION structure describes a device-removal event. The PnP manager sends this structure to a driver that registered a callback routine for notification of EventCategoryTargetDeviceChange events.
TRANSACTION_BASIC_INFORMATION	The TRANSACTION_BASIC_INFORMATION structure contains information about a transaction object.
TRANSACTION_ENLISTMENT_PAIR	The TRANSACTION_ENLISTMENT_PAIR structure contains information about an enlistment that is associated with a transaction object.
TRANSACTION_ENLISTMENTS_INFORMATION	The TRANSACTION_ENLISTMENTS_INFORMATION structure contains information about the enlistments that are associated with a transaction object.
TRANSACTION_PROPERTIES_INFORMATION	The TRANSACTION_PROPERTIES_INFORMATION structure contains a transaction object's properties.
TRANSACTIONMANAGER_BASIC_INFORMATION	The TRANSACTIONMANAGER_BASIC_INFORMATION structure contains information about a transaction manager object.
TRANSACTIONMANAGER_LOG_INFORMATION	The TRANSACTIONMANAGER_LOG_INFORMATION structure contains information about a transaction manager object.
TRANSACTIONMANAGER_LOGPATH_INFORMATION	The TRANSACTIONMANAGER_LOGPATH_INFORMATION structure contains information about a transaction manager object.

TITLE	DESCRIPTION
TRANSACTIONMANAGER_RECOVERY_INFORMATION	The TRANSACTIONMANAGER_RECOVERY_INFORMATION structure contains information about a transaction manager object.
UNICODE_STRING	The UNICODE_STRING structure is used to define Unicode strings.
WMIGUIDREGINFO	The WMIGUIDREGINFO structure contains registration information for a given data block or event block exposed by a driver that uses the WMI library support routines.
WMILIB_CONTEXT	The WMILIB_CONTEXT structure provides registration information for a driver's data blocks and event blocks and defines entry points for the driver's WMI library callback routines.
WMIREGGUIDW	The WMIREGGUID structure contains new or updated registration information for a data block or event block.
WMIREGINFOW	The WMIREGINFO structure contains information provided by a driver to register or update its data blocks and event blocks.
WNODE_ALL_DATA	The WNODE_ALL_DATA structure contains data for all instances of a data block or event block.
WNODE_EVENT_ITEM	The WNODE_EVENT_ITEM structure contains data generated by a driver for an event.
WNODE_EVENT_REFERENCE	The WNODE_EVENT_REFERENCE structure contains information that WMI can use to query for an event that exceeds the event size limit set in the registry.
WNODE_HEADER	The WNODE_HEADER structure is the first member of all other WNODE_XXX structures. It contains information common to all such structures.
WNODE_METHOD_ITEM	The WNODE_METHOD_ITEM structure indicates a method associated with an instance of a data block and contains any input data for the method.
WNODE_SINGLE_INSTANCE	The WNODE_SINGLE_INSTANCE structure contains values for all data items in one instance of a data block.
WNODE_SINGLE_ITEM	The WNODE_SINGLE_ITEM structure contains the value of a single data item in an instance of a data block.
WNODE_TOO_SMALL	The WNODE_TOO_SMALL structure indicates the size of the buffer needed to receive output from a request.
XVARIABLE_NAME	Stores the name of a system environment variable using SysEnv device. This structure is used in the IOCTL_SYSENV_ENUM_VARIABLES request.

TITLE	DESCRIPTION
XVARIABLE_NAME_AND_VALUE	Stores the name and value of a system environment variable using SysEnv device. This structure is used in the IOCTL_SYSENV_ENUM_VARIABLES and IOCTL_SYSENV_SET_VARIABLE requests.

aux_klib.h header

1/8/2019 • 2 minutes to read • Edit Online

This header is used by kernel. For more information, see:

- Windows kernel aux_klib.h contains the following programming interfaces:

Functions

TITLE	DESCRIPTION
AuxKlibEnumerateSystemFirmwareTables	The AuxKlibEnumerateSystemFirmwareTables routine enumerates all system firmware tables of the specified type.
AuxKlibGetBugCheckData	The AuxKlibGetBugCheckData routine retrieves information about a bug check that has just occurred.
AuxKlibGetImageExportDirectory	The AuxKlibGetImageExportDirectory routine returns an image module's export directory.
AuxKlibGetSystemFirmwareTable	The AuxKlibGetSystemFirmwareTable routine retrieves the specified firmware table from the firmware table provider.
AuxKlibInitialize	The AuxKlibInitialize routine initializes the Auxiliary Kernel-Mode Library.
AuxKlibQueryModuleInformation	The AuxKlibQueryModuleInformation routine retrieves information about the image modules that the operating system has loaded.

Structures

TITLE	DESCRIPTION
AUX_MODULE_BASIC_INFO	The AUX_MODULE_BASIC_INFO structure contains basic information about a loaded image module.
AUX_MODULE_EXTENDED_INFO	The AUX_MODULE_EXTENDED_INFO structure contains extended information about a loaded image module.
KBUGCHECK_DATA	The KBUGCHECK_DATA structure contains bug check parameters.

AUX_MODULE_BASIC_INFO structure

1/30/2019 • 2 minutes to read • Edit Online

The **AUX_MODULE_BASIC_INFO** structure contains basic information about a loaded image module.

Syntax

```
typedef struct _AUX_MODULE_BASIC_INFO {
  PVOID ImageBase;
} AUX_MODULE_BASIC_INFO, *PAUX_MODULE_BASIC_INFO;
```

Members

`ImageBase`

A pointer to the base of the loaded image.

Remarks

The **AUX_MODULE_BASIC_INFO** structure is used as input to the AuxKlibQueryModuleInformation routine.

Requirements

Header	aux_klib.h (include Aux_klib.h)

See Also

AuxKlibQueryModuleInformation

AUX_MODULE_EXTENDED_INFO structure

1/30/2019 • 2 minutes to read • Edit Online

The **AUX_MODULE_EXTENDED_INFO** structure contains extended information about a loaded image module.

Syntax

```
typedef struct _AUX_MODULE_EXTENDED_INFO {
  AUX_MODULE_BASIC_INFO BasicInfo;
  ULONG                 ImageSize;
  USHORT                FileNameOffset;
  UCHAR                 FullPathName[AUX_KLIB_MODULE_PATH_LEN];
} AUX_MODULE_EXTENDED_INFO, *PAUX_MODULE_EXTENDED_INFO;
```

Members

`BasicInfo`

An AUX_MODULE_BASIC_INFO structure.

`ImageSize`

The size, in bytes, of the loaded image.

`FileNameOffset`

The offset, in bytes, from the beginning of the full path name to the file name of the module's image file.

`FullPathName`

The full path name of the module's image file.

Remarks

The **AUX_MODULE_EXTENDED_INFO** structure is used as input to the AuxKlibQueryModuleInformation routine.

Requirements

Header	aux_klib.h (include Aux_klib.h)

See Also

AuxKlibQueryModuleInformation

KBUGCHECK_DATA structure

1/30/2019 • 2 minutes to read • Edit Online

The **KBUGCHECK_DATA** structure contains bug check parameters.

Syntax

```
typedef struct _KBUGCHECK_DATA {
  ULONG     BugCheckDataSize;
  ULONG     BugCheckCode;
  ULONG_PTR Parameter1;
  ULONG_PTR Parameter2;
  ULONG_PTR Parameter3;
  ULONG_PTR Parameter4;
} KBUGCHECK_DATA, *PKBUGCHECK_DATA;
```

Members

`BugCheckDataSize`

The size, in bytes, of the **KBUGCHECK_DATA** structure. Callers of AuxKlibGetBugCheckData must supply this value.

`BugCheckCode`

The bug check code. This value identifies that type of bug check that has occurred.

`Parameter1`

Bug check parameter 1. For more information about this parameter, see specific bug check codes.

`Parameter2`

Bug check parameter 2. For more information about this parameter, see specific bug check codes.

`Parameter3`

Bug check parameter 3. For more information about this parameter, see specific bug check codes.

`Parameter4`

Bug check parameter 4. For more information about this parameter, see specific bug check codes.

Remarks

The **KBUGCHECK_DATA** structure is used as a parameter to AuxKlibGetBugCheckData.

Requirements

Header	aux_klib.h (include Aux_klib.h)

See Also

AuxKlibGetBugCheckData

AuxKlibEnumerateSystemFirmwareTables function

1/25/2019 • 2 minutes to read • Edit Online

The **AuxKlibEnumerateSystemFirmwareTables** routine enumerates all system firmware tables of the specified type.

Syntax

```
NTSTATUS AuxKlibEnumerateSystemFirmwareTables(
  ULONG  FirmwareTableProviderSignature,
  PVOID  FirmwareTableBuffer,
  ULONG  BufferLength,
  PULONG ReturnLength
);
```

Parameters

`FirmwareTableProviderSignature`

The identifier of the firmware table provider to which the query is to be directed. This parameter can be one of the following values.

VALUE	MEANING
'ACPI'	The ACPI firmware table provider.
'FIRM'	The raw firmware table provider.
'RSMB'	The raw SMBIOS firmware table provider.

`FirmwareTableBuffer`

A pointer to a caller-allocated buffer to which the routine writes the list of firmware tables. If this parameter is NULL, the value written to **ReturnLength* is the required buffer size. For more information about the contents of this buffer, see the Remarks section.

`BufferLength`

The size, in bytes, of the buffer pointed to by *FirmwareTableBuffer*.

`ReturnLength`

A pointer to a location to which the routine writes the number of bytes of data written to the buffer pointed to by *FirmwareTableBuffer*.

Return Value

AuxKlibEnumerateSystemFirmwareTables returns STATUS_SUCCESS if the call is successful. Possible return values include the following error codes.

RETURN CODE	DESCRIPTION

STATUS_INVALID_PARAMETER	An invalid parameter was supplied to the routine.
STATUS_BUFFER_TOO_SMALL	The caller-allocated buffer is too small, but the required buffer size has been written to the *ReturnLength* output parameter.

Remarks

If the call is successful, this routine writes an array of one or more table identifiers to the buffer pointed to by the *FirmwareTableBuffer* parameter. Each element of this array is a DWORD value that identifies a firmware table that is available from the provider specified by the *FirmwareTableProviderSignature* parameter.

The raw SMBIOS table provider ('RSMB') currently returns a single table identifier, 0x00000000. This corresponds to the raw SMBIOS firmware table.

The raw firmware table provider ('FIRM') retrieves a list of DWORD table identifiers. Each identifier corresponds to the beginning of a physical address range. Currently, this provider returns two identifiers, 0x000C0000 and 0x000E0000. These identifiers represent physical memory from 0x000C0000 to 0x000DFFFF and from 0x000E0000 to 0x000FFFFF, respectively.

The ACPI table provider ('ACPI') returns a list of DWORD table identifiers. Each identifier returned corresponds to **Signature** field of the **DESCRIPTION_HEADER** structure for an ACPI table currently in the ACPI namespace of the system. For more information about this structure, see the Advanced Configuration and Power Interface Specification at the Advanced Configuration and Power Interface website.

For ACPI, if the system firmware contains multiple tables with the same name, **AuxKlibEnumerateSystemFirmwareTables** enumerates them all. However, AuxKlibGetSystemFirmwareTable retrieves only the first table in the list that has this name.

AuxKlibEnumerateSystemFirmwareTables is the kernel-mode equivalent of the Win32 EnumSystemFirmwareTables function.

Drivers must call AuxKlibInitialize before calling **AuxKlibEnumerateSystemFirmwareTable**.

AuxKlibEnumerateSystemFirmwareTables is defined in the Aux_klib.h header file that is included in the WDK for Windows 8 and later versions of Windows. To use this routine, drivers should link to the version of Aux_klib.lib that is included in the WDK for Windows 8 and later versions of Windows. The implementation of **AuxKlibEnumerateSystemFirmwareTables** in these versions of the WDK can be used in versions of Windows starting with Windows Vista.

Requirements

Minimum supported client	Supported starting with Windows Vista.
Target Platform	Universal
Header	aux_klib.h (include Aux_klib.h)
Library	Aux_Klib.lib
IRQL	PASSIVE_LEVEL

See Also

EnumSystemFirmwareTables

AuxKlibGetBugCheckData function

1/25/2019 • 2 minutes to read • Edit Online

The **AuxKlibGetBugCheckData** routine retrieves information about a bug check that has just occurred.

Syntax

```
NTSTATUS AuxKlibGetBugCheckData(
  PKBUGCHECK_DATA BugCheckData
);
```

Parameters

`BugCheckData`

A pointer to a KBUGCHECK_DATA structure that contains information about the bug check. The *BugCheckData* size of this structure should be set equal to the size, in bytes, of the **KBUGCHECK_DATA** structure.

Return Value

AuxKlibGetBugCheckData returns STATUS_SUCCESS if the operation succeeds. The routine returns STATUS_INFO_LENGTH_MISMATCH if the **KBUGCHECK_DATA** structure's size is incorrect.

Remarks

The **AuxKlibGetBugCheckData** routine can be called only from a BugCheckCallback routine.

Drivers must call AuxKlibInitialize before calling **AuxKlibGetBugCheckData**.

Requirements

Minimum supported client	Supported starting with Windows 2000.
Target Platform	Universal
Header	aux_klib.h (include Aux_klib.h)
Library	Aux_Klib.lib

See Also

AuxKlibInitialize

BugCheckCallback

KBUGCHECK_DATA

AuxKlibGetImageExportDirectory function

1/25/2019 • 2 minutes to read • Edit Online

The **AuxKlibGetImageExportDirectory** routine returns an image module's export directory.

Syntax

```
PIMAGE_EXPORT_DIRECTORY AuxKlibGetImageExportDirectory(
  PVOID ImageBase
);
```

Parameters

`ImageBase`

A pointer to the base of an image, which is obtained by calling AuxKlibQueryModuleInformation.

Return Value

AuxKlibGetImageExportDirectory returns a pointer to an **IMAGE_EXPORT_DIRECTORY** structure. This structure is defined in Ntimage.h, which is included in the Microsoft Windows Driver Kit (WDK).

Remarks

Drivers must call AuxKlibInitialize before calling **AuxKlibGetImageExportDirectory**.

Requirements

Minimum supported client	Supported starting with Windows 2000.
Target Platform	Universal
Header	aux_klib.h (include Aux_klib.h)
Library	Aux_Klib.lib

See Also

AuxKlibQueryModuleInformation

AuxKlibGetSystemFirmwareTable function

1/25/2019 • 2 minutes to read • Edit Online

The **AuxKlibGetSystemFirmwareTable** routine retrieves the specified firmware table from the firmware table provider.

Syntax

```
NTSTATUS AuxKlibGetSystemFirmwareTable(
  ULONG  FirmwareTableProviderSignature,
  ULONG  FirmwareTableID,
  PVOID  FirmwareTableBuffer,
  ULONG  BufferLength,
  PULONG ReturnLength
);
```

Parameters

`FirmwareTableProviderSignature`

The identifier of the firmware table provider to which the query is to be directed. This parameter can be one of the following values.

VALUE	MEANING
'ACPI'	The ACPI firmware table provider.
'FIRM'	The raw firmware table provider.
'RSMB'	The raw SMBIOS firmware table provider.

`FirmwareTableID`

The identifier of the firmware table. The characters in the identifier are in little-endian order.

For example, FACP is the name of a table provided by ACPI. The FACP table is identified by the 4-byte value 'PCAF' (0x50434146) in the **Signature** field of the **DESCRIPTION_HEADER** structure at the start of the table. The following code example shows how to specify FACP in an **AuxKlibGetSystemFirmwareTable** call:

```
status = AuxKlibGetSystemFirmwareTable('ACPI', 'PCAF', pBuffer, BUFSIZE, &dataSize);
```

In this example, `pBuffer` points to the caller-allocated buffer, `BUFSIZE` is the size in bytes of this buffer, and `dataSize` is a variable to which the routine writes the number of bytes written to the buffer. For more information about the **DESCRIPTION_HEADER** structure, see the Advanced Configuration and Power Interface Specification at the Advanced Configuration and Power Interface website.

`FirmwareTableBuffer`

A pointer to a caller-allocated buffer that receives the list of firmware tables. If this parameter is NULL, the value written to **ReturnLength* is the required buffer size. For more information about the contents of this buffer, see the Remarks section.

`BufferLength`

The size, in bytes, of the buffer pointed to by *FirmwareTableBuffer*.

`ReturnLength`

A pointer to a location to which the routine writes the number of bytes of data written to the buffer pointed to by *FirmwareTableBuffer*.

Return Value

AuxKlibGetSystemFirmwareTable returns STATUS_SUCCESS if the call is successful. Possible return values include the following error codes.

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	An invalid parameter was supplied to the routine.
STATUS_BUFFER_TOO_SMALL	The caller-allocated buffer is too small, but the required buffer size has been written to the *ReturnLength* output parameter.

Remarks

The raw SMBIOS table provider ('RSMB') retrieves the contents of the raw SMBIOS firmware table. The data written to the *FirmwareTableBuffer* buffer starts with the following structure:

```
struct RawSMBIOSData
{
  BYTE  Used20CallingMethod;
  BYTE  SMBIOSMajorVersion;
  BYTE  SMBIOSMinorVersion;
  BYTE  DmiRevision;
  DWORD  Length;
  BYTE  SMBIOSTableData[];
};
```

The raw firmware table provider ('FIRM') retrieves the contents of the specified physical address range. The value written to **ReturnLength* is the size of the address range.

The ACPI table provider ('ACPI') retrieves the contents of the specified ACPI table. Because OEMs can include ACPI firmware tables that are not listed in the ACPI specification, you should first call

AuxKlibEnumerateSystemFirmwareTables to enumerate all ACPI tables that are currently available from the system firmware.

For ACPI, if the system firmware contains multiple tables with the same name, **AuxKlibEnumerateSystemFirmwareTables** enumerates them all. However, **AuxKlibGetSystemFirmwareTable** retrieves only the first table in the list that has this name.

AuxKlibGetSystemFirmwareTable is the kernel-mode equivalent of the Win32 GetSystemFirmwareTable function.

Drivers must call AuxKlibInitialize before calling **AuxKlibGetSystemFirmwareTable**.

AuxKlibGetSystemFirmwareTable is defined in the Aux_klib.h header file that is included in the WDK for Windows 8 and later versions of Windows. To use this routine, drivers should link to the version of Aux_klib.lib that is included in the WDK for Windows 8 and later versions of Windows. The implementation of **AuxKlibGetSystemFirmwareTable** in these versions of the WDK can be used in versions of Windows starting with Windows Vista.

Requirements

Minimum supported client	Supported starting with Windows Vista.
Target Platform	Universal
Header	aux_klib.h (include Aux_klib.h)
Library	Aux_Klib.lib
IRQL	PASSIVE_LEVEL

AuxKlibEnumerateSystemFirmwareTables

AuxKlibInitialize

GetSystemFirmwareTable

AuxKlibInitialize function

1/25/2019 • 2 minutes to read • Edit Online

The **AuxKlibInitialize** routine initializes the Auxiliary Kernel-Mode Library.

Syntax

```
NTSTATUS AuxKlibInitialize(

);
```

Parameters

This function has no parameters.

Return Value

AuxKlibInitialize returns STATUS_SUCCESS if the operation succeeds. Otherwise, the routine returns an appropriate NTSTATUS value.

Remarks

Drivers that use the Auxiliary Kernel-Mode Library must call **AuxKlibInitialize** before calling any of the library's other routines.

Requirements

Minimum supported client	Supported starting with Windows 2000.
Target Platform	Universal
Header	aux_klib.h (include Aux_klib.h)
Library	Aux_Klib.lib

AuxKlibQueryModuleInformation function

1/25/2019 • 2 minutes to read • Edit Online

The **AuxKlibQueryModuleInformation** routine retrieves information about the image modules that the operating system has loaded.

Syntax

```
NTSTATUS AuxKlibQueryModuleInformation(
  PULONG BufferSize,
  ULONG  ElementSize,
  PVOID  QueryInfo
);
```

Parameters

`BufferSize`

A pointer to a location that contains or receives a buffer size, in bytes. If *QueryInfo* is **NULL**, the location receives the number of bytes that the driver must allocate for the array that receives the retrieved information. If *QueryInfo* is not **NULL**, the location must contain the specified number of bytes.

`ElementSize`

The size, in bytes, of each element of the array that *QueryInfo* points to. This value must be **sizeof**(**AUX_MODULE_BASIC_INFO**) or **sizeof**(**AUX_MODULE_EXTENDED_INFO**).

`QueryInfo`

A pointer to an array of AUX_MODULE_BASIC_INFO or AUX_MODULE_EXTENDED_INFO structures that receives information about loaded image modules. If this pointer is **NULL**, **AuxKlibQueryModuleInformation** writes the required buffer size to the location that *BufferSize* points to.

Return Value

AuxKlibQueryModuleInformation returns STATUS_SUCCESS if the operation succeeds. **AuxKlibQueryModuleInformation** returns STATUS_BUFFER_TOO_SMALL if the *QueryInfo* pointer is not **NULL** and the driver-supplied *BufferSize* value is too small.

The routine might return other NTSTATUS values.

Remarks

To obtain information about the operating system's loaded image modules, a driver must:

1. Call **AuxKlibQueryModuleInformation** with a **NULL** *QueryInfo* pointer. After **AuxKlibQueryModuleInformation** returns, the location that the *BufferSize* parameter points to will contain the number of bytes that the driver will have to allocate for the array.
2. Call a memory allocation routine, such as ExAllocatePoolWithTag, to allocate a buffer for the array.
3. Call **AuxKlibQueryModuleInformation** again. This time, the *QueryInfo* pointer must contain the address of the allocated buffer. After **AuxKlibQueryModuleInformation** returns, the buffer contains an array of module

information.

The number of loaded modules can change between the first and second calls to **AuxKlibQueryModuleInformation**. As a result, the second call to **AuxKlibQueryModuleInformation** might return STATUS_BUFFER_TOO_SMALL even if the driver allocates a buffer that is based on the size that was obtained from the first call.

If a call to **AuxKlibQueryModuleInformation** succeeds, the routine writes an **ImageBase** value to each element in the *QueryInfo* array. Each **ImageBase** value is a pointer to the base of a loaded driver image. This pointer remains valid only while the driver remains loaded. The caller should assume that the driver can be unloaded at any time unless the caller can guarantee otherwise. For example, a driver might be unloaded between a call to **AuxKlibQueryModuleInformation** that obtains a pointer to the driver image and a call to AuxKlibGetImageExportDirectory that uses this pointer.

Drivers must call AuxKlibInitialize before calling **AuxKlibQueryModuleInformation**.

Examples

The following code example illustrates the steps that are listed in the preceding Remarks section.

```
NTSTATUS  status;
ULONG  modulesSize;
AUX_MODULE_EXTENDED_INFO*  modules;
ULONG  numberOfModules;
//
// Get the required array size.
//
status = AuxKlibQueryModuleInformation(
                                       &modulesSize,
                                       sizeof(AUX_MODULE_EXTENDED_INFO),
                                       NULL
                                       );

if (!NT_SUCCESS(status) || modulesSize == 0) {
    break;
    }

//
// Calculate the number of modules.
//
numberOfModules = modulesSize / sizeof(AUX_MODULE_EXTENDED_INFO);

//
// Allocate memory to receive data.
//
modules =
    (AUX_MODULE_EXTENDED_INFO*) ExAllocatePoolWithTag(
                                     PagedPool,
                                     modulesSize,
                                     '3LxF'
                                     );
if (modules == NULL) {
    status = STATUS_INSUFFICIENT_RESOURCES;
    break;
    }

RtlZeroMemory(
              modules,
              modulesSize
              );

//
// Obtain the module information.
//
status = AuxKlibQueryModuleInformation(
                                       &modulesSize,
                                       sizeof(AUX_MODULE_EXTENDED_INFO),
                                       modules
                                       );
if (!NT_SUCCESS(status)) {
    break;
    }
```

Requirements

Minimum supported client	Supported starting with Windows 2000.
Target Platform	Universal
Header	aux_klib.h (include Aux_klib.h)

buffring.h header

1/8/2019 • 2 minutes to read • Edit Online

This header defines the change buffering state requests related data structures in RDBSS. For information about the programming interfaces, see the header comments.

- Windows kernel

ioaccess.h header

1/8/2019 • 2 minutes to read • Edit Online

Thsi header defines function prototypes for accessing I/O ports and memory on I/O adapters.

For information about accessing device registers, see:

- Reading and Writing to Device Registers ioaccess.h contains the following programming interfaces:

Functions

TITLE	DESCRIPTION
READ_PORT_UCHAR	The READ_PORT_UCHAR routine reads a byte from the specified port address.
READ_PORT_ULONG	The READ_PORT_ULONG routine reads a ULONG value from the specified port address.
READ_PORT_USHORT	The READ_PORT_USHORT routine reads a USHORT value from the specified port address.
READ_REGISTER_UCHAR	The READ_REGISTER_UCHAR routine reads a byte from the specified register address.
READ_REGISTER_ULONG	The READ_REGISTER_ULONG routine reads a ULONG value from the specified register address.
READ_REGISTER_USHORT	The READ_REGISTER_USHORT routine reads a USHORT value from the specified register address.
WRITE_PORT_UCHAR	The WRITE_PORT_UCHAR routine writes a byte to the specified port address.
WRITE_PORT_ULONG	The WRITE_PORT_ULONG routine writes a ULONG value to the specified port address.
WRITE_PORT_USHORT	The WRITE_PORT_USHORT routine writes a USHORT value to the specified port address.
WRITE_REGISTER_UCHAR	The WRITE_REGISTER_UCHAR routine writes a byte to the specified address.
WRITE_REGISTER_ULONG	The WRITE_REGISTER_ULONG routine writes a ULONG value to the specified address.
WRITE_REGISTER_USHORT	The WRITE_REGISTER_USHORT routine writes a USHORT value to the specified address.

READ_PORT_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_PORT_UCHAR** routine reads a byte from the specified port address.

Syntax

```
UCHAR READ_PORT_UCHAR(
  PVOID Port
);
```

Parameters

`Port`

Specifies the port address, which must be a mapped memory range in I/O space.

Return Value

READ_PORT_UCHAR returns the byte that is read from the specified port address.

Remarks

Callers of **READ_PORT_UCHAR** can be running at any IRQL, assuming the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ioaccess.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h)
Library	Hal.lib
IRQL	Any level (see Remarks section)

READ_PORT_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_PORT_ULONG** routine reads a ULONG value from the specified port address.

Syntax

```
ULONG READ_PORT_ULONG(
  PVOID Port
);
```

Parameters

`Port`

Specifies the port address, which must be a mapped range in I/O space.

Return Value

READ_PORT_ULONG returns the ULONG value that is read from the specified port address.

Remarks

Callers of **READ_PORT_ULONG** can be running at any IRQL, assuming the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ioaccess.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h)
Library	Hal.lib
IRQL	Any level (see Remarks section)

READ_PORT_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_PORT_USHORT** routine reads a USHORT value from the specified port address.

Syntax

```
USHORT READ_PORT_USHORT(
  PVOID Port
);
```

Parameters

`Port`

Specifies the port address, which must be a mapped range in I/O space.

Return Value

READ_PORT_USHORT returns the USHORT value that is read from the specified port address.

Remarks

Callers of **READ_PORT_USHORT** can be running at any IRQL, assuming the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ioaccess.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h)
Library	Hal.lib
IRQL	Any level (see Remarks section)

READ_REGISTER_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_UCHAR** routine reads a byte from the specified register address.

Syntax

```
UCHAR READ_REGISTER_UCHAR(
  _In_ PUCHAR Register
);
```

Parameters

`Register`

Pointer to the register address, which must be a mapped range in memory space.

Return Value

READ_REGISTER_UCHAR returns the byte read from the specified register address.

Remarks

Callers of **READ_REGISTER_UCHAR** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ioaccess.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

READ_REGISTER_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_ULONG** routine reads a ULONG value from the specified register address.

Syntax

```
ULONG READ_REGISTER_ULONG(
  _In_ PULONG Register
);
```

Parameters

`Register`

Pointer to the register address, which must be a mapped range in memory space.

Return Value

READ_REGISTER_ULONG returns the ULONG value read from the specified register address.

Remarks

Callers of **READ_REGISTER_ULONG** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ioaccess.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

READ_REGISTER_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_USHORT** routine reads a USHORT value from the specified register address.

Syntax

```
USHORT READ_REGISTER_USHORT(
  _In_ PUSHORT Register
);
```

Parameters

`Register`

Pointer to the register address, which must be a mapped range in memory space.

Return Value

READ_REGISTER_USHORT returns the USHORT value read from the specified register address.

Remarks

Callers of **READ_REGISTER_USHORT** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ioaccess.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

WRITE_PORT_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_PORT_UCHAR** routine writes a byte to the specified port address.

Syntax

```
void WRITE_PORT_UCHAR(
  PVOID Port,
  ULONG Value
);
```

Parameters

`Port`

Pointer to the port, which must be a mapped memory range in I/O space.

`Value`

Specifies a byte to be written to the port.

Return Value

None

Remarks

Callers of **WRITE_PORT_UCHAR** can be running at any IRQL, assuming the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ioaccess.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h)
Library	Hal.lib
IRQL	Any level (see Remarks section)

WRITE_PORT_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_PORT_ULONG** routine writes a ULONG value to the specified port address.

Syntax

```
void WRITE_PORT_ULONG(
  PVOID Port,
  ULONG Value
);
```

Parameters

`Port`

Pointer to the port, which must be a mapped memory range in I/O space.

`Value`

Specifies a ULONG value to be written to the port.

Return Value

None

Remarks

Callers of **WRITE_PORT_ULONG** can be running at any IRQL, assuming the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ioaccess.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h)
Library	Hal.lib
IRQL	Any level (see Remarks section)

WRITE_PORT_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_PORT_USHORT** routine writes a USHORT value to the specified port address.

Syntax

```
void WRITE_PORT_USHORT(
  PVOID Port,
  ULONG Value
);
```

Parameters

`Port`

Pointer to the port, which must be a mapped memory range in I/O space.

`Value`

Specifies a USHORT value to be written to the port.

Return Value

None

Remarks

Callers of **WRITE_PORT_USHORT** can be running at any IRQL, assuming the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ioaccess.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h)
Library	Hal.lib
IRQL	Any level (see Remarks section)

WRITE_REGISTER_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_REGISTER_UCHAR** routine writes a byte to the specified address.

Syntax

```
VOID WRITE_REGISTER_UCHAR(
  _In_ PUCHAR Register,
  _In_ UCHAR  Value
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Value`

Specifies a byte to be written to the register.

Return Value

None

Remarks

Callers of **WRITE_REGISTER_UCHAR** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ioaccess.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

WRITE_REGISTER_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_REGISTER_ULONG** routine writes a ULONG value to the specified address.

Syntax

```
VOID WRITE_REGISTER_ULONG(
  _In_ PULONG Register,
  _In_ ULONG  Value
);
```

Parameters

`Register`

Pointer to the register which must be a mapped range in memory space.

`Value`

Specifies a ULONG value to be written to the register.

Return Value

None

Remarks

Callers of **WRITE_REGISTER_ULONG** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ioaccess.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

WRITE_REGISTER_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_REGISTER_USHORT** routine writes a USHORT value to the specified address.

Syntax

```
VOID WRITE_REGISTER_USHORT(
  _In_ PUSHORT Register,
  _In_ USHORT  Value
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Value`

Specifies a USHORT value to be written to the register.

Return Value

None

Remarks

Callers of **WRITE_REGISTER_USHORT** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ioaccess.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

iointex.h header

1/8/2019 • 2 minutes to read • Edit Online

This header exposes the programming interfaces to connect and disconnect interrupts allowing drivers to use those interfaces to run on downlevel systems. For more information, see:

- Registering an ISR
- Servicing Interrupts iointex.h contains the following programming interfaces:

Functions

TITLE	DESCRIPTION
WdmlibIoConnectInterruptEx	The WdmlibIoConnectInterruptEx function registers an interrupt-handling routine for a device's interrupts.
WdmlibIoDisconnectInterruptEx	The WdmlibIoDisconnectInterruptEx function unregisters an interrupt service routine (ISR) that was registered by a previous call to the WdmlibIoConnectInterruptEx function.
WdmlibIoGetAffinityInterrupt	The WdmlibIoGetAffinityInterrupt function gets the group affinity of an interrupt object.

WdmlibIoConnectInterruptEx function

1/25/2019 • 2 minutes to read • Edit Online

The **WdmlibIoConnectInterruptEx** function registers an interrupt-handling routine for a device's interrupts.

Syntax

```
NTSTATUS WdmlibIoConnectInterruptEx(
  PIO_CONNECT_INTERRUPT_PARAMETERS Parameters
);
```

Parameters

`Parameters`

Pointer to an IO_CONNECT_INTERRUPT_PARAMETERS structure that specifies the device and interrupt-handling routine. On return, **WdmlibIoConnectInterruptEx** updates this structure to hold information about the device's interrupts.

Return Value

The function returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error value on failure. Possible error values include:

RETURN CODE	DESCRIPTION
STATUS_INVALID_DEVICE_REQUEST	The operation is invalid for the specified device. For example, *Parameters*->**Version** = CONNECT_LINE_BASED, and the system has assigned multiple interrupt messages to the device.
STATUS_INVALID_PARAMETER	The caller specified an invalid parameter. This error occurs, for example, when the caller specified **NULL** for the device's device object.

STATUS_INVALID_PARAMETER_1	The caller specified an invalid value for the **Version** member of the structure that *Parameters* points to. *Parameters*->**Version** must be one of CONNECT_LINE_BASED, CONNECT_MESSAGE_BASED, or CONNECT_FULLY_SPECIFIED.
STATUS_INVALID_PARAMETER_10	The caller specified an invalid value for the tenth member of the structure that *Parameters* points to. This error occurs, for example, when *Parameters*->**FullySpecified.ProcessorEnableMask** does not have any bits set.
STATUS_NOT_FOUND	One of the arguments was not found. For example, the specified device has no interrupts, or the specified interrupt vector is not assigned to any device.

Remarks

WdmlibIoConnectInterruptEx can be used to register an interrupt-handling routine for both traditional line-based interrupts (such as that supported by the PCI bus), and the newer message-signaled interrupts (such as that supported by PCI versions 2.2 and 3.0).

Drivers register an InterruptService routine for line-based interrupts, and an InterruptMessageService routine for message-signaled interrupts. For more information about how to specify the members of *Parameters* in each case, see IO_CONNECT_INTERRUPT_PARAMETERS.

WdmlibIoConnectInterruptEx updates the members of *Parameters* to provide information about the device's interrupts. For more information about the information provided by **WdmlibIoConnectInterruptEx**, see IO_CONNECT_INTERRUPT_PARAMETERS.

Use WdmlibIoDisconnectInterruptEx to unregister a routine registered with **WdmlibIoConnectInterruptEx**.

The driver should not program its device to generate interrupts until it has connected its ISR. Thus, the ISR cannot fire before **WdmlibIoConnectInterruptEx** returns. However, there are certain devices, such as buttons, that are not programmable. For those devices, the driver should be prepared to handle the ISR as soon as it calls **WdmlibIoConnectInterruptEx**. The interrupt line may already be asserted when **WdmlibIoConnectInterruptEx** is called and can fire immediately after the line is enabled at the interrupt controller, before the **WdmlibIoConnectInterruptEx** call unwinds.

For more information about registering an interrupt-handling routine, see Registering an ISR.

Requirements

Minimum supported client	Available on Windows Vista and later versions of the Windows operating system. Drivers that must also work on Windows 2000, Windows XP, or Windows Server 2003 can instead link to Iointex.lib to use the routine.
Target Platform	Universal
Header	iointex.h (include Iointex.h, Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	HwStorPortProhibitedDDIs

IO_CONNECT_INTERRUPT_PARAMETERS

InterruptMessageService

InterruptService

WdmlibIoDisconnectInterruptEx

WdmlibIoDisconnectInterruptEx function

1/25/2019 • 2 minutes to read • Edit Online

The **WdmlibIoDisconnectInterruptEx** function unregisters an interrupt service routine (ISR) that was registered by a previous call to the WdmlibIoConnectInterruptEx function.

Syntax

```
NTSTATUS WdmlibIoDisconnectInterruptEx(
  PIO_DISCONNECT_INTERRUPT_PARAMETERS Parameters
);
```

Parameters

`Parameters`

Pointer to an IO_DISCONNECT_INTERRUPT_PARAMETERS structure that contains the connection context for the interrupt being disconnected.

Return Value

None.

Remarks

The driver should configure the device to issue interrupts only when these interrupts are connected. Failure to prevent a device from issuing interrupts when the interrupts are disconnected might cause system instability. For example, if a device shares a level-triggered interrupt line with other devices, and the device issues an interrupt request when the device's interrupts are disconnected, the other devices on the line will not acknowledge the interrupt and the interrupt will continue to fire. Before calling **WdmlibIoDisconnectInterruptEx**, the driver should configure the device to stop issuing interrupts. After calling WdmlibIoConnectInterruptEx, the driver should configure the device to start issuing interrupts.

Requirements

Minimum supported client	Available starting with Windows Vista. Drivers that must also work Microsoft Windows 2000, Windows XP, or Windows Server 2003 can instead link to Iointex.lib to use the routine.
Target Platform	Universal
Header	iointex.h (include Iointex.h, Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib; Iointex.lib
DLL	NtosKrnl.exe

IRQL	PASSIVE_LEVEL

IO_DISCONNECT_INTERRUPT_PARAMETERS

WdmlibIoConnectInterruptEx

WdmlibIoGetAffinityInterrupt function

1/25/2019 • 2 minutes to read • Edit Online

The **WdmlibIoGetAffinityInterrupt** function gets the group affinity of an interrupt object.

Syntax

```
NTSTATUS WdmlibIoGetAffinityInterrupt(
  PKINTERRUPT     InterruptObject,
  PGROUP_AFFINITY GroupAffinity
);
```

Parameters

`InterruptObject`

A pointer to an interrupt object. This parameter points to a KINTERRUPT structure that represents a registration by a driver to receive device interrupts. The structure is opaque. The caller obtained this pointer value in a previous call to the WdmlibIoConnectInterruptEx or IoConnectInterrupt routine.

`GroupAffinity`

A pointer to a caller-allocated buffer into which the routine writes a GROUP_AFFINITY structure that specifies the group affinity of the interrupt object that *InterruptObject* points to. This buffer must be large enough to contain the structure.

Return Value

WdmlibIoGetAffinityInterrupt returns STATUS_SUCCESS if the call is successful. Possible error return values include the following:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The *InterruptObject* parameter does not point to a valid interrupt object.

Remarks

A kernel-mode driver calls this routine to get the set of logical processors on which the driver's registered interrupt service routine (ISR) can receive device interrupts. This set of processors is described by a **GROUP_AFFINITY** structure, which specifies a group number and an affinity mask. All the processors that are assigned to a particular ISR registration must belong to the same group.

The driver registered the ISR in a previous call to the WdmlibIoConnectInterruptEx or **IoConnectInterrupt**

routine.

In Windows 7, WdmlibIoConnectInterruptEx and **IoConnectInterrupt** assign device interrupts only to logical processors in group 0. This is by default. A driver can specify a different interrupt affinity for its device in an INF file or in its response to an IRP_MN_FILTER_RESOURCE_REQUIREMENTS request. For more information about how to change the interrupt affinity, see the Supporting Systems That Have More Than 64 Processors white paper on the WHDC website.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Windows
Header	iointex.h (include Iointex.h, Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

miniport.h header

1/8/2019 • 9 minutes to read • Edit Online

This header is used by storage. For more information, see:

- Storage miniport.h contains the following programming interfaces:

Functions

TITLE	DESCRIPTION
ARM64_SYSREG_CRM	Returns the CRm field for a given ARM system register encoding value. For more information, see the ARM Architecture Reference Manual.
ARM64_SYSREG_CRN	Returns the CRn field for a given ARM system register encoding value. For more information, see the ARM Architecture Reference Manual.
ARM64_SYSREG_OP1	Returns the op1 field for a given ARM system register encoding value. For more information, see the ARM Architecture Reference Manual.
ARM64_SYSREG_OP2	Returns the op2 field for a given ARM system register encoding value. For more information, see the ARM Architecture Reference Manual.
FIELD_OFFSET	The FIELD_OFFSET macro returns the byte offset of a named field in a known structure type.
InterlockedAnd	The InterlockedAnd macro atomically computes a bitwise AND operation.
InterlockedCompareExchange	The InterlockedCompareExchange routine performs an atomic operation that compares the input value pointed to by Destination with the value of Comparand.
InterlockedCompareExchangePointer	The InterlockedCompareExchangePointer routine performs an atomic operation that compares the input pointer value pointed to by Destination with the pointer value Comparand.
InterlockedDecrement	The InterlockedDecrement routine decrements a caller-supplied variable of type LONG as an atomic operation.
InterlockedExchange	The InterlockedExchange routine sets an integer variable to a given value as an atomic operation.
InterlockedExchangeAdd	The InterlockedExchangeAdd routine adds a value to a given integer as an atomic operation and returns the original value of the given integer.

TITLE	DESCRIPTION
InterlockedExchangePointer	The InterlockedExchangePointer routine performs an atomic operation that sets a pointer to a new value.
InterlockedIncrement	The InterlockedIncrement routine increments a caller-supplied variable as an atomic operation.
InterlockedOr	The InterlockedOr routine atomically computes a bitwise OR operation.
InterlockedXor	The InterlockedOr routine atomically computes a bitwise exclusive OR operation.
READ_PORT_BUFFER_UCHAR	The READ_PORT_BUFFER_UCHAR routine reads a number of bytes from the specified port address into a buffer.
READ_PORT_BUFFER_ULONG	The READ_PORT_BUFFER_ULONG routine reads a number of ULONG values from the specified port address into a buffer.
READ_PORT_BUFFER_USHORT	The READ_PORT_BUFFER_USHORT routine reads a number of USHORT values from the specified port address into a buffer.
READ_PORT_UCHAR	The READ_PORT_UCHAR routine reads a byte from the specified port address.
READ_PORT_ULONG	The READ_PORT_ULONG routine reads a ULONG value from the specified port address.
READ_PORT_USHORT	The READ_PORT_USHORT routine reads a USHORT value from the specified port address.
READ_REGISTER_BUFFER_UCHAR	The READ_REGISTER_BUFFER_UCHAR routine reads a number of bytes from the specified register address into a buffer.
READ_REGISTER_BUFFER_ULONG	The READ_REGISTER_BUFFER_ULONG routine reads a number of ULONG values from the specified register address into a buffer.
READ_REGISTER_BUFFER_ULONG64	The READ_REGISTER_BUFFER_ULONG64 function reads a number of ULONG64 values from the specified register address into a buffer.
READ_REGISTER_BUFFER_USHORT	The READ_REGISTER_BUFFER_USHORT routine reads a number of USHORT values from the specified register address into a buffer.
READ_REGISTER_UCHAR	The READ_REGISTER_UCHAR routine reads a byte from the specified register address.
READ_REGISTER_ULONG	The READ_REGISTER_ULONG routine reads a ULONG value from the specified register address.
READ_REGISTER_ULONG64	The READ_REGISTER_ULONG64 function reads a ULONG64 value from the specified register address.

TITLE	DESCRIPTION
READ_REGISTER_USHORT	The READ_REGISTER_USHORT routine reads a USHORT value from the specified register address.
WRITE_PORT_BUFFER_UCHAR	The WRITE_PORT_BUFFER_UCHAR routine writes a number of bytes from a buffer to the specified port.
WRITE_PORT_BUFFER_ULONG	The WRITE_PORT_BUFFER_ULONG routine writes a number of ULONG values from a buffer to the specified port address.
WRITE_PORT_BUFFER_USHORT	The WRITE_PORT_BUFFER_USHORT routine writes a number of USHORT values from a buffer to the specified port address.
WRITE_PORT_UCHAR	The WRITE_PORT_UCHAR routine writes a byte to the specified port address.
WRITE_PORT_ULONG	The WRITE_PORT_ULONG routine writes a ULONG value to the specified port address.
WRITE_PORT_USHORT	The WRITE_PORT_USHORT routine writes a USHORT value to the specified port address.
WRITE_REGISTER_BUFFER_UCHAR	The WRITE_REGISTER_BUFFER_UCHAR routine writes a number of bytes from a buffer to the specified register.
WRITE_REGISTER_BUFFER_ULONG	The WRITE_REGISTER_BUFFER_ULONG routine writes a number of ULONG values from a buffer to the specified register.
WRITE_REGISTER_BUFFER_ULONG64	The WRITE_REGISTER_BUFFER_ULONG64 function writes a number of ULONG64 values from a buffer to the specified register.
WRITE_REGISTER_BUFFER_USHORT	The WRITE_REGISTER_BUFFER_USHORT routine writes a number of USHORT values from a buffer to the specified register.
WRITE_REGISTER_UCHAR	The WRITE_REGISTER_UCHAR routine writes a byte to the specified address.
WRITE_REGISTER_ULONG	The WRITE_REGISTER_ULONG routine writes a ULONG value to the specified address.
WRITE_REGISTER_ULONG64	The WRITE_REGISTER_ULONG64 function writes a ULONG64 value to the specified address.
WRITE_REGISTER_USHORT	The WRITE_REGISTER_USHORT routine writes a USHORT value to the specified address.

Callback functions

TITLE	DESCRIPTION

TITLE	DESCRIPTION
PINTERFACE_DEREFERENCE	The InterfaceDereference routine decrements the reference count on a driver-defined interface.
PINTERFACE_REFERENCE	The InterfaceReference routine increments the reference count on a driver-defined interface.

Structures

TITLE	DESCRIPTION
CM_EISA_FUNCTION_INFORMATION	The CM_EISA_FUNCTION_INFORMATION structure defines detailed EISA configuration information returned by HalGetBusData for the input BusDataType EisaConfiguration, or by HalGetBusDataByOffset for the input BusDataType EisaConfiguration and the Offset zero, assuming the caller-allocated Buffer is of sufficient Length.
CM_EISA_SLOT_INFORMATION	The CM_EISA_SLOT_INFORMATION structure defines EISA configuration header information returned by HalGetBusData for the input BusDataType = EisaConfiguration, or by HalGetBusDataByOffset for the inputs BusDataType = EisaConfiguration and Offset = 0, assuming the caller-allocated Buffer is of sufficient Length.
CM_MCA_POS_DATA	The CM_MCA_POS_DATA structure is obsolete. It defines IBM-compatible MCA POS configuration information for a slot.
EMULATOR_ACCESS_ENTRY	The EMULATOR_ACCESS_ENTRY structure specifies an element in the EmulatorAccessEntries array set up in the VIDEO_PORT_CONFIG_INFO structure by drivers of VGA-compatible (SVGA) adapters on x86-based NT-based operating system platforms.
GROUP_AFFINITY	The GROUP_AFFINITY structure specifies a group number and the processor affinity within that group.
INTERFACE	The INTERFACE structure describes an interface that is exported by a driver for use by other drivers.
IO_RESOURCE_DESCRIPTOR	The IO_RESOURCE_DESCRIPTOR structure describes a range of raw hardware resources, of one type, that can be used by a device. An array of IO_RESOURCE_DESCRIPTOR structures is contained within each IO_RESOURCE_LIST structure.
IO_RESOURCE_LIST	The IO_RESOURCE_LIST structure describes a range of raw hardware resources, of various types, that can be used by a device.
IO_RESOURCE_REQUIREMENTS_LIST	The IO_RESOURCE_REQUIREMENTS_LIST structure describes sets of resource configurations that can be used by a device. Each configuration represents a range of raw resources, of various types, that can be used by a device.
PCI_CAPABILITIES_HEADER	The PCI_CAPABILITIES_HEADER structure defines a header that is present in every PCI capability structure.

TITLE	DESCRIPTION
PCI_COMMON_CONFIG	The PCI_COMMON_CONFIG structure is obsolete.
PCI_EXPRESS_AER_CAPABILITIES	The PCI_EXPRESS_AER_CAPABILITIES structure describes a PCI Express (PCIe) advanced error capabilities and control register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_AER_CAPABILITY	The PCI_EXPRESS_AER_CAPABILITY structure describes a PCI Express (PCIe) advanced error reporting capability structure.
PCI_EXPRESS_BRIDGE_AER_CAPABILITY	The PCI_EXPRESS_BRIDGE_AER_CAPABILITY structure describes a PCI Express (PCIe) advanced error reporting capability structure for a PCIe bridge device.
PCI_EXPRESS_CAPABILITIES_REGISTER	The PCI_EXPRESS_CAPABILITIES_REGISTER structure describes a PCI Express (PCIe) capabilities register of a PCIe capability structure.
PCI_EXPRESS_CAPABILITY	The PCI_EXPRESS_CAPABILITY structure describes a PCI Express (PCIe) capability structure.
PCI_EXPRESS_CORRECTABLE_ERROR_MASK	The PCI_EXPRESS_CORRECTABLE_ERROR_MASK structure describes a PCI Express (PCIe) correctable error mask register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_CORRECTABLE_ERROR_STATUS	The PCI_EXPRESS_CORRECTABLE_ERROR_STATUS structure describes a PCI Express (PCIe) correctable error status register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_DEVICE_CAPABILITIES_REGISTER	The PCI_EXPRESS_DEVICE_CAPABILITIES_REGISTER structure describes a PCI Express (PCIe) device capabilities register of a PCIe capability structure.
PCI_EXPRESS_DEVICE_CONTROL_REGISTER	The PCI_EXPRESS_DEVICE_CONTROL_REGISTER structure describes a PCI Express (PCIe) device control register of a PCIe capability structure.
PCI_EXPRESS_DEVICE_STATUS_REGISTER	The PCI_EXPRESS_DEVICE_STATUS_REGISTER structure describes a PCI Express (PCIe) device status register of a PCIe capability structure.
PCI_EXPRESS_ENHANCED_CAPABILITY_HEADER	The PCI_EXPRESS_ENHANCED_CAPABILITY_HEADER structure describes the header for a PCI Express (PCIe) extended capability structure.
PCI_EXPRESS_ERROR_SOURCE_ID	The PCI_EXPRESS_ERROR_SOURCE_ID structure describes the identifiers of the first correctable error and the first uncorrectable error that are reported in the PCI Express (PCIe) root error status register.
PCI_EXPRESS_LINK_CAPABILITIES_REGISTER	The PCI_EXPRESS_LINK_CAPABILITIES_REGISTER structure describes a PCI Express (PCIe) link capabilities register of a PCIe capability structure.

TITLE	DESCRIPTION
PCI_EXPRESS_LINK_CONTROL_REGISTER	The PCI_EXPRESS_LINK_CONTROL_REGISTER structure describes a PCI Express (PCIe) link control register of a PCIe capability structure.
PCI_EXPRESS_LINK_STATUS_REGISTER	The PCI_EXPRESS_LINK_STATUS_REGISTER structure describes a PCI Express (PCIe) link status register of a PCIe capability structure.
PCI_EXPRESS_PME_REQUESTOR_ID	The PCI_EXPRESS_PME_REQUESTOR_ID structure describes the identifier of the requester of a power management event (PME).
PCI_EXPRESS_ROOT_CAPABILITIES_REGISTER	The PCI_EXPRESS_ROOT_CAPABILITIES_REGISTER structure describes a PCI Express (PCIe) root capabilities register of a PCIe capability structure.
PCI_EXPRESS_ROOT_CONTROL_REGISTER	The PCI_EXPRESS_ROOT_CONTROL_REGISTER structure describes a PCI Express (PCIe) root control register of a PCIe capability structure.
PCI_EXPRESS_ROOT_ERROR_COMMAND	The PCI_EXPRESS_ROOT_ERROR_COMMAND structure describes a PCI Express (PCIe) root error command register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_ROOT_ERROR_STATUS	The PCI_EXPRESS_ROOT_ERROR_STATUS structure describes a PCI Express (PCIe) root error status register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_ROOT_STATUS_REGISTER	The PCI_EXPRESS_ROOT_STATUS_REGISTER structure describes a PCI Express (PCIe) root status register of a PCIe capability structure.
PCI_EXPRESS_ROOTPORT_AER_CAPABILITY	The PCI_EXPRESS_ROOTPORT_AER_CAPABILITY structure describes a PCI Express (PCIe) advanced error reporting capability structure for a root port or a root complex event collector.
PCI_EXPRESS_SEC_AER_CAPABILITIES	The PCI_EXPRESS_SEC_AER_CAPABILITIES structure describes a PCI Express (PCIe) secondary error capabilities and control register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_SEC_UNCORRECTABLE_ERROR_MASK	The PCI_EXPRESS_SEC_UNCORRECTABLE_ERROR_MASK structure describes a PCI Express (PCIe) secondary uncorrectable error mask register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_SEC_UNCORRECTABLE_ERROR_SEVERITY	The PCI_EXPRESS_SEC_UNCORRECTABLE_ERROR_SEVERITY structure describes a PCI Express (PCIe) secondary uncorrectable error severity register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_SEC_UNCORRECTABLE_ERROR_STATUS	The PCI_EXPRESS_SEC_UNCORRECTABLE_ERROR_STATUS structure describes a PCI Express (PCIe) secondary uncorrectable error status register of a PCIe advanced error reporting capability structure.

TITLE	DESCRIPTION
PCI_EXPRESS_SERIAL_NUMBER_CAPABILITY	The PCI_EXPRESS_SERIAL_NUMBER_CAPABILITY structure describes a serial number for a PCI Express (PCIe) device.
PCI_EXPRESS_SLOT_CAPABILITIES_REGISTER	The PCI_EXPRESS_SLOT_CAPABILITIES_REGISTER structure describes a PCI Express (PCIe) slot capabilities register of a PCIe capability structure.
PCI_EXPRESS_SLOT_CONTROL_REGISTER	The PCI_EXPRESS_SLOT_CONTROL_REGISTER structure describes a PCI Express (PCIe) slot control register of a PCIe capability structure.
PCI_EXPRESS_SLOT_STATUS_REGISTER	The PCI_EXPRESS_SLOT_STATUS_REGISTER structure describes a PCI Express (PCIe) slot status register of a PCIe capability structure.
PCI_EXPRESS_UNCORRECTABLE_ERROR_MASK	The PCI_EXPRESS_UNCORRECTABLE_ERROR_MASK structure describes a PCI Express (PCIe) uncorrectable error mask register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_UNCORRECTABLE_ERROR_SEVERITY	The PCI_EXPRESS_UNCORRECTABLE_ERROR_SEVERITY structure describes a PCI Express (PCIe) uncorrectable error severity register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_UNCORRECTABLE_ERROR_STATUS	The PCI_EXPRESS_UNCORRECTABLE_ERROR_STATUS structure describes a PCI Express (PCIe) uncorrectable error status register of a PCIe advanced error reporting capability structure.
PCI_PM_CAPABILITY	The PCI_PM_CAPABILITY structure reports the power management capabilities of the device.
PCI_PMC	The PCI_PMC structure is used to report the contents of the power management capabilities register.
PCI_PMCSR	The PCI_PMCSR structure is used to report the contents of the device's power management control status register.
PCI_PMCSR_BSE	The PCI_PMCSR_BSE structure is used to report the contents of the power management control status register for PCI bridge support extensions.
PCI_SLOT_NUMBER	The PCI_SLOT_NUMBER structure is obsolete.
PCI_X_CAPABILITY	The PCI_X_CAPABILITY structure reports the contents of the command and status registers of a device that is compliant with the PCI-X Addendum to the PCI Local Bus Specification.
PROCESSOR_NUMBER	The PROCESSOR_NUMBER structure identifies a processor by its group number and group-relative processor number.

Enumerations

TITLE	DESCRIPTION
BUS_DATA_TYPE	The BUS_DATA_TYPE enumeration indicates the type of bus configuration space.
INTERFACE_TYPE	The INTERFACE_TYPE enumeration indicates the bus type.
IRQ_DEVICE_POLICY	The IRQ_DEVICE_POLICY enumeration type indicates the policy the operating system can use to assign the interrupts from a device to different processors.
IRQ_PRIORITY	The IRQ_PRIORITY enumeration type indicates the priority the system should give to servicing a device's interrupts.
KINTERRUPT_MODE	The KINTERRUPT_MODE enumeration type indicates whether an interrupt is level-triggered or edge-triggered.
KINTERRUPT_POLARITY	The KINTERRUPT_POLARITY enumeration indicates how a device signals an interrupt request on an interrupt line.
MEMORY_CACHING_TYPE	The MEMORY_CACHING_TYPE enumeration type specifies the permitted caching behavior when allocating or mapping memory.

BUS_DATA_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **BUS_DATA_TYPE** enumeration indicates the type of bus configuration space.

Syntax

```
typedef enum _BUS_DATA_TYPE {
  ConfigurationSpaceUndefined,
  Cmos,
  EisaConfiguration,
  Pos,
  CbusConfiguration,
  PCIConfiguration,
  VMEConfiguration,
  NuBusConfiguration,
  PCMCIAConfiguration,
  MPIConfiguration,
  MPSAConfiguration,
  PNPISAConfiguration,
  SgiInternalConfiguration,
  MaximumBusDataType
} BUS_DATA_TYPE, *PBUS_DATA_TYPE;
```

Constants

ConfigurationSpaceUndefined	Indicates that the type of bus configuration space is undefined.
Cmos	Indicates CMOS data.
EisaConfiguration	Indicates an EISA bus configuration space.
Pos	For internal use only.
CbusConfiguration	Indicates Cbus configuration space.
PCIConfiguration	Indicates PCI configuration space.
VMEConfiguration	Indicates VME configuration space.
NuBusConfiguration	Indicates NuBus configuration space.
PCMCIAConfiguration	Indicates PCMCIA configuration space.
MPIConfiguration	Indicates MPI configuration space.
MPSAConfiguration	Indicates MPSA configuration space.
PNPISAConfiguration	Indicates PNPISA configuration space.

SgiInternalConfiguration	Indicates SGI internal bus configuration space.
MaximumBusDataType	Indicates the upper limit of the bus configuration space types.

Requirements

Header	miniport.h (include Ntddk.h, Miniport.h)

CM_EISA_FUNCTION_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **CM_EISA_FUNCTION_INFORMATION** structure defines detailed EISA configuration information returned by HalGetBusData for the input *BusDataType***EisaConfiguration**, or by **HalGetBusDataByOffset** for the input *BusDataType***EisaConfiguration** and the *Offset* zero, assuming the caller-allocated *Buffer* is of sufficient *Length*.

Syntax

```
typedef struct _CM_EISA_FUNCTION_INFORMATION {
  ULONG                     CompressedId;
  UCHAR                     IdSlotFlags1;
  UCHAR                     IdSlotFlags2;
  UCHAR                     MinorRevision;
  UCHAR                     MajorRevision;
  UCHAR                     Selections[26];
  UCHAR                     FunctionFlags;
  UCHAR                     TypeString[80];
  EISA_MEMORY_CONFIGURATION EisaMemory[9];
  EISA_IRQ_CONFIGURATION    EisaIrq[7];
  EISA_DMA_CONFIGURATION    EisaDma[4];
  EISA_PORT_CONFIGURATION   EisaPort[20];
  UCHAR                     InitializationData[60];
} CM_EISA_FUNCTION_INFORMATION, *PCM_EISA_FUNCTION_INFORMATION;
```

Members

`CompressedId`

The EISA compressed identification of the device at this slot. The value is identical to the **CompressedId** member of the CM_EISA_SLOT_INFORMATION structure.

`IdSlotFlags1`

The EISA slot identification flags.

`IdSlotFlags2`

The EISA slot identification flags.

`MinorRevision`

Information supplied by the manufacturer.

`MajorRevision`

Information supplied by the manufacturer.

`Selections`

The EISA selections for the device.

`FunctionFlags`

Indicates which of the members has available information. Callers can use the following system-defined masks to determine whether a particular type of configuration information can be or has been returned by **HalGetBusData**

or HalGetBusDataByOffset:

EISA_FUNCTION_ENABLED

EISA_FREE_FORM_DATA

EISA_HAS_PORT_INIT_ENTRY

EISA_HAS_PORT_RANGE

EISA_HAS_DMA_ENTRY

EISA_HAS_IRQ_ENTRY

EISA_HAS_MEMORY_ENTRY

EISA_HAS_TYPE_ENTRY

EISA_HAS_INFORMATION

The EISA_HAS_INFORMATION mask is a combination of the following:

EISA_HAS_PORT_RANGE

EISA_HAS_DMA_ENTRY

EISA_HAS_IRQ_ENTRY

EISA_HAS_MEMORY_ENTRY

EISA_HAS_TYPE_ENTRY

`TypeString`

Specifies the type of device.

`EisaMemory`

Describes the EISA device memory configuration information, defined as follows:

```
typedef struct _EISA_MEMORY_CONFIGURATION {
    EISA_MEMORY_TYPE ConfigurationByte;
    UCHAR DataSize;
    USHORT AddressLowWord;
    UCHAR AddressHighByte;
    USHORT MemorySize;
} EISA_MEMORY_CONFIGURATION, *PEISA_MEMORY_CONFIGURATION;
```

`EisaIrq`

Describes the EISA interrupt configuration information, defined as follows:

```
typedef struct _EISA_IRQ_CONFIGURATION {
    EISA_IRQ_DESCRIPTOR ConfigurationByte;
    UCHAR Reserved;
} EISA_IRQ_CONFIGURATION, *PEISA_IRQ_CONFIGURATION;
```

`EisaDma`

Describes the EISA DMA configuration information, defined as follows:

```
typedef struct _EISA_DMA_CONFIGURATION {
    DMA_CONFIGURATION_BYTE0 ConfigurationByte0;
    DMA_CONFIGURATION_BYTE1 ConfigurationByte1;
} EISA_DMA_CONFIGURATION, *PEISA_DMA_CONFIGURATION;
```

`EisaPort`

Describes the EISA device port configuration information, defined as follows:

```
typedef struct _EISA_PORT_CONFIGURATION {
    EISA_PORT_DESCRIPTOR Configuration;
    USHORT PortAddress;
} EISA_PORT_CONFIGURATION, *PEISA_PORT_CONFIGURATION;
```

`InitializationData`

Vendor-supplied, device-specific initialization data, if any.

Remarks

The information returned by **HalGetBusData** or **HalGetBusDataByOffset** in **CM_EISA_FUNCTION_INFORMATION** and/or in the CM_EISA_SLOT_INFORMATION header immediately preceding it is read-only.

Requirements

Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

See Also

CM_EISA_SLOT_INFORMATION

HalGetBusData

HalGetBusDataByOffset

CM_EISA_SLOT_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **CM_EISA_SLOT_INFORMATION** structure defines EISA configuration header information returned by HalGetBusData for the input *BusDataType* = **EisaConfiguration**, or by HalGetBusDataByOffset for the inputs *BusDataType* = **EisaConfiguration** and *Offset* = 0, assuming the caller-allocated *Buffer* is of sufficient *Length*.

Syntax

```
typedef struct _CM_EISA_SLOT_INFORMATION {
  UCHAR  ReturnCode;
  UCHAR  ReturnFlags;
  UCHAR  MajorRevision;
  UCHAR  MinorRevision;
  USHORT Checksum;
  UCHAR  NumberFunctions;
  UCHAR  FunctionInformation;
  ULONG  CompressedId;
} CM_EISA_SLOT_INFORMATION, *PCM_EISA_SLOT_INFORMATION;
```

Members

`ReturnCode`

Contains a status code if an error occurs when the EISA BIOS is queried. Possible status codes include the following:

- EISA_INVALID_SLOT
- EISA_INVALID_FUNCTION
- EISA_INVALID_CONFIGURATION
- EISA_EMPTY_SLOT
- EISA_INVALID_BIOS_CALL

`ReturnFlags`

The return flags.

`MajorRevision`

Information supplied by the manufacturer.

`MinorRevision`

Information supplied by the manufacturer.

`Checksum`

The checksum value, allowing validation of the configuration data.

`NumberFunctions`

The number at this slot.

`FunctionInformation`

Whether there is available CM_EISA_FUNCTION_INFORMATION for this slot.

`CompressedId`

The EISA compressed identification of the device at this slot. This value is identical to the **CompressedId** member of the **CM_EISA_FUNCTION_INFORMATION** structure. This member can be read to determine whether the caller should call **HalGetBusData** or **HalGetBusDataByOffset** again with sufficient buffer space to get more detailed **CM_EISA_FUNCTION_INFORMATION** for a device it supports.

Remarks

The information returned by **HalGetBusData** or **HalGetBusDataByOffset** in **CM_EISA_SLOT_INFORMATION** and in **CM_EISA_FUNCTION_INFORMATION** immediately following it is read-only.

The driver of an EISA device might call **HalGetBusData** or **HalGetBusDataByOffset** for each slot on each EISA bus in the system, requesting only **CM_EISA_SLOT_INFORMATION** in order to find the device(s) it supports by examining the returned **CompressedId** values. Then, such a driver could allocate sufficient buffer space to call **HalGetBusData(ByOffset)** again for **CM_EISA_SLOT_INFORMATION** and **CM_EISA_FUNCTION_INFORMATION** at slots where its device(s) can be found.

Requirements

Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

HalGetBusDataByOffset

CM_MCA_POS_DATA structure

1/30/2019 • 2 minutes to read • Edit Online

The **CM_MCA_POS_DATA** structure is obsolete. It defines IBM-compatible MCA POS configuration information for a slot.

Syntax

```
typedef struct _CM_MCA_POS_DATA {
  USHORT AdapterId;
  UCHAR  PosData1;
  UCHAR  PosData2;
  UCHAR  PosData3;
  UCHAR  PosData4;
} CM_MCA_POS_DATA, *PCM_MCA_POS_DATA;
```

Members

`AdapterId`

`PosData1`

`PosData2`

`PosData3`

`PosData4`

Remarks

This structure is used by the obsolete HalGetBusData and HalGetBusDataByOffset routines.

Requirements

Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

See Also

HalGetBusData

HalGetBusDataByOffset

GROUP_AFFINITY structure

1/30/2019 • 2 minutes to read • Edit Online

The **GROUP_AFFINITY** structure specifies a group number and the processor affinity within that group.

Syntax

```
typedef struct _GROUP_AFFINITY {
  KAFFINITY Mask;
  USHORT    Group;
  USHORT    Reserved[3];
} GROUP_AFFINITY, *PGROUP_AFFINITY;
```

Members

`Mask`

Specifies the affinity mask. This parameter is a **KAFFINITY** value. The bits in the affinity mask identify a set of processors within the group identified by **Group**.

`Group`

Specifies the group number. In Windows 7, the group number must be in the range from 0 to 3.

`Reserved`

Reserved for future use. Set all three **Reserved** array elements to zero.

Remarks

This structure describes a group-specific affinity.

A **GROUP_AFFINITY** structure can describe a thread affinity, which is a set of processors on which a thread is allowed to run. All of the processors in this set belong to the group that is identified by the **Group** member of the structure. The **Mask** member contains an affinity mask that identifies the processors in the set. For example, the KeSetSystemGroupAffinityThread and KeRevertToUserGroupAffinityThread routines use **GROUP_AFFINITY** structures to specify thread affinities.

A **GROUP_AFFINITY** structure can describe an interrupt affinity, which is a set of processors on which an interrupt service routine can receive interrupts. For example, the IoGetDeviceNumaNode routine uses **GROUP_AFFINITY** structures to specify interrupt affinities.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of Windows.
Header	miniport.h (include Winnt.h, Ntdef.h, Windef.h, Minitape.h)

See Also

IoGetDeviceNumaNode

KAFFINITY

KeRevertToUserGroupAffinityThread

KeSetSystemGroupAffinityThread

INTERFACE structure

1/30/2019 • 2 minutes to read • Edit Online

The **INTERFACE** structure describes an interface that is exported by a driver for use by other drivers.

Syntax

```
typedef struct _INTERFACE {
  USHORT                 Size;
  USHORT                 Version;
  PVOID                  Context;
  PINTERFACE_REFERENCE   InterfaceReference;
  PINTERFACE_DEREFERENCE InterfaceDereference;
} INTERFACE, *PINTERFACE;
```

Members

`Size`

Size, in bytes, of a structure defining a driver interface, including this structure and interface-specific members.

`Version`

Driver-defined interface version.

`Context`

Pointer to interface-specific context information.

`InterfaceReference`

Pointer to a driver-supplied InterfaceReference routine that increments the interface's reference count.

`InterfaceDereference`

Pointer to a driver-supplied InterfaceDereference routine that decrements the interface's reference count.

Remarks

The **INTERFACE** structure must be included as the first member of all structures that describe interfaces returned by drivers in response to an IRP_MN_QUERY_INTERFACE request.

The *InterfaceReference* routine must be called by the driver that exports the interface, each time the driver supplies that interface in response to **IRP_MN_QUERY_INTERFACE**. Likewise, if the driver that requests the interface subsequently passes it to another driver, the driver that passes the interface must call *InterfaceReference* on behalf of the driver that receives it.

Each driver that imports the interface (whether by sending **IRP_MN_QUERY_INTERFACE** or by receiving the interface from another driver) must call the *InterfaceDereference* routine after it has finished using the interface. After calling the *InterfaceDereference* routine, a driver cannot use the interface again without first reobtaining it.

Requirements

Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

See Also

IRP_MN_QUERY_INTERFACE

InterfaceDereference

InterfaceReference

INTERFACE_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **INTERFACE_TYPE** enumeration indicates the bus type.

Syntax

```
typedef enum _INTERFACE_TYPE {
  InterfaceTypeUndefined,
  Internal,
  Isa,
  Eisa,
  MicroChannel,
  TurboChannel,
  PCIBus,
  VMEBus,
  NuBus,
  PCMCIABus,
  CBus,
  MPIBus,
  MPSABus,
  ProcessorInternal,
  InternalPowerBus,
  PNPISABus,
  PNPBus,
  Vmcs,
  ACPIBus,
  MaximumInterfaceType
} INTERFACE_TYPE, *PINTERFACE_TYPE;
```

Constants

InterfaceTypeUndefined	Indicates that the interface type is undefined.
Internal	For internal use only.
Isa	Indicates that the interface is published by the ISA bus driver.
Eisa	Indicates that the interface is published by the EISA bus driver.
MicroChannel	Indicates that the interface is published by the MicroChannel bus driver.
TurboChannel	Indicates that the interface is published by the TurboChannel bus driver.
PCIBus	Indicates that the interface is published by the PCI bus driver.
VMEBus	Indicates that the interface is published by the VME bus driver.
NuBus	Indicates that the interface is published by the NuBus driver.

PCMCIABus	Indicates that the interface is published by the PCMCIA bus driver.
CBus	Indicates that the interface is published by the Cbus driver.
MPIBus	Indicates that the interface is published by the MPI bus driver.
MPSABus	Indicates that the interface is published by the MPSA bus driver.
ProcessorInternal	Indicates that the interface is published by the ISA bus driver.
InternalPowerBus	Indicates that the interface is published for an internal power bus. Some devices have power control ports that allow them to share power control with other devices. The Windows architecture represents these devices as slots on a virtual bus called an "internal power bus."
PNPISABus	Indicates that the interface is published by the PNPISA bus driver.
PNPBus	Indicates that the interface is published by the PNP bus driver.
Vmcs	Reserved for use by the operating system.
ACPIBus	Indicates that the interface is published by the ACPI bus driver. The ACPI bus driver enumerates devices that are described in the ACPI firmware of the hardware platform. These devices might physically reside on buses that are controlled by other bus drivers, but the ACPI bus driver must enumerate these devices because the other bus drivers cannot detect them. This interface type is defined starting with Windows 8.
MaximumInterfaceType	Marks the upper limit of the possible bus types.

Requirements

Header	miniport.h (include Wdm.h, Miniport.h, Wudfwdm.h)

IO_RESOURCE_DESCRIPTOR structure

1/30/2019 • 7 minutes to read • Edit Online

The **IO_RESOURCE_DESCRIPTOR** structure describes a range of raw hardware resources, of one type, that can be used by a device. An array of **IO_RESOURCE_DESCRIPTOR** structures is contained within each IO_RESOURCE_LIST structure.

Syntax

```
typedef struct _IO_RESOURCE_DESCRIPTOR {
  UCHAR  Option;
  UCHAR  Type;
  UCHAR  ShareDisposition;
  UCHAR  Spare1;
  USHORT Flags;
  USHORT Spare2;
  union {
    struct {
      ULONG            Length;
      ULONG            Alignment;
      PHYSICAL_ADDRESS MinimumAddress;
      PHYSICAL_ADDRESS MaximumAddress;
    } Port;
    struct {
      ULONG            Length;
      ULONG            Alignment;
      PHYSICAL_ADDRESS MinimumAddress;
      PHYSICAL_ADDRESS MaximumAddress;
    } Memory;
    struct {
      ULONG             MinimumVector;
      ULONG             MaximumVector;
      IRQ_DEVICE_POLICY AffinityPolicy;
      USHORT            Group;
      IRQ_PRIORITY      PriorityPolicy;
      KAFFINITY         TargetedProcessors;
    } Interrupt;
    struct {
      ULONG MinimumChannel;
      ULONG MaximumChannel;
    } Dma;
    struct {
      ULONG RequestLine;
      ULONG Reserved;
      ULONG Channel;
      ULONG TransferWidth;
    } DmaV3;
    struct {
      ULONG            Length;
      ULONG            Alignment;
      PHYSICAL_ADDRESS MinimumAddress;
      PHYSICAL_ADDRESS MaximumAddress;
    } Generic;
    struct {
      ULONG Data[3];
    } DevicePrivate;
    struct {
      ULONG Length;
      ULONG MinBusNumber;
      ULONG MaxBusNumber;
      ULONG Reserved;
```

```
      ULONG Reserved;
    } BusNumber;
    struct {
      ULONG Priority;
      ULONG Reserved1;
      ULONG Reserved2;
    } ConfigData;
    struct {
      ULONG            Length40;
      ULONG            Alignment40;
      PHYSICAL_ADDRESS MinimumAddress;
      PHYSICAL_ADDRESS MaximumAddress;
    } Memory40;
    struct {
      ULONG            Length48;
      ULONG            Alignment48;
      PHYSICAL_ADDRESS MinimumAddress;
      PHYSICAL_ADDRESS MaximumAddress;
    } Memory48;
    struct {
      ULONG            Length64;
      ULONG            Alignment64;
      PHYSICAL_ADDRESS MinimumAddress;
      PHYSICAL_ADDRESS MaximumAddress;
    } Memory64;
    struct {
      UCHAR Class;
      UCHAR Type;
      UCHAR Reserved1;
      UCHAR Reserved2;
      ULONG IdLowPart;
      ULONG IdHighPart;
    } Connection;
  } u;
} IO_RESOURCE_DESCRIPTOR, *PIO_RESOURCE_DESCRIPTOR;
```

Members

`Option`

Specifies whether this resource description is required, preferred, or alternative. One of the following values must be used:

VALUE	MEANING
0	The specified resource range is required, unless alternative ranges are also specified.
IO_RESOURCE_PREFERRED	The specified resource range is preferred to any alternative ranges.

IO_RESOURCE_ALTERNATIVE	The specified resource range is an alternative to the range preceding it. For example, if one **IO_RESOURCE_DESCRIPTOR** structure specifies IRQ 5, with IO_RESOURCE_PREFERRED set, and the next structure specifies IRQ 3, with IO_RESOURCE_ALTERNATIVE set, the PnP manager assigns IRQ 3 to the device only if IRQ 5 is unavailable. (Multiple alternatives can be specified for each resource. Both IO_RESOURCE_ALTERNATIVE and IO_RESOURCE_PREFERRED can be set, indicating a preferred alternative.)
IO_RESOURCE_DEFAULT	Not used.

`Type`

Identifies the resource type. For a list of valid values, see the **Type** member of the CM_PARTIAL_RESOURCE_DESCRIPTOR structure.

`ShareDisposition`

Indicates whether the described resource can be shared. For a list of valid values, see the **ShareDisposition** member of the CM_PARTIAL_RESOURCE_DESCRIPTOR structure.

`Spare1`

`Flags`

Contains bit flags that are specific to the resource type. The following table shows the flags that are valid if **Type** = **CmResourceTypeInterrupt.**

VALUE	MEANING
CM_RESOURCE_INTERRUPT_LEVEL_SENSITIVE	The IRQ line is level-triggered. (These IRQs are usually sharable.)

CM_RESOURCE_INTERRUPT_LATCHED	The IRQ line is edge-triggered.
CM_RESOURCE_INTERRUPT_MESSAGE	If this flag is set, the interrupt is a message-signaled interrupt. Otherwise, the interrupt is a line-based interrupt. This flag can be set starting with Windows Vista.
CM_RESOURCE_INTERRUPT_POLICY_INCLUDED	If this flag is set, the u.Interrupt member includes data that describes the device's interrupt policy. This flag can be set starting with Windows Vista.
CM_RESOURCE_INTERRUPT_SECONDARY_INTERRUPT	The interrupt is a secondary interrupt. This flag can be set starting with Windows 8. For more information about secondary interrupts, see GPIO Interrupts.

CM_ RES OU RCE _IN TER RUP T_W AKE _HI NT	The interrupt is capable of waking the operating system from a low-power idle state or a system sleep state. This flag can be set starting with Windows 8. For more information about wake capabilities, see Enabling Device Wake-Up.

For a list of valid flags for other resource types, see the description of the **Flags** member of the CM_PARTIAL_RESOURCE_DESCRIPTOR structure.

`Spare2`

`u`

port

Specifies a range of I/O port addresses, using the following members.

Drivers for Windows Vista and later versions of the Windows operating system must use RtlIoDecodeMemIoResource and RtlIoEncodeMemIoResource to read and update this member, rather than updating it directly.

Length

The length, in bytes, of the range of assignable I/O port addresses.

Alignment

The alignment, in bytes, that the assigned starting address must adhere to. The assigned starting address must be an integer multiple of *Alignment*.

MinimumAddress

The minimum bus-relative I/O port address that can be assigned to the device.

MaximumAddress

The maximum bus-relative I/O port address that can be assigned to the device.

`u.Port`

`u.Port.Length`

`u.Port.Alignment`

`u.Port.MinimumAddress`

`u.Port.MaximumAddress`

`u.Memory`

`u.Memory.Length`

The length, in bytes, of the range of assignable memory addresses.

`u.Memory.Alignment`

The alignment, in bytes, that the assigned starting address must adhere to. The assigned starting address must be an integer multiple of *Alignment*.

`u.Memory.MinimumAddress`

The minimum bus-relative memory address that can be assigned to the device.

`u.Memory.MaximumAddress`

The maximum bus-relative memory address that can be assigned to the device.

`u.Interrupt`

`u.Interrupt.MinimumVector`

The minimum bus-relative vector that can be assigned to the device.

`u.Interrupt.MaximumVector`

The maximum bus-relative vector that can be assigned to the device.

If the **CM_RESOURCE_INTERRUPT_MESSAGE** flag bit is set, the values of the **MinimumVector** and **MaximumVector** members have special meanings. For more information, see Using Interrupt Resource Descriptors.

The system supplies the following additional members on Windows Vista and later versions of the Windows operating system:

`u.Interrupt.AffinityPolicy`

Specifies an IRQ_DEVICE_POLICY value that indicates how the system should distribute a device's interrupts between processors.

Specifies an IRQ_DEVICE_POLICY value that indicates how the system should distribute a device's interrupts between processors.

`u.Interrupt.Group`

Specifies a processor group number. **Group** is a valid (but optional) member of **u.Interrupt** only in Windows 7 and later versions of Windows. This member exists only if NT_PROCESSOR_GROUPS is defined at compile time. If the **Group** member exists, the **Group** and **TargetedProcessors** members together specify a group affinity that identifies the set of processors that should handle the device's interrupts. To specify an affinity for a particular group, set **AffinityPolicy** to **IrqPolicySpecifiedProcessors** and set **Group** to the appropriate group number. In addition, **TargetedProcessors** must specify the target processors in the group. If you set **AffinityPolicy** to a value other than **IrqPolicySpecifiedProcessors**, set **Group** to ALL_PROCESSOR_GROUPS to indicate that the driver is group-aware (that is, designed to handle information about processor groups). A driver cannot specify target processors if **Group** equals ALL_PROCESSOR_GROUPS; such target specifications are ignored.

`u.Interrupt.PriorityPolicy`

Specifies an IRQ_PRIORITY value that indicates the priority with which the system should dispatch the device's interrupts.

`u.Interrupt.TargetedProcessors`

Specifies a **KAFFINITY** value that indicates which processors should handle the device's interrupts. This value is used only if **AffinityPolicy** is **IrqPolicySpecifiedProcessors.**

`u.Dma`

`u.Dma.MinimumChannel`

The minimum bus-relative DMA channel that can be assigned to the device.

`u.Dma.MaximumChannel`

The maximum bus-relative DMA channel that can be assigned to the device.

`u.DmaV3`

`u.DmaV3.RequestLine`

The number of the request line on the system DMA controller that is allocated to the device.

`u.DmaV3.Reserved`

Not used.

`u.DmaV3.Channel`

The number of the DMA channel on the system DMA controller that is allocated to the device.

`u.DmaV3.TransferWidth`

Specifies the width, in bits, of the data bus that the system DMA controller that is allocated to the device uses to transfer data to or from the device.

`u.Generic`

`u.Generic.Length`

`u.Generic.Alignment`

`u.Generic.MinimumAddress`

`u.Generic.MaximumAddress`

`u.DevicePrivate`

`u.DevicePrivate.Data`

`u.BusNumber`

`u.BusNumber.Length`

The number of bus numbers required.

`u.BusNumber.MinBusNumber`

The minimum bus-relative bus number that can be assigned to the device.

`u.BusNumber.MaxBusNumber`

The maximum bus-relative bus number that can be assigned to the device.

`u.BusNumber.Reserved`

Not used.

`u.ConfigData`

`u.ConfigData.Priority`

`u.ConfigData.Reserved1`

`u.ConfigData.Reserved2`

`u.Memory40`

`u.Memory40.Length40`

The high 32 bits of the 40-bit length, in bytes, of the range of assignable memory addresses. The lower 8 bits are treated as zero.

`u.Memory40.Alignment40`

The high 32 bits of the 40-bit alignment, in bytes, that the assigned starting address must adhere to. The lower 8 bits are treated as zero. The assigned starting address will be a multiple of the alignment.

`u.Memory40.MinimumAddress`

The minimum bus-relative memory address that can be assigned to the device.

`u.Memory40.MaximumAddress`

The maximum bus-relative memory address that can be assigned to the device.

`u.Memory48`

`u.Memory48.Length48`

The high 32 bits of the 48-bit length, in bytes, of the range of assignable memory addresses. The lower 16 bits are treated as zero.

`u.Memory48.Alignment48`

The high 32 bits of the 48-bit alignment, in bytes, that the assigned starting address must adhere to. The lower 16 bits are treated as zero. The assigned starting address will be a multiple of the alignment.

`u.Memory48.MinimumAddress`

The minimum bus-relative memory address that can be assigned to the device.

`u.Memory48.MaximumAddress`

The maximum bus-relative memory address that can be assigned to the device.

`u.Memory64`

`u.Memory64.Length64`

The high 32 bits of the 64-bit length, in bytes, of the range of assignable memory addresses. The lower 32 bits are treated as zero.

`u.Memory64.Alignment64`

The high 32 bits of the 64-bit alignment, in bytes, that the assigned starting address must adhere to. The lower 32 bits are treated as zero. The assigned starting address will be a multiple of the alignment.

`u.Memory64.MinimumAddress`

The minimum bus-relative memory address that can be assigned to the device.

`u.Memory64.MaximumAddress`

The maximum bus-relative memory address that can be assigned to the device.

`u.Connection`

`u.Connection.Class`

The connection class. This member is set to one of the following values.

VALUE	MEANING

CM_RESOURCE_CONNECTION_CLASS_GPIO	Access the device through one or more pins on a GPIO controller.
CM_RESOURCE_CONNECTION_CLASS_SERIAL	Access the device through a serial bus or serial port.

`u.Connection.Type`

The connection type. If *Class* = CM_RESOURCE_CONNECTION_CLASS_GPIO, *Type* is set to the following value:

VALUE	MEANING
CM_RESOURCE_CONNECTION_TYPE_GPIO_IO	Access the device through GPIO pins that are configured for I/O.

Note A GPIO pin that is configured as an interrupt request input is accessed as an ordinary interrupt resource (**CmResourceTypeInterrupt**).

If **Class** = CM_RESOURCE_CONNECTION_CLASS_SERIAL, **Type** is set to one of the following values:

VALUE	MEANING

CM_RESOURCE_CONNECTION_TYPE_I2C	The device is connected to an I²C bus.
CM_RESOURCE_CONNECTION_TYPE_SPI	The device is connected to an SPI bus.
CM_RESOURCE_CONNECTION_TYPE_SERIAL_UART	The device is connected to a serial port.

`u.Connection.Reserved1`

Not used.

`u.Connection.Reserved2`

Not used.

`u.Connection.IdLowPart`

The lower 32 bits of the 64-bit connection ID.

`u.Connection.IdHighPart`

The upper 32 bits of the 64-bit connection ID.

Requirements

Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

CM_PARTIAL_RESOURCE_DESCRIPTOR

IO_RESOURCE_LIST

IO_RESOURCE_REQUIREMENTS_LIST

IoConnectInterrupt

IO_RESOURCE_LIST structure

1/30/2019 • 2 minutes to read • Edit Online

The **IO_RESOURCE_LIST** structure describes a range of raw hardware resources, of various types, that can be used by a device. The resources specified represent a single, acceptable resource configuration for a device. An array of **IO_RESOURCE_LIST** structures is contained within each IO_RESOURCE_REQUIREMENTS_LIST structure.

Syntax

```
typedef struct _IO_RESOURCE_LIST {
  USHORT                  Version;
  USHORT                  Revision;
  ULONG                   Count;
  IO_RESOURCE_DESCRIPTOR Descriptors[1];
} IO_RESOURCE_LIST, *PIO_RESOURCE_LIST;
```

Members

`Version`

The version number of this structure. This value should be 1.

`Revision`

The revision of this structure. This value should be 1.

`Count`

The number of elements in the **Descriptors** array.

`Descriptors`

The first element in an array of one or more IO_RESOURCE_DESCRIPTOR structures.

Remarks

This structure is the header for an array of **IO_RESOURCE_DESCRIPTOR** structures. The **Descriptors** member contains the first element in this array, and the **Count** member specifies the total number of array elements. If the array contains more than one element, the remaining elements in the array immediately follow the **IO_RESOURCE_LIST** structure in memory. The total number of bytes occupied by the **IO_RESOURCE_LIST** structure and any array elements that follow this structure is **sizeof**(**IO_RESOURCE_LIST**) + (**Count** - 1) * **sizeof**(**IO_RESOURCE_DESCRIPTOR**).

Requirements

Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

Members

`ListSize`

The total number of bytes that constitute the **IO_RESOURCE_REQUIREMENTS_LIST** structure, its IO_RESOURCE_LIST array, and the latter's IO_RESOURCE_DESCRIPTOR array.

`InterfaceType`

Specifies an interface type. This must be one of the types defined by INTERFACE_TYPE, in Wdm.h or Ntddk.h. (Not used by WDM drivers.)

`BusNumber`

A system-assigned, zero-based bus number. (Not used by WDM drivers.)

`SlotNumber`

A system slot number. (Not used by WDM drivers.)

`Reserved`

Not used.

`AlternativeLists`

The number of alternative lists (or configurations) of hardware resources that are described by this **IO_RESOURCE_REQUIREMENTS_LIST** structure. The **List** member is the header for the first alternative list.

`List`

The IO_RESOURCE_LIST structure that serves as the header for the first alternative list of hardware resources. If the **IO_RESOURCE_REQUIREMENTS_LIST** structure describes more than one alternative list, the second alternative list immediately follows the first alternative list in memory, and so on. The size of each alternative list depends on the length of the IO_RESOURCE_DESCRIPTOR array that it contains. For more information, see the following Remarks section.

Remarks

This structure is used by the IRP_MN_FILTER_RESOURCE_REQUIREMENTS and IRP_MN_QUERY_RESOURCE_REQUIREMENTS IRPs to describe one or more alternative configurations of hardware resources.

The **IO_RESOURCE_REQUIREMENTS_LIST** structure is a header for a larger data structure, of variable size, that specifies one or more alternative lists of resources. All of the data in this larger structure occupies a contiguous block of memory, whose size is specified by the **ListSize** member. Each alternative list occupies a subblock within the larger block.

Each alternative list begins with an **IO_RESOURCE_LIST** structure, which serves as a header for an array of **IO_RESOURCE_DESCRIPTOR** structures. The length of this array determines the size of the list, which can vary from one alternative list to the next. Driver code can use pointer arithmetic to step from one alternative list to the next. For example, if a parameter named *list* is a pointer to the **IO_RESOURCE_LIST** structure at the start of one alternative list, *list* can be updated to point to the start of the next list as follows:

```
list = (PIO_RESOURCE_LIST)(list->Descriptors + list->Count);
```

In this example, `list->Descriptors` is a pointer to the start of the **IO_RESOURCE_DESCRIPTOR** array, and `list->Count` is the number of elements in the array. For more information about the **Descriptors** and **Count** members, see IO_RESOURCE_LIST. #### Examples If a driver contains a handler for an **IRP_MN_FILTER_RESOURCE_REQUIREMENTS** IRP, the handler typically walks the resource list that is pointed to by the **IoStatus.Information** field in the IRP. The following code example contains a function—named FilterResources—that is called in the handler to walk the list. This function either verifies that a particular resource is specified in the list, or changes the resource requirements in the list without changing the size of the list. (A function that changes the size of the list would need to allocate a buffer for the updated list, write the list to this buffer, update the **IoStatus.Information** field in the IRP to point to the updated list, and free the buffer that contains the original list.) The FilterResources function returns **TRUE** (probably from the **switch** statement, although the details are omitted to simplify the code example) if it finds the resource that it is looking for in the list, or if it makes a change to the list that does not change the size of the list. Otherwise, it returns **FALSE**.

```
/* Modify the resource list in place (without changing its size). */

BOOLEAN FilterResources(PIO_RESOURCE_REQUIREMENTS_LIST reqlist)
{
    PIO_RESOURCE_LIST list;

    list = reqlist->List;

    for (int ix = 0; ix < reqlist->AlternativeLists; ++ix)
    {
        /* Process resources in IO_RESOURCE_LIST block number ix. */

        for (int jx = 0; jx < list->Count; ++jx)
        {
            PIO_RESOURCE_DESCRIPTOR desc;

            desc = list->Descriptors + jx;

            switch (desc->Type)
            {
               /* Process element jx in Descriptors array. */

               ...

            }
        }

        /* Advance to next IO_RESOURCE_LIST block in memory. */

        list = (PIO_RESOURCE_LIST)(list->Descriptors + list->Count);
    }

    return FALSE;
}
```

Requirements

Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

IRP_MN_QUERY_RESOURCE_REQUIREMENTS

IRQ_DEVICE_POLICY Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **IRQ_DEVICE_POLICY** enumeration type indicates the policy the operating system can use to assign the interrupts from a device to different processors.

Syntax

```
typedef enum _IRQ_DEVICE_POLICY {
  IrqPolicyMachineDefault,
  IrqPolicyAllCloseProcessors,
  IrqPolicyOneCloseProcessor,
  IrqPolicyAllProcessorsInMachine,
  IrqPolicySpecifiedProcessors,
  IrqPolicySpreadMessagesAcrossAllProcessors,
  IrqPolicyAllProcessorsInMachineWhenSteered
} IRQ_DEVICE_POLICY, *PIRQ_DEVICE_POLICY;
```

Constants

IrqPolicyMachineDefault	The device does not require any particular assignment of interrupts to processors.
IrqPolicyAllCloseProcessors	The operating system should assign interrupts from the device to processors that are close to the device. On non-NUMA computers, the effect of this value is identical to that of **IrqPolicyAllProcessorsInMachine**.
IrqPolicyOneCloseProcessor	The operating system should assign a single interrupt for the device to one processor that is close to the device. On non-NUMA computers, the operating system can assign the interrupt to any processor.
IrqPolicyAllProcessorsInMachine	The operating system should assign interrupts from the device to all processors.
IrqPolicySpecifiedProcessors	The operating system should assign interrupts from the device to a specific set of processors.
IrqPolicySpreadMessagesAcrossAllProcessors	The operating system should assign different message-signaled interrupts to different processors, if possible.
IrqPolicyAllProcessorsInMachineWhenSteered	

Remarks

The **Interrupt.AffinityPolicy** member of the IO_RESOURCE_DESCRIPTOR structure is an **IRQ_DEVICE_POLICY** enumeration value.

Requirements

Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

See Also

IO_RESOURCE_DESCRIPTOR

IRQ_PRIORITY Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **IRQ_PRIORITY** enumeration type indicates the priority the system should give to servicing a device's interrupts.

Syntax

```
typedef enum _IRQ_PRIORITY {
  IrqPriorityUndefined,
  IrqPriorityLow,
  IrqPriorityNormal,
  IrqPriorityHigh
} IRQ_PRIORITY, *PIRQ_PRIORITY;
```

Constants

IrqPriorityUndefined	Specifies that the device does not require any particular priority for its interrupts.
IrqPriorityLow	Specifies that the device's interrupts are of low priority. This setting is appropiate for devices that can tolerate higher-than-normal latency.
IrqPriorityNormal	Specifies that the device's interrupts are of normal priority.
IrqPriorityHigh	Specifies that the device's interrupts are of high priority. This setting is appropriate for devices that require low latency.

Remarks

The system uses **IRQ_PRIORITY** to assign IRQLs for devices. For example, it might assign a higher IRQL to a device that has an **IRQ_PRIORITY** of **IrqPriorityHigh** than it does to a device that has an **IRQ_PRIORITY** of **IrqPriorityLow**.

Requirements

Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

IO_RESOURCE_DESCRIPTOR

KINTERRUPT_MODE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **KINTERRUPT_MODE** enumeration type indicates whether an interrupt is level-triggered or edge-triggered.

Syntax

```
typedef enum _KINTERRUPT_MODE {
  LevelSensitive,
  Latched
} KINTERRUPT_MODE;
```

Constants

LevelSensitive	The interrupt is level-triggered. This is the mode for traditional PCI line-based interrupts.
Latched	The interrupt is edge-triggered. This is the mode for PCI message-signaled interrupts.

Remarks

The interrupt mode is an electrical characteristic of the interrupt. A device signals a level-triggered interrupt by changing the voltage on the interrupt pin, and holding it there until the processor signals that the interrupt is received. In contrast, to signal an edge-triggered interrupt, the device changes the voltage state for a fixed period of time, before reverting to the original voltage state.

Requirements

Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)

See Also

IoConnectInterrupt

IoConnectInterruptEx

KINTERRUPT_POLARITY

KINTERRUPT_POLARITY Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **KINTERRUPT_POLARITY** enumeration indicates how a device signals an interrupt request on an interrupt line.

Syntax

```
typedef enum _KINTERRUPT_POLARITY {
  InterruptPolarityUnknown,
  InterruptActiveHigh,
  InterruptRisingEdge,
  InterruptActiveLow,
  InterruptFallingEdge,
  InterruptActiveBoth,
  InterruptActiveBothTriggerLow,
  InterruptActiveBothTriggerHigh
} KINTERRUPT_POLARITY, *PKINTERRUPT_POLARITY;
```

Constants

InterruptPolarityUnknown	The interrupt polarity is unknown.
InterruptActiveHigh	Active-high interrupt. The interrupt input type is level-triggered, and an interrupt request is indicated by a high signal level on the interrupt line. The request remains active as long as the line remains high.
InterruptRisingEdge	Rising-edge-triggered interrupt. The interrupt input type is edge-triggered, and an interrupt request is indicated by a low-to-high transition on the interrupt line.
InterruptActiveLow	Active-low interrupt. The interrupt input type is level-triggered, and an interrupt request is indicated by a low signal level on the interrupt line. The request remains active as long as the line remains low.
InterruptFallingEdge	Falling-edge-triggered interrupt. The interrupt input type is edge-triggered, and an interrupt request is indicated by a high-to-low transition on the interrupt line.
InterruptActiveBoth	Active-both interrupt. The interrupt input type is edge-triggered, and an interrupt request is indicated by a low-to-high or a high-to-low transition on the interrupt line. After a low-to-high transition signals an interrupt request, the interrupt line remains high until a high-to-low transition signals the next interrupt request. Similarly, after a high-to-low transition signals an interrupt request, the interrupt line remains low until a low-to-high transition signals the next interrupt request.
InterruptActiveBothTriggerLow	Reserved for use by the operating system.

InterruptActiveBothTriggerHigh	Reserved for use by the operating system.

Remarks

A **KINTERRUPT_POLARITY** enumeration constant is frequently used in conjunction with a KINTERRUPT_MODE enumeration constant to describe an interrupt signal. A **KINTERRUPT_MODE** enumeration constant indicates whether the interrupt signal from a device is level-triggered or edge-triggered.

Requirements

Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

See Also

KINTERRUPT_MODE

MEMORY_CACHING_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **MEMORY_CACHING_TYPE** enumeration type specifies the permitted caching behavior when allocating or mapping memory.

Syntax

```
typedef enum _MEMORY_CACHING_TYPE {
  MmNonCached,
  MmCached,
  MmWriteCombined,
  MmHardwareCoherentCached,
  MmNonCachedUnordered,
  MmUSWCCached,
  MmMaximumCacheType,
  MmNotMapped
} MEMORY_CACHING_TYPE;
```

Constants

MmNonCached	The requested memory should not be cached by the processor.
MmCached	The processor should cache the requested memory.
MmWriteCombined	The requested memory should not be cached by the processor, but writes to the memory can be combined by the processor.
MmHardwareCoherentCached	Reserved for system use.
MmNonCachedUnordered	Reserved for system use.
MmUSWCCached	Reserved for system use.
MmMaximumCacheType	Reserved for system use.
MmNotMapped	

Remarks

Processor translation buffers cache virtual to physical address translations. These translation buffers allow many virtual addresses to map a single physical address. However, only one caching behavior is allowed for any given physical address translation. Therefore, if a driver maps two different virtual address ranges to the same physical address, it must ensure that it specifies the same caching behavior for both. Otherwise, the processor behavior is undefined with unpredictable system results.

Requirements

Minimum supported client	Supported in Windows 2000 and later versions of Windows.
Header	miniport.h (include Ntddk.h, Wdm.h, Miniport.h, Wudfwdm.h)

PCI_COMMON_CONFIG structure

1/30/2019 • 2 minutes to read • Edit Online

The **PCI_COMMON_CONFIG** structure is obsolete. It defines standard PCI configuration information returned by the obsolete HalGetBusData or HalGetBusDataByOffset routine for the input *BusDataType* PCIConfiguration, assuming the caller-allocated *Buffer* is of sufficient *Length*.

Syntax

```
typedef struct _PCI_COMMON_CONFIG {
  UCHAR      DeviceSpecific[192];
  base_class PCI_COMMON_HEADER;
} PCI_COMMON_CONFIG, *PPCI_COMMON_CONFIG;
```

Members

`DeviceSpecific`

Contains any device-specific initialization information that is available.

`PCI_COMMON_HEADER`

Remarks

Certain members of this structure have read-only values, so attempts to reset them are ignored. These members include the following: **VendorID**, **DeviceID**, **RevisionID**, **ProgIf**, **SubClass**, **BaseClass**, **HeaderType**, **InterruptPin**, **MinimumGrant**, and **MaximumLatency.**

Other members are provisionally read-only: that is, the system initializes them to their correct values, so drivers can safely treat them as read-only. However, they can be reset if a bus-master driver finds it necessary. These members include the following: **CacheLineSize** and **LatencyTimer**.

Requirements

Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

HalGetBusData

HalGetBusDataByOffset

HalSetBusData

HalSetBusDataByOffset

PCI_SLOT_NUMBER structure

1/30/2019 • 2 minutes to read • Edit Online

The **PCI_SLOT_NUMBER** structure is obsolete. It defines the format of the *Slot* parameter to the obsolete **Hal*Xxx* BusData** routines when they are called with the *BusDataType* value **PCIConfiguration**.

Syntax

```
typedef struct _PCI_SLOT_NUMBER {
  union {
    struct {
      ULONG DeviceNumber : 5;
      ULONG FunctionNumber : 3;
      ULONG Reserved : 24;
    } bits;
    ULONG AsULONG;
  } u;
} PCI_SLOT_NUMBER, *PPCI_SLOT_NUMBER;
```

Members

`u`

`u.bits`

`u.bits.DeviceNumber`

`u.bits.FunctionNumber`

`u.bits.Reserved`

`u.AsULONG`

Specifies the logical slot number of the device being configured.

Remarks

Drivers of PCI devices can call HalGetBusData or HalGetBusDataByOffset more than once for the same slot number to get the configuration information for their device(s).

For example, a driver might search for devices it supports on all PCI buses in the machine first, and then call `HalGetBusData(ByOffset)` again to request more configuration information about devices of interest. Such a driver could code a loop that calls `HalGetBusData(ByOffset)` with an input `Buffer` of sufficient `Length` only to contain enough of the PCI_COMMON_CONFIG to determine the `VendorID` and `DeviceID` of each PCI device. After finding the `Slot` numbers for any promising PCI devices, the driver would call HalGetBusData or HalGetBusDataByOffset one or more times with additional buffer space to get the information needed to configure its devices.

Requirements

Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

PCI_COMMON_CONFIG

PROCESSOR_NUMBER structure

1/30/2019 • 2 minutes to read • Edit Online

The **PROCESSOR_NUMBER** structure identifies a processor by its group number and group-relative processor number.

Syntax

```
typedef struct _PROCESSOR_NUMBER {
  USHORT Group;
  UCHAR  Number;
  UCHAR  Reserved;
} PROCESSOR_NUMBER, *PPROCESSOR_NUMBER;
```

Members

`Group`

The group number. If multiprocessor system contains *n* groups, the groups are numbered from 0 to *n*-1.

`Number`

The group-relative processor number. If a group contains *m* logical processors, the processors are numbered from 0 to *m*-1.

`Reserved`

Reserved for future use. Initialize to zero.

Remarks

Windows 7 is the first version of Windows to support processor groups. In Windows 7, only 64-bit versions of Windows support multiple groups; 32-bit versions of Windows support only one group. If a multiprocessor system is running a 64-bit version of Windows and contains no more than 64 logical processors, Windows assigns all processors to group 0. A multiprocessor system that is running a 32-bit version of Windows can contain no more than 32 processors.

In Windows 7, the maximum number of groups in a multiprocessor system is four, but this value might change in future versions of Windows. The safest way to determine the maximum number of groups in Windows 7 or a later version of Windows is to call the KeQueryMaximumGroupCount routine. Kernel-mode drivers that call **KeQueryMaximumGroupCount** will not require code changes if the formula that is used to calculate the maximum number of groups changes in a future version of Windows.

Kernel-mode routines that use the **PROCESSOR_NUMBER** structure include KeGetCurrentProcessorNumberEx, KeGetProcessorIndexFromNumber, KeGetProcessorNumberFromIndex, and KeQueryLogicalProcessorRelationship.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of the Windows operating system.
Header	miniport.h (include Windows.h, Ntdef.h, Wdm.h, Ntddk.h, Winnt.h, Minitape.h)

FIELD_OFFSET macro

1/25/2019 • 2 minutes to read • Edit Online

The **FIELD_OFFSET** macro returns the byte offset of a named field in a known structure type.

Syntax

```
void FIELD_OFFSET(
   type,
   field
);
```

Parameters

`type`

Specifies the name of a known structure type containing *Field*.

`field`

Specifies the name of a field in a structure of type *Type*.

Return Value

Returns the byte offset of the caller supplied Field in the Type structure.

Remarks

Used by device driver writers to symbolically determine the offset of a known field in a known structure type.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	miniport.h (include Wdm.h, Ntddk.h, Miniport.h, Minitape.h, Scsi.h, Storport.h)
IRQL	Any level

CONTAINING_RECORD

InterlockedAnd function

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedAnd** macro atomically computes a bitwise AND operation.

Syntax

```
LONG InterlockedAnd(
  LONG volatile *Destination,
  LONG          Value
);
```

Parameters

`Destination`

A pointer to the variable to be ANDed with *Value*. The result of the operation is stored in the variable.

`Value`

Specifies the value to be ANDed with the variable that is pointed to by *Destination*.

Return Value

InterlockedAnd returns the original value stored in the variable pointed to by *Destination*.

Remarks

InterlockedAnd atomically computes ***Destination*&=*Value***.

Interlocked operations cannot be used on non-cached memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
IRQL	Any level

InterlockedOr

InterlockedXor

InterlockedCompareExchange function

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedCompareExchange** routine performs an atomic operation that compares the input value pointed to by *Destination* with the value of *Comparand*.

Syntax

```
LONG InterlockedCompareExchange(
  LONG volatile *Destination,
  LONG          ExChange,
  LONG          Comperand
);
```

Parameters

`Destination`

A pointer to the input value that is compared with the value of *Comparand*.

`ExChange`

Specifies the output value pointed to by *Destination* if the input value pointed to by *Destination* equals the value of *Comparand*.

`Comperand`

Specifies the value that is compared with the input value pointed to by *Destination*.

Return Value

InterlockedCompareExchange returns the original value of **Destination*.

Remarks

If *Comparand* is equal to **Destination*, then **Destination* is set to equal *Exchange*. Otherwise, **Destination* is unchanged.

InterlockedCompareExchange provides a fast, atomic way to synchronize the testing and updating of a variable that is shared by multiple threads. If the input value pointed to by *Destination* equals the value of *Comparand*, the output value of *Destination* is set to the value of *Exchange*.

InterlockedCompareExchange is designed for speed and, typically, is implemented inline by a compiler. **InterlockedCompareExchange** is atomic only with respect to other **Interlocked*Xxx*** calls. It does not use a spin lock and can be safely used on pageable data.

Interlocked operations cannot be used on non-cached memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
Library	OneCoreUAP.lib on Windows 10

InterlockedDecrement

InterlockedExchange

InterlockedExchangePointer

InterlockedIncrement

InterlockedCompareExchangePointer function

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedCompareExchangePointer** routine performs an atomic operation that compares the input pointer value pointed to by *Destination* with the pointer value *Comparand*.

Syntax

```
PVOID InterlockedCompareExchangePointer(
  PVOID volatile *Destination,
  PVOID          Exchange,
  PVOID          Comperand
);
```

Parameters

`Destination`

A pointer to a PVOID value. If (*Destination) = Comparand, then the routine sets (Destination*) to *Exchange*.

`Exchange`

Specifies the PVOID value to set (**Destination*) to.

`Comperand`

Specifies the PVOID value to compare with (**Destination*).

Return Value

InterlockedCompareExchangePointer returns the original value of the pointer at **Destination* (that is, the value of this pointer at entry to the routine).

Remarks

If *Comparand* is equal to **Destination*, then **Destination* is set to equal *Exchange*. Otherwise, **Destination* is unchanged.

InterlockedCompareExchangePointer provides a fast, atomic way to synchronize the testing and updating of a pointer variable that is shared by multiple threads. If the input value pointed to by *Destination* equals the value of *Comparand*, the value pointed to by *Destination* is set to the value of *Exchange*.

InterlockedCompareExchangePointer is designed for speed and, typically, is implemented inline by a compiler. **InterlockedCompareExchangePointer** is atomic only with respect to other **InterlockedXxx** calls. It does not use a spin lock and can be safely used on pageable data.

The **InterlockedCompareExchangePointer** routine is atomic only with respect to other **InterlockedXxx** calls.

Interlocked operations cannot be used on non-cached memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop

InterlockedExchangePointer

InterlockedDecrement function

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedDecrement** routine decrements a caller-supplied variable of type LONG as an atomic operation.

Syntax

```
LONG InterlockedDecrement(
  LONG volatile *Addend
);
```

Parameters

`Addend`

A pointer to a variable to be decremented.

Return Value

InterlockedDecrement returns the decremented value.

Remarks

InterlockedDecrement should be used instead of **ExInterlockedDecrementLong** because it is both more efficient and faster.

InterlockedDecrement is implemented inline by the compiler when appropriate and possible. It does not require a spin lock and can therefore be safely used on pageable data.

InterlockedDecrement is atomic only with respect to other **Interlocked*Xxx*** calls.

Interlocked operations cannot be used on non-cached memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

InterlockedExchangePointer function

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedExchangePointer** routine performs an atomic operation that sets a pointer to a new value.

Syntax

```
PVOID InterlockedExchangePointer(
  PVOID volatile *Target,
  PVOID          Value
);
```

Parameters

`Target`

A pointer to a PVOID value. The routine sets (**Target*) to *Value*.

`Value`

Specifies the PVOID value to set (**Target*) to.

Return Value

InterlockedExchangePointer returns the original value of the pointer at **Target* (that is, the value of this pointer at entry to the routine).

Remarks

InterlockedExchangePointer provides a fast, atomic way to synchronize updating a pointer variable that is shared by multiple threads.

InterlockedExchangePointer is designed for speed and, typically, is implemented inline by a compiler. **InterlockedExchangePointer** is atomic only with respect to other **Interlocked*Xxx*** calls. It does not use a spin lock and can be safely used on pageable data.

The *Target* parameter should be aligned on either a 32-bit or 64-bit boundary, depending on the system type, for better performance.

A call to **InterlockedExchangePointer** is atomic only with respect to other **Interlocked*Xxx*** calls.

Interlocked operations cannot be used on non-cached memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedIncrement** routine increments a caller-supplied variable as an atomic operation.

Syntax

```
LONG InterlockedIncrement(
  LONG volatile *Addend
);
```

Parameters

`Addend`

A pointer to a variable of type LONG.

Return Value

InterlockedIncrement returns the incremented value.

Remarks

InterlockedIncrement should be used instead of **ExInterlockedIncrementLong** because it is both more efficient and faster.

InterlockedIncrement is implemented inline by the compiler when appropriate and possible. It does not require a spin lock and can therefore be safely used on pageable data.

InterlockedIncrement is atomic only with respect to other **Interlocked*Xxx*** calls.

Interlocked operations cannot be used on non-cached memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
Library	OneCoreUAP.lib on Windows 10
IRQL	Any level

InterlockedExchange

InterlockedOr function

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedOr** routine atomically computes a bitwise OR operation.

Syntax

```
LONG InterlockedOr(
  LONG volatile *Destination,
  LONG          Value
);
```

Parameters

`Destination`

A pointer to the variable to be ORed with *Value*. The result of the operation is stored in the variable.

`Value`

Specifies the value to be ORed with the variable that is pointed to by *Destination*.

Return Value

InterlockedOr returns the original value stored in the variable pointed to by *Destination*.

Remarks

InterlockedOr atomically computes ***Destination*|=*Value*.

Interlocked operations cannot be used on non-cached memory.

Requirements

Target Platform	Desktop
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
IRQL	Any level

InterlockedXor

InterlockedXor function

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedOr** routine atomically computes a bitwise exclusive OR operation.

Syntax

```
LONG InterlockedXor(
  LONG volatile *Destination,
  LONG          Value
);
```

Parameters

`Destination`

A pointer to the variable to be exclusive ORed with *Value*. The result of the operation is stored in the variable.

`Value`

Specifies the value to be exclusive ORed with the variable that is pointed to by *Destination*.

Return Value

InterlockedXor returns the original value stored in the variable pointed to by *Destination*.

Remarks

InterlockedXor atomically computes ***Destination*^=*Value***.

Interlocked operations cannot be used on non-cached memory.

Requirements

Target Platform	Desktop
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
IRQL	Any level

PINTERFACE_DEREFERENCE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *InterfaceDereference* routine decrements the reference count on a driver-defined interface.

Syntax

```
PINTERFACE_DEREFERENCE PinterfaceDereference;

void PinterfaceDereference(
  PVOID Context
)
{...}
```

Parameters

`Context`

A pointer to interface-specific context information. The caller passes the value that is passed as the **Context** member of the INTERFACE structure for the interface.

Return Value

None

Remarks

You can use the InterfaceReference routine to increment the reference count for the interface.

The driver that imports the interface is responsible for calling the *InterfaceDereference* routine to decrement the reference count after the driver is no longer using the interface. For example, a driver that requests a pointer to the interface by sending an IRP_MN_QUERY_INTERFACE request calls *InterfaceDereference*. Also, a driver that receives a pointer to the interface to another driver must call *InterfaceDereference*.

Requirements

Target Platform	Desktop
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)

See Also

PINTERFACE_REFERENCE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *InterfaceReference* routine increments the reference count on a driver-defined interface.

Syntax

```
PINTERFACE_REFERENCE PinterfaceReference;

void PinterfaceReference(
  PVOID Context
)
{...}
```

Parameters

`Context`

A pointer to interface-specific context information. The caller passes the value that is passed as the **Context** member of the INTERFACE structure for the interface.

Return Value

None

Remarks

You can use the InterfaceDereference routine to decrement the reference count for the interface.

The driver that exports the interface is responsible for calling *InterfaceReference* to increment the reference count before the driver exports the interface. For example, the driver that initially exported the interface in response to an IRP_MN_QUERY_INTERFACE request calls *InterfaceReference*. Also, a driver that passes a pointer to the interface to another driver must call *InterfaceReference*.

Requirements

Target Platform	Desktop
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)

READ_PORT_BUFFER_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_PORT_BUFFER_UCHAR** routine reads a number of bytes from the specified port address into a buffer.

Syntax

```
void READ_PORT_BUFFER_UCHAR(
  PUCHAR Port,
  PUCHAR Buffer,
  ULONG  Count
);
```

Parameters

`Port`

Specifies the port address, which must be a mapped memory range in I/O space.

`Buffer`

Pointer to a buffer into which an array of UCHAR values is read.

`Count`

Specifies the number of bytes to be read into the buffer.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of bytes.

Callers of **READ_PORT_BUFFER_UCHAR** can be running at any IRQL, assuming the *Buffer* is resident and the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
Library	Hal.lib

IRQL	Any level (see Remarks section)

READ_PORT_BUFFER_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_PORT_BUFFER_ULONG** routine reads a number of ULONG values from the specified port address into a buffer.

Syntax

```
void READ_PORT_BUFFER_ULONG(
  PULONG Port,
  PULONG Buffer,
  ULONG  Count
);
```

Parameters

`Port`

Specifies the port address, which must be a mapped memory range in I/O space.

`Buffer`

Pointer to a buffer into which an array of ULONG values is read.

`Count`

Specifies the number of ULONG values to be read into the buffer.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of ULONG values.

Callers of **READ_PORT_BUFFER_ULONG** can be running at any IRQL, assuming the *Buffer* is resident and the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
Library	Hal.lib

IRQL	Any level (see Remarks section)

READ_PORT_BUFFER_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_PORT_BUFFER_USHORT** routine reads a number of USHORT values from the specified port address into a buffer.

Syntax

```
void READ_PORT_BUFFER_USHORT(
  PUSHORT Port,
  PUSHORT Buffer,
  ULONG   Count
);
```

Parameters

`Port`

Specifies the port address, which must be a mapped memory range in I/O space.

`Buffer`

Pointer to a buffer into which an array of USHORT values is read.

`Count`

Specifies the number of USHORT values to be read into the buffer.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of USHORT values.

Callers of **READ_PORT_BUFFER_USHORT** can be running at any IRQL, assuming the *Buffer* is resident and the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
Library	Hal.lib

IRQL	Any level (see Remarks section)

READ_PORT_UCHAR function

READ_REGISTER_BUFFER_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_BUFFER_UCHAR** routine reads a number of bytes from the specified register address into a buffer.

Syntax

```
void READ_REGISTER_BUFFER_UCHAR(
  volatile UCHAR *Register,
  PUCHAR         Buffer,
  ULONG          Count
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Buffer`

Pointer to a buffer into which an array of UCHAR values is read.

`Count`

Specifies the number of bytes to be read into the buffer.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of bytes.

Callers of **READ_REGISTER_BUFFER_UCHAR** can be running at any IRQL, assuming the *Buffer* is resident and the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

READ_REGISTER_BUFFER_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_BUFFER_ULONG** routine reads a number of ULONG values from the specified register address into a buffer.

Syntax

```
void READ_REGISTER_BUFFER_ULONG(
  volatile ULONG *Register,
  PULONG         Buffer,
  ULONG          Count
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Buffer`

Pointer to a buffer into which an array of ULONG values is read.

`Count`

Specifies the number of ULONG values to be read into the buffer.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of ULONG values.

Callers of **READ_REGISTER_BUFFER_ULONG** can be running at any IRQL, assuming the *Buffer* is resident and the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe

READ_REGISTER_BUFFER_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_BUFFER_USHORT** routine reads a number of USHORT values from the specified register address into a buffer.

Syntax

```
void READ_REGISTER_BUFFER_USHORT(
  volatile USHORT *Register,
  PUSHORT         Buffer,
  ULONG           Count
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Buffer`

Pointer to a buffer into which an array of USHORT values is read.

`Count`

Specifies the number of USHORT values to be read into the buffer.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of USHORT values.

Callers of **READ_REGISTER_BUFFER_USHORT** can be running at any IRQL, assuming the *Buffer* is resident and the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

READ_REGISTER_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_ULONG** routine reads a ULONG value from the specified register address.

Syntax

```
ULONG READ_REGISTER_ULONG(
  volatile ULONG *Register
);
```

Parameters

`Register`

Return Value

READ_REGISTER_ULONG returns the ULONG value read from the specified register address.

Remarks

Callers of **READ_REGISTER_ULONG** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

READ_REGISTER_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_USHORT** routine reads a USHORT value from the specified register address.

Syntax

```
USHORT READ_REGISTER_USHORT(
  volatile USHORT *Register
);
```

Parameters

`Register`

Return Value

READ_REGISTER_USHORT returns the USHORT value read from the specified register address.

Remarks

Callers of **READ_REGISTER_USHORT** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)

WRITE_PORT_BUFFER_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_PORT_BUFFER_UCHAR** routine writes a number of bytes from a buffer to the specified port.

Syntax

```
void WRITE_PORT_BUFFER_UCHAR(
  PUCHAR Port,
  PUCHAR Buffer,
  ULONG  Count
);
```

Parameters

`Port`

Pointer to the port, which must be a mapped memory range in I/O space.

`Buffer`

Pointer to a buffer from which an array of UCHAR values is to be written.

`Count`

Specifies the number of bytes to be written to the port.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of bytes.

Callers of **WRITE_PORT_BUFFER_UCHAR** can be running at any IRQL, assuming the *Buffer* is resident and the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

  volatile USHORT *Register,
  USHORT          Value
);
```

Parameters

`Register`

`Value`

Return Value

None

Remarks

Callers of **WRITE_REGISTER_USHORT** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	miniport.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

ntddk.h header

1/8/2019 • 35 minutes to read • Edit Online

This header is used by kernel. For more information, see:

- Windows kernel ntddk.h contains the following programming interfaces:

Functions

TITLE	DESCRIPTION
CUSTOM_SYSTEM_EVENT_TRIGGER_INIT	Initializes the **_CUSTOM_SYSTEM_EVENT_TRIGGER_CONFIG** structure.
DbgPrompt	The DbgPrompt routine displays a caller-specified user prompt string on the kernel debugger's display device and obtains a user response string.
ExFreePool	The ExFreePool routine deallocates a block of pool memory.
ExRaiseAccessViolation	The ExRaiseAccessViolation routine can be used with structured exception handling to throw a driver-determined exception for a memory access violation that occurs when a driver processes I/O requests.
ExRaiseDatatypeMisalignment	The ExRaiseDatatypeMisalignment routine can be used with structured exception handling to throw a driver-determined exception for a misaligned data type that occurs when a driver processes I/O requests.
ExUuidCreate	The ExUuidCreate routine initializes a UUID (GUID) structure to a newly generated value.
FsRtlIsTotalDeviceFailure	The FsRtlIsTotalDeviceFailure routine determines whether a media or other hardware failure has occurred.
HalAllocateHardwareCounters	The HalAllocateHardwareCounters routine allocates a set of hardware performance counters.
HalExamineMBR	The HalExamineMBR routine reads the master boot record (MBR) of a disk and returns data from the MBR if the MBR is of the type specified by the caller.
HalFreeHardwareCounters	The HalFreeHardwareCounters routine frees a set of hardware performance counters that was acquired in a previous call to HalAllocateHardwareCounters routine.
IoAllocateAdapterChannel	Deprecated. Use PALLOCATE_ADAPTER_CHANNEL.

TITLE	DESCRIPTION
IoAllocateController	The IoAllocateController routine sets up the call to a driver-supplied ControllerControl routine as soon as the device controller, represented by the given controller object, is available to carry out an I/O operation for the target device, represented by the given device object.
IoAssignArcName	The IoAssignArcName routine creates a symbolic link between the ARC name of a physical device and the name of the corresponding device object when it has been created.
IoAttachDeviceToDeviceStackSafe	The IoAttachDeviceToDeviceStackSafe routine attaches the caller's device object to the topmost device object in a driver stack.
IoCancelFileOpen	The IoCancelFileOpen routine can be used by a file system filter driver to close a file that has been opened by a file system driver in the filter driver's device stack.
IoClearActivityIdThread	The IoClearActivityIdThread routine clears the activity ID of the current thread.
IoCreateController	The IoCreateController routine allocates memory for and initializes a controller object with a controller extension of a driver-determined size.
IoCreateDisk	The IoCreateDisk routine initializes a raw disk by creating a new partition table.
IoCreateFileEx	The IoCreateFileEx routine either causes a new file or directory to be created, or opens an existing file, device, directory, or volume and gives the caller a handle for the file object.
IoCreateFileSpecifyDeviceObjectHint	The IoCreateFileSpecifyDeviceObjectHint routine is used by file system filter drivers to send a create request only to the filters below a specified device object and to the file system.
IoDeassignArcName	The IoDeassignArcName routine removes a symbolic link between the ARC name for a device and the named device object.
IoDecrementKeepAliveCount	The IoDecrementKeepAliveCount routine decrements a reference count associated with an Windows app on a specific device.
IoDeleteController	The IoDeleteController routine removes a given controller object from the system, for example, when the driver that created it is being unloaded.
IoFreeController	The IoFreeController routine releases a previously allocated controller object when the driver has completed an I/O request.
IoGetActivityIdIrp	The IoGetActivityIdIrp routine retrieves the current activity ID associated with an IRP.

TITLE	DESCRIPTION
IoGetActivityIdThread	The IoGetActivityIdThread routine returns the activity ID associated with the current thread.
IoGetConfigurationInformation	The IoGetConfigurationInformation routine returns a pointer to the I/O manager's global configuration information structure, which contains the current values for how many physical disk, floppy, CD-ROM, tape, SCSI HBA, serial, and parallel devices have device objects created to represent them by drivers as they are loaded.
IoGetFileObjectGenericMapping	The IoGetFileObjectGenericMapping routine returns information about the mapping between each generic access right and the set of specific access rights for file objects.
IoGetInitiatorProcess	The IoGetInitiatorProcess routine retrieves the process which initiated the creation of a file object if different than the process which is issuing the create.
IoGetOplockKeyContext	The IoGetOplockKeyContext routine returns a target oplock key context for a file object.
IoGetOplockKeyContextEx	The IoGetOplockKeyContext routine returns a target oplock key context for a file object.
IoGetPagingIoPriority	The IoGetPagingIoPriority routine indicates the priority level of a paging I/O request.
IoGetSiloParameters	This routine indicates if a file is within a Container context.
IoGetTransactionParameterBlock	The IoGetTransactionParameterBlock routine returns the transaction parameter block for a transacted file operation.
IoIncrementKeepAliveCount	The IoIncrementKeepAliveCount routine increments a reference count associated with an Windows app process on a specific device.
IoInitializeDriverCreateContext	The IoInitializeDriverCreateContext routine initializes a caller-allocated variable of type IO_DRIVER_CREATE_CONTEXT.
IoIsFileObjectIgnoringSharing	The IoIsFileObjectIgnoringSharing routine determines if a file object is set with the option to ignore file sharing access checks.
IoIsFileOriginRemote	The IoIsFileOriginRemote routine determines whether a given file object is for a remote create request.
IoIsValidIrpStatus	The IoIsValidIrpStatus routine validates the specified NTSTATUS status code value.
IoMakeAssociatedIrp	This routine is reserved for use by file systems and file system filter drivers.
IoPropagateActivityIdToThread	The IoPropagateActivityIdToThread routine associates the activity ID from an IRP with the current thread.

TITLE	DESCRIPTION
IoQueryFullDriverPath	The IoQueryFullDriverPath routine retrieves the full path name of the binary file that is loaded for the specified driver object.
IoRaiseHardError	The IoRaiseHardError routine causes a dialog box to appears that warns the user that a device I/O error has occurred, which might indicate that a physical device is failing.
IoRaiseInformationalHardError	The IoRaiseInformationalHardError routine sends a dialog box to the user, warning about a device I/O error that indicates why a user I/O request failed.
IoReadDiskSignature	The IoReadDiskSignature routine reads the disk signature information for the partition table of a disk.
IoReadPartitionTable	The IoReadPartitionTable routine is obsolete and is provided only to support existing drivers.
IoReadPartitionTableEx	The IoReadPartitionTableEx routine reads a list of partitions on a disk having a specified sector size and creates an entry in the partition list for each recognized partition.
IoRegisterBootDriverCallback	The IoRegisterBootDriverCallback routine registers a BOOT_DRIVER_CALLBACK_FUNCTION routine to be called during the initialization of a boot-start driver and its dependent DLLs.
IoRegisterBootDriverReinitialization	The IoRegisterBootDriverReinitialization routine is called by a boot driver to register the driver's reinitialization routine with the I/O manager to be called after all devices have been enumerated and started.
IoRegisterDriverReinitialization	The IoRegisterDriverReinitialization routine is called by a driver during its initialization or reinitialization to register its Reinitialize routine to be called again before the driver's and, possibly the system's, initialization is complete.
IoReportDetectedDevice	The IoReportDetectedDevice routine reports a non-PnP device to the PnP manager.
IoReportResourceForDetection	The IoReportResourceForDetection routine claims hardware resources in the configuration registry for a legacy device.
IoReportRootDevice	The IoReportRootDevice routine reports a device that cannot be detected by a PnP bus driver to the PnP Manager. IoReportRootDevice allows only one device per driver to be created.
IoSetActivityIdIrp	The IoSetActivityIdIrp routine associates an activity ID with an IRP.
IoSetActivityIdThread	The IoSetActivityIdThread routine associates an activity ID with the current thread. Drivers should use this routine when they are tracing aware and are issuing I/O on a worker thread.

TITLE	DESCRIPTION
IoSetFileObjectIgnoreSharing	The IoSetFileObjectIgnoreSharing routine sets a file object to ignore file sharing access checks.
IoSetFileOrigin	The IoSetFileOrigin routine specifies whether a given file object is for a remote create request.
IoSetHardErrorOrVerifyDevice	Lower-level drivers call the IoSetHardErrorOrVerifyDevice routine to identify a removable media device that has encountered an error, so that a file system driver can prompt the user to verify that the medium is valid.
IoSetMasterIrpStatus	The IoSetMasterIrpStatus routine conditionally replaces the Status value in an IRP with the specified NTSTATUS value.
IoSetPartitionInformation	The IoSetPartitionInformation routine is obsolete and is provided only to support existing drivers.
IoSetPartitionInformationEx	For the disk represented by DeviceObject, the IoSetPartitionInformationEx routine initializes a partition table entry with the information specified in the SET_PARTITION_INFORMATION_EX structure.
IoSetSystemPartition	The IoSetSystemPartition routine sets the boot partition for the system.
IoSetThreadHardErrorMode	The IoSetThreadHardErrorMode routine enables or disables hard error reporting for the current thread.
IoTransferActivityId	The IoTransferActivityId routine logs an ETW transfer event using the I/O tracing provider on behalf of the caller. This allows a driver to associate two related activity IDs without requiring a specific provider to be enabled.
IoUnregisterBootDriverCallback	The IoUnRegisterBootDriverCallback routine unregisters a previously registered BOOT_DRIVER_CALLBACK_FUNCTION routine.
IoVerifyPartitionTable	The IoVerifyPartitionTable routine checks the validity of the partition table for a disk.
IoVolumeDeviceToDosName	The IoVolumeDeviceToDosName routine returns the MS-DOS path for a specified device object that represents a file system volume.
IoWritePartitionTable	The IoWritePartitionTable routine is obsolete and is provided only to support existing drivers.
IoWritePartitionTableEx	The IoWritePartitionTableEx routine writes partition tables from the entries in the partition list buffer for each partition on the disk represented by the given device object.
KeAreApcsDisabled	The KeAreApcsDisabled routine returns whether the calling thread is within a critical region or a guarded region, which disables normal kernel APC delivery.

TITLE	DESCRIPTION
KeBugCheck	The KeBugCheck routine brings down the system in a controlled manner when the caller discovers an unrecoverable inconsistency that would corrupt the system if the caller continued to run.
KeEnterCriticalRegion	The KeEnterCriticalRegion routine temporarily disables the execution of normal kernel APCs, but does not prevent special kernel APCs from running.
KeEnterGuardedRegion	The KeEnterGuardedRegion routine enters a guarded region, which disables all kernel-mode APC delivery to the current thread.
KeExpandKernelStackAndCallout	The KeExpandKernelStackAndCallout routine calls a routine with a guaranteed amount of stack space.
KeGetCurrentNodeNumber	The KeGetCurrentNodeNumber routine gets the NUMA node number for the logical processor that the caller is running on.
KeGetCurrentProcessorNumber	The KeGetCurrentProcessorNumber routine returns the system-assigned number of the current processor on which the caller is running.
KeGetCurrentProcessorNumberEx	The KeGetCurrentProcessorNumberEx routine gets the processor number of the logical processor that the caller is running on.
KeInitializeCrashDumpHeader	The KeInitializeCrashDumpHeader routine supplies the header information the system requires for a crash dump file.
KeInvalidateAllCaches	The KeInvalidateAllCaches routine flushes all processor caches.
KeLeaveCriticalRegion	The KeLeaveCriticalRegion routine reenables the delivery of normal kernel-mode APCs that were disabled by a preceding call to KeEnterCriticalRegion.
KeLeaveGuardedRegion	The KeLeaveGuardedRegion routine exits a guarded region entered by KeEnterGuardedRegion.
KePulseEvent	The KePulseEvent routine atomically sets an event object to a signaled state, attempts to satisfy as many waits as possible, and then resets the event object to a not-signaled state.
KeQueryActiveGroupCount	The KeQueryActiveGroupCount routine returns the number of active processor groups in a multiprocessor system.
KeQueryActiveProcessorCount	The KeQueryActiveProcessorCount routine returns the number of currently active processors.
KeQueryActiveProcessorCountEx	The KeQueryActiveProcessorCountEx routine returns the number of active logical processors in a specified group in a multiprocessor system or in the entire system.
KeQueryActiveProcessors	The KeQueryActiveProcessors routine returns a bitmask of the currently active processors.

TITLE	DESCRIPTION
KeQueryGroupAffinity	The KeQueryGroupAffinity routine returns an affinity mask that identifies the active logical processors in a specified group in a multiprocessor system.
KeQueryHardwareCounterConfiguration	The KeQueryHardwareCounterConfiguration routine queries the operating system for the list of hardware counters to use for thread profiling.
KeQueryHighestNodeNumber	The KeQueryHighestNodeNumber routine returns the highest node number in a multiprocessor system that has a non-uniform memory access (NUMA) architecture.
KeQueryLogicalProcessorRelationship	The KeQueryLogicalProcessorRelationship routine gets information about the relationships of one or more processors to the other processors in a multiprocessor system.
KeQueryMaximumGroupCount	The KeQueryMaximumGroupCount routine returns the maximum number of groups in a multiprocessor system.
KeQueryMaximumProcessorCount	The KeQueryMaximumProcessorCount routine returns the maximum number of processors.
KeQueryMaximumProcessorCountEx	The KeQueryMaximumProcessorCountEx routine returns the maximum number of logical processors in a specified group in a multiprocessor system.
KeQueryNodeActiveAffinity	The KeQueryNodeActiveAffinity routine gets the current processor affinity of a specified node in a multiprocessor system that has a non-uniform memory access (NUMA) architecture.
KeQueryNodeMaximumProcessorCount	The KeQueryNodeMaximumProcessorCount routine returns the maximum number of logical processors that a specified node in a non-uniform memory access (NUMA) multiprocessor system can contain.
KeQueryTickCount	The KeQueryTickCount routine maintains a count of the interval timer interrupts that have occurred since the system was booted.
KeRaiseIrqlToDpcLevel	The KeRaiseIrqlToDpcLevel routine raises the hardware priority to IRQL = DISPATCH_LEVEL, thereby masking off interrupts of equivalent or lower IRQL on the current processor.
KeSetBasePriorityThread	The KeSetBasePriorityThread routine sets the run-time priority, relative to the current process, for a given thread.
KeSetHardwareCounterConfiguration	The KeSetHardwareCounterConfiguration routine specifies a list of hardware counters to use for thread profiling.
KeSetImportanceDpc	The KeSetImportanceDpc routine specifies how soon the DPC routine is run.

TITLE	DESCRIPTION
KeSetTargetProcessorDpc	The KeSetTargetProcessorDpc routine specifies the processor that a DPC routine will be run on.
MmAllocateContiguousMemory	The MmAllocateContiguousMemory routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateContiguousMemorySpecifyCache	The MmAllocateContiguousMemorySpecifyCache routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateContiguousMemorySpecifyCacheNode	The MmAllocateContiguousMemorySpecifyCacheNode routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateContiguousNodeMemory	The MmAllocateContiguousNodeMemory routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateNonCachedMemory	The MmAllocateNonCachedMemory routine allocates a virtual address range of noncached and cache-aligned memory.
MmCopyMemory	The MmCopyMemory routine copies the specified range of virtual or physical memory into the caller-supplied buffer.
MmFreeContiguousMemory	The MmFreeContiguousMemory routine releases a range of physically contiguous memory that was allocated by an MmAllocateContiguousMemoryXxx routine.
MmFreeContiguousMemorySpecifyCache	The MmFreeContiguousMemorySpecifyCache routine frees a buffer that was allocated by an MmAllocateContiguousMemorySpecifyCacheXxx routine.
MmFreeNonCachedMemory	The MmFreeNonCachedMemory routine releases a range of noncached memory that was allocated by the MmAllocateNonCachedMemory routine.
MmGetPhysicalAddress	The MmGetPhysicalAddress routine returns the physical address corresponding to a valid nonpaged virtual address.
MmIsAddressValid	The MmIsAddressValid routine checks whether a page fault will occur for a read or write operation at a given virtual address.Warning We do not recommend using this function.
MmIsThisAnNtAsSystem	The MmIsThisAnNtAsSystem routine is obsolete for Windows XP and later versions of Windows. Use RtlGetVersion or RtlVerifyVersionInfo instead.
MmLockPagableSectionByHandle	The MmLockPagableSectionByHandle routine locks a pageable code or data section into system memory by incrementing the reference count on the handle to the section.
MmMapViewInSystemSpace	The MmMapViewInSystemSpace function maps the specified section into the system's address space.

TITLE	DESCRIPTION
MmSecureVirtualMemory	The MmSecureVirtualMemory routine secures a user-space memory address range so that it cannot be freed and its protection type cannot be made more restrictive.
MmUnmapViewInSystemSpace	
MmUnsecureVirtualMemory	The MmUnsecureVirtualMemory routine unsecures a memory address range secured by the MmSecureVirtualMemory routine.
NtOpenProcess	The ZwOpenProcess routine opens a handle to a process object and sets the access rights to this object.
PsAllocSiloContextSlot	This routine allocates a slot that can be used to insert, retrieve, and delete an object in all silos. .
PsAttachSiloToCurrentThread	This routine places a thread temporarily into the specified Silo.
PsCreateSiloContext	This routine creates an object that will be inserted in a Silo.
PsDereferenceSiloContext	This routine decrements the reference count on the object.
PsDetachSiloFromCurrentThread	This routine removes a thread from a silo which was added by an attach. For more info about attaching, see the PsAttachSiloToCurrentThread routine.
PsFreeSiloContextSlot	This routine frees the specified slot and makes it available in the system. It undoes the effects of the PsAllocSiloContextSlot routine.
PsGetCurrentProcessId	The PsGetCurrentProcessId routine identifies the current thread's process.
PsGetCurrentServerSilo	This routine returns the effective server silo for the thread.
PsGetCurrentSilo	This routine returns the current silo for the calling thread. First the thread is checked to see if it has been attached to a silo. If not, then the thread is checked to see if it is in a silo.
PsGetCurrentThread	The PsGetCurrentThread routine identifies the current thread.
PsGetCurrentThreadId	The PsGetCurrentThreadId routine identifies the current thread.
PsGetCurrentThreadTeb	The PsGetCurrentThreadTeb routine returns the Thread Environment Block (TEB) of the current thread. The call must be made in kernel-mode.
PsGetEffectiveServerSilo	This routine traverses the parent chain of the Silo until finding the effective server silo or host silo.
PsGetHostSilo	This routine returns the host silo.

TITLE	DESCRIPTION
PsGetJobServerSilo	This routine returns the effective ServerSilo for the job. The returned pointer is valid as long as the supplied Job object remains referenced.
PsGetJobSilo	This routine returns the first job in the hierarchy that is a Silo. The returned pointer is valid as long as the supplied Job object remains referenced.
PsGetParentSilo	Retrieves the most immediate parent silo in the hierarchy for a given job object.
PsGetPermanentSiloContext	This routine retrieves an object that was inserted in the Silo without incrementing the reference count.
PsGetProcessCreateTimeQuadPart	The PsGetProcessCreateTimeQuadPart routine returns a LONGLONG value that represents the time at which the process was created.
PsGetProcessId	The PsGetProcessId routine returns the process identifier (process ID) that is associated with a specified process.
PsGetServerSiloActiveConsoleId	Gets the active console for the current server silo context for the supplied thread.
PsGetSiloContainerId	Gets the ContainerId for the given Silo.
PsGetSiloContext	This routine retrieves the silo context from the specified silo and slot.
PsGetSiloMonitorContextSlot	This routine returns the silo context slot that was allocated by the monitor during the registration.
PsGetThreadProcessId	The PsGetThreadProcessId routine returns the process identifier that is associated with a specified thread's process.
PsGetThreadServerSilo	Determines whether the given thread is a silo.
PshedAllocateMemory	The PshedAllocateMemory function allocates a block of memory from the nonpaged pool.
PshedFreeMemory	The PshedFreeMemory function frees a block of memory that was previously allocated by calling the PshedAllocateMemory function.
PshedIsSystemWheaEnabled	The PshedIsSystemWheaEnabled function returns a Boolean value that indicates whether the system is WHEA-enabled.
PshedRegisterPlugin	The PshedRegisterPlugin function registers a PSHED plug-in with the PSHED.
PshedSynchronizeExecution	The PshedSynchronizeExecution function synchronizes the execution of a given function with the hardware error processing for an error source.

TITLE	DESCRIPTION
PsInsertPermanentSiloContext	This routine inserts an object in an empty slot in a Silo.
PsInsertSiloContext	This routine inserts an object in an empty slot in a Silo.
PsIsHostSilo	This routine will check if the supplied Silo is the host silo.
PsMakeSiloContextPermanent	This routine makes the slot in a silo instance read-only, allowing the object in the slot to be retrieved without affecting the reference count on that object.
PsReferenceSiloContext	This routine increments the reference count on the object.
PsRegisterSiloMonitor	This routine registers a server silo monitor that can receive notifications about server silo events.
PsRemoveCreateThreadNotifyRoutine	The PsRemoveCreateThreadNotifyRoutine routine removes a callback routine that was registered by the PsSetCreateThreadNotifyRoutine routine.
PsRemoveLoadImageNotifyRoutine	The PsRemoveLoadImageNotifyRoutine routine removes a callback routine that was registered by the PsSetLoadImageNotifyRoutine routine.
PsRemoveSiloContext	This routine removes an object that was inserted in the Silo.
PsReplaceSiloContext	This routine inserts an object in a Silo.
PsSetCreateProcessNotifyRoutine	The PsSetCreateProcessNotifyRoutine routine adds a driver-supplied callback routine to, or removes it from, a list of routines to be called whenever a process is created or deleted.
PsSetCreateProcessNotifyRoutineEx	The PsSetCreateProcessNotifyRoutineEx routine registers or removes a callback routine that notifies the caller when a process is created or exits.
PsSetCreateProcessNotifyRoutineEx2	The PsSetCreateProcessNotifyRoutineEx2 routine registers or removes a callback routine that notifies the caller when a process is created or deleted.
PsSetCreateThreadNotifyRoutine	The PsSetCreateThreadNotifyRoutine routine registers a driver-supplied callback that is subsequently notified when a new thread is created and when such a thread is deleted.
PsSetCreateThreadNotifyRoutineEx	The PsSetCreateThreadNotifyRoutineEx routine registers a driver-supplied callback that is subsequently notified when a new thread is created and when such a thread is deleted.
PsSetLoadImageNotifyRoutine	The PsSetLoadImageNotifyRoutine routine registers a driver-supplied callback that is subsequently notified whenever an image is loaded (or mapped into memory).
PsSetLoadImageNotifyRoutineEx	The PsSetLoadImageNotifyRoutineEx routine registers a driver-supplied callback that is subsequently notified whenever an image is loaded (or mapped into memory).

TITLE	DESCRIPTION
PsStartSiloMonitor	This routine tries to start the server silo monitor.
PsTerminateServerSilo	This routine terminates the specified silo.
PsUnregisterSiloMonitor	This routine unregisters a server silo monitor.
RtlCharToInteger	The RtlCharToInteger routine converts a single-byte character string to an integer value in the specified base.
RtlCompareString	The RtlCompareString routine compares two counted strings.
RtlConvertLongToLuid	The RtlConvertLongToLuid routine converts a long integer to a locally unique identifier (LUID), which is used by the system to represent a security privilege.
RtlConvertUlongToLuid	The RtlConvertUlongToLuid routine converts an unsigned long integer to a locally unique identifier (LUID), which is used by the system to represent a security privilege.
RtlCopyString	The RtlCopyString routine copies a source string to a destination string.
RtlDelete	The RtlDelete routine deletes the specified node from the splay link tree.
RtlDeleteElementGenericTable	The RtlDeleteElementGenericTable routine deletes an element from a generic table.
RtlDeleteElementGenericTableAvl	The RtlDeleteElementGenericTableAvl routine deletes an element from a generic table.
RtlDeleteNoSplay	The RtlDeleteNoSplay routine deletes the specified node from the splay link tree.
RtlDrainNonVolatileFlush	The routine RtlDrainNonVolatileFlush waits for the flushes initiated by RtlFlushNonVolatileMemory to finish.
RtlEnumerateGenericTable	The RtlEnumerateGenericTable routine is used to enumerate the elements in a generic table.
RtlEnumerateGenericTableAvl	The RtlEnumerateGenericTableAvl routine is used to enumerate the elements in a generic table.
RtlEnumerateGenericTableLikeADirectory	The RtlEnumerateGenericTableLikeADirectory routine returns the elements of a generic table, one-by-one, in collation order.
RtlEnumerateGenericTableWithoutSplaying	The RtlEnumerateGenericTableWithoutSplaying routine is used to enumerate the elements in a generic table.
RtlEnumerateGenericTableWithoutSplayingAvl	The RtlEnumerateGenericTableWithoutSplayingAvl routine is used to enumerate the elements in a generic table.

TITLE	DESCRIPTION
RtlEqualString	The RtlEqualString routine compares two counted strings to determine whether they are equal.
RtlExtendCorrelationVector	This routine extends the supplied correlation vector. For a correlation vector of the form X.i, the extended value is X.i.0.
RtlFlushNonVolatileMemory	The routine RtlFlushNonVolatileMemory optimally flushes the given non-volatile memory region.
RtlFlushNonVolatileMemoryRanges	The routine RtlFlushNonVolatileMemoryRanges optimally flushes the given non-volatile memory regions.
RtlFreeNonVolatileToken	The routine RtlFreeNonVolatileToken is a cleanup function for the opaque NvToken which is given by a successful call to RtlGetNonVolatileToken.
RtlGetElementGenericTable	The RtlGetElementGenericTable routine returns a pointer to the caller-supplied data for a particular generic table element.
RtlGetElementGenericTableAvl	The RtlGetElementGenericTableAvl routine returns a pointer to the caller-supplied data for a particular generic Adelson-Velsky/Landis (AVL) table element.
RtlGetEnabledExtendedFeatures	The RtlGetEnabledExtendedFeatures routine returns a mask of extended processor features that are enabled by the system.
RtlGetNonVolatileToken	The routine, RtlGetNonVolatileToken, gets various properties about a non-volatile memory buffer and stores them in the variable NvToken.
RtlGetPersistedStateLocation	Retrieves the redirected location for the specified SourceID from the redirection map.
RtlIncrementCorrelationVector	Increments the specified correlation vector. For a correlation vector of the form X.i, the incremented value is be X.(i+1).
RtlInitializeCorrelationVector	Initializes the specified correlation vector with the supplied GUID.
RtlInitializeGenericTable	The RtlInitializeGenericTable routine initializes a generic table.
RtlInitializeGenericTableAvl	The RtlInitializeGenericTableAvl routine initializes a generic table using Adelson-Velsky/Landis (AVL) trees.
RtlInitializeSplayLinks	The RtlInitializeSplayLinks routine initializes a splay link node.
RtlInsertAsLeftChild	The RtlInsertAsLeftChild routine inserts a splay link node into the tree as the left child of the specified node.
RtlInsertAsRightChild	The RtlInsertAsRightChild routine inserts a given splay link into the tree as the right child of a given node in that tree.
RtlInsertElementGenericTable	The RtlInsertElementGenericTable routine adds a new element to a generic table.

TITLE	DESCRIPTION
RtlInsertElementGenericTableAvl	The RtlInsertElementGenericTableAvl routine adds a new entry to a generic table.
RtlInsertElementGenericTableFullAvl	The RtlInsertElementGenericTableFullAvl routine adds a new entry to a generic table.
RtlIsGenericTableEmpty	The RtlIsGenericTableEmpty routine determines if a generic table is empty.
RtlIsGenericTableEmptyAvl	The RtlIsGenericTableEmptyAvl routine determines if a generic table is empty.
RtlIsLeftChild	The RtlIsLeftChild routine determines whether a given splay link is the left child of a node in a splay link tree.
RtlIsRightChild	The RtlIsRightChild routine determines whether a given splay link is the right child of a node in a splay link tree.
RtlIsRoot	The RtlIsRoot routine determines whether the specified node is the root node of a splay link tree.
RtlIsStateSeparationEnabled	Checks if the SKU for the current context supports multiple sessions.
RtlLeftChild	The RtlLeftChild routine returns a pointer to the left child of the specified splay link node.
RtlLookupElementGenericTable	The RtlLookupElementGenericTable routine searches a generic table for an element that matches the specified data.
RtlLookupElementGenericTableAvl	The RtlLookupElementGenericTableAvl routine searches a generic table for an element that matches the specified data.
RtlLookupElementGenericTableFullAvl	The RtlLookupElementGenericTableFullAvl routine searches a generic table for an element that matches the specified data.
RtlLookupFirstMatchingElementGenericTableAvl	The RtlLookupFirstMatchingElementGenericTableAvl routine finds the left-most element in the tree that matches the indicated data.
RtlMapGenericMask	The RtlMapGenericMask routine determines the nongeneric access rights specified by an ACCESS_MASK.
RtlNumberGenericTableElements	The RtlNumberGenericTableElements routine returns the number of elements in a generic table.
RtlNumberGenericTableElementsAvl	The RtlNumberGenericTableElementsAvl routine returns the number of elements in a generic table.
RtlParent	The RtlParent routine returns a pointer to the parent of the specified node in a splay link tree.

TITLE	DESCRIPTION
RtlPrefixUnicodeString	The RtlPrefixUnicodeString routine compares two Unicode strings to determine whether one string is a prefix of the other.
RtlQueryRegistryValueWithFallback	Retrieves a value entry for a registry key by using, a primary handle; if not found, uses the fallback handle.
RtlRaiseCustomSystemEventTrigger	Allows NT services and kernel-mode and user-mode drivers to raise a custom trigger for a device.
RtlRealPredecessor	The RtlRealPredecessor routine returns a pointer to the predecessor of the specified node in the splay link tree.
RtlRealSuccessor	The RtlRealSuccessor routine returns a pointer to the successor of the specified node in the splay link tree.
RtlRightChild	The RtlRightChild routine returns a pointer to the right child of the specified splay link node.
RtlRunOnceBeginInitialize	The RtlRunOnceBeginInitialize routine begins a one-time initialization.
RtlRunOnceComplete	The RtlRunOnceComplete routine completes the one-time initialization began by RtlRunOnceBeginInitialize.
RtlRunOnceExecuteOnce	The RtlRunOnceExecuteOnce performs a one-time initialization.
RtlRunOnceInitialize	The RtlRunOnceInitialize routine initializes a RTL_RUN_ONCE structure.
RtlSplay	The RtlSplay routine rebalances, or "splays," a splay link tree around the specified splay link, making that link the new root of the tree.
RtlSubtreePredecessor	The RtlSubtreePredecessor routine returns a pointer to the predecessor of the specified node within the subtree that is rooted at that node.
RtlSubtreeSuccessor	The RtlSubtreeSuccessor routine returns a pointer to the successor of the specified node within the subtree that is rooted at that node.
RtlUpcaseUnicodeString	The RtlUpcaseUnicodeString routine converts a copy of the source string to uppercase and writes the converted string in the destination buffer.
RtlUpperChar	The RtlUpperChar routine converts the specified character to uppercase.
RtlUpperString	The RtlUpperString routine copies the given SourceString to the DestinationString buffer, converting it to uppercase.

TITLE	DESCRIPTION
RtlValidateCorrelationVector	Validates the specified correlation vector to check whether it conforms to the Correlation Vector Specification (v2).
RtlVolumeDeviceToDosName	The RtlVolumeDeviceToDosName routine is obsolete for Windows XP and later versions of Windows. Use IoVolumeDeviceToDosName instead.RtlVolumeDeviceToDosName returns the MS-DOS path for a specified device object that represents a file system volume.
RtlWriteNonVolatileMemory	The routine RtlWriteNonVolatileMemory copies the contents of a source buffer to a non-volatile destination memory buffer.
SeSinglePrivilegeCheck	The SeSinglePrivilegeCheck routine checks for the passed privilege value in the context of the current thread.
WheaFindErrorRecordSection	The WheaFindErrorRecordSection function searches for a specified Windows Hardware Error Architecture (WHEA) error record section within a WHEA error record. The error record section is formatted as a WHEA_ERROR_RECORD_SECTION_DESCRIPTOR structure.
WheaFindNextErrorRecordSection	The WheaFindNextErrorRecordSection function allows a caller to iteratively examine the WHEA error record sections within a WHEA error record. Each error record section is formatted as a WHEA_ERROR_RECORD_SECTION_DESCRIPTOR structure.
WheaGetErrPacketFromErrRecord	The WheaGetErrPacketFromErrRecord function returns a pointer to the hardware error packet that is contained within a WHEA error record. The hardware error packet is formatted as a WHEA_ERROR_PACKET structure.
WheaIsValidErrorRecordSignature	The WheaIsValidErrorRecordSignature function verifies whether a WHEA error record is valid.
ZwAllocateLocallyUniqueId	The ZwAllocateLocallyUniqueId routine allocates a locally unique identifier (LUID).
ZwDeviceIoControlFile	The ZwDeviceIoControlFile routine sends a control code directly to a specified device driver, causing the corresponding driver to perform the specified operation.
ZwOpenProcess	The ZwOpenProcess routine opens a handle to a process object and sets the access rights to this object.
ZwPowerInformation	The ZwPowerInformation routine sets or retrieves system power information.
ZwQueryVolumeInformationFile	The ZwQueryVolumeInformationFile routine retrieves information about the volume associated with a given file, directory, storage device, or volume.
ZwSetInformationThread	The ZwSetInformationThread routine sets the priority of a thread.

TITLE	DESCRIPTION
ZwTerminateProcess	The ZwTerminateProcess routine terminates a process and all of its threads.

Callback functions

TITLE	DESCRIPTION
BOOT_DRIVER_CALLBACK_FUNCTION	
DRIVER_REINITIALIZE	The Reinitialize routine continues driver and device initialization after the driver's DriverEntry routine returns.
EXPAND_STACK_CALLOUT	The ExpandedStackCall routine executes with a guaranteed stack size.
PCREATE_PROCESS_NOTIFY_ROUTINE	Process-creation callback implemented by a driver to track the system-wide creation and deletion of processes against the driver's internal state.
PCREATE_PROCESS_NOTIFY_ROUTINE_EX	A callback routine implemented by a driver to notify the caller when a process is created or exits.
PCREATE_THREAD_NOTIFY_ROUTINE	A callback routine implemented by a driver to notify the caller when a thread is created or deleted.
PGET_LOCATION_STRING	The PnpGetLocationString routine provides the device-specific part of the device's SPDRP_LOCATION_PATHS property.
pHalExamineMBR	The HalExamineMBR routine reads the master boot record (MBR) of a disk and returns data from the MBR if the MBR is of the type specified by the caller.
pHalQuerySystemInformation	
pHalSetSystemInformation	Register MCA driver with the HAL.
PLOAD_IMAGE_NOTIFY_ROUTINE	Called by the operating system to notify the driver when a driver image or a user image (for example, a DLL or EXE) is mapped into virtual memory.
PSHED_PI_ATTEMPT_ERROR_RECOVERY	A PSHED plug-in's AttemptRecovery callback function attempts to recover from a recoverable hardware error.
PSHED_PI_CLEAR_ERROR_RECORD	A PSHED plug-in's ClearErrorRecord callback function clears the specified error record from the system's persistent data storage.
PSHED_PI_CLEAR_ERROR_STATUS	A PSHED plug-in's ClearErrorStatus callback function clears any platform-specific error status registers for a corrected hardware error condition.
PSHED_PI_DISABLE_ERROR_SOURCE	A PSHED plug-in's DisableErrorSource callback function disables an error source.

TITLE	DESCRIPTION
PSHED_PI_ENABLE_ERROR_SOURCE	A PSHED plug-in's EnableErrorSource callback function enables an error source.
PSHED_PI_FINALIZE_ERROR_RECORD	A PSHED plug-in's FinalizeErrorRecord callback function adds supplementary error record sections to an error record that more fully describe the error condition.
PSHED_PI_GET_ALL_ERROR_SOURCES	A PSHED plug-in's GetAllErrorSources callback function returns a list of error source descriptor structures that represents all of the error sources that are implemented by the hardware platform.
PSHED_PI_GET_ERROR_SOURCE_INFO	A PSHED plug-in's GetErrorSourceInfo callback function returns an error source descriptor structure that represents a particular error source that is implemented by the hardware platform.
PSHED_PI_GET_INJECTION_CAPABILITIES	A PSHED plug-in's GetInjectionCapabilities callback function returns an error injection capabilities union that describes the types of hardware errors that can be injected into the hardware platform.
PSHED_PI_INJECT_ERROR	A PSHED plug-in's InjectError callback function injects an error into the hardware platform.
PSHED_PI_READ_ERROR_RECORD	A PSHED plug-in's ReadErrorRecord callback function reads an error record from the system's persistent data storage.
PSHED_PI_RETRIEVE_ERROR_INFO	A PSHED plug-in's RetrieveErrorInfo callback function retrieves platform-specific error information about a hardware error that has occurred.
PSHED_PI_SET_ERROR_SOURCE_INFO	A PSHED plug-in's SetErrorSourceInfo callback function configures an error source.
PSHED_PI_WRITE_ERROR_RECORD	A PSHED plug-in's WriteErrorRecord callback function writes an error record to the system's persistent data storage.
RTL_RUN_ONCE_INIT_FN	The RunOnceInitialization routine performs a one-time initialization operation.
SILO_CONTEXT_CLEANUP_CALLBACK	This callback is invoked when the context object reaches a reference count of zero.
SILO_MONITOR_CREATE_CALLBACK	This is callback is invoked when a new silo is created.
SILO_MONITOR_TERMINATE_CALLBACK	This callback is invoked when a silo is terminated.

Structures

TITLE	DESCRIPTION

TITLE	DESCRIPTION
WHEA_ERROR_RECORD	The WHEA_ERROR_RECORD structure describes an error record that contains error information about a hardware error condition that occurred.
WHEA_ERROR_SOURCE_DESCRIPTOR	The WHEA_ERROR_SOURCE_DESCRIPTOR structure describes an error source.
BDCB_IMAGE_INFORMATION	The BDCB_IMAGE_INFORMATION structure describes information about a boot-start driver that is about to be initialized, provided by Windows to a boot-start driver's BOOT_DRIVER_CALLBACK_FUNCTION routine.
BDCB_STATUS_UPDATE_CONTEXT	The BDCB_STATUS_UPDATE_CONTEXT structure describes a status update provided by Windows to a boot-start driver's BOOT_DRIVER_CALLBACK_FUNCTION routine.
CONTROLLER_OBJECT	A controller object represents a hardware adapter or controller with homogenous devices that are the actual targets for I/O requests.
CORRELATION_VECTOR	Store the correlation vector that is used to reference events and the generated logs for diagnostic purposes.
CUSTOM_SYSTEM_EVENT_TRIGGER_CONFIG	Contains information about a custom system event trigger.
DEBUG_TRANSPORT_DATA	Describes debug-transport specific data for use by the transport.
DISK_SIGNATURE	DISK_SIGNATURE contains the disk signature information for a disk's partition table.
FILE_ALIGNMENT_INFORMATION	The FILE_ALIGNMENT_INFORMATION structure is used as an argument to the ZwQueryInformationFile routine.
FILE_ATTRIBUTE_TAG_INFORMATION	The FILE_ATTRIBUTE_TAG_INFORMATION structure is used as an argument to ZwQueryInformationFile.
FILE_DISPOSITION_INFORMATION	The FILE_DISPOSITION_INFORMATION structure is used as an argument to the ZwSetInformationFile routine.
FILE_DISPOSITION_INFORMATION_EX	The FILE_DISPOSITION_INFORMATION_EX structure is used as an argument to the ZwSetInformationFileEx routine and indicates how the operating system should delete a file.
FILE_END_OF_FILE_INFORMATION	The FILE_END_OF_FILE_INFORMATION structure is used as an argument to the ZwSetInformationFile routine.
FILE_FS_FULL_SIZE_INFORMATION	The FILE_FS_FULL_SIZE_INFORMATION structure is used to query sector size information for a file system volume.
FILE_FS_FULL_SIZE_INFORMATION_EX	Used in a request to query sector size information for a file system volume.

TITLE	DESCRIPTION
FILE_FS_LABEL_INFORMATION	The FILE_FS_LABEL_INFORMATION structure is used to set the label for a file system volume.
FILE_FS_OBJECTID_INFORMATION	The FILE_FS_OBJECTID_INFORMATION structure is used to query or set the object ID for a file system volume.
FILE_FS_SECTOR_SIZE_INFORMATION	The FILE_FS_SECTOR_SIZE_INFORMATION structure is used to query physical and logical sector size information for a file system volume.
FILE_FS_SIZE_INFORMATION	The FILE_FS_SIZE_INFORMATION structure is used to query sector size information for a file system volume.
FILE_FS_VOLUME_INFORMATION	The FILE_FS_VOLUME_INFORMATION structure is used to query information about a volume on which a file system is mounted.
FILE_NAME_INFORMATION	The FILE_NAME_INFORMATION structure is used as argument to the ZwQueryInformationFile and ZwSetInformationFile routines.
FILE_VALID_DATA_LENGTH_INFORMATION	The FILE_VALID_DATA_LENGTH_INFORMATION structure is used as an argument to ZwSetInformationFile.
HARDWARE_COUNTER	The HARDWARE_COUNTER structure contains information about a hardware counter.
IMAGE_INFO	Used by driver's load-image routine (PLOAD_IMAGE_NOTIFY_ROUTINE) to specify image information.
IMAGE_INFO_EX	Extended version of the image information structure (see IMAGE_INFO).
IO_DRIVER_CREATE_CONTEXT	The IO_DRIVER_CREATE_CONTEXT structure is used to pass additional parameters to the IoCreateFileEx and FltCreateFileEx2 routines.
IO_FOEXT_SILO_PARAMETERS	This structure describes the Container context that's identified by the IoGetSiloParameters routine.
KEY_CACHED_INFORMATION	The KEY_CACHED_INFORMATION structure holds the cached information available for a registry key or subkey.
KEY_NAME_INFORMATION	The KEY_NAME_INFORMATION structure holds the name and name length of the key.
KEY_VIRTUALIZATION_INFORMATION	The KEY_VIRTUALIZATION_INFORMATION structure defines the basic information that is available for a registry key or subkey.
MM_COPY_ADDRESS	The MM_COPY_ADDRESS structure contains either a virtual memory address or a physical memory address.

TITLE	DESCRIPTION
OPLOCK_KEY_CONTEXT	The OPLOCK_KEY_CONTEXT structure is returned from IoGetOplockKeyContextEx. This structure contains oplock keys for a specific file object.
PCI_EXPRESS_CAPABILITIES_REGISTER	The PCI_EXPRESS_CAPABILITIES_REGISTER structure describes a PCI Express (PCIe) capabilities register of a PCIe capability structure.
PCI_EXPRESS_CAPABILITY	The PCI_EXPRESS_CAPABILITY structure describes a PCI Express (PCIe) capability structure.
PCI_EXPRESS_DESIGNATED_VENDOR_SPECIFIC_CAPABILITY	Represents the Designated Vendor-Specific Extended Capability defined by PCI-SIG.
PCI_EXPRESS_DESIGNATED_VENDOR_SPECIFIC_HEADER_1	Represents the Designated Vendor-Specific Extended Capability Header 1 defined by PCI-SIG.
PCI_EXPRESS_DESIGNATED_VENDOR_SPECIFIC_HEADER_2	Represents the Designated Vendor-Specific Extended Capability Header 2 defined by PCI-SIG.
PCI_EXPRESS_DEVICE_CAPABILITIES_REGISTER	The PCI_EXPRESS_DEVICE_CAPABILITIES_REGISTER structure describes a PCI Express (PCIe) device capabilities register of a PCIe capability structure.
PCI_EXPRESS_DEVICE_CONTROL_REGISTER	The PCI_EXPRESS_DEVICE_CONTROL_REGISTER structure describes a PCI Express (PCIe) device control register of a PCIe capability structure.
PCI_EXPRESS_DEVICE_STATUS_REGISTER	The PCI_EXPRESS_DEVICE_STATUS_REGISTER structure describes a PCI Express (PCIe) device status register of a PCIe capability structure.
PCI_EXPRESS_LINK_CAPABILITIES_REGISTER	The PCI_EXPRESS_LINK_CAPABILITIES_REGISTER structure describes a PCI Express (PCIe) link capabilities register of a PCIe capability structure.
PCI_EXPRESS_LINK_CONTROL_REGISTER	The PCI_EXPRESS_LINK_CONTROL_REGISTER structure describes a PCI Express (PCIe) link control register of a PCIe capability structure.
PCI_EXPRESS_LINK_STATUS_REGISTER	The PCI_EXPRESS_LINK_STATUS_REGISTER structure describes a PCI Express (PCIe) link status register of a PCIe capability structure.
PCI_EXPRESS_PME_REQUESTOR_ID	The PCI_EXPRESS_PME_REQUESTOR_ID structure describes the identifier of the requester of a power management event (PME).
PCI_EXPRESS_ROOT_CAPABILITIES_REGISTER	The PCI_EXPRESS_ROOT_CAPABILITIES_REGISTER structure describes a PCI Express (PCIe) root capabilities register of a PCIe capability structure.
PCI_EXPRESS_ROOT_CONTROL_REGISTER	The PCI_EXPRESS_ROOT_CONTROL_REGISTER structure describes a PCI Express (PCIe) root control register of a PCIe capability structure.

TITLE	DESCRIPTION
PCI_EXPRESS_ROOT_STATUS_REGISTER	The PCI_EXPRESS_ROOT_STATUS_REGISTER structure describes a PCI Express (PCIe) root status register of a PCIe capability structure.
PCI_EXPRESS_SLOT_CAPABILITIES_REGISTER	The PCI_EXPRESS_SLOT_CAPABILITIES_REGISTER structure describes a PCI Express (PCIe) slot capabilities register of a PCIe capability structure.
PCI_EXPRESS_SLOT_CONTROL_REGISTER	The PCI_EXPRESS_SLOT_CONTROL_REGISTER structure describes a PCI Express (PCIe) slot control register of a PCIe capability structure.
PCI_EXPRESS_SLOT_STATUS_REGISTER	The PCI_EXPRESS_SLOT_STATUS_REGISTER structure describes a PCI Express (PCIe) slot status register of a PCIe capability structure.
PCI_FPB_CAPABILITIES_REGISTER	The Flattening Portal Bridge (FPB) Capabilities register. See section 7.y.2.
PCI_FPB_CAPABILITY	Flattening Portal Bridge (FPB) Capabilities that is required for any bridge Function that implements FPB. See section 7.y.
PCI_FPB_CAPABILITY_HEADER	The Flattening Portal Bridge (FPB) Capabilities header. See section 7.y.1.
PCI_FPB_MEM_HIGH_VECTOR_CONTROL1_REGISTER	The FPB MEM High Vector Control 1 Register. See section 7.y.6.
PCI_FPB_MEM_HIGH_VECTOR_CONTROL2_REGISTER	The FPB MEM High Vector Control 2 Register. See section 7.y.7.
PCI_FPB_MEM_LOW_VECTOR_CONTROL_REGISTER	FPB MEM Low Vector Control Register. See section 7.y.5.
PCI_FPB_RID_VECTOR_CONTROL1_REGISTER	The FPB RID Vector Control 1 Register. See section 7.y.3.
PCI_FPB_RID_VECTOR_CONTROL2_REGISTER	The FPB RID Vector Control 1 Register. See section 7.y.3.
PCI_FPB_VECTOR_ACCESS_CONTROL_REGISTER	The FPB Vector Access Control Register. See section 7.y.8.
PCI_FPB_VECTOR_ACCESS_DATA_REGISTER	The FPB Vector Access Data Register. See section 7.y.9.
PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR	The PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR structure describes the counter resources available on the platform.
PHYSICAL_COUNTER_RESOURCE_LIST	The PHYSICAL_COUNTER_RESOURCE_LIST structure describes an array of PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR structures.
PNP_LOCATION_INTERFACE	The PNP_LOCATION_INTERFACE structure describes the GUID_PNP_LOCATION_INTERFACE interface.
POWER_THROTTLING_PROCESS_STATE	Stores the throttling policies and how to apply them to a target process when that process is subject to power management.

TITLE	DESCRIPTION
POWER_THROTTLING_THREAD_STATE	Stores the throttling policies and how to apply them to a target thread when that thread is subject to power management.
PROCESS_MITIGATION_CHILD_PROCESS_POLICY	Stores policy information about creating child processes.
PROCESS_MITIGATION_PAYLOAD_RESTRICTION_POLICY	Stores information about process mitigation policy.
PROCESS_MITIGATION_SYSTEM_CALL_FILTER_POLICY	This structure is not supported.
PS_CREATE_NOTIFY_INFO	The PS_CREATE_NOTIFY_INFO structure provides information about a newly created process.
RTL_AVL_TABLE	The RTL_AVL_TABLE structure contains file system-specific data for an Adelson-Velsky/Landis (AVL) tree.
RTL_GENERIC_TABLE	The RTL_GENERIC_TABLE structure contains file system-specific data for a splay tree.
RTL_SPLAY_LINKS	The RTL_SPLAY_LINKS structure is an opaque structure and is used by the system to represent a splay link tree node.
SILO_MONITOR_REGISTRATION	This structure specifies a server silo monitor that can receive notifications about server silo events.
SOC_SUBSYSTEM_FAILURE_DETAILS	The SOC_SUBSYSTEM_FAILURE_DETAILS structure holds information related to a System on a Chip (SoC) bug code.
TXN_PARAMETER_BLOCK	The TXN_PARAMETER_BLOCK structure contains information about a transacted file operation.
WHEA_AER_BRIDGE_DESCRIPTOR	The WHEA_AER_BRIDGE_DESCRIPTOR structure describes a PCI Express (PCIe) bridge error source.
WHEA_AER_ENDPOINT_DESCRIPTOR	The WHEA_AER_ENDPOINT_DESCRIPTOR structure describes a PCI Express (PCIe) endpoint error source.
WHEA_AER_ROOTPORT_DESCRIPTOR	The WHEA_AER_ROOTPORT_DESCRIPTOR structure describes a PCI Express (PCIe) root port error source.
WHEA_ERROR_INJECTION_CAPABILITIES	The WHEA_ERROR_INJECTION_CAPABILITIES union describes the types of hardware errors that can be injected into a hardware platform.
WHEA_ERROR_PACKET_FLAGS	The WHEA_ERROR_PACKET_FLAGS union defines the error condition reported through a WHEA_ERROR_PACKET structure.
WHEA_ERROR_PACKET_V1	The WHEA_ERROR_PACKET_V1 structure describes the hardware error data that is passed to the operating system by a low-level hardware error handler (LLHEH).Note The WHEA_ERROR_PACKET_V1 structure is supported in Windows Server 2008 and Windows Vista SP1.

TITLE	DESCRIPTION
WHEA_ERROR_PACKET_V2	The WHEA_ERROR_PACKET_V1 structure describes the hardware error data that is passed to the operating system by a low-level hardware error handler (LLHEH).Note The WHEA_ERROR_PACKET_V1 structure is supported in Windows Server 2008 and Windows Vista SP1.
WHEA_ERROR_RECORD_HEADER	The WHEA_ERROR_RECORD_HEADER structure describes general information about a hardware error condition.
WHEA_ERROR_RECORD_HEADER_VALIDBITS	The WHEA_ERROR_RECORD_HEADER_VALIDBITS union describes which members of a WHEA_ERROR_RECORD_HEADER structure contain valid data.
WHEA_ERROR_RECORD_SECTION_DESCRIPTOR	The WHEA_ERROR_RECORD_SECTION_DESCRIPTOR structure describes a section of error information that is part of an error record.
WHEA_ERROR_RECORD_SECTION_DESCRIPTOR_VALIDBITS	The WHEA_ERROR_RECORD_SECTION_DESCRIPTOR_VALIDBITS union describes which members of a WHEA_ERROR_RECORD_SECTION_DESCRIPTOR structure contain valid data.
WHEA_ERROR_STATUS	The WHEA_ERROR_STATUS union describes generic error codes that are abstracted from the data contained in implementation-specific error registers.
WHEA_FIRMWARE_ERROR_RECORD_REFERENCE	The WHEA_FIRMWARE_ERROR_RECORD_REFERENCE structure describes a reference to a firmware error record that is specific to the Itanium processor architecture.
WHEA_GENERIC_ERROR	The WHEA_GENERIC_ERROR structure describes error status data for a generic error source.
WHEA_GENERIC_ERROR_BLOCKSTATUS	The WHEA_GENERIC_ERROR_BLOCKSTATUS union indicates what kind of error data is reported in a generic error status block.
WHEA_GENERIC_ERROR_DATA_ENTRY_V2	The WHEA_GENERIC_ERROR_DATA_ENTRY structure describes an error data section in a generic error status block.
WHEA_GENERIC_ERROR_DESCRIPTOR	The WHEA_GENERIC_ERROR_DESCRIPTOR structure describes a generic error source.
WHEA_IPF_CMC_DESCRIPTOR	The WHEA_IPF_CMC_DESCRIPTOR structure describes a corrected machine check (CMC) error source for an Itanium processor.
WHEA_IPF_CPE_DESCRIPTOR	The WHEA_IPF_CPE_DESCRIPTOR structure describes a corrected platform error (CPE) error source for an Itanium processor.
WHEA_IPF_MCA_DESCRIPTOR	The WHEA_IPF_MCA_DESCRIPTOR structure describes a machine check abort (MCA) error source for an Itanium processor.

TITLE	DESCRIPTION
WHEA_MEMORY_ERROR_SECTION	The WHEA_MEMORY_ERROR_SECTION structure describes platform memory error data.
WHEA_MEMORY_ERROR_SECTION_VALIDBITS	The WHEA_MEMORY_ERROR_SECTION_VALIDBITS union describes which members of a WHEA_MEMORY_ERROR_SECTION structure contain valid data.
WHEA_NMI_ERROR_SECTION	The WHEA_NMI_ERROR_SECTION structure describes nonmaskable interrupt (NMI) error data.
WHEA_NOTIFICATION_DESCRIPTOR	The WHEA_NOTIFICATION_DESCRIPTOR structure describes the notification mechanism that is used by an error source.
WHEA_PCI_SLOT_NUMBER	The WHEA_PCI_SLOT_NUMBER structure describes a logical PCI slot.
WHEA_PCIEXPRESS_ERROR_SECTION	The WHEA_PCIEXPRESS_ERROR_SECTION structure describes PCI Express (PCIe) error data.
WHEA_PCIEXPRESS_ERROR_SECTION_VALIDBITS	The WHEA_PCIEXPRESS_ERROR_SECTION_VALIDBITS union describes which members of a WHEA_PCIEXPRESS_ERROR_SECTION structure contain valid data.
WHEA_PCIXBUS_ERROR_SECTION	The WHEA_PCIXBUS_ERROR_SECTION structure describes PCI or PCI-X bus error data.
WHEA_PCIXBUS_ERROR_SECTION_VALIDBITS	The WHEA_PCIXBUS_ERROR_SECTION_VALIDBITS union describes which members of a WHEA_PCIXBUS_ERROR_SECTION structure contain valid data.
WHEA_PCIXDEVICE_ERROR_SECTION	The WHEA_PCIXDEVICE_ERROR_SECTION structure describes PCI or PCI-X device error data.
WHEA_PCIXDEVICE_ERROR_SECTION_VALIDBITS	The WHEA_PCIXDEVICE_ERROR_SECTION_VALIDBITS union describes which members of a WHEA_PCIXDEVICE_ERROR_SECTION structure contain valid data.
WHEA_PERSISTENCE_INFO	The WHEA_PERSISTENCE_INFO union describes data that is used by the error record persistence interface for storing an error record.
WHEA_PROCESSOR_FAMILY_INFO	The WHEA_PROCESSOR_FAMILY_INFO union describes the processor family information for an x86 or x64 processor.
WHEA_PROCESSOR_GENERIC_ERROR_SECTION	Describes processor error data that is not specific to a particular processor architecture.
WHEA_PROCESSOR_GENERIC_ERROR_SECTION_VALIDBITS	The WHEA_PROCESSOR_GENERIC_ERROR_SECTION_VALIDBITS union describes which members of a WHEA_PROCESSOR_GENERIC_ERROR_SECTION structure contain valid data.

TITLE	DESCRIPTION
WHEA_PSHED_PLUGIN_CALLBACKS	The WHEA_PSHED_PLUGIN_CALLBACKS structure describes the callback functions for a PSHED plug-in.
WHEA_PSHED_PLUGIN_REGISTRATION_PACKET	The WHEA_PSHED_PLUGIN_REGISTRATION_PACKET structure describes the data required for registering a PSHED plug-in with the PSHED.
WHEA_REVISION	The WHEA_REVISION union describes the revision of the error record data structures.
WHEA_TIMESTAMP	The WHEA_TIMESTAMP union describes the time that an error was reported to the operating system.
WHEA_X64_REGISTER_STATE	The WHEA_X64_REGISTER_STATE structure describes the state of an x64 processor's registers.
WHEA_X86_REGISTER_STATE	The WHEA_X86_REGISTER_STATE structure describes the state of an x86 processor's registers.
WHEA_XPF_BUS_CHECK	The WHEA_XPF_BUS_CHECK union describes bus error information for an x86 or x64 processor.
WHEA_XPF_CACHE_CHECK	The WHEA_XPF_CACHE_CHECK union describes cache error information for an x86 or x64 processor.
WHEA_XPF_CMC_DESCRIPTOR	The WHEA_XPF_CMC_DESCRIPTOR structure describes a corrected machine check (CMC) error source for an x86 or x64 processor.
WHEA_XPF_CONTEXT_INFO	The WHEA_XPF_CONTEXT_INFO structure describes processor context information for an x86 or x64 processor.
WHEA_XPF_MC_BANK_DESCRIPTOR	The WHEA_XPF_MC_BANK_DESCRIPTOR structure describes a bank of machine check registers for an x86 or x64 processor.
WHEA_XPF_MCA_SECTION	
WHEA_XPF_MCE_DESCRIPTOR	The WHEA_XPF_MCE_DESCRIPTOR structure describes a machine check exception (MCE) error source for an x86 or x64 processor.
WHEA_XPF_MS_CHECK	The WHEA_XPF_MS_CHECK union describes microarchitecture-specific error information for an x86 or x64 processor.
WHEA_XPF_NMI_DESCRIPTOR	The WHEA_XPF_NMI_DESCRIPTOR structure describes a nonmaskable interrupt (NMI) error source for an x86 or x64 processor.
WHEA_XPF_PROCESSOR_ERROR_SECTION	The WHEA_XPF_PROCESSOR_ERROR_SECTION structure describes processor error data that is specific to the x86/x64 processor architecture.

TITLE	DESCRIPTION
WHEA_XPF_PROCESSOR_ERROR_SECTION_VALIDBITS	The WHEA_XPF_PROCESSOR_ERROR_SECTION_VALIDBITS union describes which members of a WHEA_XPF_PROCESSOR_ERROR_SECTION structure contain valid data and the number of structures that are contained in the WHEA_XPF_PROCESSOR_ERROR_SECTION structure's VariableInfo member.
WHEA_XPF_PROCINFO	The WHEA_XPF_PROCINFO structure describes processor error information that is specific to the x86 and x64 processor architectures.
WHEA_XPF_PROCINFO_VALIDBITS	The WHEA_XPF_PROCINFO_VALIDBITS union describes which members of a WHEA_XPF_PROCINFO structure contain valid data.
WHEA_XPF_TLB_CHECK	The WHEA_XPF_TLB_CHECK union describes translation lookaside buffer (TLB) error information for an x86 or x64 processor.

Enumerations

TITLE	DESCRIPTION
BDCB_CALLBACK_TYPE	The BDCB_CALLBACK_TYPE enumeration specifies whether the callback being passed to a BOOT_DRIVER_CALLBACK_FUNCTION routine is a status update or a boot-start driver initialization notification.
BDCB_CLASSIFICATION	The BDCB_CLASSIFICATION enumeration lists different classifications of boot start images.
BDCB_STATUS_UPDATE_TYPE	The BDCB_STATUS_UPDATE_TYPE enumeration lists the types of boot-driver callback status updates.
BUS_DATA_TYPE	The BUS_DATA_TYPE enumeration indicates the type of bus configuration space.
HAL_QUERY_INFORMATION_CLASS	The values are reserved for internal use.
HAL_SET_INFORMATION_CLASS	The values are reserved for internal use.
HARDWARE_COUNTER_TYPE	The HARDWARE_COUNTER_TYPE enumeration specifies the type of a hardware counter.
PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR_TYPE	The PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR_TYPE enumeration contains constants that indicate the type of hardware performance counter resource that is described by a PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR structure.
PROCESS_MITIGATION_POLICY	Represents the different process mitigation policies.
PSCREATEPROCESSNOTIFYTYPE	Indicates the type of process notification. This enumeration is used in PsSetCreateProcessNotifyRoutineEx2 to register callback notifications.

TITLE	DESCRIPTION
PSCREATETHREADNOTIFYTYPE	Indicates the type of thread notification. This enumeration is used in PsSetCreateThreadNotifyRoutineEx to register callback notifications associated with thread creation or deletion.
SOC_SUBSYSTEM_TYPE	The SOC_SYBSYSTEM_TYPE enumeration defines different types of System on a Chip (SoC) subsystems.
STATE_LOCATION_TYPE	Defines values for persisted state locations for device and driver files.
SUBSYSTEM_INFORMATION_TYPE	Indicates the type of subsystem for a process or thread. This enumeration is used in NtQueryInformationProcess and NtQueryInformationThread calls.
WELL_KNOWN_SID_TYPE	A list of commonly used security identifiers (SIDs). Programs can pass these values to the **CreateWellKnownSid** function to create a SID from this list. For information about these values, see WELL_KNOWN_SID_TYPE.
WHEA_ERROR_PACKET_DATA_FORMAT	The WHEA_ERROR_PACKET_DATA_FORMAT enumeration defines the raw hardware error data format in a hardware error packet.
WHEA_ERROR_SEVERITY	The WHEA_ERROR_SEVERITY enumeration defines the possible severity levels of a hardware error condition.
WHEA_ERROR_SOURCE_STATE	The WHEA_ERROR_SOURCE_STATE enumeration defines the different runtime states for an error source.
WHEA_ERROR_SOURCE_TYPE	The WHEA_ERROR_SOURCE_TYPE enumeration defines the different types of error sources that can report hardware errors.
WHEA_ERROR_TYPE	The WHEA_ERROR_TYPE enumeration defines the different types of hardware components that can report a hardware error.
WHEA_RAW_DATA_FORMAT	The WHEA_RAW_DATA_FORMAT enumeration defines the possible formats that raw hardware error data can be encoded in a hardware error packet.

BDCB_CALLBACK_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The BDCB_CALLBACK_TYPE enumeration specifies whether the callback being passed to a BOOT_DRIVER_CALLBACK_FUNCTION routine is a status update or a boot-start driver initialization notification.

Syntax

```
typedef enum _BDCB_CALLBACK_TYPE {
  BdCbStatusUpdate,
  BdCbInitializeImage
} BDCB_CALLBACK_TYPE, *PBDCB_CALLBACK_TYPE;
```

Constants

BdCbStatusUpdate	A status update provided by the system to a boot-start driver.
BdCbInitializeImage	A boot image is about to be initialized. During this callback, boot-start drivers may classify a boot image as a known good image or a known bad image.

Remarks

The two callback types have unique context structures that provide additional information specific to the callback.

VALUE	CORRESPONDING STRUCTURE TO USE
BdCbStatusUpdate	BDCB_STATUS_UPDATE_TYPE
BdCbInitializeImage	BDCB_CLASSIFICATION

Requirements

Minimum supported client	Available starting with Windows 8.
Header	ntddk.h (include Ntddk.h)

See Also

BDCB_CLASSIFICATION

BDCB_STATUS_UPDATE_TYPE

BOOT_DRIVER_CALLBACK_FUNCTION

BDCB_CLASSIFICATION Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The BDCB_CLASSIFICATION enumeration lists different classifications of boot start images.

Syntax

```
typedef enum _BDCB_CLASSIFICATION {
  BdCbClassificationUnknownImage,
  BdCbClassificationKnownGoodImage,
  BdCbClassificationKnownBadImage,
  BdCbClassificationKnownBadImageBootCritical,
  BdCbClassificationEnd
} BDCB_CLASSIFICATION, *PBDCB_CLASSIFICATION;
```

Constants

BdCbClassificationUnknownImage	The boot start image has not been inspected by anti-malware or anti-malware does not have enough information to determine whether the binary is malware.
BdCbClassificationKnownGoodImage	The boot start image has been inspected by anti-malware and found not to be malware.
BdCbClassificationKnownBadImage	The boot start image has been inspected by anti-malware and found to be malware.
BdCbClassificationKnownBadImageBootCritical	The boot start image has been inspected by anti-malware and found to be malware, but the anti-malware boot-start driver also knows it to be critical to the success of the boot.
BdCbClassificationEnd	Do not use. Reserved for future use.

Requirements

Minimum supported client	Available starting with Windows 8.
Header	ntddk.h (include Ntddk.h)

BDCB_IMAGE_INFORMATION

BOOT_DRIVER_CALLBACK_FUNCTION

BDCB_IMAGE_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **BDCB_IMAGE_INFORMATION** structure describes information about a boot-start driver that is about to be initialized, provided by Windows to a boot-start driver's BOOT_DRIVER_CALLBACK_FUNCTION routine.

Syntax

```
typedef struct _BDCB_IMAGE_INFORMATION {
  BDCB_CLASSIFICATION Classification;
  ULONG               ImageFlags;
  UNICODE_STRING      ImageName;
  UNICODE_STRING      RegistryPath;
  UNICODE_STRING      CertificatePublisher;
  UNICODE_STRING      CertificateIssuer;
  PVOID               ImageHash;
  PVOID               CertificateThumbprint;
  ULONG               ImageHashAlgorithm;
  ULONG               ThumbprintHashAlgorithm;
  ULONG               ImageHashLength;
  ULONG               CertificateThumbprintLength;
} BDCB_IMAGE_INFORMATION, *PBDCB_IMAGE_INFORMATION;
```

Members

`Classification`

The classification of the boot start image.

`ImageFlags`

Bit flags that describe the image. The following values are defined.

VALUE	MEANING
Bit 0	The boot start image is a dependent DLL.
Bit 1	The boot start image failed code integrity but load was allowed because of boot policy (code integrity not required on the platform, or code integrity disabled because of boot setting, debugging, or both).
Bits 2-31	Do not use. Reserved.

`ImageName`

The name of the boot-start driver's binary image.

`RegistryPath`

The path in the registry where the boot-start driver is registered.

`CertificatePublisher`

The publisher of the image's certificate. If the image is not signed, the string is empty ("").

`CertificateIssuer`

The issuer of the image's certificate. If the image is not signed, the string is empty ("").

`ImageHash`

The Authenticode hash of the image, which can be calculated by using SignTool.exe (Sign Tool).

`CertificateThumbprint`

The hash of the certificate of the signer to be signed. Run **certutil –dump x,cer** to view this value as "Signature Hash".

`ImageHashAlgorithm`

The algorithm of the image hash. The following values are listed for reference.

VALUE
ALG_CLASS_HASH
ALG_CLASS_ANY
ALG_SID_MD5
ALG_SID_SHA1
ALG_SID_SHA_256
ALG_SID_SHA_384
ALG_SID_SHA_512
CALG_MD5
CALG_SHA1
CALG_SHA_256
CALG_SHA_384
CALG_SHA_512

`ThumbprintHashAlgorithm`

The algorithm of the certificate thumbprint. This member should be ignored if **CertificateThumbprint** is NULL.

`ImageHashLength`

The length of data pointed to by the **ImageHash** member.

`CertificateThumbprintLength`

The length of data pointed to by the **CertificateThumbprint** member.

Requirements

Minimum supported client	Available starting with Windows 8.
Header	ntddk.h (include Ntddk.h)

BDCB_CLASSIFICATION

BOOT_DRIVER_CALLBACK_FUNCTION

BDCB_STATUS_UPDATE_CONTEXT structure

1/30/2019 • 2 minutes to read • Edit Online

The BDCB_STATUS_UPDATE_CONTEXT structure describes a status update provided by Windows to a boot-start driver's BOOT_DRIVER_CALLBACK_FUNCTION routine.

Syntax

```
typedef struct _BDCB_STATUS_UPDATE_CONTEXT {
  BDCB_STATUS_UPDATE_TYPE StatusType;
} BDCB_STATUS_UPDATE_CONTEXT, *PBDCB_STATUS_UPDATE_CONTEXT;
```

Members

`StatusType`

The type of the status update.

Remarks

Boot-start drivers must not unregister their boot-start driver callbacks during a callback. Doing so may result in a bug check. To properly unregister a boot-driver callback, boot-start drivers must specify an Unload routine in their driver object and call IoUnRegisterBootDriverCallback from within the Unload dispatch routine.

Requirements

Minimum supported client	Available starting with Windows 8.
Header	ntddk.h (include Ntddk.h)

See Also

BDCB_STATUS_UPDATE_TYPE

BOOT_DRIVER_CALLBACK_FUNCTION

IoUnRegisterBootDriverCallback

BDCB_STATUS_UPDATE_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The BDCB_STATUS_UPDATE_TYPE enumeration lists the types of boot-driver callback status updates.

Syntax

```
typedef enum _BDCB_STATUS_UPDATE_TYPE {
  BdCbStatusPrepareForDependencyLoad,
  BdCbStatusPrepareForDriverLoad,
  BdCbStatusPrepareForUnload
} BDCB_STATUS_UPDATE_TYPE, *PBDCB_STATUS_UPDATE_TYPE;
```

Constants

BdCbStatusPrepareForDependencyLoad	Windows will start loading driver dependencies next.
BdCbStatusPrepareForDriverLoad	Windows has completed loading driver dependencies and will start loading boot-start drivers.
BdCbStatusPrepareForUnload	Windows has completed the initialization of all boot-start drivers. After the completion of this callback, the Boot Driver Callback Facility will be torn down and no more callbacks will be received. During this callback, Early Launch AM drivers must clean up and prepare to be unloaded.

Requirements

Minimum supported client	Available starting with Windows 8.
Header	ntddk.h (include Ntddk.h)

See Also

BDCB_STATUS_UPDATE_CONTEXT

BOOT_DRIVER_CALLBACK_FUNCTION

BUS_DATA_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **BUS_DATA_TYPE** enumeration indicates the type of bus configuration space.

Syntax

```
typedef enum _BUS_DATA_TYPE {
  ConfigurationSpaceUndefined,
  Cmos,
  EisaConfiguration,
  Pos,
  CbusConfiguration,
  PCIConfiguration,
  VMEConfiguration,
  NuBusConfiguration,
  PCMCIAConfiguration,
  MPIConfiguration,
  MPSAConfiguration,
  PNPISAConfiguration,
  SgiInternalConfiguration,
  MaximumBusDataType
} BUS_DATA_TYPE, *PBUS_DATA_TYPE;
```

Constants

ConfigurationSpaceUndefined	Indicates that the type of bus configuration space is undefined.
Cmos	Indicates CMOS data.
EisaConfiguration	Indicates an EISA bus configuration space.
Pos	For internal use only.
CbusConfiguration	Indicates Cbus configuration space.
PCIConfiguration	Indicates PCI configuration space.
VMEConfiguration	Indicates VME configuration space.
NuBusConfiguration	Indicates NuBus configuration space.
PCMCIAConfiguration	Indicates PCMCIA configuration space.
MPIConfiguration	Indicates MPI configuration space.
MPSAConfiguration	Indicates MPSA configuration space.
PNPISAConfiguration	Indicates PNPISA configuration space.

SgiInternalConfiguration	Indicates SGI internal bus configuration space.
MaximumBusDataType	Indicates the upper limit of the bus configuration space types.

Requirements

Header	ntddk.h (include Ntddk.h, Miniport.h)

HalSetBusDataByOffset

CONTROLLER_OBJECT structure

1/30/2019 • 2 minutes to read • Edit Online

A controller object represents a hardware adapter or controller with homogenous devices that are the actual targets for I/O requests. A controller object can be used to synchronize a device driver's I/O to the target devices through its hardware adapter/controller.

A controller object is partially opaque. Driver writers must know about a certain field associated with the controller object because their drivers access this field through the controller object pointer returned by **IoCreateController**. The following field in a controller object is accessible to the creating driver.

Syntax

```
typedef struct _CONTROLLER_OBJECT {
  CSHORT         Type;
  CSHORT         Size;
  PVOID          ControllerExtension;
  KDEVICE_QUEUE DeviceWaitQueue;
  ULONG          Spare1;
  LARGE_INTEGER Spare2;
} CONTROLLER_OBJECT, *PCONTROLLER_OBJECT;
```

Members

`Type`

`Size`

`ControllerExtension`

Pointer to the controller extension. The structure and contents of the controller extension are driver-defined. The size is driver-determined, specified in the driver's call to **IoCreateController**. Usually, drivers maintain common state about I/O operations in the controller extension and device-specific state about I/O for a target device in the corresponding device extension.

`DeviceWaitQueue`

`Spare1`

`Spare2`

Remarks

Most driver routines that process IRPs are given a pointer to the target device object. Consequently, device drivers that use controller objects frequently store the controller object pointer returned by **IoCreateController** in each device extension.

Note that a controller object has no name so it cannot be the target of an I/O request, and higher-level drivers cannot connect or attach their device objects to a device driver's controller object.

Undocumented fields within a controller object should be considered inaccessible. Drivers with dependencies on object field locations or access to undocumented fields might not remain portable and interoperable with other drivers over time.

Requirements

Header	ntddk.h (include Ntddk.h)

See Also

IoCreateController

FILE_ALIGNMENT_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_ALIGNMENT_INFORMATION** structure is used as an argument to the ZwQueryInformationFile routine.

Syntax

```
typedef struct _FILE_ALIGNMENT_INFORMATION {
  ULONG AlignmentRequirement;
} FILE_ALIGNMENT_INFORMATION, *PFILE_ALIGNMENT_INFORMATION;
```

Members

`AlignmentRequirement`

The buffer alignment required by the underlying device. For a list of system-defined values, see DEVICE_OBJECT. The value must be one of the FILE_*XXX*_ALIGNMENT values defined in Wdm.h. For more information, see DEVICE_OBJECT and Initializing a Device Object.

Requirements

Header	ntddk.h (include Ntddk.h, Ntifs.h)

See Also

DEVICE_OBJECT

ZwQueryInformationFile

ZwSetInformationFile

FILE_ATTRIBUTE_TAG_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_ATTRIBUTE_TAG_INFORMATION** structure is used as an argument to ZwQueryInformationFile.

Syntax

```
typedef struct _FILE_ATTRIBUTE_TAG_INFORMATION {
  ULONG FileAttributes;
  ULONG ReparseTag;
} FILE_ATTRIBUTE_TAG_INFORMATION, *PFILE_ATTRIBUTE_TAG_INFORMATION;
```

Members

`FileAttributes`

Specifies one or more FILE_ATTRIBUTE_*XXX* flags. For descriptions of these flags, see the documentation of the **GetFileAttributes** function in the Microsoft Windows SDK.

`ReparseTag`

Specifies the reparse point tag. If the **FileAttributes** member includes the FILE_ATTRIBUTE_REPARSE_POINT attribute flag, this member specifies the reparse tag. Otherwise, this member is unused.

Remarks

FILE_READ_ATTRIBUTES access to the file is required to query this information.

For more information about reparse points and reparse point tags, see the Windows SDK.

This structure must be aligned on a LONG (4-byte) boundary.

Requirements

Header	ntddk.h (include Ntddk.h, Ntifs.h)

See Also

ZwQueryInformationFile

FILE_DISPOSITION_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_DISPOSITION_INFORMATION** structure is used as an argument to the ZwSetInformationFile routine.

Syntax

```
typedef struct _FILE_DISPOSITION_INFORMATION {
  BOOLEAN DeleteFile;
} FILE_DISPOSITION_INFORMATION, *PFILE_DISPOSITION_INFORMATION;
```

Members

`DeleteFile`

Indicates whether the operating system file should delete the file when the file is closed. Set this member to **TRUE** to delete the file when it is closed. Otherwise, set to **FALSE**. Setting this member to **FALSE** has no effect if the handle was opened with FILE_FLAG_DELETE_ON_CLOSE.

Remarks

The caller must have DELETE access to a given file in order to call **ZwSetInformationFile** with **DeleteFile** set to **TRUE** in this structure. Subsequently, the only legal operation by such a caller is to close the open file handle.

A file marked for deletion is not actually deleted until all open handles for the file object have been closed and the link count for the file is zero.

Requirements

Header	ntddk.h (include Ntddk.h, Ntifs.h)

See Also

ZwClose

ZwSetInformationFile

FILE_END_OF_FILE_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_END_OF_FILE_INFORMATION** structure is used as an argument to the ZwSetInformationFile routine.

Syntax

```
typedef struct _FILE_END_OF_FILE_INFORMATION {
  LARGE_INTEGER EndOfFile;
} FILE_END_OF_FILE_INFORMATION, *PFILE_END_OF_FILE_INFORMATION;
```

Members

`EndOfFile`

The absolute new end of file position as a byte offset from the start of the file.

Remarks

EndOfFile specifies the byte offset to the end of the file. Because this value is zero-based, it actually refers to the first free byte in the file: that is, it is the offset to the byte immediately following the last valid byte in the file.

Requirements

Header	ntddk.h (include Ntddk.h, Ntifs.h)

See Also

ZwQueryInformationFile

ZwSetInformationFile

FILE_NAME_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_NAME_INFORMATION** structure is used as argument to the ZwQueryInformationFile and ZwSetInformationFile routines.

Syntax

```
typedef struct _FILE_NAME_INFORMATION {
  ULONG FileNameLength;
  WCHAR FileName[1];
} FILE_NAME_INFORMATION, *PFILE_NAME_INFORMATION;
```

Members

`FileNameLength`

Specifies the length, in bytes, of the file name string.

`FileName`

Specifies the first character of the file name string. This is followed in memory by the remainder of the string.

Remarks

The **ZwQueryInformationFile** routine uses this structure to return the file name string to the caller. For more information about the form of the name returned, see ZwQueryInformationFile.

Callers of ZwSetInformationFile can use this structure to specify a new short name for a file.

Requirements

Header	ntddk.h (include Ntddk.h)

See Also

ZwQueryInformationFile

ZwSetInformationFile

FILE_VALID_DATA_LENGTH_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_VALID_DATA_LENGTH_INFORMATION** structure is used as an argument to ZwSetInformationFile.

Syntax

```
typedef struct _FILE_VALID_DATA_LENGTH_INFORMATION {
  LARGE_INTEGER ValidDataLength;
} FILE_VALID_DATA_LENGTH_INFORMATION, *PFILE_VALID_DATA_LENGTH_INFORMATION;
```

Members

`ValidDataLength`

Specifies the new valid data length for the file. This parameter must be a positive value that is greater than the current valid data length, but less than or equal to the current file size.

Remarks

The **FILE_VALID_DATA_LENGTH_INFORMATION** structure is used to set a new valid data length for a file on an NTFS volume. A file's *valid data length* is the length, in bytes, of the data that has been written to the file. This *valid data* extends from the beginning of the file to the last byte in the file that has not been zeroed or left uninitialized.

Setting this information requires FILE_WRITE_DATA access to the file. In addition, nonadministrators and remote users must have **SeManageVolumePrivilege** (SE_MANAGE_VOLUME_PRIVILEGE) for the volume on which the file resides.

File system filter drivers can find it useful to set a valid data length in the following scenarios:

- When writing raw clusters directly to disk through a hardware channel. This allows the filter driver to inform the file system that this range contains valid data that can be returned to the user.
- When creating large files where performance is an issue. This avoids the time it takes to fill the file with zeros when the file is created or extended.
- When remotely extending a file and writing to disk on a served-metadata cluster file system.

The size of the *FileInformation* buffer passed to **ZwSetInformationFile** must be at least **sizeof**(**FILE_VALID_DATA_LENGTH_INFORMATION**).

This structure must be aligned on a LONGLONG (8-byte) boundary.

Requirements

Minimum supported client	Available on Microsoft Windows XP and later versions of the Windows operating system.

Header	ntddk.h (include Ntddk.h)

See Also

ZwSetInformationFile

HARDWARE_COUNTER structure

1/30/2019 • 2 minutes to read • Edit Online

The **HARDWARE_COUNTER** structure contains information about a hardware counter.

Syntax

```
typedef struct _HARDWARE_COUNTER {
  HARDWARE_COUNTER_TYPE Type;
  ULONG                 Reserved;
  ULONG64               Index;
} HARDWARE_COUNTER, *PHARDWARE_COUNTER;
```

Members

`Type`

Specifies the type of the hardware counter. Set this member to the following HARDWARE_COUNTER_TYPE enumeration value:

- **PMCCounter**

`Reserved`

Reserved for use by the operating system. Initialize this member to zero.

`Index`

Specifies the hardware counter index. Each hardware counter in a performance monitoring unit (PMU) for a processor is identified by an index.

Remarks

This structure is used by the KeQueryHardwareCounterConfiguration and KeSetHardwareCounterConfiguration routines.

The **Type** member specifies the type of hardware counter that is described by the structure. In Windows 7, the only defined hardware counter type is **PMCCounter**, which is a performance monitor counter. This type of counter is used by thread-profiling applications.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of Windows.
Header	ntddk.h (include Ntddk.h)

See Also

HARDWARE_COUNTER_TYPE

KeQueryHardwareCounterConfiguration

KeSetHardwareCounterConfiguration

HARDWARE_COUNTER_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **HARDWARE_COUNTER_TYPE** enumeration specifies the type of a hardware counter.

Syntax

```
typedef enum _HARDWARE_COUNTER_TYPE {
  PMCCounter,
  MaxHardwareCounterType
} HARDWARE_COUNTER_TYPE, *PHARDWARE_COUNTER_TYPE;
```

Constants

PMCCounter	Performance monitor counter. This type of counter is used by thread-profiling applications.
MaxHardwareCounterType	The maximum value in this enumeration type.

Remarks

The **Type** member of the HARDWARE_COUNTER structure contains a **HARDWARE_COUNTER_TYPE** enumeration value.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of Windows.
Header	ntddk.h (include Winnt.h, Ntddk.h)

HARDWARE_COUNTER

IMAGE_INFO structure

2/5/2019 • 2 minutes to read • Edit Online

Used by driver's load-image routine (PLOAD_IMAGE_NOTIFY_ROUTINE) to specify image information.

Syntax

```
typedef struct _IMAGE_INFO {
  union {
    ULONG Properties;
    struct {
      ULONG ImageAddressingMode : 8;
      ULONG SystemModeImage : 1;
      ULONG ImageMappedToAllPids : 1;
      ULONG ExtendedInfoPresent : 1;
      ULONG MachineTypeMismatch : 1;
      ULONG ImageSignatureLevel : 4;
      ULONG ImageSignatureType : 3;
      ULONG ImagePartialMap : 1;
      ULONG Reserved : 12;
    };
  };
  PVOID  ImageBase;
  ULONG  ImageSelector;
  SIZE_T ImageSize;
  ULONG  ImageSectionNumber;
} IMAGE_INFO, *PIMAGE_INFO;
```

Members

`Properties`

`ImageAddressingMode`

Always set to IMAGE_ADDRESSING_MODE_32BIT.

`SystemModeImage`

Set either to one for newly loaded kernel-mode components, such as drivers, or to zero for images that are mapped into user space.

`ImageMappedToAllPids`

Always set to zero.

`ExtendedInfoPresent`

If the **ExtendedInfoPresent** flag is set, the **IMAGE_INFO** structure is part of a larger, extended version of the image information structure (see IMAGE_INFO_EX). Added in Windows Vista. For more information, see "Extended version of the image information structure" later in this Remarks section.

`MachineTypeMismatch`

Always set to zero. Added in Windows 8/Windows Server 2012.

`ImageSignatureLevel`

The level of signature with which code integrity has labeled the image. This value is one of the `#define SE_SIGNING_LEVEL_*` constants in ntddk.h. Added in Windows 8.1/Windows Server 2012 R2.

`ImageSignatureType`

The type of signature with which code integrity has labeled the image. This value is a **SE_IMAGE_SIGNATURE_TYPE** enumeration value, defined in ntddk.h. Added in Windows 8.1/Windows Server 2012 R2.

`ImagePartialMap`

This value is non-zero if the image mapping view called out for is a partial view that does not map the entire image; 0 if the view maps the entire image. Added in Windows 10/Windows Server 2016.

`Reserved`

Always set to zero.

`ImageBase`

Set to the virtual base address of the image.

`ImageSelector`

Always set to zero.

`ImageSize`

Set to the virtual size, in bytes, of the image.

`ImageSectionNumber`

Always set to zero.

Remarks

If the **ExtendedInfoPresent** flag is set, the **IMAGE_INFO** structure is part of a larger, extended version of the image information structure, IMAGE_INFO_EX.

Requirements

Header	ntddk.h (include Ntddk.h)

See Also

IMAGE_INFO_EX

PLOAD_IMAGE_NOTIFY_ROUTINE

PsSetLoadImageNotifyRoutine

IMAGE_INFO_EX structure

1/30/2019 • 2 minutes to read • Edit Online

Extended version of the image information structure (see IMAGE_INFO).

Syntax

```
typedef struct _IMAGE_INFO_EX {
  SIZE_T               Size;
  IMAGE_INFO           ImageInfo;
  struct _FILE_OBJECT *FileObject;
} IMAGE_INFO_EX, *PIMAGE_INFO_EX;
```

Members

`Size`

Specifies the size, in bytes, of the **IMAGE_INFO_EX** structure.

`ImageInfo`

An IMAGE_INFO structure that specifies image information.

`FileObject`

Contains a pointer to the file object of the backing file for the image. The driver can take a reference to this object or use it for other operations.

Remarks

If the **ExtendedInfoPresent** flag is set, the **IMAGE_INFO** structure is part of a larger, extended version of the image information structure. In this case, the load-image notify routine can use the **CONTAINING_RECORD** macro in the Winnt.h header file to obtain the base address of the **IMAGE_INFO_EX** structure.

Requirements

Header	ntddk.h (include Ntddk.h)

See Also

KEY_CACHED_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **KEY_CACHED_INFORMATION** structure holds the cached information available for a registry key or subkey.

Syntax

```
typedef struct _KEY_CACHED_INFORMATION {
  LARGE_INTEGER LastWriteTime;
  ULONG         TitleIndex;
  ULONG         SubKeys;
  ULONG         MaxNameLen;
  ULONG         Values;
  ULONG         MaxValueNameLen;
  ULONG         MaxValueDataLen;
  ULONG         NameLength;
} KEY_CACHED_INFORMATION, *PKEY_CACHED_INFORMATION;
```

Members

`LastWriteTime`

The last time the key or any of its values changed. This time value is expressed in absolute system time format. Absolute system time is the number of 100-nanosecond intervals since the start of the year 1601 in the Gregorian calendar.

`TitleIndex`

Device and intermediate drivers should ignore this member.

`SubKeys`

The number of subkeys for a key.

`MaxNameLen`

The maximum number of bytes for a subkey name.

`Values`

The number of value entries.

`MaxValueNameLen`

The maximum length, in bytes, of any value entry name.

`MaxValueDataLen`

The maximum length, in bytes, of a value entry data field.

`NameLength`

The size, in bytes, of the key name.

Requirements

Minimum supported client	Available in Windows Vista and later versions of the Windows operating system.
Header	ntddk.h (include Ntddk.h)

KEY_NAME_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **KEY_NAME_INFORMATION** structure holds the name and name length of the key.

Syntax

```
typedef struct _KEY_NAME_INFORMATION {
  ULONG NameLength;
  WCHAR Name[1];
} KEY_NAME_INFORMATION, *PKEY_NAME_INFORMATION;
```

Members

`NameLength`

The size, in bytes, of the key name string in the **Name** array.

`Name`

An array of wide characters that contains the name of the key. This character string is not null-terminated. Only the first element in this array is included in the **KEY_NAME_INFORMATION** structure definition. The storage for the remaining elements in the array immediately follows this element.

Remarks

The ZwQueryKey routine uses the **KEY_NAME_INFORMATION** structure to contain the registry key name. When the *KeyInformationClass* parameter of this routine is **KeyNameInformation**, the *KeyInformation* buffer is treated as a **KEY_NAME_INFORMATION** structure. For more information about the **KeyNameInformation** enumeration value, see KEY_INFORMATION_CLASS.

KEY_VIRTUALIZATION_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **KEY_VIRTUALIZATION_INFORMATION** structure defines the basic information that is available for a registry key or subkey.

Syntax

```
typedef struct _KEY_VIRTUALIZATION_INFORMATION {
  ULONG VirtualizationCandidate : 1;
  ULONG VirtualizationEnabled : 1;
  ULONG VirtualTarget : 1;
  ULONG VirtualStore : 1;
  ULONG VirtualSource : 1;
  ULONG Reserved : 27;
} KEY_VIRTUALIZATION_INFORMATION, *PKEY_VIRTUALIZATION_INFORMATION;
```

Members

`VirtualizationCandidate`

Specifies whether the key is part of the virtualization namespace scope.

`VirtualizationEnabled`

Specifies whether virtualization is enabled on this key. This value can be set to 1 only if **VirtualizationCandidate** is 1.

`VirtualTarget`

Specifies whether the key is a virtual key. This value can be set to 1 only if **VirtualizationCandidate** and **VirtualizationEnabled** are both 0. This value is valid only on the virtual store key handles.

`VirtualStore`

Specified whether the key is a part of the virtual store path.

`VirtualSource`

Specifies whether the key has ever been virtualized. This value can be set to 1 only if **VirtualizationCandidate** is 1.

`Reserved`

This value is reserved for system use.

Requirements

Minimum supported client	Available on Windows Vista and later versions of the Windows operating system.

MmCopyMemory

PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR structure

1/30/2019 • 2 minutes to read • Edit Online

The **PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR** structure describes the counter resources available on the platform.

Syntax

```
typedef struct _PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR {
  PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR_TYPE Type;
  ULONG                                     Flags;
  union {
    ULONG CounterIndex;
    ULONG ExtendedRegisterAddress;
    struct {
      ULONG Begin;
      ULONG End;
    } Range;
  } u;
} PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR, *PPHYSICAL_COUNTER_RESOURCE_DESCRIPTOR;
```

Members

`Type`

Indicates the type of counter resource described by the structure. Set this parameter to one of the following PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR_TYPE enumeration constants:

- **ResourceTypeSingle**
- **ResourceTypeRange**
- **ResourceTypeExtendedCounterConfiguration**
- **ResourceTypeOverflow**

`Flags`

No flags are currently defined. Set this member to zero.

`u`

A union that can contain a **CounterIndex**, **ExtendedRegisterAddress**, or **Range** value.

`u.CounterIndex`

A physical counter index.

`u.ExtendedRegisterAddress`

An extended configuration register address.

`u.Range`

`u.Range.Begin`

The starting counter index of a block of contiguous counters.

`u.Range.End`

The ending counter index of a block of contiguous counters.

Remarks

Most processors have performance monitor units that contain a number of hardware counters for measuring various aspects of system performance. The **PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR** structure describes a counter resource, which can be a single hardware counter, a block of contiguous counters, or a counter overflow interrupt. This structure's **Type** member indicates which type of counter resource is described by the structure.

To specify a set of counter resources, a kernel-mode client can provide an array of **PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR** structures. A PHYSICAL_COUNTER_RESOURCE_LIST structure serves as a header for the array. The client can allocate and free the set of counter resources described by the array as a single unit.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of Windows.
Header	ntddk.h (include Ntddk.h, Ntifs.h)

See Also

PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR_TYPE

PHYSICAL_COUNTER_RESOURCE_LIST

PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR_TYPE** enumeration contains constants that indicate the type of hardware performance counter resource that is described by a PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR structure.

Syntax

```
typedef enum _PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR_TYPE {
  ResourceTypeSingle,
  ResourceTypeRange,
  ResourceTypeExtendedCounterConfiguration,
  ResourceTypeOverflow,
  ResourceTypeMax
} PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR_TYPE;
```

Constants

ResourceTypeSingle	A single hardware counter. The counter is described by the **u.CounterIndex** member of the **PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR** structure.
ResourceTypeRange	A range of counter indexes. The counter indexes are described by the **u.Range** member of the **PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR** structure.
ResourceTypeExtendedCounterConfiguration	An extended counter configuration register address. The register address is contained in the **u.ExtendedRegisterAddress** member of the **PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR** structure. This value is used only on Intel NetBurst systems.
ResourceTypeOverflow	A counter overflow interrupt. The **u** member of the **PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR** structure is not used for this counter resource type.
ResourceTypeMax	The maximum value in this enumeration type.

Remarks

The **Type** member of a **PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR** structure uses a **PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR_TYPE** enumeration constant to indicate the type of counter resource that is described by the structure.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of Windows.
Header	ntddk.h (include Ntddk.h, Ntifs.h)

See Also

PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR

PHYSICAL_COUNTER_RESOURCE_LIST structure

1/30/2019 • 2 minutes to read • Edit Online

The **PHYSICAL_COUNTER_RESOURCE_LIST** structure describes an array of PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR structures.

Syntax

```
typedef struct _PHYSICAL_COUNTER_RESOURCE_LIST {
  ULONG                                Count;
  PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR Descriptors[ANYSIZE_ARRAY];
} PHYSICAL_COUNTER_RESOURCE_LIST, *PPHYSICAL_COUNTER_RESOURCE_LIST;
```

Members

`Count`

The number of elements in the **Descriptors** array.

`Descriptors`

The first element in an array of **PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR** structures. If the array contains more than one element, the remaining elements immediately follow the first element.

Remarks

This structure describes a set of counter resources. Most processors have performance monitor units (PMUs) that contain a number of hardware counters to measure various aspects of system performance. A counter resource is a single hardware counter, a block of contiguous counters, or a counter overflow interrupt in a PMU.

The buffer allocated to contain a **PHYSICAL_COUNTER_RESOURCE_LIST** structure must be large enough to contain the structure plus any **PHYSICAL_COUNTER_RESOURCE_DESCRIPTOR** array elements that follow the structure.

The HalAllocateHardwareCounters routine's *ResourceList* parameter is a pointer to a **PHYSICAL_COUNTER_RESOURCE_LIST** structure. In Windows 7, this parameter is unused and must be set to **NULL**.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of Windows.
Header	ntddk.h (include Ntddk.h, Ntifs.h)

PNP_LOCATION_INTERFACE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PNP_LOCATION_INTERFACE** structure describes the GUID_PNP_LOCATION_INTERFACE interface.

Syntax

```
typedef struct _PNP_LOCATION_INTERFACE {
  USHORT                 Size;
  USHORT                 Version;
  PVOID                  Context;
  PINTERFACE_REFERENCE   InterfaceReference;
  PINTERFACE_DEREFERENCE InterfaceDereference;
  PGET_LOCATION_STRING   GetLocationString;
} PNP_LOCATION_INTERFACE, *PPNP_LOCATION_INTERFACE;
```

Members

`Size`

The size, in bytes, of this structure.

`Version`

The driver-defined version of the interface.

`Context`

A pointer to interface-specific context information.

`InterfaceReference`

A pointer to an InterfaceReference routine that increments the reference count for the interface. The PINTERFACE_REFERENCE function pointer type is defined in the Wdm.h header file.

`InterfaceDereference`

A pointer to an InterfaceDereference routine that decrements the reference count for the interface. The PINTERFACE_DEREFERENCE function pointer type is defined in the Wdm.h header file.

`GetLocationString`

A pointer to the PnpGetLocationString routine for the interface. The routine supplies the device-specific part of the SPDRP_LOCATION_PATHS property for the device.

Remarks

A driver obtains a pointer to the **PNP_LOCATION_INTERFACE** structure by sending an IRP_MN_QUERY_INTERFACE IRP to its bus driver with **InterfaceType** set to GUID_PNP_LOCATION_INTERFACE.

Requirements

Minimum supported client	Windows Server 2003 and later versions of the Windows operating system.
Header	ntddk.h (include Ntddk.h, Ntifs.h)

See Also

POWER_THROTTLING_PROCESS_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

Stores the throttling policies and how to apply them to a target process when that process is subject to power management.

Syntax

```
typedef struct _POWER_THROTTLING_PROCESS_STATE {
  ULONG Version;
  ULONG ControlMask;
  ULONG StateMask;
} POWER_THROTTLING_PROCESS_STATE, *PPOWER_THROTTLING_PROCESS_STATE;
```

Members

`Version`

The version of this structure. Set to PROCESS_POWER_THROTTLING_CURRENT_VERSION.

`ControlMask`

Flags that enable the caller to take control of the power throttling mechanism.

- PROCESS_POWER_THROTTLING_EXECUTION_SPEED: Manages the execution speed of the process.

`StateMask`

Flags that manage the power throttling mechanism on/off state.

- PROCESS_POWER_THROTTLING_EXECUTION_SPEED: Manages the execution speed of the process.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Header	ntddk.h

POWER_THROTTLING_THREAD_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

Stores the throttling policies and how to apply them to a target thread when that thread is subject to power management.

Syntax

```
typedef struct _POWER_THROTTLING_THREAD_STATE {
  ULONG Version;
  ULONG ControlMask;
  ULONG StateMask;
} POWER_THROTTLING_THREAD_STATE, *PPOWER_THROTTLING_THREAD_STATE;
```

Members

`Version`

The version of this structure. Set to THREAD_POWER_THROTTLING_CURRENT_VERSION.

`ControlMask`

Flags that enable the caller to take control of the power throttling mechanism.

- THREAD_POWER_THROTTLING_EXECUTION_SPEED: Manages the execution speed of the process.

`StateMask`

Flags that manage the power throttling mechanism on/off state.

- THREAD_POWER_THROTTLING_EXECUTION_SPEED: Manages the execution speed of the process.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Header	ntddk.h

PROCESS_MITIGATION_CHILD_PROCESS_POLICY structure

1/30/2019 • 2 minutes to read • Edit Online

Stores policy information about creating child processes.

Syntax

```
typedef struct _PROCESS_MITIGATION_CHILD_PROCESS_POLICY {
  union {
    ULONG Flags;
    struct {
      ULONG NoChildProcessCreation : 1;
      ULONG AuditNoChildProcessCreation : 1;
      ULONG AllowSecureProcessCreation : 1;
      ULONG ReservedFlags : 29;
    } DUMMYSTRUCTNAME;
  } DUMMYUNIONNAME;
} PROCESS_MITIGATION_CHILD_PROCESS_POLICY, *PPROCESS_MITIGATION_CHILD_PROCESS_POLICY;
```

Members

`DUMMYUNIONNAME`

`DUMMYUNIONNAME.Flags`

`DUMMYUNIONNAME.DUMMYSTRUCTNAME`

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.NoChildProcessCreation`

If set, the process cannot create child processes.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.AuditNoChildProcessCreation`

If set, causes audit events to be generated when child processes are created by the process. If both **NoChildProcessCreation** and **AuditNoChildProcessCreation** are set, **NoChildProcessCreation** takes precedence over audit setting.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.AllowSecureProcessCreation`

Denies creation of child processes unless the child process is a secure process and if creation was previously blocked. It allows a process to spawn a child process on behalf of another process that cannot itself create child processes. See PROCESS_CREATION_CHILD_PROCESS_OVERRIDE in UpdateProcThreadAttribute.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.ReservedFlags`

Reserved.

Requirements

Minimum supported client	Windows 10, version 1709

Minimum supported server	Windows Server 2016
Header	ntddk.h

PROCESS_MITIGATION_PAYLOAD_RESTRICTION_POLICY structure

1/30/2019 • 2 minutes to read • Edit Online

Stores information about process mitigation policy.

Syntax

```
typedef struct _PROCESS_MITIGATION_PAYLOAD_RESTRICTION_POLICY {
  union {
    ULONG Flags;
    struct {
      ULONG EnableExportAddressFilter : 1;
      ULONG AuditExportAddressFilter : 1;
      ULONG EnableExportAddressFilterPlus : 1;
      ULONG AuditExportAddressFilterPlus : 1;
      ULONG EnableImportAddressFilter : 1;
      ULONG AuditImportAddressFilter : 1;
      ULONG EnableRopStackPivot : 1;
      ULONG AuditRopStackPivot : 1;
      ULONG EnableRopCallerCheck : 1;
      ULONG AuditRopCallerCheck : 1;
      ULONG EnableRopSimExec : 1;
      ULONG AuditRopSimExec : 1;
      ULONG ReservedFlags : 20;
    } DUMMYSTRUCTNAME;
  } DUMMYUNIONNAME;
} PROCESS_MITIGATION_PAYLOAD_RESTRICTION_POLICY, *PPROCESS_MITIGATION_PAYLOAD_RESTRICTION_POLICY;
```

Members

`DUMMYUNIONNAME`

`DUMMYUNIONNAME.Flags`

Bitwise of flags in this structure.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME`

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.EnableExportAddressFilter`

If set this enables the Export Address Filter mitigation in enforcement mode for the process.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.AuditExportAddressFilter`

If set this enables the Export Address Filter mitigation in audit mode for the process.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.EnableExportAddressFilterPlus`

If set this enables the Export Address Filter Plus mitigation in enforcement mode for the process.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.AuditExportAddressFilterPlus`

If set this enables the Export Address Filter mitigation in audit mode for the process.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.EnableImportAddressFilter`

If set this enables the Import Address Filter mitigation in enforcement mode for the process.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.AuditImportAddressFilter`

If set this enables the Import Address Filter mitigation in enforcement mode for the process.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.EnableRopStackPivot`

If set this enables the stack pivot anti-ROP (Return-oriented-programming) mitigation in enforcement mode for the process.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.AuditRopStackPivot`

If set this enables the stack pivot anti-ROP (Return-oriented-programming) mitigation in audit mode for the process.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.EnableRopCallerCheck`

If set this enables the caller check anti-ROP (Return-oriented-programming) mitigation in enforcement mode for the process. Applies to 32-bit processes only.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.AuditRopCallerCheck`

If set this enables the caller check anti-ROP (Return-oriented-programming) mitigation in audit mode for the process. Applies to 32-bit processes only.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.EnableRopSimExec`

If set this enables the simulated execution anti-ROP (Return-oriented-programming) mitigation in enforcement mode for the process. Applies to 32-bit processes only.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.AuditRopSimExec`

If set this enables the simulated execution anti-ROP (Return-oriented-programming) mitigation in audit mode for the process. Applies to 32-bit processes only.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.ReservedFlags`

Reserved.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016

PS_CREATE_NOTIFY_INFO structure

2/5/2019 • 2 minutes to read • Edit Online

The **PS_CREATE_NOTIFY_INFO** structure provides information about a newly created process.

Syntax

```
typedef struct _PS_CREATE_NOTIFY_INFO {
  SIZE_T              Size;
  union {
    ULONG Flags;
    struct {
      ULONG FileOpenNameAvailable : 1;
      ULONG IsSubsystemProcess : 1;
      ULONG Reserved : 30;
    };
  };
  HANDLE              ParentProcessId;
  CLIENT_ID           CreatingThreadId;
  struct _FILE_OBJECT *FileObject;
  PCUNICODE_STRING    ImageFileName;
  PCUNICODE_STRING    CommandLine;
  NTSTATUS            CreationStatus;
} PS_CREATE_NOTIFY_INFO, *PPS_CREATE_NOTIFY_INFO;
```

Members

`Size`

The size, in bytes, of this structure. The operating system uses this size to indicate the type of structure that it passes to CreateProcessNotifyEx. Currently, this member is always **sizeof**(**PS_CREATE_NOTIFY_INFO**).

`Flags`

Reserved. Use the **FileOpenNameAvailable** member instead.

`FileOpenNameAvailable`

A Boolean value that specifies whether the **ImageFileName** member contains the exact file name that is used to open the process executable file.

`IsSubsystemProcess`

A Boolean value that indicates the type of process subsystem is a subsystem other than Win32.

> **Note**
>
> **IsSubsystemProcess** is only populated for subsystem processes other than Win32 when a driver has registered through PsSetCreateProcessNotifyRoutineEx2 with a type that allows for notifications from subsystem processes. When **IsSubsystemProcess** is set, the **FileObject**, **ImageFileName**, and **CommandLine** may be NULL. Drivers should use **ProcessSubsystemInformation** to query the subsystem type if needed. For more information, see NtQueryInformationProcess.

`Reserved`

Reserved for system use.

`ParentProcessId`

The process ID of the parent process for the new process. Note that the parent process is not necessarily the same process as the process that created the new process. The new process can inherit certain properties of the parent process, such as handles or shared memory. (The process ID of the process creator is given by **CreatingThreadId->UniqueProcess**.)

`CreatingThreadId`

The process ID and thread ID of the process and thread that created the new process. **CreatingThreadId->UniqueProcess** contains the process ID, and **CreatingThreadId->UniqueThread** contains the thread ID.

`FileObject`

A pointer to the file object for the process executable file.

> **Note**
> If **IsSubsystemProcess** is TRUE, this value may be NULL.

`ImageFileName`

A pointer to a UNICODE_STRING string that holds the file name of the executable. If the **FileOpenNameAvailable** member is **TRUE**, the string specifies the exact file name that is used to open the executable file. If **FileOpenNameAvailable** is **FALSE**, the operating system might provide only a partial name.

> **Note**
> If **IsSubsystemProcess** is TRUE, this value maybe NULL.

`CommandLine`

A pointer to a **UNICODE_STRING** string that holds the command that is used to execute the process. If the command is not available, **CommandLine** is **NULL**.

> **Note**
> If **IsSubsystemProcess** is TRUE, this value maybe NULL.

`CreationStatus`

The NTSTATUS value to return for the process-creation operation. Drivers can change this value to an error code to prevent the process from being created.

Requirements

Minimum supported client	Available in Windows Vista and later versions of the Windows operating system.
Header	ntddk.h (include Ntddk.h)

PsSetCreateProcessNotifyRoutineEx

UNICODE_STRING

PSCREATEPROCESSNOTIFYTYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

Indicates the type of process notification. This enumeration is used in PsSetCreateProcessNotifyRoutineEx2 to register callback notifications.

Syntax

```
typedef enum _PSCREATEPROCESSNOTIFYTYPE {
  PsCreateProcessNotifySubsystems
} PSCREATEPROCESSNOTIFYTYPE;
```

Constants

PsCreateProcessNotifySubsystems	Indicates that the driver-registered callback is invoked for processes of all subsystems, including the Win32 subsystem. Drivers can call NtQueryInformationProcess to determine the underlying subsystem. The query retrieves a SUBSYSTEM_INFORMATION_TYPE value.

Requirements

Minimum supported client	Windows 10, version 1703
Minimum supported server	Windows Server 2016
Header	ntddk.h (include Ntddk.h)

See Also

NtQueryInformationProcess

PsSetCreateProcessNotifyRoutineEx2

SUBSYSTEM_INFORMATION_TYPE

PSCREATETHREADNOTIFYTYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

Indicates the type of thread notification. This enumeration is used in PsSetCreateThreadNotifyRoutineEx to register callback notifications associated with thread creation or deletion.

Syntax

```
typedef enum _PSCREATETHREADNOTIFYTYPE {
  PsCreateThreadNotifyNonSystem,
  PsCreateThreadNotifySubsystems
} PSCREATETHREADNOTIFYTYPE;
```

Constants

PsCreateThreadNotifyNonSystem	The driver-registered callback function is executed on the new non-system thread, which enables the callback function to perform tasks such as setting the initial thread context.
PsCreateThreadNotifySubsystems	Indicates that the driver-registered callback function is invoked for threads of all subsystems. Drivers can call NtQueryInformationThread to determine the underlying subsystem. The query retrieves a SUBSYSTEM_INFORMATION_TYPE value.

Requirements

Minimum supported client	Windows 10, version 1703
Minimum supported server	Windows Server 2016
Header	ntddk.h (include Ntddk.h)

PsSetCreateThreadNotifyRoutineEx

SUBSYSTEM_INFORMATION_TYPE

SILO_MONITOR_REGISTRATION structure

2/5/2019 • 2 minutes to read • Edit Online

This structure specifies a server silo monitor that can receive notifications about server silo events.

Syntax

```
typedef struct _SILO_MONITOR_REGISTRATION {
  UCHAR                          Version;
  BOOLEAN                        MonitorHost;
  BOOLEAN                        MonitorExistingSilos;
  UCHAR                          Reserved[5];
  union {
    PUNICODE_STRING DriverObjectName;
    PUNICODE_STRING ComponentName;
  };
  SILO_MONITOR_CREATE_CALLBACK    CreateCallback;
  SILO_MONITOR_TERMINATE_CALLBACK TerminateCallback;
} SILO_MONITOR_REGISTRATION, *PSILO_MONITOR_REGISTRATION;
```

Members

`Version`

Set to **SERVER_SILO_MONITOR_REGISTRATION_VERSION**.

`MonitorHost`

If **true**, a create notification will be delivered for the host context.

`MonitorExistingSilos`

If **true**, create and terminate notifications will be delivered for any silos that currently exist at the time of registration; otherwise, only notifications for new silos will be delivered.

`Reserved`

Reserved for system use.

`DriverObjectName`

`ComponentName`

`CreateCallback`

A pointer to a callback that is invoked whenever a new server silo is created on the system. This value may be **NULL**. This gives drivers to opportunity to handle the event and set up per-silo data structures.

`TerminateCallback`

A pointer to a callback that is invoked whenever a server silo is terminated (about to be destroyed) on the system. This value may be **NULL**. This gives drivers the opportunity to complete work within the silo and begin tearing down their per-silo data structures.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Header	ntddk.h

SUBSYSTEM_INFORMATION_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

Indicates the type of subsystem for a process or thread. This enumeration is used in NtQueryInformationProcess and NtQueryInformationThread calls.

Syntax

```
typedef enum _SUBSYSTEM_INFORMATION_TYPE {
  SubsystemInformationTypeWin32,
  SubsystemInformationTypeWSL,
  MaxSubsystemInformationType
} SUBSYSTEM_INFORMATION_TYPE, *PSUBSYSTEM_INFORMATION_TYPE;
```

Constants

SubsystemInformationTypeWin32	The subsystem type for the process or thread is Win32.
SubsystemInformationTypeWSL	The subsystem type for the process or thread is Windows Subsystem for Linux (WSL). For this process, these members of the PS_CREATE_NOTIFY_INFO structure are set as follows: • The **FileObject** member is the NTFS file object from LxFs or DriveFs, the file system that is used for interoperability with Windows. • The **ImageFileName** member is the Linux path of the image file. • The **CommandLine** member is the Linux NULL-separated command line. The preceding member values may be NULL.
MaxSubsystemInformationType	Reserved.

Requirements

Header	ntddk.h

NtQueryInformationProcess

NtQueryInformationThread

CORRELATION_VECTOR structure

1/25/2019 • 2 minutes to read • Edit Online

Store the correlation vector that is used to reference events and the generated logs for diagnostic purposes.

Syntax

```
typedef struct CORRELATION_VECTOR {
  CHAR Version;
  CHAR Vector[RTL_CORRELATION_VECTOR_STRING_LENGTH];
} CORRELATION_VECTOR;
```

Members

`Version`

The version of the correlation vector. Possible values are:

- RTL_CORRELATION_VECTOR_VERSION_1
- RTL_CORRELATION_VECTOR_VERSION_2
- RTL_CORRELATION_VECTOR_VERSION_CURRENT

`Vector`

An array CHARs that represents the correlation vector.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Header	ntddk.h

DRIVER_REINITIALIZE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *Reinitialize* routine continues driver and device initialization after the driver's **DriverEntry** routine returns.

Syntax

```
DRIVER_REINITIALIZE DriverReinitialize;

void DriverReinitialize(
  _DRIVER_OBJECT *DriverObject,
  PVOID Context,
  ULONG Count
)
{...}
```

Parameters

`*DriverObject`

Caller-supplied pointer to a DRIVER_OBJECT structure. This is the driver's driver object.

`Context`

Caller-supplied pointer to context information, specified in a previous call to IoRegisterDriverReinitialization or IoRegisterBootDriverReinitialization.

`Count`

Caller-supplied value representing the number of times the *Reinitialize* routine has been called, including the current call.

Return Value

None

Remarks

To queue a *Reinitialize* routine for execution, a driver's DriverEntry routine must call either IoRegisterDriverReinitialization or IoRegisterBootDriverReinitialization. The *Reinitialize* routine can also call **IoRegisterDriverReinitialization** itself, which causes the routine to be requeued. This requeuing can occur multiple times, and the routine's *Count* parameter indicates the number of times it has been called. The first call to **IoRegisterDriverReinitialization** must be made from **DriverEntry**, and **DriverEntry** must return STATUS_SUCCESS.

For more information about implementing a *Reinitialize* routine, see Writing a Reinitialize Routine.

Examples

To define a *Reinitialize* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *Reinitialize* callback routine that is named `MyReinitialize`, use the DRIVER_REINITIALIZE type as shown in this code example:

```
DRIVER_REINITIALIZE MyReinitialize;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyReinitialize(
    struct _DRIVER_OBJECT  *DriverObject,
    PVOID  Context,
    ULONG  Count
    )
  {
      // Function body
  }
```

The DRIVER_REINITIALIZE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the DRIVER_REINITIALIZE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	ntddk.h (include Ntddk.h, Ntifs.h)
IRQL	Called at PASSIVE_LEVEL.

ExFreePool macro

1/25/2019 • 2 minutes to read • Edit Online

The **ExFreePool** routine deallocates a block of pool memory.

Syntax

```
void ExFreePool(
   a
);
```

Parameters

`a`

Specifies the address of the block of pool memory being deallocated.

Return Value

None

Remarks

This routine releases memory allocated by ExAllocatePool, ExAllocatePoolWithTag, ExAllocatePoolWithQuota, or ExAllocatePoolWithQuotaTag. The memory block must not be accessed after it is freed.

Drivers can also use the **ExFreePoolWithTag** routine to free buffers allocated by ExAllocatePoolWithTag and ExAllocatePoolWithQuotaTag.

Callers of **ExFreePool** must be running at IRQL <= DISPATCH_LEVEL. A caller at DISPATCH_LEVEL must have specified a **NonPaged***XxxPoolType* when the memory was allocated. Otherwise, the caller must be running at IRQL <= APC_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL (see Remarks section)"

DDI compliance rules	DoubleExFreePool

EXPAND_STACK_CALLOUT callback function

1/25/2019 • 2 minutes to read • Edit Online

The *ExpandedStackCall* routine executes with a guaranteed stack size.

Syntax

```
EXPAND_STACK_CALLOUT ExpandStackCallout;

VOID() ExpandStackCallout(
  PVOID Parameter
)
{...}
```

Parameters

`Parameter`

The value passed to the KeExpandKernelStackAndCallout routine that executed *ExpandedStackCall*.

Return Value

None

Remarks

The *ExpandedStackCall* routine must handle all exceptions. Any unhandled exception causes the system to bug check with Bug Check 0x1E: KMODE_EXCEPTION_NOT_HANDLED.

If the *ExpandedStackCall* changes the current IRQL, it must restore the original value before returning.

Examples

To define an *ExpandedStackCall* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define an *ExpandedStackCall* callback routine that is named `MyExpandedStackCall`, use the EXPAND_STACK_CALLOUT type as shown in this code example:

```
EXPAND_STACK_CALLOUT MyExpandedStackCall;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyExpandedStackCall(
    PVOID  Parameter
    )
  {
      // Function body
  }
```

The EXPAND_STACK_CALLOUT function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the EXPAND_STACK_CALLOUT function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Drivers can implement ExpandedStackCall routines on Windows Server 2003 for an x64-based processor, and on Windows Vista and later versions of Windows for all processors.
Target Platform	Desktop
Header	ntddk.h (include Ntddk.h, Ntifs.h)

ExRaiseAccessViolation function

1/25/2019 • 2 minutes to read • Edit Online

The **ExRaiseAccessViolation** routine can be used with structured exception handling to throw a driver-determined exception for a memory access violation that occurs when a driver processes I/O requests.

Syntax

```
void ExRaiseAccessViolation(

);
```

Parameters

This function has no parameters.

Return Value

None

Remarks

ExRaiseAccessViolation raises an exception with the exception code set to STATUS_ACCESS_VIOLATION.

Because **ExRaiseAccessViolation** can only be used at IRQL = PASSIVE_LEVEL, only high-level drivers typically use this routine—for example, file system drivers.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL (see Remarks section)

ExRaiseDatatypeMisalignment function

1/25/2019 • 2 minutes to read • Edit Online

The **ExRaiseDatatypeMisalignment** routine can be used with structured exception handling to throw a driver-determined exception for a misaligned data type that occurs when a driver processes I/O requests.

Syntax

```
void ExRaiseDatatypeMisalignment(

);
```

Parameters

This function has no parameters.

Return Value

None

Remarks

ExRaiseDatatypeMisalignment raises an exception with the exception code set to STATUS_DATATYPE_MISALIGNMENT.

Because **ExRaiseDatatypeMisalignment** can only be used at IRQL = PASSIVE_LEVEL, only high-level drivers typically use this routine — for example, file system drivers.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)

ExUuidCreate function

1/25/2019 • 2 minutes to read • Edit Online

The **ExUuidCreate** routine initializes a UUID (GUID) structure to a newly generated value.

Syntax

```
NTSTATUS ExUuidCreate(
  UUID *Uuid
);
```

Parameters

`Uuid`

A pointer to a caller-allocated UUID (GUID) structure that is set to a new UUID value.

Return Value

Possible return values include the following status codes.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The routine successfully generated a UUID that is universally unique.
RPC_NT_UUID_LOCAL_ONLY	The routine generated a UUID that is unique only to this computer. This can occur when the MAC address is not an IEEE universally-administered address or when no NICs are present.
STATUS_RETRY	The system is not ready to generate a new UUID.

Remarks

A UUID and a GUID are the same data type.

The caller can iteratively attempt to obtain a new UUID value.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

HalAllocateHardwareCounters function

1/25/2019 • 2 minutes to read • Edit Online

The **HalAllocateHardwareCounters** routine allocates a set of hardware performance counters.

Syntax

```
NTHALAPI NTSTATUS HalAllocateHardwareCounters(
  PGROUP_AFFINITY                GroupAffinty,
  ULONG                          GroupCount,
  PPHYSICAL_COUNTER_RESOURCE_LIST ResourceList,
  PHANDLE                        CounterSetHandle
);
```

Parameters

`GroupAffinty`

Reserved for future use. Set this parameter to **NULL**.

`GroupCount`

Reserved for future use. Set this parameter to zero.

`ResourceList`

Reserved for future use. Set this parameter to **NULL**.

`CounterSetHandle`

A pointer to a location into which the routine writes a handle to the allocated counter resources. To release these resources later, the caller must pass this handle to the HalFreeHardwareCounters routine. If the requested counter resources are unavailable, **HalAllocateHardwareCounters** sets **CounterSetHandle* = **NULL** and returns STATUS_INSUFFICIENT_RESOURCES.

Return Value

HalAllocateHardwareCounters returns STATUS_SUCCESS if the call was successful. Possible error return values include the following status codes.

RETURN CODE	DESCRIPTION
STATUS_INSUFFICIENT_RESOURCES	The requested counter resources are currently unavailable.

STATUS_INVALID_PARAMETER	The caller specified an invalid parameter value.

Remarks

Most processors have performance monitor units (PMUs) that contain a number of hardware counters. Software tools use these counters to monitor various aspects of system performance. Typically, such a tool consists of a custom kernel-mode driver to program the counters and a user-mode application that communicates with the driver.

If more than one such tool is installed on a computer, the associated drivers must avoid trying to use the same hardware counters simultaneously. To avoid such resource conflicts, all drivers that use counter resources should use the **HalAllocateHardwareCounters** and **HalFreeHardwareCounters** routines to coordinate their sharing of these resources.

A counter resource is a single hardware counter, a block of contiguous counters, or a counter overflow interrupt in a PMU.

Before configuring the counters, a driver can call the **HalAllocateHardwareCounters** routine to acquire exclusive access to a set of counter resources. After the driver no longer needs these resources, it must free the resources by calling the **HalFreeHardwareCounters** routine.

In Windows 8 and Windows 7, a successful call to **HalAllocateHardwareCounters** grants the caller exclusive access to all counter resources in the performance monitor unit of a single-processor system. In a multiprocessor system, a successful call grants the caller exclusive access to all counter resources in all processors in the system. Future versions of this routine might provide more fine-grained allocation of counter resources.

Virtualization software typically does not virtualize hardware performance counters. Thus, these counters might not be available in a virtual machine, regardless of whether **HalAllocateHardwareCounters** returns a status code of STATUS_SUCCESS. For example, hardware performance counters are not available in a Hyper-V virtual machine, but **HalAllocateHardwareCounters** might still return STATUS_SUCCESS.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h, Ntifs.h)
Library	Hal.lib
DLL	Hal.dll

IRQL	PASSIVE_LEVEL

HalFreeHardwareCounters

PHYSICAL_COUNTER_RESOURCE_LIST

HalExamineMBR function

1/25/2019 • 2 minutes to read • Edit Online

The **HalExamineMBR** routine reads the master boot record (MBR) of a disk and returns data from the MBR if the MBR is of the type specified by the caller.

Syntax

```
void HalExamineMBR(
  PDEVICE_OBJECT DeviceObject,
  ULONG          SectorSize,
  ULONG          MBRTypeIdentifier,
  PVOID          *Buffer
);
```

Parameters

`DeviceObject`

A pointer to the device object for the device being examined.

`SectorSize`

The minimum number of bytes that an I/O operation can fetch from the device being examined. If this value is less than 512, **HalExamineMBR** reads 512 bytes to ensure that it reads an entire partition table.

`MBRTypeIdentifier`

MBR partition type identifier. This parameter specifies the type of MBR that may be on the disk. For more information, see Remarks.

`Buffer`

A pointer to a location to which **HalExamineMBR** writes a pointer to a buffer that contains data from the MBR. The layout of the buffer depends on the MBR partition type. **HalExamineMBR** allocates the storage for this buffer. The caller must deallocate this buffer as soon as possible by calling the ExFreePool routine.

HalExamineMBR sets **Buffer* = **NULL** if the MBR partition type of the disk does not match that specified by *MBRTypeIdentifier* or if there is an error.

Return Value

None

Remarks

For a list of system-defined MBR partition type identifiers, see the table in PARTITION_INFORMATION. These identifiers are defined in the Ntdddisk.h header file.

Requirements

Minimum supported client	Available starting with Windows XP.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

PARTITION_INFORMATION

HalFreeHardwareCounters function

1/25/2019 • 2 minutes to read • Edit Online

The **HalFreeHardwareCounters** routine frees a set of hardware performance counters that was acquired in a previous call to HalAllocateHardwareCounters routine.

Syntax

```
NTSTATUS HalFreeHardwareCounters(
  _In_ HANDLE CounterSetHandle
);
```

Parameters

`CounterSetHandle`

A handle to the allocated counter resources. The caller acquired this handle in a previous call to **HalAllocateHardwareCounters**.

Return Value

HalFreeHardwareCounters returns STATUS_SUCCESS if the call was successful. Possible error return values include the following:

RETURN CODE	DESCRIPTION
STA TUS _IN VAL ID_ PAR AM ETE R	Parameter *CounterSetHandle* is not a valid counter resources handle.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h, Ntifs.h)
Library	Hal.lib

DLL	Hal.dll
IRQL	PASSIVE_LEVEL

HalAllocateHardwareCounters

IoAllocateController function

1/25/2019 • 2 minutes to read • Edit Online

The **IoAllocateController** routine sets up the call to a driver-supplied ControllerControl routine as soon as the device controller, represented by the given controller object, is available to carry out an I/O operation for the target device, represented by the given device object.

Syntax

```
void IoAllocateController(
  PCONTROLLER_OBJECT ControllerObject,
  PDEVICE_OBJECT     DeviceObject,
  PDRIVER_CONTROL    ExecutionRoutine,
  PVOID              Context
);
```

Parameters

`ControllerObject`

Pointer to a driver-created controller object, usually representing a physical controller to be allocated for an I/O operation on an attached device.

`DeviceObject`

Pointer to the device object, representing the target device of the current IRP.

`ExecutionRoutine`

Pointer to the driver-supplied ControllerControl routine.

`Context`

Pointer to a driver-determined context, passed to the driver's *ControllerControl* routine when it is called.

Return Value

None

Remarks

This routine reserves exclusive access to the hardware controller for the specified device.

The ControllerControl routine returns a value indicating whether the controller remains allocated to the device, either **DeallocateObject** or **KeepObject**. If it returns **KeepObject**, the driver must subsequently call **IoFreeController** to release the controller object.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoAssignArcName macro

1/25/2019 • 2 minutes to read • Edit Online

The **IoAssignArcName** routine creates a symbolic link between the ARC name of a physical device and the name of the corresponding device object when it has been created.

Syntax

```
void IoAssignArcName(
   ArcName,
   DeviceName
);
```

Parameters

`ArcName`

Pointer to a buffer containing the ARC name of the device. The ARC name must be a Unicode string.

`DeviceName`

Pointer to a buffer containing the name of the device object, representing the same device. The device object name must be a Unicode string.

Return Value

None

Remarks

Drivers of hard disk devices need not call this routine. Drivers of other mass storage devices, including floppy, CD-ROM, and tape devices, should call **IoAssignArcName** during their initialization.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

DDI compliance rules	HwStorPortProhibitedDDIs

IoCreateDevice

IoClearActivityIdThread function

1/25/2019 • 2 minutes to read • Edit Online

The IoClearActivityIdThread routine clears the activity ID of the current thread.

Syntax

```
void IoClearActivityIdThread(
  LPCGUID OriginalId
);
```

Parameters

`OriginalId`

The activity ID that was previously set on the thread.

Return Value

None.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

IoCreateController function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCreateController** routine allocates memory for and initializes a controller object with a controller extension of a driver-determined size.

Syntax

```
PCONTROLLER_OBJECT IoCreateController(
  ULONG Size
);
```

Parameters

`Size`

Specifies the number of bytes to be allocated for the controller extension.

Return Value

IoCreateController returns a pointer to the controller object or a **NULL** pointer if memory could not be allocated for the requested device extension.

Remarks

A controller object usually represents a physical device controller with attached devices on which a single driver carries out I/O requests. The controller extension is allocated from nonpaged pool and is guaranteed to be accessible by any driver routine and in an arbitrary thread context.

The controller object is used to synchronize I/O operations to target devices for which I/O requests can come in concurrently to a single, monolithic driver. A driver also might use a controller object to synchronize operations through device channels.

If **IoCreateController** returns **NULL**, the driver should fail device start-up.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoFreeController

IoDeassignArcName macro

1/25/2019 • 2 minutes to read • Edit Online

The **IoDeassignArcName** routine removes a symbolic link between the ARC name for a device and the named device object.

Syntax

```
void IoDeassignArcName(
   ArcName
);
```

Parameters

`ArcName`

Pointer to a buffered Unicode string that is the ARC name.

Return Value

None

Remarks

IoDeassignArcName is generally called if the driver is deleting the device object, for example, when the driver is unloading.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	HwStorPortProhibitedDDIs

IoAssignArcName

IoDecrementKeepAliveCount function

1/25/2019 • 2 minutes to read • Edit Online

The **IoDecrementKeepAliveCount** routine decrements a reference count associated with an Windows app on a specific device. This routine is called by a kernel mode driver when the app's I/O process has completed. If the app's reference count drops to 0, Windows can suspend the app.

Syntax

```
NTSTATUS IoDecrementKeepAliveCount(
  PFILE_OBJECT FileObject,
  PEPROCESS    Process
);
```

Parameters

`FileObject`

The file object handle to the device.

`Process`

The process associated with the device.

Return Value

This routine returns **STATUS_SUCCESS** on success, or the appropriate **NTSTATUS** error code on failure. **NTSTATUS** error codes are defined in Ntstatus.h.

Requirements

Minimum supported client	Available in Windows 8.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	Ntoskrnl.lib
DLL	Ntoskrnl.exe

IoDeleteController function

1/25/2019 • 2 minutes to read • Edit Online

The **IoDeleteController** routine removes a given controller object from the system, for example, when the driver that created it is being unloaded.

Syntax

```
void IoDeleteController(
  PCONTROLLER_OBJECT ControllerObject
);
```

Parameters

`ControllerObject`

Pointer to the controller object to be released.

Return Value

None

Remarks

IoDeleteController deallocates the memory for the controller object, including the controller extension.

This routine must be called when a driver that created a controller object is being unloaded or when the driver encounters a fatal error during device start-up, such as being unable to properly initialize a physical device.

A driver must release certain resources for which the driver supplied storage in its controller extension before it calls **IoDeleteController**. For example, if the driver stores the pointer to its interrupt object(s) in the controller extension, it must call IoDisconnectInterrupt before **IoDeleteController**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

DDI compliance rules	IrqlIoPassive4, PowerIrpDDis, HwStorPortProhibitedDDIs

IoCreateController

IoDisconnectInterrupt

IoFreeController function

1/25/2019 • 2 minutes to read • Edit Online

The **IoFreeController** routine releases a previously allocated controller object when the driver has completed an I/O request.

Syntax

```
void IoFreeController(
  PCONTROLLER_OBJECT ControllerObject
);
```

Parameters

`ControllerObject`

Pointer to the driver's controller object, which was allocated for the current I/O operation on a particular device by calling **IoAllocateController**.

Return Value

None

Remarks

The connection between the current target device object and the controller object is released only if no requests are currently queued to the same device. Otherwise, the driver's ControllerControl routine is called with the next IRP bound through the device controller to the target device.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoGetActivityIdIrp function

1/25/2019 • 2 minutes to read • Edit Online

The IoGetActivityIdIrp routine retrieves the current activity ID associated with an IRP.

Syntax

```
NTSTATUS IoGetActivityIdIrp(
  PIRP   Irp,
  LPGUID Guid
);
```

Parameters

`Irp`

The IRP from which to retrieve the activity ID.

`Guid`

A pointer to a location to store the retrieved GUID.

Return Value

IoGetActivityIdIrp returns STATUS_SUCCESS if the call is successful. Possible error return values include the following.

RETURN CODE	DESCRIPTION
STA TUS _NO T_F OU ND	No activity ID is associated with the request.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

IoGetConfigurationInformation function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetConfigurationInformation** routine returns a pointer to the I/O manager's global configuration information structure, which contains the current values for how many physical disk, floppy, CD-ROM, tape, SCSI HBA, serial, and parallel devices have device objects created to represent them by drivers as they are loaded.

Syntax

```
PCONFIGURATION_INFORMATION IoGetConfigurationInformation(

);
```

Parameters

This function has no parameters.

Return Value

IoGetConfigurationInformation returns a pointer to the configuration information structure. This structure is defined as follows:

```
typedef struct _CONFIGURATION_INFORMATION {

    //
    // This field indicates the total number of disks in the system. This
    // number should be used by the driver to determine the names of new
    // disks. This field should be updated by the driver as it finds new
    // disks.
    //

    ULONG DiskCount;                // Count of hard disks thus far
    ULONG FloppyCount;              // Count of floppy disks thus far
    ULONG CdRomCount;               // Count of CD-ROM drives thus far
    ULONG TapeCount;                // Count of tape drives thus far
    ULONG ScsiPortCount;            // Count of SCSI port adapters thus far
    ULONG SerialCount;              // Count of serial devices thus far
    ULONG ParallelCount;            // Count of parallel devices thus far

    //
    // These next two fields indicate ownership of the two I/O address
    // spaces that are used by WD1003-compatible disk controllers.
    //

    BOOLEAN AtDiskPrimaryAddressClaimed;    // 0x1F0 - 0x1FF
    BOOLEAN AtDiskSecondaryAddressClaimed;  // 0x170 - 0x17F

    //
    // Indicates the structure version, as anything value beyond this will have been added.
    // Use the structure size as the version.
    //

    ULONG Version;

    //
    // Indicates the total number of medium changer devices in the system.
    // This field will be updated by the drivers as it determines that
    // new devices have been found and will be supported.
    //

    ULONG MediumChangerCount;

} CONFIGURATION_INFORMATION, *PCONFIGURATION_INFORMATION;
```

Remarks

Certain types of device drivers can use the configuration information structure's values to construct device object names with appropriate digit suffixes when each driver creates its device objects. Note that the digit suffix for device object names is a zero-based count, while the counts maintained in the configuration information structure represent the number of device objects of a particular type already created. That is, the configuration information counts are one-based.

Any driver that calls **IoGetConfigurationInformation** must increment the count for its kind of device in this structure when it creates a device object to represent a physical device.

The system-supplied SCSI port driver supplies the count of SCSI HBAs present in the computer. SCSI class drivers can read this value to determine how many HBA-specific miniport drivers might control a SCSI bus with an attached device of the class driver's type.

The configuration information structure also contains a value indicating whether an already loaded driver has claimed either of the "AT" disk I/O address ranges.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoGetFileObjectGenericMapping function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetFileObjectGenericMapping** routine returns information about the mapping between each generic access right and the set of specific access rights for file objects.

Syntax

```
PGENERIC_MAPPING IoGetFileObjectGenericMapping(

);
```

Parameters

This function has no parameters.

Return Value

IoGetFileObjectGenericMapping returns a pointer to the GENERIC_MAPPING structure that describes the mapping between each generic access right and the implied set of specific access rights.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwCreateFile

IoGetInitiatorProcess function

1/25/2019 • 2 minutes to read • Edit Online

The IoGetInitiatorProcess routine retrieves the process which initiated the creation of a file object if different than the process which is issuing the create.

Syntax

```
PEPROCESS IoGetInitiatorProcess(
  PFILE_OBJECT FileObject
);
```

Parameters

`FileObject`

The file object from which to retrieve the initiator process.

Return Value

NULL if there is no initiator process. Otherwise, a pointer to which process initiated the creation of the file object.

Remarks

A driver normally uses IoGetInitiatorProcess to determine which process has issued a request. However, there are situations where a system component may issue a create on behalf of another process (after a successful create the component will duplicate the handle to the process). This routine can be used if the driver must know which process the create operation is ultimately intended for.

Requirements

Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

IoGetPagingIoPriority function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetPagingIoPriority** routine indicates the priority level of a paging I/O request.

Syntax

```
IO_PAGING_PRIORITY IoGetPagingIoPriority(
  PIRP Irp
);
```

Parameters

`Irp`

Pointer to the IRP to be tested for paging priority.

Return Value

IoGetPagingIoPriority returns the IO_PAGING_PRIORITY value for the associated IRP.

Remarks

For I/O requests that causing paging, the system associates an **IO_PAGING_PRIORITY** value that describes the IRP's priority. Drivers can use this value when queuing IRPs.

Requirements

Minimum supported client	Available in Microsoft Windows Server 2003 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IO_PAGING_PRIORITY

IoIncrementKeepAliveCount function

1/25/2019 • 2 minutes to read • Edit Online

The **IoIncrementKeepAliveCount** routine increments a reference count associated with an Windows app process on a specific device. This routine is called by a kernel mode driver in response to the app opening a process for I/O. This prevents Windows from suspending the app before the I/O process is complete.

Syntax

```
NTSTATUS IoIncrementKeepAliveCount(
  PFILE_OBJECT FileObject,
  PEPROCESS    Process
);
```

Parameters

`FileObject`

The file object handle to the device.

`Process`

The process associated with the device.

Return Value

This routine returns **STATUS_SUCCESS** on success, or the appropriate **NTSTATUS** error code on failure. **NTSTATUS** error codes are defined in Ntstatus.h.

Requirements

Minimum supported client	Available in Windows 8.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	Ntoskrnl.lib
DLL	Ntoskrnl.exe

IoDecrementKeepAliveCount

IoIsValidIrpStatus function

1/25/2019 • 2 minutes to read • Edit Online

The **IoIsValidIrpStatus** routine validates the specified NTSTATUS status code value.

Syntax

```
LOGICAL IoIsValidIrpStatus(
  IN NTSTATUS Status
);
```

Parameters

`Status`

The status code to be validated.

Return Value

IoIsValidIrpStatus returns **TRUE** if the *Status* parameter is a well-formed NTSTATUS value. Otherwise, the routine returns **FALSE**.

Remarks

Driver developers can define custom NTSTATUS values for use as status codes for IRP_MJ_INTERNAL_DEVICE_CONTROL requests. Drivers can call **IoIsValidIrpStatus** to validate the status codes for these requests. This routine is useful for detecting an uninitialized or corrupted **Status** value in the I/O status block of an IRP.

IoIsValidIrpStatus detects invalid status codes that obviously violate the rules for defining custom NTSTATUS values, but might not detect invalid status codes that appear to follow the rules. The routine might return **TRUE** for a *Status* parameter that is not a valid NTSTATUS code value, but rarely, if ever, returns **FALSE** for a valid NTSTATUS code.

IoIsValidIrpStatus examines the **Sev**, **Facility**, and **Code** fields in the *Status* parameter value to determine whether the combination of values in these fields conforms to the published guidelines. If the **C** bit of the *Status* parameter is set, **IoIsValidIrpStatus** returns **TRUE** regardless of the other field values in *Status*.

For more information about these fields, see Defining New NTSTATUS Values.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level.

IRP_MJ_INTERNAL_DEVICE_CONTROL

IoMakeAssociatedIrp function

1/25/2019 • 2 minutes to read • Edit Online

This routine is reserved for use by file systems and file system filter drivers. The **IoMakeAssociatedIrp** routine allocates and initializes an IRP to be associated with a master IRP sent to a highest-level driver, allowing the caller to split the original request and send associated IRPs on to lower-level drivers.

Syntax

```
PIRP IoMakeAssociatedIrp(
  PIRP  Irp,
  CCHAR StackSize
);
```

Parameters

`Irp`

Pointer to the master IRP that was input to a highest-level driver's Dispatch routine.

`StackSize`

Specifies the number of stack locations to be allocated for the associated IRP. The value must be at least equal to the *StackSize* of the next-lower driver's device object, but the associated IRP can have an additional stack location for the caller.

Return Value

IoMakeAssociatedIrp returns a pointer to the associated IRP or returns a **NULL** pointer if an IRP cannot be allocated.

Remarks

Only a highest-level driver can call this routine.

The I/O manager completes the master IRP automatically when lower drivers have completed all associated IRPs as long as the caller has not set its IoCompletion routine in an associated IRP and returned STATUS_MORE_PROCESSING_REQUIRED from its *IoCompletion* routine. In these circumstances, the caller must explicitly complete the master IRP when that driver has determined that all associated IRPs were completed.

Only the master IRP is associated with a thread; associated IRPs are not. For this reason, the I/O manager cannot call Cancel routines for associated IRPs when a thread exits. When the master IRP's thread exits, the I/O manager calls the master IRP's *Cancel* routine. The *Cancel* routine is responsible for tracking down all associated IRPs and calling IoCancelIrp to cancel them.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoPropagateActivityIdToThread function

1/25/2019 • 2 minutes to read • Edit Online

The **IoPropagateActivityIdToThread** routine associates the activity ID from an IRP with the current thread.

Syntax

```
NTSTATUS IoPropagateActivityIdToThread(
  PIRP    Irp,
  LPGUID  PropagatedId,
  LPCGUID *OriginalId
);
```

Parameters

`Irp`

The IRP whose ID will be propagated to the thread.

`PropagatedId`

A pointer to memory allocated by the caller to store the ID in the thread.

`OriginalId`

Upon successfully returning from the call, holds the ID that was previously set on the thread. The driver must call **IoClearActivityIdThread** with this pointer when tracing is completed within the same thread context.

Return Value

IoPropagateActivityIdToThread returns STATUS_SUCCESS if the call is successful. Possible error return values include the following.

RETURN CODE	DESCRIPTION
STA TUS _NO T_F OU ND	The IRP does not have an ID associated with it.

Remarks

This routine should be used by drivers that are tracing aware and are issuing I/O on a worker thread. Note that such drivers must call IoClearActivityIdThread with the *OriginalId* before they return control from the thread, if the call was successful.

Drivers that use I/O work items do not need to call this routine because the I/O subsystem takes care of propagating activity IDs to threads in that case.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

IoQueryFullDriverPath function

1/25/2019 • 2 minutes to read • Edit Online

The **IoQueryFullDriverPath** routine retrieves the full path name of the binary file that is loaded for the specified driver object. Starting in Windows 10 version 1709, callers may query for driver objects that are not their own, as long as they use proper synchronization to ensure that the DRIVER_OBJECT structure remains valid during the call.

Syntax

```
NTSTATUS IoQueryFullDriverPath(
  PDRIVER_OBJECT  DriverObject,
  PUNICODE_STRING FullPath
);
```

Parameters

`DriverObject`

A pointer to a DRIVER_OBJECT structure. If you are calling **IoQueryFullDriverPath** on a computer running a version of Windows 10 earlier than version 1709, this structure is required to be the driver object for the calling driver.

`FullPath`

A pointer to a caller-allocated UNICODE_STRING structure. On successful return, this structure contains the path name.

Return Value

IoQueryFullDriverPath returns STATUS_SUCCESS if the call successfully fetches the path name. Possible error return values include the following status codes.

RETURN CODE	DESCRIPTION
STATUS_ACCESS_DENIED	The target driver object does not belong to the caller. This status code is only returned on versions of Windows 10 earlier than 1709.
STATUS_NOT_FOUND	The driver object has no section (loaded memory image) associated with it.

STA **TUS** **_IN** **SUF** **FICI** **ENT** **_RE** **SO** **URC** **ES**	Insufficient resources are available to perform the requested operation.

Remarks

A driver can call this routine to query for the full path name of its binary file, or, starting in Windows 10 version 1709, the full path name of the binary file for another driver.

The caller allocates the UNICODE_STRING structure pointed to by the *FullPath* parameter, but does not need to initialize this structure. **IoQueryFullDriverPath** assumes that the original contents of this structure are invalid and overwrites them. This routine allocates a string buffer from paged system memory, sets the **Buffer** member of the structure to point to this buffer, and sets the **MaximumLength** and **Buffer** members to describe the buffer and its contents.

The caller is responsible for freeing the storage pointed to by *FullPath*->**Buffer** when the full path string is no longer needed. Typically, the caller frees this storage by calling a routine such as ExFreePool.

Requirements

Minimum supported client	Available starting with Windows 8.1.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

UNICODE_STRING

IoRaiseHardError function

1/25/2019 • 2 minutes to read • Edit Online

The **IoRaiseHardError** routine causes a dialog box to appears that warns the user that a device I/O error has occurred, which might indicate that a physical device is failing.

Syntax

```
void IoRaiseHardError(
  PIRP           Irp,
  PVPB           Vpb,
  PDEVICE_OBJECT RealDeviceObject
);
```

Parameters

`Irp`

Pointer to the IRP that failed because of a device I/O error.

`Vpb`

Pointer to the volume parameter block (VPB), if any, for the mounted file object. This parameter is **NULL** if no VPB is associated with the device object.

`RealDeviceObject`

Pointer to the device object that represents the physical device on which the I/O operation failed.

Return Value

None

Remarks

Highest-level drivers, particularly file system drivers, call **IoRaiseHardError**.

Warning Because **IoRaiseHardError**

```
  uses a normal kernel APC to create a user dialog box, a deadlock can occur if normal kernel APCs are
disabled when a device error occurs. For example:</div>
```

1. An upper-level filter driver calls KeEnterCriticalRegion (which disables normal kernel APCs) and sends an I/O request to a file system driver. The filter driver waits on the completion of the request by the file system driver before the filter driver calls KeLeaveCriticalRegion (which reenables normal kernel APCs).
2. An error occurs on the file system, and the file system driver calls **IoRaiseHardError** to report the error to the user. The file system driver waits on the dialog box.
3. Deadlock now exists: The normal kernel APC created by **IoRaiseHardError** to create the dialog box waits for normal kernel APCs to be enabled. The file system waits on the dialog box before it completes the I/O request. The filter driver waits on completion of the I/O request before it calls **KeLeaveCriticalRegion** (which reenables normal kernel APCs).

The behavior of this routine is dependent of the current state of hard errors for the running thread. If hard errors have been disabled by calling IoSetThreadHardErrorMode, this routine completes the IRP specified by *Irp* without transferring any data into user buffers. In addition, no message is sent to notify the user of this failure.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoSetHardErrorOrVerifyDevice

IoSetThreadHardErrorMode

IoRaiseInformationalHardError function

1/25/2019 • 2 minutes to read • Edit Online

The **IoRaiseInformationalHardError** routine sends a dialog box to the user, warning about a device I/O error that indicates why a user I/O request failed.

Syntax

```
BOOLEAN IoRaiseInformationalHardError(
  NTSTATUS         ErrorStatus,
  PUNICODE_STRING String,
  PKTHREAD         Thread
);
```

Parameters

`ErrorStatus`

The error status code (IO_ERR_*XXX*).

`String`

A pointer to a Unicode string, which provides additional information about the error. Some NT status codes require a string parameter, such as a file or directory name. If the specified *ErrorStatus* value does not require a string parameter, set *String* to **NULL**.

`Thread`

A pointer to the thread whose IRP was failed due to the error specified by the *ErrorStatus* parameter.

Return Value

IoRaiseInformationalHardError returns **TRUE** if the dialog box was successfully queued. This routine returns **FALSE** if dialog boxes are disabled for *Thread*, a pool allocation failed, too many dialog boxes are already queued, or an equivalent dialog box is already pending a user response (such as waiting for the user to press RETURN).

Remarks

IoRaiseInformationalHardError takes a system-defined NT error value as a parameter. Driver writers can use the event log APIs to communicate driver-defined event strings to the user.

IoRaiseInformationalHardError behaves as follows:

- If the caller-supplied *ErrorStatus* value is not defined in the Ntstatus.h header file, the dialog box always shows the text "Unknown Hard Error", regardless of the *String* parameter value.
- If the caller-supplied *ErrorStatus* value is defined in the Ntstatus.h header file, the dialog box shows the text in the corresponding MessageText string in Ntstatus.h, regardless of the *String* parameter value.
- If the *Thread* parameter specifies a thread that is running in the context of an application, the text shown in the dialog box is "ApplicationName.exe - System Error".
- If the *Thread* parameter is NULL or if it specifies a thread that is running in an arbitrary system context, the text shown in the dialog box is "System Process - System Error". Additionally, if the *ErrorStatus* value is defined in

Ntstatus.h, the corresponding MessageText string is written to the event log.

If a previous call to the IoSetThreadHardErrorMode routine disabled hard errors for the specified thread, **IoRaiseInformationalHardError** returns **FALSE**.

Starting with Windows Vista, if the routine is called from a thread in session 0 (that is, from any system thread), no dialog box appears when the routine succeeds and returns **TRUE**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib

IoRegisterBootDriverCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **IoRegisterBootDriverCallback** routine registers a **BOOT_DRIVER_CALLBACK_FUNCTION** routine to be called during the initialization of a boot-start driver and its dependent DLLs.

Syntax

```
PVOID IoRegisterBootDriverCallback(
  PBOOT_DRIVER_CALLBACK_FUNCTION CallbackFunction,
  PVOID                          CallbackContext
);
```

Parameters

`CallbackFunction`

A pointer to the **BOOT_DRIVER_CALLBACK_FUNCTION** routine to be called when initializing a boot-start driver or DLL.

`CallbackContext`

A driver-defined context to be passed to the **BOOT_DRIVER_CALLBACK_FUNCTION** routine pointed to by *CallbackFunction*.

Return Value

A handle that represents the registration. This handle must be supplied as an input parameter in the call to the IoUnRegisterBootDriverCallback routine that unregisters the **BOOT_DRIVER_CALLBACK_FUNCTION** routine.

Remarks

Boot-start drivers must call IoUnRegisterBootDriverCallback and pass the returned handle to unregister the boot-start driver callback before Windows unloads them.

Any error returned from a status update callback is treated as fatal and leads to a system bug check. Additionally, if an initialize image callback returns an error, the driver's image is treated as unknown. To be notified of boot-start driver initialization operations, an *early launch anti-malware* (ELAM) driver can call **IoRegisterBootDriverCallback** to register a **BOOT_DRIVER_CALLBACK_FUNCTION** routine.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

BDCB_CALLBACK_TYPE

BDCB_IMAGE_INFORMATION

IoUnRegisterBootDriverCallback

IoRegisterBootDriverReinitialization function

1/25/2019 • 2 minutes to read • Edit Online

The **IoRegisterBootDriverReinitialization** routine is called by a boot driver to register the driver's reinitialization routine with the I/O manager to be called after all devices have been enumerated and started.

Syntax

```
void IoRegisterBootDriverReinitialization(
  PDRIVER_OBJECT       DriverObject,
  PDRIVER_REINITIALIZE DriverReinitializationRoutine,
  PVOID                Context
);
```

Parameters

`DriverObject`

Pointer to the driver object for the boot driver to be reinitialized.

`DriverReinitializationRoutine`

Pointer to the driver's Reinitialize routine.

`Context`

Optional context pointer to be passed to the driver's reinitialization routine.

Return Value

None

Remarks

A boot driver normally calls **IoRegisterBootDriverReinitialization** from its DriverEntry routine, which is run during boot driver initialization. **IoRegisterBootDriverReinitialization** registers the driver's reinitialization callback routine to be called by the I/O manager after all devices have been enumerated and started. The *DriverReinitializationRoutine* is run in a system thread at IRQL = PASSIVE_LEVEL.

A driver should call **IoRegisterBootDriverReinitialization** only if its *DriverEntry* routine will return STATUS_SUCCESS.

If the *DriverReinitializationRoutine* uses the registry, the *DriverEntry* routine must include in **IoRegisterBootDriverReinitialization**'s *Context* parameter a copy of the string to which *DriverEntry*'s own *RegistryPath* parameter points.

The *DriverEntry* routine can call **IoRegisterBootDriverReinitialization** only once. If the reinitialization routine needs to be run more than once, the *DriverReinitializationRoutine* can call **IoRegisterBootDriverReinitialization** as many additional times as needed, using the *Count* parameter to keep track of the number of times the *DriverReinitializationRoutine* has been called.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntifs.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

DRIVER_OBJECT

IoRegisterDriverReinitialization

Reinitialize

IoRegisterDriverReinitialization function

1/25/2019 • 2 minutes to read • Edit Online

The **IoRegisterDriverReinitialization** routine is called by a driver during its initialization or reinitialization to register its Reinitialize routine to be called again before the driver's and, possibly the system's, initialization is complete.

Syntax

```
void IoRegisterDriverReinitialization(
  PDRIVER_OBJECT       DriverObject,
  PDRIVER_REINITIALIZE DriverReinitializationRoutine,
  PVOID                Context
);
```

Parameters

`DriverObject`

Pointer to the driver object that was input to the DriverEntry routine.

`DriverReinitializationRoutine`

Pointer to the driver's Reinitialize routine.

`Context`

Pointer to the context to be passed to the driver's *Reinitialize* routine.

Return Value

None

Remarks

A driver can call this routine only if its *DriverEntry* routine will return STATUS_SUCCESS. If the driver-supplied Reinitialize routine must use the registry, the *DriverEntry* routine should include a copy of the string to which *RegistryPath* points as part of the context passed to the *Reinitialize* routine in this call.

If the driver is loaded dynamically, it is possible for this to occur during a normally running system, so all references to the reinitialization queue must be synchronized.

The *Count* input to a *DriverReinitializationRoutine* indicates how many times this routine has been called, including the current call.

The *DriverEntry* routine can call **IoRegisterDriverReinitialization** only once. If the *Reinitialize* routine should be run again after any other drivers' *Reinitialize* routines have returned control, the *Reinitialize* routine also can call **IoRegisterDriverReinitialization** as many times as the driver's *Reinitialize* routine should be run.

Usually, a driver with a *Reinitialize* routine is a higher-level driver that controls both PnP and legacy devices. Such a driver must not only create device objects for the devices that the PnP manager detects (and for which the PnP manager calls the driver's AddDevice routine), the driver must also create device objects for legacy devices that the PnP manager does not detect. A driver can use a *Reinitialize* routine to create those device objects and layer the

driver over the next-lower driver for the underlying device.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

DRIVER_OBJECT

IoRegisterBootDriverReinitialization

IoReportDetectedDevice function

1/25/2019 • 4 minutes to read • Edit Online

The **IoReportDetectedDevice** routine reports a non-PnP device to the PnP manager.

Syntax

```
NTSTATUS IoReportDetectedDevice(
  PDRIVER_OBJECT                 DriverObject,
  INTERFACE_TYPE                 LegacyBusType,
  ULONG                          BusNumber,
  ULONG                          SlotNumber,
  PCM_RESOURCE_LIST              ResourceList,
  PIO_RESOURCE_REQUIREMENTS_LIST ResourceRequirements,
  BOOLEAN                        ResourceAssigned,
  PDEVICE_OBJECT                 *DeviceObject
);
```

Parameters

`DriverObject`

Pointer to the driver object of the driver that detected the device.

`LegacyBusType`

Specifies the type of bus on which the device resides. The PnP manager uses this information to match the reported device to its PnP-enumerated instance, if one exists.

The interface types, such as **PCIBus**, are defined in Wdm.h. If a driver does not know the *LegacyBusType* for the device, the driver supplies the value **InterfaceTypeUndefined** for this parameter.

`BusNumber`

Specifies the bus number for the device. The PnP manager uses this information to match the reported device to its PnP-enumerated instance, if one exists.

The bus number distinguishes the bus on which the device resides from other buses of the same type on the computer. The bus-numbering scheme is bus-specific. If a driver does not know the *BusNumber* for the device, the driver supplies the value -1 for this parameter.

`SlotNumber`

Specifies the logical slot number of the device. The PnP manager uses this information to match the reported device to its PnP-enumerated instance, if one exists.

If a driver does not know the *SlotNumber* for the device, the driver supplies the value -1 for this parameter.

`ResourceList`

Pointer to the resource list the driver used to detect the device. Resources in this list are in raw, untranslated form.

`ResourceRequirements`

Optionally points to a resource requirements list for the detected device. **NULL** if the caller does not have this information for the device.

`ResourceAssigned`

Specifies whether the device's resources have already been reported to the PnP manager. If*ResourceAssigned* is **TRUE**, the resources have already been reported, possibly with IoReportResourceForDetection, and the PnP manager will not attempt to claim them on behalf of the device. If **TRUE**, the PnP manager will also not claim resources when the device is root-enumerated on subsequent boots.

`DeviceObject`

Optionally points to a PDO for the detected device.

NULL if the caller does not have a PDO for the device, which is typically the case. If *DeviceObject* is **NULL**, the PnP manager creates a PDO for the device and returns a pointer to the caller.

If the caller supplies a PDO, the PnP manager does not create a new PDO. On a given call to this routine the *DeviceObject* parameter is either an IN or an OUT parameter, but not both.

Return Value

IoReportDetectedDevice returns STATUS_SUCCESS on success, or the appropriate error code on failure.

Remarks

Drivers for legacy devices use **IoReportDetectedDevice** to report their devices to the system. A driver should only call **IoReportDetectedDevice** to report a legacy, non-PnP device. PnP devices should be reported in response to an IRP_MN_QUERY_DEVICE_RELATIONS request.

Drivers only need to call **IoReportDetectedDevice** the first time they are loaded because the PnP manager caches the reported information. Drivers that use this routine should store a flag in the registry to indicate whether they have already done device detection.

A driver typically calls this routine from its DriverEntry routine. A few drivers, like certain NDIS or EISA drivers, might call this routine from an AddDevice routine.

On successful completion of **IoReportDetectedDevice**, the caller should attach an FDO to the PDO returned at *DeviceObject*. Once the caller attaches its FDO, the caller is the function driver for the device, at least temporarily. There are no filter drivers. The PnP manager owns the PDO.

The PnP manager considers the device to be started and therefore does not call the driver's AddDevice routine and does not send an IRP_MN_START_DEVICE request. The driver must be prepared to handle all other PnP IRPs, however.

IoReportDetectedDevice marks the device as a root-enumerated device and this identification is persistent across system boots. During subsequent system boots the PnP manager "detects" the device on the root-enumerated list and configures it like a PnP device: the PnP manager queries for device information, identifies the appropriate drivers and calls their *AddDevice* routines, and sends all the appropriate PnP IRPs.

The system generates two compatible ID strings for the device, of the form DETECTED*Interface*<i>Driver and DETECTED<i>Driver. *Interface* is the string name of the INTERFACE_TYPE of the first bus specified in the *ResourceList* parameter. *Interface* is set to "Internal" if no bus is specified. *Driver* is the driver's service name. A driver can provide additional hardware IDs or compatible IDs by handling the IRP_MN_QUERY_ID request.

A driver writer must provide an INF file that matches any of the specified hardware IDs or compatible IDs. The INF file should specify the original driver that called **IoReportDetectedDevice** as the driver to load for those IDs. The system uses this information to rebuild the driver stack for the device, for example on restart. Callers of **IoReportDetectedDevice** must be running at IRQL = PASSIVE_LEVEL in the context of a system thread.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)

IRP_MN_QUERY_DEVICE_RELATIONS

IoReportResourceForDetection

IoReportResourceForDetection function

1/25/2019 • 3 minutes to read • Edit Online

The **IoReportResourceForDetection** routine claims hardware resources in the configuration registry for a legacy device.

Syntax

```
NTSTATUS IoReportResourceForDetection(
  PDRIVER_OBJECT    DriverObject,
  PCM_RESOURCE_LIST DriverList,
  ULONG             DriverListSize,
  PDEVICE_OBJECT    DeviceObject,
  PCM_RESOURCE_LIST DeviceList,
  ULONG             DeviceListSize,
  PBOOLEAN          ConflictDetected
);
```

Parameters

`DriverObject`

Pointer to the driver object that was input to the driver's DriverEntry routine.

`DriverList`

Optionally points to a caller-supplied buffer that contains the driver's resource list, if the driver claims the same resources for all its devices. If the caller specifies a *DeviceList*, this parameter is ignored.

`DriverListSize`

Specifies the size in bytes of an optional *DriverList*. If *DriverList* is **NULL**, this parameter should be zero.

`DeviceObject`

Optionally points to the device object representing device for which the driver is attempting to claim resources.

`DeviceList`

Optionally points to a caller-supplied buffer containing the device's resource list. If the driver claims the same resources for all its devices, the caller can specify a *DriverList* instead.

`DeviceListSize`

Specifies the size in bytes of an optional *DeviceList*. If *DeviceList* is **NULL**, this parameter should be zero.

`ConflictDetected`

Pointer to a caller-supplied Boolean value that is set to **TRUE** on return if the resources are not available.

Return Value

IoReportResourceForDetection returns STATUS_SUCCESS if the resources are claimed. Possible error return values include the following.

RETURN CODE	DESCRIPTION
STATUS_CONFLICTING_ADDRESSES	The resources could not be claimed because they are already in use or are needed for a PnP-enumerable device.
STATUS_UNSUCCESSFUL	The *DeviceList* or *DriverList* is invalid.

Remarks

This routine is for drivers that detect earlier hardware which cannot be enumerated by Plug and Play (PnP).

If a driver supports only PnP hardware, it does no detection and therefore does not call **IoReportResourceForDetection**. The PnP system enumerates each PnP device, assigns resources to the device, and passes those resources to the device's drivers in an IRP_MN_START_DEVICE request.

If a PnP driver supports legacy hardware, however, it must call **IoReportResourceForDetection** to claim hardware resources before it attempts to detect the device.

Callers of this routine specify a CM_RESOURCE_LIST in either a *DeviceList* or a *DriverList* that is allocated from paged memory and that consists of raw, untranslated resources. The caller is responsible for freeing the memory.

A driver that can control more than one legacy card at the same time should claim the resources for each device against the device object for the respective device (using the *DeviceObject*, *DeviceList*, and *DeviceListSize* parameters). Such a driver must not claim these resources against their driver object.

A **CM_RESOURCE_LIST** contains two variable-sized arrays. Each array has a default size of one. If either array has more than one element, the caller must allocate memory dynamically to contain the additional elements. Only one CM_PARTIAL_RESOURCE_DESCRIPTOR can be part of each CM_FULL_RESOURCE_DESCRIPTOR in the list, except for the last full resource descriptor in the **CM_RESOURCE_LIST**, which can have additional partial resource descriptors in its array.

IoReportResourceForDetection, with the help of the PnP manager, determines whether the resources being requested conflict with resources that have already been claimed.

If a conflict is detected, this routine sets the BOOLEAN at *ConflictDetected* to **TRUE** and returns STATUS_CONFLICTING_ADDRESSES.

If no conflict is detected, this routine claims the resources, sets the BOOLEAN at *ConflictDetected* to **FALSE**, and returns STATUS_SUCCESS.

If this routine succeeds and the driver detects a legacy device, the driver reports the device to the PnP manager by calling IoReportDetectedDevice. In that call, the driver sets *ResourceAssigned* to **TRUE** so the PnP manager does

not attempt to claim the resources again.

When a driver no longer requires the resources claimed by a call to this routine, the driver calls this routine again with a *DriverList* or *DeviceList* with a **Count** of zero.

If a driver claims resources on a device-specific basis for more than one device, the driver must call this routine for each such device.

A driver can call this routine more than once for a given device. If one set of resources fails, the driver can call the routine again for the same device with a different set of resources. If a set of resources succeeds, the driver can call this routine again with a new list; the new list replaces the previous list.

Callers of **IoReportResourceForDetection** must be running at IRQL = PASSIVE_LEVEL in the context of a system thread.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

CM_RESOURCE_LIST

IoReportDetectedDevice

IoReportRootDevice function

1/25/2019 • 2 minutes to read • Edit Online

The **IoReportRootDevice** routine reports a device that cannot be detected by a PnP bus driver to the PnP Manager. **IoReportRootDevice** allows only one device per driver to be created.

Syntax

```
NTSTATUS IoReportRootDevice(
  PDRIVER_OBJECT DriverObject
);
```

Parameters

`DriverObject`

Pointer to the driver object of the driver that detected the device.

Return Value

IoReportRootDevice returns STATUS_SUCCESS on success, or the appropriate error code on failure.

Remarks

Drivers for devices that cannot be detected by a PnP bus driver use **IoReportRootDevice** to report their device to the system. Devices that can be detected by a PnP bus driver should be reported in response to an IRP_MN_QUERY_DEVICE_RELATIONS request.

A driver typically calls this routine from its DriverEntry routine.

IoReportRootDevice marks the device as a root-enumerated device and this identification is persistent across system boots. The PnP manager "detects" the device on the root-enumerated list and configures it like a PnP device: the PnP manager queries for device information, identifies the appropriate drivers and calls their *AddDevice* routines, and sends all the appropriate PnP IRPs.

The system generates a single Hardware ID string for the device, of the form ROOT<i>Driver where *Driver* is the driver's service name. A driver can provide additional hardware IDs or compatible IDs by handling the IRP_MN_QUERY_ID request.

A driver writer must provide an INF file that matches any of the specified hardware IDs or compatible IDs. The INF file should specify the original driver that called **IoReportRootDevice** as the driver to load for those IDs. The system uses this information to rebuild the driver stack for the device, for example on restart. Callers of **IoReportRootDevice** must be running at IRQL = PASSIVE_LEVEL in the context of a system thread.

> **Note** Drivers should use IoReportDetectedDevice to report hardware devices that use resources but cannot be detected by a PnP bus driver instead of **IoReportRootDevice**.

Requirements

Minimum supported client	Available in Windows 8 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)

IoSetActivityIdIrp function

1/25/2019 • 2 minutes to read • Edit Online

The IoSetActivityIdIrp routine associates an activity ID with an IRP.

Syntax

```
NTSTATUS IoSetActivityIdIrp(
  PIRP    Irp,
  LPCGUID Guid
);
```

Parameters

`Irp`

The IRP to associate the activity ID with.

`Guid`

A pointer to the GUID that represents the ID to store in the IRP. If NULL, IoSetActivityIdIrp attempts to retrieve the activity ID from the current thread if it was the thread that originally issued the request.

Return Value

IoSetActivityIdIrp returns STATUS_SUCCESS if the call is successful. Possible error return values include the following.

RETURN CODE	DESCRIPTION
STATUS_NOT_SUPPORTED	No GUID was provided and the ETW activity ID was unavailable.
STATUS_UNSUCCESSFUL	The I/O tracing provider has not been enabled on the IRP.

Remarks

Drivers should use IoSetActivityIdIrp only on IRPs that have been allocated using IoAllocateIrp (and freed using IoFreeIrp). Otherwise, memory leakage may result.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level if a GUID is passed in, otherwise PASSIVE_LEVEL.

IoSetActivityIdThread function

1/25/2019 • 2 minutes to read • Edit Online

The IoSetActivityIdThread routine associates an activity ID with the current thread. Drivers should use this routine when they are tracing aware and are issuing I/O on a worker thread.

Syntax

```
LPCGUID IoSetActivityIdThread(
  LPCGUID ActivityId
);
```

Parameters

`ActivityId`

The activity ID provided by caller.

Return Value

The activity ID that was previously set on the thread. Drivers must call IoClearActivityIdThread with this pointer when tracing is completed within the same thread context.

Remarks

Drivers that use I/O work items do not need to call this routine because the I/O subsystem takes care of propagating activity IDs to threads in that case.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

IoSetHardErrorOrVerifyDevice function

1/25/2019 • 2 minutes to read • Edit Online

Lower-level drivers call the **IoSetHardErrorOrVerifyDevice** routine to identify a removable media device that has encountered an error, so that a file system driver can prompt the user to verify that the medium is valid.

Syntax

```
void IoSetHardErrorOrVerifyDevice(
  PIRP           Irp,
  PDEVICE_OBJECT DeviceObject
);
```

Parameters

`Irp`

Pointer to the IRP for which the driver encountered a user-induced error.

`DeviceObject`

Pointer to the target device to be verified for the I/O operation.

Return Value

None

Remarks

Lower-level drivers for removal media devices must call **IoSetHardErrorOrVerifyDevice** before completing an IRP, if a call to IoIsErrorUserInduced returns **TRUE**. For more information, see Supporting Removable Media.

Subsequently, a file system driver will use information supplied in the specified device object to send a dialog box to the user, who can correct the error and retry the operation or cancel it.

The IRP passed to **IoSetHardErrorOrVerifyDevice** must be associated with a thread. Therefore, before a driver calls **IoSetHardErrorOrVerifyDevice**, it must verify that *irp*->**Tail.Overlay**.Thread is not **NULL**. If the value is **NULL**, **IoSetHardErrorOrVerifyDevice** must not be called using the current IRP. Instead, the driver should check all IRPs subsequently received and processed, until one is received for which *irp*->**Tail.Overlay**.Thread is not **NULL**. At that point, **IoSetHardErrorOrVerifyDevice** can be called.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=DISPATCH_LEVEL"

IoRaiseHardError

IoRaiseInformationalHardError

IoSetMasterIrpStatus function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetMasterIrpStatus** routine conditionally replaces the **Status** value in an IRP with the specified NTSTATUS value.

Syntax

```
void IoSetMasterIrpStatus(
  PIRP     MasterIrp,
  NTSTATUS Status
);
```

Parameters

`MasterIrp`

A pointer to the master IRP. For more information, see Remarks.

`Status`

An NTSTATUS value to compare to the **Status** member of the I/O status block in the master IRP.

Return Value

None.

Remarks

On receipt of an IRP, a driver can create two or more subordinate IRPs to perform the work requested by the original (or master) IRP. When the subordinate IRPs complete, the driver gathers the completion status codes from the subordinate IRPs and merges them to form a single completion status code for the master IRP.

IoSetMasterIrpStatus implements a uniform policy for merging the status codes from multiple subordinate IRPs into a status code for a master IRP. For example, if a master IRP is split into two subordinate IRPs, and one of these subordinate IRPs succeeds and the other fails, the status code from the failing IRP is used as the status code for the master IRP. However, if both subordinate IRPs fail, the more severe failure code is used as the status for the master IRP.

Before the first call to **IoSetMasterIrpStatus**, the driver sets the **IoStatus.Status** member in the master IRP to STATUS_SUCCESS (or to STATUS_FT_READ_FROM_COPY in case it is expected). Next, as each subordinate IRP completes, the driver calls **IoSetMasterIrpStatus** to merge the status code from this IRP with the status code in the master IRP. In this call, the *PIRP* parameter points to the master IRP, and the *Status* parameter is set to the value of the **IoStatus.Status** member in the subordinate IRP.

As a general rule, **IoSetMasterIrpStatus** replaces the status code in *PIRP*->**IoStatus.Status** with the *Status* value in the following cases:

- The status value in **PIRP* is STATUS_SUCCESS, and *Status* is an error code.
- The status value in **PIRP* is an error code, but *Status* is a more severe error code.

There are two exceptions to the general rule. A *Status* value of STATUS_VERIFY_REQUIRED always replaces the status

value in **PIRP*. A *Status* value of STATUS_FT_READ_FROM_COPY never replaces the status value in **PIRP*.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level.

IRP

IoSetSystemPartition function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetSystemPartition** routine sets the boot partition for the system.

Syntax

```
NTSTATUS IoSetSystemPartition(
  PUNICODE_STRING VolumeNameString
);
```

Parameters

`VolumeNameString`

Pointer to a Unicode string that specifies the MS-DOS name of the system partition.

Return Value

STATUS_SUCCESS if the boot partition can be set, or an error code on failure.

Remarks

The specified partition must contain the boot loader.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

IoSetThreadHardErrorMode function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetThreadHardErrorMode** routine enables or disables hard error reporting for the current thread.

Syntax

```
BOOLEAN IoSetThreadHardErrorMode(
  BOOLEAN EnableHardErrors
);
```

Parameters

`EnableHardErrors`

Specifies whether hard error reporting to the user should be enabled or disabled for this thread. A value of **TRUE** enables hard error reporting. **FALSE** disables it.

Return Value

IoSetThreadHardErrorMode returns **TRUE** if hard errors were enabled from this thread before this routine completed execution. Otherwise, this routine returns **FALSE**.

Remarks

If hard errors are disabled for a given thread, calls to **IoRaiseHardError** will not display a message to the user indicating that a serious error has occurred. In addition, the IRP that is passed to **IoRaiseHardError** is completed without any data being copied into user buffers. Calling **IoRaiseInformationalHardError** after disabling hard errors causes that routine to always return **FALSE** for this thread.

Requirements

Minimum supported client	Available in Microsoft Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=DISPATCH_LEVEL"

IoTransferActivityId function

1/25/2019 • 2 minutes to read • Edit Online

The IoTransferActivityId routine logs an ETW transfer event using the I/O tracing provider on behalf of the caller. This allows a driver to associate two related activity IDs without requiring a specific provider to be enabled.

Syntax

```
void IoTransferActivityId(
  LPCGUID ActivityId,
  LPCGUID RelatedActivityId
);
```

Parameters

`ActivityId`

The source activity ID.

`RelatedActivityId`

The new activity ID to be transferred from the source activity ID.

Return Value

None.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

IoUnregisterBootDriverCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **IoUnRegisterBootDriverCallback** routine unregisters a previously registered **BOOT_DRIVER_CALLBACK_FUNCTION** routine.

Syntax

```
void IoUnregisterBootDriverCallback(
  PVOID CallbackHandle
);
```

Parameters

`CallbackHandle`

A handle returned from a previous call to IoRegisterBootDriverCallback.

Return Value

None

Remarks

A driver that calls IoRegisterBootDriverCallback must call **IoUnRegisterBootDriverCallback** before being unloaded.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	<= APC_LEVEL

IoRegisterBootDriverCallback

IoVerifyPartitionTable function

1/25/2019 • 2 minutes to read • Edit Online

The **IoVerifyPartitionTable** routine checks the validity of the partition table for a disk.

Syntax

```
NTSTATUS IoVerifyPartitionTable(
  PDEVICE_OBJECT DeviceObject,
  BOOLEAN        FixErrors
);
```

Parameters

`DeviceObject`

Specifies the device object of the disk to verify.

`FixErrors`

Specifies if the routine should correct any correctable errors in the partition table.

Return Value

The routine returns STATUS_SUCCESS if the partition table is error-free.

If the caller specifies **FALSE** for the *FixErrors* parameter and the partition table has errors, the routine returns STATUS_DISK_CORRUPT_ERROR. If the caller specifies **TRUE** for *FixErrors*, and the routine is able to correct all errors in the partition table, it returns STATUS_SUCCESS. Otherwise it returns STATUS_DISK_CORRUPT_ERROR.

The routine might also return other NT status error codes.

Remarks

IoVerifyPartitionTable must be used only by disk drivers.

Requirements

Minimum supported client	Available starting with Windows XP.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IRQL	"<= APC_LEVEL"

IoVolumeDeviceToDosName function

1/25/2019 • 2 minutes to read • Edit Online

The **IoVolumeDeviceToDosName** routine returns the MS-DOS path for a specified device object that represents a file system volume.

Syntax

```
NTSTATUS IoVolumeDeviceToDosName(
  PVOID           VolumeDeviceObject,
  PUNICODE_STRING DosName
);
```

Parameters

`VolumeDeviceObject`

A pointer to a device object that represents a volume device object created by a storage class driver.

`DosName`

A pointer to a caller-allocated UNICODE_STRING structure. If the call is successful, **IoVolumeDeviceToDosName** sets the values of the **Length**, **MaximumLength**, and **Buffer** members of this structure. On exit, the **Buffer** member points to a wide-character, null-terminated string that contains the MS-DOS path of the volume device object specified by *VolumeDeviceObject*. For more information, see Remarks.

Return Value

IoVolumeDeviceToDosName returns STATUS_SUCCESS if the call is successful. Possible error return values include the following status codes.

RETURN VALUE	DESCRIPTION
STA TUS _IN VAL ID_P ARA MET ER	The routine failed due to invalid parameter values passed by the caller.

STA TUS _INS UFFI CIE NT_ RES OU RCE S	The routine failed to allocate resources required for this operation.

Remarks

IoVolumeDeviceToDosName allocates the string buffer pointed to by the **Buffer** member of the UNICODE_STRING structure that the *DosName* parameter points to. After this buffer is no longer required, a caller of this routine should call the ExFreePool routine to free the buffer.

Starting with Windows Vista, you must ensure that APCs are not disabled before calling this routine. The KeAreAllApcsDisabled routine can be used to verify that APCs are not disabled.

Requirements

Minimum supported client	Available starting with Windows XP. Drivers that must work in earlier versions of Windows NT-based operating systems can use RtlVolumeDeviceToDosName, which behaves identically.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

KeAreAllApcsDisabled

UNICODE_STRING

KeAreApcsDisabled function

1/25/2019 • 2 minutes to read • Edit Online

The **KeAreApcsDisabled** routine returns whether the calling thread is within a critical region or a guarded region, which disables normal kernel APC delivery.

Syntax

```
BOOLEAN KeAreApcsDisabled(

);
```

Parameters

This function has no parameters.

Return Value

KeAreApcsDisabled returns **TRUE** if the thread is within a critical region or a guarded region, and **FALSE** otherwise.

Remarks

A thread running at IRQL = PASSIVE_LEVEL can use **KeAreApcsDisabled** to determine if normal kernel APCs are disabled. A thread that is inside a critical region has both user APCs and normal kernel APCs disabled, but not special kernel APCs. A thread that is inside a guarded region has all APCs disabled, including special kernel APCs.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeLeaveCriticalRegion

KeBugCheck function

1/25/2019 • 2 minutes to read • Edit Online

The **KeBugCheck** routine brings down the system in a controlled manner when the caller discovers an unrecoverable inconsistency that would corrupt the system if the caller continued to run.

Syntax

```
void KeBugCheck(
  ULONG BugCheckCode
);
```

Parameters

`BugCheckCode`

Specifies a value that indicates the reason for the bug check.

Return Value

None

Remarks

A bug check is a system-detected error that causes an immediate, controlled shutdown of the system. Various kernel-mode components perform run-time consistency checking. When such a component discovers an unrecoverable inconsistency, it causes a bug check to be generated.

Whenever possible, all kernel-mode components should log an error and continue to run, rather than calling **KeBugCheck**. For example, if a driver is unable to allocate required resources, it should log an error so that the system continues to run; it must not generate a bug check.

A driver or other kernel-mode component should call this routine only in cases of a fatal, unrecoverable error that could corrupt the system itself.

KeBugCheck can be useful in the early stages of developing a driver, or while it is undergoing testing. In these circumstances, the *BugCheckCode* passed to this routine should be distinct from those codes already in use by Windows or its drivers. For a list of these codes, see Bug Check Codes.

However, even during driver development, this routine is of only limited utility, since it results in a complete system shutdown. A more effective debugging method is to attach a kernel debugger to the system and then use routines that send messages to the debugger or break into the debugger. For further information, see Using Debugging Code in a Driver.

When a bug check is unavoidable, most system components call KeBugCheckEx, which provides more information about the cause of such an inconsistency than **KeBugCheck**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeRegisterBugCheckReasonCallback

KeEnterCriticalRegion function

1/25/2019 • 2 minutes to read • Edit Online

The **KeEnterCriticalRegion** routine temporarily disables the execution of normal kernel APCs, but does not prevent special kernel APCs from running.

Syntax

```
void KeEnterCriticalRegion(

);
```

Parameters

This function has no parameters.

Return Value

None

Remarks

A driver calls this routine to enter a critical region in which the execution of normal kernel APCs is deferred until this driver exits the critical region by calling the KeLeaveCriticalRegion routine. Any caller of **KeEnterCriticalRegion** should call **KeLeaveCriticalRegion** as quickly as possible after entering a critical region.

Highest-level drivers can call **KeEnterCriticalRegion** while running in the context of the thread that requested the current I/O operation.

A thread that is inside a critical region has both user APCs and normal kernel APCs disabled, but not special kernel APCs. For more information about these APC types, see Types of APCs.

Critical regions can be entered recursively and each call to **KeEnterCriticalRegion** must have a matching call to **KeLeaveCriticalRegion**.

A driver can use a critical region to acquire and release exclusive access to a shared resource. In this case, the ExEnterCriticalRegionAndAcquireResourceExclusive and ExReleaseResourceAndLeaveCriticalRegion routines can be used instead of the **KeEnterCriticalRegion** and **KeLeaveCriticalRegion** routines. For more information, see the code example in ExEnterCriticalRegionAndAcquireResourceExclusive.

For more information about APCs, see Asynchronous Procedure Calls.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeLeaveCriticalRegion

KeEnterGuardedRegion function

1/25/2019 • 2 minutes to read • Edit Online

The **KeEnterGuardedRegion** routine enters a guarded region, which disables all kernel-mode APC delivery to the current thread.

Syntax

```
void KeEnterGuardedRegion(

);
```

Parameters

This function has no parameters.

Return Value

None

Remarks

To exit a guarded region entered with **KeEnterGuardedRegion**, call the **KeLeaveGuardedRegion** routine. Guarded regions can be nested. APCs are not reenabled until the thread exits the outermost guarded region.

For more information about guarded regions, see Critical Regions and Guarded Regions.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

KeLeaveGuardedRegion

KeExpandKernelStackAndCallout function

1/25/2019 • 2 minutes to read • Edit Online

The **KeExpandKernelStackAndCallout** routine calls a routine with a guaranteed amount of stack space.

Syntax

```
NTSTATUS KeExpandKernelStackAndCallout(
  PEXPAND_STACK_CALLOUT Callout,
  PVOID                 Size,
  SIZE_T                Parameter
);
```

Parameters

`Callout`

Pointer to an ExpandedStackCall routine.

`Size`

Specifies the number of bytes on the stack to provide to the *ExpandedStackCall* routine. This value must be large enough to accommodate the stack usage of the *ExpandedStackCall* routine and any call that this routine might make. This value must not exceed MAXIMUM_EXPANSION_SIZE.

`Parameter`

Specifies the parameter to pass to the *ExpandedStackCall* routine.

Return Value

KeExpandKernelStackAndCallout returns STATUS_SUCCESS if the operation succeeds or an appropriate NTSTATUS value if the operation fails.

Remarks

KeExpandKernelStackAndCallout expands the kernel stack by *Size* bytes for use by the ExpandedStackCall routine. If there is not enough space available on the stack, **KeExpandKernelStackAndCallout** allocates a new kernel stack segment. The routine then calls the *ExpandedStackCall* routine.

In Windows 7, Windows Server 2008 R2, and later versions of Windows, consider using the KeExpandKernelStackAndCalloutEx routine instead of **KeExpandKernelStackAndCallout**. **KeExpandKernelStackAndCalloutEx** is similar to **KeExpandKernelStackAndCallout** but has additional parameters and can be called at IRQL <= DISPATCH_LEVEL.

The calling thread must not call the PsTerminateSystemThread routine until the thread's *ExpandedStackCall* routine returns. **PsTerminateSystemThread** checks to determine if the *ExpandedStackCall* routine is still active and, if it is, causes a bug check.

Requirements

Minimum supported client	Available starting with Windows Server 2003 on x64-based processors, and starting with Windows Vista on all processors.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

KeExpandKernelStackAndCalloutEx

PsTerminateSystemThread

KeGetCurrentNodeNumber function

1/25/2019 • 2 minutes to read • Edit Online

The **KeGetCurrentNodeNumber** routine gets the NUMA node number for the logical processor that the caller is running on.

Syntax

```
USHORT KeGetCurrentNodeNumber(

);
```

Parameters

This function has no parameters.

Return Value

KeGetCurrentNodeNumber returns the node number.

Remarks

In a non-uniform memory access (NUMA) multiprocessor architecture, a node is a collection of processors that share fast access to a region of memory. Memory access is non-uniform because a processor can access the memory in its node faster than it can access the memory in other nodes.

In a NUMA multiprocessor system that contains *n* nodes, the nodes are numbered from 0 to *n*-1. To get the highest node number (*n*-1) in the system, call the KeQueryHighestNodeNumber routine.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h, Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

See Also

KeQueryHighestNodeNumber

KeGetCurrentProcessorNumber function

1/25/2019 • 2 minutes to read • Edit Online

The **KeGetCurrentProcessorNumber** routine returns the system-assigned number of the current processor on which the caller is running.

Syntax

```
ULONG KeGetCurrentProcessorNumber(

);
```

Parameters

This function has no parameters.

Return Value

KeGetCurrentProcessorNumber returns a ULONG value that represents the processor on which the caller is currently running.

Remarks

KeGetCurrentProcessorNumber can be called to debug spin lock usage on SMP machines during driver development. A driver also might call **KeGetCurrentProcessorNumber** if it maintained some per-processor data and attempted to reduce cache-line contention.

The number of processors in an SMP machine is a zero-based value.

Windows 7 and later versions of Windows support processor groups. Drivers that are designed to handle information about processor groups should use the KeGetCurrentProcessorNumberEx routine, which specifies a processor group, instead of **KeGetCurrentProcessorNumber**, which does not. However, the implementation of **KeGetCurrentProcessorNumber** in Windows 7 and later versions of Windows provides compatibility for drivers that were written for earlier versions of Windows. In this implementation, **KeGetCurrentProcessorNumber** returns the group-relative processor number if the caller is running on a processor in group 0, which is compatible with the behavior of this routine in earlier versions of Windows that do not support processor groups. If the caller is running on a processor in any group other than group 0, this routine returns a number that is less than the number of processors in group 0. This behavior ensures that the return value is less than the return value of the KeQueryActiveProcessorCount routine.

If the call to **KeGetCurrentProcessorNumber** occurs at IRQL <= APC_LEVEL, a processor switch can occur between instructions. Consequently, callers of **KeGetCurrentProcessorNumber** usually run at IRQL >= DISPATCH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Desktop
Header	ntddk.h (include Ntddk.h)
IRQL	See Remarks section.
DDI compliance rules	Irql_Miscellaneous_Function

See Also

KeGetCurrentProcessorNumberEx

KeQueryActiveProcessorCount

KeGetCurrentProcessorNumberEx function

1/25/2019 • 2 minutes to read • Edit Online

The **KeGetCurrentProcessorNumberEx** routine gets the processor number of the logical processor that the caller is running on.

Syntax

```
ULONG KeGetCurrentProcessorNumberEx(
  PPROCESSOR_NUMBER ProcNumber
);
```

Parameters

`ProcNumber`

A pointer to a caller-allocated buffer into which the routine writes a PROCESSOR_NUMBER structure that identifies the current logical processor. This structure contains the group number and the group-relative processor number. You can set this parameter to **NULL** if you do not need this information.

Return Value

KeGetCurrentProcessorNumberEx returns the systemwide processor index of the logical processor that the caller is running on.

Remarks

If *ProcNumber* is non-**NULL**, the buffer that is pointed to by *ProcNumber* must be large enough to contain a PROCESSOR_NUMBER structure. In contrast to this structure, which contains a group number and a group-relative processor number, the return value is a processor index that identifies the processor across the entire multiprocessor system.

For example, if a multiprocessor system contains two groups, and each group contains 64 logical processors, the processor numbers in each group range from 0 to 63, but the systemwide processor indexes range from 0 to 127.

A related routine, KeGetCurrentProcessorNumber, returns the current processor number, but this routine, unlike **KeGetCurrentProcessorNumberEx**, does not provide a group number for the processor. In Windows 7 and later versions of the Windows operating system, **KeGetCurrentProcessorNumber** returns the group-relative processor number if the caller is running on a processor in group 0, which is compatible with the behavior of this routine in earlier versions of Windows that do not support groups. However, if the caller is running on a processor in any group other than group 0, this routine returns a number that is less than the number of processors in group 0. This behavior ensures that the return value is less than the return value of the KeQueryActiveProcessorCount routine. Existing drivers that call **KeGetCurrentProcessorNumber** and that use no group-oriented features run correctly in multiprocessor systems that have two or more groups. However, drivers that use any group-oriented features in Windows 7 and later versions of the Windows operating system should call **KeGetCurrentProcessorNumberEx** instead of **KeGetCurrentProcessorNumber**.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.

PROCESSOR_NUMBER

KeInitializeCrashDumpHeader function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInitializeCrashDumpHeader** routine supplies the header information the system requires for a crash dump file.

Syntax

```
NTSTATUS KeInitializeCrashDumpHeader(
  ULONG  DumpType,
  ULONG  Flags,
  PVOID  Buffer,
  ULONG  BufferSize,
  PULONG BufferNeeded
);
```

Parameters

`DumpType`

Specifies the type of dump file. The only valid value is DUMP_TYPE_FULL.

`Flags`

Specifies flags for the dump file. The only valid value is 0.

`Buffer`

Pointer to the buffer that receives the header information.

`BufferSize`

Specifies the size in bytes of the buffer pointed to by *Buffer*.

`BufferNeeded`

Optionally, a pointer to a variable that receives the size necessary to hold the complete header information.

Return Value

KeInitializeCrashDumpHeader returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure.

Remarks

Drivers can use this routine to manually create a crash dump file. The file can be created at any time, and used by a debugger to examine the state of the system.

To create a crash-dump file, call **KeInitializeCrashDumpHeader** to create the header, then append the contents of memory to the header. Note that the driver is not required to record the contents of memory immediately after calling the routine: the header can normally be created at any time before the crash-dump file is written.

Because the routine is designed to be called well before the memory contents are recorded, it has the following limitations:

- The routine does not record any information about active exception records.
- If the size of system RAM changes, the header must be recreated.

The routine does not record any secondary dump data.

Starting with Windows 8, **KeInitializeCrashDumpHeader** always writes the base address of the system process page directory to the crash-dump header, regardless of the process context from which **KeInitializeCrashDumpHeader** is called. The debugger can use this directory to access the crash-dump file in the context of the system process.

In earlier versions of Windows, **KeInitializeCrashDumpHeader** writes the base address of the page directory of the caller's current process context to the crash-dump header. Thus, **KeInitializeCrashDumpHeader** must be called from the system process. Otherwise, the debugger will be unable to access the crash-dump file in the process context in which the file was saved.

Starting with Windows 8, **KeInitializeCrashDumpHeader** is declared in the Wdm.h header file in the Windows Driver Kit (WDK). To use this routine with earlier versions of the WDK, include the following function declaration in your driver code:

C++

```
NTSTATUS
  KeInitializeCrashDumpHeader(
    __in ULONG  DumpType,
    __in ULONG  Flags,
    __out PVOID  Buffer,
    __in ULONG  BufferSize,
    __out_opt PULONG  BufferNeeded
    );
```

Requirements

Minimum supported client	Available starting with Windows Server 2003 with SP1.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeInvalidateAllCaches function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInvalidateAllCaches** routine flushes all processor caches.

Syntax

```
BOOLEAN KeInvalidateAllCaches(

);
```

Parameters

This function has no parameters.

Return Value

KeInvalidateAllCaches returns a value that is reserved for system use. Treat this value as VOID.

Remarks

The **KeInvalidateAllCaches** routine flushes each processor's caches and marks each cache's contents invalid. The processor caches are guaranteed to have completed the flush operation before **KeInvalidateAllCaches** returns.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of Windows.

KeLeaveCriticalRegion function

1/25/2019 • 2 minutes to read • Edit Online

The **KeLeaveCriticalRegion** routine reenables the delivery of normal kernel-mode APCs that were disabled by a preceding call to **KeEnterCriticalRegion**.

Syntax

```
void KeLeaveCriticalRegion(

);
```

Parameters

This function has no parameters.

Return Value

None

Remarks

Highest-level drivers can call this routine while running in the context of the thread that requested the current I/O operation.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"
DDI compliance rules	CriticalRegions, IrqlKeApcLte2, WithinCriticalRegion, HwStorPortProhibitedDDIs, WithinCriticalRegion(storport)

KeAreApcsDisabled

KeEnterCriticalRegion

KeLeaveGuardedRegion function

1/25/2019 • 2 minutes to read • Edit Online

The **KeLeaveGuardedRegion** routine exits a guarded region entered by **KeEnterGuardedRegion**.

Syntax

```
void KeLeaveGuardedRegion(

);
```

Parameters

This function has no parameters.

Return Value

None

Remarks

Guarded regions can be nested, so APCs are only reenabled once the thread exists the outermost guarded region.

For more information about guarded regions, see Critical Regions and Guarded Regions.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"
DDI compliance rules	GuardedRegions, IrqlKeApcLte2, WithinCriticalRegion, HwStorPortProhibitedDDIs

KeEnterGuardedRegion

KePulseEvent function

1/25/2019 • 2 minutes to read • Edit Online

The **KePulseEvent** routine atomically sets an event object to a signaled state, attempts to satisfy as many waits as possible, and then resets the event object to a not-signaled state.

Syntax

```
LONG KePulseEvent(
  PRKEVENT  Event,
  KPRIORITY Increment,
  BOOLEAN   Wait
);
```

Parameters

`Event`

A pointer to a dispatcher object of type KEVENT.

`Increment`

Specifies the priority increment that is to be applied if setting the event causes a wait to be satisfied.

`Wait`

Specifies a Boolean value that signifies whether the call to **KePulseEvent** will be immediately followed by a call to one of the **KeWait*Xxx*** routines. If **TRUE**, the **KePulseEvent** call is immediately followed by a call to KeWaitForMultipleObjects, KeWaitForMutexObject, or KeWaitForSingleObject. For more information, see the following Remarks section.

Return Value

The previous signal state of the event object.

Remarks

For more information about event objects, see Event Objects.

The **KePulseEvent** routine might temporarily raise the IRQL. If the *Wait* parameter is **FALSE**, the routine, before it returns, restores the IRQL to the original value that it had at the start of the call.

If *Wait* = **TRUE**, the routine returns without lowering the IRQL. In this case, the **KePulseEvent** call must be immediately followed by a **KeWait*Xxx*** call. By setting *Wait* = **TRUE**, the caller can prevent an unnecessary context switch from occurring between the **KePulseEvent** call and the **KeWait*Xxx*** call. The **KeWait*Xxx*** routine, before it returns, restores the IRQL to its original value at the start of the **KePulseEvent** call. Although the IRQL disables context switches between the two calls, these calls cannot reliably be used as the start and end of an atomic operation. For example, between these two calls, a thread that is running at the same time on another processor might change the state of the event object or of the target of the wait.

If the caller is executing at IRQL = DISPATCH_LEVEL or in an arbitrary thread context, the *Timeout* parameter to **KeWait*Xxx*** must be zero.

Warning If a thread waiting for *Event* is currently running a kernel APC, then, when **KePulseEvent** is called, this thread's wait is not satisfied. After the kernel APC completes, the thread remains in the wait state.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"
DDI compliance rules	IrqlKeDispatchLte, HwStorPortProhibitedDDIs

KeQueryActiveGroupCount function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryActiveGroupCount** routine returns the number of active processor groups in a multiprocessor system.

Syntax

```
USHORT KeQueryActiveGroupCount(

);
```

Parameters

This function has no parameters.

Return Value

KeQueryActiveGroupCount returns a count of the active groups.

Remarks

A processor group is active if it contains one or more active logical processors.

An active logical processor is a logical processor that Windows has started up and added to a multiprocessor system. The term *active processor* applies to a processor that is available to perform processing work, regardless of whether the processor is currently performing processing work or is idle. In some systems, the number of active processors might remain unchanged from system startup to shutdown. In other systems, Windows might dynamically add active processors while the system is running. Windows never removes active processors from a system.

Thus, the number of active processors in a multiprocessor system can increase between system startup and shutdown, but this number never decreases. Similarly, the number of active groups in the system can increase if a processor is dynamically added to an inactive group while the system is running. The number of active groups never decreases.

In contrast, the value that is returned by KeQueryMaximumGroupCount remains constant during runtime. This value is the maximum number of groups that the system can have.

Call the KeQueryActiveProcessorCountEx routine to determine the number of active logical processors in a particular group.

Windows 7 is the first version of Windows to support processor groups. In Windows 7, only 64-bit versions of Windows support multiple groups; 32-bit versions of Windows support only one group. If a multiprocessor system is running a 64-bit version of Windows and contains no more than 64 logical processors, Windows assigns all processors to group 0. A multiprocessor system that is running a 32-bit version of Windows can contain no more than 32 processors.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h, Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeQueryActiveProcessorCountEx

KeQueryMaximumGroupCount

KeQueryActiveProcessorCount function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryActiveProcessorCount** routine returns the number of currently active processors.

Syntax

```
ULONG KeQueryActiveProcessorCount(
  PKAFFINITY ActiveProcessors
);
```

Parameters

`ActiveProcessors`

A pointer to a **KAFFINITY**-typed variable into which the routine writes a bitmask that represents the set of currently active processors. In a hot-add environment, this mask may change during runtime. This parameter is optional and can be specified as **NULL** if the caller does not require the mask of active processors.

Return Value

KeQueryActiveProcessorCount returns the number of currently active processors.

Remarks

A device driver calls the **KeQueryActiveProcessorCount** routine to retrieve the number of currently active processors. Device drivers that are built for Windows Vista and later versions of the Windows operating system should not use the **KeNumberProcessors** kernel variable for this purpose.

Callers cannot assume that the **KeQueryActiveProcessorCount** routine maps processors to bits in the returned **KAFFINITY** value consecutively, or that the routine will return the same bitmask each time it is called.

Callers must also be aware that the value returned by **KeQueryActiveProcessorCount** can change at runtime on versions of Windows that support hot-add CPU functionality.

If necessary, register for notification of changes to the number of processors by calling the KeRegisterProcessorChangeCallback routine.

To query just the affinity mask without getting the number of active processors, use KeQueryActiveProcessors.

Windows 7 and later versions of Windows support processor groups. Drivers that are designed to handle information about processor groups should use the KeQueryActiveProcessorCountEx routine, which specifies a processor group, instead of **KeQueryActiveProcessorCount**, which does not. However, the implementation of **KeQueryActiveProcessorCount** in Windows 7 and later versions of Windows provides compatibility for drivers that were written for earlier versions of Windows, which do not support processor groups. In this implementation, **KeQueryActiveProcessorCount** returns the number of active logical processors in group 0, and writes an affinity mask to **ActiveProcessors* that specifies the set of active logical processors in group 0.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeQueryActiveProcessorCountEx

KeQueryActiveProcessors

KeRegisterProcessorChangeCallback

KeQueryActiveProcessorCountEx function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryActiveProcessorCountEx** routine returns the number of active logical processors in a specified group in a multiprocessor system or in the entire system.

Syntax

```
ULONG KeQueryActiveProcessorCountEx(
  USHORT GroupNumber
);
```

Parameters

`GroupNumber`

The group number. If a multiprocessor system contains *n* groups, valid group numbers range from 0 to *n*-1. To count all active processors in all groups in the system, set this parameter to ALL_PROCESSOR_GROUPS, which is defined in header files Winnt.h and Ntdef.h.

Return Value

KeQueryActiveProcessorCountEx returns the number of active logical processors in the group. If *GroupNumber* is not a valid group number and is not ALL_PROCESSOR_GROUPS, it returns zero.

Remarks

An active logical processor is a logical processor that Windows has started up and added to a multiprocessor system. The term active processor applies to a processor that is available to perform processing work, regardless of whether the processor is currently performing processing work or is idle. In some systems, the number of active processors might remain unchanged from system startup to shutdown. In other systems, Windows might dynamically add active processors while the system is running. Windows never removes active processors from a system. Thus, the number of active processors in a multiprocessor system can increase between system startup and shutdown, but this number never decreases.

A related routine, KeQueryActiveProcessorCount, returns an active processor count, but this routine, unlike **KeQueryActiveProcessorCountEx**, does not accept a group number as an input parameter. In Windows 7 and later versions of the Windows operating system, **KeQueryActiveProcessorCount** returns the active processor count in group 0, which is compatible with the behavior of this routine in earlier versions of Windows that do not support groups. This behavior ensures that existing drivers that call **KeQueryActiveProcessorCount** and that use no group-oriented features will run correctly in multiprocessor systems that have two or more groups. However, drivers that use any group-oriented features in Windows 7 and later versions of the Windows operating system should call **KeQueryActiveProcessorCountEx** instead of **KeQueryActiveProcessorCount**.

For a code example that uses **KeQueryActiveProcessorCountEx**, see KeGetProcessorNumberFromIndex.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h, Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeGetProcessorNumberFromIndex

KeQueryActiveProcessorCount

KeQueryActiveProcessors function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryActiveProcessors** routine returns a bitmask of the currently active processors.

Syntax

```
KAFFINITY KeQueryActiveProcessors(

);
```

Parameters

This function has no parameters.

Return Value

KeQueryActiveProcessors returns a **KAFFINITY** value that represents the set of currently active processors.

Remarks

Callers cannot assume that **KeQueryActiveProcessors** maps processors to bits consecutively, or that the routine consistently uses the same mapping each time it is called. The only valid use for the return value is to determine the number of active processors by counting the number of bits that are set.

Callers must also be aware that the value returned by **KeQueryActiveProcessors** can change during runtime on versions of Windows that support hot-add CPU functionality.

Windows 7 and later versions of Windows support processor groups. Drivers that are designed to handle information about processor groups should use the KeQueryGroupAffinity routine, which specifies a processor group, instead of **KeQueryActiveProcessors**, which does not. However, the implementation of **KeQueryActiveProcessors** in Windows 7 and later versions of Windows provides compatibility for drivers that were written for earlier versions of Windows, which do not support processor groups. In this implementation, **KeQueryActiveProcessors** returns an affinity mask that specifies the set of active logical processors in group 0.

In Windows Vista and later versions of Windows, this routine can be called at any IRQL. However, in Windows Server 2003 and earlier versions of Windows, this routine must be called at IRQL <= APC_LEVEL.

The **KeNumberProcessors** kernel variable is obsolete in Windows Vista with Service Pack 1 (SP1), Windows Server 2008, and later versions of Windows. **KeNumberProcessors** does not appear in WDK headers for WDK releases starting with Windows Vista SP1; however, the variable is still exported from the kernel, so drivers built for earlier platforms will not break

Windows Server 2008 includes support for Dynamic Hardware Partitioning (DHP) in the Windows Datacenter and Enterprise Edition SKUs. As part of DHP, Windows Server 2008 supports hot adding CPUs at runtime. In a hot-add CPU environment, the number of processors may not remain constant during runtime.

Accordingly, in Windows Server 2008, code that can determine the number of processors must use **KeQueryActiveProcessors** instead of direct references to the kernel variable, **KeNumberProcessors**.

Review any code that currently references **KeNumberProcessors** to make sure that it accommodates changes to

CPU count in hot-add CPU environments.

You can use the PNPCPU tool to simulate hot adding a CPU for testing purposes.

C++

```
#if (NTDDI_VERSION >= NTDDI_VISTA)
extern NTSYSAPI volatile CCHAR KeNumberProcessors;
#else
#if (NTDDI_VERSION >= NTDDI_WINXP)
extern NTSYSAPI CCHAR KeNumberProcessors;
#else
extern PCCHAR KeNumberProcessors;
#endif
#endif
```

Starting with Windows XP, **KeNumberProcessors** is an 8-bit integer value that indicates the number of processors in the platform. In earlier versions of Windows, **KeNumberProcessors** is a pointer to an 8-bit integer value that indicates the number of processors in the platform.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	See Remarks section.

KeQueryActiveProcessorCount

KeQueryGroupAffinity

KeQueryGroupAffinity function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryGroupAffinity** routine returns an affinity mask that identifies the active logical processors in a specified group in a multiprocessor system.

Syntax

```
KAFFINITY KeQueryGroupAffinity(
  USHORT GroupNumber
);
```

Parameters

`GroupNumber`

The group number. If a multiprocessor system contains *n* groups, the groups are numbered from 0 to *n*-1. To obtain the number of active groups in the system, call the KeQueryActiveGroupCount routine.

Return Value

KeQueryGroupAffinity returns a **KAFFINITY** value that identifies the active logical processors in the specified group. If the *GroupNumber* parameter value is not a valid group number, the routine returns zero.

Remarks

A related routine, KeQueryActiveProcessors, returns an affinity mask that represents a set of active processors, but this routine, unlike **KeQueryGroupAffinity**, does not accept a group number as an input parameter. In Windows 7 and later versions of the Windows operating system, **KeQueryActiveProcessors** returns an affinity mask for the active processors in group 0, which is compatible with the behavior of this routine in earlier versions of Windows that do not support groups. This behavior ensures that existing drivers that call **KeQueryActiveProcessors** and that use no group-oriented features will run correctly in multiprocessor systems that have two or more groups. However, drivers that use any group-oriented features in Windows 7 and later versions of the Windows operating system should call **KeQueryGroupAffinity** instead of **KeQueryActiveProcessors**.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeQueryActiveProcessors

KeQueryHardwareCounterConfiguration function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryHardwareCounterConfiguration** routine queries the operating system for the list of hardware counters to use for thread profiling.

Syntax

```
NTSTATUS KeQueryHardwareCounterConfiguration(
  PHARDWARE_COUNTER CounterArray,
  ULONG             MaximumCount,
  PULONG            Count
);
```

Parameters

`CounterArray`

A pointer to a caller-allocated buffer into which the routine writes an array of elements of type HARDWARE_COUNTER. Each array element is a structure that contains information about a hardware counter. The array contains one element for each hardware counter that is assigned to thread profiling. If the routine fails, it writes nothing to this buffer.

`MaximumCount`

Specifies the maximum number of elements that the routine can write to the buffer that is pointed to by the *CounterArray* parameter. The size of the caller-allocated buffer must be at least *MaximumCount* * **sizeof**(**HARDWARE_COUNTER**) bytes.

`Count`

A pointer to a location into which the routine writes the number of array elements that it has written to the buffer that is pointed to by the *CounterArray* parameter. If the buffer length that is specified by *MaximumCount* is not large enough to contain the entire array, the routine writes the required length to **Count* and returns STATUS_BUFFER_TOO_SMALL.

Return Value

KeQueryHardwareCounterConfiguration returns STATUS_SUCCESS if the call is successful. Possible error return values include the following:

RETURN CODE	DESCRIPTION
STATUS_BUFFER_TOO_SMALL	The *MaximumCount* parameter specifies a buffer length that is not large enough to contain the counter configuration information.

STA **TUS** **_NO** **T_I** **MP** **LEM** **ENT** **ED**	This routine is not implemented for the processor architecture that the caller is running on.

Remarks

In Windows 7, this routine is implemented only for the x86-based, x64-based, and Itanium-based architectures. If the caller is running on a processor architecture that is not supported, the routine returns STATUS_NOT_IMPLEMENTED.

To set the hardware counter configuration to use for thread profiling, call the KeSetHardwareCounterConfiguration routine.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

HARDWARE_COUNTER

KeSetHardwareCounterConfiguration

KeQueryHighestNodeNumber function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryHighestNodeNumber** routine returns the highest node number in a multiprocessor system that has a non-uniform memory access (NUMA) architecture.

Syntax

```
USHORT KeQueryHighestNodeNumber(

);
```

Parameters

This function has no parameters.

Return Value

KeQueryHighestNodeNumber returns the highest node number.

Remarks

In a non-uniform memory access (NUMA) multiprocessor architecture, a node is a collection of processors that share fast access to a region of memory. Memory access is non-uniform because a processor can access the memory in its node faster than it can access the memory in other nodes.

If a NUMA multiprocessor system contains *n* nodes, the nodes are numbered from 0 to *n*-1, and **KeQueryHighestNodeNumber** returns *n*-1. If a system contains one node, **KeQueryHighestNodeNumber** returns zero.

If a system does not have a NUMA architecture, **KeQueryHighestNodeNumber** returns zero. An example of non-NUMA architecture is a symmetric multiprocessor system (SMP).

When Windows initializes a NUMA multiprocessor system, it assigns logical processors to nodes and counts the number of resulting nodes. Windows defines the capacity of a node as the number of processors that are present when the system starts in addition to any other logical processors that can be added to the node while the system is running. If, during initialization, Windows encounters a NUMA hardware node that contains more logical processors than will fit into a group, Windows splits the node into smaller, logical nodes. Each of these nodes does not exceed the maximum group size. The value that is returned by **KeQueryHighestNodeNumber** indicates the number of logical nodes in the system.

After the system has been initialized, the node count remains fixed while the system continues to run. This count might include memory-only nodes, which are nodes that contain memory but no active logical processors.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.

Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeQueryLogicalProcessorRelationship function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryLogicalProcessorRelationship** routine gets information about the relationships of one or more processors to the other processors in a multiprocessor system.

Syntax

```
NTSTATUS KeQueryLogicalProcessorRelationship(
  PPROCESSOR_NUMBER                       ProcessorNumber,
  LOGICAL_PROCESSOR_RELATIONSHIP          RelationshipType,
  PSYSTEM_LOGICAL_PROCESSOR_INFORMATION_EX Information,
  PULONG                                  Length
);
```

Parameters

`ProcessorNumber`

A pointer to a PROCESSOR_NUMBER structure that identifies the logical processor for which the caller requests relationship information. To request information about all logical processors in the system, set this parameter to **NULL**.

`RelationshipType`

Specifies the type of relationship information that is requested by the caller. Set this parameter to one of the following LOGICAL_PROCESSOR_RELATIONSHIP enumeration values:

- **RelationProcessorCore**
- **RelationNumaNode**
- **RelationCache**
- **RelationProcessorPackage**
- **RelationGroup**
- **RelationAll**

`Information`

A pointer to a caller-allocated buffer into which the routine writes an array of one or more SYSTEM_LOGICAL_PROCESSOR_INFORMATION_EX structures that contain the information requested by the caller. If the function fails, the contents of this buffer are undefined. Set *Information* = **NULL** to obtain the required buffer length before you allocate the buffer. For more information, see the following Remarks section.

`Length`

A pointer to a location that contains the size, in bytes, of the buffer that is pointed to by *Information*. On entry, * *Length* contains the size of the caller-allocated buffer that is pointed to by *Information*. During the call, the routine overwrites the value that is pointed to by *Length* with the buffer size that is required to contain the requested relationship information.

Return Value

KeQueryLogicalProcessorRelationship returns STATUS_SUCCESS if the call is successful. Possible error return

values include the following:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The *ProcessorNumber* parameter points to a PROCESSOR_NUMBER structure that contains invalid information.
STATUS_INFO_LENGTH_MISMATCH	The caller-allocated buffer that is pointed to by the *Information* parameter is not large enough to contain the requested relationship information.

Remarks

To determine the buffer size to allocate, initially call **KeQueryLogicalProcessorRelationship** with *Information* = **NULL** and **Length* = 0. In response, the routine writes the required buffer size to **Length* and returns STATUS_INFO_LENGTH_MISMATCH. Next, allocate a buffer of the required size and call **KeQueryLogicalProcessorRelationship** a second time. In this second call, set *Information* to the buffer address and **Length* to the buffer size. If the second call succeeds, the routine writes the requested relationship information to the buffer and returns STATUS_SUCCESS.

Examples

The following code example gets processor relationship information for all the logical processors in a multiprocessor system:

```
//
// Get required buffer size.
//
NTSTATUS Status;
PSYSTEM_LOGICAL_PROCESSOR_INFORMATION_EX Info = NULL;
ULONG BufferSize = 0;
Status = KeQueryLogicalProcessorRelationship(NULL, RelationAll, NULL, &BufferSize);

NT_ASSERT(Status == STATUS_INFO_LENGTH_MISMATCH && BufferSize > 0);

//
// Allocate buffer (assume IRQL <= APC_LEVEL).
//
Info = ExAllocatePoolWithTag(PagedPool, BufferSize, ' gaT');
if (Info == NULL)
{
    Status = STATUS_INSUFFICIENT_RESOURCES;
}

//
// Get processor relationship information.
//
if (NT_SUCCESS(Status))
{
    Status = KeQueryLogicalProcessorRelationship(NULL, RelationAll, Info, &BufferSize);
}
```

The NT_ASSERT macro is defined in the Wdm.h header file. The NT_SUCCESS macro is defined in the Ntdef.h header file.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h, Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

LOGICAL_PROCESSOR_RELATIONSHIP

PROCESSOR_NUMBER

SYSTEM_LOGICAL_PROCESSOR_INFORMATION_EX

KeQueryMaximumGroupCount function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryMaximumGroupCount** routine returns the maximum number of groups in a multiprocessor system.

Syntax

```
USHORT KeQueryMaximumGroupCount(

);
```

Parameters

This function has no parameters.

Return Value

KeQueryMaximumGroupCount returns the maximum number of groups.

Remarks

The value that is returned by **KeQueryMaximumGroupCount** remains constant during runtime. This value depends on the hardware configuration of the multiprocessor system, but it can never exceed a fixed limit that is set by the Windows operating system.

In Windows 7, the maximum number of groups in a multiprocessor system is four, but this value might change in future versions of Windows. The safest way to determine the maximum number of groups in Windows 7 or a later versions of the Windows operating system is to call **KeQueryMaximumGroupCount**. Kernel-mode drivers that call **KeQueryMaximumGroupCount** will not require code changes if the formula that is used to calculate the maximum number of groups changes in a future version of Windows.

To obtain the number of active groups in a multiprocessor system, call the KeQueryActiveGroupCount routine.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeQueryActiveGroupCount

KeQueryMaximumProcessorCount function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryMaximumProcessorCount** routine returns the maximum number of processors.

Syntax

```
ULONG KeQueryMaximumProcessorCount(

);
```

Parameters

This function has no parameters.

Return Value

KeQueryMaximumProcessorCount returns the maximum number of processors as a ULONG value.

Remarks

The value returned by the **KeQueryMaximumProcessorCount** routine does not change at runtime.

If your code uses an array of buffers, one buffer for each processor, you must decide whether to have a statically sized array based on **KeQueryMaximumProcessorCount** or a dynamically sized array based on KeQueryActiveProcessorCount.

To optimize based on the number of processors, you need a resizable structure for Windows Server 2008. In this case, use **KeQueryActiveProcessorCount**.

If you are not optimizing and if the data structures that result from using maximum processor count are relatively small, a resizable structure is not necessary. In this case, use **KeQueryMaximumProcessorCount** to determine size for a static array.

Windows 7 and later versions of Windows support processor groups. Drivers that are designed to handle information about processor groups should use the KeQueryMaximumProcessorCountEx routine, which specifies a processor group, instead of **KeQueryMaximumProcessorCount**, which does not. However, the implementation of **KeQueryMaximumProcessorCount** in Windows 7 and later versions of Windows provides compatibility for drivers that were written for earlier versions of Windows, which do not support processor groups. In this implementation, **KeQueryMaximumProcessorCount** returns the maximum number of logical processors that can be in group 0.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal

Header	ntddk.h (include Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeQueryActiveProcessorCount

KeQueryMaximumProcessorCountEx

KeQueryMaximumProcessorCountEx function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryMaximumProcessorCountEx** routine returns the maximum number of logical processors in a specified group in a multiprocessor system.

Syntax

```
ULONG KeQueryMaximumProcessorCountEx(
  USHORT GroupNumber
);
```

Parameters

`GroupNumber`

Specifies a group number. If a multiprocessor system contains *n* groups, the groups are numbered from 0 to *n*-1. To obtain the maximum number of processors in the system, set this parameter to ALL_PROCESSOR_GROUPS, which is defined in the Winnt.h and Ntdef.h header files.

Return Value

KeQueryMaximumProcessorCountEx returns the maximum number of logical processors in the specified group or in the system, as indicated by the value of the *GroupNumber* parameter.

Remarks

The value that is returned by **KeQueryMaximumProcessorCountEx** remains constant during runtime. This value depends on the hardware configuration of the multiprocessor system, but it can never exceed a fixed limit that is set by the Windows operating system. This limit is 32 logical processors for 32-bit versions of Windows and 64 logical processors for 64-bit versions of Windows.

In contrast, the value that is returned by the KeQueryActiveProcessorCountEx routine can change during runtime as processors are dynamically added to the system.

A related routine, KeQueryMaximumProcessorCount, returns a maximum processor count, but this routine, unlike **KeQueryMaximumProcessorCountEx**, does not accept a group number as an input parameter. In Windows 7 and later versions of the Windows operating system, **KeQueryMaximumProcessorCount** returns the maximum number of logical processors in group 0, which is compatible with the behavior of this routine in earlier versions of Windows that do not support groups. This behavior ensures that existing drivers that call **KeQueryMaximumProcessorCount** and that use no group-oriented features will run correctly in multiprocessor systems that have two or more groups. However, drivers that use any group-oriented features in Windows 7 and later versions of the Windows operating system should call **KeQueryMaximumProcessorCountEx** instead of **KeQueryMaximumProcessorCount**.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeQueryActiveProcessorCountEx

KeQueryMaximumProcessorCount

KeQueryNodeActiveAffinity function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryNodeActiveAffinity** routine gets the current processor affinity of a specified node in a multiprocessor system that has a non-uniform memory access (NUMA) architecture.

Syntax

```
void KeQueryNodeActiveAffinity(
  USHORT          NodeNumber,
  PGROUP_AFFINITY Affinity,
  PUSHORT         Count
);
```

Parameters

`NodeNumber`

The node number. If a multiprocessor system contains *n* nodes, the nodes are numbered from 0 to *n*-1. To obtain the highest node number (*n*-1) in the system, call the KeQueryHighestNodeNumber routine.

`Affinity`

A pointer to a caller-allocated buffer into which the routine writes a GROUP_AFFINITY structure. This structure contains the group number of the group that contains the node that is identified by *NodeNumber*, and an affinity mask that indicates which logical processors in the node are active. You can set this parameter to **NULL** if you do not need this information.

`Count`

A pointer to a location into which the routine writes the number of active processors that are represented in the node affinity mask that is pointed to by *Affinity*. You can set this parameter to **NULL** if you do not need this information.

Return Value

None

Remarks

The caller-allocated buffer that is pointed to by the *Affinity* parameter must be large enough to contain a **GROUP_AFFINITY** structure. The **Mask** member of this structure contains an affinity mask that indicates which processors are active. If a processor is active, the corresponding bit in the mask is one. All other bits are zero.

In a NUMA multiprocessor architecture, a node is a collection of processors that share fast access to a region of memory. Memory access is non-uniform because a processor can access the memory in its node faster than it can access the memory in other nodes.

The number of processors in a node cannot exceed the number of bits in the affinity mask in the structure that is pointed to by *Affinity*. The affinity mask also determines the maximum number of processors in a group.

If, during system initialization, Windows encounters a NUMA hardware node that contains more logical processors

than will fit into a group, Windows splits the node into smaller, logical nodes. Each of these nodes does not exceed the maximum group size. The *NodeNumber* parameter identifies a logical node. To obtain the maximum number of processors per group, call the KeQueryMaximumProcessorCountEx routine.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

GROUP_AFFINITY

KeQueryHighestNodeNumber

KeQueryMaximumProcessorCountEx

KeQueryNodeMaximumProcessorCount function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryNodeMaximumProcessorCount** routine returns the maximum number of logical processors that a specified node in a non-uniform memory access (NUMA) multiprocessor system can contain.

Syntax

```
USHORT KeQueryNodeMaximumProcessorCount(
  USHORT NodeNumber
);
```

Parameters

`NodeNumber`

The node number. If a NUMA multiprocessor system contains *n* nodes, valid node numbers are in the range 0 to *n*-1. To get the highest node number (*n*-1) in the system, call the KeQueryHighestNodeNumber routine.

Return Value

KeQueryNodeMaximumProcessorCount returns the maximum number of logical processors.

Remarks

In a multiprocessor system with a NUMA architecture, a node is a collection of processors that share fast access to a region of memory. Memory access is non-uniform because a processor can access the memory in its node faster than it can access the memory in other nodes.

The count returned by this routine includes any logical processors that can be dynamically added to the node while the multiprocessor system is running.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeQueryHighestNodeNumber

KeQueryTickCount macro

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryTickCount** routine maintains a count of the interval timer interrupts that have occurred since the system was booted.

Syntax

```
void KeQueryTickCount(
   CurrentCount
);
```

Parameters

`CurrentCount`

Pointer to the tick count value on return from **KeQueryTickCount**.

Return Value

None

Remarks

The *TickCount* value increases by one at each interval timer interrupt while the system is running.

The preferred method of determining elapsed time is by using *TickCount* for relative timing and time stamps.

To determine the absolute elapsed time multiply the returned *TickCount* by the KeQueryTimeIncrement return value using compiler support for 64-bit integer operations.

You should not make any assumptions about the length of a tick, because it might vary depending on hardware and other considerations.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeRaiseIrqlToDpcLevel function

1/25/2019 • 2 minutes to read • Edit Online

The **KeRaiseIrqlToDpcLevel** routine raises the hardware priority to IRQL = DISPATCH_LEVEL, thereby masking off interrupts of equivalent or lower IRQL on the current processor.

Syntax

```
_DECL_HAL_KE_IMPORT KIRQL KeRaiseIrqlToDpcLevel(

);
```

Parameters

This function has no parameters.

Return Value

KeRaiseIrqlToDpcLevel returns the IRQL at which the call occurred.

Remarks

Any caller of **KeRaiseIrqlToDpcLevel** should save the returned IRQL value. Every such caller must restore the original IRQL as quickly as possible by passing this returned IRQL in a subsequent call to KeLowerIrql.

Callers of **KeRaiseIrqlToDpcLevel** must be running at IRQL <= DISPATCH_LEVEL. Otherwise, a call to this routine causes a bug check.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h)
Library	Hal.lib
IRQL	"<= DISPATCH_LEVEL (see Remarks section)"
DDI compliance rules	HwStorPortProhibitedDDIs

KeSetBasePriorityThread function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSetBasePriorityThread** routine sets the run-time priority, relative to the current process, for a given thread.

Syntax

```
LONG KeSetBasePriorityThread(
  PKTHREAD Thread,
  LONG     Increment
);
```

Parameters

`Thread`

Pointer to a dispatcher object of type KTHREAD.

`Increment`

Specifies the value to be added to the base priority of the process for the *Thread*.

Return Value

KeSetBasePriorityThread returns the previous base priority increment of the given thread. The previous base priority increment is defined as the difference between the specified thread's old base priority and the base priority of the thread's process.

Remarks

The new base priority is computed by adding the given *Increment*, which can be a negative value, to the base priority of the specified thread's process. The resultant value is stored as the base priority of the specified thread.

Drivers that set up device-dedicated threads with variable priority attributes can call this routine to set such a thread's priority relative to the system process in which the thread is created.

The new base priority is restricted to the priority class of the given thread's process. Therefore, the base priority is not allowed to cross over from a variable priority class to a real-time priority class or vice versa.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

KeGetCurrentThread

KeQueryPriorityThread

KeSetPriorityThread

KeSetHardwareCounterConfiguration function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSetHardwareCounterConfiguration** routine specifies a list of hardware counters to use for thread profiling.

Syntax

```
NTSTATUS KeSetHardwareCounterConfiguration(
  PHARDWARE_COUNTER CounterArray,
  ULONG             Count
);
```

Parameters

`CounterArray`

A pointer to a HARDWARE_COUNTER array that describes the hardware counter configuration to use for thread profiling. Each array element is a structure that describes a hardware counter. Before the routine returns, it copies the contents of this array into its internal data structures.

`Count`

Specifies the number of elements in the array that is pointed to by the *CounterArray* parameter.

Return Value

KeSetHardwareCounterConfiguration returns STATUS_SUCCESS if the call is successful. Possible error return values include the following:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The value of the *Count* parameter exceeds the maximum number of counters that is specified by the MAX_HW_COUNTERS constant, which is defined in the Ntddk.h header file.

STATUS_WMI_ALREADY_ENABLED	One or more of the counters that are specified in the *CounterArray* array are already enabled.
STATUS_NOT_IMPLEMENTED	This routine is not implemented for the processor architecture that the caller is running on.

Remarks

In Windows 7, this routine is implemented only for the x86-based, x64-based, and Itanium-based architectures. If a caller is running on a processor architecture that is not supported, the routine returns STATUS_NOT_IMPLEMENTED.

This routine tells the operating system which hardware counters to use for thread profiling. Call this routine only when thread profiling is disabled. If the *CounterArray* array specifies any hardware counters that are currently being used, the routine fails and returns STATUS_WMI_ALREADY_ENABLED.

An application thread can enable thread profiling to obtain a set of performance measurements from the hardware counters in the performance monitoring unit (PMU) of the local processor. The operating system supports only one profiling application at a time. Concurrent instances of a thread-profiling application are not supported. A thread can enable thread profiling for itself but not for other threads.

When thread profiling is enabled, the operating system uses the hardware counters that were specified in the last call to **KeSetHardwareCounterConfiguration**. Each successful **KeSetHardwareCounterConfiguration** call replaces any hardware counter configuration that might have been set in a previous **KeSetHardwareCounterConfiguration** call.

Set *Count* = 0 to specify an empty hardware counter configuration. This configuration effectively prevents the use of hardware counters for thread profiling. The default hardware counter configuration that exists after system startup and before the initial **KeSetHardwareCounterConfiguration** call is an empty configuration.

The effect of a successful **KeSetHardwareCounterConfiguration** call is global. If a thread in any process is profiled, the profiler uses the hardware counter configuration that was set by the last call to **KeSetHardwareCounterConfiguration**. In a multiprocessor system, a **KeSetHardwareCounterConfiguration** call sets the hardware counter configuration to use for thread profiling across all processors in the system, although each processor uses its own set of hardware counters.

To avoid resource conflicts, all drivers that use counter resources should use the HalAllocateHardwareCounters and HalFreeHardwareCounters routines to coordinate their sharing of these resources.

To query the operating system for the hardware counter configuration that is currently in effect for thread profiling, call the KeQueryHardwareCounterConfiguration routine.

Virtualization software typically does not virtualize hardware performance counters. Thus, hardware performance counters are unlikely to be available in a virtual machine.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

HARDWARE_COUNTER

HalAllocateHardwareCounters

HalFreeHardwareCounters

KeQueryHardwareCounterConfiguration

KeSetImportanceDpc function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSetImportanceDpc** routine specifies how soon the DPC routine is run.

Syntax

```
void KeSetImportanceDpc(
  PRKDPC          Dpc,
  KDPC_IMPORTANCE Importance
);
```

Parameters

`Dpc`

Pointer to the caller's DPC object, which KeInitializeDpc already initialized.

`Importance`

Specifies one of the following system-defined values to determine the behavior of KeInsertQueueDpc and IoRequestDpc when either routine is used to queue the DPC.

LowImportance

Place the DPC at the end of the DPC queue, and do not begin processing of the queue.

MediumImportance

Place the DPC at the end of the DPC queue. If the DPC is assigned to the current processor's DPC queue, begin processing the queue immediately. **MediumImportance** is the default value for *Importance*.

MediumHighImportance

Place the DPC at the end of the DPC queue, and begin processing the queue immediately. MediumHighImportance is available only on Windows Vista and later versions of Windows.

HighImportance

Place the DPC at the beginning of the DPC queue, and begin processing the queue immediately.

Return Value

None

Remarks

The **KeSetImportanceDpc** routine influences how soon a DPC is run after it is queued by determining:

- The location of the DPC within the DPC queue. Typically, the **KeInsertQueueDpc** and **IoRequestDpc** routines place a DPC at the end of the queue. If a driver first calls **KeSetImportanceDpc** with *Importance* = **HighImportance**, **KeInsertQueueDpc** and **IoRequestDpc** will place the DPC at the beginning of the queue.
- When the system begins processing the DPC queue. Typically, **KeInsertQueueDpc** and **IoRequestDpc** immediately begin processing the DPC queue for the current processor. Drivers can specify different values for *Importance* to change this behavior.

By default, DPCs are assigned to the DPC queue for the current processor, so specifying **MediumImportance** or **MediumHighImportance** for *Importance* has the same effect. However, drivers can use KeSetTargetProcessorDpc to change the processor that the DPC will be assigned to.

For Windows Vista and later versions of the Windows operating system, you can use **KeSetImportanceDpc** for threaded DPCs. If the caller sets *Importance* to **HighImportance**, the DPC is placed at the beginning of the queue; otherwise, it is placed at the end. The routine does not affect when the threaded DPC queue is processed. Threaded DPCs are always processed by a dedicated thread at IRQL = PASSIVE_LEVEL. For more information about threaded DPCs, see Threaded DPCs.

Note that a driver must call **KeSetImportanceDpc** before it calls **KeInsertQueueDpc** and **IoRequestDpc** to have any effect.

For more information about how the system processes the DPC queue, see Organization of DPC Queues.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

IoRequestDpc

KeInitializeDpc

KeInsertQueueDpc

KeSetTargetProcessorDpc

KeSynchronizeExecution

KeSetTargetProcessorDpc function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSetTargetProcessorDpc** routine specifies the processor that a DPC routine will be run on.

Syntax

```
void KeSetTargetProcessorDpc(
  PRKDPC Dpc,
  CCHAR  Number
);
```

Parameters

`Dpc`

Pointer to the caller's DPC object, which KeInitializeDpc already initialized.

`Number`

Specifies the zero-based number of the target processor on which the DPC should be queued and executed.

Return Value

None

Remarks

On multiprocessor systems, each processor has its own DPC queue. The **KeSetTargetProcessorDpc** routine specifies which processor's queue the system should use when the driver calls KeInsertQueueDpc or IoRequestDpc to queue a DPC to be run later.

Starting with Windows Vista, you can also use **KeSetTargetProcessorDpc** to specify the target processor for threaded DPCs.

A call to **KeSetTargetProcessorDpcEx** that occurs after a DPC object has been queued has no effect on the selection of a processor for the DPC routine to run on. To control the selection of the target processor, a **KeSetTargetProcessorDpc** call must occur before the call to **KeInsertQueueDpc** or **IoRequestDpc** that queues the DPC object.

For more information about DPC queues, see Organization of DPC Queues.

Windows 7 and later versions of Windows support processor groups. Drivers that are designed to handle information about processor groups should use the KeSetTargetProcessorDpcEx routine, which specifies a processor group, instead of **KeSetTargetProcessorDpc**, which does not. However, the implementation of **KeSetTargetProcessorDpc** in Windows 7 and later versions of Windows provides compatibility for drivers that were written for earlier versions of Windows, which do not support processor groups. In this implementation, if *Number* is less than the number of active logical processors in group 0, **KeSetTargetProcessorDpc** sets the target for the DPC to the processor in group 0 that is specified by *Number*. Otherwise, the DPC target does not change.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

MmAllocateContiguousMemory function

1/25/2019 • 2 minutes to read • Edit Online

The **MmAllocateContiguousMemory** routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.

Syntax

```
PVOID MmAllocateContiguousMemory(
  SIZE_T           NumberOfBytes,
  PHYSICAL_ADDRESS HighestAcceptableAddress
);
```

Parameters

`NumberOfBytes`

The size, in bytes, of the block of contiguous memory to allocate. For more information, see Remarks.

`HighestAcceptableAddress`

The highest valid physical address the caller can use. For example, if a device can address only locations in the first 16 megabytes of the processor's physical memory address range, the driver for this device should set *HighestAcceptableAddress* to 0x0000000000FFFFFF.

Return Value

MmAllocateContiguousMemory returns the base virtual address for the allocated memory. If the request cannot be satisfied, the routine returns **NULL**.

Remarks

MmAllocateContiguousMemory allocates a block of nonpaged memory that is contiguous in physical address space. The routine maps this block to a contiguous block of virtual memory in the system address space and returns the virtual address of the base of this block. The routine aligns the starting address of a contiguous memory allocation to a memory page boundary.

Drivers must not access memory beyond the requested allocation size. For example, developers should not assume that their drivers can safely use memory between the end of their requested allocation and the next page boundary.

Because contiguous physical memory is usually in short supply, it should be used sparingly and only when necessary. A driver that must use contiguous memory should allocate this memory during driver initialization because physical memory is likely to become fragmented over time as the operating system allocates and frees memory. Typically, a driver calls **MmAllocateContiguousMemory** from its DriverEntry routine to allocate an internal buffer for long-term use, and frees the buffer just before the driver is unloaded.

Memory allocated by **MmAllocateContiguousMemory** must be freed when the memory is no longer needed. Call the MmFreeContiguousMemory routine to free memory that is allocated by **MmAllocateContiguousMemory**.

Note When physical memory is fragmented on a computer that has a large amount of RAM, calls to **MmAllocateContiguousMemory**, which require the operating system to search for contiguous blocks of memory, can severely degrade performance. This degradation is greatly reduced starting with Windows Vista SP1 and Windows Server 2008, but contiguous memory can still be expensive to allocate. For this reason, drivers should avoid repeated calls to **MmAllocateContiguousMemory**. Instead, drivers should allocate all required contiguous buffers in their **DriverEntry** routines and reuse these buffers.

Memory that **MmAllocateContiguousMemory** allocates is uninitialized. A kernel-mode driver must first set this memory to zero if it is going to make it visible to user-mode software (to avoid leaking potentially privileged contents).

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

MmAllocateContiguousMemorySpecifyCache

MmAllocateNonCachedMemory

MmFreeContiguousMemory

MmAllocateContiguousMemorySpecifyCache function

1/25/2019 • 3 minutes to read • Edit Online

The **MmAllocateContiguousMemorySpecifyCache** routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.

Syntax

```
PVOID MmAllocateContiguousMemorySpecifyCache(
  SIZE_T              NumberOfBytes,
  PHYSICAL_ADDRESS    LowestAcceptableAddress,
  PHYSICAL_ADDRESS    HighestAcceptableAddress,
  PHYSICAL_ADDRESS    BoundaryAddressMultiple,
  MEMORY_CACHING_TYPE CacheType
);
```

Parameters

`NumberOfBytes`

The size, in bytes, of the block of contiguous memory to allocate. For more information, see Remarks.

`LowestAcceptableAddress`

The lowest valid physical address the caller can use. For example, if a device can address only locations above the first 8 megabytes of the processor's physical memory address range, the driver for this device should set *LowestAcceptableAddress* to 0x0000000000800000.

`HighestAcceptableAddress`

The highest valid physical address the caller can use. For example, if a device can address only locations in the first 16 megabytes of the processor's physical memory address range, the driver for this device should set *HighestAcceptableAddress* to 0x0000000000FFFFFF.

`BoundaryAddressMultiple`

The physical address multiple that the allocated buffer must not cross. A physical address multiple must always be a power of two. This parameter is optional and can be specified as zero to indicate that the device has no special memory boundary restrictions. For more information, see Remarks.

`CacheType`

Specifies a MEMORY_CACHING_TYPE value, which indicates the type of caching allowed for the requested memory.

Return Value

MmAllocateContiguousMemorySpecifyCache returns the base virtual address for the allocated memory. If the system is unable to allocate the requested buffer, the routine returns **NULL**.

Remarks

MmAllocateContiguousMemorySpecifyCache allocates a block of nonpaged memory that is contiguous in physical address space. The routine maps this block to a contiguous block of virtual memory in the system address space and returns the virtual address of the base of this block. The routine aligns the starting address of a contiguous memory allocation to a memory page boundary.

Drivers must not access memory beyond the requested allocation size. For example, developers should not assume that their drivers can safely use memory between the end of their requested allocation and the next page boundary.

Because contiguous physical memory is usually in short supply, it should be used sparingly and only when necessary. A driver that must use contiguous memory should allocate this memory during driver initialization because physical memory is likely to become fragmented over time as the operating system allocates and frees memory. Typically, a driver calls **MmAllocateContiguousMemorySpecifyCache** from its DriverEntry routine to allocate an internal buffer for long-term use, and frees the buffer just before the driver is unloaded.

Memory allocated by **MmAllocateContiguousMemorySpecifyCache** must be freed when the memory is no longer needed. Call the MmFreeContiguousMemory routine to free memory that is allocated by **MmAllocateContiguousMemorySpecifyCache**.

If you specify a nonzero value for the *BoundaryAddressMultiple* parameter, the physical address range of the allocated memory block will not cross an address boundary that is an integer multiple of this value. A driver should set this parameter to zero unless a nonzero value is required to work around a hardware limitation. For example, if a device cannot transfer data across 16-megabyte physical boundaries, the driver should specify a value of 0x1000000 for this parameter to ensure that the addresses that the device sees do not wrap around at a 16-megabyte boundary.

> **Note** If you use the **MmAllocateContiguousMemorySpecifyCache** routine on computers with large amounts of memory, the operating system's performance might severely degrade when the system tries to create a contiguous chunk of memory. This degradation is greatly reduced starting with Windows Vista SP1 and Windows Server 2008, but contiguous memory can still be expensive to allocate. For this reason, drivers should avoid repeated calls to **MmAllocateContiguousMemorySpecifyCache**. Instead, drivers should allocate all required contiguous buffers in their **DriverEntry** routines and reuse these buffers.

> **Note** Memory that **MmAllocateContiguousMemorySpecifyCache** allocates is uninitialized. A kernel-mode driver must first zero this memory if it is going to make it visible to user-mode software (to avoid leaking potentially privileged contents).

MmAllocateContiguousMemory

MmFreeContiguousMemory

MmAllocateContiguousMemorySpecifyCacheNode function

1/25/2019 • 3 minutes to read • Edit Online

The **MmAllocateContiguousMemorySpecifyCacheNode** routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.

Syntax

```
PVOID MmAllocateContiguousMemorySpecifyCacheNode(
  SIZE_T              NumberOfBytes,
  PHYSICAL_ADDRESS    LowestAcceptableAddress,
  PHYSICAL_ADDRESS    HighestAcceptableAddress,
  PHYSICAL_ADDRESS    BoundaryAddressMultiple,
  MEMORY_CACHING_TYPE CacheType,
  NODE_REQUIREMENT    PreferredNode
);
```

Parameters

`NumberOfBytes`

The size, in bytes, of the block of contiguous memory to allocate. For more information, see Remarks.

`LowestAcceptableAddress`

The lowest valid physical address the caller can use. For example, if a device can address only locations above the first 8 megabytes of the processor's physical memory address range, the driver for this device should set *LowestAcceptableAddress* to 0x0000000000800000.

`HighestAcceptableAddress`

The highest valid physical address the caller can use. For example, if a device can address only locations in the first 16 megabytes of the processor's physical memory address range, the driver for this device should set *HighestAcceptableAddress* to 0x0000000000FFFFFF.

`BoundaryAddressMultiple`

The physical address multiple that the allocated buffer must not cross. A physical address multiple must always be a power of two. This parameter is optional and can be specified as zero to indicate that the device has no special memory boundary restrictions. For more information, see Remarks.

`CacheType`

Specifies a MEMORY_CACHING_TYPE value, which indicates the type of caching requested for the contiguous physical memory.

`PreferredNode`

The preferred node number. If a multiprocessor system contains N nodes, the nodes are numbered 0 to N-1. If MM_ANY_NODE_OK is specified or the machine only has one node, then the allocation is satisfied from any node. Otherwise, the allocation is made from the preferred node or if a satisfactory range cannot be found from the preferred node, then **NULL** is returned.

Return Value

MmAllocateContiguousMemorySpecifyCacheNode returns the base virtual address for the allocated memory. If the request cannot be satisfied, the routine returns **NULL**.

Remarks

A kernel-mode device driver calls this routine to allocate a contiguous block of physical memory. In a non-uniform memory access (NUMA) multiprocessor system, the caller can specify a preferred node from which to allocate the memory. A node is a collection of processors that share fast access to a region of memory. In a non-NUMA multiprocessor or a single-processor system, **MmAllocateContiguousMemorySpecifyCacheNode** treats all memory as belonging to a single node and allocates memory from this node.

MmAllocateContiguousMemorySpecifyCacheNode allocates a block of nonpaged memory that is contiguous in physical address space. The routine maps this block to a contiguous block of virtual memory in the system address space and returns the virtual address of the base of this block. The routine aligns the starting address of a contiguous memory allocation to a memory page boundary.

Drivers must not access memory beyond the requested allocation size. For example, developers should not assume that their drivers can safely use memory between the end of their requested allocation and the next page boundary.

Because contiguous physical memory is usually in short supply, it should be used sparingly and only when necessary. A driver that must use contiguous memory should allocate this memory during driver initialization because physical memory is likely to become fragmented over time as the operating system allocates and frees memory. Typically, a driver calls **MmAllocateContiguousMemorySpecifyCacheNode** from its DriverEntry routine to allocate an internal buffer for long-term use, and frees the buffer just before the driver is unloaded.

Memory allocated by **MmAllocateContiguousMemorySpecifyCacheNode** must be freed when the memory is no longer needed. Call the MmFreeContiguousMemory routine to free memory that is allocated by **MmAllocateContiguousMemorySpecifyCacheNode**.

If you specify a nonzero value for the *BoundaryAddressMultiple* parameter, the physical address range of the allocated memory block will not cross an address boundary that is an integer multiple of this value. A driver should set this parameter to zero unless a nonzero value is required to work around a hardware limitation. For example, if a device cannot transfer data across 16-megabyte physical boundaries, the driver should specify a value of 0x1000000 for this parameter to ensure that the addresses that the device sees do not wrap around at a 16-megabyte boundary.

> **Note** If you use the **MmAllocateContiguousMemorySpecifyCacheNode** routine on computers with large amounts of memory, the operating system's performance might severely degrade when the system tries to create a contiguous chunk of memory. This degradation is greatly reduced starting with Windows Vista SP1 and Windows Server 2008, but contiguous memory can still be expensive to allocate. For this reason, drivers should avoid repeated calls to **MmAllocateContiguousMemorySpecifyCacheNode**. Instead, drivers should allocate all required contiguous buffers in their **DriverEntry** routines and reuse these buffers.

> **Note** Memory that **MmAllocateContiguousMemorySpecifyCacheNode** allocates is uninitialized. A kernel-mode driver must first zero this memory if it is going to make it visible to user-mode software (to avoid leaking potentially privileged contents).

MmFreeContiguousMemory

MmAllocateContiguousNodeMemory function

1/25/2019 • 4 minutes to read • Edit Online

The **MmAllocateContiguousNodeMemory** routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.

Syntax

```
PVOID MmAllocateContiguousNodeMemory(
  SIZE_T           NumberOfBytes,
  PHYSICAL_ADDRESS LowestAcceptableAddress,
  PHYSICAL_ADDRESS HighestAcceptableAddress,
  PHYSICAL_ADDRESS BoundaryAddressMultiple,
  ULONG            Protect,
  NODE_REQUIREMENT PreferredNode
);
```

Parameters

`NumberOfBytes`

The size, in bytes, of the block of contiguous memory to allocate. For more information, see Remarks.

`LowestAcceptableAddress`

The lowest valid physical address the caller can use. For example, if a device can address only locations above the first 8 megabytes of the processor's physical memory address range, the driver for this device should set *LowestAcceptableAddress* to 0x0000000000800000.

`HighestAcceptableAddress`

The highest valid physical address the caller can use. For example, if a device can address only locations in the first 16 megabytes of the processor's physical memory address range, the driver for this device should set *HighestAcceptableAddress* to 0x0000000000FFFFFF.

`BoundaryAddressMultiple`

The physical address multiple that the allocated buffer must not cross. A physical address multiple must always be a power of two. This parameter is optional and can be specified as zero to indicate that the device has no special memory boundary restrictions. For more information, see Remarks.

`Protect`

Flag bits that specify the protection to use for the allocated memory. The caller must set one (but not both) of the following flag bits in the *Protect* parameter.

FLAG BIT	MEANING
PAGE_READWRITE	Allocate read/write, no-execute (NX) memory. Most callers should set this flag bit. For more information, see Remarks.

PAGE_EXECUTE_READWRITE	Allocate read/write memory that is executable. This flag bit should be set only if the caller requires the ability to execute instructions in the allocated memory.

In addition, the caller can set one (but not both) of the following optional flag bits in the *Protect* parameter.

FLAG BIT	MEANING
PAGE_NOCACHE	Allocate non-cached memory. This flag bit is similar in effect to calling MmAllocateContiguousMemorySpecifyCache with *CacheType* set to **MmNonCached**.
PAGE_WRITECOMBINE	Allocate write-combined memory. This flag bit is similar in effect to calling **MmAllocateContiguousMemorySpecifyCache** with *CacheType* set to **MmWriteCombined**.

If neither PAGE_NOCACHE nor PAGE_WRITECOMBINE is specified, the allocated memory is fully cached. In this case, the effect is similar to calling **MmAllocateContiguousMemorySpecifyCache** with *CacheType* set to **MmCached**.

`PreferredNode`

The preferred node number. If a multiprocessor system contains N nodes, the nodes are numbered from 0 to N-1. If the caller sets *PreferredNode* to MM_ANY_NODE_OK, the routine chooses which node to allocate memory from. Otherwise, if memory in the specified address range cannot be allocated from the preferred node, the routine returns **NULL**.

Return Value

MmAllocateContiguousNodeMemory returns the base virtual address for the allocated memory. If the request cannot be satisfied, the routine returns **NULL**.

Remarks

A kernel-mode device driver calls this routine to allocate a contiguous block of physical memory. The calling driver can specify whether to use no-execute (NX) memory for the allocation. In a non-uniform memory access (NUMA) multiprocessor system, the caller can specify a preferred node from which to allocate the memory. A node is a collection of processors that share fast access to a region of memory. In a non-NUMA multiprocessor or a single-processor system, **MmAllocateContiguousNodeMemory** treats all memory as belonging to a single node and allocates memory from this node.

MmAllocateContiguousNodeMemory allocates a block of nonpaged memory that is contiguous in physical address space. The routine maps this block to a contiguous block of virtual memory in the system address space and returns the virtual address of the base of this block. The routine aligns the starting address of a contiguous memory allocation to a memory page boundary.

Drivers must not access memory beyond the requested allocation size. For example, developers should not assume that their drivers can safely use memory between the end of their requested allocation and the next page boundary.

Because contiguous physical memory is usually in short supply, it should be used sparingly and only when necessary. A driver that must use contiguous memory should allocate this memory during driver initialization because physical memory is likely to become fragmented over time as the operating system allocates and frees memory. Typically, a driver calls **MmAllocateContiguousNodeMemory** from its DriverEntry routine to allocate an internal buffer for long-term use, and frees the buffer just before the driver is unloaded.

Memory allocated by **MmAllocateContiguousNodeMemory** must be freed when the memory is no longer needed. Call the MmFreeContiguousMemory routine to free memory that is allocated by **MmAllocateContiguousNodeMemory**.

MmAllocateContiguousNodeMemory is similar to the MmAllocateContiguousMemorySpecifyCacheNode routine. Unlike **MmAllocateContiguousMemorySpecifyCacheNode**, **MmAllocateContiguousNodeMemory** can be used to allocate no-execute (NX) memory. As a best practice, a driver should allocate NX memory unless the driver explicitly requires the ability to execute instructions in the allocated memory. By allocating NX memory, a driver improves security by preventing malicious software from executing instructions in this memory. Memory allocated by the MmAllocateContiguousMemory, MmAllocateContiguousMemorySpecifyCache, and **MmAllocateContiguousMemorySpecifyCacheNode** routines is always executable.

If you specify a nonzero value for the *BoundaryAddressMultiple* parameter, the physical address range of the allocated memory block will not cross an address boundary that is an integer multiple of this value. A driver should set this parameter to zero unless a nonzero value is required to work around a hardware limitation. For example, if a device cannot transfer data across 16-megabyte physical boundaries, the driver should specify a value of 0x1000000 for this parameter to ensure that the addresses that the device sees do not wrap around at a 16-megabyte boundary.

> **Note** Memory that **MmAllocateContiguousNodeMemory** allocates is uninitialized. A kernel-mode driver must first zero this memory if it is going to make it visible to user-mode software (to avoid leaking potentially privileged contents).

Requirements

Minimum supported client	Available starting with Windows 8.

MmFreeContiguousMemory

MmAllocateNonCachedMemory function

1/25/2019 • 2 minutes to read • Edit Online

The **MmAllocateNonCachedMemory** routine allocates a virtual address range of noncached and cache-aligned memory.

Syntax

```
PVOID MmAllocateNonCachedMemory(
  SIZE_T NumberOfBytes
);
```

Parameters

`NumberOfBytes`

Specifies the size in bytes of the range to be allocated.

Return Value

If the requested memory cannot be allocated, the return value is **NULL**. Otherwise, it is the base virtual address of the allocated range.

Remarks

MmAllocateNonCachedMemory can be called from a DriverEntry routine to allocate a noncached block of virtual memory for various device-specific buffers. The function always returns a full multiple of the virtual memory page size, of nonpaged system-address-space memory, regardless of the requested allocation size.

Noncached allocations are aligned on an integral multiple of the processor's data-cache-line size to prevent cache and coherency problems.

The physical memory pages that **MmAllocateNonCachedMemory** returns are typically not contiguous pages.

> **Note** Memory that **MmAllocateNonCachedMemory** allocates is uninitialized. A kernel-mode driver must first zero this memory if it is going to make it visible to user-mode software (to avoid leaking potentially privileged contents).

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe

AllocateCommonBuffer

KeGetDcacheFillSize

MmAllocateContiguousMemory

MmAllocateContiguousMemorySpecifyCache

MmFreeNonCachedMemory

MmCopyMemory function

1/25/2019 • 2 minutes to read • Edit Online

The **MmCopyMemory** routine copies the specified range of virtual or physical memory into the caller-supplied buffer.

Syntax

```
NTSTATUS MmCopyMemory(
  PVOID           TargetAddress,
  MM_COPY_ADDRESS SourceAddress,
  SIZE_T          NumberOfBytes,
  ULONG           Flags,
  PSIZE_T         NumberOfBytesTransferred
);
```

Parameters

`TargetAddress`

A pointer to a caller-supplied buffer. This buffer must be in nonpageable memory.

`SourceAddress`

An MM_COPY_ADDRESS structure, passed by value, that contains either the virtual address or the physical address of the data to be copied to the buffer pointed to by *TargetAddress*.

`NumberOfBytes`

The number of bytes to copy from *SourceAddress* to *TargetAddress*.

`Flags`

Flags that indicate whether *SourceAddress* is a virtual address or a physical address. The following flag bits are defined for this parameter.

FLAG BIT	DESCRIPTION
MM_COPY_MEMORY_PHYSICAL	*SourceAddress* specifies a physical address.
MM_COPY_MEMORY_VIRTUAL	*SourceAddress* specifies a virtual address.

These two flag bits are mutually exclusive. The caller must set one or the other, but not both.

`NumberOfBytesTransferred`

A pointer to a location to which the routine writes the number of bytes successfully copied from the *SourceAddress* location to the buffer at *TargetAddress*.

Return Value

MmCopyMemory returns STATUS_SUCCESS if the entire range has been copied successfully. Otherwise, an error status is returned and the caller must inspect the output value pointed to by the *NumberOfBytesTransferred*

parameter to determine how many bytes were actually copied.

Remarks

Kernel-mode drivers can call this routine to safely access arbitrary physical or virtual addresses.

If the MM_COPY_MEMORY_PHYSICAL flag is set, *SourceAddress* should point to regular memory that is under control of the operating system. **MmCopyMemory** will return an error status code for physical addresses that refer to I/O space, which includes memory-mapped devices and firmware tables. To access physical memory in I/O space, drivers can use the MmMapIoSpace routine.

If the MM_COPY_MEMORY_VIRTUAL flag is set, *SourceAddress* can point to either a buffer in system address space, or a buffer in the user address space of the current process. If the caller does not control the lifetime of the allocation containing the specified source address, **MmCopyMemory** might fail or might return inconsistent data, but will not cause a system crash—even for system addresses that are invalid and would trigger a bug check if referenced directly. **MmCopyMemory** will return an error status code for system virtual addresses that refer to I/O space.

If memory at the virtual address specified by *SourceAddress* is not resident, **MmCopyMemory** will try to make it resident.

Requirements

Minimum supported client	Available starting with Windows 8.1.
Target Platform	Universal
Header	ntddk.h
Library	Ntoskrnl.lib
IRQL	"<= APC_LEVEL"

MM_COPY_ADDRESS

MmMapIoSpace

MmFreeContiguousMemory function

1/25/2019 • 2 minutes to read • Edit Online

The **MmFreeContiguousMemory** routine releases a range of physically contiguous memory that was allocated by an **MmAllocateContiguousMemory*Xxx*** routine.

Syntax

```
void MmFreeContiguousMemory(
  PVOID BaseAddress
);
```

Parameters

`BaseAddress`

Pointer to the virtual address of the memory to be freed.

Return Value

None

Remarks

The **MmFreeContiguousMemory** routine frees a block of physically contiguous memory that was allocated by a previous call to the MmAllocateContiguousMemory, MmAllocateContiguousMemorySpecifyCache, or MmAllocateContiguousMemorySpecifyCacheNode routine. The *BaseAddress* parameter must be the base address that was obtained from the previous call to the **MmAllocateContiguousMemory*Xxx*** routine.

A device driver that must use contiguous memory should allocate only what it needs during driver initialization because physical memory is likely to become fragmented as the system runs. Such a driver must deallocate the memory when the driver is done using the memory.

Callers of **MmFreeContiguousMemory** must be running at IRQL = APC_LEVEL. For Windows Server 2008 and later versions of the Windows operating system, you can also call **MmFreeContiguousMemory** with IRQL <= DISPATCH_LEVEL. However, you can improve driver performance by calling at APC_LEVEL or below.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	See Remarks section.
DDI compliance rules	IrqlMmDispatch, HwStorPortProhibitedDDIs

MmAllocateContiguousMemory

MmAllocateContiguousMemorySpecifyCache

MmAllocateContiguousMemorySpecifyCacheNode

MmFreeContiguousMemorySpecifyCache function

1/25/2019 • 2 minutes to read • Edit Online

The **MmFreeContiguousMemorySpecifyCache** routine frees a buffer that was allocated by an **MmAllocateContiguousMemorySpecifyCache*Xxx*** routine.

Syntax

```
void MmFreeContiguousMemorySpecifyCache(
  PVOID               BaseAddress,
  SIZE_T              NumberOfBytes,
  MEMORY_CACHING_TYPE CacheType
);
```

Parameters

`BaseAddress`

Specifies the base address of the buffer to be freed. Must match the address returned by the **MmAllocateContiguousMemorySpecifyCache*Xxx*** call that allocated the buffer.

`NumberOfBytes`

Specifies the size in bytes of the buffer to be freed. Must match the size requested when the buffer was allocated by the **MmAllocateContiguousMemorySpecifyCache*Xxx*** routine.

`CacheType`

Specifies the cache type of the buffer to be freed. Must match the cache type requested when the buffer was allocated by the **MmAllocateContiguousMemorySpecifyCache*Xxx*** routine.

Return Value

None

Remarks

The **MmFreeContiguousMemorySpecifyCache** routine frees a block of physically contiguous memory that was allocated by a previous call to the MmAllocateContiguousMemorySpecifyCache or MmAllocateContiguousMemorySpecifyCacheNode routine. However, MmFreeContiguousMemory is the preferred routine to use to free memory that was allocated by an **MmAllocateContiguousMemorySpecifyCache*Xxx*** routine. **MmFreeContiguousMemory** is faster than **MmFreeContiguousMemorySpecifyCache** and requires fewer parameters.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

MmFreeNonCachedMemory function

1/25/2019 • 2 minutes to read • Edit Online

The **MmFreeNonCachedMemory** routine releases a range of noncached memory that was allocated by the MmAllocateNonCachedMemory routine.

Syntax

```
void MmFreeNonCachedMemory(
  PVOID  BaseAddress,
  SIZE_T NumberOfBytes
);
```

Parameters

`BaseAddress`

Pointer to the virtual address of the memory to be freed.

`NumberOfBytes`

Specifies the size of the range to be freed. This value must match the size passed in a preceding call to **MmAllocateNonCachedMemory**.

Return Value

None

Remarks

The **MmFreeNonCachedMemory** routine performs the opposite action of MmAllocateNonCachedMemory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

MmAllocateNonCachedMemory

MmGetPhysicalAddress function

1/25/2019 • 2 minutes to read • Edit Online

The **MmGetPhysicalAddress** routine returns the physical address corresponding to a valid nonpaged virtual address.

Syntax

```
PHYSICAL_ADDRESS MmGetPhysicalAddress(
  PVOID BaseAddress
);
```

Parameters

`BaseAddress`

Pointer to the virtual address for which to return the physical address.

Return Value

MmGetPhysicalAddress returns the physical address that corresponds to the given virtual address.

Do not use this routine to obtain physical addresses for use with DMA operations. For information about the proper techniques for performing DMA operations, see Adapter Objects and DMA.

Remarks

Callers of **MmGetPhysicalAddress** can be running at any IRQL, provided that the *BaseAddress* value is valid.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

MmProbeAndLockPages

MmIsAddressValid function

1/25/2019 • 2 minutes to read • Edit Online

The **MmIsAddressValid** routine checks whether a page fault will occur for a read or write operation at a given virtual address.

> **Warning** We do not recommend using this function.

Syntax

```
BOOLEAN MmIsAddressValid(
  PVOID VirtualAddress
);
```

Parameters

`VirtualAddress`

A pointer to the nonpaged virtual address to check. The caller must ensure that this address cannot be paged out or deleted for the duration of this call. Even after the return from the call, you must not page out or delete this address. If you do page out or delete this address, the return value might be unreliable. Paging out or deleting this address might cause the computer to stop responding (that is, *crash*).

Return Value

If no page fault would occur from reading or writing at the given virtual address, **MmIsAddressValid** returns **TRUE**.

Remarks

Even if **MmIsAddressValid** returns **TRUE**, accessing the address can cause page faults unless the memory has been locked down or the address is a valid nonpaged pool address.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=DISPATCH_LEVEL"

MmIsThisAnNtAsSystem function

1/25/2019 • 2 minutes to read • Edit Online

The **MmIsThisAnNtAsSystem** routine is obsolete for Windows XP and later versions of Windows. Use RtlGetVersion or RtlVerifyVersionInfo instead.

The **MmIsThisAnNtAsSystem** routine checks whether the current platform is running a server version of the NT-based operating system.

Syntax

```
BOOLEAN MmIsThisAnNtAsSystem(

);
```

Parameters

This function has no parameters.

Return Value

If the current platform is a server, **MmIsThisAnNtAsSystem** returns **TRUE**.

Remarks

Drivers can use this routine during initialization, along with **MmQuerySystemSize**, for sizing estimates of how many resources to allocate. For example, if **MmIsThisAnNtAsSystem** returns **TRUE**, the caller can increase the number of threads or the number of initially allocated entries for a lookaside list that it creates in medium and large systems.

Requirements

Minimum supported client	Obsolete for Windows XP and later versions of Windows. Use RtlGetVersion or RtlVerifyVersionInfo instead.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

MmQuerySystemSize

MmLockPagableSectionByHandle function

1/25/2019 • 2 minutes to read • Edit Online

The **MmLockPagableSectionByHandle** routine locks a pageable code or data section into system memory by incrementing the reference count on the handle to the section.

Syntax

```
void MmLockPagableSectionByHandle(
  PVOID ImageSectionHandle
);
```

Parameters

`ImageSectionHandle`

The handle to a pageable code or data section. The caller obtained this handle from a previous call to the MmLockPagableCodeSection or MmLockPagableDataSection routine.

Return Value

None

Remarks

A driver initially calls **MmLockPagableCodeSection** or **MmLockPagableDataSection** to obtain a handle to a pageable code or data section. Thereafter, the driver can call **MmLockPagableSectionByHandle** and MmUnlockPagableImageSection to increment and decrement the reference count on the handle.

The **MmLockPagableCodeSection** or **MmLockPagableDataSection** call locks the pageable section into system memory, returns a handle to the section, and initializes the reference count on the handle to one. **MmLockPagableSectionByHandle** increments the reference count by one, and **MmUnlockPagableImageSection** decrements the reference count by one.

If the reference count on the handle is nonzero, the pageable section is locked. If the reference count is zero, the section is unlocked.

The handle to the pageable section remains valid as long as the driver stays loaded in memory. The driver can use the same handle to repeatedly lock and unlock the section. That is, the driver can reuse a handle whose reference count is zero. **MmLockPagableSectionByHandle** checks to see if the referenced section is resident in the caller's address space and, if it is, simply increments the reference count on the section. If the section is not resident, **MmLockPagableSectionByHandle** pages in the section, locks it in system space, and sets the reference count to one.

To avoid leaking system memory, the reference count on the handle must be zero when the driver is unloaded from memory. Otherwise, the pageable section will stay locked into system memory after the driver unloads.

If the driver is preparing to unload, and the reference count on the handle is nonzero, the driver should call **MmUnlockPagableImageSection** to decrement the count to zero before the unload occurs.

A driver cannot call **MmLockPagableSectionByHandle** to lock down user buffers passed in IRPs. Use

MmProbeAndLockPages instead.

For more information about paging code and data, see Making Drivers Pageable.

Requirements

MmSecureVirtualMemory function

1/25/2019 • 2 minutes to read • Edit Online

The **MmSecureVirtualMemory** routine secures a user-space memory address range so that it cannot be freed and its page protection cannot be made more restrictive.

Syntax

```
HANDLE MmSecureVirtualMemory(
  PVOID  Address,
  SIZE_T Size,
  ULONG  ProbeMode
);
```

Parameters

`Address`

The beginning of the user virtual address range to secure.

`Size`

The size, in bytes, of the virtual address range to secure.

`ProbeMode`

The most restrictive page protection that is allowed. Use PAGE_READWRITE to specify that the address range must remain both readable and writable, or use PAGE_READONLY to specify that the address range must only remain readable.

PROBEMODE	MEANING
PAGE_READWRITE	Protection cannot be changed to PAGE_NOACCESS or PAGE_READONLY. All other protection changes are allowed.
PAGE_READONLY	Protection cannot be changed to PAGE_NOACCESS. All other protection changes are allowed.

Return Value

On success, **MmSecureVirtualMemory** returns an opaque pointer value that the driver passes to the MmUnsecureVirtualMemory routine to unsecure the memory address range. If the routine is unable to secure the memory address range, it returns **NULL**.

Remarks

MmSecureVirtualMemory can be used to avoid certain race conditions on user-mode buffers. For example, if a driver checks to see if the buffer is writable, but then the originating user-mode process changes the buffer to be read-only before the driver can write to the buffer, then a race condition can result. The driver can use **MmSecureVirtualMemory** with PAGE_READWRITE probe mode to guarantee that the buffer will remain writable until the driver calls **MmUnsecureVirtualMemory**. The routine also protects against the originating

user-mode process freeing the buffer. Here are a few guidelines about calling these routines:

- Calling **MmSecureVirtualMemory** with PAGE_READONLY does not guarantee that the buffer will remain read-only. The read-only probe mode prevents the user from changing the protection of the buffer to PAGE_NOACCESS. It does *not* prevent changing the protection to PAGE_READWRITE (or PAGE_WRITECOPY, for mapped views).
- If a driver calls **MmSecureVirtualMemory** and does not call MmUnsecureVirtualMemory, the memory is automatically unsecured when the process terminates.
- If the driver calls MmUnsecureVirtualMemory, it must call it in the context of the process in which the memory was originally secured, and before that process terminates.
- Typically drivers need to reference the process when they secure the memory, then later call KeStackAttachProcess to switch to the context of that process before calling MmUnsecureVirtualMemory.
- To detect process termination drivers can use PsSetCreateProcessNotifyRoutine. Alternatively, the process can submit an IRP with a cancel routine that is invoked by the I/O manager when the process is exiting. In the cancel routine the driver can attach to the process and call MmUnsecureVirtualMemory.

While **MmSecureVirtualMemory** can be used to guarantee that reading or writing user memory will not raise an exception due to insufficient page permissions, it does not protect against other types of exceptions. For example, it does not protect against exceptions raised when the system finds a bad disk block in the page file. Therefore, drivers must still wrap all user memory accesses in a **try/except** block. Because of this, we recommend that drivers do not use this function. For more information, see Handling Exceptions.

MmSecureVirtualMemory

NtOpenProcess function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenProcess** routine opens a handle to a process object and sets the access rights to this object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtOpenProcess(
  PHANDLE            ProcessHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  PCLIENT_ID         ClientId
);
```

Parameters

`ProcessHandle`

A pointer to a variable of type HANDLE. The **ZwOpenProcess** routine writes the process handle to the variable that this parameter points to.

`DesiredAccess`

An ACCESS_MASK value that contains the access rights that the caller has requested to the process object.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the attributes to apply to the process object handle. In Windows Vista and later versions of Windows, the **ObjectName** field of this structure must be set to **NULL**. In Windows Server 2003, Windows XP, and Windows 2000, this field can, as an option, point to an object name. For more information, see the following Remarks section.

`ClientId`

A pointer to a client ID that identifies the thread whose process is to be opened. In Windows Vista and later versions of Windows, this parameter must be a non-**NULL** pointer to a valid client ID. In Windows Server 2003, Windows XP, and Windows 2000, this parameter is optional and can be set to **NULL** if the **OBJECT_ATTRIBUTES** structure that *ObjectAttributes* points to specifies an object name. For more information, see the following Remarks section.

Return Value

ZwOpenProcess returns STATUS_SUCCESS if the call is successful. Possible return values include the following error status codes.

RETURN CODE	DESCRIPTION

STATUS_INVALID_PARAMETER_MIX	In Windows Vista and later versions of Windows, the caller either supplied an object name or failed to supply a client ID. In Windows Server 2003, Windows XP, and Windows 2000, the caller supplied both an object name and a client ID.
STATUS_INVALID_CID	The specified client ID is not valid.
STATUS_INVALID_PARAMETER	The requested access rights are not valid for a process object.
STATUS_ACCESS_DENIED	The requested access rights cannot be granted.

Remarks

In Windows Vista and later versions of Windows, the *ClientId* parameter must point to a client ID that identifies the thread whose process is to be opened. In addition, the **ObjectName** field of the structure pointed to by *ObjectAttributes* must be set to **NULL**.

In Windows Server 2003, Windows XP, and Windows 2000, the caller has the option of supplying either a client ID or an object name (but not both). If the **ObjectName** field of the structure pointed to by *ObjectAttributes* contains a non-**NULL** pointer to an object name, *ClientId* must be **NULL**.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtOpenProcess**" instead of "**ZwOpenProcess**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Process-creation callback implemented by a driver to track the system-wide creation and deletion of processes against the driver's internal state.

> **Warning** The actions that you can perform in this routine are restricted for safe calls. See Best Practices.

Syntax

```
PCREATE_PROCESS_NOTIFY_ROUTINE PcreateProcessNotifyRoutine;

void PcreateProcessNotifyRoutine(
  HANDLE ParentId,
  HANDLE ProcessId,
  BOOLEAN Create
)
{...}
```

Parameters

`ParentId`

The process ID of the parent process.

`ProcessId`

The process ID of the process.

`Create`

Indicates whether the process was created (**TRUE**) or deleted (**FALSE**).

Return Value

This callback function does not return a value.

Remarks

Highest-level drivers call **PsSetCreateProcessNotifyRoutine** to register their process-creation notify routines.

A driver's process-notify routine is also called with *Create* set to **FALSE**, typically when the last thread within a process has terminated and the process address space is about to be deleted.

The operating system calls the driver's process-notify routine at PASSIVE_LEVEL inside a critical region with normal kernel APCs disabled. When a process is created, the process-notify routine runs in the context of the thread that created the new process. When a process is deleted, the process-notify routine runs in the context of the last thread to exit from the process.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
IRQL	PASSIVE_LEVEL

See Also

PsSetCreateProcessNotifyRoutine

PCREATE_PROCESS_NOTIFY_ROUTINE_EX callback function

1/25/2019 • 2 minutes to read • Edit Online

A callback routine implemented by a driver to notify the caller when a process is created or exits.

Warning The actions that you can perform in this routine are restricted for safe calls. See Best Practices.

Syntax

```
PCREATE_PROCESS_NOTIFY_ROUTINE_EX PcreateProcessNotifyRoutineEx;

void PcreateProcessNotifyRoutineEx(
  PEPROCESS Process,
  HANDLE ProcessId,
  PPS_CREATE_NOTIFY_INFO CreateInfo
)
{...}
```

Parameters

`Process`

A pointer to the EPROCESS structure that represents the process. Drivers can use the **PsGetCurrentProcess** and **ObReferenceObjectByHandle** routines to obtain a pointer to the EPROCESS structure for a process.

`ProcessId`

The process ID of the process.

`CreateInfo`

A pointer to a PS_CREATE_NOTIFY_INFO structure that contains information about the new process. If this parameter is NULL, the specified process is exiting.

Return Value

This callback function does not return a value.

Remarks

Highest-level drivers call PsSetCreateProcessNotifyRoutineEx to register their implementation of *PCREATE_PROCESS_NOTIFY_ROUTINE_EX* routine. An installable file system (IFS) or highest-level system-profiling driver might register a process-creation callback routine to track which processes are created and deleted against the driver's internal state across the system.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
IRQL	PASSIVE_LEVEL

See Also

PsSetCreateProcessNotifyRoutineEx

PsSetCreateProcessNotifyRoutineEx2

PCREATE_THREAD_NOTIFY_ROUTINE callback function

1/25/2019 • 2 minutes to read • Edit Online

A callback routine implemented by a driver to notify the caller when a thread is created or deleted.

Warning The actions that you can perform in this routine are restricted for safe calls. See Best Practices.

Syntax

```
PCREATE_THREAD_NOTIFY_ROUTINE PcreateThreadNotifyRoutine;

void PcreateThreadNotifyRoutine(
  HANDLE ProcessId,
  HANDLE ThreadId,
  BOOLEAN Create
)
{...}
```

Parameters

`ProcessId`

The process ID of the process.

`ThreadId`

The thread ID of the thread.

`Create`

Indicates whether the thread was created (**TRUE**) or deleted (**FALSE**).

Return Value

This callback function does not return a value.

Remarks

Highest-level drivers can call PsSetCreateThreadNotifyRoutine or PsSetCreateThreadNotifyRoutineEx to register their thread-creation notify routine.

The driver's thread-notify routine runs at IRQL = PASSIVE_LEVEL or APC_LEVEL. When a thread is created, the thread-notify routine runs in the context of the thread that created the new thread. When a thread is deleted, the thread-notify routine runs in the context of this thread when the thread exits.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
IRQL	"<=APC_LEVEL"

See Also

PsSetCreateThreadNotifyRoutine

PsSetCreateThreadNotifyRoutineEx

PGET_LOCATION_STRING callback function

1/25/2019 • 2 minutes to read • Edit Online

The *PnpGetLocationString* routine provides the device-specific part of the device's SPDRP_LOCATION_PATHS property.

Syntax

```
PGET_LOCATION_STRING PgetLocationString;

NTSTATUS PgetLocationString(
  PVOID Context,
  PZZWSTR *LocationStrings
)
{...}
```

Parameters

`Context`

A pointer to interface-specific context information. The caller passes the value that is passed as the **Context** member of the PNP_LOCATION_INTERFACE structure.

`*LocationStrings`

A pointer to a sequence of null-terminated Unicode strings, that is terminated by another zero. Each string serves as a location string for the device. Drivers typically return a single string.

Return Value

The routine returns an NTSTATUS value to indicate the status of the operation.

Remarks

The PNP_LOCATION_INTERFACE structure supplies a pointer to the *PnpGetLocationString* routine.

The *PnpGetLocationString* routine provides the device-specific part of the location string for the device. The Plug and Play (PnP) manager assembles the location string for a device by querying the driver for the device, for the device's bus, and any parent buses, and concatenating the provided strings together.

The routine must return a string that is unique to the device relative to its bus. The string must be the same for the device across all versions of the operating system. Once you select a string for this purpose, you must not change it.

By convention, the location string takes the form *ServiceName(BusSpecificLocation)*. For example, PCI devices use PCI(*XXYY*), where *XX* is the device number, and *YY* is the function number.

The *PnpGetLocationString* routine calls a routine such as ExAllocatePoolWithTag to allocate the memory for the location string. The caller is responsible for calling the ExFreePool routine to free the memory pointed to by *LocationStrings* when the location string is no longer needed.

Requirements

Minimum supported client	Available starting with Windows Server 2003.
Target Platform	Desktop
Header	ntddk.h (include Ntddk.h, Ntifs.h)
IRQL	"<= PASSIVE_LEVEL"

See Also

ExAllocatePoolWithTag

ExFreePool

PNP_LOCATION_INTERFACE

pHalExamineMBR callback function

1/25/2019 • 2 minutes to read • Edit Online

The **HalExamineMBR** routine reads the master boot record (MBR) of a disk and returns data from the MBR if the MBR is of the type specified by the caller.

Syntax

```
pHalExamineMBR Phalexaminembr;

void Phalexaminembr(
  PDEVICE_OBJECT DeviceObject,
  ULONG SectorSize,
  ULONG MBRTypeIdentifier,
  PVOID *Buffer
)
{...}
```

Parameters

`DeviceObject`

A pointer to the device object for the device being examined.

`SectorSize`

The minimum number of bytes that an I/O operation can fetch from the device being examined. If this value is less than 512, **HalExamineMBR** reads 512 bytes to ensure that it reads an entire partition table.

`MBRTypeIdentifier`

MBR partition type identifier. This parameter specifies the type of MBR that may be on the disk. For more information, see Remarks.

`*Buffer`

A pointer to a location to which **HalExamineMBR** writes a pointer to a buffer that contains data from the MBR. The layout of the buffer depends on the MBR partition type. **HalExamineMBR** allocates the storage for this buffer. The caller must deallocate this buffer as soon as possible by calling the ExFreePool routine.

HalExamineMBR sets **Buffer* = **NULL** if the MBR partition type of the disk does not match that specified by *MBRTypeIdentifier* or if there is an error.

Return Value

None

Remarks

For a list of system-defined MBR partition type identifiers, see the table in PARTITION_INFORMATION. These identifiers are defined in the Ntdddisk.h header file.

Requirements

Minimum supported client	Available starting with Windows XP.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

See Also

PARTITION_INFORMATION

PLOAD_IMAGE_NOTIFY_ROUTINE callback function

1/25/2019 • 2 minutes to read • Edit Online

Called by the operating system to notify the driver when a driver image or a user image (for example, a DLL or EXE) is mapped into virtual memory.

> **Warning** The actions that you can perform in this routine are restricted for safe calls. See Best Practices.

Syntax

```
PLOAD_IMAGE_NOTIFY_ROUTINE PloadImageNotifyRoutine;

void PloadImageNotifyRoutine(
  PUNICODE_STRING FullImageName,
  HANDLE ProcessId,
  PIMAGE_INFO ImageInfo
)
{...}
```

Parameters

`FullImageName`

A pointer to a buffered Unicode string that identifies the executable image file. (The *FullImageName* parameter can be **NULL** in cases in which the operating system is unable to obtain the full name of the image at process creation time.)

`ProcessId`

The process ID of the process in which the image has been mapped, but this handle is zero if the newly loaded image is a driver.

`ImageInfo`

A pointer to an IMAGE_INFO structure that contains image information. See Remarks.

Return Value

This callback function does not return a value.

Remarks

Highest-level system-profiling drivers can call PsSetLoadImageNotifyRoutine to set up their load-image notify routine.

The operating system does not call load-image notify routines when sections created with the SEC_IMAGE_NO_EXECUTE attribute are mapped to virtual memory.

In Windows 7, Windows Server 2008 R2, and earlier versions of Windows, the operating system holds an internal system lock during calls to load-image notify routines for images loaded in user process address space (user space). To avoid deadlocks, load-image notify routines must not call system routines that map, allocate, query, free, or perform other operations on user-space virtual memory.

A driver must remove any callbacks it registers before it unloads. You can remove the callback by calling the PsRemoveLoadImageNotifyRoutine routine.

When the main executable image for a newly created process is loaded, the load-image notify routine runs in the context of the new process. The operating system calls the driver's load-image notify routine at PASSIVE_LEVEL inside a critical region with normal kernel APCs always disabled and sometimes with both kernel and special APCs disabled.

```
    When the load-image notify routine is called, the input <i>FullImageName</i> points to a buffered Unicode
string that identifies the executable image file. (The <i>FullImageName</i> parameter can be <b>NULL</b> in
cases in which the operating system is unable to obtain the full name of the image at process creation time.)
The <i>ProcessId</i> handle identifies the process in which the image has been mapped, but this handle is zero
if the newly loaded image is a driver. To see the format of the buffered data at <i>ImageInfo</i>, see  <a
href="https://msdn.microsoft.com/library/windows/hardware/mt764083">IMAGE_INFO</a>. If the
<b>ExtendedInfoPresent</b> flag is set in the <b>IMAGE_INFO</b> structure, the information is part of a larger,
extended version of the image information structure, <a
href="https://msdn.microsoft.com/library/windows/hardware/mt764084">IMAGE_INFO_EX</a>.
```

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
IRQL	PASSIVE_LEVEL

IMAGE_INFO_EX

PsSetLoadImageNotifyRoutine

PsAllocSiloContextSlot function

1/25/2019 • 2 minutes to read • Edit Online

This routine allocates a slot that can be used to insert, retrieve, and delete an object in all silos.

Syntax

```
NTSTATUS PsAllocSiloContextSlot(
  ULONG_PTR Reserved,
  ULONG     *ReturnedContextSlot
);
```

Parameters

`Reserved`

This parameter is reserved for future use and **must be set to zero**.

> **Warning** Setting *Reserved* to a non-zero value causes the system to execute an **ASSERT** on a checked build.

`ReturnedContextSlot`

A pointer to a caller-allocated variable that receives the newly allocated slot index. This parameter is required and it cannot be **NULL**.

Return Value

The following NT status codes are returned.

RETURN CODE	DESCRIPTION
STATUS_INSUFFICIENT_RESOURCES	There are no more slots available in the system. This is an error code.
STATUS_SUCCESS	The operation completed successfully.

Remarks

Use of this API is uncommon because all silo monitors are assigned a storage slot when calling the PsRegisterSiloMonitor routine. That slot can be retrieved with the PsGetSiloMonitorContextSlot routine and used by a driver for its context operations.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsFreeSiloContextSlot

PsAttachSiloToCurrentThread function

1/25/2019 • 2 minutes to read • Edit Online

This routine places a thread temporarily into the specified *Silo*.

Syntax

```
PESILO PsAttachSiloToCurrentThread(
  PESILO Silo
);
```

Parameters

`Silo`

The silo that the thread is to impersonate. The caller must hold a reference to the silo throughout the duration of the impersonation.

Return Value

The previous silo that was attached to the current thread.

Remarks

The specified *Silo* is attached to the current thread so that it becomes the effective silo for the thread.

The thread then operates within the namespace of the attached silo until PsDetachSiloFromCurrentThread is called.

Examples

C++

```
PESILO PreviousSilo = PsAttachSiloToCurrentThread();

// Do work within the silo context

PsDetachSiloFromCurrentThread(PreviousSilo);
```

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows

Header	ntddk.h

See Also

PsDetachSiloFromCurrentThread

PsCreateSiloContext function

1/25/2019 • 2 minutes to read • Edit Online

This routine creates an object that will be inserted in a *Silo*.

Syntax

```
NTSTATUS PsCreateSiloContext(
  PESILO                        Silo,
  ULONG                         Size,
  POOL_TYPE                     PoolType,
  SILO_CONTEXT_CLEANUP_CALLBACK ContextCleanupCallback,
  PVOID                         *ReturnedSiloContext
);
```

Parameters

`Silo`

A pointer to a silo. This parameter is required and it cannot be **NULL**.

`Size`

The size, in bytes, of the portion of the object defined by the caller.

`PoolType`

The type of pool to allocate from. This parameter is required and must be one of the following: **NonPagedPoolNx** or **PagedPool**.

`ContextCleanupCallback`

A pointer to a SILO_CONTEXT_CLEANUP_CALLBACK callback function. The function will be called when the returned object has zero references to it. This parameter is optional and can be **NULL**.

`ReturnedSiloContext`

A pointer to a caller-allocated variable that receives the address of the newly created object.

Return Value

The following NT status codes are returned.

RETURN CODE	DESCRIPTION

STA TUS _IN SUF FICI ENT _RE SO URC ES	The routine encountered a pool allocation failure. This is an error code.
STA TUS _IN VAL ID_ PAR AM ETE R	The pool type is not valid. This is an error code.
STA TUS _SU CCE SS	The operation completed successfully.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsDereferenceSiloContext function

1/25/2019 • 2 minutes to read • Edit Online

This routine decrements the reference count on the object.

Syntax

```
void PsDereferenceSiloContext(
  PVOID SiloContext
);
```

Parameters

`SiloContext`

A pointer to the object created by the PsCreateSiloContext routine. This parameter is required and it cannot be **NULL**.

Return Value

This routine does not return a value.

Remarks

If the reference count reaches zero it will call the cleanup callback provided when the PsCreateSiloContext routine created the object.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h
IRQL	"*IRQL_requires_max*(DISPATCH_LEVEL)"

PsDetachSiloFromCurrentThread function

1/25/2019 • 2 minutes to read • Edit Online

This routine removes a thread from a silo which was added by an attach. For more info about attaching, see the PsAttachSiloToCurrentThread routine.

> **Note** The caller is responsible for dereferencing the object after the detach has completed.

Syntax

```
void PsDetachSiloFromCurrentThread(
  PESILO PreviousSilo
);
```

Parameters

`PreviousSilo`

The value returned from the silo attach call.

Return Value

This routine does not return a value.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

See Also

PsAttachSiloToCurrentThread

PsFreeSiloContextSlot function

1/25/2019 • 2 minutes to read • Edit Online

This routine frees the specified slot and makes it available in the system. It undoes the effects of the PsAllocSiloContextSlot routine.

Syntax

```
NTSTATUS PsFreeSiloContextSlot(
  ULONG ContextSlot
);
```

Parameters

`ContextSlot`

A slot allocated by the PsAllocSiloContextSlot routine.

> **Warning** Setting this parameter to a slot that is still in use causes the system to execute bug check.

Return Value

The following NT status codes are returned.

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The slot is not allocated in the system. This is an error code.
STATUS_SUCCESS	The operation completed successfully.

Requirements

Minimum supported client	Windows 10, version 1607

Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsGetCurrentServerSilo function

1/25/2019 • 2 minutes to read • Edit Online

This routine returns the effective server silo for the thread.

Syntax

```
PESILO PsGetCurrentServerSilo(

);
```

Parameters

This function has no parameters.

Return Value

A pointer to the current server silo. This pointer is valid for the current thread, but must be referenced before transferring to another thread (for example, via a workitem).

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h
IRQL	"*IRQL_requires_max*(DISPATCH_LEVEL)"

PsGetCurrentSilo function

1/25/2019 • 2 minutes to read • Edit Online

This routine returns the current silo for the calling thread. First the thread is checked to see if it has been attached to a silo. If not, then the thread is checked to see if it is in a silo.

Syntax

```
PESILO PsGetCurrentSilo(

);
```

Parameters

This function has no parameters.

Return Value

A pointer to the **ESILO** object. This pointer is valid for the current thread, but must be referenced before transferring to another thread (for example, via a workitem).

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h
IRQL	"*IRQL_requires_max*(DISPATCH_LEVEL)"

PsGetCurrentThread function

1/25/2019 • 2 minutes to read • Edit Online

The **PsGetCurrentThread** routine identifies the current thread.

Syntax

```
PETHREAD PsGetCurrentThread(

);
```

Parameters

This function has no parameters.

Return Value

PsGetCurrentThread returns a pointer to the executive thread object that represents the currently executing thread.

Remarks

This macro

Requirements

PsGetEffectiveServerSilo function

1/25/2019 • 2 minutes to read • Edit Online

This routine traverses the parent chain of the *Silo* until finding the effective server silo or host silo.

Syntax

```
PESILO PsGetEffectiveServerSilo(
  PESILO Silo
);
```

Parameters

`Silo`

A pointer to a silo.

Return Value

The effective server silo. If a server silo is not found, the host silo is returned. In that case, `PsIsHostSilo(ReturnValue)` would return **TRUE**.

Remarks

This routine does not fail because it always returns a silo: the server silo or the host silo.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PESILO PsGetHostSilo(

);
```

Parameters

This function has no parameters.

Return Value

The host silo.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsGetJobServerSilo function

1/25/2019 • 2 minutes to read • Edit Online

This routine returns the effective *ServerSilo* for the job. The returned pointer is valid as long as the supplied *Job* object remains referenced.

> **Note** This returns a *ServerSilo* or a value indicating the host silo. Unlike PsGetJobSilo, it will not return an app silo, even if one is present.

Syntax

```
NTSTATUS PsGetJobServerSilo(
  PEJOB  Job,
  PESILO *ServerSilo
);
```

Parameters

`Job`

A job object.

`ServerSilo`

A pointer that receives the server silo for the job.

Return Value

The following NT status codes are returned.

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The *Job* parameter is **NULL**.
STATUS_SUCCESS	A PESILO is returned successfully.

Remarks

STATUS_SUCCESS is returned even if a server silo is not in effect for the job. In that case, it will return the default host silo.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsGetJobSilo function

1/25/2019 • 2 minutes to read • Edit Online

This routine returns the first job in the hierarchy that is a *Silo*. The returned pointer is valid as long as the supplied *Job* object remains referenced.

> **Note** This returns both app silos and server silos, whichever is first.

Syntax

```
NTSTATUS PsGetJobSilo(
  PEJOB  Job,
  PESILO *Silo
);
```

Parameters

`Job`

A job object.

`Silo`

A pointer that receives the silo for the job.

Return Value

The following NT status codes are returned.

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The *Job* parameter is **NULL**.
STATUS_JOB_NO_CONTAINER	No silo is present.

STA **TUS** **_SU** **CCE** **SS**	A PESILO is returned successfully.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsGetParentSilo function

1/25/2019 • 2 minutes to read • Edit Online

Retrieves the most immediate parent silo in the hierarchy for a given job object.

Syntax

```
PESILO PsGetParentSilo(
  PEJOB Job
);
```

Parameters

`Job`

A pointer to an **EJOB** structure that represents the job object.

Return Value

A pointer to the parent silo of the job. his value may be PSP_HOST_SILO, because all silos descend from the host.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode)
IRQL	PASSIVE_LEVEL

PsGetPermanentSiloContext function

1/25/2019 • 2 minutes to read • Edit Online

This routine retrieves an object that was inserted in the *Silo* without incrementing the reference count.

Syntax

```
NTSTATUS PsGetPermanentSiloContext(
  PESILO Silo,
  ULONG  ContextSlot,
  PVOID  *ReturnedSiloContext
);
```

Parameters

`Silo`

The silo in which the object was inserted. This parameter is required and it cannot be **NULL**.

`ContextSlot`

The read-only slot that was previously allocated byPsAllocSiloContextSlot and made read-only by PsMakeSiloContextPermanent.

`ReturnedSiloContext`

A pointer to a caller-allocated variable that receives the address of the existing object. This parameter is required and it cannot be **NULL**.

Return Value

The following NT status codes are returned.

RETURN CODE	DESCRIPTION
STA TUS _NO T_F OU ND	The slot is empty. This is an error code.
STA TUS _NO T_S UPP ORT ED	The slot is not read-only and it cannot safely retrieve the object. This is an error code.

STA **TUS** **_SU** **CCE** **SS**	The operation completed successfully.

Remarks

A successful call to **PsGetPermanentSiloContext** does not increment the reference count on the object that the *ReturnedSiloContext* parameter points to. The returned object pointer is valid as long as there is a valid reference on the silo object.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsGetProcessCreateTimeQuadPart function

1/25/2019 • 2 minutes to read • Edit Online

The **PsGetProcessCreateTimeQuadPart** routine returns a LONGLONG value that represents the time at which the process was created.

Syntax

```
LONGLONG PsGetProcessCreateTimeQuadPart(
  PEPROCESS Process
);
```

Parameters

`Process`

A pointer to the EPROCESS structure that represents the process. Drivers can use the PsGetCurrentProcess and ObReferenceObjectByHandle routines to obtain a pointer to the EPROCESS structure for a process.

Return Value

PsGetProcessCreateTimeQuadPart returns the process creation time, in 100-nanosecond intervals, since January 1, 1601. The return value is the same as the value that the KeQuerySystemTime routine returns when the process was created. (Note that if the system time is changed, the value that **PsGetProcessCreateTimeQuadPart** returns is unaffected.)

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Ntoskrnl.lib
DLL	Ntoskrnl.exe

PsGetProcessId function

1/25/2019 • 2 minutes to read • Edit Online

The **PsGetProcessId** routine returns the process identifier (process ID) that is associated with a specified process.

Syntax

```
HANDLE PsGetProcessId(
  PEPROCESS Process
);
```

Parameters

`Process`

A pointer to a process object structure.

Return Value

PsGetProcessId returns the process ID of the process that the *Process* parameter specifies.

Remarks

The EPROCESS-typed process object structure is an opaque data structure that the operating system uses internally. To obtain a pointer to the EPROCESS structure for the current process, a driver can call PsGetCurrentProcess. To obtain a pointer to the EPROCESS structure for a different process, the driver can call ObReferenceObjectByHandle.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

See Also

ObReferenceObjectByHandle

PsGetCurrentProcess

PsGetServerSiloActiveConsoleId function

1/25/2019 • 2 minutes to read • Edit Online

Gets the active console for the current server silo context for the supplied thread.

Syntax

```
ULONG PsGetServerSiloActiveConsoleId(
  PESILO Silo
);
```

Parameters

`Silo`

A pointer to the silo of the job.

Return Value

Returns the session id for the active console session.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode)
IRQL	PASSIVE_LEVEL

PsGetSiloContext function

1/25/2019 • 2 minutes to read • Edit Online

This routine retrieves the silo context from the specified silo and slot.

Syntax

```
NTSTATUS PsGetSiloContext(
  PESILO Silo,
  ULONG  ContextSlot,
  PVOID  *ReturnedSiloContext
);
```

Parameters

`Silo`

The silo where the silo context is to exist. This parameter is required and it cannot be **NULL**.

`ContextSlot`

The slot where the silo context is to exist. A slot allocated by the PsAllocSiloContextSlot routine.

`ReturnedSiloContext`

Receives a referenced pointer to the silo context. On failure, the value received will be **NULL**.

Return Value

The following NT status codes are returned.

RETURN CODE	DESCRIPTION
STATUS_NOT_FOUND	Status code if the silo context is not found.
STATUS_INVALID_PARAMETER	Status code if an invalid slot number was supplied as the *ContextSlot* parameter.

STA **TUS** **_SU** **CCE** **SS**	The operation completed successfully.

Remarks

The **PsGetSiloContext** routine retrieves an object that was inserted in the specified silo. A successful call to this routine increments the reference count on the object that the *ReturnedSiloContext* parameter points to. The object that the *ReturnedSiloContext* parameter points to, must be decremented by calling PsDereferenceSiloContext when it is no longer needed. A context slot may go empty if the silo is being terminated by either having no more processes or a specific call to **NtTerminateJobObject**. The return status in this case is **STATUS_NOT_FOUND**.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsGetSiloMonitorContextSlot function

1/25/2019 • 2 minutes to read • Edit Online

This routine returns the silo context slot that was allocated by the monitor during the registration.

Syntax

```
ULONG PsGetSiloMonitorContextSlot(
  PSILO_MONITOR Monitor
);
```

Parameters

`Monitor`

A pointer to the silo monitor.

Return Value

A valid silo context slot.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsInsertPermanentSiloContext function

1/25/2019 • 2 minutes to read • Edit Online

This routine inserts an object in an empty slot in a *Silo*.

Syntax

```
NTSTATUS PsInsertPermanentSiloContext(
  PESILO Silo,
  ULONG  ContextSlot,
  PVOID  SiloContext
);
```

Parameters

`Silo`

The silo in which the object is to be inserted. This parameter is required and it cannot be **NULL**.

`ContextSlot`

The slot in which the object is to be inserted. A slot allocated by the PsAllocSiloContextSlot routine.

`SiloContext`

The object to be inserted, created by the PsCreateSiloContext routine. The object must be created using the same silo as specified in the *Silo* parameter. This parameter is required and it cannot be **NULL**.

Return Value

The following NT status codes are returned.

RETURN CODE	DESCRIPTION
STA TUS _IN SUF FICI ENT _RE SO URC ES	There are no resources in the system to perform the insert. This is an error code.

STA TUS _NO T_S UPP ORT ED	The slot is not empty. This is an error code.
STA TUS _SU CCE SS	The operation completed successfully.

Remarks

A successful call to **PsInsertPermanentSiloContext** increments the reference count on *SiloContext*. If **PsInsertPermanentSiloContext** fails, the reference count remains unchanged. In either case, after the routine completes, the caller must call PsDereferenceSiloContext to decrement the *SiloContext* object.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsInsertSiloContext function

1/25/2019 • 2 minutes to read • Edit Online

This routine inserts an object in an empty slot in a *Silo*.

Syntax

```
NTSTATUS PsInsertSiloContext(
  PESILO Silo,
  ULONG  ContextSlot,
  PVOID  SiloContext
);
```

Parameters

`Silo`

A pointer to a silo. This parameter is required and it cannot be **NULL**.

`ContextSlot`

A slot allocated by the PsAllocSiloContextSlot routine.

`SiloContext`

A pointer to the object created by the PsCreateSiloContext routine. The object must be created using the same silo pointer as the one specified in this routine. This parameter is required and it cannot be **NULL**.

Return Value

The following NT status codes are returned.

RETURN CODE	DESCRIPTION
STA TUS _IN SUF FICI ENT _RE SO URC ES	There are no resources in the system to perform the insert. This is an error code.

STA TUS _NO T_S UPP ORT ED	The slot is not empty. This is an error code.
STA TUS _SU CCE SS	The operation completed successfully.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsIsHostSilo function

1/25/2019 • 2 minutes to read • Edit Online

This routine will check if the supplied *Silo* is the host silo.

Syntax

```
BOOLEAN PsIsHostSilo(
  PESILO Silo
);
```

Parameters

`Silo`

The silo to evaluate.

Return Value

Returns **true** if the specified silo is the host silo; otherwise, **false**.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsMakeSiloContextPermanent function

1/25/2019 • 2 minutes to read • Edit Online

This routine makes the slot in a silo instance read-only, allowing the object in the slot to be retrieved without affecting the reference count on that object.

Syntax

```
NTSTATUS PsMakeSiloContextPermanent(
  PESILO Silo,
  ULONG  ContextSlot
);
```

Parameters

`Silo`

The silo in which the slot resides. This parameter is required and it cannot be **NULL**.

`ContextSlot`

The slot to make read-only. The slot must be previously allocated by the PsAllocSiloContextSlot routine.

Return Value

The following NT status codes are returned.

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The slot does not contain a valid object. This is an error code.
STATUS_NOT_FOUND	The slot has not been allocated. This is an error code.

STA **TUS** **_SU** **CCE** **SS**	The operation completed successfully.

Remarks

Before calling this routine, the slot must contain a valid object. After it completes, the PsReplaceSiloContext and PsRemoveSiloContext routines will fail with **STATUS_NOT_SUPPORTED**.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsReferenceSiloContext function

1/25/2019 • 2 minutes to read • Edit Online

This routine increments the reference count on the object.

Syntax

```
void PsReferenceSiloContext(
  PVOID SiloContext
);
```

Parameters

`SiloContext`

A pointer to the object created by the PsCreateSiloContext routine. This parameter is required and it cannot be **NULL**.

Return Value

This routine does not return a value.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h
IRQL	"*IRQL_requires_max*(DISPATCH_LEVEL)"

PsCreateSiloContext

PsRegisterSiloMonitor function

1/25/2019 • 2 minutes to read • Edit Online

This routine registers a server silo monitor that can receive notifications about server silo events.

> **Note** To start receiving notifications, call the PsStartSiloMonitor routine.

Syntax

```
NTSTATUS PsRegisterSiloMonitor(
  PSILO_MONITOR_REGISTRATION Registration,
  PSILO_MONITOR              *ReturnedMonitor
);
```

Parameters

`Registration`

Specifies the server silo monitor to be registered, of type SILO_MONITOR_REGISTRATION.

`ReturnedMonitor`

Receives a pointer to the monitor. This pointer is used to make further monitor-related calls.

Return Value

The following NT status codes are returned.

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The version specified in **ntddk.h** does not match **SILO_MONITOR_REGISTRATION_VERSION**, the component name is not specified, or the terminate callback is not supplied.
STATUS_PRIVILEGE_NOT_HELD	The routine is called in a silo.

STA TUS _IN SUF FICI ENT _RE SO URC ES	There is no memory to register a silo monitor or there is no available silo slot.
STA TUS _SU CCE SS	The operation completed successfully.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsRemoveCreateThreadNotifyRoutine function

1/25/2019 • 2 minutes to read • Edit Online

The **PsRemoveCreateThreadNotifyRoutine** routine removes a callback routine that was registered by the PsSetCreateThreadNotifyRoutine routine.

Syntax

```
NTSTATUS PsRemoveCreateThreadNotifyRoutine(
  PCREATE_THREAD_NOTIFY_ROUTINE NotifyRoutine
);
```

Parameters

`NotifyRoutine`

Pointer to the callback routine that the driver has previously registered through PsSetCreateThreadNotifyRoutine.

Return Value

PsRemoveCreateThreadNotifyRoutine returns STATUS_SUCCESS if it successfully removes the callback routine, or STATUS_PROCEDURE_NOT_FOUND if the value of *NotifyRoutine* does not match any registered callback routine.

Remarks

If the driver's callback routine is currently running, **PsRemoveCreateThreadNotifyRoutine** waits until the callback routine exits before removing it. Therefore, the callback routine itself must not call **PsRemoveCreateThreadNotifyRoutine**.

Requirements

Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=APC_LEVEL"

See Also

PsSetCreateThreadNotifyRoutine

PsRemoveLoadImageNotifyRoutine function

1/25/2019 • 2 minutes to read • Edit Online

The **PsRemoveLoadImageNotifyRoutine** routine removes a callback routine that was registered by the PsSetLoadImageNotifyRoutine routine.

Syntax

```
NTSTATUS PsRemoveLoadImageNotifyRoutine(
  PLOAD_IMAGE_NOTIFY_ROUTINE NotifyRoutine
);
```

Parameters

`NotifyRoutine`

Pointer to the callback routine that the driver has previously registered through PsSetLoadImageNotifyRoutine.

Return Value

PsRemoveLoadImageNotifyRoutine returns STATUS_SUCCESS if it successfully removes the callback routine, or STATUS_PROCEDURE_NOT_FOUND if the value of *NotifyRoutine* does not match any registered callback routine.

Remarks

If the driver's callback routine is currently running, **PsRemoveLoadImageNotifyRoutine** waits until the callback routine exits before removing it. Therefore, the callback routine itself must not call **PsRemoveLoadImageNotifyRoutine**.

Requirements

Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=APC_LEVEL"
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

PsSetLoadImageNotifyRoutine

PsRemoveSiloContext function

1/25/2019 • 2 minutes to read • Edit Online

This routine removes an object that was inserted in the *Silo*.

Syntax

```
NTSTATUS PsRemoveSiloContext(
  PESILO Silo,
  ULONG  ContextSlot,
  PVOID  *RemovedSiloContext
);
```

Parameters

`Silo`

The silo from which the object is to be removed. This parameter is required and it cannot be **NULL**.

`ContextSlot`

A slot allocated by the PsAllocSiloContextSlot routine.

`RemovedSiloContext`

A pointer to a caller-allocated variable that receives the address of the removed object. This parameter is optional and can be **NULL**.

Return Value

The following NT status codes are returned.

RETURN CODE	DESCRIPTION
STATUS_NOT_FOUND	The slot is empty. This is an error code.
STATUS_UPPORTED	The slot is read-only and it cannot be modified. This is an error code.

STA **TUS** **_SU** **CCE** **SS**	The operation completed successfully.

Remarks

In a successful call to **PsRemoveSiloContext** where the *RemovedSiloContext* parameter is not **NULL** and does not point to **NULL**, the caller must decrement the object that the *RemovedSiloContext* parameter points to, by calling PsDereferenceSiloContext when it is no longer needed.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsReplaceSiloContext function

1/25/2019 • 2 minutes to read • Edit Online

This routine inserts an object in a *Silo*.

Syntax

```
NTSTATUS PsReplaceSiloContext(
  PESILO Silo,
  ULONG  ContextSlot,
  PVOID  NewSiloContext,
  PVOID  *OldSiloContext
);
```

Parameters

`Silo`

A pointer to a silo. This parameter is required and it cannot be **NULL**.

`ContextSlot`

A slot allocated by the PsAllocSiloContextSlot routine.

`NewSiloContext`

A pointer to the object created by the PsCreateSiloContext routine. The object must be created using the same silo pointer as the one specified in this routine. This parameter is required and it cannot be **NULL**.

`OldSiloContext`

A pointer to a caller-allocated variable that receives the address of the existing object. This parameter is optional and can be **NULL**. The address that the parameter receives can be **NULL**.

Return Value

The following NT status codes are returned.

RETURN CODE	DESCRIPTION
STA TUS _IN SUF FICI ENT _RE SO URC ES	There are no resources in the system to perform the insert. This is an error code.

STA TUS _NO T_S UPP ORT ED	The slot is read-only and it cannot be modified. This is an error code.
STA TUS _SU CCE SS	The operation completed successfully.

Remarks

A successful call to **PsReplaceSiloContext** increments the reference count on *NewSiloContext*. If **PsReplaceSiloContext** fails, the reference count remains unchanged. In either case, the caller of **PsReplaceSiloContext** must call PsDereferenceSiloContext to decrement the **PsReplaceSiloContext** object. If **PsReplaceSiloContext** fails and if the *OldSiloContext* parameter is not **NULL** and does not point to **NULL** then **NULL** is a referenced pointer. After the routine completes, the caller must call **PsDereferenceSiloContext** to decrement the object that the **NULL** parameter points to.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsSetCreateProcessNotifyRoutine function

1/25/2019 • 2 minutes to read • Edit Online

The **PsSetCreateProcessNotifyRoutine** routine adds a driver-supplied callback routine to, or removes it from, a list of routines to be called whenever a process is created or deleted.

Syntax

```
NTSTATUS PsSetCreateProcessNotifyRoutine(
  PCREATE_PROCESS_NOTIFY_ROUTINE NotifyRoutine,
  BOOLEAN                        Remove
);
```

Parameters

`NotifyRoutine`

Specifies the entry point of a caller-supplied process-creation callback routine. See PCREATE_PROCESS_NOTIFY_ROUTINE.

`Remove`

Indicates whether the routine specified by *NotifyRoutine* should be added to or removed from the system's list of notification routines. If **FALSE**, the specified routine is added to the list. If **TRUE**, the specified routine is removed from the list.

Return Value

PsSetCreateProcessNotifyRoutine can return one of the following:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The given *NotifyRoutine* is now registered with the system.
STATUS_INVALID_PARAMETER	The given *NotifyRoutine* has already been registered, so this call is a redundant call, or the system has reached its limit for registering process-creation callbacks.

Remarks

Highest-level drivers can call **PsSetCreateProcessNotifyRoutine** to set up their process-creation notify routines implemented as PCREATE_PROCESS_NOTIFY_ROUTINE.

An IFS or highest-level system-profiling driver might register a process-creation callback to track the system-wide creation and deletion of processes against the driver's internal state. For Windows Vista and later versions of Windows, the system can register up to 64 process-creation callback routines.

A driver must remove any callbacks that it registers before it unloads. You can remove the callback by calling **PsSetCreateProcessNotify** with *Remove* = **TRUE**.

After a driver-supplied routine is registered, it is called with *Create* set to **TRUE** just after the initial thread is created within the newly created process designated by the input *ProcessId* handle. The input *ParentId* handle identifies the parent process of the newly-created process (this is the parent used for priority, affinity, quota, token, and handle inheritance, among others).

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	IrqlPsPassive, PowerIrpDDis, HwStorPortProhibitedDDIs

See Also

PCREATE_PROCESS_NOTIFY_ROUTINE

PsGetCurrentProcessId

PsSetCreateProcessNotifyRoutineEx

PsSetCreateThreadNotifyRoutine

PsSetLoadImageNotifyRoutine

PsSetCreateProcessNotifyRoutineEx function

1/25/2019 • 2 minutes to read • Edit Online

The **PsSetCreateProcessNotifyRoutineEx** routine registers or removes a callback routine that notifies the caller when a process is created or exits.

Syntax

```
NTSTATUS PsSetCreateProcessNotifyRoutineEx(
  PCREATE_PROCESS_NOTIFY_ROUTINE_EX NotifyRoutine,
  BOOLEAN                           Remove
);
```

Parameters

`NotifyRoutine`

A pointer to the PCREATE_PROCESS_NOTIFY_ROUTINE_EX routine to register or remove. The operating system calls this routine whenever a new process is created.

`Remove`

A Boolean value that specifies whether **PsSetCreateProcessNotifyRoutineEx** will add or remove a specified routine from the list of callback routines. If this parameter is **TRUE**, the specified routine is removed from the list of callback routines. If this parameter is **FALSE**, the specified routine is added to the list of callback routines. If *Remove* is **TRUE**, the system also waits for all in-flight callback routines to complete before returning.

Return Value

PsSetCreateProcessNotifyRoutineEx returns one of the following NTSTATUS values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The specified routine is now registered with the operating system. The operating system calls this routine whenever a new process is created.
STATUS_INVALID_PARAMETER	The specified routine was already registered, or the operating system has reached its limit for registering process-creation callback routines.

STA TUS _AC CES S_D ENI ED	The image that contains the callback routine pointer did not have IMAGE_DLLCHARACTERISTICS_FORCE_INTEGRITY set in its image header.

Remarks

Highest-level drivers can call **PsSetCreateProcessNotifyRoutineEx** to register a PCREATE_PROCESS_NOTIFY_ROUTINE_EX routine. An installable file system (IFS) or highest-level system-profiling driver might register a process-creation callback routine to track which processes are created and deleted against the driver's internal state across the system.

A driver must remove any callback routines that it registers before it unloads. You can remove the callback routine by calling **PsSetCreateProcessNotifyRoutineEx** with *Remove* set to **TRUE**.

The operating system calls the driver's process-notify routine at PASSIVE_LEVEL inside a critical region with normal kernel APCs disabled. When a process is created, the process-notify routine runs in the context of the thread that created the new process. When a process is deleted, the process-notify routine runs in the context of the last thread to exit from the process.

Requirements

Minimum supported client	Available starting with Windows Vista with SP1 and Windows Server 2008.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

PS_CREATE_NOTIFY_INFO

PsSetCreateProcessNotifyRoutine

PsSetCreateProcessNotifyRoutineEx2 function

1/25/2019 • 2 minutes to read • Edit Online

The **PsSetCreateProcessNotifyRoutineEx2** routine registers or removes a callback routine that notifies the caller when a process is created or deleted.

Syntax

```
NTSTATUS PsSetCreateProcessNotifyRoutineEx2(
  PSCREATEPROCESSNOTIFYTYPE NotifyType,
  PVOID                     NotifyInformation,
  BOOLEAN                   Remove
);
```

Parameters

`NotifyType`

A PSCREATEPROCESSNOTIFYTYPE-type value that indicates the type of process notification.

`NotifyInformation`

The address of the notification information for the specified type of process notification. If *NotifyType* is **PsCreateProcessNotifySubsystems**, *NotifyInformation* is a PCREATE_PROCESS_NOTIFY_ROUTINE_EX that specifies the entry point of the caller-supplied process-creation callback.

`Remove`

A Boolean value that specifies whether **PsSetCreateProcessNotifyRoutineEx2** will add or remove a specified routine from the list of callback routines. If this parameter is **TRUE**, the specified routine is removed from the list of callback routines. If this parameter is **FALSE**, the specified routine is added to the list of callback routines. If *Remove* is **TRUE**, the system also waits for all in-flight callback routines to complete before returning.

Return Value

PsSetCreateProcessNotifyRoutineEx2 returns one of the following NTSTATUS values:

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	The specified routine is now registered with the operating system. The operating system calls this routine whenever a new process is created.

STATUS_INVALID_PARAMETER	The specified routine was already registered, or the operating system has reached its limit for registering process-creation callback routines. *NotifyType* is not **PsCreateProcessNotifySubsystems**.
STATUS_ACCESS_DISENIED	The image that contains the callback routine pointer did not have IMAGE_DLLCHARACTERISTICS_FORCE_INTEGRITY set in its image header.

Remarks

Drivers can call **PsSetCreateProcessNotifyRoutineEx2** to register their process-creation notify routines.

After a driver-supplied routine is registered, it is called with the unique ID (indicated by *ProcessId*) of the created or deleted process. The *ParentId* identifies the parent process of the new process (this is the parent used for priority, affinity, quota, token, and handle inheritance, among others) if it was created with the inherit handles option. If it was created without the inherit handle options, then the parent process ID is NULL.

If the *Create* value is TRUE, the subsystem process was created; FALSE indicates the process was deleted.

When the process is created, the callback function is invoked just after the first thread in the process has been created. Conversely, for deletion, the function is invoked after the last thread in the process has terminated and the address space is about to be deleted. It is possible that the callback is only invoked for deletion without getting a creation call in cases where the process was created and deleted without a thread ever being created.

A driver must remove any callback function that it registers before it unloads. You can remove the callback by calling **PsSetCreateProcessNotifyRoutineEx2** with *Remove* = **TRUE**.

Requirements

Minimum supported client	Windows 10, version 1703
Minimum supported server	Windows Server 2016
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

PCREATE_PROCESS_NOTIFY_ROUTINE_EX

PsSetCreateProcessNotifyRoutine

PsSetCreateProcessNotifyRoutineEx

PsSetCreateThreadNotifyRoutine function

1/25/2019 • 2 minutes to read • Edit Online

The **PsSetCreateThreadNotifyRoutine** routine registers a driver-supplied callback that is subsequently notified when a new thread is created and when such a thread is deleted.

Syntax

```
NTSTATUS PsSetCreateThreadNotifyRoutine(
  PCREATE_THREAD_NOTIFY_ROUTINE NotifyRoutine
);
```

Parameters

`NotifyRoutine`

A pointer to the driver's implementation of PCREATE_THREAD_NOTIFY_ROUTINE routine.

Return Value

PsSetCreateThreadNotifyRoutine either returns STATUS_SUCCESS or it returns STATUS_INSUFFICIENT_RESOURCES if it failed the callback registration.

Remarks

Highest-level drivers can call **PsSetCreateThreadNotifyRoutine** to set up their thread-creation notify routines, declared as follows:

```
VOID
(*PCREATE_THREAD_NOTIFY_ROUTINE) (
    IN HANDLE  ProcessId,
    IN HANDLE  ThreadId,
    IN BOOLEAN  Create
    );
```

For example, an IFS or highest-level system-profiling driver might register such a thread-creation callback to track the system-wide creation and deletion of threads against the driver's internal state.

A driver must remove any callbacks it registers before it unloads. You can remove the callback by calling the PsRemoveCreateThreadNotifyRoutine routine.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	IrqlPsPassive, PowerIrpDDis, HwStorPortProhibitedDDIs

PsIsSystemThread

PsRemoveCreateThreadNotifyRoutine

PsSetCreateProcessNotifyRoutine

PsSetLoadImageNotifyRoutine

PsSetCreateThreadNotifyRoutineEx function

1/25/2019 • 2 minutes to read • Edit Online

The **PsSetCreateThreadNotifyRoutineEx** routine registers a driver-supplied callback that is subsequently notified when a new thread is created and when such a thread is deleted.

Syntax

```
NTSTATUS PsSetCreateThreadNotifyRoutineEx(
  PSCREATETHREADNOTIFYTYPE NotifyType,
  PVOID                   NotifyInformation
);
```

Parameters

`NotifyType`

A PSCREATETHREADNOTIFYTYPE value that indicates the type of thread notification.

`NotifyInformation`

Provides the address of the notification information for the specified type of thread notification.

Return Value

PsSetCreateThreadNotifyRoutineEx either returns STATUS_SUCCESS or it returns STATUS_INSUFFICIENT_RESOURCES if it failed the callback registration.

Remarks

Highest-level drivers can call **PsSetCreateThreadNotifyRoutineEx** to set up their thread-creation notify routines.

For example, an IFS or highest-level system-profiling driver might register such a thread-creation callback to track the system-wide creation and deletion of threads against the driver's internal state.

If *NotifyType* is **PsCreateThreadNotifyNonSystem**, the **PsSetCreateThreadNotifyRoutineEx** routine differs from PsSetCreateThreadNotifyRoutine in the context in which the callback is executed. With **PsSetCreateThreadNotifyRoutine**, the callback is executed on the creator thread. With **PsSetCreateThreadNotifyRoutineEx**, the callback is executed on the newly created thread.

A driver must remove any callback function it registers before it unloads. You can remove the callback by calling the PsRemoveCreateThreadNotifyRoutine routine.

Requirements

Minimum supported client	Available starting with Windows 10.
Target Platform	Universal

Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

PsRemoveCreateThreadNotifyRoutine

PsSetCreateProcessNotifyRoutine

PsSetCreateThreadNotifyRoutine

PsSetLoadImageNotifyRoutine

PsSetLoadImageNotifyRoutine function

1/25/2019 • 2 minutes to read • Edit Online

The **PsSetLoadImageNotifyRoutine** routine registers a driver-supplied callback that is subsequently notified whenever an image is loaded (or mapped into memory).

Syntax

```
NTSTATUS PsSetLoadImageNotifyRoutine(
  PLOAD_IMAGE_NOTIFY_ROUTINE NotifyRoutine
);
```

Parameters

`NotifyRoutine`

A pointer to the caller-implemented PLOAD_IMAGE_NOTIFY_ROUTINE callback routine for load-image notifications.

Return Value

PsSetLoadImageNotifyRoutine either returns STATUS_SUCCESS or it returns STATUS_INSUFFICIENT_RESOURCES if it failed the callback registration.

Remarks

Highest-level system-profiling drivers can call **PsSetLoadImageNotifyRoutine** to set up their load-image notify routines (see PLOAD_IMAGE_NOTIFY_ROUTINE).

The maximum number of drivers that can be simultaneously registered to receive load-image notifications is eight. If the maximum number of load-image notify routines is already registered when a driver calls **PsSetLoadImageNotifyRoutine** to try to register an additional notify routine, **PsSetLoadImageNotifyRoutine** fails and returns STATUS_INSUFFICIENT_RESOURCES.

Notes

- An update for Windows 8.1 increases the maximum number of drivers registered to receive load-image notifications from eight to 64. This update is installed as part of a cumulative update that is available through Windows Update starting on April 8, 2014. In addition, this cumulative update is available at https://support.microsoft.com/kb/2919355.
- Users of Windows 7 with Service Pack 1 (SP1) can install a hotfix to increase the maximum number of drivers registered to receive load-image notifications from eight to 64. This hotfix is available at https://support.microsoft.com/kb/2922790.

A driver must remove any callbacks it registers before it unloads. You can remove the callback by calling the PsRemoveLoadImageNotifyRoutine routine.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	IrqlPsPassive, PowerIrpDDis, HwStorPortProhibitedDDIs

PsSetCreateProcessNotifyRoutine

PsSetCreateThreadNotifyRoutine

PsSetLoadImageNotifyRoutineEx function

1/25/2019 • 2 minutes to read • Edit Online

The **PsSetLoadImageNotifyRoutineEx** routine registers a driver-supplied callback that is subsequently notified whenever an image is loaded (or mapped into memory).

Syntax

```
NTSTATUS PsSetLoadImageNotifyRoutineEx(
  PLOAD_IMAGE_NOTIFY_ROUTINE NotifyRoutine,
  ULONG_PTR                  Flags
);
```

Parameters

`NotifyRoutine`

A pointer to the caller-implemented PLOAD_IMAGE_NOTIFY_ROUTINE callback routine for load-image notifications.

`Flags`

Supplies a bitmask of flags that control the callback function. Here are the possible values:

- PS_IMAGE_NOTIFY_CONFLICTING_ARCHITECTURE indicates that the callback routine should be invoked for all potentially executable images, including images that have a different architecture from the native architecture of the operating system.

Return Value

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The callback was successfully registered.
STATUS_INVALID_PARAMETER_2	Invalid flag was supplied in *Flags*.

STA TUS _IN SUF FICI ENT _RE SO URC ES	The routine failed allocate a callback block due to lack of resources.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode)
IRQL	PASSIVE_LEVEL

PsStartSiloMonitor function

1/25/2019 • 2 minutes to read • Edit Online

This routine tries to start the server silo monitor.

Syntax

```
NTSTATUS PsStartSiloMonitor(
  PSILO_MONITOR Monitor
);
```

Parameters

`Monitor`

A pointer to the silo monitor.

Return Value

The following NT status codes are returned.

RETURN CODE	DESCRIPTION
STATUS_ABORTED	The monitor was not able to start.
STATUS_NOT_SUPPORTED	The monitor does not allow existing silos and one was found in the system.
STATUS_SUCCESS	The operation completed successfully.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsTerminateServerSilo function

1/25/2019 • 2 minutes to read • Edit Online

This routine terminates the specified silo.

Syntax

```
void PsTerminateServerSilo(
  PESILO   ServerSilo,
  NTSTATUS ExitStatus
);
```

Parameters

`ServerSilo`

A pointer to the silo being terminated.

`ExitStatus`

The exit status for the silo.

Return Value

This routine does not return a value.

Remarks

This routine can be called within or from outside a silo context. Note that this is different from a BugCheck; this routine will return to the caller.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

PsUnregisterSiloMonitor function

1/25/2019 • 2 minutes to read • Edit Online

This routine unregisters a server silo monitor.

Syntax

```
void PsUnregisterSiloMonitor(
  PSILO_MONITOR Monitor
);
```

Parameters

`Monitor`

The server silo monitor to unregister.

Return Value

This routine does not return a value.

Remarks

The monitor will not receive further notifications after this routine completes.

If the monitor allocated a silo context slot, this routine will not complete until all silo contexts have been removed from slot.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

RTL_RUN_ONCE_INIT_FN callback function

1/25/2019 • 2 minutes to read • Edit Online

The *RunOnceInitialization* routine performs a one-time initialization operation.

Syntax

```
RTL_RUN_ONCE_INIT_FN RtlRunOnceInitFn;

ULONG RtlRunOnceInitFn(
  PRTL_RUN_ONCE RunOnce,
  PVOID Context,
  PVOID *Parameter
)
{...}
```

Parameters

`RunOnce`

A pointer to the RTL_RUN_ONCE one-time initialization structure that the driver previously passed as a parameter to the RtlRunOnceExecuteOnce routine that called this *RunOnceInitialization* routine.

`Context`

A pointer to a PVOID variable to which the routine writes the initialization data.

`Parameter`

The *Parameter* value that the driver passed to the **RtlRunOnceExecuteOnce** routine that called this *RunOnceInitialization* routine.

Return Value

The *RunOnceInitialization* routine returns a nonzero value to indicate success, and returns zero to indicate failure.

Remarks

A driver-implemented *RunOnceInitialization* routine performs driver-specific initialization and then writes the initialization data to the memory location that the *Context* parameter points to. Drivers use the **RtlRunOnceExecuteOnce** routine to make a one-time call to a *RunOnceInitialization* routine. The operating system guarantees that the *RunOnceInitialization* routine is not called twice for the same value of the *RunOnce* parameter.

A small number of low-order bits in the location pointed to by the *Context* parameter are reserved for use by the operating system. Your driver's *RunOnceInitialization* routine should set these reserved bits to zero in the output value that it writes to **Context*. The RTL_RUN_ONCE_CTX_RESERVED_BITS constant defined in Ntddk.h specifies the number of low-order bits that are reserved. Currently, RTL_RUN_ONCE_CTX_RESERVED_BITS is defined to be two, which means that the driver must set the two least significant bits of the PVOID value pointed to by *Context* to zero.

Examples

To define a *RunOnceInitialization* callback routine, you must first provide a function declaration that identifies the

type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *RunOnceInitialization* callback routine that is named `MyRunOnceInitialization`, use the RTL_RUN_ONCE_INIT_FN type as shown in this code example:

```
RTL_RUN_ONCE_INIT_FN MyRunOnceInitialization;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
ULONG
  MyRunOnceInitialization(
    PRTL_RUN_ONCE  RunOnce,
    PVOID  Parameter,
    PVOID  *Context
    )
  {
      // Function body
  }
```

The RTL_RUN_ONCE_INIT_FN function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the RTL_RUN_ONCE_INIT_FN function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Drivers can implement the RunOnceInitialization routine only on Windows Vista and later versions of Windows.
Target Platform	Desktop
Header	ntddk.h (include Ntddk.h, Ntifs.h)
IRQL	Called at IRQL <= APC_LEVEL.

RtlCharToInteger function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlCharToInteger** routine converts a single-byte character string to an integer value in the specified base.

Syntax

```
NTSYSAPI NTSTATUS RtlCharToInteger(
  PCSZ   String,
  ULONG  Base,
  PULONG Value
);
```

Parameters

`String`

Pointer to a null-terminated, single-byte character string.

`Base`

Specifies decimal, binary, octal, or hexadecimal base. If this parameter is not given, the routine will look for 0x, 0o, and 0b prefixes in the input string to determine if the base should be decimal (default), binary, octal, or hexadecimal.

`Value`

Pointer to a location to which the converted value is returned.

Return Value

RtlCharToInteger returns STATUS_SUCCESS if the given character string is converted. Otherwise, it can return STATUS_INVALID_PARAMETER.

Remarks

RtlCharToInteger converts ANSI alphanumeric characters.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

RtlIntegerToUnicodeString

RtlCompareString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlCompareString** routine compares two counted strings.

Syntax

```
NTSYSAPI LONG RtlCompareString(
  const STRING *String1,
  const STRING *String2,
  BOOLEAN      CaseInSensitive
);
```

Parameters

`String1`

Pointer to the first string.

`String2`

Pointer to the second string.

`CaseInSensitive`

If **TRUE**, case should be ignored when doing the comparison.

Return Value

RtlCompareString returns a signed value that gives the results of the comparison:

RETURN CODE	DESCRIPTION
Zero	*String1* equals *String2*.
< Zero	*String1* is less than *String2*.
> Zero	*String1* is greater than *String2*.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)

RtlConvertLongToLuid function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlConvertLongToLuid** routine converts a long integer to a locally unique identifier (LUID), which is used by the system to represent a security privilege.

Syntax

```
LUID NTAPI_INLINE RtlConvertLongToLuid(
  LONG Long
);
```

Parameters

`Long`

Specifies the long integer to convert.

Return Value

RtlConvertLongToLuid returns the converted LUID.

Remarks

RtlConvertLongToLuid is used to convert a system-defined privilege value to the locally unique identifier (LUID) used by the system to represent that privilege. Drivers typically pass a LUID to **SeSinglePrivilegeCheck**, which is usually called by network transport drivers.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	ntddk.h (include Ntddk.h, Ntifs.h)
IRQL	Any level

SeSinglePrivilegeCheck

RtlConvertUlongToLuid function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlConvertUlongToLuid** routine converts an unsigned long integer to a locally unique identifier (LUID), which is used by the system to represent a security privilege.

Syntax

```
LUID NTAPI_INLINE RtlConvertUlongToLuid(
  ULONG Ulong
);
```

Parameters

`Ulong`

Specifies the unsigned long integer to convert.

Return Value

RtlConvertUlongToLuid returns the converted LUID.

Remarks

RtlConvertUlongToLuid is used to convert a system-defined privilege value, passed as a ULONG, to a locally unique identifier (LUID) used by the system to represent that privilege. Drivers typically pass a LUID to **SeSinglePrivilegeCheck**.

Requirements

RtlCopyString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlCopyString** routine copies a source string to a destination string.

Syntax

```
NTSYSAPI VOID RtlCopyString(
  PSTRING      DestinationString,
  const STRING *SourceString
);
```

Parameters

`DestinationString`

A pointer to the destination string buffer.

`SourceString`

A pointer to the source string buffer.

Return Value

None

Remarks

The*DestinationString***Length** is set to zero if no source string is supplied. The **MaximumLength** and **Buffer** members of the *DestinationString* are not modified by this routine.

The number of bytes copied from the *SourceString* is either the length of *SourceString* or the maximum length of *DestinationString*, whichever is smaller.

The *DestinationString* and *SourceString* buffers must be resident if the caller is running at IRQL >= DISPATCH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IRQL	Any level (See Remarks section)

RtlEqualString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlEqualString** routine compares two counted strings to determine whether they are equal.

Syntax

```
NTSYSAPI BOOLEAN RtlEqualString(
  const STRING *String1,
  const STRING *String2,
  BOOLEAN      CaseInSensitive
);
```

Parameters

`String1`

Pointer to the first string.

`String2`

Pointer to the second string.

`CaseInSensitive`

If **TRUE**, case should be ignored when doing the comparison.

Return Value

RtlEqualString returns **TRUE** if the two strings are equal, otherwise it returns **FALSE**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)

RtlExtendCorrelationVector function

1/25/2019 • 2 minutes to read • Edit Online

This routine extends the supplied correlation vector. For a correlation vector of the form X.i, the extended value is X.i.0.

Syntax

```
NTSYSAPI NTSTATUS RtlExtendCorrelationVector(
  PCORRELATION_VECTOR CorrelationVector
);
```

Parameters

`CorrelationVector`

A pointer to a CORRELATION_VECTOR structure that represents the correlation vector to be extended.

Return Value

Returns an NTSTATUS value that indicates the success of failure of the operation.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The correlation vector was successfully incremented.
STATUS_INVALID_PARAMETER	Extending the correlation vector resulted in a buffer overflow because as the extended value is no longer a valid correlation vector.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016

Target Platform	Windows
Header	ntddk.h
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode)
IRQL	PASSIVE_LEVEL

RtlGetEnabledExtendedFeatures function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlGetEnabledExtendedFeatures** routine returns a mask of extended processor features that are enabled by the system.

Syntax

```
NTSYSAPI ULONG64 RtlGetEnabledExtendedFeatures(
  ULONG64 FeatureMask
);
```

Parameters

`FeatureMask`

A 64-bit feature mask. This parameter indicates a set of extended processor features for which the caller requests information about whether the features are enabled. If a mask bit is one, the caller requests information about the feature that corresponds to this mask bit. The caller sets all other mask bits to zero. Set this parameter to (ULONG64)(-1) to get the mask of all enabled features. To determine whether a particular set of features is enabled, set this parameter to the bitwise OR of one or more of the following **XSTATE_MASK_*XXX*** flag bits:

VALUE	MEANING
XSTATE_MASK_LEGACY_FLOATING_POINT	The floating-point extension (x87/MMX).
XSTATE_MASK_LEGACY_SSE	The streaming SIMD extension (SSE).

XST ATE _M ASK _LE GA CY	Both the x87/MMX and SSE extensions.
XST ATE _M ASK _GS SE	The Intel Sandy Bridge (formerly Gesher) SSE extension.

Return Value

RtlGetEnabledExtendedFeatures returns a 64-bitmask of enabled extended processor features. The routine calculates this mask as the intersection (bitwise AND) between all enabled features and the value of the *FeatureMask* parameter. For more information about the features that are indicated by this return value, see XSTATE_MASK_XXX.

RtlGetEnabledExtendedFeatures returns 0 if the XSAVE and XRSTOR instructions are disabled by the system. This happens even if the system supports XSTATE_MASK_LEGACY_FLOATING_POINT and XSTATE_MASK_LEGACY_SSE features. Use **ExIsProcessorFeaturePresent** or CPUID to determine the availability of x87, MMX, and SSE processor features on x86 or x64 systems.

Remarks

Another routine, ExIsProcessorFeaturePresent, indicates whether an extended processor feature is available. Unlike **RtlGetEnabledExtendedFeatures**, however, it does not indicate whether the operating system has enabled the feature for use by kernel-mode drivers.

Requirements

Minimum supported client	Available in Windows 7 and later versions of the Windows operating system.
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Ntdll.lib (user mode); NtosKrnl.lib (kernel mode); OneCoreUAP.lib on Windows 10
DLL	NtDll.dll (user mode); NtosKrnl.exe (kernel mode)
IRQL	PASSIVE_LEVEL

RtlIncrementCorrelationVector function

1/25/2019 • 2 minutes to read • Edit Online

Increments the specified correlation vector. For a correlation vector of the form X.i, the incremented value is be X.(i+1).

Syntax

```
NTSYSAPI NTSTATUS RtlIncrementCorrelationVector(
  PCORRELATION_VECTOR CorrelationVector
);
```

Parameters

`CorrelationVector`

A pointer to a CORRELATION_VECTOR structure that represents the correlation vector to be incremented.

Return Value

Returns an NTSTATUS value that indicates the success of failure of the operation.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The correlation vector was successfully incremented.
STATUS_BUFFER_OVERFLOW	Incrementing the correlation vector resulted in a buffer overflow because as the incremented value is no longer a valid correlation vector.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Target Platform	Windows

IRQL	PASSIVE_LEVEL

RtlInitializeCorrelationVector function

1/25/2019 • 2 minutes to read • Edit Online

Initializes the specified correlation vector with the supplied GUID.

Syntax

```
NTSYSAPI NTSTATUS RtlInitializeCorrelationVector(
  PCORRELATION_VECTOR CorrelationVector,
  int                 Version,
  const GUID          *Guid
);
```

Parameters

`CorrelationVector`

A pointer to a CORRELATION_VECTOR structure that represents the correlation vector to be initialized.

`Version`

The version of the correlation vector. Possible values are:

- RTL_CORRELATION_VECTOR_VERSION_1
- RTL_CORRELATION_VECTOR_VERSION_2
- RTL_CORRELATION_VECTOR_VERSION_CURRENT

`Guid`

The GUID to initialize the correlation vector. The first 22 bytes of the correlation vector are a base64 representation of the GUID. This value must not be NULL.

Return Value

Returns an NTSTATUS value that indicates the success of failure of the operation.

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	The correlation vector was successfully initialized.

STA TUS _IN VAL ID_ PAR AM ETE R	The supplied GUID is null.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Target Platform	Windows

RtlMapGenericMask function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlMapGenericMask** routine determines the nongeneric access rights specified by an ACCESS_MASK.

Syntax

```
NTSYSAPI VOID RtlMapGenericMask(
  PACCESS_MASK     AccessMask,
  PGENERIC_MAPPING GenericMapping
);
```

Parameters

`AccessMask`

Pointer to an ACCESS_MASK variable. The routine updates this to contain only those access rights that are not also granted by any GENERIC_*XXX* access rights originally specified the variable. The routine also clears any GENERIC_*XXX* bits that are set.

`GenericMapping`

Pointer to a GENERIC_MAPPING structure that describes the specific access rights that correspond to each generic access right.

Return Value

None

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

RtlPrefixUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlPrefixUnicodeString** routine compares two Unicode strings to determine whether one string is a prefix of the other.

Syntax

```
NTSYSAPI BOOLEAN RtlPrefixUnicodeString(
  PCUNICODE_STRING String1,
  PCUNICODE_STRING String2,
  BOOLEAN          CaseInSensitive
);
```

Parameters

`String1`

Pointer to the first string, which might be a prefix of the buffered Unicode string at *String2*.

`String2`

Pointer to the second string.

`CaseInSensitive`

If **TRUE**, case should be ignored when doing the comparison.

Return Value

RtlPrefixUnicodeString returns **TRUE** if *String1* is a prefix of *String2*.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

RtlCompareUnicodeString

RtlQueryRegistryValueWithFallback function

1/25/2019 • 2 minutes to read • Edit Online

Retrieves a value entry for a registry key by using, a primary handle; if not found, uses the fallback handle.

Syntax

```
NTSYSAPI NTSTATUS RtlQueryRegistryValueWithFallback(
  HANDLE          PrimaryHandle,
  HANDLE          FallbackHandle,
  PUNICODE_STRING ValueName,
  ULONG           ValueLength,
  PULONG          ValueType,
  PVOID           ValueData,
  PULONG          ResultLength
);
```

Parameters

`PrimaryHandle`

[in] The handle to the key that is first used to query the value entries. This handle is created by a successful call to **ZwCreateKey** or **ZwOpenKey**.

`FallbackHandle`

[in] The handle to use for querying the key if value is not found using the handle specified by *PrimaryHandle*.

`ValueName`

[in] A pointer to string that contains the name of the value for which to retrieve data.

`ValueLength`

[in] Specifies the size, in bytes, of the *ValueName* string.

`ValueType`

[Out] A pointer to a ULONG variable that receives the the type of the value being queried.

`ValueData`

[out] A pointer to a buffer that receives the value data.

`ResultLength`

[out] A pointer to a variable that receives the value data size, in bytes. If the return value is STATUS_SUCCESS, indicates the number of bytes written to the *ValueData* buffer. If the call returns STATUS_BUFFER_OVERFLOW, indicates the number of bytes required. Callers can use that value to determine the size of *ValueData* buffer required to hold the data information.

Return Value

Returns STATUS_SUCCESS on success, or the appropriate error code on failure.

Requirements

Minimum supported client	Windows 10, version 1809
Header	ntddk.h (include wdm.h)
Library	NtosKrnl.lib
IRQL	PASSIVE_LEVEL

Using the Registry in a Driver

RtlRunOnceBeginInitialize function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlRunOnceBeginInitialize** routine begins a one-time initialization.

Syntax

```
NTSYSAPI NTSTATUS RtlRunOnceBeginInitialize(
  PRTL_RUN_ONCE RunOnce,
  ULONG         Flags,
  PVOID         *Context
);
```

Parameters

`RunOnce`

Pointer to the RTL_RUN_ONCE one-time initialization structure.

`Flags`

Drivers can optionally specify one or more of the following flags:

RTL_RUN_ONCE_ASYNC

Perform initialization asynchronously. The driver can perform multiple completion attempts in parallel. If this flag is used, subsequent calls to this routine will fail unless this flag is also specified.

RTL_RUN_ONCE_CHECK_ONLY

Do not begin initialization, but check to determine if initialization has already occurred. If **RtlRunOnceBeginInitialize** returns STATUS_SUCCESS, the initialization succeeded, and **Context* contains the initialized data.

`Context`

Specifies a pointer to a PVOID variable that receives the initialized data. The value of **Context* is valid only when the routine returns STATUS_SUCCESS.

Return Value

RtlRunOnceBeginInitialize returns one of the following NTSTATUS values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The one-time initialization has already completed. The initialized data is stored in the memory location that *Context* points to.

STA **TUS** **_PE** **NDI** **NG**	The caller has successfully begun one-time initialization. The caller now performs the driver-specific initialization steps and then calls RtlRunOnceComplete to complete the initialization.

Remarks

Drivers can alternatively perform one-time initialization by calling RtlRunOnceExecuteOnce and supplying a RunOnceInitialization routine.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

See Also

RtlRunOnceComplete

RtlRunOnceExecuteOnce

RtlRunOnceInitialize

RunOnceInitialization

RtlRunOnceComplete function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlRunOnceComplete** routine completes the one-time initialization began by RtlRunOnceBeginInitialize.

Syntax

```
NTSYSAPI NTSTATUS RtlRunOnceComplete(
  PRTL_RUN_ONCE RunOnce,
  ULONG         Flags,
  PVOID         Context
);
```

Parameters

`RunOnce`

Pointer to the RTL_RUN_ONCE one-time initialization structure.

`Flags`

Drivers can optionally specify one or more of the following flags:

RTL_RUN_ONCE_ASYNC

Operate in asynchronous mode. This mode enables multiple completion attempts to execute in parallel. If this flag is used, subsequent calls to the **RtlRunOnceComplete** routine will fail unless this flag is also specified.

RTL_RUN_ONCE_INIT_FAILED

The initialization attempt failed.

`Context`

Specifies the initialized data.

Return Value

RtlRunOnceComplete returns one of the following NTSTATUS values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The operation completed successfully.

STA TUS _UN SUC CES SFU L	The operation could not be completed. If the caller specified RTL_RUN_ONCE_ASYNC in the *Flags* parameter, this value can indicate that another thread completed the initialization.

Remarks

If **RtlRunOnceComplete** returns STATUS_SUCCESS, any subsequent call to RtlRunOnceBeginInitialize for the same RTL_RUN_ONCE structure supplies *Context* as the initialized data.

If the caller specified RTL_RUN_ONCE_ASYNC in the *Flags* parameter and **RtlRunOnceComplete** returns any value other than STATUS_SUCCESS, the caller must clean up any initialization that it attempted.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RunOnceInitialization

RtlRunOnceExecuteOnce function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlRunOnceExecuteOnce** performs a one-time initialization.

Syntax

```
NTSYSAPI NTSTATUS RtlRunOnceExecuteOnce(
  PRTL_RUN_ONCE         RunOnce,
  PRTL_RUN_ONCE_INIT_FN InitFn,
  PVOID                 Context,
  PVOID                 *Parameter
);
```

Parameters

`RunOnce`

A pointer to the RTL_RUN_ONCE one-time initialization structure.

`InitFn`

A pointer to a RunOnceInitialization routine.

`Context`

A pointer to a PVOID variable that receives the initialized data.

`Parameter`

The value to pass as the *Parameter* parameter to the *RunOnceInitialization* routine.

Return Value

RtlRunOnceExecuteOnce returns STATUS_SUCCESS if the operation succeeds, or the appropriate NTSTATUS error code if the operation fails.

Remarks

For the first call to **RtlRunOnceExecuteOnce** for a particular RTL_RUN_ONCE structure, **RtlRunOnceExecuteOnce** calls the RunOnceInitialization routine to initialize the data. Every subsequent call to **RtlRunOnceExecuteOnce** for that structure supplies the same initialized data. The *RunOnceInitialization* routine will not be called twice for the same **RTL_RUN_ONCE** structure.

RtlRunOnceExecuteOnce runs with normal kernel APCs disabled. The routine should not be called within a special kernel APC unless all calls occur at APC_LEVEL.

Requirements

Minimum supported client	Available starting with Windows Vista.

Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL (See Remarks section.)"

See Also

RtlRunOnceBeginInitialize

RtlRunOnceComplete

RtlRunOnceInitialize

RunOnceInitialization

RtlRunOnceInitialize function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlRunOnceInitialize** routine initializes a RTL_RUN_ONCE structure.

Syntax

```
NTSYSAPI VOID RtlRunOnceInitialize(
  PRTL_RUN_ONCE RunOnce
);
```

Parameters

`RunOnce`

Pointer to the **RTL_RUN_ONCE** one-time initialization structure.

Return Value

None

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

RunOnceInitialization

RtlUpcaseUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUpcaseUnicodeString** routine converts a copy of the source string to uppercase and writes the converted string in the destination buffer.

Syntax

```
NTSYSAPI NTSTATUS RtlUpcaseUnicodeString(
  PUNICODE_STRING  DestinationString,
  PCUNICODE_STRING SourceString,
  BOOLEAN          AllocateDestinationString
);
```

Parameters

`DestinationString`

Pointer to a caller-allocated buffer for the converted Unicode string.

`SourceString`

Pointer to the source Unicode string to be converted to uppercase.

`AllocateDestinationString`

Specifies if **RtlUpcaseUnicodeString** is to allocate the buffer space for the *DestinationString*. If it does, the buffer must be deallocated by calling **RtlFreeUnicodeString**.

Return Value

If the operation succeeds, **RtlUpcaseUnicodeString** returns STATUS_SUCCESS. Otherwise, no storage was allocated, and no conversion was done.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)
IRQL	"<= APC_LEVEL"

See Also

RtlFreeUnicodeString

RtlUpcaseUnicodeChar

RtlUpperChar function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUpperChar** routine converts the specified character to uppercase.

Syntax

```
NTSYSAPI CHAR RtlUpperChar(
  CHAR Character
);
```

Parameters

`Character`

Specifies the character to convert.

Return Value

RtlUpperChar returns the uppercase version of the specified character or returns the value specified by the caller for *Character* if the specified character cannot be converted.

Remarks

RtlUpperChar returns the input *Character* unconverted if it is the lead byte of a multibyte character or if the uppercase equivalent of *Character* is a double-byte character. To convert such characters, use **RtlUpcaseUnicodeChar**.

RtlUpperChar is not recommended because the function is designed to work for ASCII range A-Z letters. Instead, use **RtlUpcaseUnicodeChar**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=APC_LEVEL"

See Also

RtlUpcaseUnicodeChar

RtlUpperString

RtlUpperString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUpperString** routine copies the given *SourceString* to the *DestinationString* buffer, converting it to uppercase.

Syntax

```
NTSYSAPI VOID RtlUpperString(
  PSTRING      DestinationString,
  const STRING *SourceString
);
```

Parameters

`DestinationString`

Pointer to the buffer for the converted destination string.

`SourceString`

Pointer to the source string to be converted to uppercase.

Return Value

None

Remarks

The **MaximumLength** and **Buffer** members of *DestinationString* are not modified by this routine.

The number of bytes copied from *SourceString* is either the **Length** of *SourceString* or the **MaximumLength** of *DestinationString*, whichever is smaller.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=APC_LEVEL"

RtlUpperChar

RtlValidateCorrelationVector function

1/25/2019 • 2 minutes to read • Edit Online

Validates the specified correlation vector to check whether it conforms to the Correlation Vector Specification (v2). The function specifically checks if the first 22 bytes are a valid base64 representation of a 16 byte buffer and the remaining characters match the (.\d+)+ regular expression.

Syntax

```
NTSYSAPI NTSTATUS RtlValidateCorrelationVector(
  PCORRELATION_VECTOR Vector
);
```

Parameters

`Vector`

A pointer to a **CORRELATION_VECTOR** structure that represents the correlation vector to be validated.

Return Value

Returns an NTSTATUS value that indicates the success of failure of the operation.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The correlation vector is valid.
STATUS_INVALID_PARAMETER	The supplied correlation vector is invalid.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016

Target Platform	Windows
Header	ntddk.h
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode)
IRQL	PASSIVE_LEVEL

RtlVolumeDeviceToDosName function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlVolumeDeviceToDosName** routine is obsolete for Windows XP and later versions of Windows. Use IoVolumeDeviceToDosName instead.

RtlVolumeDeviceToDosName returns the MS-DOS path for a specified device object that represents a file system volume.

Syntax

```
NTSYSAPI NTSTATUS RtlVolumeDeviceToDosName(
  PVOID           VolumeDeviceObject,
  PUNICODE_STRING DosName
);
```

Parameters

`VolumeDeviceObject`

Pointer to a device object that represents a volume device object created by a storage class driver.

`DosName`

Pointer to a Unicode string containing the MS-DOS path of the volume device object specified by *VolumeDeviceObject*.

Return Value

RtlVolumeDeviceToDosName returns STATUS_SUCCESS or an appropriate error status.

Remarks

The behavior of this routine is identical to that of IoVolumeDeviceToDosName. For more information about how to use this routine, see **IoVolumeDeviceToDosName**.

Drivers that must work on older NT-based operating systems may use this routine. Drivers written for Windows XP and later must use **IoVolumeDeviceToDosName** instead.

Requirements

Minimum supported client	Obsolete for Microsoft Windows XP and later versions of Windows. Use IoVolumeDeviceToDosName instead.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe

SeSinglePrivilegeCheck function

1/25/2019 • 2 minutes to read • Edit Online

The **SeSinglePrivilegeCheck** routine checks for the passed privilege value in the context of the current thread.

Syntax

```
BOOLEAN SeSinglePrivilegeCheck(
  LUID            PrivilegeValue,
  KPROCESSOR_MODE PreviousMode
);
```

Parameters

`PrivilegeValue`

Specifies the LUID value of the privilege being checked.

`PreviousMode`

Specifies the previous execution mode, one of **UserMode** or **KernelMode**.

Return Value

SeSinglePrivilegeCheck returns **TRUE** if the current subject has the required privilege.

Remarks

If *PreviousMode* is **KernelMode**, the privilege check always succeeds. Otherwise, this routine uses the token of the user-mode thread to determine whether the current (user-mode) thread has been granted the given privilege.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

SILO_CONTEXT_CLEANUP_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

This callback is invoked when the context object reaches a reference count of zero.

Syntax

```
SILO_CONTEXT_CLEANUP_CALLBACK SiloContextCleanupCallback;

void SiloContextCleanupCallback(
  PVOID SiloContext
)
{...}
```

Parameters

`SiloContext`

A pointer provided by the user with the call to PsCreateSiloContext.

Return Value

This callback function does not return a value.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

SILO_MONITOR_CREATE_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

This is callback is invoked when a new silo is created.

Syntax

```
SILO_MONITOR_CREATE_CALLBACK SiloMonitorCreateCallback;

NTSTATUS SiloMonitorCreateCallback(
  PESILO Silo
)
{...}
```

Parameters

`Silo`

The silo that was created.

Return Value

The NT code returned by the operation.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

SILO_MONITOR_TERMINATE_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

This callback is invoked when a silo is terminated.

Syntax

```
SILO_MONITOR_TERMINATE_CALLBACK SiloMonitorTerminateCallback;

void SiloMonitorTerminateCallback(
  PESILO Silo
)
{...}
```

Parameters

`Silo`

The silo to be terminated.

Return Value

This callback function does not return a value.

Remarks

The expected behavior is that the component will drop any outstanding silo references. A driver may no longer operate within the namespace of a silo (via PsAttachSiloToCurrentThread) once it has returned from this function.

Requirements

Minimum supported client	Windows 10, version 1607
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	ntddk.h

ZwAllocateLocallyUniqueId function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwAllocateLocallyUniqueId** routine allocates a locally unique identifier (LUID).

Syntax

```
NTSYSAPI NTSTATUS ZwAllocateLocallyUniqueId(
  PLUID Luid
);
```

Parameters

`Luid`

Pointer to a caller-allocated buffer to receive a copy of the source LUID structure. The buffer must be at least **sizeof**(*LUID*).

Return Value

ZwAllocateLocallyUniqueId returns STATUS_SUCCESS if the operation succeeds or the appropriate NTSTATUS value if the operation fails. If the output parameter cannot be written to, the routine returns STATUS_ACCESS_VIOLATION.

Remarks

The allocated LUID is unique to the local system only, and uniqueness is guaranteed only until the system is next restarted.

> **Note** If the call to the **ZwAllocateLocallyUniqueId** function occurs in user mode, you should use the name "**NtAllocateLocallyUniqueId**" instead of "**ZwAllocateLocallyUniqueId**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs, SpNoWait, StorPortStartIo

LUID

Using Nt and Zw Versions of the Native System Services Routines

ZwDeviceIoControlFile function

1/25/2019 • 4 minutes to read • Edit Online

The **ZwDeviceIoControlFile** routine sends a control code directly to a specified device driver, causing the corresponding driver to perform the specified operation.

Syntax

```
NTSYSAPI NTSTATUS ZwDeviceIoControlFile(
  HANDLE           FileHandle,
  HANDLE           Event,
  PIO_APC_ROUTINE  ApcRoutine,
  PVOID            ApcContext,
  PIO_STATUS_BLOCK IoStatusBlock,
  ULONG            IoControlCode,
  PVOID            InputBuffer,
  ULONG            InputBufferLength,
  PVOID            OutputBuffer,
  ULONG            OutputBufferLength
);
```

Parameters

`FileHandle`

Handle returned by ZwCreateFile or ZwOpenFile for the file object representing the device to which the control information should be given or from which information should be returned. The file object must have been opened for asynchronous I/O if the caller specifies an *Event*, *ApcRoutine*, and an APC context (in *ApcContext*), or a completion context (in *ApcContext*). For I/O to an underlying mass-storage device, the file object must have been opened for Direct Access to Storage Device (DASD) access.

`Event`

Handle for a caller-created event. If this parameter is supplied, the caller will be put into a wait state until the requested operation is completed and the given event is set to the Signaled state. This parameter is optional and can be **NULL**. It must be **NULL** if the caller will wait for the *FileHandle* to be set to the Signaled state.

`ApcRoutine`

Address of an optional, caller-supplied APC routine to be called when the requested operation completes. This parameter can be **NULL**. It must be **NULL** if there is an I/O completion object associated with the file object.

`ApcContext`

Pointer to a caller-determined context area. This parameter value is used as the APC context if the caller supplies an APC, or is used as the completion context if an I/O completion object has been associated with the file object. When the operation completes, either the APC context is passed to the APC, if one was specified, or the completion context is included as part of the completion message that the I/O Manager posts to the associated I/O completion object.

This parameter is optional and can be **NULL**. It must be **NULL** if *ApcRoutine* is **NULL** and there is no I/O completion object associated with the file object.

`IoStatusBlock`

Pointer to a variable that receives the final completion status and information about the operation. For successful calls that return data, the number of bytes written to the *OutputBuffer* is returned in the **Information** member.

`IoControlCode`

IOCTL_*XXX* code that indicates which device I/O control operation is to be carried out on, usually by the underlying device driver. The value of this parameter determines the format and required length of the *InputBuffer* and *OutputBuffer*, as well as which of the following parameter pairs are required. For detailed information about the system-defined, device-type-specific IOCTL_*XXX* codes, see the device technology-specific section of the Microsoft Windows Driver Kit (WDK) documentation and Device Input and Output Control Codes in the Microsoft Windows SDK documentation.

`InputBuffer`

Pointer to a caller-allocated input buffer that contains device-specific information to be given to the target device. If *IoControlCode* specifies an operation that does not require input data, this pointer can be **NULL**.

`InputBufferLength`

Size, in bytes, of the buffer at *InputBuffer*. If *InputBuffer* is **NULL**, set *InputBufferLength* to zero.

`OutputBuffer`

Pointer to a caller-allocated output buffer in which information is returned from the target device. If *IoControlCode* specifies an operation that does not produce output data, this pointer can be **NULL**.

`OutputBufferLength`

Size, in bytes, of the buffer at *OutputBuffer*. If *OutputBuffer* is **NULL**, set *OutputBufferLength* to zero.

Return Value

ZwDeviceIoControlFile returns STATUS_SUCCESS if the underlying driver(s) successfully carried out the requested operation. Otherwise, the return value can be an error status code propagated from an underlying driver. Possible error status codes include the following:

Remarks

ZwDeviceIoControlFile provides a consistent view of the input and output data to the system and to kernel-mode drivers, while providing applications and underlying drivers with a device-dependent method of specifying a communications interface.

For more information about system-defined IOCTL_*XXX* codes, and about defining driver-specific IOCTL_*XXX* or FSCTL_*XXX* values, see Using I/O Control Codes in the *Kernel Mode Architecture Guide* and Device Input and Output Control Codes in the Microsoft Windows SDK documentation.

If the caller opened the file for asynchronous I/O (with neither FILE_SYNCHRONOUS_*XXX* create/open option set), the specified event, if any, will be set to the signaled state when the device control operation completes. Otherwise, the file object specified by *FileHandle* will be set to the signaled state. If an *ApcRoutine* was specified, it is called with the *ApcContext* and *IoStatusBlock* pointers.

Minifilters should use FltDeviceIoControlFile instead of **ZwDeviceIoControlFile**.

Callers of **ZwDeviceIoControlFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to the **ZwDeviceIoControlFile** function occurs in user mode, you should use the name "**NtDeviceIoControlFile**" instead of "**ZwDeviceIoControlFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntddk.h (include Ntifs.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL (see Remarks section)
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

ZwOpenProcess function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenProcess** routine opens a handle to a process object and sets the access rights to this object.

Syntax

```
NTSYSAPI NTSTATUS ZwOpenProcess(
  PHANDLE            ProcessHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  PCLIENT_ID         ClientId
);
```

Parameters

`ProcessHandle`

A pointer to a variable of type HANDLE. The **ZwOpenProcess** routine writes the process handle to the variable that this parameter points to.

`DesiredAccess`

An ACCESS_MASK value that contains the access rights that the caller has requested to the process object.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the attributes to apply to the process object handle. In Windows Vista and later versions of Windows, the **ObjectName** field of this structure must be set to **NULL**. In Windows Server 2003, Windows XP, and Windows 2000, this field can, as an option, point to an object name. For more information, see the following Remarks section.

`ClientId`

A pointer to a client ID that identifies the thread whose process is to be opened. In Windows Vista and later versions of Windows, this parameter must be a non-**NULL** pointer to a valid client ID. In Windows Server 2003, Windows XP, and Windows 2000, this parameter is optional and can be set to **NULL** if the **OBJECT_ATTRIBUTES** structure that *ObjectAttributes* points to specifies an object name. For more information, see the following Remarks section.

Return Value

ZwOpenProcess returns STATUS_SUCCESS if the call is successful. Possible return values include the following error status codes.

RETURN CODE	DESCRIPTION

STATUS_INVALID_PARAMETER_MIX	In Windows Vista and later versions of Windows, the caller either supplied an object name or failed to supply a client ID. In Windows Server 2003, Windows XP, and Windows 2000, the caller supplied both an object name and a client ID.
STATUS_INVALID_CID	The specified client ID is not valid.
STATUS_INVALID_PARAMETER	The requested access rights are not valid for a process object.
STATUS_ACCESS_DENIED	The requested access rights cannot be granted.

Remarks

In Windows Vista and later versions of Windows, the *ClientId* parameter must point to a client ID that identifies the thread whose process is to be opened. In addition, the **ObjectName** field of the structure pointed to by *ObjectAttributes* must be set to **NULL**.

In Windows Server 2003, Windows XP, and Windows 2000, the caller has the option of supplying either a client ID or an object name (but not both). If the **ObjectName** field of the structure pointed to by *ObjectAttributes* contains a non-**NULL** pointer to an object name, *ClientId* must be **NULL**.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtOpenProcess**" instead of "**ZwOpenProcess**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	ntddk.h (include Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

See Also

ACCESS_MASK

OBJECT_ATTRIBUTES

Using Nt and Zw Versions of the Native System Services Routines

ZwPowerInformation function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwPowerInformation** routine sets or retrieves system power information.

Syntax

```
NTSYSAPI NTSTATUS ZwPowerInformation(
  POWER_INFORMATION_LEVEL InformationLevel,
  PVOID                   InputBuffer,
  ULONG                   InputBufferLength,
  PVOID                   OutputBuffer,
  ULONG                   OutputBufferLength
);
```

Parameters

`InformationLevel`

Specifies the requested information level, which indicates the specific power information to be set or retrieved. Currently, the only supported *POWER_INFORMATION_LEVEL* value is **PlatformInformation**.

VALUE	MEANING
PlatformInformation	Information represents the currently supported power capabilities of the system. Information may change as drivers are installed. For example, the installation of legacy device drivers that do not support power management might modify the capabilities of the system.

`InputBuffer`

Pointer to a caller-allocated input buffer. This parameter must be **NULL**, otherwise **ERROR_INVALID_PARAMETER** is returned.

`InputBufferLength`

Size, in bytes, of the buffer at *InputBuffer*. The parameter must be set to zero.

`OutputBuffer`

A pointer to an output buffer. The data type of this buffer depends on the information level requested in the *InformationLevel* parameter. For the **PlatformInformation** level, the only currently supported value, the *OutputBuffer* parameter is required and should be of the POWER_PLATFORM_INFORMATION type.

`OutputBufferLength`

Size, in bytes, of the output buffer. Depending on the information level requested, the buffer may be variably sized. *PlatformInformation*, the only currently supported value, requires a buffer that is the size of a POWER_PLATFORM_INFORMATION structure.

Return Value

Returns STATUS_SUCCESS if the call is successful. If the call fails, possible error codes include the following:

RETURN CODE	DESCRIPTION
STATUS_BUFFER_TOO_SMALL	The output buffer is of insufficient size to contain the data being returned.
STATUS_INVALID_PARAMETER	The **PlatformInformation** information level, which is the only currently supported value, requires no input buffer and must contain an output buffer. The caller either supplied an input buffer or no output buffer.
STATUS_ACCESS_DENIED	The caller had insufficient access rights to perform the requested action.

Remarks

NtPowerInformation and **ZwPowerInformation** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Examples

This example illustrates a valid function call.

C++

```
POWER_PLATFORM_INFORMATION PlatformInfo = {0};
NTSTATUS Result = NtPowerInformation(PlatformInformation, NULL, 0, &PlatformInfo, sizeof(PlatformInfo));
```

Requirements

Minimum supported client	Windows 8
Minimum supported server	Windows Server 2012
Target Platform	Universal
Header	ntddk.h (include Wdm.h, Ntddk.h, Ntpoapi.h)
Library	Ntoskrnl.lib
DLL	Ntoskrnl.lib
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

POWER_PLATFORM_INFORMATION

Using Nt and Zw Versions of the Native System Services Routines

ZwQueryVolumeInformationFile function

1/25/2019 • 3 minutes to read • Edit Online

The **ZwQueryVolumeInformationFile** routine retrieves information about the volume associated with a given file, directory, storage device, or volume.

Syntax

```
NTSYSAPI NTSTATUS ZwQueryVolumeInformationFile(
  HANDLE               FileHandle,
  PIO_STATUS_BLOCK     IoStatusBlock,
  PVOID                FsInformation,
  ULONG                Length,
  FS_INFORMATION_CLASS FsInformationClass
);
```

Parameters

`FileHandle`

A handle to a file object returned by ZwCreateFile or ZwOpenFile for an open file, directory, storage device, or volume for which volume information is being requested.

`IoStatusBlock`

A pointer to an IO_STATUS_BLOCK structure that receives the final completion status and information about the query operation. For successful calls that return data, the number of bytes written to the *FsInformation* buffer is returned in the structure's **Information** member.

`FsInformation`

A pointer to a caller-allocated buffer that receives the desired information about the volume. The structure of the information returned in the buffer is defined by the *FsInformationClass* parameter.

`Length`

Size in bytes of the buffer pointed to by *FsInformation*. The caller should set this parameter according to the given *FsInformationClass*.

`FsInformationClass`

Type of information to be returned about the volume. Set this member to one of the following FS_INFORMATION_CLASS enumeration values.

VALUE	MEANING
FileFsAttributeInformation	Return a FILE_FS_ATTRIBUTE_INFORMATION structure containing attribute information about the file system responsible for the volume.
FileFsControlInformation	Return a FILE_FS_CONTROL_INFORMATION structure containing file system control information about the volume.

FileFsDeviceInformation	Return a FILE_FS_DEVICE_INFORMATION structure containing device information for the volume.
FileFsDriverPathInformation	Return a FILE_FS_DRIVER_PATH_INFORMATION structure containing information about whether a specified driver is in the I/O path for the volume. The caller must store the name of the driver into the **FILE_FS_DRIVER_PATH_INFORMATION** structure before calling **ZwQueryVolumeInformationFile**.
FileFsFullSizeInformation	Return a FILE_FS_FULL_SIZE_INFORMATION structure containing information about the total amount of space available on the volume.
FileFsObjectIdInformation	Return a FILE_FS_OBJECTID_INFORMATION structure containing file system-specific object ID information for the volume. Note that this is not the same as the (GUID-based) unique volume name assigned by the operating system.
FileFsSizeInformation	Return a FILE_FS_SIZE_INFORMATION structure containing information about the amount of space on the volume that is available to the user associated with the calling thread.
FileFsVolumeInformation	Return a FILE_FS_VOLUME_INFORMATION containing information about the volume such as the volume label, serial number, and creation time.
FileFsSectorSizeInformation	Return a FILE_FS_SECTOR_SIZE_INFORMATION structure that contains information about the physical and logical sector sizes of a volume.

Return Value

ZwQueryVolumeInformationFile returns STATUS_SUCCESS or an appropriate error status.

Remarks

ZwQueryVolumeInformationFile retrieves information about the volume associated with a given file, directory, storage device, or volume.

If the *FileHandle* represents a direct device open, only *FileFsDeviceInformation* can be specified as the value of *FsInformationClass*.

ZwQueryVolumeInformationFile returns zero in any member of a **FILE_*XXX*_INFORMATION** structure that is not supported by the file system.

For information about other file information query routines, see File Objects.

Minifilters should use FltQueryVolumeInformationFile instead of **ZwQueryVolumeInformationFile**.

Callers of **ZwQueryVolumeInformationFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to the **ZwQueryVolumeInformationFile** function occurs in user mode, you should use the name "**NtQueryVolumeInformationFile**" instead of "**ZwQueryVolumeInformationFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the

relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows XP.
Target Platform	Universal
Header	ntddk.h (include Ntifs.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL (see Remarks section)
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

ZwSetInformationThread function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwSetInformationThread** routine sets the priority of a thread.

Syntax

```
NTSYSAPI NTSTATUS ZwSetInformationThread(
  HANDLE          ThreadHandle,
  THREADINFOCLASS ThreadInformationClass,
  PVOID           ThreadInformation,
  ULONG           ThreadInformationLength
);
```

Parameters

`ThreadHandle`

Handle to the thread object. To create a new thread and get a handle to it, call PsCreateSystemThread. To specify the current thread, use the ZwCurrentThread macro.

`ThreadInformationClass`

One of the system-defined values in the THREADINFOCLASS enumeration (see ntddk.h), **ThreadPriority**, **ThreadBasePriority**, **ThreadPagePriority**, or **ThreadPowerThrottlingState**.

`ThreadInformation`

Pointer to a variable that specifies the information to set.

If **ThreadInformationClass** is **ThreadPriority**, this value must be > LOW_PRIORITY and <= HIGH_PRIORITY.

If **ThreadInformationClass** is **ThreadBasePriority**, this value must fall within the system's valid base-priority range and the original priority class for the given thread. That is, if a thread's priority class is variable, that thread's base priority cannot be reset to a real-time priority value, and vice versa.

If **ThreadInformationClass** is **ThreadPagePriority**, this value is a pointer to a **PAGE_PRIORITY_INFORMATION** structure, see ntddk.h. The **PagePriority** member value must be one of these values.

If **ThreadInformationClass** is **ThreadPowerThrottlingState**, this value is a pointer to a POWER_THROTTLING_THREAD_STATE structure, see ntddk.h. The **PagePriority** member value must be one of these values.

VALUE	MEANING

MEMORY_PRIORITY_VERY_LOW 1	Very low memory priority.
MEMORY_PRIORITY_LOW 2	Low memory priority.
MEMORY_PRIORITY_MEDIUM 3	Medium memory priority.
MEMORY_PRIORITY_BELOW_NORMAL 4	Below normal memory priority.
MEMORY_PRIORITY_NORMAL 5	Normal memory priority. This is the default priority for all threads and processes on the system.

`ThreadInformationLength`

The size, in bytes, of **ThreadInformation**.

Return Value

ZwSetInformationThread returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure. Possible error codes include STATUS_INFO_LENGTH_MISMATCH or STATUS_INVALID_PARAMETER.

Remarks

ZwSetInformationThread can be called by higher-level drivers to set the priority of a thread for which they have a handle.

The caller must have THREAD_SET_INFORMATION access rights for the given thread in order to call this routine.

Usually, device and intermediate drivers that set up driver-created threads call KeSetBasePriorityThread or KeSetPriorityThread from their driver-created threads, rather than calling **ZwSetInformationThread**. However, a driver can call **ZwSetInformationThread** to raise the priority of a driver-created thread before that thread runs.

Kernel mode drivers can call the **ZwSetInformationThread** function with **ThreadPagePriority** to specify a thread's page priority.

To help improve system performance, drivers should use the function with **ThreadPagePriority** to lower the page priority of threads that perform background operations or access files and data that are not expected to be accessed again soon. For example, an anti-malware application might lower the priority of threads involved in scanning files.

To determine the page priority for a thread, call ZwQueryInformationThread.

> **Note** If the call to this function occurs in user mode, you should use the name NtSetInformationThread instead of **ZwSetInformationThread**.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

ZwTerminateProcess function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwTerminateProcess** routine terminates a process and all of its threads.

Syntax

```
NTSYSAPI NTSTATUS ZwTerminateProcess(
  HANDLE   ProcessHandle,
  NTSTATUS ExitStatus
);
```

Parameters

`ProcessHandle`

A handle to the process object that represents the process to be terminated.

`ExitStatus`

An NTSTATUS value that the operating system uses as the final status for the process and each of its threads.

Return Value

ZwTerminateProcess returns STATUS_SUCCESS if the operation succeeds. Additional return values include:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a process handle.
STATUS_INVALID_HANDLE	The specified handle is not valid.

STA TUS _AC CES S_D ENI ED	The driver cannot access the specified process object.
STA TUS _PR OCE SS_I S_T ER MIN ATI NG	The specified process is already terminating.

If the caller specifies the current process in the *ProcessHandle* parameter, **ZwTerminateProcess** does not return.

Remarks

To obtain a process handle that a driver can specify for the *ProcessHandle* parameter, the driver can call ZwOpenProcess. The handle must be a *kernel handle*, a handle that can only be accessed in kernel mode. A handle is a kernel handle if it is created with the OBJ_KERNEL_HANDLE flag. For more info see InitializeObjectAttributes.

Drivers must not specify the current process if resources have not been freed from the kernel stack, because the operating system will not unwind the kernel stack for the calling thread.

> **Note** If the call to this function occurs in user mode, you should use the name "NtTerminateProcess" instead of "**ZwTerminateProcess**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

ntddsfio.h header

1/8/2019 • 2 minutes to read • Edit Online

This is the include file that defines all common constants, ioctls and types for Scheduled File I/O (SFIO).

This header is used by kernel. For more information, see:

- Windows kernel ntddsfio.h contains the following programming interfaces:

Enumerations

TITLE	DESCRIPTION
IO_ACCESS_MODE	Defines the types of access mode for Scheduled File I/O (SFIO).
IO_ACCESS_TYPE	Defines the access rights for Scheduled File I/O (SFIO).

IO_ACCESS_MODE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

Defines the types of access mode for Scheduled File I/O (SFIO).

Syntax

```
typedef enum _IO_ACCESS_MODE {
  SequentialAccess,
  RandomAccess
} IO_ACCESS_MODE;
```

Constants

SequentialAccess	Indicates that the input/output will be sent down in a sequential order.
RandomAccess	Indicates that the input/output might not be in a predictable order.

Requirements

Header	ntddsfio.h (include Wdm.h, Ntddsfio.h)

IO_ACCESS_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

Defines the access rights for Scheduled File I/O (SFIO).

Syntax

```
typedef enum _IO_ACCESS_TYPE {
  ReadAccess,
  WriteAccess,
  ModifyAccess
} IO_ACCESS_TYPE;
```

Constants

ReadAccess	Indicates that the input/output will be comprised solely of reads.
WriteAccess	Indicates that the input/output will be comprised solely of writes.
ModifyAccess	Indicates that the input/output will be comprised of reads and writes.

Requirements

Header	ntddsfio.h (include Ntddsfio.h)

ntddsysenv.h header

1/8/2019 • 2 minutes to read • Edit Online

This is the include file that defines all constants and types for accessing the system variable device interface.

- Windows kernel ntddsysenv.h contains the following programming interfaces:

IOCTLs

TITLE	DESCRIPTION
IOCTL_SYSENV_ENUM_VARIABLES	Returns information about system environment variables using SysEnv device.
IOCTL_SYSENV_GET_VARIABLE	Gets the value of the specified system environment variables using SysEnv device.
IOCTL_SYSENV_QUERY_VARIABLE_INFO	Returns information about system environment variables using SysEnv device.
IOCTL_SYSENV_SET_VARIABLE	Sets the value of the specified system environment variables using SysEnv device.

Structures

TITLE	DESCRIPTION
SYSENV_VALUE	Stores the value of a system environment variable using SysEnv device. This structure is used in the IOCTL_SYSENV_GET_VARIABLE request.
SYSENV_VARIABLE	Stores the name a system environment variable using SysEnv device. This structure is used in the IOCTL_SYSENV_GET_VARIABLE request.
SYSENV_VARIABLE_INFO	Stores the information about a system environment variable using SysEnv device. This structure is used in the IOCTL_SYSENV_QUERY_VARIABLE_INFO request.
XVARIABLE_NAME	Stores the name of a system environment variable using SysEnv device. This structure is used in the IOCTL_SYSENV_ENUM_VARIABLES request.
XVARIABLE_NAME_AND_VALUE	Stores the name and value of a system environment variable using SysEnv device. This structure is used in the IOCTL_SYSENV_ENUM_VARIABLES and IOCTL_SYSENV_SET_VARIABLE requests.

SYSENV_VALUE structure

1/30/2019 • 2 minutes to read • Edit Online

Stores the value of a system environment variable using SysEnv device. This structure is used in the IOCTL_SYSENV_GET_VARIABLE request.

Syntax

```
typedef struct _SYSENV_VALUE {
  ULONG Attributes;
  ULONG ValueLength;
  UCHAR ValueData[ANYSIZE_ARRAY];
} SYSENV_VALUE, *PSYSENV_VALUE;
```

Members

`Attributes`

Attributes of the system environment variable.

`ValueLength`

The length of the value of the system environment variable.

`ValueData`

Requirements

Header	ntddsysenv.h

See Also

IOCTL_SYSENV_GET_VARIABLE

SYSENV_VARIABLE structure

1/30/2019 • 2 minutes to read • Edit Online

Stores the name a system environment variable using SysEnv device. This structure is used in the IOCTL_SYSENV_GET_VARIABLE request.

Syntax

```
typedef struct _SYSENV_VARIABLE {
  GUID  VendorGuid;
  ULONG VariableNameLength;
  WCHAR VariableName[ANYSIZE_ARRAY];
} SYSENV_VARIABLE, *PSYSENV_VARIABLE;
```

Members

`VendorGuid`

The vendor GUID.

`VariableNameLength`

The length of the string pointed to by **VariableName**, which contains the name of the variable.

`VariableName`

A string that contains the name of the variable.

Requirements

Header	ntddsysenv.h

See Also

IOCTL_SYSENV_GET_VARIABLE

SYSENV_VARIABLE_INFO structure

1/30/2019 • 2 minutes to read • Edit Online

Stores the information about a system environment variable using SysEnv device. This structure is used in the IOCTL_SYSENV_QUERY_VARIABLE_INFO request.

Syntax

```
typedef struct _SYSENV_VARIABLE_INFO {
  ULONGLONG MaximumVariableStorageSize;
  ULONGLONG RemainingVariableStorageSize;
  ULONGLONG MaximumVariableSize;
} SYSENV_VARIABLE_INFO, *PSYSENV_VARIABLE_INFO;
```

Members

`MaximumVariableStorageSize`

The size of the variable.

`RemainingVariableStorageSize`

The remaining size of the variable.

`MaximumVariableSize`

The maximum size of the variable.

Requirements

Header	ntddsysenv.h

See Also

IOCTL_SYSENV_QUERY_VARIABLE_INFO

XVARIABLE_NAME structure

1/30/2019 • 2 minutes to read • Edit Online

Stores the name of a system environment variable using SysEnv device. This structure is used in the IOCTL_SYSENV_ENUM_VARIABLES request.

Syntax

```
typedef struct _XVARIABLE_NAME {
  ULONG NextEntryOffset;
  GUID  VendorGuid;
  WCHAR Name[ANYSIZE_ARRAY];
} XVARIABLE_NAME, *PXVARIABLE_NAME;
```

Members

`NextEntryOffset`

The location of the next entry in the array of **XVARIABLE_NAME** structures reprieved by the IOCTL_SYSENV_ENUM_VARIABLES request.

`VendorGuid`

The vendor GUID.

`Name`

Name of the system environment variable.

Requirements

Header	ntddsysenv.h

See Also

IOCTL_SYSENV_ENUM_VARIABLES

XVARIABLE_NAME_AND_VALUE structure

1/30/2019 • 2 minutes to read • Edit Online

Stores the name and value of a system environment variable using SysEnv device. This structure is used in the IOCTL_SYSENV_ENUM_VARIABLES and IOCTL_SYSENV_SET_VARIABLE requests.

Syntax

```
typedef struct _XVARIABLE_NAME_AND_VALUE {
  ULONG NextEntryOffset;
  ULONG ValueOffset;
  ULONG ValueLength;
  ULONG Attributes;
  GUID  VendorGuid;
  WCHAR Name[ANYSIZE_ARRAY];
} XVARIABLE_NAME_AND_VALUE, *PXVARIABLE_NAME_AND_VALUE;
```

Members

`NextEntryOffset`

The location of the next entry in the array of XVARIABLE_NAME structures reprieved by the IOCTL_SYSENV_ENUM_VARIABLES request.

`ValueOffset`

The value of the system environment variable.

`ValueLength`

The length of the value.

`Attributes`

Attributes of the system environment variable.

`VendorGuid`

The vendor GUID.

`Name`

Name of the system environment variable.

Requirements

Header	ntddsysenv.h

See Also

IOCTL_SYSENV_ENUM_VARIABLES

IOCTL_SYSENV_ENUM_VARIABLES IOCTL

1/25/2019 • 2 minutes to read • Edit Online

Returns information about system environment variables using SysEnv device.

Major Code

IRP_MJ_DEVICE_CONTROL

Input Buffer

A boolean value indicating whether values should be included.

Input Buffer Length

Size of BOOLEAN.

Output Buffer

A pointer to a buffer that contains the system environment variable information. If values have been requested, the buffer points to an array of XVARIABLE_NAME_AND_VALUE structures. Otherwise, returns an array of XVARIABLE_NAME structures.

The location of the next entry is determined by **NextEntryOffset** of the XVARIABLE_NAME_AND_VALUE and XVARIABLE_NAME.

Output Buffer Length

On input, the length in bytes of the output buffer. On output, the length in bytes of the returned data. If the input buffer is large enough, then this value indicates the amount of data copied into output buffer. If the input buffer is too small, then it indicates the required buffer length.

Status Block

Irp->IoStatus.Status is set to STATUS_SUCCESS if the request is successful. Otherwise, **Status** to the appropriate error condition as a NTSTATUS code.

Requirements

Header	ntddsysenv.h

ntifs.h header

1/8/2019 • 35 minutes to read • Edit Online

This header is used by ifsk. For more information, see:

- Installable file system ntifs.h contains the following programming interfaces:

IOCTLs

TITLE	DESCRIPTION
IOCTL_REDIR_QUERY_PATH	The IOCTL_REDIR_QUERY_PATH control code is sent by the multiple UNC provider (MUP) to network redirectors to determine which provider can handle a specific UNC path in a name-based operation, typically an IRP_MJ_CREATE request.
IOCTL_REDIR_QUERY_PATH_EX	The IOCTL_REDIR_QUERY_PATH_EX control code is sent by the multiple UNC provider (MUP) on Windows Vista or later to network redirectors to determine which provider can handle a specific UNC path in a name-based operation, typically an IRP_MJ_CREATE request.
IOCTL_VOLSNAP_FLUSH_AND_HOLD_WRITES	The IOCTL_VOLSNAP_FLUSH_AND_HOLD_WRITES control code is sent to force a flush of a file system before a volume shadow copy occurs.

Functions

TITLE	DESCRIPTION
CcCopyWriteWontFlush	The CcCopyWriteWontFlush macro determines whether the amount of data to be copied in a call to CcCopyWrite is small enough not to require immediate flushing to disk if CcCopyWrite is called with Wait set to FALSE.
ExAdjustLookasideDepth	Reserved for system use.
ExDisableResourceBoostLite	Reserved for system use.
ExQueryPoolBlockSize	Obsolete.
FsRtlAllocatePoolWithQuotaTag	The FsRtlAllocatePoolWithQuotaTag routine allocates pool memory, charging quota against the current process.
FsRtlAllocatePoolWithTag	The FsRtlAllocatePoolWithTag routine allocates pool memory.
FsRtlAreThereCurrentFileLocks	The FsRtlAreThereCurrentFileLocks macro checks whether any byte range locks exist for the specified file.
FsRtlCompleteRequest	The FsRtlCompleteRequest macro completes an IRP with the specified status.

TITLE	DESCRIPTION
FsRtlFastLock	The FsRtlFastLock macro is used by file systems and filter drivers to request a byte-range lock for a file stream.
FsRtlGetPerStreamContextPointer	The FsRtlGetPerStreamContextPointer macro returns the file system's stream context for a file stream.
FsRtlInitPerStreamContext	The FsRtlInitPerStreamContext macro initializes a filter driver context structure.
FsRtlIsAnsiCharacterLegal	The FsRtlIsAnsiCharacterLegal macro determines whether a character is a legal ANSI character.
FsRtlIsAnsiCharacterLegalFat	The FsRtlIsAnsiCharacterLegalFat macro determines whether an ANSI character is legal for FAT file names.
FsRtlIsAnsiCharacterLegalHpfs	The FsRtlIsAnsiCharacterLegalHpfs macro determines whether an ANSI character is legal for HPFS file names.
FsRtlIsAnsiCharacterLegalNtfs	The FsRtlIsAnsiCharacterLegalNtfs macro determines whether an ANSI character is legal for NTFS file names.
FsRtlIsAnsiCharacterLegalNtfsStream	The FsRtlIsAnsiCharacterLegalNtfsStream macro determines whether an ANSI character is legal for NTFS stream names.
FsRtlIsAnsiCharacterWild	The FsRtlIsAnsiCharacterWild macro determines whether an ANSI character is a wildcard character.
FsRtlIsLeadDbcsCharacter	The FsRtlIsLeadDbcsCharacter macro determines whether a character is a lead byte (the first byte of a character) in a double-byte character set (DBCS).
FsRtlIsUnicodeCharacterWild	The FsRtlIsUnicodeCharacterWild macro determines whether a Unicode character is a wildcard character.
FsRtlLookupPerStreamContext	The FsRtlLookupPerStreamContext macro retrieves a per-stream context structure for a file stream.
FsRtlRegisterFileSystemFilterCallbacks	File system filter drivers and file systems call the FsRtlRegisterFileSystemFilterCallbacks routine to register notification callback routines to be invoked when the underlying file system performs certain operations.
FsRtlSetupAdvancedHeaderEx	The FsRtlSetupAdvancedHeaderEx macro is used by file systems to initialize an FSRTL_ADVANCED_FCB_HEADER structure for use with both stream and file contexts.
FsRtlSupportsPerFileContexts	The FsRtlSupportsPerFileContexts macro checks if per file context information is supported by the file system that is associated with a specified FILE_OBJECT.
FsRtlTestAnsiCharacter	The FsRtlTestAnsiCharacter macro determines whether an ANSI or double-byte character set (DBCS) character meets the specified criteria.

TITLE	DESCRIPTION
IoAcquireVpbSpinLock	The IoAcquireVpbSpinLock routine acquires the Volume Parameter Block (VPB) spin lock.
IoCheckDesiredAccess	Reserved for system use.
IoCheckEaBufferValidity	The IoCheckEaBufferValidity routine checks whether the specified extended attribute (EA) buffer is valid.
IoCheckFunctionAccess	Reserved for system use.
IoCheckQuerySetFileInformation	Reserved for system use.
IoCheckQuerySetVolumeInformation	Reserved for system use.
IoCheckQuotaBufferValidity	The IoCheckQuotaBufferValidity routine checks whether the specified quota buffer is valid.
IoCreateStreamFileObject	The IoCreateStreamFileObject routine creates a new stream file object.
IoCreateStreamFileObjectEx	The IoCreateStreamFileObjectEx routine creates a new stream file object.
IoCreateStreamFileObjectEx2	The IoCreateStreamFileObjectEx2 routine creates a new stream file object with create options for a target device object.
IoCreateStreamFileObjectLite	The IoCreateStreamFileObjectLite routine creates a new stream file object, but does not cause an IRP_MJ_CLEANUP request to be sent to the file system driver stack.
IoEnumerateDeviceObjectList	The IoEnumerateDeviceObjectList routine enumerates a driver's device object list.
IoEnumerateRegisteredFiltersList	The IoEnumerateRegisteredFiltersList routine enumerates the file system filter drivers that have registered with the system.
IoFastQueryNetworkAttributes	Reserved for system use.
IoGetAttachedDevice	The IoGetAttachedDevice routine returns a pointer to the highest-level device object associated with the specified device.
IoGetAttachedDeviceReference	The IoGetAttachedDeviceReference routine returns a pointer to the highest level device object in a driver stack and increments the reference count on that object.
IoGetBaseFileSystemDeviceObject	Reserved for system use.
IoGetConfigurationInformation	The IoGetConfigurationInformation routine returns a pointer to the I/O manager's global configuration information structure, which contains the current values for how many physical disk, floppy, CD-ROM, tape, SCSI HBA, serial, and parallel devices have device objects created to represent them by drivers as they are loaded.

TITLE	DESCRIPTION
IoGetDeviceAttachmentBaseRef	The IoGetDeviceAttachmentBaseRef routine returns a pointer to the lowest-level device object in a file system or device driver stack.
IoGetDeviceToVerify	The IoGetDeviceToVerify routine returns a pointer to the device object, representing a removable-media device, that is the target of the given thread's I/O request.
IoGetDiskDeviceObject	The IoGetDiskDeviceObject routine retrieves a pointer to the disk device object associated with a given file system volume device object.
IoGetLowerDeviceObject	The IoGetLowerDeviceObject routine returns a pointer to the next-lower-level device object on the driver stack.
IoGetRequestorProcess	The IoGetRequestorProcess routine returns a process pointer for the thread that originally requested a given I/O operation.
IoGetRequestorProcessId	The IoGetRequestorProcessId routine returns the unique 32-bit process ID for the thread that originally requested a given I/O operation.
IoGetRequestorSessionId	The IoGetRequestorSessionId routine returns the session ID for the process that originally requested a given I/O operation.
IoGetTopLevelIrp	The IoGetTopLevelIrp routine returns the value of the TopLevelIrp field of the current thread.
IoInitializePriorityInfo	The IoInitializePriorityInfo routine initializes a structure of type IO_PRIORITY_INFO.
IoIsFileOpenedExclusively	Reserved for system use.
IoIsOperationSynchronous	The IoIsOperationSynchronous routine determines whether a given IRP represents a synchronous or asynchronous I/O request.
IoIsSystemThread	The IoIsSystemThread routine checks whether a given thread is a system thread.
IoIsValidNameGraftingBuffer	Reserved for system use.
IoPageRead	Reserved for system use.
IoQueryFileDosDeviceName	The IoQueryFileDosDeviceName routine retrieves an MS-DOS device name for a file.
IoQueryFileInformation	Reserved for system use.
IoQueryVolumeInformation	Reserved for system use.
IoQueueThreadIrp	Reserved for system use.

TITLE	DESCRIPTION
IoRegisterFileSystem	The IoRegisterFileSystem routine adds a file system's control device object to the global file system queue.
IoRegisterFsRegistrationChange	The IoRegisterFsRegistrationChange routine registers a file system filter driver's notification routine to be called whenever a file system registers or unregisters itself as an active file system.
IoRegisterFsRegistrationChangeEx	The IoRegisterFsRegistrationChangeEx routine registers a file system filter driver's notification routine to be called whenever a file system registers or unregisters itself as an active file system.
IoRegisterFsRegistrationChangeMountAware	The IoRegisterFsRegistrationChangeMountAware routine registers a file system filter driver's notification routine. This notification routine is called whenever a file system registers or unregisters itself as an active file system.
IoReleaseVpbSpinLock	The IoReleaseVpbSpinLock routine releases the Volume Parameter Block (VPB) spin lock.
IoReplaceFileObjectName	The IoReplaceFileObjectName routine replaces the name of a file object.
IoSetDeviceToVerify	The IoSetDeviceToVerify routine specifies a device object to be verified. The specified device object represents a removable media device.
IoSetInformation	Reserved for system use.
IoSetStartIoAttributes	The IoSetStartIoAttributes routine sets attributes for the driver's StartIo routine.
IoSetTopLevelIrp	The IoSetTopLevelIrp routine sets the value of the TopLevelIrp field of the current thread.
IoSizeOfIrp	The IoSizeOfIrp routine determines the size in bytes for an IRP, given the number of stack locations in the IRP.
IoStartNextPacket	The IoStartNextPacket routine dequeues the next IRP, if any, from the given device object's associated device queue and calls the driver's StartIo routine.
IoStartNextPacketByKey	The IoStartNextPacketByKey routine dequeues the next I/O request packet from the specified device object's associated device queue according to a specified sort-key value and calls the driver's StartIo routine with that IRP.
IoStartPacket	The IoStartPacket routine calls the driver's StartIo routine with the given IRP or inserts the IRP into the device queue associated with the given device object if the device is already busy.

TITLE	DESCRIPTION
IoStartTimer	The IoStartTimer routine enables the timer associated with a given device object so the driver-supplied IoTimer routine is called once per second.
IoStopTimer	The IoStopTimer routine disables the timer for a specified device object so the driver-supplied IoTimer routine is not called.
IoSynchronousPageWrite	Reserved for system use.
IoThreadToProcess	The IoThreadToProcess routine returns a pointer to the process for the specified thread.
IoUnregisterFileSystem	The IoUnregisterFileSystem routine removes a file system's control device object from the global file system queue.
IoUnregisterFsRegistrationChange	The IoUnregisterFsRegistrationChange routine unregisters file system filter driver's file system registration change notification routine.
IoVerifyVolume	The IoVerifyVolume routine sends a volume verify request to the given removable-media device.
IoWriteErrorLogEntry	The IoWriteErrorLogEntry routine queues a given error log packet to the system error logging thread.
IsReparseTagMicrosoft	The IsReparseTagMicrosoft macro determines whether a reparse point tag indicates a Microsoft reparse point.
IsReparseTagNameSurrogate	The IsReparseTagNameSurrogate macro determines whether a tag's associated reparse point is a surrogate for another named entity, such as a volume mount point.
IsReparseTagValid	Reserved for system use.
KeAttachProcess	Obsolete.
KeDetachProcess	Obsolete.
KeGetProcessorIndexFromNumber	The KeGetProcessorIndexFromNumber routine converts a group number and a group-relative processor number to a systemwide processor index.
KeGetProcessorNumberFromIndex	The KeGetProcessorNumberFromIndex routine converts a systemwide processor index to a group number and a group-relative processor number.
KeInitializeMutant	Reserved for system use.
KeInitializeQueue	The KeInitializeQueue routine initializes a queue object on which threads can wait for entries.

TITLE	DESCRIPTION
KeInsertHeadQueue	The KeInsertHeadQueue routine inserts an entry at the head of the given queue if it cannot immediately use the entry to satisfy a thread wait.
KeInsertQueue	The KeInsertQueue routine inserts an entry at the tail of the given queue if it cannot immediately use the entry to satisfy a thread wait.
KeQueryPerformanceCounter	The KeQueryPerformanceCounter routine retrieves the current value and frequency of the performance counter.Use KeQueryPerformanceCounter to acquire high resolution (<1us) time stamps for time interval measurements.
KeReadStateMutant	Reserved for system use.
KeReadStateQueue	Reserved for system use.
KeReleaseMutant	Reserved for system use.
KeReleaseQueuedSpinLock	Reserved for system use.
KeRemoveQueue	The KeRemoveQueue routine gives the calling thread a pointer to a dequeued entry from the given queue object or allows the caller to wait, up to an optional timeout interval, on the queue object.
KeRundownQueue	The KeRundownQueue routine cleans up a queue object, flushing any queued entries.
KeSetIdealProcessorThread	Reserved for system use.
KeSetKernelStackSwapEnable	The KeSetKernelStackSwapEnable routine enables and disables swapping of the caller's stack to disk.
KeStackAttachProcess	The KeStackAttachProcess routine attaches the current thread to the address space of the target process.
KeStallExecutionProcessor	The KeStallExecutionProcessor routine stalls the caller on the current processor for a specified time interval.
KeTryToAcquireQueuedSpinLock	Reserved for system use.
KeUnstackDetachProcess	The KeUnstackDetachProcess routine detaches the current thread from the address space of a process and restores the previous attach state.
MmCanFileBeTruncated	The MmCanFileBeTruncated routine checks whether a file can be truncated.
MmDoesFileHaveUserWritableReferences	The MmDoesFileHaveUserWritableReferences function returns the number of writable references for a file object.
MmFlushImageSection	The MmFlushImageSection routine flushes the image section for a file.

TITLE	DESCRIPTION
MmForceSectionClosed	The MmForceSectionClosed routine deletes the data and image sections for a file that is no longer in use.
MmForceSectionClosedEx	The MmForceSectionClosedEx function examines the section object pointers. If they are NULL, no further action is taken and the value TRUE is returned.
MmGetMaximumFileSectionSize	The MmGetMaximumFileSectionSize returns the maximum possible size of a file section for the current version of Windows.
MmIsRecursiveIoFault	The MmIsRecursiveIoFault routine determines whether the current page fault is occurring during an I/O operation.
MmPrefetchPages	The MmPrefetchPages routine reads groups of pages from secondary storage in the optimal fashion.
MmSetAddressRangeModified	The MmSetAddressRangeModified routine marks currently valid pages in the specified range of the system cache as modified.
NtAllocateVirtualMemory	The ZwAllocateVirtualMemory routine reserves, commits, or both, a region of pages within the user-mode virtual address space of a specified process.
NtClose	The ZwClose routine closes an object handle.
NtCreateFile	The ZwCreateFile routine creates a new file or opens an existing file.
NtCreateSection	The ZwCreateSection routine creates a section object.
NtCreateSectionEx	Creates a section object.
NtDeviceIoControlFile	The ZwDeviceIoControlFile routine sends a control code directly to a specified device driver, causing the corresponding driver to perform the specified operation.
NtDuplicateToken	The ZwDuplicateToken function creates a handle to a new access token that duplicates an existing token. This function can create either a primary token or an impersonation token.
NtFlushBuffersFileEx	The ZwFlushBuffersFileEx routine is called by a file system filter driver to send a flush request for a given file to the file system. An optional flush operation flag can be set to control how file data is written to storage.
NtFreeVirtualMemory	The ZwFreeVirtualMemory routine releases, decommits, or both, a region of pages within the virtual address space of a specified process.
NtFsControlFile	The ZwFsControlFile routine sends a control code directly to a specified file system or file system filter driver, causing the corresponding driver to perform the specified action.

TITLE	DESCRIPTION
NtLockFile	The NtLockFile routine requests a byte-range lock for the specified file.
NtOpenFile	The ZwOpenFile routine opens an existing file, directory, device, or volume.
NtOpenProcessTokenEx	The ZwOpenProcessTokenEx routine opens the access token associated with a process.
NtOpenThreadTokenEx	The ZwOpenThreadTokenEx routine opens the access token associated with a thread.
NtQueryDirectoryFile	The ZwQueryDirectoryFile routine returns various kinds of information about files in the directory specified by a given file handle.
NtQueryInformationFile	The ZwQueryInformationFile routine returns various kinds of information about a file object.
NtQueryInformationToken	The ZwQueryInformationToken routine retrieves a specified type of information about an access token. The calling process must have appropriate access rights to obtain the information.
NtQueryObject	The ZwQueryObject routine provides information about a supplied object.
NtQueryQuotaInformationFile	The ZwQueryQuotaInformationFile routine retrieves quota entries associated with the volume specified by the FileHandle parameter.
NtQuerySecurityObject	The ZwQuerySecurityObject routine retrieves a copy of an object's security descriptor.
NtQueryVirtualMemory	The ZwQueryVirtualMemory routine determines the state, protection, and type of a region of pages within the virtual address space of the subject process.
NtQueryVolumeInformationFile	The ZwQueryVolumeInformationFile routine retrieves information about the volume associated with a given file, directory, storage device, or volume.
NtReadFile	The ZwReadFile routine reads data from an open file.
NtSetInformationFile	The ZwSetInformationFile routine changes various kinds of information about a file object.
NtSetInformationThread	The ZwSetInformationThread routine sets the priority of a thread.
NtSetInformationToken	The ZwSetInformationToken routine modifies information in a specified token. The calling process must have appropriate access rights to set the information.

TITLE	DESCRIPTION
NtSetQuotaInformationFile	The ZwSetQuotaInformationFile routine changes quota entries for the volume associated with the FileHandle parameter. All of the quota entries in the specified buffer are applied to the volume.
NtSetSecurityObject	The ZwSetSecurityObject routine sets an object's security state.
NtUnlockFile	The ZwUnlockFile routine unlocks a byte-range lock in a file.
NtWriteFile	The ZwWriteFile routine writes data to an open file.
ObInsertObject	Reserved for system use.
ObIsKernelHandle	The ObIsKernelHandle routine determines whether the specified handle is a kernel handle.
ObMakeTemporaryObject	Reserved for system use.
ObOpenObjectByPointer	The ObOpenObjectByPointer function opens an object referenced by a pointer and returns a handle to the object.
ObQueryNameString	The ObQueryNameString routine supplies the name, if there is one, of a given object to which the caller has a pointer.
ObQueryObjectAuditingByHandle	Reserved for system use.
PoCallDriver	The PoCallDriver routine passes a power IRP to the next-lower driver in the device stack. (Windows Server 2003, Windows XP, and Windows 2000 only.).
PoClearPowerRequest	The PoClearPowerRequest routine decrements the count for the specified power request type.
PoCreatePowerRequest	The PoCreatePowerRequest routine creates a power request object.
PoDeletePowerRequest	The PoDeletePowerRequest routine deletes a power request object.
PoEndDeviceBusy	The PoEndDeviceBusy routine marks the end of a period of time in which the device is busy.
PoQueryWatchdogTime	The PoQueryWatchdogTime routine indicates whether the power manager has enabled a watchdog time-out counter for any power IRP that is currently assigned to the device stack.
PoRegisterDeviceForIdleDetection	The PoRegisterDeviceForIdleDetection routine enables or cancels idle detection and sets idle time-out values for a device.
PoRegisterPowerSettingCallback	The PoRegisterPowerSettingCallback routine registers a power-setting callback routine to receive notifications of changes in the specified power setting.

TITLE	DESCRIPTION
PoRegisterSystemState	The PoRegisterSystemState routine registers the system as busy due to certain activity.
PoSetDeviceBusyEx	The PoSetDeviceBusyEx routine notifies the power manager that the device associated with the specified idle counter is busy.
PoSetPowerRequest	The PoSetPowerRequest routine increments the count for the specified power request type.
PoSetPowerState	The PoSetPowerState routine notifies the system of a change in the device power state for a device.
PoStartDeviceBusy	The PoStartDeviceBusy routine marks the start of a period of time in which the device is busy.
PoStartNextPowerIrp	The PoStartNextPowerIrp routine signals the power manager that the driver is ready to handle the next power IRP. (Windows Server 2003, Windows XP, and Windows 2000 only.).
PoUnregisterPowerSettingCallback	The PoUnregisterPowerSettingCallback routine unregisters a power-setting callback routine that a driver previously registered by calling the PoRegisterPowerSettingCallback routine.
PoUnregisterSystemState	The PoUnregisterSystemState routine cancels a system state registration created by PoRegisterSystemState.
PsChargePoolQuota	The PsChargePoolQuota routine charges pool quota of the specified pool type to the specified process.
PsDereferenceImpersonationToken	The PsDereferenceImpersonationToken routine decrements the reference count of an impersonation token.
PsDereferencePrimaryToken	The PsDereferencePrimaryToken routine decrements the reference count of a primary token.
PsGetCurrentThread	The PsGetCurrentThread routine identifies the current thread.
PsGetProcessExitTime	The PsGetProcessExitTime routine returns the exit time for the current process.
PsImpersonateClient	The PsImpersonateClient routine causes a server thread to impersonate a client.
PsIsDiskCountersEnabled	The enabled state of the per process disk I/O counters is returned by the PsIsDiskCountersEnabled routine.
PsIsSystemThread	The PsIsSystemThread routine checks whether a given thread is a system thread.
PsIsThreadTerminating	The PsIsThreadTerminating routine checks whether a thread is terminating.

TITLE	DESCRIPTION
PsLookupProcessByProcessId	The PsLookupProcessByProcessId routine accepts the process ID of a process and returns a referenced pointer to EPROCESS structure of the process.
PsLookupThreadByThreadId	The PsLookupThreadByThreadId routine accepts the thread ID of a thread and returns a referenced pointer to the ETHREAD structure of the thread.
PsReferenceImpersonationToken	The PsReferenceImpersonationToken routine increments the reference count of the impersonation token for the specified thread.
PsReferencePrimaryToken	The PsReferencePrimaryToken routine increments the reference count of the primary token for the specified process.
PsReturnPoolQuota	The PsReturnPoolQuota routine returns pool quota of the specified pool type to the specified process.
PsRevertToSelf	The PsRevertToSelf routine ends the calling thread's impersonation of a client.
PsUpdateDiskCounters	The PsUpdateDiskCounters routine updates the disk I/O counters of a given process.
RtlAbsoluteToSelfRelativeSD	The RtlAbsoluteToSelfRelativeSD routine creates a new security descriptor in self-relative format by using a security descriptor in absolute format as a template.
RtlAddAccessAllowedAce	The RtlAddAccessAllowedAce routine adds an access-allowed access control entry (ACE) to an access control list (ACL). The access is granted to the specified security identifier (SID).
RtlAddAccessAllowedAceEx	The RtlAddAccessAllowedAceEx routine adds an access-allowed access control entry (ACE) with inheritance ACE flags to an access control list (ACL). The access is granted to the specified security identifier (SID).
RtlAddAce	The RtlAddAce routine adds one or more access control entries (ACEs) to a specified access control list (ACL).
RtlAllocateAndInitializeSid	Reserved for system use.
RtlAllocateHeap	The RtlAllocateHeap routine allocates a block of memory from a heap.
RtlAppendStringToString	The RtlAppendStringToString routine concatenates two counted strings. It copies bytes from the source up to the length of the destination buffer.
RtlCaptureContext	The RtlCaptureContext function retrieves a context record in the context of the caller.
RtlCaptureStackBackTrace	The RtlCaptureStackBackTrace routine captures a stack back trace by walking up the stack and recording the information for each frame.

TITLE	DESCRIPTION
RtlCompareMemoryUlong	The RtlCompareMemoryUlong routine returns how many bytes in a block of memory match a specified pattern.
RtlCompressBuffer	The RtlCompressBuffer function compresses a buffer and can be used by a file system driver to facilitate the implementation of file compression.
RtlCompressChunks	Reserved for system use.
RtlConvertSidToUnicodeString	The RtlConvertSidToUnicodeString routine generates a printable Unicode string representation of a security identifier (SID).
RtlCopyLuid	The RtlCopyLuid routine copies a locally unique identifier (LUID) to a buffer.
RtlCopySid	The RtlCopySid routine copies the value of a security identifier (SID) to a buffer.
RtlCreateAcl	The RtlCreateAcl routine creates and initializes an access control list (ACL).
RtlCreateHeap	The RtlCreateHeap routine creates a heap object that can be used by the calling process. This routine reserves space in the virtual address space of the process and allocates physical storage for a specified initial portion of this block.
RtlCreateSecurityDescriptorRelative	The RtlCreateSecurityDescriptorRelative routine initializes a new security descriptor in self-relative format.
RtlCreateSystemVolumeInformationFolder	The RtlCreateSystemVolumeInformationFolder routine verifies the existence of the "System Volume Information" folder on a file system volume. If the folder is not present, then the folder is created.
RtlCreateUnicodeString	The RtlCreateUnicodeString routine creates a new counted Unicode string.
RtlCustomCPToUnicodeN	Reserved for system use.
RtlDecompressBuffer	The RtlDecompressBuffer function decompresses an entire compressed buffer.
RtlDecompressBufferEx	The RtlDecompressBufferEx function decompresses an entire compressed buffer.
RtlDecompressBufferEx2	The RtlDecompressBufferEx2 function decompresses an entire compressed buffer, using multiple processors where possible. Multiple processor support is only implemented for kernel mode callers.

TITLE	DESCRIPTION
RtlDecompressChunks	Reserved for system use.
RtlDecompressFragment	The RtlDecompressFragment function is used to decompress part of a compressed buffer (that is, a buffer "fragment").
RtlDecompressFragmentEx	The RtlDecompressFragmentEx function is used to decompress part of a compressed buffer (that is, a buffer "fragment"), using multiple processors where possible.
RtlDeleteAce	The RtlDeleteAce routine deletes an access control entry (ACE) from a specified access control list (ACL).
RtlDescribeChunk	Reserved for system use.
RtlDestroyHeap	The RtlDestroyHeap routine destroys the specified heap object. RtlDestroyHeap decommits and releases all the pages of a private heap object, and it invalidates the handle to the heap.
RtlDowncaseUnicodeString	The RtlDowncaseUnicodeString routine converts the specified Unicode source string to lowercase. The translation conforms to the current system locale information.
RtlEqualPrefixSid	The RtlEqualPrefixSid routine determines whether two security-identifier (SID) prefixes are equal. An SID prefix is the entire SID except for the last subauthority value.
RtlEqualSid	The RtlEqualSid routine determines whether two security identifier (SID) values are equal. Two SIDs must match exactly to be considered equal.
RtlFillMemoryUlong	The RtlFillMemoryUlong routine fills the specified range of memory with one or more repetitions of a ULONG value.
RtlFillMemoryUlonglong	The RtlFillMemoryUlonglong routine fills a given range of memory with one or more repetitions of a given ULONGLONG value.
RtlFindUnicodePrefix	The RtlFindUnicodePrefix routine searches for the best match for a given Unicode file name in a prefix table.
RtlFreeHeap	The RtlFreeHeap routine frees a memory block that was allocated from a heap by RtlAllocateHeap.
RtlFreeOemString	The RtlFreeOemString routine releases storage that was allocated by any of the Rtl..ToOemString routines.
RtlFreeSid	Reserved for system use.
RtlGenerate8dot3Name	The RtlGenerate8dot3Name routine generates a short (8.3) name for the specified long file name.
RtlGetAce	The RtlGetAce routine obtains a pointer to an access control entry (ACE) in an access control list (ACL).

TITLE	DESCRIPTION
RtlGetCompressionWorkSpaceSize	The RtlGetCompressionWorkSpaceSize function is used to determine the correct size of the WorkSpace buffer for the RtlCompressBuffer and RtlDecompressFragment functions.
RtlGetDaclSecurityDescriptor	The RtlGetDaclSecurityDescriptor routine returns a pointer to the discretionary ACL (DACL) for a security descriptor.
RtlGetGroupSecurityDescriptor	The RtlGetGroupSecurityDescriptor routine returns the primary group information for a given security descriptor.
RtlGetOwnerSecurityDescriptor	The RtlGetOwnerSecurityDescriptor routine returns the owner information for a given security descriptor.
RtlGetSaclSecurityDescriptor	The RtlGetSaclSecurityDescriptor routine returns a pointer to the system ACL (SACL) for a security descriptor.
RtlIdentifierAuthoritySid	Reserved for system use.
RtlInitCodePageTable	Reserved for system use.
RtlInitializeSid	The RtlInitializeSid routine initializes a security identifier (SID) structure.
RtlInitializeSidEx	The RtlInitializeSidEx routine initializes a pre-allocated security identifier (SID) structure.
RtlInitializeUnicodePrefix	The RtlInitializeUnicodePrefix routine initializes a prefix table.
RtlInitStringEx	The RtlInitStringEx routine initializes a counted string of 8-bit characters.
RtlInsertUnicodePrefix	The RtlInsertUnicodePrefix routine inserts a new element into a Unicode prefix table.
RtlIsCloudFilesPlaceholder	The RtlIsCloudFilesPlaceholder routine determines if a file or a directory is a CloudFiles placeholder, based on the FileAttributes and ReparseTag values of the file.
RtlIsNameLegalDOS8Dot3	The RtlIsNameLegalDOS8Dot3 routine determines whether a given name represents a valid short (8.3) file name.
RtlIsPartialPlaceholder	The RtlIsPartialPlaceholder routine determines if a file or a directory is a CloudFiles placeholder, based on the FileAttributes and ReparseTag values of the file.
RtlIsPartialPlaceholderFileHandle	The RtlIsPartialPlaceholderFileHandle routine determines if a file is a known type of placeholder, based on a file handle.
RtlIsPartialPlaceholderFileInfo	The RtlIsPartialPlaceholderFileInfo routine determines if a file is a known type of placeholder, based on the information returned by NtQueryInformationFile or NtQueryDirectoryFile.
RtlIsValidOemCharacter	The RtlIsValidOemCharacter routine determines if the specified Unicode character can be mapped to a valid OEM character.

TITLE	DESCRIPTION
RtlLengthRequiredSid	The RtlLengthRequiredSid routine returns the length, in bytes, of the buffer required to store a security identifier (SID) with a specified number of subauthorities.
RtlLengthSid	The RtlLengthSid routine returns the length, in bytes, of a valid security identifier (SID).
RtlMultiByteToUnicodeN	The RtlMultiByteToUnicodeN routine translates the specified source string into a Unicode string, using the current system ANSI code page (ACP). The source string is not necessarily from a multibyte character set.
RtlMultiByteToUnicodeSize	The RtlMultiByteToUnicodeSize routine determines the number of bytes that are required to store the Unicode translation for the specified source string.
RtlNextUnicodePrefix	The RtlNextUnicodePrefix routine is used to enumerate the elements in a Unicode prefix table.
RtlNtStatusToDosError	The RtlNtStatusToDosError routine converts the specified NTSTATUS code to its equivalent system error code.
RtlNtStatusToDosErrorNoTeb	Reserved for system use.
RtlOemStringToCountedUnicodeSize	The RtlOemStringToCountedUnicodeSize routine determines the size, in bytes, that a given OEM string will be after it is translated into a counted Unicode string.
RtlOemStringToCountedUnicodeString	The RtlOemStringToCountedUnicodeString routine translates the specified source string into a Unicode string using the current system OEM code page.
RtlOemStringToUnicodeSize	The RtlOemStringToUnicodeSize routine determines the size, in bytes, that a given OEM string will be after it is translated into a null-terminated Unicode string.
RtlOemStringToUnicodeString	The RtlOemStringToUnicodeString routine translates a given source string into a null-terminated Unicode string using the current system OEM code page.
RtlOemToUnicodeN	The RtlOemToUnicodeN routine translates the specified source string into a Unicode string, using the current system OEM code page.
RtlQueryProcessPlaceholderCompatibilityMode	The RtlSetProcessPlaceholderCompatibilityMode function returns the placeholder compatibility mode for the current process.
RtlQueryThreadPlaceholderCompatibilityMode	RtlQueryThreadPlaceholderCompatibilityMode is a routine which returns the placeholder compatibility mode for the current thread.
RtlRandom	The RtlRandom routine returns a random number that was generated from a given seed value.

TITLE	DESCRIPTION
RtlRandomEx	The RtlRandomEx routine returns a random number that was generated from a given seed value.
RtlRemoveUnicodePrefix	The RtlRemoveUnicodePrefix routine removes an element from a prefix table.
RtlReserveChunk	Reserved for system use.
RtlSecondsSince1970ToTime	The RtlSecondsSince1970ToTime routine converts the elapsed time, in seconds, since the beginning of 1970 to an absolute system time value.
RtlSecondsSince1980ToTime	The RtlSecondsSince1980ToTime routine converts the elapsed time, in seconds, since the beginning of 1980 to an absolute system time value.
RtlSelfRelativeToAbsoluteSD	The RtlSelfRelativeToAbsoluteSD routine creates a new security descriptor in absolute format by using a security descriptor in self-relative format as a template.
RtlSetGroupSecurityDescriptor	The RtlSetGroupSecurityDescriptor routine sets the primary group information of an absolute-format security descriptor. It replaces any primary group information that is already present in the security descriptor.
RtlSetOwnerSecurityDescriptor	The RtlSetOwnerSecurityDescriptor routine sets the owner information of an absolute-format security descriptor. It replaces any owner information that is already present in the security descriptor.
RtlSetProcessPlaceholderCompatibilityMode	The RtlSetProcessPlaceholderCompatibilityMode function returns the placeholder compatibility mode for the current process.
RtlSetThreadPlaceholderCompatibilityMode	RtlSetThreadPlaceholderCompatibilityMode is a routine which sets the placeholder compatibility mode for the current thread.
RtlSubAuthorityCountSid	Reserved for system use.
RtlSubAuthoritySid	The RtlSubAuthoritySid routine returns a pointer to a specified subauthority of a security identifier (SID).
RtlTimeToSecondsSince1970	The RtlTimeToSecondsSince1970 routine converts a given absolute system time value to the elapsed time, in seconds, since the beginning of 1970.
RtlTimeToSecondsSince1980	The RtlTimeToSecondsSince1980 routine converts a given absolute system time value to the elapsed time, in seconds, since the beginning of 1980.
RtlUnicodeStringToCountedOemString	The RtlUnicodeStringToCountedOemString routine translates the specified Unicode source string into a counted OEM string using the current system OEM code page.

TITLE	DESCRIPTION
RtlUnicodeStringToOemSize	The RtlUnicodeStringToOemSize routine determines the size, in bytes, that a given Unicode string will be after it is translated into an OEM string.
RtlUnicodeStringToOemString	The RtlUnicodeStringToOemString routine translates a given Unicode source string into an OEM string using the current system OEM code page.
RtlUnicodeToCustomCPN	Reserved for system use.
RtlUnicodeToMultiByteN	The RtlUnicodeToMultiByteN routine translates the specified Unicode string into a new character string, using the current system ANSI code page (ACP). The translated string is not necessarily from a multibyte character set.
RtlUnicodeToMultiByteSize	The RtlUnicodeToMultiByteSize routine determines the number of bytes that are required to store the multibyte translation for the specified Unicode string. The translation is assumed to use the current system ANSI code page (ACP).
RtlUnicodeToOemN	The RtlUnicodeToOemN routine translates a given Unicode string to an OEM string, using the current system OEM code page.
RtlUnicodeToUTF8N	The RtlUnicodeToUTF8N routine converts a Unicode string to a UTF-8 string.
RtlUpcaseUnicodeStringToCountedOemString	The RtlUpcaseUnicodeStringToCountedOemString routine translates a given Unicode source string into an uppercase counted OEM string using the current system OEM code page.
RtlUpcaseUnicodeStringToOemString	The RtlUpcaseUnicodeStringToOemString routine translates a given Unicode source string into an uppercase OEM string using the current system OEM code page.
RtlUpcaseUnicodeToCustomCPN	Reserved for system use.
RtlUpcaseUnicodeToMultiByteN	The RtlUpcaseUnicodeToMultiByteN routine translates the specified Unicode string into a new uppercase character string, using the current system ANSI code page (ACP). The translated string is not necessarily from a multibyte character set.
RtlUpcaseUnicodeToOemN	The RtlUpcaseUnicodeToOemN routine translates a given Unicode string into an uppercase OEM string, using the current system OEM code page.
RtlUTF8ToUnicodeN	The RtlUTF8ToUnicodeN routine converts a UTF-8 string to a Unicode string.
RtlValidSid	The RtlValidSid routine validates a security identifier (SID) by verifying that the revision number is within a known range and that the number of subauthorities is less than the maximum.

TITLE	DESCRIPTION
RtlxOemStringToUnicodeSize	Reserved for system use.
RtlxUnicodeStringToOemSize	Reserved for system use.
SeAppendPrivileges	The SeAppendPrivileges routine appends additional privileges to the privilege set in an access state structure.
SeAuditHardLinkCreation	Reserved for system use.
SeAuditingFileEvents	The SeAuditingFileEvents routine determines whether file open events are currently being audited.
SeAuditingFileOrGlobalEvents	The SeAuditingFileOrGlobalEvents routine determines whether file or global events are currently being audited.
SeAuditingHardLinkEvents	Reserved for system use.
SeCaptureSubjectContext	The SeCaptureSubjectContext routine captures the security context of the calling thread for access validation and auditing.
SeCreateClientSecurity	The SeCreateClientSecurity routine initializes a security client context structure with the information needed to call SeImpersonateClientEx.
SeCreateClientSecurityFromSubjectContext	The SeCreateClientSecurityFromSubjectContext routine retrieves the access token for a security subject context and uses the result to initialize a security client context with the information needed to call SeImpersonateClientEx.
SeDeleteClientSecurity	The SeDeleteClientSecurity routine deletes a client security context.
SeDeleteObjectAuditAlarm	The SeDeleteObjectAuditAlarm routine generates audit and alarm messages for an object that is marked for deletion.
SeFilterToken	The SeFilterToken routine creates a new access token that is a restricted version of an existing access token.
SeFreePrivileges	The SeFreePrivileges routine frees a privilege set returned by SeAccessCheck.
SeImpersonateClient	Obsolete.
SeImpersonateClientEx	The SeImpersonateClientEx routine causes a thread to impersonate a user.
SeLengthSid	Obsolete.
SeLockSubjectContext	The SeLockSubjectContext routine locks the primary and impersonation tokens of a captured subject context.

TITLE	DESCRIPTION
SeMarkLogonSessionForTerminationNotification	The SeMarkLogonSessionForTerminationNotification routine marks a logon session so that the caller's registered callback routine is called when the logon session terminates.
SeOpenObjectAuditAlarm	The SeOpenObjectAuditAlarm routine generates audit and alarm messages when an attempt is made to open an object.
SeOpenObjectForDeleteAuditAlarm	The SeOpenObjectForDeleteAuditAlarm routine generates audit and alarm messages when an attempt is made to open an object for deletion.
SePrivilegeCheck	The SePrivilegeCheck routine determines whether a specified set of privileges is enabled in the subject's access token.
SeQueryAuthenticationIdToken	The SeQueryAuthenticationIdToken routine retrieves the authentication ID of an access token.
SeQueryInformationToken	The SeQueryInformationToken routine retrieves a specified type of information about an access token. The calling process must have appropriate access rights to obtain the information.
SeQuerySecurityDescriptorInfo	The SeQuerySecurityDescriptorInfo routine retrieves a copy of an object's security descriptor.
SeQuerySessionIdToken	Reserved for system use.
SeQuerySubjectContextToken	The SeQuerySubjectContextToken macro retrieves the access token for a security subject context.
SeRegisterLogonSessionTerminatedRoutine	The SeRegisterLogonSessionTerminatedRoutine routine registers a callback routine to be called when a logon session terminates. A logon session terminates when the last token referencing the logon session is deleted.
SeReleaseSubjectContext	The SeReleaseSubjectContext routine releases a subject security context captured by an earlier call to SeCaptureSubjectContext.
SeSetAccessStateGenericMapping	The SeSetAccessStateGenericMapping routine sets the generic mapping field of an ACCESS_STATE structure.
SeSetSecurityDescriptorInfo	The SeSetSecurityDescriptorInfo routine sets an object's security descriptor.
SeSetSecurityDescriptorInfoEx	The SeSetSecurityDescriptorInfoEx routine modifies an object's security descriptor and specifies whether the object supports automatic inheritance of access control entries (ACE).
SeSetSessionIdToken	Reserved for system use.
SeTokenGetNoChildProcessRestricted	The SeTokenGetNoChildProcessRestricted routine determines the state of the no child process mitigation. It is not possible to be enforced and audit-only at the same time.

TITLE	DESCRIPTION
SeTokenIsAdmin	The SeTokenIsAdmin routine determines whether a token contains the local administrators group.
SeTokenIsNoChildProcessRestrictionEnforced	The SeTokenIsNoChildProcessRestrictionEnforced routine determines if the token carries the no child process restriction.
SeTokenIsRestricted	The SeTokenIsRestricted routine determines whether a token contains a list of restricting security identifiers (SID).
SeTokenSetNoChildProcessRestricted	The SeTokenSetNoChildProcessRestricted routine sets the TOKEN_AUDIT_NO_CHILD_PROCESS or TOKEN_AUDIT_NO_CHILD_PROCESS flags in the token.
SeTokenType	Reserved for system use.
SeUnlockSubjectContext	The SeUnlockSubjectContext routine unlocks the tokens of a captured subject context that were locked by a call to SeLockSubjectContext.
SeUnregisterLogonSessionTerminatedRoutine	The SeUnregisterLogonSessionTerminatedRoutine routine unregisters a callback routine that was registered by an earlier call to SeRegisterLogonSessionTerminatedRoutine.

Callback functions

TITLE	DESCRIPTION
DRIVER_FS_NOTIFICATION	A PDRIVER_FS_NOTIFICATION-typed routine is called by the operating system when a file system registers or unregisters itself by using IoRegisterFileSystem or IoUnregisterFileSystem.

Structures

TITLE	DESCRIPTION
ACCESS_ALLOWED_ACE	The ACCESS_ALLOWED_ACE structure defines an access-control entry (ACE) for the discretionary access-control list (DACL) that controls access to an object.
ACCESS_DENIED_ACE	The ACCESS_DENIED_ACE structure defines an access-control entry (ACE) for the discretionary access-control list (DACL) controlling access to an object.
ACE_HEADER	The ACE_HEADER structure describes the type and size of an access-control entry (ACE).
BOOT_AREA_INFO	The BOOT_AREA_INFO structure contains the output for the FSCTL_GET_BOOT_AREA_INFO control code.
ENCRYPTION_KEY_CTRL_INPUT	

TITLE	DESCRIPTION
FILE_ACCESS_INFORMATION	The FILE_ACCESS_INFORMATION structure is used to query for or set the access rights of a file.
FILE_ALL_INFORMATION	The FILE_ALL_INFORMATION structure is a container for several FILE_XXX_INFORMATION structures.
FILE_ALLOCATION_INFORMATION	The FILE_ALLOCATION_INFORMATION structure is used to set the allocation size for a file.
FILE_BOTH_DIR_INFORMATION	The FILE_BOTH_DIR_INFORMATION structure is used to query detailed information for the files in a directory.
FILE_CASE_SENSITIVE_INFORMATION	The FILE_CASE_SENSITIVE_INFORMATION structure is used to query or set per-directory case-sensitive information.
FILE_COMPLETION_INFORMATION	The FILE_COMPLETION_INFORMATION structure contains the port handle and key for an I/O completion port created for a file handle.
FILE_COMPRESSION_INFORMATION	The FILE_COMPRESSION_INFORMATION structure describes the state of a compressed data buffer.
FILE_DESIRED_STORAGE_CLASS_INFORMATION	Contains the information for the Desired Storage Class attribute.
FILE_DIRECTORY_INFORMATION	The FILE_DIRECTORY_INFORMATION structure is used to query detailed information for the files in a directory.
FILE_EA_INFORMATION	The FILE_EA_INFORMATION structure is used to query for the size of the extended attributes (EA) for a file.
FILE_FS_ATTRIBUTE_INFORMATION	The FILE_FS_ATTRIBUTE_INFORMATION structure is used to query attribute information for a file system.
FILE_FS_CONTROL_INFORMATION	The FILE_FS_CONTROL_INFORMATION structure is used to query or set control information for the files in a directory.
FILE_FS_DRIVER_PATH_INFORMATION	The FILE_FS_DRIVER_PATH_INFORMATION structure is used to query whether a given driver is in the I/O path for a file system volume.
FILE_FS_PERSISTENT_VOLUME_INFORMATION	The FILE_FS_PERSISTENT_VOLUME_INFORMATION structure is used to control persistent settings for a file system volume. Persistent settings persist on a file system volume between reboots of the computer.
FILE_FULL_DIR_INFORMATION	The FILE_FULL_DIR_INFORMATION structure is used to query detailed information for the files in a directory.
FILE_GET_EA_INFORMATION	The FILE_GET_EA_INFORMATION structure is used to query for extended-attribute (EA) information.
FILE_GET_QUOTA_INFORMATION	The FILE_GET_QUOTA_INFORMATION structure is used to query for quota information.

TITLE	DESCRIPTION
FILE_ID_BOTH_DIR_INFORMATION	The FILE_ID_BOTH_DIR_INFORMATION structure is used to query file reference number information for the files in a directory.
FILE_ID_EXTD_BOTH_DIR_INFORMATION	The FILE_ID_EXTD_BOTH_DIR_INFORMATION structure is used to query file reference number information for the files in a directory.
FILE_ID_FULL_DIR_INFORMATION	The FILE_ID_FULL_DIR_INFORMATION structure is used to query detailed information for the files in a directory.
FILE_ID_GLOBAL_TX_DIR_INFORMATION	The FILE_ID_GLOBAL_TX_DIR_INFORMATION structure contains information about transactional visibility for the files in a directory.
FILE_INTERNAL_INFORMATION	The FILE_INTERNAL_INFORMATION structure is used to query for the file system's 8-byte file reference number for a file.
FILE_LEVEL_TRIM	The FILE_LEVEL_TRIM structure contains an array of byte ranges to trim for a file.
FILE_LEVEL_TRIM_OUTPUT	The FILE_LEVEL_TRIM_OUTPUT structure contains the results of a trim operation performed by an FSCTL_FILE_LEVEL_TRIM request.
FILE_LEVEL_TRIM_RANGE	Contains the offset and length of a trim range for a file.
FILE_LINK_ENTRY_INFORMATION	The FILE_LINK_ENTRY_INFORMATION structure describes a single NTFS hard link to an existing file.
FILE_LINK_INFORMATION	The FILE_LINK_INFORMATION structure is used to create an NTFS hard link to an existing file.
FILE_LINKS_INFORMATION	The FILE_LINKS_INFORMATION structure is used to query NTFS hard links to an existing file.
FILE_MAILSLOT_QUERY_INFORMATION	The FILE_MAILSLOT_QUERY_INFORMATION structure contains information about a mailslot.
FILE_MAILSLOT_SET_INFORMATION	The FILE_MAILSLOT_SET_INFORMATION structure is used to set a value on a mailslot.
FILE_MODE_INFORMATION	The FILE_MODE_INFORMATION structure is used to query or set the access mode of a file.
FILE_NAMES_INFORMATION	A FILE_NAMES_INFORMATION structure used to query detailed information about the names of files in a directory.
FILE_NETWORK_PHYSICAL_NAME_INFORMATION	Contains the full UNC physical pathname for a file or directory on a remote file share.
FILE_OBJECTID_INFORMATION	The FILE_OBJECTID_INFORMATION structure is used to query for object ID information for the files in a directory on an NTFS volume.

TITLE	DESCRIPTION
FILE_PIPE_INFORMATION	The FILE_PIPE_INFORMATION structure contains information about a named pipe that is not specific to the local or the remote end of the pipe.
FILE_PIPE_LOCAL_INFORMATION	The FILE_PIPE_LOCAL_INFORMATION structure contains information about the local end of a named pipe.
FILE_PIPE_REMOTE_INFORMATION	The FILE_PIPE_REMOTE_INFORMATION structure contains information about the remote end of a named pipe.
FILE_PROVIDER_EXTERNAL_INFO_V0	This structure may be altered or unavailable. Instead, use FILE_PROVIDER_EXTERNAL_INFO_V1.
FILE_PROVIDER_EXTERNAL_INFO_V1	The FILE_PROVIDER_EXTERNAL_INFO_V1 structure defines metadata specific to files provided by WOF_PROVIDER_FILE.
FILE_QUOTA_INFORMATION	The FILE_QUOTA_INFORMATION structure is used to query or set per-user quota information for each of the files in a directory.
FILE_RENAME_INFORMATION	The FILE_RENAME_INFORMATION structure is used to rename a file.
FILE_REPARSE_POINT_INFORMATION	The FILE_REPARSE_POINT_INFORMATION structure is used to query for information about a reparse point.
FILE_STAT_INFORMATION	Contains metadata about a file.
FILE_STAT_LX_INFORMATION	The _FILE_STAT_LX_INFORMATION structure contains metadata about a file.
FILE_STORAGE_RESERVE_ID_INFORMATION	Queries and sets the storage reserve ID on a file or directory.
FILE_STREAM_INFORMATION	The FILE_STREAM_INFORMATION structure is used to enumerate the streams for a file.
FILE_ZERO_DATA_INFORMATION	Contains a range of a file to set to zeros.
FILE_ZERO_DATA_INFORMATION_EX	Contains a range of a file to set to zeros.
FS_FILTER_SECTION_SYNC_OUTPUT	The FS_FILTER_SECTION_SYNC_OUTPUT structure contains information describing the attributes of the section that is being created.
FSCTL_OFFLOAD_READ_INPUT	The FSCTL_OFFLOAD_READ_INPUT structure contains the input for the FSCTL_OFFLOAD_READ control code request.
FSCTL_OFFLOAD_READ_OUTPUT	The FSCTL_OFFLOAD_READ_OUTPUT structure contains the output for the FSCTL_OFFLOAD_READ control code request.
FSCTL_OFFLOAD_WRITE_INPUT	The FSCTL_OFFLOAD_WRITE_INPUT structure contains the input for the FSCTL_OFFLOAD_WRITE control code request.

TITLE	DESCRIPTION
FSCTL_OFFLOAD_WRITE_OUTPUT	The FSCTL_OFFLOAD_WRITE_OUTPUT structure contains the output for the FSCTL_OFFLOAD_WRITE control code request.
FSCTL_QUERY_VOLUME_NUMA_INFO_OUTPUT	The FSCTL_QUERY_VOLUME_NUMA_INFO_OUTPUT structure specifies the Non-Uniform Memory Architecture (NUMA) node the volume resides on.
FSRTL_ADVANCED_FCB_HEADER	The FSRTL_ADVANCED_FCB_HEADER structure contains context information that a file system maintains about a file.
FSRTL_COMMON_FCB_HEADER	Do not use the FSRTL_COMMON_FCB_HEADER structure outside of the FSRTL_ADVANCED_FCB_HEADER structure.
IO_PRIORITY_INFO	The IO_PRIORITY_INFO structure is used to hold thread priority information.
MEMORY_BASIC_INFORMATION	Contains information about a range of pages in the virtual address space of a process.
NETWORK_APP_INSTANCE_EA	
PUBLIC_OBJECT_BASIC_INFORMATION	The PUBLIC_OBJECT_BASIC_INFORMATION structure holds a subset of the full information that is available for an object.
PUBLIC_OBJECT_TYPE_INFORMATION	The PUBLIC_OBJECT_TYPE_INFORMATION structure holds the type name of the object.
QUERY_FILE_LAYOUT_INPUT	The QUERY_FILE_LAYOUT_INPUT structure selects which file layout entries are returned from a FSCTL_QUERY_FILE_LAYOUT request.
QUERY_FILE_LAYOUT_OUTPUT	The QUERY_FILE_LAYOUT_OUTPUT structure serves as a header for the file layout entries that are returned from a FSCTL_QUERY_FILE_LAYOUT request.
REFS_SMR_VOLUME_GC_PARAMETERS	The REFS_SMR_VOLUME_GC_PARAMETERS structure.
REFS_SMR_VOLUME_INFO_OUTPUT	The REFS_SMR_VOLUME_INFO_OUTPUT structure describes a Shingled Magnetic Recording (SMR) volume's current state on space and garbage collection activities.
REPARSE_DATA_BUFFER	The REPARSE_DATA_BUFFER structure contains reparse point data for a Microsoft reparse point.
REPARSE_DATA_BUFFER_EX	
REPARSE_GUID_DATA_BUFFER	The REPARSE_GUID_DATA_BUFFER structure contains reparse point data for a reparse point.
RTL_SEGMENT_HEAP_MEMORY_SOURCE	The RTL_SEGMENT_HEAP_MEMORY_SOURCE structure specifies the segment heap memory source.
RTL_SEGMENT_HEAP_PARAMETERS	The RTL_SEGMENT_HEAP_PARAMETERS structure contains the segment heap parameters.

TITLE	DESCRIPTION
SE_EXPORTS	The SeExports structure is a large external static SE_EXPORTS structure that defines a number of well-known security constants for privilege values and security identifiers.
SE_SID	The SE_SID union holds the maximum-sized valid Security Identifier (SID). The structure occupies 68-bytes and is suitable for stack allocation.
SE_TOKEN_USER	The SE_TOKEN_USER structure holds the maximum-sized valid user SID that can be returned by SeQueryInformationToken, GetTokenInformation, or ZwQueryInformationToken with the TokenUser information class. This structure is suitable for stack allocation.
SECURITY_DESCRIPTOR	The SECURITY_DESCRIPTOR structure contains the security information associated with an object. Drivers use this structure to set and query an object's security status.
SET_DAX_ALLOC_ALIGNMENT_HINT_INPUT	This structure is for internal use only and should not be called from your code.
SID	The security identifier (SID) structure is a variable-length structure used to uniquely identify users or groups.
SID_AND_ATTRIBUTES	The SID_AND_ATTRIBUTES structure represents a security identifier (SID) and its attributes. SIDs are used to uniquely identify users or groups.
SID_IDENTIFIER_AUTHORITY	The SID_IDENTIFIER_AUTHORITY structure represents the top-level authority of a security identifier (SID).
SYSTEM_ALARM_ACE	Reserved for future use.
SYSTEM_AUDIT_ACE	The SYSTEM_AUDIT_ACE structure defines an access-control entry (ACE) for the system access-control list (ACL) specifying what types of access cause system-level notifications.
SYSTEM_PROCESS_TRUST_LABEL_ACE	Reserved.
SYSTEM_RESOURCE_ATTRIBUTE_ACE	The SYSTEM_RESOURCE_ATTRIBUTE_ACE structure defines an access-control entry (ACE) for the system access-control list (ACL) specifying what rights a particular claim has to a resource.
SYSTEM_SCOPED_POLICY_ID_ACE	The SYSTEM_SCOPED_POLICY_ID_ACE structure defines an access-control entry (ACE) for the system access-control list (ACL) specifying rights for a scoped policy identifer.
TOKEN_CONTROL	The TOKEN_CONTROL structure contains information that identifies an access token.
TOKEN_DEFAULT_DACL	The TOKEN_DEFAULT_DACL structure specifies a discretionary access-control list (DACL).

TITLE	DESCRIPTION
TOKEN_GROUPS	TOKEN_GROUPS contains information about the group security identifiers (SID) in an access token.
TOKEN_GROUPS_AND_PRIVILEGES	TOKEN_GROUPS_AND_PRIVILEGES contains information about the group security identifiers (SIDs) and privileges in an access token.
TOKEN_ORIGIN	The TOKEN_ORIGIN structure contains information about the origin of the logon session.
TOKEN_OWNER	TOKEN_OWNER contains the default owner security identifier (SID) that will be applied to newly created objects.
TOKEN_PRIMARY_GROUP	TOKEN_PRIMARY_GROUP specifies a group security identifier (SID) for an access token.
TOKEN_PRIVILEGES	TOKEN_PRIVILEGES contains information about a set of privileges for an access token.
TOKEN_SOURCE	TOKEN_SOURCE identifies the source of an access token.
TOKEN_STATISTICS	TOKEN_STATISTICS contains information about an access token. A driver can retrieve this information by calling SeQueryInformationToken or ZwQueryInformationToken.
TOKEN_USER	TOKEN_USER identifies the user associated with an access token.
VIRTUAL_STORAGE_SET_BEHAVIOR_INPUT	
VIRTUALIZATION_INSTANCE_INFO_INPUT_EX	
WIM_PROVIDER_ADD_OVERLAY_INPUT	A new Windows Image File (WIM) data source is added to the WIM provider with the WIM_PROVIDER_ADD_OVERLAY_INPUT structure.
WIM_PROVIDER_EXTERNAL_INFO	The WIM_PROVIDER_EXTERNAL_INFO structure holds the identifier and status information for the Windows Image File (WIM) external backing provider.
WIM_PROVIDER_OVERLAY_ENTRY	Contains the a Windows Image Format (WIM) file configuration information for a data source entry. It is used to identify specific WIM file names and indices that supply data to externally backed files on a volume.
WIM_PROVIDER_REMOVE_OVERLAY_INPUT	A Windows Image File (WIM) data source to remove from the WIM provider is specified in the WIM_PROVIDER_REMOVE_OVERLAY_INPUT structure.
WIM_PROVIDER_SUSPEND_OVERLAY_INPUT	A Windows Image File (WIM) data source to suspend from the WIM provider is specified in the WIM_PROVIDER_SUSPEND_OVERLAY_INPUT structure.

TITLE	DESCRIPTION
WIM_PROVIDER_UPDATE_OVERLAY_INPUT	A current Windows Image File (WIM) data source is updated with a new WIM file using the FSCTL_UPDATE_OVERLAY control request with a WIM_PROVIDER_UPDATE_OVERLAY_INPUT structure.
WOF_EXTERNAL_FILE_ID	The WOF_EXTERNAL_FILE_ID structure contains a file ID that is used to open a handle to a mini-filter or driver.
WOF_EXTERNAL_INFO	The WOF_EXTERNAL_INFO structure identifies a file backing provider and the overlay service version it supports.
WOF_VERSION_INFO	The WOF_VERSION_INFO structure contains the version corresponding to the driver supporting a given provider.

Enumerations

TITLE	DESCRIPTION
CSV_CONTROL_OP	Specifies the type of CSV control operation to use with the FSCTL_CSV_CONTROL control code.
FILE_STORAGE_TIER_CLASS	Defines values for the type of desired storage class.
MEMORY_INFORMATION_CLASS	Defines classes of memory information that can be retrieved by using the ZwQueryVirtualMemory function.
OBJECT_INFORMATION_CLASS	The OBJECT_INFORMATION_CLASS enumeration type represents the type of information to supply about an object.
REFS_SMR_VOLUME_GC_ACTION	The REFS_SMR_VOLUME_GC_ACTION enum contains the available garbage collection commands for FSCTL_SET_REFS_SMR_VOLUME_GC_PARAMETERS.
REFS_SMR_VOLUME_GC_METHOD	The REFS_SMR_VOLUME_GC_METHOD enum specifies the garbage collection method or strategy for FSCTL_SET_REFS_SMR_VOLUME_GC_PARAMETERS.
REFS_SMR_VOLUME_GC_STATE	The REFS_SMR_VOLUME_GC_STATE enum specifies the garbage collection's current state.
RTL_MEMORY_TYPE	Defines the memory type the heap is supposed to use.
SID_NAME_USE	The SID_NAME_USE enumeration type contains values that specify the type of a security identifier (SID).
STORAGE_RESERVE_ID	Defines the storage reserve ID of a file, directory, or storage reserve area.
TOKEN_INFORMATION_CLASS	The TOKEN_INFORMATION_CLASS enumeration type contains values that specify the type of information being assigned to or retrieved from an access token.

TITLE	DESCRIPTION
TOKEN_TYPE	The TOKEN_TYPE enumeration type contains values that differentiate between a primary token and an impersonation token.
VIRTUAL_STORAGE_BEHAVIOR_CODE	Configures file system-specific behaviors used on virtual storage devices.

FILE_ACCESS_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_ACCESS_INFORMATION** structure is used to query for or set the access rights of a file.

Syntax

```
typedef struct _FILE_ACCESS_INFORMATION {
  ACCESS_MASK AccessFlags;
} FILE_ACCESS_INFORMATION, *PFILE_ACCESS_INFORMATION;
```

Members

`AccessFlags`

Flags that specify a set of access rights in the access mask of an access control entry. This member is a value of type ACCESS_MASK.

Remarks

This structure is used by the ZwQueryInformationFile routine.

The *AccessFlags* parameter is an access mask that encodes the user rights to a file object. An access mask can be used to encode the rights to an object that is assigned to a user or a user group, or to encode the requested access when a user opens an object. For more information, see ACCESS_MASK.

Requirements

Minimum supported client	Supported in Windows XP and later versions of Windows.
Header	ntifs.h (include Ntifs.h, Fltkernel.h)

See Also

ACCESS_MASK

ZwQueryInformationFile

FILE_ALL_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_ALL_INFORMATION** structure is a container for several **FILE_*XXX*_INFORMATION** structures.

Syntax

```
typedef struct _FILE_ALL_INFORMATION {
  FILE_BASIC_INFORMATION     BasicInformation;
  FILE_STANDARD_INFORMATION  StandardInformation;
  FILE_INTERNAL_INFORMATION  InternalInformation;
  FILE_EA_INFORMATION        EaInformation;
  FILE_ACCESS_INFORMATION    AccessInformation;
  FILE_POSITION_INFORMATION  PositionInformation;
  FILE_MODE_INFORMATION      ModeInformation;
  FILE_ALIGNMENT_INFORMATION AlignmentInformation;
  FILE_NAME_INFORMATION      NameInformation;
} FILE_ALL_INFORMATION, *PFILE_ALL_INFORMATION;
```

Members

`BasicInformation`

Contains basic information about the file, which includes the file attributes and the file creation time. This member is a FILE_BASIC_INFORMATION structure.

`StandardInformation`

Contains standard information about a file, which includes the file allocation size, the end-of-file offset, and whether the file is a directory. This member is a FILE_STANDARD_INFORMATION structure.

`InternalInformation`

Contains the 8-byte file reference number for the file. This member is a FILE_INTERNAL_INFORMATION structure.

`EaInformation`

Specifies the size of the extended attributes of the file. This member is a FILE_EA_INFORMATION structure.

`AccessInformation`

Specifies the client's access rights to the file. This member is a FILE_ACCESS_INFORMATION structure.

`PositionInformation`

Specifies the current file position. This member is a FILE_POSITION_INFORMATION structure.

`ModeInformation`

Specifies the access mode in which the file was created or opened. This member is a FILE_MODE_INFORMATION structure.

`AlignmentInformation`

Specifies the device's memory address alignment requirement for data transfers. This member is a

FILE_ALIGNMENT_INFORMATION structure.

`NameInformation`

Contains the file name. This member is a FILE_NAME_INFORMATION structure. This structure contains the first character in the file name string. The additional characters in the file name string immediately follow the structure. To accommodate the full file name, the buffer that is allocated to contain a **FILE_ALL_INFORMATION** structure must be large enough to contain both the structure and the part of the file name string that follows the structure.

Remarks

This structure is used by the ZwQueryInformationFile routine.

FILE_ALL_INFORMATION combines several file-information structures into a single structure to reduce the number of queries that are required to obtain information about a file.

Requirements

Minimum supported client	Supported in Windows XP and later versions of Windows.
Header	ntifs.h (include Ntifs.h, Fltkernel.h)

ZwQueryInformationFile

FILE_EA_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_EA_INFORMATION** structure is used to query for the size of the extended attributes (EA) for a file.

Syntax

```
typedef struct _FILE_EA_INFORMATION {
  ULONG EaSize;
} FILE_EA_INFORMATION, *PFILE_EA_INFORMATION;
```

Members

`EaSize`

Specifies the combined length, in bytes, of the extended attributes for the file.

Remarks

This structure is used by the ZwQueryInformationFile routine.

An extended attribute is a piece of application-specific metadata that an application can associate with a file that is not part of the file's data. In addition to the built-in attributes of a file, such as creation and modification times, applications can add non-file system attributes, such as the author's name and a description of the file content.

Requirements

Minimum supported client	Supported in Windows XP and later versions of Windows.
Header	ntifs.h (include Ntifs.h, Fltkernel.h)

ZwQueryInformationFile

FILE_MODE_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_MODE_INFORMATION** structure is used to query or set the access mode of a file.

Syntax

```
typedef struct _FILE_MODE_INFORMATION {
  ULONG Mode;
} FILE_MODE_INFORMATION, *PFILE_MODE_INFORMATION;
```

Members

`Mode`

Specifies the mode in which the file will be accessed following a create-file or open-file operation. This parameter is either zero or the bitwise OR of one or more of the following file option flags:

FILE_WRITE_THROUGH

Any system services, file system drivers (FSDs), and drivers that write data to the file must actually transfer the data into the file before any requested write operation is considered complete.

FILE_SEQUENTIAL_ONLY

All accesses to the file will be sequential.

FILE_NO_INTERMEDIATE_BUFFERING

The file cannot be cached or buffered in a driver's internal buffers.

FILE_SYNCHRONOUS_IO_ALERT

All operations on the file are performed synchronously. Any wait on behalf of the caller is subject to premature termination from alerts. This flag also causes the I/O system to maintain the file position context.

FILE_SYNCHRONOUS_IO_NONALERT

All operations on the file are performed synchronously. Wait requests in the system that must synchronize I/O queuing and completion are not subject to alerts. This flag also causes the I/O system to maintain the file position context.

FILE_DELETE_ON_CLOSE

Delete the file when the last handle to the file is closed.

These flags are defined in the Wdm.h header file. For more information, see the Remarks section.

Remarks

This structure contains a set of flags that specify the mode in which the file can be accessed. These flags are a subset of the options that can be specified in the *CreateOptions* parameter of the IoCreateFile routine.

This structure is used by the ZwQueryInformationFile routine.

Requirements

Minimum supported client	Supported in Windows XP and later versions of Windows.
Header	ntifs.h (include Ntifs.h, Fltkernel.h)

ZwQueryInformationFile

MEMORY_BASIC_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

Contains information about a range of pages in the virtual address space of a process. The ZwQueryVirtualMemory routine uses this structure.

Syntax

```
typedef struct _MEMORY_BASIC_INFORMATION {
  PVOID  BaseAddress;
  PVOID  AllocationBase;
  ULONG  AllocationProtect;
  SIZE_T RegionSize;
  ULONG  State;
  ULONG  Protect;
  ULONG  Type;
} MEMORY_BASIC_INFORMATION, *PMEMORY_BASIC_INFORMATION;
```

Members

`BaseAddress`

A pointer to the base address of the region of pages.

`AllocationBase`

A pointer to the base address of a range of allocated pages. The page pointed to by the **BaseAddress** member is contained within this allocation range.

`AllocationProtect`

The memory protection option when the region was initially allocated. This member can be one of the following constants defined in wdm.h, or 0 if the caller does not have access.

VALUE	MEANING
PAGE_NOACCESS 0x01	No access to the region of pages is allowed. An attempt to read, write, or execute within the region results in an access violation.
PAGE_EXECUTE 0x10	Execute access to the region of pages is allowed. An attempt to read or write within the region results in an access violation.

PAGE_READONLY 0x02	Read-only and execute access to the region of pages is allowed. An attempt to write within the region results in an access violation.
PAGE_READWRITE 0x04	Read, write, and execute access to the region of pages is allowed. If write access to the underlying section is allowed, then a single copy of the pages are shared. Otherwise, the pages are shared read-only/copy-on-write.
PAGE_GUARD 0x100	Read, write, and execute access to the region of pages is allowed; however, access to the region causes a "guard region entered" condition to be raised in the subject process.
PAGE_NOCACHE 0x200	Disable the placement of committed pages into the data cache.
PAGE_WRITECOMBINE 0x400	Disable the placement of committed pages into the data cache, combine the writes as well.

`RegionSize`

The size of the region in bytes beginning at the base address in which all pages have identical attributes.

`State`

The state of the pages in the region. This member can be one of the following values.

STATE	MEANING

MEM_COMMIT 0x1000	Indicates committed pages for which physical storage has been allocated, either in memory or in the paging file on disk.
MEM_FREE 0x10000	Indicates free pages not accessible to the calling process and available to be allocated.
MEM_RESERVE 0x2000	Indicates reserved pages where a range of the process's virtual address space is reserved without any physical storage being allocated.

`Protect`

The access protection of the pages in the region. This member is one of the values listed for the **AllocationProtect** member.

`Type`

The type of pages in the region. The following types are defined.

TYPE	MEANING
MEM_IMAGE 0x1000000	Indicates that the memory pages within the region are mapped into the view of an image section.
MEM_MAPPED 0x40000	Indicates that the memory pages within the region are mapped into the view of a section.

ME **M_P** **RIV** **ATE** 0x2 000 0	Indicates that the memory pages within the region are private (that is, not shared by other processes).

Requirements

Minimum supported client	Available starting with Windows 10.
Header	ntifs.h

ZwQueryVirtualMemory

MEMORY_INFORMATION_CLASS Enumeration

1/30/2019 • 2 minutes to read • Edit Online

Defines classes of memory information that can be retrieved by using the ZwQueryVirtualMemory function.

Syntax

```
typedef enum _MEMORY_INFORMATION_CLASS {
  MemoryBasicInformation
} MEMORY_INFORMATION_CLASS;
```

Constants

MemoryBasicInformation	Memory information described in the MEMORY_BASIC_INFORMATION structure will be retrieved.

Remarks

Currently, only the **MemoryBasicInformation** value is supported for use with the ZwQueryVirtualMemory routine.

Requirements

Minimum supported client	Available starting with Windows 10.
Header	ntifs.h

See Also

ZwQueryVirtualMemory

IoGetAttachedDeviceReference function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetAttachedDeviceReference** routine returns a pointer to the highest level device object in a driver stack and increments the reference count on that object.

Syntax

```
PDEVICE_OBJECT IoGetAttachedDeviceReference(
  PDEVICE_OBJECT DeviceObject
);
```

Parameters

`DeviceObject`

Pointer to the device object for which the topmost attached device object is retrieved.

Return Value

IoGetAttachedDeviceReference returns a pointer to the highest level device object in a stack of attached device objects after incrementing the reference count on the object.

Remarks

If the device object at *DeviceObject* has no device objects attached to it, *DeviceObject* and the returned pointer are equal.

Device driver writers must ensure that when they have completed all operations that required them to make this call, that they call ObDereferenceObject with the device object pointer returned by this routine. Failure to do so will prevent the system from freeing or deleting the device object because of an outstanding reference count.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"
DDI compliance rules	DanglingDeviceObjectReference, HwStorPortProhibitedDDIs

ObDereferenceObject

IoGetConfigurationInformation function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetConfigurationInformation** routine returns a pointer to the I/O manager's global configuration information structure, which contains the current values for how many physical disk, floppy, CD-ROM, tape, SCSI HBA, serial, and parallel devices have device objects created to represent them by drivers as they are loaded.

Syntax

```
PCONFIGURATION_INFORMATION IoGetConfigurationInformation(

);
```

Parameters

This function has no parameters.

Return Value

IoGetConfigurationInformation returns a pointer to the configuration information structure. This structure is defined as follows:

```
typedef struct _CONFIGURATION_INFORMATION {

    //
    // This field indicates the total number of disks in the system. This
    // number should be used by the driver to determine the names of new
    // disks. This field should be updated by the driver as it finds new
    // disks.
    //

    ULONG DiskCount;                // Count of hard disks thus far
    ULONG FloppyCount;              // Count of floppy disks thus far
    ULONG CdRomCount;               // Count of CD-ROM drives thus far
    ULONG TapeCount;                // Count of tape drives thus far
    ULONG ScsiPortCount;            // Count of SCSI port adapters thus far
    ULONG SerialCount;              // Count of serial devices thus far
    ULONG ParallelCount;            // Count of parallel devices thus far

    //
    // These next two fields indicate ownership of the two I/O address
    // spaces that are used by WD1003-compatible disk controllers.
    //

    BOOLEAN AtDiskPrimaryAddressClaimed;    // 0x1F0 - 0x1FF
    BOOLEAN AtDiskSecondaryAddressClaimed;  // 0x170 - 0x17F

    //
    // Indicates the structure version, as anything value beyond this will have been added.
    // Use the structure size as the version.
    //

    ULONG Version;

    //
    // Indicates the total number of medium changer devices in the system.
    // This field will be updated by the drivers as it determines that
    // new devices have been found and will be supported.
    //

    ULONG MediumChangerCount;

} CONFIGURATION_INFORMATION, *PCONFIGURATION_INFORMATION;
```

Remarks

Certain types of device drivers can use the configuration information structure's values to construct device object names with appropriate digit suffixes when each driver creates its device objects. Note that the digit suffix for device object names is a zero-based count, while the counts maintained in the configuration information structure represent the number of device objects of a particular type already created. That is, the configuration information counts are one-based.

Any driver that calls **IoGetConfigurationInformation** must increment the count for its kind of device in this structure when it creates a device object to represent a physical device.

The system-supplied SCSI port driver supplies the count of SCSI HBAs present in the computer. SCSI class drivers can read this value to determine how many HBA-specific miniport drivers might control a SCSI bus with an attached device of the class driver's type.

The configuration information structure also contains a value indicating whether an already loaded driver has claimed either of the "AT" disk I/O address ranges.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Ntddk.h, Ntifs.h)

IoSetStartIoAttributes function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetStartIoAttributes** routine sets attributes for the driver's StartIo routine.

Syntax

```
void IoSetStartIoAttributes(
  PDEVICE_OBJECT DeviceObject,
  BOOLEAN        DeferredStartIo,
  BOOLEAN        NonCancelable
);
```

Parameters

`DeviceObject`

Pointer to the device object for the driver's device.

`DeferredStartIo`

If **TRUE**, the I/O manager will defer any call to the driver's StartIo routine while the driver is already inside the routine. In particular, if the *StartIo* routine calls IoStartNextPacket, the *StartIo* routine will not be called again until the current invocation completes. The default is **FALSE**.

`NonCancelable`

If **TRUE**, the IRP cannot be canceled once it has been dequeued by a call to **IoStartNextPacket**. The default is **FALSE**. Drivers that set this member to **FALSE** must synchronize their IRP handling with the cancel spin lock.

Return Value

None

Requirements

Minimum supported client	Available for Microsoft Windows XP and later versions of the Windows operating system.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoSizeOfIrp macro

1/25/2019 • 2 minutes to read • Edit Online

The **IoSizeOfIrp** routine determines the size in bytes for an IRP, given the number of stack locations in the IRP.

Syntax

```
void IoSizeOfIrp(
   StackSize
);
```

Parameters

`StackSize`

Specifies the number of stack locations for the IRP.

Return Value

IoSizeOfIrp returns the size, in bytes, of the IRP.

Remarks

The input *StackSize* value is either that of the next-lower driver's device object or one more than that value.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Any level

See Also

IoAllocateIrp

IoMakeAssociatedIrp

IoStartNextPacket function

1/25/2019 • 2 minutes to read • Edit Online

The **IoStartNextPacket** routine dequeues the next IRP, if any, from the given device object's associated device queue and calls the driver's StartIo routine.

Syntax

```
void IoStartNextPacket(
  PDEVICE_OBJECT DeviceObject,
  BOOLEAN        Cancelable
);
```

Parameters

`DeviceObject`

Pointer to the device object for which the IRP is to be dequeued.

`Cancelable`

Specifies whether IRPs in the device queue can be canceled.

Return Value

None

Remarks

If there are no IRPs currently in the device queue for the target *DeviceObject*, this routine simply returns control to the caller.

If the driver passed a pointer to a cancel routine when it called **IoStartPacket**, it should pass **TRUE** in the *Cancelable* parameter. If *Cancelable* is **TRUE**, the I/O manager will use the cancel spin lock to protect the device queue and the current IRP.

Drivers that do not have a *StartIo* routine cannot call **IoStartNextPacket**.

Drivers that call **IoStartNextPacket** from their *StartIo* routine should be aware of recursion issues. If a driver can call **IoStartNextPacket** on a large number of requests in succession from its *StartIo* routine (for example, when a device error occurs and the driver is clearing out it device queue), you should set the *DeferredStartIo* attribute for the device by using IoSetStartIoAttributes routine. This attribute ensures that the next packet will not be issued until the previous *StartIo* call returns.

Callers of **IoStartNextPacket** must be running at IRQL = DISPATCH_LEVEL. Usually, this routine is called from a device driver's DpcForIsr or CustomDpc routine, both of which are run at IRQL = DISPATCH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	DISPATCH_LEVEL (see Remarks section)
DDI compliance rules	IrqlDispatch, SpinLockSafe, StartIoRecursion, HwStorPortProhibitedDDIs, IrqlDispatch(storport), SpinLockSafe(storport)

DEVICE_OBJECT

IoSetStartIoAttributes

IoStartNextPacketByKey

IoStartPacket

IoStartNextPacketByKey function

1/25/2019 • 2 minutes to read • Edit Online

The **IoStartNextPacketByKey** routine dequeues the next I/O request packet from the specified device object's associated device queue according to a specified sort-key value and calls the driver's StartIo routine with that IRP.

Syntax

```
void IoStartNextPacketByKey(
  PDEVICE_OBJECT DeviceObject,
  BOOLEAN        Cancelable,
  ULONG          Key
);
```

Parameters

`DeviceObject`

Pointer to the device object for which the IRP is to be dequeued.

`Cancelable`

Specifies whether IRPs in the device queue can be canceled.

`Key`

Specifies the sort key that determines which entry to remove from the queue.

Return Value

None

Remarks

If there are no IRPs currently in the device queue for the target device object, this routine simply returns control to the caller.

If the driver passed a pointer to a cancel routine when it called **IoStartPacket**, it should pass **TRUE** in the *Cancelable* parameter. If *Cancelable* is **TRUE**, the I/O manager will use the cancel spin lock to protect the device queue and the current IRP.

Drivers that do not have a *StartIo* routine cannot call **IoStartNextPacketByKey**.

Callers of **IoStartNextPacketByKey** must be running at IRQL <= DISPATCH_LEVEL. Usually, this routine is called from a device driver's DpcForIsr or CustomDpc routine, both of which are run at IRQL = DISPATCH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

DEVICE_OBJECT

IoStartNextPacket

IoStartPacket

IoStartPacket function

1/25/2019 • 2 minutes to read • Edit Online

The **IoStartPacket** routine calls the driver's StartIo routine with the given IRP or inserts the IRP into the device queue associated with the given device object if the device is already busy.

Syntax

```
void IoStartPacket(
  PDEVICE_OBJECT DeviceObject,
  PIRP           Irp,
  PULONG         Key,
  PDRIVER_CANCEL CancelFunction
);
```

Parameters

`DeviceObject`

Pointer to the target device object for the IRP.

`Irp`

Pointer to the IRP to be processed.

`Key`

Pointer to a value that determines where to insert the packet into the device queue. If this is zero, the packet is inserted at the tail of the device queue.

`CancelFunction`

Specifies the entry point for a driver-supplied Cancel routine.

Return Value

None

Remarks

If the driver is already busy processing a request for the target device object, then the packet is queued in the device queue. Otherwise, this routine calls the driver's *StartIo* routine with the specified IRP.

If a non-NULL *CancelFunction* pointer is supplied, it is set in the IRP so the driver's *Cancel* routine is called if the IRP is canceled before its completion.

Drivers that do not have a *StartIo* routine cannot call **IoStartPacket**.

Callers of **IoStartPacket** must be running at IRQL <= DISPATCH_LEVEL. Usually, this routine is called from a device driver's Dispatch routine at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoStartTimer function

1/25/2019 • 2 minutes to read • Edit Online

The **IoStartTimer** routine enables the timer associated with a given device object so the driver-supplied IoTimer routine is called once per second.

Syntax

```
void IoStartTimer(
  PDEVICE_OBJECT DeviceObject
);
```

Parameters

`DeviceObject`

Pointer to a device object whose timer routine is to be called.

Return Value

None

Remarks

The driver must already have set up the IoTimer routine for the *DeviceObject* by calling **IoInitializeTimer**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Windows
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

KeSetTimer

IoStopTimer function

1/25/2019 • 2 minutes to read • Edit Online

The **IoStopTimer** routine disables the timer for a specified device object so the driver-supplied IoTimer routine is not called.

Syntax

```
void IoStopTimer(
  PDEVICE_OBJECT DeviceObject
);
```

Parameters

`DeviceObject`

Pointer to the device object with which the IoTimer routine is associated.

Return Value

None

Remarks

The driver-supplied IoTimer routine can be reenabled with a call to **IoStartTimer**.

Do not call **IoStopTimer** from within the *IoTimer* routine.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Windows

IoStartTimer

IoWriteErrorLogEntry function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWriteErrorLogEntry** routine queues a given error log packet to the system error logging thread.

Syntax

```
void IoWriteErrorLogEntry(
  PVOID ElEntry
);
```

Parameters

`ElEntry`

Pointer to the error log packet the driver has allocated with IoAllocateErrorLogEntry and filled in by the caller.

Return Value

None

Remarks

IoWriteErrorLogEntry frees the error log entry. Drivers must not call **IoFreeErrorLogEntry** on a log entry that they have already passed to **IoWriteErrorLogEntry**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

KeGetProcessorIndexFromNumber function

1/25/2019 • 2 minutes to read • Edit Online

The **KeGetProcessorIndexFromNumber** routine converts a group number and a group-relative processor number to a systemwide processor index.

Syntax

```
ULONG KeGetProcessorIndexFromNumber(
  PPROCESSOR_NUMBER ProcNumber
);
```

Parameters

`ProcNumber`

A pointer to a caller-allocated PROCESSOR_NUMBER structure that contains a group number and a group-relative processor number.

Return Value

KeGetProcessorIndexFromNumber returns a systemwide processor index if the call is successful. If *ProcNumber* points to an invalid **PROCESSOR_NUMBER** value, the routine returns INVALID_PROCESSOR_INDEX, which is defined in the Wdm.h header file.

Remarks

This routine accepts as input a **PROCESSOR_NUMBER** structure that identifies a processor by its group number and its processor number within the group. The return value is a processor index that identifies the processor across the entire multiprocessor system.

For example, if a multiprocessor system contains two groups, and each group contains 64 logical processors, the processor numbers in each group range from 0 to 63, but the systemwide processor indexes range from 0 to 127.

To obtain the total number of active logical processors in the system, call the KeQueryActiveProcessorCountEx routine and set this routine's *GroupNumber* parameter to ALL_PROCESSOR_GROUPS.

The KeGetProcessorNumberFromIndex routine converts a systemwide processor index to a group number and a group-relative processor number.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeQueryActiveProcessorCountEx

PROCESSOR_NUMBER

KeGetProcessorNumberFromIndex function

1/25/2019 • 2 minutes to read • Edit Online

The **KeGetProcessorNumberFromIndex** routine converts a systemwide processor index to a group number and a group-relative processor number.

Syntax

```
NTSTATUS KeGetProcessorNumberFromIndex(
  ULONG             ProcIndex,
  PPROCESSOR_NUMBER ProcNumber
);
```

Parameters

`ProcIndex`

A systemwide processor index. If a multiprocessor system contains a total of *n* logical processors, valid processor indexes range from 0 to *n*-1.

`ProcNumber`

A pointer to a caller-allocated PROCESSOR_NUMBER structure into which the routine writes the group number and group-relative processor number of the processor that is identified by *ProcIndex*.

Return Value

KeGetProcessorNumberFromIndex returns STATUS_SUCCESS if the call is successful. Possible error return values include the following:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The *ProcIndex* parameter value is not a valid processor index.

Remarks

This routine accepts as input a processor index that identifies the processor across the entire multiprocessor system. The output value is a **PROCESSOR_NUMBER** structure that identifies a processor by its group number and its processor number within the group.

For example, if a multiprocessor system contains two groups, and each group contains 64 logical processors, the processor numbers in each group range from 0 to 63, but the systemwide processor indexes range from 0 to 127.

To obtain the total number of active logical processors in the system, call the KeQueryActiveProcessorCountEx routine.

The KeGetProcessorIndexFromNumber routine converts a group number and a group-relative processor number to a systemwide processor index.

Examples

The following code example uses the **KeQueryActiveProcessorCountEx** and **KeGetProcessorNumberFromIndex** routines to enumerate all active logical processors in the system:

```
ULONG Count;
ULONG ProcIndex;
PROCESSOR_NUMBER ProcNumber;

Count = KeQueryActiveProcessorCountEx(ALL_PROCESSOR_GROUPS);
for (ProcIndex = 0; ProcIndex < Count; ProcIndex += 1)
{
    KeGetProcessorNumberFromIndex(ProcIndex, &ProcNumber);

    // Do something with the contents of ProcNumber.
    ...
}
```

The constant value ALL_PROCESSOR_GROUPS is defined in Winnt.h and Ntdef.h.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	ntifs.h (include Ntddk.h, Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

PROCESSOR_NUMBER

KeQueryPerformanceCounter function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryPerformanceCounter** routine retrieves the current value and frequency of the performance counter.

Use **KeQueryPerformanceCounter** to acquire high resolution (<1us) time stamps for time interval measurements.

Syntax

```
NTHALAPI LARGE_INTEGER KeQueryPerformanceCounter(
  PLARGE_INTEGER PerformanceFrequency
);
```

Parameters

`PerformanceFrequency`

A pointer to a variable to which **KeQueryPerformanceCounter** writes the performance counter frequency, in ticks per second. This parameter is optional and can be NULL if the caller does not need the counter frequency value.

Return Value

KeQueryPerformanceCounter returns the performance counter value in units of ticks.

Remarks

KeQueryPerformanceCounter returns a 64-bit integer that represents the current value of a high-resolution monotonically nondecreasing counter.

To obtain the frequency of the performance counter, specify a non-**NULL** pointer value for the *PerformanceFrequency* parameter. The frequency of the performance counter is fixed at system boot and is consistent across all processors. Therefore, a driver can cache the frequency of the performance counter during initialization.

For more info about this function and its usage, see Acquiring high-resolution time stamps.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Hal.lib
DLL	Hal.dll

IRQL	Any level

KeSetKernelStackSwapEnable function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSetKernelStackSwapEnable** routine enables and disables swapping of the caller's stack to disk.

Syntax

```
BOOLEAN KeSetKernelStackSwapEnable(
  BOOLEAN Enable
);
```

Parameters

`Enable`

Specifies whether to enable swapping of the stack that belongs to the calling thread. If **TRUE**, swapping is enabled and the contents of the stack can be paged in and out of memory. If **FALSE**, swapping is disabled and the stack is memory-resident.

Return Value

KeSetKernelStackSwapEnable returns a BOOLEAN value that indicates whether stack swapping was enabled at the time that the call was initiated. This value is **TRUE** if stack swapping was previously enabled and is **FALSE** if it was disabled.

Remarks

A kernel-mode driver can call this routine to control whether its stack is pageable or locked in memory.

Stack swapping can occur only if the thread is in a wait state that was caused by a request from a user-mode application. Stack swapping never occurs for wait states that are initiated by kernel-mode components, regardless of whether stack swapping is enabled.

It is not typically necessary to disable stack swapping. Do this only in rare cases. For an example that discusses alternatives to disabling stack swapping, see the following Examples section.

In a call to a kernel-mode wait routine, such as KeWaitForSingleObject, the caller specifies a *WaitMode* parameter to indicate whether the caller waits in kernel mode or user mode. If *WaitMode* = **UserMode**, and if the wait duration is sufficiently long, the memory manager might page out sections of the stack that belongs to the waiting thread. However, if the stack contains data items that must remain memory-resident for the duration of the wait, the thread can prevent the stack from being paged out by calling **KeSetKernelStackSwapEnable** and specifying *Enable* = **FALSE**.

A thread must not exit (terminate) while stack swapping is disabled or a system bug check will occur.

Examples

In the following code example, a driver thread allocates an event on its stack and calls **KeSetKernelStackSwap** to temporarily lock the stack in memory until the event is signaled. After the wait completes, the thread calls **KeSetKernelStackSwap** again, if necessary, to restore the original stack-swapping state of the thread.

```
KEVENT event;
BOOLEAN oldSwapEnable;
NTSTATUS status;

oldSwapEnable = KeSetKernelStackSwapEnable(FALSE);

KeInitializeEvent(&event, SynchronizationEvent, FALSE);

//
// TO DO: Insert code here to pass the event to another thread
// that will set the event to the signaled state.
//
...

status = KeWaitForSingleObject(&event, UserRequest, KernelMode, FALSE, NULL);

if (oldSwapEnable)
{
    KeSetKernelStackSwapEnable(TRUE);
}
```

An event object must be memory-resident while it can be set to a signaled or nonsignaled state, or while a thread waits on the event. For more information, see Defining and Using an Event Object. Frequently, the use of the **KeSetKernelStackSwap** routine is unnecessary and can be avoided by allocating only pageable data items on the stack. In the previous example, the driver thread must lock the stack because the event object is allocated on the stack. A better alternative might be to simply allocate the event from nonpaged pool.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Ntifs.h, Fltkernel.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeInitializeEvent

KeWaitForSingleObject

KeStallExecutionProcessor function

1/25/2019 • 2 minutes to read • Edit Online

The **KeStallExecutionProcessor** routine stalls the caller on the current processor for a specified time interval.

Syntax

```
NTHALAPI VOID KeStallExecutionProcessor(
  ULONG MicroSeconds
);
```

Parameters

`MicroSeconds`

Specifies the number of microseconds to stall.

Return Value

None

Remarks

KeStallExecutionProcessor is a processor-dependent routine that busy-waits for at least the specified number of microseconds, but not significantly longer.

This routine is for use by device drivers and other software that must wait for an interval of less than a clock tick but more than for a few instructions. If you use this routine you must minimize the stall interval, typically to less than 50 microseconds. If a driver must wait for a longer interval, you should use a different synchronization technique.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Hal.lib
DLL	Hal.dll

NtAllocateVirtualMemory function

1/25/2019 • 6 minutes to read • Edit Online

The **NtAllocateVirtualMemory** routine reserves, commits, or both, a region of pages within the user-mode virtual address space of a specified process.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtAllocateVirtualMemory(
  HANDLE    ProcessHandle,
  PVOID     *BaseAddress,
  ULONG_PTR ZeroBits,
  PSIZE_T   RegionSize,
  ULONG     AllocationType,
  ULONG     Protect
);
```

Parameters

`ProcessHandle`

A handle for the process for which the mapping should be done. Use the **NtCurrentProcess** macro, defined in Ntddk.h, to specify the current process.

`BaseAddress`

A pointer to a variable that will receive the base address of the allocated region of pages. If the initial value of this parameter is non-**NULL**, the region is allocated starting at the specified virtual address rounded down to the next host page size address boundary. If the initial value of this parameter is **NULL**, the operating system will determine where to allocate the region.

`ZeroBits`

The number of high-order address bits that must be zero in the base address of the section view. Used only when the operating system determines where to allocate the region, as when *BaseAddress* is **NULL**. Note that when ZeroBits is larger than 32, it becomes a bitmask.

`RegionSize`

A pointer to a variable that will receive the actual size, in bytes, of the allocated region of pages. The initial value of this parameter specifies the size, in bytes, of the region and is rounded up to the next host page size boundary. **RegionSize* cannot be zero on input.

`AllocationType`

A bitmask containing flags that specify the type of allocation to be performed. The following table describes these flags.

FLAG	MEANING
MEM_COMMIT	The specified region of pages is to be committed. One of MEM_COMMIT, MEM_RESET, or MEM_RESERVE must be set.

MEM_PHYSICAL	Allocate physical memory. This flag is solely for use with Address Windowing Extensions (AWE) memory. If MEM_PHYSICAL is set, MEM_RESERVE must also be set. No other flags may be set. If MEM_PHYSICAL is set, *Protect* must be set to PAGE_READWRITE.
MEM_RESERVE	The specified region of pages is to be reserved. One of MEM_COMMIT, MEM_RESET, or MEM_RESERVE must be set.
MEM_RESET	Reset the state of the specified region so that if the pages are in paging file, they are discarded and pages of zeros are brought in. If the pages are in memory and modified, they are marked as not modified so that they will not be written out to the paging file. The contents are not zeroed. The *Protect* parameter is not used, but it must be set to a valid value. One of MEM_COMMIT, MEM_RESET, or MEM_RESERVE must be set. If MEM_RESET is set, no other flag may be set.
MEM_TOP_DOWN	The specified region should be created at the highest virtual address possible based on *ZeroBits*.
MEM_WRITE_WATCH	The specified region should be created at the highest virtual address possible based on *ZeroBits*.

`Protect`

A bitmask containing page protection flags that specify the protection desired for the committed region of pages. The following table describes these flags.

FLAG	MEANING
PAGE_NOACCESS	No access to the committed region of pages is allowed. An attempt to read, write, or execute the committed region results in an access violation exception, called a general protection (GP) fault.
PAGE_READONLY	Read-only and execute access to the committed region of pages is allowed. An attempt to write the committed region results in an access violation.
PAGE_READWRITE	Read, write, and execute access to the committed region of pages is allowed. If write access to the underlying section is allowed, then a single copy of the pages is shared. Otherwise the pages are shared read only/copy on write.
PAGE_EXECUTE	Execute access to the committed region of pages is allowed. An attempt to read or write to the committed region results in an access violation.
PAGE_EXECUTE_READ	Execute and read access to the committed region of pages are allowed. An attempt to write to the committed region results in an access violation.

PAGE_GUARD	Pages in the region become guard pages. Any attempt to read from or write to a guard page causes the system to raise a STATUS_GUARD_PAGE exception. Guard pages thus act as a one-shot access alarm. This flag is a page protection modifier, valid only when used with one of the page protection flags other than PAGE_NOACCESS. When an access attempt leads the system to turn off guard page status, the underlying page protection takes over. If a guard page exception occurs during a system service, the service typically returns a failure status indicator.
PAGE_NOCACHE	The region of pages should be allocated as noncacheable. PAGE_NOCACHE is not allowed for sections.
PAGE_WRITECOMBINE	Enables write combining, that is, coalescing writes from cache to main memory, where the hardware supports it. This flag is used primarily for frame buffer memory so that writes to the same cache line are combined where possible before being written to the device. This can greatly reduce writes across the bus to (for example) video memory. If the hardware does not support write combining, the flag is ignored. This flag is a page protection modifier, valid only when used with one of the page protection flags other than PAGE_NOACCESS.

Return Value

ZwAllocateVirtualMemory returns either STATUS_SUCCESS or an error status code. Possible error status codes include the following:

STATUS_ACCESS_DENIED

STATUS_ALREADY_COMMITTED

STATUS_COMMITMENT_LIMIT

STATUS_CONFLICTING_ADDRESSES

STATUS_INSUFFICIENT_RESOURCES

STATUS_INVALID_HANDLE

STATUS_INVALID_PAGE_PROTECTION

STATUS_NO_MEMORY

STATUS_OBJECT_TYPE_MISMATCH

STATUS_PROCESS_IS_TERMINATING

Remarks

ZwAllocateVirtualMemory can perform the following operations:

- Commit a region of pages reserved by a previous call to **ZwAllocateVirtualMemory**.
- Reserve a region of free pages.
- Reserve and commit a region of free pages.

Kernel-mode drivers can use **ZwAllocateVirtualMemory** to reserve a range of application-accessible virtual addresses in the specified process and then make additional calls to **ZwAllocateVirtualMemory** to commit

individual pages from the reserved range. This enables a process to reserve a range of its virtual address space without consuming physical storage until it is needed.

Each page in the process's virtual address space is in one of the three states described in the following table.

STATE	MEANING
FREE	The page is not committed or reserved and is not accessible to the process. **ZwAllocateVirtualMemory** can reserve, or simultaneously reserve and commit, a free page.
RESERVED	The range of addresses cannot be used by other allocation functions, but the page is not accessible to the process and has no physical storage associated with it. **ZwAllocateVirtualMemory** can commit a reserved page, but it cannot reserve it a second time. **ZwFreeVirtualMemory** can release a reserved page, making it a free page.
COMMITTED	Physical storage is allocated for the page, and access is controlled by a protection code. The system initializes and loads each committed page into physical memory only at the first attempt to read or write to that page. When the process terminates, the system releases the storage for committed pages. **ZwAllocateVirtualMemory** can commit an already committed page. This means that you can commit a range of pages, regardless of whether they have already been committed, and the function will not fail. **ZwFreeVirtualMemory** can decommit a committed page, releasing the page's storage, or it can simultaneously decommit and release a committed page.

Memory allocated by calling **ZwAllocateVirtualMemory** must be freed by calling **ZwFreeVirtualMemory**.

For more information about memory management, see Memory Management for Windows Drivers.

> **Note** If the call to the **ZwAllocateVirtualMemory** function occurs in user mode, you should use the name "**NtAllocateVirtualMemory**" instead of "**ZwAllocateVirtualMemory**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Using Nt and Zw Versions of the Native System Services Routines

ZwFreeVirtualMemory

NtClose function

1/25/2019 • 2 minutes to read • Edit Online

The **NtClose** routine closes an object handle.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtClose(
  HANDLE Handle
);
```

Parameters

`Handle`

Handle to an object of any type.

Return Value

NtClose returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure. In particular, it returns STATUS_INVALID_HANDLE if *Handle* is not a valid handle, or STATUS_HANDLE_NOT_CLOSABLE if the calling thread does not have permission to close the handle.

Remarks

NtClose is a generic routine that operates on any type of object.

Closing an open object handle causes that handle to become invalid. The system also decrements the handle count for the object and checks whether the object can be deleted. The system does not actually delete the object until all of the object's handles are closed and no referenced pointers remain.

A driver must close every handle that it opens as soon as the handle is no longer required. Kernel handles, which are those that are opened by a system thread or by specifying the OBJ_KERNEL_HANDLE flag, can be closed only when the previous processor mode is **KernelMode**. This requirement applies both to system threads and to dispatch routines for IRPs that were issued from kernel mode. (For more information about the previous processor mode, see ExGetPreviousMode.) For example, a handle that NtCreateKey returns to a DriverEntry routine cannot subsequently be closed by the same driver's dispatch routines. A **DriverEntry** routine runs in a system process, whereas dispatch routines usually run either in the context of the thread issuing the current I/O request, or, for lower-level drivers, in an arbitrary thread context.

A nonkernel handle can be closed only if one of two conditions is met: The previous processor mode is **KernelMode**, or the calling thread has sufficient permission to close the handle. An example of the latter occurs when the calling thread is the one that created the handle.

Callers of **NtClose** should not assume that this routine automatically waits for all I/O to complete prior to returning.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtClose**" instead of "**ZwClose**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can

behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

  ULONG              CreateDisposition,
  ULONG              CreateOptions,
  PVOID              EaBuffer,
  ULONG              EaLength
);
```

Parameters

`FileHandle`

A pointer to a HANDLE variable that receives a handle to the file.

`DesiredAccess`

Specifies an ACCESS_MASK value that determines the requested access to the object. In addition to the access rights that are defined for all types of objects, the caller can specify any of the following access rights, which are specific to files.

ACCESS_MASK FLAG	ALLOWS CALLER TO DO THIS
FILE_READ_DATA	Read data from the file.
FILE_READ_ATTRIBUTES	Read the attributes of the file. (For more information, see the description of the *FileAttributes* parameter.)
FILE_READ_EA	Read the extended attributes (EAs) of the file. This flag is irrelevant for device and intermediate drivers.
FILE_WRITE_DATA	Write data to the file.
FILE_WRITE_ATTRIBUTES	Write the attributes of the file. (For more information, see the description of the *FileAttributes* parameter.)
FILE_WRITE_EA	Change the extended attributes (EAs) of the file. This flag is irrelevant for device and intermediate drivers.
FILE_APPEND_DATA	Append data to the file.

FILE_EXECUTE	Use system paging I/O to read data from the file into memory. This flag is irrelevant for device and intermediate drivers.

> **Note** Do not specify FILE_READ_DATA, FILE_WRITE_DATA, FILE_APPEND_DATA, or FILE_EXECUTE when you create or open a directory.

The caller can only specify a generic access right, GENERIC_*XXX*, for a file, not a directory. Generic access rights correspond to specific access rights as shown in the following table.

GENERIC ACCESS RIGHT	SET OF SPECIFIC ACCESS RIGHTS
GENERIC_READ	STANDARD_RIGHTS_READ, FILE_READ_DATA, FILE_READ_ATTRIBUTES, FILE_READ_EA, and SYNCHRONIZE.
GENERIC_WRITE	STANDARD_RIGHTS_WRITE, FILE_WRITE_DATA, FILE_WRITE_ATTRIBUTES, FILE_WRITE_EA, FILE_APPEND_DATA, and SYNCHRONIZE.
GENERIC_EXECUTE	STANDARD_RIGHTS_EXECUTE, FILE_EXECUTE, FILE_READ_ATTRIBUTES, and SYNCHRONIZE. This value is irrelevant for device and intermediate drivers.
GENERIC_ALL	FILE_ALL_ACCESS.

For example, if you specify GENERIC_READ for a file object, the routine maps this value to the FILE_GENERIC_READ bitmask of specific access rights. In the preceding table, the specific access rights that are listed for GENERIC_READ correspond to the access flags that are contained in the FILE_GENERIC_READ bitmask. If the file is actually a directory, the caller can also specify the following generic access rights.

DESIREDACCESS FLAG	ALLOWS CALLER TO DO THIS
FILE_LIST_DIRECTORY	List the files in the directory.
FILE_TRAVERSE	Traverse the directory, in other words, include the directory in the path of a file.

For more information about access rights, see ACCESS_MASK. `ObjectAttributes` A pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use InitializeObjectAttributes to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**. `IoStatusBlock` A pointer to an IO_STATUS_BLOCK structure that receives the final completion status and other information about the requested operation. In particular, the **Information** member receives one of the following values:

- FILE_CREATED
- FILE_OPENED
- FILE_OVERWRITTEN
- FILE_SUPERSEDED
- FILE_EXISTS
- FILE_DOES_NOT_EXIST

`AllocationSize` A pointer to a LARGE_INTEGER that contains the initial allocation size, in bytes, for a file that is created or overwritten. If *AllocationSize* is **NULL**, no allocation size is specified. If no file is created or overwritten, *AllocationSize* is ignored. `FileAttributes` Specifies one or more FILE_ATTRIBUTE_*XXX* flags, which represent the file attributes to set if you create or overwrite a file. The caller usually specifies FILE_ATTRIBUTE_NORMAL, which sets

the default attributes. For a list of valid FILE_ATTRIBUTE_*XXX* flags, see the CreateFile routine in the Microsoft Windows SDK documentation. If no file is created or overwritten, *FileAttributes* is ignored. `ShareAccess` Type of share access, which is specified as zero or any combination of the following flags.

***ShareAccess* flag**	**Allows other threads to do this**
FILE_SHARE_READ	Read the file
FILE_SHARE_WRITE	Write the file
FILE_SHARE_DELETE	Delete the file

Device and intermediate drivers usually set *ShareAccess* to zero, which gives the caller exclusive access to the open file. `CreateDisposition` Specifies the action to perform if the file does or does not exist. *CreateDisposition* can be one of the values in the following table.

***CreateDisposition* value**	**Action if file exists**	**Action if file does not exist**
FILE_SUPERSEDE	Replace the file.	Create the file.
FILE_CREATE	Return an error.	Create the file.
FILE_OPEN	Open the file.	Return an error.
FILE_OPEN_IF	Open the file.	Create the file.
FILE_OVERWRITE	Open the file, and overwrite it.	Return an error.
FILE_OVERWRITE_IF	Open the file, and overwrite it.	Create the file.

`CreateOptions` Specifies the options to apply when the driver creates or opens the file. Use one or more of the flags in the following table.

***CreateOptions* flag**	**Meaning**
FILE_DIRECTORY_FILE	The file is a directory. Compatible *CreateOptions* flags are FILE_SYNCHRONOUS_IO_ALERT, FILE_SYNCHRONOUS_IO_NONALERT, FILE_WRITE_THROUGH, FILE_OPEN_FOR_BACKUP_INTENT, and FILE_OPEN_BY_FILE_ID. The *CreateDisposition* parameter must be set to FILE_CREATE, FILE_OPEN, or FILE_OPEN_IF.
FILE_NON_DIRECTORY_FILE	The file is not a directory. The file object to open can represent a data file; a logical, virtual, or physical device; or a volume.
FILE_WRITE_THROUGH	System services, file-system drivers, and drivers that write data to the file must actually transfer the data to the file before any requested write operation is considered complete.
FILE_SEQUENTIAL_ONLY	All access to the file will be sequential.
FILE_RANDOM_ACCESS	Access to the file can be random, so no sequential read-ahead operations should be performed by file-system drivers or by the system.

FILE_NO_INTERMEDIATE_BUFFERING	The file cannot be cached or buffered in a driver's internal buffers. This flag is incompatible with the *DesiredAccess* parameter's FILE_APPEND_DATA flag.
FILE_SYNCHRONOUS_IO_ALERT	All operations on the file are performed synchronously. Any wait on behalf of the caller is subject to premature termination from alerts. This flag also causes the I/O system to maintain the file-position pointer. If this flag is set, the SYNCHRONIZE flag must be set in the *DesiredAccess* parameter.
FILE_SYNCHRONOUS_IO_NONALERT	All operations on the file are performed synchronously. Waits in the system that synchronize I/O queuing and completion are not subject to alerts. This flag also causes the I/O system to maintain the file-position context. If this flag is set, the SYNCHRONIZE flag must be set in the *DesiredAccess* parameter.
FILE_CREATE_TREE_CONNECTION	Create a tree connection for this file in order to open it over the network. This flag is not used by device and intermediate drivers.
FILE_COMPLETE_IF_OPLOCKED	Complete this operation immediately with an alternate success code of STATUS_OPLOCK_BREAK_IN_PROGRESS if the target file is oplocked, rather than blocking the caller's thread. If the file is oplocked, another caller already has access to the file. This flag is not used by device and intermediate drivers.
FILE_NO_EA_KNOWLEDGE	If the extended attributes (EAs) for an existing file being opened indicate that the caller must understand EAs to properly interpret the file, **NtCreateFile** should return an error. This flag is irrelevant for device and intermediate drivers.
FILE_OPEN_REPARSE_POINT	Open a file with a reparse point and bypass normal reparse point processing for the file. For more information, see the following Remarks section.
FILE_DELETE_ON_CLOSE	The system deletes the file when the last handle to the file is passed to NtClose. If this flag is set, the DELETE flag must be set in the *DesiredAccess* parameter.

FILE_OPEN_BY_FILE_ID	The file name that is specified by the *ObjectAttributes* parameter includes a binary 8-byte or 16-byte file reference number or object ID for the file, depending on the file system as shown below. Optionally, a device name followed by a backslash character may proceed these binary values. For example, a device name will have the following format.
	
	`??\C:<8 bytes of binary FileID>`
	`\device\HardDiskVolume1<16 bytes of binary ObjectID>`
	
	• On NTFS, this can be a 8-byte or 16-byte reference number or object ID. A 16-byte reference number is the same as an 8-byte number padded with zeros.
	• On ReFS, this can be an 8-byte or 16-byte reference number. A 16-byte number is not related to an 8-byte number. Object IDs are not supported.
	• The FAT, ExFAT, UDFS, and CDFS file systems do not support this flag.
	
	This number is assigned by and specific to the particular file system.
	
	Note Because the filename field will partly contain a binary blob, it is incorrect to assume that this is a valid Unicode string, and more importantly may not be a null terminated string.

FILE_OPEN_FOR_BACKUP_INTENT	The file is being opened for backup intent. Therefore, the system should check for certain access rights and grant the caller the appropriate access to the file—before checking the *DesiredAccess* parameter against the file's security descriptor. This flag not used by device and intermediate drivers.
FILE_RESERVE_OPFILTER	This flag allows an application to request a Filter opportunistic lock (oplock) to prevent other applications from getting share violations. If there are already open handles, the create request will fail with STATUS_OPLOCK_NOT_GRANTED. For more information, see the following Remarks section.
FILE_OPEN_REQUIRING_OPLOCK	The file is being opened and an opportunistic lock (oplock) on the file is being requested as a single atomic operation. The file system checks for oplocks before it performs the create operation, and will fail the create with a return code of STATUS_CANNOT_BREAK_OPLOCK if the result would be to break an existing oplock. **Note** The FILE_OPEN_REQUIRING_OPLOCK flag is available in Windows 7, Windows Server 2008 R2 and later Windows operating systems.
FILE_SESSION_AWARE	The client opening the file or device is session aware and per session access is validated if necessary. **Note** The FILE_SESSION_AWARE flag is available starting withWindows 8.

`EaBuffer` For device and intermediate drivers, this parameter must be a **NULL** pointer. `EaLength` For device and intermediate drivers, this parameter must be zero. ## Return Value **NtCreateFile** returns STATUS_SUCCESS on success or an appropriate NTSTATUS error code on failure. In the latter case, the caller can determine the cause of the failure by checking the *IoStatusBlock* parameter.

> **Note NtCreateFile** might return STATUS_FILE_LOCK_CONFLICT as the return value or in the **Status** member of the **IO_STATUS_BLOCK** structure that is pointed to by the *IoStatusBlock* parameter. This would occur only if the NTFS log file is full, and an error occurs while **NtCreateFile** tries to handle this situation.

Remarks

NtCreateFile supplies a handle that the caller can use to manipulate a file's data, or the file object's state and attributes. For more information, see Using Files in a Driver.

Once the handle pointed to by *FileHandle* is no longer in use, the driver must call NtClose to close it.

If the caller is not running in a system thread context, it must ensure that any handles it creates are private handles. Otherwise, the handle can be accessed by the process in whose context the driver is running. For more information, see Object Handles.

There are two alternate ways to specify the name of the file to be created or opened with **NtCreateFile**:

1. As a fully qualified pathname, supplied in the **ObjectName** member of the input *ObjectAttributes*.
2. As pathname relative to the directory file represented by the handle in the **RootDirectory** member of the input *ObjectAttributes*.

Setting certain flags in the *DesiredAccess* parameter results in the following effects:

- For a caller to synchronize an I/O completion by waiting for the returned *FileHandle*, the SYNCHRONIZE flag must be set. Otherwise, a caller that is a device or intermediate driver must synchronize an I/O completion by using an event object.
- If the caller sets only the FILE_APPEND_DATA and SYNCHRONIZE flags, it can write only to the end of the file, and any offset information about write operations to the file is ignored. The file will automatically be extended as necessary for this type of operation.
- Setting the FILE_WRITE_DATA flag for a file also allows the caller to write beyond the end of the file. Again, the file is automatically extended as necessary.
- If the caller sets only the FILE_EXECUTE and SYNCHRONIZE flags, it cannot directly read or write any data to the file using the returned *FileHandle*. That is, all operations on the file occur through the system pager in response to instruction and data-access operations. Device and intermediate drivers should not set the FILE_EXECUTE flag.

The *ShareAccess* parameter determines whether separate threads can access the same file, possibly simultaneously. Provided that both callers have the appropriate access privileges, the file can be successfully opened and shared. If the original caller of **NtCreateFile** does not specify FILE_SHARE_READ, FILE_SHARE_WRITE, or FILE_SHARE_DELETE, no other caller can open the file—that is, the original caller is granted exclusive access.

To successfully open a shared file, the *DesiredAccess* flags must be compatible with the *DesiredAccess* and *ShareAccess* flags of all the previous open operations that have not yet been released through . That is, the *DesiredAccess* specified to **NtCreateFile** for a given file must not conflict with the accesses that other openers of the file have disallowed.

The *CreateDisposition* value FILE_SUPERSEDE requires that the caller have DELETE access to a existing file object. If so, a successful call to **NtCreateFile** with FILE_SUPERSEDE on an existing file effectively deletes that file, and

then recreates it. This implies that, if the file has already been opened by another thread, it opened the file by specifying a *ShareAccess* parameter with the FILE_SHARE_DELETE flag set. Note that this type of disposition is consistent with the POSIX style of overwriting files.

The *CreateDisposition* values FILE_OVERWRITE_IF and FILE_SUPERSEDE are similar. If **NtCreateFile** is called with a existing file and either of these *CreateDisposition* values, the file will be replaced.

Overwriting a file is semantically equivalent to a supersede operation, except for the following:

- The caller must have write access to the file, rather than delete access. This implies that, if the file has already been opened by another thread, it opened the file with the FILE_SHARE_WRITE flag set in the input *ShareAccess*.
- The specified file attributes are logically ORed with those already on the file. This implies that, if the file has already been opened by another thread, a subsequent caller of **NtCreateFile** cannot disable existing *FileAttributes* flags but can enable additional flags for the same file. Note that this style of overwriting files is consistent with MS-DOS, Microsoft Windows 3.1, and OS/2.

The FILE_DIRECTORY_FILE *CreateOptions* value specifies that the file to be created or opened is a directory. When a directory file is created, the file system creates an appropriate structure on the disk to represent an empty directory for that particular file system's on-disk structure. If this option was specified and the given file to be opened is not a directory file, or if the caller specified an inconsistent *CreateOptions* or *CreateDisposition* value, the call to **NtCreateFile** will fail.

The FILE_NO_INTERMEDIATE_BUFFERING *CreateOptions* flag prevents the file system from performing any intermediate buffering on behalf of the caller. Specifying this flag places the following restrictions on the caller's parameters to other **Zw*Xxx*File** routines.

- Any optional *ByteOffset* passed to NtReadFile or NtWriteFile must be a multiple of the sector size.
- The *Length* passed to **NtReadFile** or **NtWriteFile** must be an integral of the sector size. Note that specifying a read operation to a buffer whose length is exactly the sector size might result in a lesser number of significant bytes being transferred to that buffer if the end of the file was reached during the transfer.
- Buffers must be aligned in accordance with the alignment requirement of the underlying device. To obtain this information, call **NtCreateFile** to get a handle for the file object that represents the physical device, and pass that handle to NtQueryInformationFile. For a list of the system's FILE_*XXX*_ALIGNMENT values, see DEVICE_OBJECT.
- Calls to NtSetInformationFile with the *FileInformationClass* parameter set to **FilePositionInformation** must specify an offset that is a multiple of the sector size.

The FILE_SYNCHRONOUS_IO_ALERT and FILE_SYNCHRONOUS_IO_NONALERT *CreateOptions* flags, which are mutually exclusive as their names suggest, specify that all I/O operations on the file will be synchronous—as long as they occur through the file object referred to by the returned *FileHandle*. All I/O on such a file is serialized across all threads using the returned handle. If either of these *CreateOptions* flags is set, the SYNCHRONIZE *DesiredAccess* flag must also be set—to compel the I/O manager to use the file object as a synchronization object. In these cases, the I/O manager keeps track of the current file-position offset, which you can pass to **NtReadFile** and **NtWriteFile**. Call **NtQueryInformationFile** or **NtSetInformationFile** to get or set this position.

If the *CreateOptions* FILE_OPEN_REPARSE_POINT flag is not specified and **NtCreateFile** attempts to open a file with a reparse point, normal reparse point processing occurs for the file. If, on the other hand, the FILE_OPEN_REPARSE_POINT flag is specified, normal reparse processing does not occur and **NtCreateFile** attempts to directly open the reparse point file. In either case, if the open operation was successful, **NtCreateFile** returns STATUS_SUCCESS; otherwise, the routine returns an NTSTATUS error code. **NtCreateFile** never returns STATUS_REPARSE.

The *CreateOptions* FILE_OPEN_REQUIRING_OPLOCK flag eliminates the time between when you open the file and request an oplock that could potentially allow a third party to open the file and get a sharing violation. An application can use the FILE_OPEN_REQUIRING_OPLOCK flag on **NtCreateFile** and then request any oplock. This ensures that an oplock owner will be notified of any subsequent open request that causes a sharing violation.

In Windows 7, if other handles exist on the file when an application uses the FILE_OPEN_REQUIRING_OPLOCK flag, the create operation will fail with STATUS_OPLOCK_NOT_GRANTED. This restriction no longer exists starting with Windows 8.

If this create operation would break an oplock that already exists on the file, then setting the FILE_OPEN_REQUIRING_OPLOCK flag will cause the create operation to fail with STATUS_CANNOT_BREAK_OPLOCK. The existing oplock will not be broken by this create operation.

An application that uses the FILE_OPEN_REQUIRING_OPLOCK flag must request an oplock after this call succeeds, or all subsequent attempts to open the file will be blocked without the benefit of normal oplock processing. Similarly, if this call succeeds but the subsequent oplock request fails, an application that uses this flag must close its handle after it detects that the oplock request has failed.

> **Note** The FILE_OPEN_REQUIRING_OPLOCK flag is available in Windows 7, Windows Server 2008 R2 and later Windows operating systems. The Microsoft file systems that implement this flag in Windows 7 are NTFS, FAT, and exFAT.

The *CreateOptions* flag FILE_RESERVE_OPFILTER allows an application to request a Level 1, Batch, or Filter oplock to prevent other applications from getting share violations. However, FILE_RESERVE_OPFILTER is only practically useful for Filter oplocks. To use it, you must complete the following steps:

1. Issue a create request with *CreateOptions* of FILE_RESERVE_OPFILTER, *DesiredAccess* of exactly FILE_READ_ATTRIBUTES, and *ShareAccess* of exactly FILE_SHARE_READ | FILE_SHARE_WRITE | FILE_SHARE_DELETE.
    - If there are already open handles, the create request fails with STATUS_OPLOCK_NOT_GRANTED, and the next requested oplock also fails.
    - If you open with more access or less sharing will also cause a failure of STATUS_OPLOCK_NOT_GRANTED.
2. If the create request succeeds, request an oplock.
3. Open another handle to the file to do I/O.

Step three makes this practical only for Filter oplocks. The handle opened in step 3 can have a *DesiredAccess* that contains a maximum of FILE_READ_ATTRIBUTES | FILE_WRITE_ATTRIBUTES | FILE_READ_DATA | FILE_READ_EA | FILE_EXECUTE | SYNCHRONIZE | READ_CONTROL and still not break a Filter oplock. However, any *DesiredAccess* greater than FILE_READ_ATTRIBUTES | FILE_WRITE_ATTRIBUTES | SYNCHRONIZE will break a Level 1 or Batch oplock and make the FILE_RESERVE_OPFILTER flag useless for those oplock types.

NTFS is the only Microsoft file system that implements FILE_RESERVE_OPFILTER.

Callers of **NtCreateFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtCreateFile**" instead of "**NtCreateFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL (see Remarks section)
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

NtCreateSection function

1/25/2019 • 3 minutes to read • Edit Online

The **NtCreateSection** routine creates a section object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtCreateSection(
  PHANDLE            SectionHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  PLARGE_INTEGER     MaximumSize,
  ULONG              SectionPageProtection,
  ULONG              AllocationAttributes,
  HANDLE             FileHandle
);
```

Parameters

`SectionHandle`

Pointer to a HANDLE variable that receives a handle to the section object.

`DesiredAccess`

Specifies an ACCESS_MASK value that determines the requested access to the object. In addition to the access rights that are defined for all types of objects (see ACCESS_MASK), the caller can specify any of the following access rights, which are specific to section objects:

***DESIREDACCESS* FLAG**	**ALLOWS CALLER TO DO THIS**
SECTION_EXTEND_SIZE	Dynamically extend the size of the section.
SECTION_MAP_EXECUTE	Execute views of the section.
SECTION_MAP_READ	Read views of the section.
SECTION_MAP_WRITE	Write views of the section.
SECTION_QUERY	Query the section object for information about the section. Drivers should set this flag.
SECTION_ALL_ACCESS	All of the previous flags combined with STANDARD_RIGHTS_REQUIRED.

`ObjectAttributes`

Pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use InitializeObjectAttributes to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**.

`MaximumSize`

Specifies the maximum size, in bytes, of the section. **NtCreateSection** rounds this value up to the nearest multiple of PAGE_SIZE. If the section is backed by the paging file, *MaximumSize* specifies the actual size of the section. If the section is backed by an ordinary file, *MaximumSize* specifies the maximum size that the file can be extended or mapped to.

`SectionPageProtection`

Specifies the protection to place on each page in the section. Use one of the following four values: PAGE_READONLY, PAGE_READWRITE, PAGE_EXECUTE, or PAGE_WRITECOPY. For a description of these values, see CreateFileMapping.

`AllocationAttributes`

Specifies a bitmask of SEC_*XXX* flags that determines the allocation attributes of the section. For a description of these flags, see CreateFileMapping.

`FileHandle`

Optionally specifies a handle for an open file object. If the value of *FileHandle* is **NULL**, the section is backed by the paging file. Otherwise, the section is backed by the specified file.

Return Value

NtCreateSection returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure. Possible error status codes include the following:

RETURN CODE	DESCRIPTION
STATUS_FILE_LOCKED	The file specified by the *FileHandle* parameter is locked.
STATUS_INVALID_FILE_FOR_SECTION	The file specified by *FileHandle* does not support sections.

STA TUS _IN VAL ID_ PA GE_ PR OTE CTI ON	The value specified for the *SectionPageProtection* parameter is invalid.
STA TUS _M APP ED_ FILE _SIZ E_Z ERO	The size of the file specified by *FileHandle* is zero, and *MaximumSize* is zero.
STA TUS _SE CTI ON_ TO O_B IG	The value of *MaximumSize* is too big. This occurs when either *MaximumSize* is greater than the system-defined maximum for sections, or if *MaximumSize* is greater than the specified file and the section is not writable.

Remarks

Once the handle pointed to by *SectionHandle* is no longer in use, the driver must call NtClose to close it.

If the caller is not running in a system thread context, it must ensure that any handles it creates are private handles. Otherwise, the handle can be accessed by the process in whose context the driver is running. For more information, see Object Handles.

For more information about setting up mapped sections and views of memory, see Sections and Views.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtCreateSection**" instead of "**ZwCreateSection**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. NtDeviceIoControlFile function

1/25/2019 • 4 minutes to read • Edit Online

The **ZwDeviceIoControlFile** routine sends a control code directly to a specified device driver, causing the corresponding driver to perform the specified operation.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtDeviceIoControlFile(
  HANDLE           FileHandle,
  HANDLE           Event,
  PIO_APC_ROUTINE  ApcRoutine,
  PVOID            ApcContext,
  PIO_STATUS_BLOCK IoStatusBlock,
  ULONG            IoControlCode,
  PVOID            InputBuffer,
  ULONG            InputBufferLength,
  PVOID            OutputBuffer,
  ULONG            OutputBufferLength
);
```

Parameters

`FileHandle`

Handle returned by ZwCreateFile or ZwOpenFile for the file object representing the device to which the control information should be given or from which information should be returned. The file object must have been opened for asynchronous I/O if the caller specifies an *Event*, *ApcRoutine*, and an APC context (in *ApcContext*), or a completion context (in *ApcContext*). For I/O to an underlying mass-storage device, the file object must have been opened for Direct Access to Storage Device (DASD) access.

`Event`

Handle for a caller-created event. If this parameter is supplied, the caller will be put into a wait state until the requested operation is completed and the given event is set to the Signaled state. This parameter is optional and can be **NULL**. It must be **NULL** if the caller will wait for the *FileHandle* to be set to the Signaled state.

`ApcRoutine`

Address of an optional, caller-supplied APC routine to be called when the requested operation completes. This parameter can be **NULL**. It must be **NULL** if there is an I/O completion object associated with the file object.

`ApcContext`

Pointer to a caller-determined context area. This parameter value is used as the APC context if the caller supplies an APC, or is used as the completion context if an I/O completion object has been associated with the file object. When the operation completes, either the APC context is passed to the APC, if one was specified, or the completion context is included as part of the completion message that the I/O Manager posts to the associated I/O completion object.

This parameter is optional and can be **NULL**. It must be **NULL** if *ApcRoutine* is **NULL** and there is no I/O completion object associated with the file object.

`IoStatusBlock`

Pointer to a variable that receives the final completion status and information about the operation. For successful calls that return data, the number of bytes written to the *OutputBuffer* is returned in the **Information** member.

`IoControlCode`

IOCTL_*XXX* code that indicates which device I/O control operation is to be carried out on, usually by the underlying device driver. The value of this parameter determines the format and required length of the *InputBuffer* and *OutputBuffer*, as well as which of the following parameter pairs are required. For detailed information about the system-defined, device-type-specific IOCTL_*XXX* codes, see the device technology-specific section of the Microsoft Windows Driver Kit (WDK) documentation and Device Input and Output Control Codes in the Microsoft Windows SDK documentation.

`InputBuffer`

Pointer to a caller-allocated input buffer that contains device-specific information to be given to the target device. If *IoControlCode* specifies an operation that does not require input data, this pointer can be **NULL**.

`InputBufferLength`

Size, in bytes, of the buffer at *InputBuffer*. If *InputBuffer* is **NULL**, set *InputBufferLength* to zero.

`OutputBuffer`

Pointer to a caller-allocated output buffer in which information is returned from the target device. If *IoControlCode* specifies an operation that does not produce output data, this pointer can be **NULL**.

`OutputBufferLength`

Size, in bytes, of the buffer at *OutputBuffer*. If *OutputBuffer* is **NULL**, set *OutputBufferLength* to zero.

Return Value

ZwDeviceIoControlFile returns STATUS_SUCCESS if the underlying driver(s) successfully carried out the requested operation. Otherwise, the return value can be an error status code propagated from an underlying driver. Possible error status codes include the following:

Remarks

ZwDeviceIoControlFile provides a consistent view of the input and output data to the system and to kernel-mode drivers, while providing applications and underlying drivers with a device-dependent method of specifying a communications interface.

For more information about system-defined IOCTL_*XXX* codes, and about defining driver-specific IOCTL_*XXX* or FSCTL_*XXX* values, see Using I/O Control Codes in the *Kernel Mode Architecture Guide* and Device Input and Output Control Codes in the Microsoft Windows SDK documentation.

If the caller opened the file for asynchronous I/O (with neither FILE_SYNCHRONOUS_*XXX* create/open option set), the specified event, if any, will be set to the signaled state when the device control operation completes. Otherwise, the file object specified by *FileHandle* will be set to the signaled state. If an *ApcRoutine* was specified, it is called with the *ApcContext* and *IoStatusBlock* pointers.

Minifilters should use FltDeviceIoControlFile instead of **ZwDeviceIoControlFile**.

Callers of **ZwDeviceIoControlFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to the **ZwDeviceIoControlFile** function occurs in user mode, you should use the name "**NtDeviceIoControlFile**" instead of "**ZwDeviceIoControlFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Ntifs.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL (see Remarks section)
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

NtDuplicateToken function

1/25/2019 • 6 minutes to read • Edit Online

The **NtDuplicateToken** function creates a handle to a new access token that duplicates an existing token. This function can create either a primary token or an impersonation token.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtDuplicateToken(
  HANDLE             ExistingTokenHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  BOOLEAN            EffectiveOnly,
  TOKEN_TYPE         TokenType,
  PHANDLE            NewTokenHandle
);
```

Parameters

`ExistingTokenHandle`

A handle to an existing access token that was opened with the TOKEN_DUPLICATE access right. This parameter is required and cannot be **NULL**.

`DesiredAccess`

Bitmask that specifies the requested access rights for the new token. **NtDuplicateToken** compares the requested access rights with the existing token's discretionary access control list (DACL) to determine which rights are granted or denied to the new token. To request the same access rights as the existing token, specify zero. To request all access rights that are valid for the caller, specify MAXIMUM_ALLOWED. This parameter is optional and can either be zero, MAXIMUM_ALLOWED, or a bitwise OR combination of one or more of the following values:

VALUE	MEANING
DELETE	Required to delete the object.
READ_CONTROL	Required to read the DACL and ownership information for the object. For access to the system access control list (SACL), see ACCESS_SYSTEM_SECURITY later in this table.
WRITE_DAC	Required to change the DACL information for the object.
WRITE_OWNER	Required to change the ownership information in the object's security descriptor (SECURITY_DESCRIPTOR).
ACCESS_SYSTEM_SECURITY	Required to get or set the SACL in an object's ACL. The operating system grants this right to the new token only if the SE_SECURITY_NAME privilege is enabled in the access token of the calling thread.
STANDARD_RIGHTS_READ	Currently defined to equal READ_CONTROL.

STANDARD_RIGHTS_WRITE	Currently defined to equal READ_CONTROL.
STANDARD_RIGHTS_EXECUTE	Currently defined to equal READ_CONTROL.
STANDARD_RIGHTS_REQUIRED	Combines DELETE, READ_CONTROL, WRITE_DAC, and WRITE_OWNER access.
STANDARD_RIGHTS_ALL	Combines DELETE, READ_CONTROL, WRITE_DAC, WRITE_OWNER, and SYNCHRONIZE access. However, the SYNCHRONIZE value is not applicable to token objects. Thus, STANDARD_RIGHTS_ALL has a functionally equivalent to STANDARD_RIGHTS_REQUIRED.
TOKEN_ADJUST_DEFAULT	Required to change the default owner, primary group, or DACL of an access token.
TOKEN_ADJUST_GROUPS	Required to adjust the attributes of the groups in an access token.
TOKEN_ADJUST_PRIVILEGES	Required to enable or disable the privileges in an access token.
TOKEN_ADJUST_SESSIONID	Required to adjust the session ID (SID) of an access token. The operating system grants this right to the new token only if the SE_TCB_NAME privilege is enabled in the access token of the calling thread.
TOKEN_ASSIGN_PRIMARY	Required to attach a primary token to a process. The operating system grants this right to the new token only if the SE_ASSIGNPRIMARYTOKEN_NAME privilege is enabled in the access token of the calling thread.
TOKEN_DUPLICATE	Required to duplicate an access token. Note that the given *ExistingTokenHandle* token must contain this right in order to successfully use this routine.
TOKEN_EXECUTE	Combines STANDARD_RIGHTS_EXECUTE and TOKEN_IMPERSONATE.
TOKEN_IMPERSONATE	Required to attach an impersonation access token to a process.
TOKEN_QUERY	Required to query an access token.
TOKEN_QUERY_SOURCE	Required to query the source of an access token.
TOKEN_READ	Combines STANDARD_RIGHTS_READ and TOKEN_QUERY.
TOKEN_WRITE	Combines STANDARD_RIGHTS_WRITE, TOKEN_ADJUST_PRIVILEGES, TOKEN_ADJUST_GROUPS, and TOKEN_ADJUST_DEFAULT.
TOKEN_ALL_ACCESS	Combines all possible token access permissions for a token.

For additional information, see Access Rights for Access-Token Objects in the Microsoft Windows SDK. Note that access tokens do not support the SYNCHRONIZE right.

`ObjectAttributes`

Pointer to an OBJECT_ATTRIBUTES structure that describes the requested properties for the new token. The *ObjectAttributes* parameter is optional and can be **NULL**. If the *ObjectAttributes* parameter is **NULL** or if the **SecurityDescriptor** member of the structure pointed to by the *ObjectAttributes* parameter is **NULL**, the new token receives a default security descriptor and the new token handle cannot be inherited. In that case, this default security descriptor is created from the user group, primary group, and DACL information that is stored in the caller's token.

When the *TokenType* parameter is set to **TokenImpersonation**:

- The *ObjectAttributes*parameter may be used to specify the impersonation level of the new token. This can be accomplished by setting *ObjectAttributes*->SecurityQualityOfService.ImpersonationLevel to an appropriate SECURITY_IMPERSONATION_LEVEL enumeration value. For more information, see SECURITY_QUALITY_OF_SERVICE in the Microsoft Windows SDK documentation.
- If the existing token is an impersonation token and the *ObjectAttributes* parameter provides no impersonation information, the new token's impersonation level is set to the existing token's impersonation level.
- If the existing token is a primary token and no impersonation level information is provided, the new impersonation token will have a SECURITY_IMPERSONATION_LEVEL impersonation level.

`EffectiveOnly`

A Boolean value that indicates whether the entire existing token should be duplicated into the new token or just the effective (currently enabled) part of the token. If set to **TRUE**, only the currently enabled parts of the source token will be duplicated. If set to **FALSE**, the entire existing token will be duplicated. This provides a means for a caller of a protected subsystem to limit which optional groups and privileges are made available to the protected subsystem. For example, if *EffectiveOnly* is **TRUE**, the caller could duplicate a token but remove the Administrators group and the SeTcbPrivilege right. The resulting token could then be passed to a child process (CreateProcessAsUser), which would restrict what the child process can do. This parameter is required.

`TokenType`

Specifies one of the following values from the TOKEN_TYPE enumeration.

VALUE	MEANING
TokenPrimary	The new token is a primary token. If the existing token is an impersonation token, the existing impersonation token must have an impersonation level (as provided by the *ObjectAttributes* parameter) of **SecurityImpersonation** or **SecurityDelegation**. Otherwise, **NtDuplicateToken** returns STATUS_BAD_IMPERSONATION_LEVEL is returned.
TokenImpersonation	The new token is an impersonation token. If the existing token is an impersonation token, the requested impersonation level (as provided by the *ObjectAttributes* parameter) of the new token must not be greater than the impersonation level of the existing token. Otherwise, **NtDuplicateToken** returns STATUS_BAD_IMPERSONATION_LEVEL.

The *TokenType* parameter is required and cannot be **NULL**.

`NewTokenHandle`

A pointer to a caller-allocated variable, of type HANDLE, that receives a handle to the new token. This parameter is required and cannot be **NULL**.

Return Value

NtDuplicateToken returns STATUS_SUCCESS if the call is successfull. Possible error return codes include the following:

RETURN CODE	DESCRIPTION
STATUS_ACCESS_VIOLATION	A memory access violation occurred. For example, if the previous mode was user-mode and invalid user-mode memory was provided, **NtDuplicateToken** returns STATUS_ACCESS_VIOLATION.
STATUS_INSUFFICIENT_RESOURCES	Sufficient memory could not be allocated to duplicate the new token.
STATUS_INVALID_PARAMETER	An invalid parameter was detected.
STATUS_BAD_IMPERSONATION_LEVEL	The requested impersonation level for the new token is greater than the impersonation level of the existing token.

STATUS_ACCESS_DENIED	**NtDuplicateToken** returns STATUS_ACCESS_DENIED if it couldn't access *ExistingTokenHandle*. This would occur if the existing token does not have the TOKEN_DUPLICATE access right.
STATUS_INVALID_HANDLE	**NtDuplicateToken** returns STATUS_INVALID_HANDLE if *ExistingTokenHandle* refers to an invalid handle.

Remarks

If no impersonation level information was provided by the *ObjectAttributes* parameter, the existing token's impersonation level will be used for the new token.

With regard to the structure pointed to by the optional *ObjectAttributes* parameter, the **SecurityQualityOfService** member of OBJECT_ATTRIBUTES points to a structure of type **SECURITY_QUALITY_OF_SERVICE**. See SECURITY_QUALITY_OF_SERVICE in the Microsoft Windows SDK documentation for information on the members of this structure.

> **Note** The **SecurityQualityOfService** member must be set after calling the InitializeObjectAttributes macro because **InitializeObjectAttributes** currently sets **SecurityQualityOfService** to **NULL**.

For information on the user-mode analog of **NtDuplicateToken**, see DuplicateTokenEx in the Windows SDK documentation.

When you have finished using the new token, call the NtClose function to close the token handle.

> **Note** If the call to the **NtDuplicateToken** function occurs in user mode, you should use the name "**NtDuplicateToken**" instead of "**NtDuplicateToken**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

NtFlushBuffersFileEx function

1/25/2019 • 2 minutes to read • Edit Online

The **NtFlushBuffersFileEx** routine is called by a file system filter driver to send a flush request for a given file to the file system. An optional flush operation flag can be set to control how file data is written to storage.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtFlushBuffersFileEx(
  HANDLE           FileHandle,
  ULONG            Flags,
  PVOID            Parameters,
  ULONG            ParametersSize,
  PIO_STATUS_BLOCK IoStatusBlock
);
```

Parameters

`FileHandle`

Handle returned by NtCreateFile or NtOpenFile for the file whose buffers will be flushed. This parameter is required and cannot be **NULL**.

`Flags`

Flush operation flags. *Flags* can be 0 or one of the following values.

VALUE	MEANING
FLUSH_FLAGS_FILE_DATA_ONLY	If the file is on an NTFS file system, file data in the file cache will be written. No metadata is written and the underlying storage is not synchronized to flush its cache. This flag is not valid with volume handles.
FLUSH_FLAGS_NO_SYNC	If the file is on an NTFS file system, file data and metadata in the file cache will be written. The underlying storage is not synchronized to flush its cache. This flag is not valid with volume handles.

`Parameters`

Address of the caller's I/O status block. This parameter is required and cannot be **NULL**.

`ParametersSize`

The size, in bytes, of the parameters block.

`IoStatusBlock`

Address of the caller's I/O status block. This parameter is required and cannot be **NULL**.

Return Value

NtFlushBuffersFileEx returns **STATUS_SUCCESS** or an appropriate **NTSTATUS** value, such as one of the following:

RETURN CODE	DESCRIPTION
STATUS_MEDIA_WRITE_PROTECTED	The file resides on a write-protected volume; this is an error code.
STATUS_VOLUME_DISMOUNTED	The file resides on a volume that is not currently mounted; this is an error code.
STATUS_ACCESS_DENIED	The file does has neither write or append access.

Remarks

A file system filter driver can call **NtFlushBuffersFileEx** to issue an IRP_MJ_FLUSH_BUFFERS request to the file system for a given file. The flush operation is synchronous.

Minifilter drivers should call FltFlushBuffers instead of calling **NtFlushBuffersFileEx**.

Callers of **NtFlushBuffersFileEx** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to the **NtFlushBuffersFileEx** function occurs in user mode, you should use the name "**NtFlushBuffersFileEx**" instead of "**NtFlushBuffersFileEx**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	ntifs.h (include Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL (See Remarks section.)

NtOpenFile

NtFreeVirtualMemory function

1/25/2019 • 5 minutes to read • Edit Online

The **NtFreeVirtualMemory** routine releases, decommits, or both, a region of pages within the virtual address space of a specified process.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtFreeVirtualMemory(
  HANDLE  ProcessHandle,
  PVOID   *BaseAddress,
  PSIZE_T RegionSize,
  ULONG   FreeType
);
```

Parameters

`ProcessHandle`

A handle for the process in whose context the pages to be freed reside. Use the **NtCurrentProcess** macro, defined in Ntddk.h, to specify the current process.

`BaseAddress`

A pointer to a variable that will receive the virtual address of the freed region of pages.

If the MEM_RELEASE flag is set in the *FreeType* parameter, *BaseAddress* must be the base address returned by NtAllocateVirtualMemory when the region was reserved.

`RegionSize`

A pointer to a variable that will receive the actual size, in bytes, of the freed region of pages. The routine rounds the initial value of this variable up to the next host page size boundary and writes the rounded value back to this variable.

If the MEM_RELEASE flag is set in the *FreeType* parameter, the variable pointed to by *RegionSize* must be zero. **NtFreeVirtualMemory** frees the entire region that was reserved in the initial allocation call to **NtAllocateVirtualMemory**.

If the MEM_DECOMMIT flag is set in the *FreeType* parameter, **NtFreeVirtualMemory** decommits all memory pages that contain one or more bytes in the range from the *BaseAddress* parameter to (*BaseAddress* + **RegionSize*). This means, for example, that if a two-byte region of memory straddles a page boundary, both pages are decommitted.

NtFreeVirtualMemory decommits the entire region that was reserved by **NtAllocateVirtualMemory**. If the following three conditions are met, the entire region enters the reserved state:

- The MEM_DECOMMIT flag is set.
- *BaseAddress* is the base address returned by **NtAllocateVirtualMemory** when the region was reserved.
- **RegionSize* is zero.

`FreeType`

A bitmask that contains flags that describe the type of free operation that **NtFreeVirtualMemory** will perform for the specified region of pages. The possible values are listed in the following table.

***FREETYPE* FLAGS**	**DESCRIPTION**
MEM_DECOMMIT	**NtFreeVirtualMemory** will decommit the specified region of pages. The pages enter the reserved state. **NtFreeVirtualMemory** does not fail if you attempt to decommit an uncommitted page. This means that you can decommit a range of pages without first determining their current commitment state.
MEM_RELEASE	**NtFreeVirtualMemory** will release the specified region of pages. The pages enter the free state. If you specify this flag, * *RegionSize* must be zero, and *BaseAddress*must point to the base address returned by NtAllocateVirtualMemory when the region was reserved. **NtFreeVirtualMemory** fails if either of these conditions is not met. If any pages in the region are currently committed, **NtFreeVirtualMemory** first decommits and then releases them. **NtFreeVirtualMemory** does not fail if you attempt to release pages that are in different states, some reserved and some committed. This means that you can release a range of pages without first determining their current commitment state.

Return Value

NtFreeVirtualMemory returns either STATUS_SUCCESS or an error status code. Possible error status codes include the following.

RETURN CODE	**DESCRIPTION**
STA TUS _AC CES S_D ENI ED	A process has requested access to an object, but has not been granted those access rights.
STA TUS _IN VAL ID_ HA NDL E	An invalid *ProcessHandle* value was specified.

STA TUS _OB JEC T_T YPE _MI SM ATC H	There is a mismatch between the type of object required by the requested operation and the type of object that is specified in the request.

Remarks

Each page in the process's virtual address space is in one of the three states described in the following table.

STATE	MEANING
FREE	The page is neither committed nor reserved. The page is not accessible to the process. Attempting to read from or write to a free page results in an access violation exception. You can use **NtFreeVirtualMemory** to put reserved or committed pages into the free state.
RESERVED	The page is reserved. The range of addresses cannot be used by other allocation functions. The page is not accessible to the process and has no physical storage associated with it. Attempting to read from or write to a reserved page results in an access violation exception. You can use **NtFreeVirtualMemory** to put committed memory pages into the reserved state, and to put reserved memory pages into the free state.
COMMITTED	The page is committed. Physical storage in memory or in the paging file on disk is allocated for the page, and access is controlled by a protection code. The system initializes and loads each committed page into physical memory only at the first attempt to read from or write to that page. When a process terminates, the system releases all storage for committed pages. You can use NtAllocateVirtualMemory to put committed memory pages into either the reserved or free state.

NtFreeVirtualMemory can perform the following operations:

- Decommit a region of committed or uncommitted pages. After this operation, the pages are in the reserved state.
- Release a region of reserved pages. After this operation, the pages are in the free state.
- Decommit and release a region of committed or uncommitted pages. After this operation, the pages are in the free state.

NtFreeVirtualMemory can decommit a range of pages that are in different states, some committed and some uncommitted. This means that you can decommit a range of pages without first determining the current commitment state of each page. Decommitting a page releases its physical storage, either in memory or in the paging file on disk.

If a page is decommitted but not released, its state changes to reserved. You can subsequently call **NtAllocateVirtualMemory** to commit it, or **NtFreeVirtualMemory** to release it. Attempting to read from or

write to a reserved page results in an access violation exception.

NtFreeVirtualMemory can release a range of pages that are in different states, some reserved and some committed. This means that you can release a range of pages without first determining the current commitment state of each page. The entire range of pages originally reserved by NtAllocateVirtualMemory must be released at the same time.

If a page is released, its state changes to free, and it is available for subsequent allocation operations. After memory has been released or decommitted, you can never refer to the memory again. Any information that may have been in that memory is gone forever. Attempting to read from or write to a free page results in an access violation exception. If you require information, do not decommit or free memory that contains that information.

For more information about memory management support for kernel-mode drivers, see Memory Management for Windows Drivers.

> **Note** If the call to the **NtFreeVirtualMemory** function occurs in user mode, you should use the name "**NtFreeVirtualMemory**" instead of "**ZwFreeVirtualMemory**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Ntifs.h, Fltkernel.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

NtAllocateVirtualMemory

NtFsControlFile function

1/25/2019 • 4 minutes to read • Edit Online

The **NtFsControlFile** routine sends a control code directly to a specified file system or file system filter driver, causing the corresponding driver to perform the specified action.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtFsControlFile(
  HANDLE           FileHandle,
  HANDLE           Event,
  PIO_APC_ROUTINE  ApcRoutine,
  PVOID            ApcContext,
  PIO_STATUS_BLOCK IoStatusBlock,
  ULONG            FsControlCode,
  PVOID            InputBuffer,
  ULONG            InputBufferLength,
  PVOID            OutputBuffer,
  ULONG            OutputBufferLength
);
```

Parameters

`FileHandle`

Handle returned by NtCreateFile or NtOpenFile for the file object representing the file or directory on which the specified action is to be performed. The file object must have been opened for asynchronous I/O if the caller specifies an *Event*, *ApcRoutine*, and an APC context (in *ApcContext*), or a completion context (in *ApcContext*).

`Event`

Handle for a caller-created event. If this parameter is supplied, the caller will be put into a wait state until the requested operation is completed and the given event is set to the Signaled state. This parameter is optional and can be **NULL**. It must be **NULL** if the caller will wait for the *FileHandle* to be set to the Signaled state.

`ApcRoutine`

Address of a caller-supplied APC routine to be called when the requested operation completes. This parameter is optional and can be **NULL**. It must be **NULL** if there is an I/O completion object associated with the file object.

`ApcContext`

Pointer to a caller-determined context area. This parameter value is used as the APC context if the caller supplies an APC, or is used as the completion context if an I/O completion object has been associated with the file object. When the operation completes, either the APC context is passed to the APC, if one was specified, or the completion context is included as part of the completion message that the I/O Manager posts to the associated I/O completion object.

This parameter is optional and can be **NULL**. It must be **NULL** if *ApcRoutine* is **NULL** and there is no I/O completion object associated with the file object.

`IoStatusBlock`

Pointer to an IO_STATUS_BLOCK structure that receives the final completion status and information about the

operation. For successful calls that return data, the number of bytes written to the *OutputBuffer* is returned in the **Information** member of this structure.

`FsControlCode`

FSCTL_*XXX* code that indicates which file system control operation is to be carried out. The value of this parameter determines the formats and required lengths of the *InputBuffer* and *OutputBuffer*, as well as which of the following parameter pairs are required. For detailed information about the system-defined FSCTL_*XXX* codes, see the "Remarks" section of the reference entry for DeviceIoControl in the Microsoft Windows SDK documentation.

`InputBuffer`

Pointer to a caller-allocated input buffer that contains device-specific information to be given to the target driver. If *FsControlCode* specifies an operation that does not require input data, this pointer is optional and can be **NULL**.

`InputBufferLength`

Size, in bytes, of the buffer at *InputBuffer*. This value is ignored if *InputBuffer* is **NULL**.

`OutputBuffer`

Pointer to a caller-allocated output buffer in which information is returned from the target driver. If *FsControlCode* specifies an operation that does not produce output data, this pointer is optional and can be **NULL**.

`OutputBufferLength`

Size, in bytes, of the buffer at *OutputBuffer*. This value is ignored if *OutputBuffer* is **NULL**.

Return Value

NtFsControlFile returns STATUS_SUCCESS or an appropriate NTSTATUS value such as one of the following:

Remarks

NtFsControlFile provides a consistent view of the input and output data to the system and to kernel-mode drivers, while providing applications and underlying drivers with a driver-dependent method of specifying a communications interface.

If the caller opened the file for asynchronous I/O (with neither FILE_SYNCHRONOUS_*XXX* create/open option set), the specified event, if any, will be set to the signaled state when the device control operation completes. Otherwise, the file object specified by *FileHandle* will be set to the signaled state. If an *ApcRoutine* was specified, it is called with the *ApcContext* and *IoStatusBlock* pointers.

The following FSCTL codes are currently documented for kernel-mode drivers:

FSCTL_DELETE_REPARSE_POINT

FSCTL_GET_REPARSE_POINT

FSCTL_OPBATCH_ACK_CLOSE_PENDING

FSCTL_OPLOCK_BREAK_ACK_NO_2

FSCTL_OPLOCK_BREAK_ACKNOWLEDGE

FSCTL_OPLOCK_BREAK_NOTIFY

FSCTL_REQUEST_BATCH_OPLOCK

FSCTL_REQUEST_FILTER_OPLOCK

FSCTL_REQUEST_OPLOCK_LEVEL_1

FSCTL_REQUEST_OPLOCK_LEVEL_2

FSCTL_SET_REPARSE_POINT

For more information about system-defined FSCTL_*XXX* codes, see the "Remarks" section of the reference entry for DeviceIoControl in the Microsoft Windows SDK documentation.

For more information about system-defined IOCTL_*XXX* codes, and about defining driver-specific IOCTL_*XXX* or FSCTL_*XXX* values, see Using I/O Control Codes in the *Kernel Mode Architecture Guide* and *Device Input and Output Control Codes* in the Windows SDK documentation.

Minifilters should use FltFsControlFile instead of **NtFsControlFile**.

Callers of **NtFsControlFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to the **NtFsControlFile** function occurs in user mode, you should use the name "**NtFsControlFile**" instead of "**ZwFsControlFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

NtLockFile function

1/25/2019 • 2 minutes to read • Edit Online

The **NtLockFile** routine requests a byte-range lock for the specified file.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtLockFile(
  HANDLE           FileHandle,
  HANDLE           Event,
  PIO_APC_ROUTINE  ApcRoutine,
  PVOID            ApcContext,
  PIO_STATUS_BLOCK IoStatusBlock,
  PLARGE_INTEGER   ByteOffset,
  PLARGE_INTEGER   Length,
  ULONG            Key,
  BOOLEAN          FailImmediately,
  BOOLEAN          ExclusiveLock
);
```

Parameters

`FileHandle`

A handle for the file on which a byte-range lock is requested.

`Event`

A handle to a caller-created event. If not **NULL**, the caller is placed into a wait state until the operation succeeds, at which time the event is set into the Signaled state.

`ApcRoutine`

A pointer to a caller-supplied APC routine that is executed after the operation completes. Can be **NULL**.

`ApcContext`

A pointer to a caller-specified context for the APC routine. This value is passed to the APC routine when it is executed. Can be **NULL**.

`IoStatusBlock`

A pointer to an IO_STATUS_BLOCK structure that contains the final status.

`ByteOffset`

A pointer to a variable that specifies the starting byte offset of the range to lock.

`Length`

A pointer to a variable that specifies the length in bytes of the range to lock.

`Key`

A caller-assigned value used to describe groups of related locks. This value should be set to zero.

`FailImmediately`

If **TRUE**, immediately return if the file cannot be locked. If **FALSE**, wait for the lock request to be granted.

`ExclusiveLock`

If **TRUE**, byte-range lock is exclusive; otherwise, shared lock.

Return Value

The **NtLockFile** routine returns STATUS_SUCCESS or an appropriate error NTSTATUS value. Possible NTSTATUS values include the following:

RETURN CODE	DESCRIPTION
STA TUS _IN SUF FICI ENT _RE SO URC ES	Insufficient resources exist to grant the byte-range lock for the specified file.
STA TUS _LO CK_ NO T_G RA NTE D	The byte-range lock was not granted for the specified file.

Remarks

Callers of **NtLockFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to the **NtLockFile** function occurs in user mode, you should use the name "**NtLockFile**" instead of "**ZwLockFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal

Header	ntifs.h (include Ntifs.h, FltKernel.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL (see Remarks section)
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

See Also

ZwUnlockFile

NtOpenFile function

1/25/2019 • 2 minutes to read • Edit Online

The **NtOpenFile** routine opens an existing file, directory, device, or volume.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtOpenFile(
  PHANDLE            FileHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  PIO_STATUS_BLOCK   IoStatusBlock,
  ULONG              ShareAccess,
  ULONG              OpenOptions
);
```

Parameters

`FileHandle`

Pointer to a HANDLE variable that receives a handle to the file.

`DesiredAccess`

Specifies an ACCESS_MASK value that determines the requested access to the object. For more information, see the *DesiredAccess* parameter of NtCreateFile.

`ObjectAttributes`

Pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use InitializeObjectAttributes to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**.

`IoStatusBlock`

Pointer to an IO_STATUS_BLOCK structure that receives the final completion status and information about the requested operation.

`ShareAccess`

Specifies the type of share access for the file. For more information, see the *ShareAccess* parameter of NtCreateFile.

`OpenOptions`

Specifies the options to apply when opening the file. For more information, see the *CreateOptions* parameter of NtCreateFile.

Return Value

NtOpenFile returns STATUS_SUCCESS or the appropriate NTSTATUS error code. In the latter case, the caller can find more information about the cause of the failure by checking the *IoStatusBlock* parameter.

Remarks

NtOpenFile supplies a handle that the caller can use to manipulate a file's data, or the file object's state and attributes. **NtOpenFile** provides a subset of the functionality provided by NtCreateFile. For more information, see Using Files in a Driver.

Once the handle pointed to by *FileHandle* is no longer in use, the driver must call ZwClose to close it.

If the caller is not running in a system thread context, it must ensure that any handles it creates are private handles. Otherwise, the handle can be accessed by the process in whose context the driver is running. For more information, see Object Handles.

Callers of **NtOpenFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtOpenFile**" instead of "**ZwOpenFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

InitializeObjectAttributes

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateFile

NtOpenProcessTokenEx function

1/25/2019 • 2 minutes to read • Edit Online

The **NtOpenProcessTokenEx** routine opens the access token associated with a process.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtOpenProcessTokenEx(
  HANDLE      ProcessHandle,
  ACCESS_MASK DesiredAccess,
  ULONG       HandleAttributes,
  PHANDLE     TokenHandle
);
```

Parameters

`ProcessHandle`

Handle to the process whose access token is to be opened. The handle must have PROCESS_QUERY_INFORMATION access. Use the **NtCurrentProcess** macro, defined in Ntddk.h, to specify the current process.

`DesiredAccess`

ACCESS_MASK structure specifying the requested types of access to the access token. These requested access types are compared with the token's discretionary access-control list (DACL) to determine which accesses are granted or denied.

`HandleAttributes`

Attributes for the access token handle. Only OBJ_KERNEL_HANDLE is currently supported. If the caller is not running in the system process context, it must specify OBJ_KERNEL_HANDLE for this parameter.

`TokenHandle`

Pointer to a caller-allocated variable that receives a handle to the newly opened access token.

Return Value

NtOpenProcessTokenEx returns STATUS_SUCCESS or an appropriate error status. Possible error status codes include the following:

RETURN CODE	DESCRIPTION
STATUS_ACCESS_DENIED	*ProcessHandle* did not have PROCESS_QUERY_INFORMATION access.

STATUS_INSUFFICIENT_RESOURCES	A new token handle could not be allocated.
STATUS_INVALID_HANDLE	*ProcessHandle* was not a valid handle.
STATUS_INVALID_PARAMETER	The specified *HandleAttributes* did not include OBJ_KERNEL_HANDLE.
STATUS_OBJECT_TYPE_MISMATCH	*ProcessHandle* was not a process handle.
STATUS_PRIVILEGE_NOT_HELD	The caller does not have the privilege (SeSecurityPrivilege) necessary to create a token handle with the access specified in the *DesiredAccess* parameter.

STATUS_QUOTA_EXCEEDED	The process's memory quota is not sufficient to allocate the token handle.
STATUS_UNSUCCESSFUL	The token handle could not be created.

Remarks

NtOpenProcessTokenEx opens the access token associated with a process and returns a handle for that token.

Any handle obtained by calling **NtOpenProcessTokenEx** must eventually be released by calling **NtClose**.

Driver routines that run in a process context other than that of the system process must set the OBJ_KERNEL_HANDLE attribute for the *HandleAttributes* parameter of **NtOpenProcessTokenEx**. This restricts the use of the handle returned by **NtOpenProcessTokenEx** to processes running in kernel mode. Otherwise, the handle can be accessed by the process in whose context the driver is running.

For more information about security and access control, see the documentation on these topics in the Windows SDK.

> **Note** If the call to the **NtOpenProcessTokenEx** function occurs in user mode, you should use the name "**NtOpenProcessTokenEx**" instead of "**ZwOpenProcessTokenEx**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	ntifs.h (include Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

NtOpenThreadTokenEx

NtOpenThreadTokenEx function

1/25/2019 • 3 minutes to read • Edit Online

The **NtOpenThreadTokenEx** routine opens the access token associated with a thread.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtOpenThreadTokenEx(
  HANDLE      ThreadHandle,
  ACCESS_MASK DesiredAccess,
  BOOLEAN     OpenAsSelf,
  ULONG       HandleAttributes,
  PHANDLE     TokenHandle
);
```

Parameters

`ThreadHandle`

Handle to the thread whose access token is to be opened. The handle must have THREAD_QUERY_INFORMATION access. Use the **NtCurrentThread** macro to specify the current thread.

`DesiredAccess`

ACCESS_MASK structure specifying the requested types of access to the access token. These requested access types are compared with the token's discretionary access-control list (DACL) to determine which access rights are granted or denied.

`OpenAsSelf`

Boolean value specifying whether the access check is to be made against the security context of the thread calling **NtOpenThreadTokenEx** or against the security context of the process for the calling thread.

If this parameter is **FALSE**, the access check is performed using the security context for the calling thread. If the thread is impersonating a client, this security context can be that of a client process. If this parameter is **TRUE**, the access check is made using the security context of the process for the calling thread.

`HandleAttributes`

Attributes for the created handle. Only OBJ_KERNEL_HANDLE is currently supported. If the caller is not running in the system process context, it must specify OBJ_KERNEL_HANDLE for this parameter.

`TokenHandle`

Pointer to a caller-allocated variable that receives a handle to the newly opened access token.

Return Value

NtOpenThreadTokenEx returns STATUS_SUCCESS or an appropriate error status. Possible error status codes include the following:

RETURN CODE	DESCRIPTION

STATUS_ACCESS_DENIED	*ThreadHandle* did not have THREAD_QUERY_INFORMATION access.
STATUS_CANT_OPEN_ANONYMOUS	The client requested the SecurityAnonymous impersonation level. However, an anonymous token cannot be opened. For more information, see SECURITY_IMPERSONATION_LEVEL.
STATUS_INVALID_HANDLE	*ThreadHandle* was not a valid handle.
STATUS_INVALID_PARAMETER	The specified *HandleAttributes* did not include OBJ_KERNEL_HANDLE.
STATUS_NO_TOKEN	An attempt has been made to open a token associated with a thread that is not currently impersonating a client.

STA **TUS** **_OB** **JEC** **T_T** **YPE** **_MI** **SM** **ATC** **H**	*ThreadHandle* was not a thread handle.

Remarks

NtOpenThreadTokenEx opens the access token associated with a thread and returns a handle for that token.

The *OpenAsSelf* parameter allows a server process to open the access token for a client process when the client process has specified the SecurityIdentification impersonation level for the **SECURITY_IMPERSONATION_LEVEL** enumerated type. Without this parameter, the calling process is not be able to open the client's access token using the client's security context because it is impossible to open executive-level objects using the SecurityIdentification impersonation level.

Any handle obtained by calling **NtOpenThreadTokenEx** must eventually be released by calling **NtClose**.

Driver routines that run in a process context other than that of the system process must set the OBJ_KERNEL_HANDLE attribute for the *HandleAttributes* parameter of **NtOpenThreadTokenEx**. This restricts the use of the handle returned by **NtOpenThreadTokenEx** to processes running in kernel mode. Otherwise, the handle can be accessed by the process in whose context the driver is running.

For more information about security and access control, see the documentation on these topics in the Windows SDK.

> **Note** If the call to the **NtOpenThreadTokenEx** function occurs in user mode, you should use the name "**NtOpenThreadTokenEx**" instead of "**ZwOpenThreadTokenEx**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal

NtQueryDirectoryFile function

1/25/2019 • 6 minutes to read • Edit Online

The **NtQueryDirectoryFile** routine returns various kinds of information about files in the directory specified by a given file handle.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtQueryDirectoryFile(
  HANDLE                 FileHandle,
  HANDLE                 Event,
  PIO_APC_ROUTINE        ApcRoutine,
  PVOID                  ApcContext,
  PIO_STATUS_BLOCK       IoStatusBlock,
  PVOID                  FileInformation,
  ULONG                  Length,
  FILE_INFORMATION_CLASS FileInformationClass,
  BOOLEAN                ReturnSingleEntry,
  PUNICODE_STRING        FileName,
  BOOLEAN                RestartScan
);
```

Parameters

`FileHandle`

A handle returned by NtCreateFile or NtOpenFile for the file object that represents the directory for which information is being requested. The file object must have been opened for asynchronous I/O if the caller specifies a non-**NULL** value for *Event* or *ApcRoutine*.

`Event`

An optional handle for a caller-created event. If this parameter is supplied, the caller will be put into a wait state until the requested operation is completed and the given event is set to the Signaled state. This parameter is optional and can be **NULL**. It must be **NULL** if the caller will wait for the *FileHandle* to be set to the Signaled state.

`ApcRoutine`

An address of an optional, caller-supplied APC routine to be called when the requested operation completes. This parameter is optional and can be **NULL**. If there is an I/O completion object associated with the file object, this parameter must be **NULL**.

`ApcContext`

An optional pointer to a caller-determined context area if the caller supplies an APC or if an I/O completion object is associated with the file object. When the operation completes, this context is passed to the APC, if one was specified, or is included as part of the completion message that the I/O Manager posts to the associated I/O completion object.

This parameter is optional and can be **NULL**. It must be **NULL** if *ApcRoutine* is **NULL** and there is no I/O completion object associated with the file object.

`IoStatusBlock`

A pointer to an IO_STATUS_BLOCK structure that receives the final completion status and information about the operation. For successful calls that return data, the number of bytes written to the *FileInformation* buffer is returned in the structure's **Information** member.

`FileInformation`

A pointer to a buffer that receives the desired information about the file. The structure of the information returned in the buffer is defined by the *FileInformationClass* parameter.

`Length`

The size, in bytes, of the buffer pointed to by *FileInformation*. The caller should set this parameter according to the given *FileInformationClass*.

`FileInformationClass`

The type of information to be returned about files in the directory. One of the following.

VALUE	MEANING
FileBothDirectoryInformation	Return a FILE_BOTH_DIR_INFORMATION structure for each file.
FileDirectoryInformation	Return a FILE_DIRECTORY_INFORMATION structure for each file.
FileFullDirectoryInformation	Return a FILE_FULL_DIR_INFORMATION structure for each file.
FileIdBothDirectoryInformation	Return a FILE_ID_BOTH_DIR_INFORMATION structure for each file.
FileIdFullDirectoryInformation	Return a FILE_ID_FULL_DIR_INFORMATION structure for each file.
FileNamesInformation	Return a FILE_NAMES_INFORMATION structure for each file.
FileObjectIdInformation	Return a FILE_OBJECTID_INFORMATION structure for each file. This information class is valid only for NTFS volumes on Windows 2000 and later versions of Windows.
FileReparsePointInformation	Return a single FILE_REPARSE_POINT_INFORMATION structure for the directory.

`ReturnSingleEntry`

Set to **TRUE** if only a single entry should be returned, **FALSE** otherwise. If this parameter is **TRUE**, **NtQueryDirectoryFile** returns only the first entry that is found.

`FileName`

An optional pointer to a caller-allocated Unicode string containing the name of a file (or multiple files, if wildcards are used) within the directory specified by *FileHandle*. This parameter is optional and can be **NULL**.

If *FileName* is not **NULL**, only files whose names match the *FileName* string are included in the directory scan. If *FileName* is **NULL**, all files are included.

The *FileName* is used as a search expression and is captured on the very first call to **NtQueryDirectoryFile** for a given handle. Subsequent calls to **NtQueryDirectoryFile** will use the search expression set in the first call. The *FileName* parameter passed to subsequent calls will be ignored.

`RestartScan`

Set to **TRUE** if the scan is to start at the first entry in the directory. Set to **FALSE** if resuming the scan from a previous call.

When the **NtQueryDirectoryFile** routine is called for a particular handle, the *RestartScan* parameter is treated as if it were set to **TRUE**, regardless of its value. On subsequent **NtQueryDirectoryFile** calls, the value of the *RestartScan* parameter is honored.

Return Value

The **NtQueryDirectoryFile**routine returns STATUS_SUCCESS or an appropriate error status. Note that the set of error status values that can be returned is file-system-specific. **NtQueryDirectoryFile**also returns the number of bytes actually written to the given *FileInformation* buffer in the **Information** member of *IoStatusBlock*.

Remarks

The **NtQueryDirectoryFile** routine returns information about files that are contained in the directory represented by *FileHandle*.

If provided, the value of the *FileName* parameter determines the entries that are included in the directory scan for all subsequent calls to **NtQueryDirectoryFile** for a given *FileHandle*.

If there is at least one matching entry, **NtQueryDirectoryFile** creates a **FILE_*XXX*_INFORMATION** structure for each entry and stores them in the buffer.

Assuming that at least one matching directory entry is found, the number of entries for which information is returned is the *smallest* of the following:

- One entry, if *ReturnSingleEntry* is **TRUE** and *FileName* is **NULL**.
- The number of entries that match the *FileName* string, if *FileName* is not **NULL**. (Note that if the string contains no wildcards, there can be at most one matching entry.)
- The number of entries whose information fits into the specified buffer.
- The number of entries contained in the directory.

On the first call to **NtQueryDirectoryFile**, if the structure created for the first entry found is too large to fit into the output buffer, the routine writes the fixed portion of the structure to the output buffer. The routine then writes to the output buffer as much of the *FileName* string as will fit. (The fixed portion of the structure consists of all fields except the final *FileName* string. On the first call, but not on subsequent calls, the I/O system ensures that the buffer is large enough to hold the fixed portion of the appropriate **FILE_*XXX*_INFORMATION** structure.) When this happens, **NtQueryDirectoryFile** returns an appropriate status value such as STATUS_BUFFER_OVERFLOW.

On each call, **NtQueryDirectoryFile** returns as many **FILE_*XXX*_INFORMATION** structures (one per directory entry) as can be contained entirely in the buffer pointed to by *FileInformation*. On the first call, **NtQueryDirectoryFile** returns STATUS_SUCCESS only if the output buffer contains at least one complete structure. On subsequent calls, if the output buffer contains no structures, **NtQueryDirectoryFile** returns STATUS_SUCCESS but sets *IoStatusBlock*->**Information** = 0 to notify the caller of this condition. In this case, the caller should allocate a larger buffer and call **NtQueryDirectoryFile** again. No information about any remaining entries is reported. Thus, except in the cases listed above where only one entry is returned, **NtQueryDirectoryFile** must be called at least twice to enumerate the contents of an entire directory.

When calling **NtQueryDirectoryFile**, you may see changes made to the directory that occur in parallel with **NtQueryDirectoryFile** calls. This behavior is dependent on the implementation of the underlying file system.

The final call to **NtQueryDirectoryFile** returns an empty output buffer and reports an appropriate status value

such as STATUS_NO_MORE_FILES.

If **NtQueryDirectoryFile** is called multiple times on the same directory and some other operation changes the contents of that directory, any changes may or may not be seen, depending on the timing of the operations.

NtQueryDirectoryFilereturns zero in any member of a **FILE_*XXX*_INFORMATION** structure that is not supported by the file system.

Callers of **NtQueryDirectoryFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

For information about other file information query routines, see File Objects.

> **Note** If the call to the **NtQueryDirectoryFile** function occurs in user mode, you should use the name "**NtQueryDirectoryFile**" instead of "**ZwQueryDirectoryFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows XP.
Target Platform	Universal
Header	ntifs.h (include Ntifs.h)

NtCreateFile

NtOpenFile

NtQueryInformationFile function

1/25/2019 • 5 minutes to read • Edit Online

The **NtQueryInformationFile** routine returns various kinds of information about a file object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtQueryInformationFile(
  HANDLE                 FileHandle,
  PIO_STATUS_BLOCK       IoStatusBlock,
  PVOID                  FileInformation,
  ULONG                  Length,
  FILE_INFORMATION_CLASS FileInformationClass
);
```

Parameters

`FileHandle`

Handle to a file object. The handle is created by a successful call to NtCreateFile or NtOpenFile.

`IoStatusBlock`

Pointer to an IO_STATUS_BLOCK structure that receives the final completion status and information about the operation. The **Information** member receives the number of bytes that this routine actually writes to the *FileInformation* buffer.

`FileInformation`

Pointer to a caller-allocated buffer into which the routine writes the requested information about the file object. The *FileInformationClass* parameter specifies the type of information that the caller requests.

`Length`

The size, in bytes, of the buffer pointed to by *FileInformation*.

`FileInformationClass`

Specifies the type of information to be returned about the file, in the buffer that *FileInformation* points to. Device and intermediate drivers can specify any of the following FILE_INFORMATION_CLASS values.

FILE_INFORMATION_CLASS VALUE	TYPE OF INFORMATION RETURNED
FileAccessInformation	A FILE_ACCESS_INFORMATION structure. This structure contains an access mask. For more information about access masks, see ACCESS_MASK.
FileAlignmentInformation	A FILE_ALIGNMENT_INFORMATION structure. The caller can query this information as long as the file is open, without any particular requirements for *DesiredAccess*. This information is useful if the file was opened with the FILE_NO_INTERMEDIATE_BUFFERING flag specified in the *CreateOptions* parameter.

FileAllInformation	A FILE_ALL_INFORMATION structure. By combining several file-information structures into a single structure, **FILE_ALL_INFORMATION** reduces the number of queries required to obtain information about a file.
FileAttributeTagInformation	A FILE_ATTRIBUTE_TAG_INFORMATION structure. The caller must have opened the file with the FILE_READ_ATTRIBUTES flag specified in the *DesiredAccess* parameter.
FileBasicInformation	A FILE_BASIC_INFORMATION structure. The caller must have opened the file with the FILE_READ_ATTRIBUTES flag specified in the *DesiredAccess* parameter.
FileCaseSensitiveInformation	A FILE_CASE_SENSITIVE_INFORMATION structure. The caller must have opened the file with the FILE_READ_ATTRIBUTES flag specified in the *DesiredAccess* parameter. This value is available starting with Windows 10, version 1803.
FileCaseSensitiveInformationForceAccessCheck	A FILE_CASE_SENSITIVE_INFORMATION structure. The caller must have opened the file with the FILE_READ_ATTRIBUTES flag specified in the *DesiredAccess* parameter. This is a special version of the FileCaseSensitiveInformation operation that is used to force the IOManager to perform access checks for the kernel-mode driver, similar to the checks that apply to a user-mode caller. This operation is only recognized by the IOManager and a file system should never receive it. This value is available starting with Windows 10, version 1803.
FileEaInformation	A FILE_EA_INFORMATION structure. This structure specifies the size of the extended attributes block that is associated with the file.
FileInternalInformation	A FILE_INTERNAL_INFORMATION structure. This structure specifies a 64-bit file ID that uniquely identifies a file in NTFS. On other file systems, this file ID is not guaranteed to be unique.
FileIoPriorityHintInformation	A FILE_IO_PRIORITY_HINT_INFORMATION structure. The caller must have opened the file with the FILE_READ_DATA flag specified in the *DesiredAccess* parameter.
FileModeInformation	A FILE_MODE_INFORMATION structure. This structure contains a set of flags that specify the mode in which the file can be accessed. These flags are a subset of the options that can be specified in the *CreateOptions* parameter of the IoCreateFile routine.
FileNameInformation	A FILE_NAME_INFORMATION structure. The structure can contain the file's full path or only a portion of it. The caller can query this information as long as the file is open, without any particular requirements for *DesiredAccess*. For more information about the file-name syntax, see the Remarks section later in this topic.
FileNetworkOpenInformation	A FILE_NETWORK_OPEN_INFORMATION structure. The caller must have opened the file with the FILE_READ_ATTRIBUTES flag specified in the *DesiredAccess* parameter.

FilePositionInformation	A FILE_POSITION_INFORMATION structure. The caller must have opened the file with the *DesiredAccess* FILE_READ_DATA or FILE_WRITE_DATA flag specified in the *DesiredAccess* parameter, and with the FILE_SYNCHRONOUS_IO_ALERT or FILE_SYNCHRONOUS_IO_NONALERT flag specified in the *CreateOptions*parameter.
FileStandardInformation	A FILE_STANDARD_INFORMATION structure. The caller can query this information as long as the file is open, without any particular requirements for *DesiredAccess*.
FileIsRemoteDeviceInformation	A FILE_IS_REMOTE_DEVICE_INFORMATION structure. The caller can query this information as long as the file is open, without any particular requirements for *DesiredAccess*.

Return Value

NtQueryInformationFile returns STATUS_SUCCESS or an appropriate NTSTATUS error code.

Remarks

NtQueryInformationFile returns information about the specified file object. Note that it returns zero in any member of a **FILE_*XXX*_INFORMATION** structure that is not supported by a particular device or file system.

When *FileInformationClass* = **FileNameInformation**, the file name is returned in the FILE_NAME_INFORMATION structure. The precise syntax of the file name depends on a number of factors:

- If you opened the file by submitting a full path to NtCreateFile, **NtQueryInformationFile** returns that full path.
- If the **ObjectAttributes->RootDirectory** handle was opened by name in a call to **NtCreateFile**, and subsequently the file was opened by **NtCreateFile** relative to this root-directory handle, **NtQueryInformationFile** returns the full path.
- If the **ObjectAttributes->RootDirectory** handle was opened by file ID (using the FILE_OPEN_BY_FILE_ID flag) in a call to **NtCreateFile**, and subsequently the file was opened by **NtCreateFile** relative to this root-directory handle, **NtQueryInformationFile** returns the relative path.
- However, if the user has **SeChangeNotifyPrivilege** (described in the Microsoft Windows SDK documentation), **NtQueryInformationFile** returns the full path in all cases.
- If only the relative path is returned, the file name string will not begin with a backslash.
- If the full path and file name are returned, the string will begin with a single backslash, regardless of its location. Thus the file C:\dir1\dir2\filename.ext will appear as \dir1\dir2\filename.ext, while the file \server\share\dir1\dir2\filename.ext will appear as \server\share\dir1\dir2\filename.ext.

If **NtQueryInformationFile** fails because of a buffer overflow, drivers that implement **FileNameInformation** should return as many WCHAR characters of the file name as will fit in the buffer and specify the full length that is required in the *FileNameLength* parameter of the FILE_NAME_INFORMATION structure. You should reissue the query by using the file name length so that you can retrieve the full file name. Drivers that do not follow this pattern might require a gradual increase in length until they retrieve the full file name. For more information about working with files, see Using Files in a Driver.

Callers of **NtQueryInformationFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

Note If the call to this function occurs in user mode, you should use the name "**NtQueryInformationFile**" instead of "**ZwQueryInformationFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

NtQueryInformationToken function

1/25/2019 • 3 minutes to read • Edit Online

The **NtQueryInformationToken** routine retrieves a specified type of information about an access token. The calling process must have appropriate access rights to obtain the information.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtQueryInformationToken(
  HANDLE                  TokenHandle,
  TOKEN_INFORMATION_CLASS TokenInformationClass,
  PVOID                   TokenInformation,
  ULONG                   TokenInformationLength,
  PULONG                  ReturnLength
);
```

Parameters

`TokenHandle`

Handle for an access token from which information is to be retrieved. If *TokenInformationClass* is set to **TokenSource**, the handle must have TOKEN_QUERY_SOURCE access. For all other *TokenInformationClass* values, the handle must have TOKEN_QUERY access. For more information about access rights for access-token objects, see the Security section of the Windows SDK documentation.

`TokenInformationClass`

A value from the TOKEN_INFORMATION_CLASS enumerated type identifying the type of information to be retrieved. The possible values for this parameter are listed in the *TokenInformationClass* Value column of the table shown in the description of the *TokenInformation* parameter.

`TokenInformation`

Pointer to a caller-allocated buffer that receives the requested information about the token. The structure put into this buffer depends upon the value of *TokenInformationClass*, as shown in the following table. All structures must be aligned on a 32-bit boundary.

***TOKENINFORMATIONCLASS* VALUE**	**EFFECT ON *TOKENINFORMATION* BUFFER**
TokenDefaultDacl	The buffer receives a TOKEN_DEFAULT_DACL structure containing the default DACL for newly created objects.
TokenGroups	The buffer receives a TOKEN_GROUPS structure containing the group accounts associated with the token.
TokenImpersonationLevel	The buffer receives a SECURITY_IMPERSONATION_LEVEL value indicating the impersonation level of the token. If the access token is not an impersonation token, the call to **NtQueryInformationToken** fails.
TokenOwner	The buffer receives a TOKEN_OWNER structure containing the default owner SID for newly created objects.

TokenPrimaryGroup	The buffer receives a TOKEN_PRIMARY_GROUP structure containing the default primary group SID for newly created objects.
TokenPrivileges	The buffer receives a TOKEN_PRIVILEGES structure containing the token's privileges.
TokenSessionId	The buffer receives a 32-bit value specifying the Terminal Services session identifier associated with the token. If the token is associated with the Terminal Server console session, the session identifier is zero. A nonzero session identifier indicates a Terminal Services client session. In a non-Terminal Services environment, the session identifier is zero.
TokenSource	The buffer receives a TOKEN_SOURCE structure containing the source of the token. TOKEN_QUERY_SOURCE access is needed to retrieve this information.
TokenStatistics	The buffer receives a TOKEN_STATISTICS structure containing various token statistics.
TokenType	The buffer receives a TOKEN_TYPE value indicating whether the token is a primary or impersonation token.
TokenUser	The buffer receives a TOKEN_USER structure containing the token's user account.

`TokenInformationLength`

Length, in bytes, of the caller-allocated *TokenInformation* buffer.

`ReturnLength`

Pointer to a caller-allocated variable that receives the actual length, in bytes, of the information returned in the *TokenInformation* buffer. If either of the following conditions is true, no data is returned in the *TokenInformation* buffer:

- The size of the requested token information structure is greater than *TokenInformationLength*. In this case, *ReturnLength* receives the actual number of bytes needed to store the requested information.
- The value of *TokenInformationClass* is **TokenDefaultDacl**, and there is no default DACL established for the token. In this case, *ReturnLength* receives zero.

Return Value

NtQueryInformationToken returns STATUS_SUCCESS or an appropriate error status. Possible error status codes include the following:

RETURN CODE	DESCRIPTION
STA TUS _AC CES S_D ENI ED	*TokenHandle* did not have the required access.

STATUS_BUFFER_TOO_SMALL	The size of the requested token information structure is greater than *TokenInformationLength*. The number of bytes required is returned in *ReturnLength*.
STATUS_INVALID_HANDLE	*TokenHandle* was not a valid handle.
STATUS_INVALID_INFO_CLASS	*TokenInformationClass* was not a valid token information class.
STATUS_OBJECT_TYPE_MISMATCH	*TokenHandle* was not a token handle.

Remarks

The **NtQueryInformationToken** routine can be used by a file system or file system filter driver to determine the SID of the caller that initiated the request during IRP_MJ_CREATE processing. If **TokenUser** is specified for the *TokenInformationClass* parameter passed to **NtQueryInformationToken**, a TOKEN_USER structure is returned in the buffer pointed to by the *TokenInformation* parameter. This returned buffer contains an SID_AND_ATTRIBUTES structure with the user **SID**.

For more information about security and access control, see the documentation on these topics in the Windows SDK.

Note If the call to the **NtQueryInformationToken** function occurs in user mode, you should use the name "**NtQueryInformationToken**" instead of "**ZwQueryInformationToken**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	ntifs.h (include Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

NtQueryObject function

1/25/2019 • 2 minutes to read • Edit Online

The **NtQueryObject** routine provides information about a supplied object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtQueryObject(
  HANDLE                   Handle,
  OBJECT_INFORMATION_CLASS ObjectInformationClass,
  PVOID                    ObjectInformation,
  ULONG                    ObjectInformationLength,
  PULONG                   ReturnLength
);
```

Parameters

`Handle`

A handle to the object to obtain information about.

`ObjectInformationClass`

Specifies an OBJECT_INFORMATION_CLASS value that determines the type of information returned in the *ObjectInformation* buffer.

`ObjectInformation`

A pointer to a caller-allocated buffer that receives the requested information.

`ObjectInformationLength`

Specifies the size, in bytes, of the *ObjectInformation* buffer.

`ReturnLength`

A pointer to a variable that receives the size, in bytes, of the requested key information. If **NtQueryObject** returns STATUS_SUCCESS, the variable contains the amount of data returned. If **NtQueryObject** returns STATUS_BUFFER_OVERFLOW or STATUS_BUFFER_TOO_SMALL, you can use the value of the variable to determine the required buffer size.

Return Value

NtQueryObject returns STATUS_SUCCESS or an appropriate error status. Possible error status codes include the following:

RETURN CODE	DESCRIPTION

STA TUS _AC CES S_D ENI ED	There were insufficient permissions to perform this query.
STA TUS _IN VAL ID_ HA NDL E	The supplied object handle is invalid.
STA TUS _INF O_L ENG TH_ MIS MA TCH	The info length is not sufficient to hold the data.

Remarks

If the call to the **NtQueryObject** function occurs in user mode, you should use the name "**NtQueryObject**" instead of "**ZwQueryObject**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Ntifs.h, FltKernel.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

OBJECT_INFORMATION_CLASS

PUBLIC_OBJECT_BASIC_INFORMATION

PUBLIC_OBJECT_TYPE_INFORMATION

Using Nt and Zw Versions of the Native System Services Routines

NtQueryQuotaInformationFile function

1/25/2019 • 3 minutes to read • Edit Online

The **NtQueryQuotaInformationFile** routine retrieves quota entries associated with the volume specified by the *FileHandle* parameter.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtQueryQuotaInformationFile(
  HANDLE           FileHandle,
  PIO_STATUS_BLOCK IoStatusBlock,
  PVOID            Buffer,
  ULONG            Length,
  BOOLEAN          ReturnSingleEntry,
  PVOID            SidList,
  ULONG            SidListLength,
  PSID             StartSid,
  BOOLEAN          RestartScan
);
```

Parameters

`FileHandle`

A handle for the file object that represents the file or volume for which the quota information is requested.

`IoStatusBlock`

The address of the caller's I/O status block.

`Buffer`

A buffer to receive the quota information for the volume. The quota information is formatted as one or more FILE_QUOTA_INFORMATION structures. The **NextEntryOffset** field in the **FILE_QUOTA_INFORMATION** structure contains the offset, in bytes, of the next quota entry in the list. If there are no more entries after the current one, this member is zero.

`Length`

The length in bytes of the buffer.

`ReturnSingleEntry`

A Boolean value that indicates if only a single entry should be returned rather than filling the buffer with as many entries as possible.

`SidList`

An optional list of SIDs whose quota information is to be returned. Each entry in the list is a FILE_GET_QUOTA_INFORMATION structure. The **NextEntryOffset** field in the **FILE_GET_QUOTA_INFORMATION** structure contains the offset, in bytes, of the next quota entry in the list. If there are no more entries after the current one, this member is zero.

`SidListLength`

The length in bytes of the **SID** list, if one was specified.

`StartSid`

An optional pointer to the **SID** of the entry at which to begin scanning the quota information. This parameter should be set if the returned information is to start with an entry other than the first SID. This parameter is ignored if a *SidList* parameter is specified.

`RestartScan`

A Boolean value that indicates whether the scan of the quota information is to be restarted from the beginning. Set this parameter to **TRUE** if the scan of the quota information is to start at the first entry in the volume's quota information list. Set to **FALSE** if resuming the scan from a previous call to **NtQueryQuotaInformationFile**. The caller must set this parameter to **TRUE** when calling **NtQueryQuotaInformationFile** for the first time.

Return Value

The **NtQueryQuotaInformationFile** routine returns STATUS_SUCCESS if at least one FILE_QUOTA_INFORMATION structure is returned in the *Buffer* parameter or an appropriate NTSTATUS value such as one of the following:

RETURN CODE	DESCRIPTION
STATUS_INSUFFICIENT_RESOURCES	There were insufficient resources to complete the operation. This is an error code.
STATUS_INVALID_DEVICE_REQUEST	Quotas are not enabled on the volume. This is an error code.
STATUS_INVALID_SID	The*StartSid* parameter did not contain a valid **SID**. This is an error code.

STA **TUS** **_QU** **OT** **A_LI** **ST_I** **NC** **ON** **SIST** **ENT**	The*SidList* parameter did not contain a valid, properly formed list. This is an error code.

Remarks

The amount of information returned by **NtQueryQuotaInformationFile** is based on the size of the quota information associated with the volume, the size of the buffer, and whether a specific set of entries has been requested.

A call to **NtQueryQuotaInformationFile** will result in an IRP_MJ_QUERY_QUOTA request being sent to the device object that is associated with the file object whose handle is stored in the *FileHandle* parameter.

If the underlying file system does not support quota information (FAT and CDFS file systems, for example), **NtQueryQuotaInformationFile** will fail returning STATUS_INVALID_DEVICE_REQUEST.

> **Note** If the call to the **NtQueryQuotaInformationFile** function occurs in user mode, you should use the name "**NtQueryQuotaInformationFile**" instead of "**ZwQueryQuotaInformationFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows operating systems.
Target Platform	Universal
Header	ntifs.h (include Ntifs.h, FltKernel.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

NtQuerySecurityObject function

1/25/2019 • 2 minutes to read • Edit Online

The **NtQuerySecurityObject** routine retrieves a copy of an object's security descriptor.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtQuerySecurityObject(
  HANDLE               Handle,
  SECURITY_INFORMATION SecurityInformation,
  PSECURITY_DESCRIPTOR SecurityDescriptor,
  ULONG                Length,
  PULONG               LengthNeeded
);
```

Parameters

`Handle`

Handle for the object whose security descriptor is to be queried. This handle must have the access specified in the Meaning column of the table shown in the description of the *SecurityInformation* parameter.

`SecurityInformation`

Pointer to a SECURITY_INFORMATION value specifying the information to be queried.

VALUE	MEANING
DACL_SECURITY_INFORMATION	Indicates the discretionary access control list (DACL) of the object is being queried. Requires READ_CONTROL access.
GROUP_SECURITY_INFORMATION	Indicates the primary group identifier of the object is being queried. Requires READ_CONTROL access.
OWNER_SECURITY_INFORMATION	Indicates the owner identifier of the object is being queried. Requires READ_CONTROL access.
SACL_SECURITY_INFORMATION	Indicates the system ACL (SACL) of the object is being queried. Requires ACCESS_SYSTEM_SECURITY access.

`SecurityDescriptor`

Caller-allocated buffer that **NtQuerySecurityObject** fills with a copy of the specified security descriptor. The SECURITY_DESCRIPTOR structure is returned in self-relative format.

`Length`

Size, in bytes, of the buffer pointed to by *SecurityDescriptor*.

`LengthNeeded`

Pointer to a caller-allocated variable that receives the number of bytes required to store the copied security descriptor.

Return Value

NtQuerySecurityObject returns STATUS_SUCCESS or an appropriate error status. Possible error status codes include the following:

RETURN CODE	DESCRIPTION
STATUS_ACCESS_DENIED	*Handle* did not have the required access.
STATUS_BUFFER_TOO_SMALL	The buffer is too small for the security descriptor. None of the security information was copied to the buffer.
STATUS_INVALID_HANDLE	*Handle* was not a valid handle.
STATUS_OBJECT_TYPE_MISMATCH	*Handle* was not a handle of the expected type.

Remarks

A security descriptor can be in absolute or self-relative form. In self-relative form, all members of the structure are located contiguously in memory. In absolute form, the structure only contains pointers to the members.

The NTFS file system imposes a 64K limit on the size of the security descriptor that is written to disk for a file. (The FAT file system does not support security descriptors for files.) Thus a 64K *SecurityDescriptor* buffer is guaranteed to be large enough to hold the returned **SECURITY_DESCRIPTOR** structure.

For more information about security and access control, see the documentation on these topics in the Windows SDK.

Minifilters should call FltQuerySecurityObject instead of **NtQuerySecurityObject**.

> **Note** If the call to the **NtQuerySecurityObject** function occurs in user mode, you should use the name "**NtQuerySecurityObject**" instead of "**ZwQuerySecurityObject**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	ntifs.h (include Ntifs.h)

SECURITY_INFORMATION

Using Nt and Zw Versions of the Native System Services Routines

ZwSetSecurityObject

NtQueryVirtualMemory function

1/25/2019 • 2 minutes to read • Edit Online

The **NtQueryVirtualMemory** routine determines the state, protection, and type of a region of pages within the virtual address space of the subject process.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtQueryVirtualMemory(
  HANDLE                   ProcessHandle,
  PVOID                    BaseAddress,
  MEMORY_INFORMATION_CLASS MemoryInformationClass,
  PVOID                    MemoryInformation,
  SIZE_T                   MemoryInformationLength,
  PSIZE_T                  ReturnLength
);
```

Parameters

`ProcessHandle`

A handle for the process in whose context the pages to be queried reside. Use the NtCurrentProcess macro to specify the current process.

`BaseAddress`

The base address of the region of pages to be queried. This value is rounded down to the next host-page- address boundary.

`MemoryInformationClass`

The memory information class about which to retrieve information. Currently, the only supported MEMORY_INFORMATION_CLASS value is **MemoryBasicInformation**.

`MemoryInformation`

A pointer to a buffer that receives the specified information. The format and content of the buffer depend on the specified information class specified in the *MemoryInformationClass* parameter. When the value **MemoryBasicInformation** is passed to *MemoryInformationClass*, the *MemoryInformationClass* parameter value is a MEMORY_BASIC_INFORMATION.

`MemoryInformationLength`

Specifies the length in bytes of the memory information buffer.

`ReturnLength`

An optional pointer which, if specified, receives the number of bytes placed in the memory information buffer.

Return Value

Returns STATUS_SUCCESS if the call is successful. If the call fails, possible error codes include the following:

RETURN CODE	DESCRIPTION

STATUS_INVALID_PARAMETER	The specified base address is outside the range of accessible addresses.
STATUS_ACCESS_DENIED	The caller had insufficient access rights to perform the requested action.
STATUS_INFO_LENGTH_MISMATCH	The *MemoryInformation* buffer is larger than *MemoryInformationLength*.
STATUS_INVALID_INFO_CLASS	A value other than **MemoryBasicInformation** was passed to the *MemoryInformationClass* parameter.

Remarks

ZwQueryVirtualMemory determines the state of the first page within the region and then scans subsequent entries in the process address map from the base address upward until either the entire range of pages has been scanned or until a page with a non-matching set of attributes is encountered. The region attributes, the length of the region of pages with matching attributes, and an appropriate status value are returned.

If the entire region of pages does not have a matching set of attributes, then the *ReturnLength* parameter value can be used to compute the address and length of the region of pages that was not scanned.

NtQueryVirtualMemory and **ZwQueryVirtualMemory** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native

System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 10.
Target Platform	Universal
Header	ntifs.h
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

POWER_PLATFORM_INFORMATION

Using Nt and Zw Versions of the Native System Services Routines

NtQueryVolumeInformationFile function

1/25/2019 • 3 minutes to read • Edit Online

The **NtQueryVolumeInformationFile** routine retrieves information about the volume associated with a given file, directory, storage device, or volume.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtQueryVolumeInformationFile(
  HANDLE               FileHandle,
  PIO_STATUS_BLOCK     IoStatusBlock,
  PVOID                FsInformation,
  ULONG                Length,
  FS_INFORMATION_CLASS FsInformationClass
);
```

Parameters

`FileHandle`

A handle to a file object returned by NtCreateFile or NtOpenFile for an open file, directory, storage device, or volume for which volume information is being requested.

`IoStatusBlock`

A pointer to an IO_STATUS_BLOCK structure that receives the final completion status and information about the query operation. For successful calls that return data, the number of bytes written to the *FsInformation* buffer is returned in the structure's **Information** member.

`FsInformation`

A pointer to a caller-allocated buffer that receives the desired information about the volume. The structure of the information returned in the buffer is defined by the *FsInformationClass* parameter.

`Length`

Size in bytes of the buffer pointed to by *FsInformation*. The caller should set this parameter according to the given *FsInformationClass*.

`FsInformationClass`

Type of information to be returned about the volume. Set this member to one of the following FS_INFORMATION_CLASS enumeration values.

VALUE	MEANING
FileFsAttributeInformation	Return a FILE_FS_ATTRIBUTE_INFORMATION structure containing attribute information about the file system responsible for the volume.
FileFsControlInformation	Return a FILE_FS_CONTROL_INFORMATION structure containing file system control information about the volume.

FileFsDeviceInformation	Return a FILE_FS_DEVICE_INFORMATION structure containing device information for the volume.
FileFsDriverPathInformation	Return a FILE_FS_DRIVER_PATH_INFORMATION structure containing information about whether a specified driver is in the I/O path for the volume. The caller must store the name of the driver into the **FILE_FS_DRIVER_PATH_INFORMATION** structure before calling **NtQueryVolumeInformationFile**.
FileFsFullSizeInformation	Return a FILE_FS_FULL_SIZE_INFORMATION structure containing information about the total amount of space available on the volume.
FileFsObjectIdInformation	Return a FILE_FS_OBJECTID_INFORMATION structure containing file system-specific object ID information for the volume. Note that this is not the same as the (GUID-based) unique volume name assigned by the operating system.
FileFsSizeInformation	Return a FILE_FS_SIZE_INFORMATION structure containing information about the amount of space on the volume that is available to the user associated with the calling thread.
FileFsVolumeInformation	Return a FILE_FS_VOLUME_INFORMATION containing information about the volume such as the volume label, serial number, and creation time.
FileFsSectorSizeInformation	Return a FILE_FS_SECTOR_SIZE_INFORMATION structure that contains information about the physical and logical sector sizes of a volume.

Return Value

NtQueryVolumeInformationFile returns STATUS_SUCCESS or an appropriate error status.

Remarks

NtQueryVolumeInformationFile retrieves information about the volume associated with a given file, directory, storage device, or volume.

If the *FileHandle* represents a direct device open, only *FileFsDeviceInformation* can be specified as the value of *FsInformationClass*.

NtQueryVolumeInformationFile returns zero in any member of a **FILE_*XXX*_INFORMATION** structure that is not supported by the file system.

For information about other file information query routines, see File Objects.

Minifilters should use FltQueryVolumeInformationFile instead of **NtQueryVolumeInformationFile**.

Callers of **NtQueryVolumeInformationFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to the **NtQueryVolumeInformationFile** function occurs in user mode, you should use the name "**NtQueryVolumeInformationFile**" instead of "**ZwQueryVolumeInformationFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the

relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows XP.

NtReadFile function

1/25/2019 • 4 minutes to read • Edit Online

The **NtReadFile** routine reads data from an open file.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtReadFile(
  HANDLE           FileHandle,
  HANDLE           Event,
  PIO_APC_ROUTINE  ApcRoutine,
  PVOID            ApcContext,
  PIO_STATUS_BLOCK IoStatusBlock,
  PVOID            Buffer,
  ULONG            Length,
  PLARGE_INTEGER   ByteOffset,
  PULONG           Key
);
```

Parameters

`FileHandle`

Handle to the file object. This handle is created by a successful call to NtCreateFile or NtOpenFile.

`Event`

Optionally, a handle to an event object to set to the signaled state after the read operation completes. Device and intermediate drivers should set this parameter to **NULL**.

`ApcRoutine`

This parameter is reserved. Device and intermediate drivers should set this pointer to **NULL**.

`ApcContext`

This parameter is reserved. Device and intermediate drivers should set this pointer to **NULL**.

`IoStatusBlock`

Pointer to an IO_STATUS_BLOCK structure that receives the final completion status and information about the requested read operation. The **Information** member receives the number of bytes actually read from the file.

`Buffer`

Pointer to a caller-allocated buffer that receives the data read from the file.

`Length`

The size, in bytes, of the buffer pointed to by *Buffer*.

`ByteOffset`

Pointer to a variable that specifies the starting byte offset in the file where the read operation will begin. If an attempt is made to read beyond the end of the file, **NtReadFile** returns an error.

If the call to NtCreateFile set either of the **CreateOptions** flags FILE_SYNCHRONOUS_IO_ALERT or

FILE_SYNCHRONOUS_IO_NONALERT, the I/O Manager maintains the current file position. If so, the caller of **NtReadFile** can specify that the current file position offset be used instead of an explicit **ByteOffset** value. This specification can be made by using one of the following methods:

- Specify a pointer to a LARGE_INTEGER value with the **HighPart** member set to -1 and the **LowPart** member set to the system-defined value FILE_USE_FILE_POINTER_POSITION.
- Pass a **NULL** pointer for *ByteOffset*.

NtReadFile updates the current file position by adding the number of bytes read when it completes the read operation, if it is using the current file position maintained by the I/O Manager.

Even when the I/O Manager is maintaining the current file position, the caller can reset this position by passing an explicit *ByteOffset* value to **NtReadFile**. Doing this automatically changes the current file position to that *ByteOffset* value, performs the read operation, and then updates the position according to the number of bytes actually read. This technique gives the caller atomic seek-and-read service.

`Key`

Device and intermediate drivers should set this pointer to **NULL**.

Return Value

NtReadFile returns either STATUS_SUCCESS or the appropriate NTSTATUS error code.

Remarks

Callers of **NtReadFile** must have already called NtCreateFile with the FILE_READ_DATA or GENERIC_READ value set in the *DesiredAccess* parameter.

If the preceding call to ZwCreateFile set the FILE_NO_INTERMEDIATE_BUFFERING flag in the *CreateOptions* parameter to **NtCreateFile**, the *Length* and *ByteOffset* parameters to **NtReadFile** must be multiples of the sector size.

NtReadFile begins reading from the given *ByteOffset* or the current file position into the given *Buffer*. It terminates the read operation under one of the following conditions:

- The buffer is full because the number of bytes specified by the *Length* parameter has been read. Therefore, no more data can be placed into the buffer without an overflow.
- The end of file is reached during the read operation, so there is no more data in the file to be transferred into the buffer.

If the caller opened the file with the SYNCHRONIZE flag set in *DesiredAccess*, the calling thread can synchronize to the completion of the read operation by waiting on the file handle, *FileHandle*. The handle is signaled each time that an I/O operation that was issued on the handle completes. However, the caller must not wait on a handle that was opened for synchronous file access (FILE_SYNCHRONOUS_IO_NONALERT or FILE_SYNCHRONOUS_IO_ALERT). In this case, **NtReadFile** waits on behalf of the caller and does not return until the read operation is complete. The caller can safely wait on the file handle only if all three of the following conditions are met:

- The handle was opened for asynchronous access (that is, neither FILE_SYNCHRONOUS_IO_**XXX** flag was specified).
- The handle is being used for only one I/O operation at a time.
- **NtReadFile** returned STATUS_PENDING.

A driver should call **NtReadFile** in the context of the system process if any of the following conditions exist:

- The driver created the file handle that it passes to **NtReadFile**.
- **NtReadFile** will notify the driver of I/O completion by means of an event that the driver created.
- **NtReadFile** will notify the driver of I/O completion by means of an APC callback routine that the driver passes to **NtReadFile**.

File and event handles are valid only in the process context where the handles are created. Therefore, to avoid security holes, the driver should create any file or event handle that it passes to **NtReadFile** in the context of the system process rather than the context of the process that the driver is in.

Likewise, **NtReadFile** should be called in the context of the system process if it notifies the driver of I/O completion by means of an APC, because APCs are always fired in the context of the thread that issues the I/O request. If the driver calls **NtReadFile** in the context of a process other than the system one, the APC could be delayed indefinitely, or it might not fire at all.

For more information about working with files, see Using Files in a Driver.

Callers of **NtReadFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to this function occurs in user mode, you should use the name "NtReadFile" instead of "**ZwReadFile**".

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL (see Remarks section)

NtSetInformationFile function

1/25/2019 • 4 minutes to read • Edit Online

The **NtSetInformationFile** routine changes various kinds of information about a file object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtSetInformationFile(
  HANDLE                 FileHandle,
  PIO_STATUS_BLOCK       IoStatusBlock,
  PVOID                  FileInformation,
  ULONG                  Length,
  FILE_INFORMATION_CLASS FileInformationClass
);
```

Parameters

`FileHandle`

Handle to the file object. This handle is created by a successful call to NtCreateFile or NtOpenFile.

`IoStatusBlock`

Pointer to an IO_STATUS_BLOCK structure that receives the final completion status and information about the requested operation. The **Information** member receives the number of bytes set on the file.

`FileInformation`

Pointer to a buffer that contains the information to set for the file. The particular structure in this buffer is determined by the *FileInformationClass* parameter. Setting any member of the structure to zero tells **NtSetInformationFile** to leave the current information about the file for that member unchanged.

`Length`

The size, in bytes, of the *FileInformation* buffer.

`FileInformationClass`

The type of information, supplied in the buffer pointed to by *FileInformation*, to set for the file. Device and intermediate drivers can specify any of the following FILE_INFORMATION_CLASS values.

***FILEINFORMATIONCLASS* VALUE**	**MEANING**
FileBasicInformation	Change the information that is supplied in a FILE_BASIC_INFORMATION structure. The caller must have opened the file with the FILE_WRITE_ATTRIBUTES flag set in the *DesiredAccess* parameter.
FileCaseSensitiveInformation	Change the information that is supplied in a FILE_CASE_SENSITIVE_INFORMATION structure. The caller must have opened the file with the FILE_WRITE_ATTRIBUTES flag set in the *DesiredAccess* parameter. This value is available starting with Windows 10, version 1803.

FileCaseSensitiveInformationForceAccessCheck	Change the information that is supplied in a FILE_CASE_SENSITIVE_INFORMATION structure. The caller must have opened the file with the FILE_WRITE_ATTRIBUTES flag set in the *DesiredAccess* parameter. This is a special version of the FileCaseSensitiveInformation operation that is used to force the IOManager to perform access checks for the kernel-mode driver, similar to the checks that apply to a user-mode caller. This operation is only recognized by the IOManager and a file system should never receive it. This value is available starting with Windows 10, version 1803.
FileDispositionInformation	Usually, sets the **DeleteFile** member of a FILE_DISPOSITION_INFORMATION to **TRUE**, so the file can be deleted when NtClose is called to release the last open handle to the file object. The caller must have opened the file with the DELETE flag set in the *DesiredAccess* parameter.
FileEndOfFileInformation	Change the current end-of-file information, supplied in a FILE_END_OF_FILE_INFORMATION structure. The operation can either truncate or extend the file. The caller must have opened the file with the FILE_WRITE_DATA flag set in the *DesiredAccess* parameter.
FileIoPriorityHintInformation	Change the current default IRP priority hint for the file handle. The new value is supplied in a FILE_IO_PRIORITY_HINT_INFORMATION structure. **Note** This structure must be 8-byte aligned.
FileLinkInformation	Create a hard link to an existing file, which is specified in a FILE_LINK_INFORMATION structure. Not all file systems support hard links; for example NTFS does while FAT does not.
FilePositionInformation	Change the current file information, which is stored in a FILE_POSITION_INFORMATION structure.
FileRenameInformation	Change the current file name, which is supplied in a FILE_RENAME_INFORMATION structure. The caller must have DELETE access to the file.
FileShortNameInformation	Change the current short file name, which is supplied in a FILE_NAME_INFORMATION structure. The file must be on an NTFS volume, and the caller must have opened the file with the *DesiredAccess* DELETE flag set in the *DesiredAccess* parameter.
FileValidDataLengthInformation	Change the current valid data length for the file, which is supplied in a FILE_VALID_DATA_LENGTH_INFORMATION structure. The file must be on an NTFS volume, and the caller must have opened the file with the FILE_WRITE_DATA flag set in the *DesiredAccess* parameter. Non-administrators and remote users must have the **SeManageVolumePrivilege** privilege.

FileReplaceCompletionInformation	Change or remove the I/O completion port for the specified file handle. The caller supplies a pointer to a FILE_COMPLETION_INFORMATION structure that specifies a port handle and a completion key. If the port handle is non-NULL, this handle specifies a new I/O completion port to associate with the file handle. To remove the I/O completion port associated with the file handle, set the port handle in the structure to NULL. To get a port handle, a user-mode caller can call the CreateIoCompletionPort function.

Return Value

NtSetInformationFile returns STATUS_SUCCESS or an appropriate error status.

Remarks

NtSetInformationFile changes information about a file. It ignores any member of a **FILE_*XXX*_INFORMATION** structure that is not supported by a particular device or file system.

If you set *FileInformationClass* to **FileDispositionInformation**, you can subsequently pass *FileHandle* to NtClose but not to any other **Zw*Xxx*File** routine. Because **FileDispositionInformation** causes the file to be marked for deletion, it is a programming error to attempt any subsequent operation on the handle other than closing it.

If you set *FileInformationClass* to **FilePositionInformation**, and the preceding call to **NtCreateFile** included the FILE_NO_INTERMEDIATE_BUFFERING flag in the *CreateOptions* parameter, certain restrictions on the **CurrentByteOffset** member of the FILE_POSITION_INFORMATION structure are enforced. For more information, see NtCreateFile.

If you set *FileInformationClass* to **FileEndOfFileInformation**, and the **EndOfFile** member of FILE_END_OF_FILE_INFORMATION specifies an offset beyond the current end-of-file mark, **NtSetInformationFile** extends the file and pads the extension with zeros.

For more information about working with files, see Using Files in a Driver.

Callers of **NtSetInformationFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtSetInformationFile**" instead of "**ZwSetInformationFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

NtSetInformationThread function

1/25/2019 • 2 minutes to read • Edit Online

The **NtSetInformationThread** routine sets the priority of a thread.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtSetInformationThread(
  HANDLE          ThreadHandle,
  THREADINFOCLASS ThreadInformationClass,
  PVOID           ThreadInformation,
  ULONG           ThreadInformationLength
);
```

Parameters

`ThreadHandle`

Handle to the thread object. To create a new thread and get a handle to it, call PsCreateSystemThread. To specify the current thread, use the ZwCurrentThread macro.

`ThreadInformationClass`

One of the system-defined values in the THREADINFOCLASS enumeration (see ntddk.h), **ThreadPriority**, **ThreadBasePriority**, **ThreadPagePriority**, or **ThreadPowerThrottlingState**.

`ThreadInformation`

Pointer to a variable that specifies the information to set.

If **ThreadInformationClass** is **ThreadPriority**, this value must be > LOW_PRIORITY and <= HIGH_PRIORITY.

If **ThreadInformationClass** is **ThreadBasePriority**, this value must fall within the system's valid base-priority range and the original priority class for the given thread. That is, if a thread's priority class is variable, that thread's base priority cannot be reset to a real-time priority value, and vice versa.

If **ThreadInformationClass** is **ThreadPagePriority**, this value is a pointer to a **PAGE_PRIORITY_INFORMATION** structure, see ntddk.h. The **PagePriority** member value must be one of these values.

If **ThreadInformationClass** is **ThreadPowerThrottlingState**, this value is a pointer to a POWER_THROTTLING_THREAD_STATE structure, see ntddk.h. The **PagePriority** member value must be one of these values.

VALUE	MEANING

MEMORY_PRIORITY_VERY_LOW 1	Very low memory priority.
MEMORY_PRIORITY_LOW 2	Low memory priority.
MEMORY_PRIORITY_MEDIUM 3	Medium memory priority.
MEMORY_PRIORITY_BELOW_NORMAL 4	Below normal memory priority.
MEMORY_PRIORITY_NORMAL 5	Normal memory priority. This is the default priority for all threads and processes on the system.

`ThreadInformationLength`

The size, in bytes, of **ThreadInformation**.

Return Value

NtSetInformationThread returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure. Possible error codes include STATUS_INFO_LENGTH_MISMATCH or STATUS_INVALID_PARAMETER.

Remarks

NtSetInformationThread can be called by higher-level drivers to set the priority of a thread for which they have a handle.

The caller must have THREAD_SET_INFORMATION access rights for the given thread in order to call this routine.

Usually, device and intermediate drivers that set up driver-created threads call KeSetBasePriorityThread or KeSetPriorityThread from their driver-created threads, rather than calling **NtSetInformationThread**. However, a driver can call **NtSetInformationThread** to raise the priority of a driver-created thread before that thread runs.

Kernel mode drivers can call the **NtSetInformationThread** function with **ThreadPagePriority** to specify a thread's page priority.

To help improve system performance, drivers should use the function with **ThreadPagePriority** to lower the page priority of threads that perform background operations or access files and data that are not expected to be accessed again soon. For example, an anti-malware application might lower the priority of threads involved in scanning files.

To determine the page priority for a thread, call ZwQueryInformationThread.

> **Note** If the call to this function occurs in user mode, you should use the name NtSetInformationThread instead of **ZwSetInformationThread**.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.

NtSetInformationToken function

1/25/2019 • 3 minutes to read • Edit Online

The **NtSetInformationToken** routine modifies information in a specified token. The calling process must have appropriate access rights to set the information.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtSetInformationToken(
  HANDLE                  TokenHandle,
  TOKEN_INFORMATION_CLASS TokenInformationClass,
  PVOID                   TokenInformation,
  ULONG                   TokenInformationLength
);
```

Parameters

`TokenHandle`

Handle for an access token in which information is to be modified.

`TokenInformationClass`

A value from the TOKEN_INFORMATION_CLASS enumerated type identifying the type of information to be modified. The possible values for this parameter are listed in the *TokenInformationClass* Value column of the table shown in the description of the *TokenInformation* parameter.

`TokenInformation`

Pointer to a caller-supplied buffer containing the information to be modified in the token. The structure of the information in this buffer depends upon the value of *TokenInformationClass*, as shown in the following table. All structures must be aligned on a 32-bit boundary.

***TOKENINFORMATIONCLASS* VALUE**	**EFFECT ON *TOKENINFORMATION* BUFFER**
TokenDefaultDacl	The buffer contains a TOKEN_DEFAULT_DACL structure specifying the default DACL for newly created objects. TOKEN_ADJUST_DEFAULT access is required to set this information. The buffer contents are not validated for structural correctness or consistency.
TokenGroups	Not a valid information class. This information is read-only.
TokenOwner	The buffer contains a TOKEN_OWNER structure specifying the default owner SID for newly created objects. TOKEN_ADJUST_DEFAULT access is required to set this information. The owner values that may be specified are restricted to the user and group IDs with an attribute indicating they can be assigned as the owner of objects.

TokenPrimaryGroup	The buffer contains a TOKEN_PRIMARY_GROUP structure specifying the default primary group **SID** for newly created objects. TOKEN_ADJUST_DEFAULT access is required to set this information. Must be one of the group IDs already in the token.
TokenPrivileges	Not a valid information class. This information is read-only.
TokenSource	Not a valid information class. This information is read-only.
TokenStatistics	Not a valid information class. This information is read-only.
TokenUser	Not a valid information class. This information is read-only.

`TokenInformationLength`

Size, in bytes, of the structure passed in the *TokenInformation* buffer. Must be greater than or equal to the minimum value given in the following table.

TOKENINFORMATIONCLASS VALUE	MINIMUM *TOKENINFORMATIONLENGTH*
TokenDefaultDacl	**sizeof**(**TOKEN_DEFAULT_DACL**)
TokenOwner	**sizeof**(**TOKEN_OWNER**)
TokenPrimaryGroup	**sizeof**(**TOKEN_PRIMARY_GROUP**)

Return Value

NtSetInformationToken returns STATUS_SUCCESS or an appropriate error status. Possible error status codes include the following:

RETURN CODE	DESCRIPTION
STATUS_ACCESS_DENIED	*TokenHandle* did not have the required access.
STATUS_ALLOTTED_SPACE_EXCEEDED	The space allotted for storage of the default discretionary access control and the primary group ID is not large enough to accept the new value of one of these fields.

STATUS_INFO_LENGTH_MISMATCH	The value of *TokenInformationLength* was less than the required minimum.
STATUS_INSUFFICIENT_RESOURCES	The specified default owner's security information could not be captured.
STATUS_INVALID_HANDLE	*TokenHandle* was not a valid handle.
STATUS_INVALID_INFO_CLASS	*TokenInformationClass* was not a valid token information class.
STATUS_INVALID_OWNER	The caller cannot set the specified ID to be an owner (or default owner) of an object.

STA TUS _IN VAL ID_ PRI MA RY_ GR OU P	The caller cannot set the specified ID to be the primary group of an object.
STA TUS _IN VAL ID_S ID	The specified default owner's security information was not valid.
STA TUS _OB JEC T_T YPE _MI SM ATC H	*TokenHandle* was not a token handle.

Remarks

For more information about security and access control, see the documentation on these topics in the Windows SDK.

> **Note** If the call to the **NtSetInformationToken** function occurs in user mode, you should use the name "NtSetInformationToken" instead of "**ZwSetInformationToken**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	ntifs.h (include Ntifs.h)

NtSetQuotaInformationFile function

1/25/2019 • 2 minutes to read • Edit Online

The **NtSetQuotaInformationFile** routine changes quota entries for the volume associated with the *FileHandle* parameter. All of the quota entries in the specified buffer are applied to the volume.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtSetQuotaInformationFile(
  HANDLE           FileHandle,
  PIO_STATUS_BLOCK IoStatusBlock,
  PVOID            Buffer,
  ULONG            Length
);
```

Parameters

`FileHandle`

A handle for the file object that represents the file or volume for which the quota information is to be modified.

`IoStatusBlock`

The address of the caller's I/O status block.

`Buffer`

A buffer containing the new quota entries that should be applied to the volume. The quota information must be formatted as one or more FILE_QUOTA_INFORMATION structures. The **NextEntryOffset** field in the **FILE_QUOTA_INFORMATION** structure contains the offset, in bytes, of the next quota entry in the list. If there are no more entries after the current one, this member is zero.

`Length`

The length in bytes of the buffer.

Return Value

The **NtSetQuotaInformationFile** routine returns STATUS_SUCCESS or an appropriate NTSTATUS value such as one of the following:

RETURN CODE	DESCRIPTION

STATUS_INSUFFICIENT_RESOURCES	There were insufficient resources to complete the operation. This is an error code.
STATUS_INVALID_DEVICE_REQUEST	Quotas are not enabled on the volume. This is an error code.
STATUS_MEDIA_WRITE_PROTECTED	The volume is read only. This is an error code.

Remarks

The **NtSetQuotaInformationFile** routine applies all of the quota entries in the specified *Buffer* parameter to the volume.

The **IoCheckQuotaBufferValidity** function can check whether the specified quota buffer passed as the *Buffer* parameter is valid.

A call to **NtSetQuotaInformationFile** will result in an IRP_MJ_SET_QUOTA request being sent to the device object that is associated with the file object whose handle is stored in the *FileHandle* parameter.

If the underlying file system does not support quota information (FAT and CDFS file systems, for example), **NtSetQuotaInformationFile** will fail returning STATUS_INVALID_DEVICE_REQUEST.

> **Note** If the call to the **NtSetQuotaInformationFile** function occurs in user mode, you should use the name "NtSetQuotaInformationFile" instead of "**ZwSetQuotaInformationFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows operating systems.
Target Platform	Universal
Header	ntifs.h (include Ntifs.h, FltKernel.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

NtSetSecurityObject function

1/25/2019 • 2 minutes to read • Edit Online

The **NtSetSecurityObject** routine sets an object's security state.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtSetSecurityObject(
  HANDLE               Handle,
  SECURITY_INFORMATION SecurityInformation,
  PSECURITY_DESCRIPTOR SecurityDescriptor
);
```

Parameters

`Handle`

Handle for the object whose security state is to be set. This handle must have the access specified in the Meaning column of the table shown in the description of the *SecurityInformation* parameter.

`SecurityInformation`

SECURITY_INFORMATION value specifying the information to be set. Can be a combination of one or more of the following.

VALUE	MEANING
DACL_SECURITY_INFORMATION	Indicates the discretionary access control list (DACL) of the object is to be set. Requires WRITE_DAC access.
GROUP_SECURITY_INFORMATION	Indicates the primary group identifier of the object is to be set. Requires WRITE_OWNER access.
OWNER_SECURITY_INFORMATION	Indicates the owner identifier of the object is to be set. Requires WRITE_OWNER access.
SACL_SECURITY_INFORMATION	Indicates the system ACL (SACL) of the object is to be set. Requires ACCESS_SYSTEM_SECURITY access.

`SecurityDescriptor`

Pointer to the security descriptor to be set for the object.

Return Value

NtSetSecurityObject returns STATUS_SUCCESS or an appropriate error status. Possible error status codes include the following:

RETURN CODE	DESCRIPTION

STATUS_ACCESS_DENIED	*Handle* does not have the required access rights.
STATUS_ACCESS_VIOLATION	*SecurityDescriptor* is a **NULL** pointer.
STATUS_INSUFFICIENT_RESOURCES	The object's security descriptor could not be captured.
STATUS_INVALID_ACL	The object's security descriptor contains an invalid ACL.
STATUS_INVALID_HANDLE	*Handle* is not a valid handle.

STA TUS _IN VAL ID_S ECU RIT Y_D ESC R	*SecurityDescriptor* does not point to a valid security descriptor.
STA TUS _IN VAL ID_S ID	The object's security descriptor contains an invalid **SID**.
STA TUS _OB JEC T_T YPE _MI SM ATC H	*Handle* is not a handle of the expected type.
STA TUS _UN KN OW N_R EVIS ION	The revision level of the object's security descriptor is unknown or is not supported.

Remarks

A security descriptor can be in absolute or self-relative form. In self-relative form, all members of the structure are located contiguously in memory. In absolute form, the structure only contains pointers to the members. For more information, see "Absolute and Self-Relative Security Descriptors" in the Security section of the Windows SDK documentation.

For more information about security and access control, see the documentation on these topics in the Windows SDK.

Minifilters should use FltSetSecurityObject instead of **ZwSetSecurityObject**.

Callers of **NtSetSecurityObject** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

Note If the call to the **NtSetSecurityObject** function occurs in user mode, you should use the name "NtSetSecurityObject" instead of "**ZwSetSecurityObject**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows XP.
Target Platform	Universal

NtQuerySecurityObject

NtUnlockFile function

1/25/2019 • 2 minutes to read • Edit Online

The **NtUnlockFile** routine unlocks a byte-range lock in a file.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtUnlockFile(
  HANDLE           FileHandle,
  PIO_STATUS_BLOCK IoStatusBlock,
  PLARGE_INTEGER   ByteOffset,
  PLARGE_INTEGER   Length,
  ULONG            Key
);
```

Parameters

`FileHandle`

A handle for the file object that represents the file whose byte range is to be unlocked.

`IoStatusBlock`

A pointer to an IO_STATUS_BLOCK structure that contains the final status.

`ByteOffset`

A pointer to a variable that specifies the starting byte offset for the byte range to be unlocked.

`Length`

A pointer to a variable that specifies the length, in bytes, of the byte range to unlock.

`Key`

The caller-assigned value used to describe groups of related locks. This value should be set to zero.

Return Value

The **NtUnlockFile** routine returns STATUS_SUCCESS on success or an appropriate NTSTATUS value. Possible NTSTATUS values include:

RETURN CODE	DESCRIPTION
STATUS_RANGE_NOT_LOCKED	The byte range specified is not locked.

Remarks

The **NtUnlockFile** routine takes a range of bytes as specified by the *ByteOffset* and *Length* arguments. This range must be identical to a range of bytes in the file that was previously locked with a single call to the **NtUnlockFile** routine. It is not possible to unlock two previously locked adjacent ranges with a single call to **NtUnlockFile**. It is also not possible to unlock part of a range that was previously locked with a single call to the **NtUnlockFile** routine.

Callers of **NtUnlockFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to the **NtUnlockFile** function occurs in user mode, you should use the name "NtUnlockFile" instead of "**ZwUnlockFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	ntifs.h (include Ntifs.h, FltKernel.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL (see Remarks section)

Using Nt and Zw Versions of the Native System Services Routines

NtLockFile

NtWriteFile function

1/25/2019 • 5 minutes to read • Edit Online

The **ZwWriteFile** routine writes data to an open file.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtWriteFile(
  HANDLE           FileHandle,
  HANDLE           Event,
  PIO_APC_ROUTINE  ApcRoutine,
  PVOID            ApcContext,
  PIO_STATUS_BLOCK IoStatusBlock,
  PVOID            Buffer,
  ULONG            Length,
  PLARGE_INTEGER   ByteOffset,
  PULONG           Key
);
```

Parameters

`FileHandle`

Handle to the file object. This handle is created by a successful call to NtCreateFile or NtOpenFile.

`Event`

Optionally, a handle to an event object to set to the signaled state after the write operation completes. Device and intermediate drivers should set this parameter to **NULL**.

`ApcRoutine`

This parameter is reserved. Device and intermediate drivers should set this pointer to **NULL**.

`ApcContext`

This parameter is reserved. Device and intermediate drivers should set this pointer to **NULL**.

`IoStatusBlock`

Pointer to an IO_STATUS_BLOCK structure that receives the final completion status and information about the requested write operation. The **Information** member receives the number of bytes actually written to the file.

`Buffer`

Pointer to a caller-allocated buffer that contains the data to write to the file.

`Length`

The size, in bytes, of the buffer pointed to by *Buffer*.

`ByteOffset`

Pointer to a variable that specifies the starting byte offset in the file for beginning the write operation. If *Length* and *ByteOffset* specify a write operation past the current end-of-file mark, **NtWriteFile** automatically extends the file and updates the end-of-file mark; any bytes that are not explicitly written between such old and new end-of-file

marks are defined to be zero.

If the call to NtCreateFile set only the *DesiredAccess* flag FILE_APPEND_DATA, *ByteOffset* is ignored. Data in the given *Buffer*, for *Length* bytes, is written starting at the current end of file.

If the call to NtCreateFile set either of the *CreateOptions* flags, FILE_SYNCHRONOUS_IO_ALERT or FILE_SYNCHRONOUS_IO_NONALERT, the I/O Manager maintains the current file position. If so, the caller of **NtWriteFile** can specify that the current file position offset be used instead of an explicit *ByteOffset* value. This specification can be made by using one of the following methods:

- Specify a pointer to a LARGE_INTEGER value with the **HighPart** member set to -1 and the **LowPart** member set to the system-defined value FILE_USE_FILE_POINTER_POSITION.
- Pass a **NULL** pointer for *ByteOffset*.

NtWriteFile updates the current file position by adding the number of bytes written when it completes the write operation, if it is using the current file position maintained by the I/O Manager.

Even when the I/O Manager is maintaining the current file position, the caller can reset this position by passing an explicit *ByteOffset* value to **NtWriteFile**. Doing this automatically changes the current file position to that *ByteOffset*value, performs the write operation, and then updates the position according to the number of bytes actually written. This technique gives the caller atomic seek-and-write service.

It is also possible to cause a write operation to start at the current end of file by specifying for *ByteOffset* a pointer to a LARGE_INTEGER value with **HighPart** set to -1 and **LowPart** set to FILE_WRITE_TO_END_OF_FILE. This works regardless of whether the I/O Manager is maintaining the current file position.

`Key`

Device and intermediate drivers should set this pointer to **NULL**.

Return Value

NtWriteFile returns STATUS_SUCCESS on success or the appropriate NTSTATUS error code on failure.

Remarks

Callers of **NtWriteFile** must have already called NtCreateFile with the FILE_WRITE_DATA, FILE_APPEND_DATA, or GENERIC_WRITE flag set in the *DesiredAccess* parameter. Note that having only FILE_APPEND_DATA access to a file does not allow the caller to write anywhere in the file except at the current end-of-file mark, while having FILE_WRITE_DATA access to a file does not preclude the caller from writing to or beyond the end of a file.

If the preceding call to NtCreateFile set the *CreateOptions* flag FILE_NO_INTERMEDIATE_BUFFERING, the *Length* and *ByteOffset* parameters to **NtWriteFile** must be an integral of the sector size. For more information, see **NtCreateFile**.

NtWriteFile begins the write operation to the file at *ByteOffset*, at the current file position, or at the end-of-file mark. It terminates the write operation when it has written *Length* bytes from *Buffer*. If necessary, it extends the length of the file and resets the end-of-file mark.

If the caller opened the file with the *DesiredAccess* SYNCHRONIZE flag set, the caller can wait for this routine to set the given *FileHandle* to the signaled state.

Drivers should call **NtWriteFile** in the context of the system process in three cases:

1. The driver creates the file handle that it passes to **NtWriteFile**.
2. **NtWriteFile** notifies the driver of I/O completion by means of an event created by the driver.

3. **NtWriteFile** notifies the driver of I/O completion by means of an APC callback routine that the driver passes to **NtWriteFile**.

File and event handles are only valid in the process context where the handles are created. Therefore, to avoid security holes, the driver should create any file or event handle that it passes to **NtWriteFile** in the context of the system process instead of the process context that the driver is in.

Likewise, **NtWriteFile** should be called in the context of the system process if it notifies the driver of I/O completion by means of an APC, because APCs are always fired in the context of the thread issuing the I/O request. If the driver calls **NtWriteFile** in the context of a process other than the system process, the APC could be delayed indefinitely, or it might not fire at all as the originating thread may never enter an alertable wait state.

For more information about working with files, see Using Files in a Driver.

Callers of **NtWriteFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to this function occurs in user mode, you should use the name "NtWriteFile" instead of "**ZwWriteFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

PoCallDriver function

1/25/2019 • 2 minutes to read • Edit Online

The **PoCallDriver** routine passes a power IRP to the next-lower driver in the device stack. (Windows Server 2003, Windows XP, and Windows 2000 only.)

Syntax

```
NTSTATUS PoCallDriver(
  PDEVICE_OBJECT        DeviceObject,
  __drv_aliasesMem PIRP Irp
);
```

Parameters

`DeviceObject`

A pointer to the driver-created DEVICE_OBJECT to which the IRP is to be routed.

`Irp`

A pointer to an IRP.

Return Value

PoCallDriver returns STATUS_SUCCESS to indicate success. It returns STATUS_PENDING if it has queued the IRP.

Remarks

Beginning with Windows Vista, drivers should call IoCallDriver, not **PoCallDriver** to pass a power IRP to the next-lower driver. However, on Windows Server 2003, Windows XP, and Windows 2000, drivers must call **PoCallDriver**, not **IoCallDriver** to pass a power IRP to the next-lower driver. On Windows Server 2003, Windows XP, an Windows 2000, drivers must also call PoStartNextPowerIrp before calling **PoCallDriver**.

A driver that requires a new IRP should call PoRequestPowerIrp. A driver must not allocate its own power IRP.

When passing a power IRP down to the next-lower driver, the caller should use IoSkipCurrentIrpStackLocation or IoCopyCurrentIrpStackLocationToNext to set the IRP stack location, then call **PoCallDriver**. Use **IoCopyCurrentIrpStackLocationToNext** if processing the IRP requires setting an IoCompletion routine, or **IoSkipCurrentStackLocation** if no *IoCompletion* routine is required.

When a device is powering up, its drivers must set *IoCompletion* routines to perform start-up tasks (initializing the device, restoring context, and so on) after the bus driver has set the device in the working state. Set *IoCompletion* routines before calling **PoCallDriver**.

When a device is powering down, its drivers must perform necessary power-down tasks before passing the IRP to the next lower driver. After the IRP has reached the bus driver, the device will be powered off and its drivers will no longer have access to it. On Windows Server 2003, Windows XP, and Windows 2000, an *IoCompletion* routine that is associated with a power-down IRP is only required to call **PoStartNextPowerIrp**.

Only one inrush IRP can be active in the system at a time. When passing a power-up IRP for a device that requires

inrush current (in other words, the DO_POWER_INRUSH flag is set in the device object), **PoCallDriver** checks whether another inrush IRP is already active. If so, **PoCallDriver** queues the current IRP for handling after the previous IRP completes, and then returns STATUS_PENDING. For more information about inrush IRPs, see Setting Device Object Flags for Power Management.

If an IRP_MN_SET_POWER or IRP_MN_QUERY_POWER request is already active for *DeviceObject*, **PoCallDriver** queues this IRP and returns STATUS_PENDING.

On Windows 2000 and later systems, pageable drivers (the DO_POWER_PAGABLE flag is set in the device object) must call **PoCallDriver** at IRQL = PASSIVE_LEVEL. Drivers that cannot be paged (DO_POWER_PAGABLE is not set in the device object) or that require inrush current (DO_POWER_INRUSH is set in the device object) can call **PoCallDriver** at IRQL = PASSIVE_LEVEL or DISPATCH_LEVEL.

On Windows 98/Me, all drivers call **PoCallDriver** at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

PoStartNextPowerIrp

PoClearPowerRequest function

1/25/2019 • 2 minutes to read • Edit Online

The **PoClearPowerRequest** routine decrements the count for the specified power request type.

Syntax

```
NTSTATUS PoClearPowerRequest(
  PVOID              PowerRequest,
  POWER_REQUEST_TYPE Type
);
```

Parameters

`PowerRequest`

A pointer to a power request object that was created by the PoCreatePowerRequest routine.

`Type`

The type of the power request. Set this parameter to the following POWER_REQUEST_TYPE enumeration value:

- **PowerRequestSystemRequired**

Return Value

PoClearPowerRequest returns STATUS_SUCCESS if the call is successful. If the call fails, possible error return codes include the following:

RETURN CODE	DESCRIPTION
STATUS_UNSUPPORTED	Parameter *Type* is set to an unsupported value.

Remarks

A driver can call the PoSetPowerRequest routine to request that the power manager override several types of default power behavior, which are specified as POWER_REQUEST_TYPE enumeration values. To restore the default behavior, the driver cancels the request by calling the **PoClearPowerRequest** routine.

The power manager maintains a count of the active requests for each power request type. The **PoSetPowerRequest** routine increments the count for the specified power request type by one. The **PoClearPowerRequest** routine decrements the count by one. A nonzero count indicates that requests from one or more components are active. After the count decrements to zero, the power manager restores the default behavior for the specified power request type.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

POWER_REQUEST_TYPE

PoCreatePowerRequest

PoSetPowerRequest

PoCreatePowerRequest function

1/25/2019 • 2 minutes to read • Edit Online

The **PoCreatePowerRequest** routine creates a power request object.

Syntax

```
NTSTATUS PoCreatePowerRequest(
  PVOID                    *PowerRequest,
  PDEVICE_OBJECT           DeviceObject,
  PCOUNTED_REASON_CONTEXT Context
);
```

Parameters

`PowerRequest`

A pointer to a location into which the routine writes a pointer to the newly created power request object. If the call fails, the routine writes **NULL** to this location.

`DeviceObject`

A pointer to the device object of the caller (a DEVICE_OBJECT structure).

`Context`

A pointer to a COUNTED_REASON_CONTEXT structure that describes why the caller is creating the power request object. This parameter is optional and can be set to **NULL**.

Return Value

PoCreatePowerRequest returns STATUS_SUCCESS if the call is successful. If the call fails, possible error return codes include the following:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The *DeviceObject* parameter is **NULL**.

STA **TUS** **_IN** **SUF** **FICI** **ENT** **_RE** **SO** **URC** **ES**	There is not enough memory available to create a power request object.

Remarks

This routine creates a power request object. To enable power requests, the caller should create one power request object and use that object for all calls to the PoSetPowerRequest and PoClearPowerRequest routines.

A driver can use power requests to override certain aspects of the computer's default power behavior. For example, a driver for a TV receiver device can use power requests to prevent the power manager from automatically blanking the display during extended periods of time in which no user interaction occurs.

When the power request object is no longer needed, the caller must delete the object by calling the PoDeletePowerRequest routine. The driver must delete the power request object before it deletes the device object that was used to create the power request object.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

PoClearPowerRequest

PoDeletePowerRequest

PoSetPowerRequest

PoDeletePowerRequest function

1/25/2019 • 2 minutes to read • Edit Online

The **PoDeletePowerRequest** routine deletes a power request object.

Syntax

```
void PoDeletePowerRequest(
  PVOID PowerRequest
);
```

Parameters

`PowerRequest`

A pointer to a power request object that was created by the PoCreatePowerRequest routine.

Return Value

None

Remarks

The driver must delete the power request object before it deletes the device object that was used to create the power request object.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=APC_LEVEL"

PoCreatePowerRequest

PoEndDeviceBusy function

1/25/2019 • 2 minutes to read • Edit Online

The **PoEndDeviceBusy** routine marks the end of a period of time in which the device is busy.

Syntax

```
void PoEndDeviceBusy(
  PULONG IdlePointer
);
```

Parameters

`IdlePointer`

A pointer to an idle counter. This is a pointer value that was previously returned by the PoRegisterDeviceForIdleDetection routine. Because **PoRegisterDeviceForIdleDetection** might return a **NULL** pointer, the caller must verify that the pointer is non-**NULL** before it calls **PoEndDeviceBusy**.

Return Value

None

Remarks

The PoStartDeviceBusy and **PoEndDeviceBusy** routines mark the start and end of a time period in which a device is busy. Each call to **PoStartDeviceBusy** must be followed by a corresponding call to **PoEndDeviceBusy**. For more information about how these routines work together, see PoStartDeviceBusy.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

PoRegisterDeviceForIdleDetection

PoStartDeviceBusy

PoQueryWatchdogTime function

1/25/2019 • 2 minutes to read • Edit Online

The **PoQueryWatchdogTime** routine indicates whether the power manager has enabled a watchdog time-out counter for any power IRP that is currently assigned to the device stack.

Syntax

```
BOOLEAN PoQueryWatchdogTime(
  PDEVICE_OBJECT Pdo,
  PULONG         SecondsRemaining
);
```

Parameters

`Pdo`

A pointer to a physical device object (PDO). This parameter points to a DEVICE_OBJECT structure that represents a physical device.

`SecondsRemaining`

A pointer to a location into which the routine writes the time, in seconds, that remains before the next power watchdog time-out is set to occur.

Return Value

PoQueryWatchdogTime returns **TRUE** if a watchdog-enabled power IRP is currently assigned to the device stack. Otherwise, it returns **FALSE**.

Remarks

This routine enables kernel-mode drivers to monitor watchdog time-out counters that the power manager has enabled to keep track of power IRPs that it has issued. If one or more watchdog time-out counters are currently enabled, the routine returns **TRUE** and provides the amount of time that remains before the next time-out.

For example, a driver that experiences delays when shutting down a device can call this routine to determine how much time remains before the driver must respond to a power IRP to prevent a controlled shutdown (a bug check) of the operating system.

The power manager sets a watchdog time-out counter when it issues a power IRP to the device stack. The time-out period for this counter is typically several minutes. If a device in the stack is unresponsive and causes the IRP to stall for the time-out period, the power manager treats this condition as an unrecoverable error and initiates a controlled shutdown of the operating system.

If more than one power watchdog time-out is currently enabled, the routine sets **SecondsRemaining* to the time that remains to the next time-out.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

DEVICE_OBJECT

PoRegisterDeviceForIdleDetection function

1/25/2019 • 3 minutes to read • Edit Online

The **PoRegisterDeviceForIdleDetection** routine enables or cancels idle detection and sets idle time-out values for a device.

Syntax

```
PULONG PoRegisterDeviceForIdleDetection(
  PDEVICE_OBJECT     DeviceObject,
  ULONG              ConservationIdleTime,
  ULONG              PerformanceIdleTime,
  DEVICE_POWER_STATE State
);
```

Parameters

`DeviceObject`

A pointer to the driver-created DEVICE_OBJECT for the device. On Windows 2000 and later systems, this parameter can point to a physical device object (PDO) or a functional device object (FDO). On Windows 98/Me, this parameter must point to the PDO of the underlying device.

`ConservationIdleTime`

Sets the time-out value (in seconds) to apply when the system power policy optimizes for energy conservation. Specify zero to disable idle detection when conservation policy is in effect.

`PerformanceIdleTime`

Sets the time-out value (in seconds) to apply when the system power policy optimizes for performance. Specify zero to disable idle detection when performance policy is in effect.

`State`

Specifies the device power state to be requested in an IRP_MN_SET_POWER request when either *ConservationIdleTime* or *PerformanceIdleTime* has been met. Possible values are the DEVICE_POWER_STATE values.

Return Value

PoRegisterDeviceForIdleDetection returns a pointer to the idle counter to indicate that idle detection has been enabled. It returns **NULL** to indicate that idle detection has been disabled, that an idle counter could not be allocated, or that one or both of the time-out values were invalid.

Remarks

PoRegisterDeviceForIdleDetection enables drivers to use the idle detection mechanism provided by the power manager. Drivers call **PoRegisterDeviceForIdleDetection** for any of the following reasons:

- To enable idle detection for the device and set initial idle time-out values
- To change the idle time-out values for a device

- To disable idle detection for a device

After enabling a device for idle detection, a driver calls PoSetDeviceBusy whenever the device is in use, passing the non-**NULL** idle pointer returned by **PoRegisterDeviceForIdleDetection**. Calling **PoSetDeviceBusy** restarts the idle countdown. Note that a driver must not pass a **NULL** pointer to **PoSetDeviceBusy**.

Whenever the device satisfies the current idle time-out value, the power manager sends an **IRP_MN_SET_POWER** request to the top of the device stack, specifying device power state *State*. In response to the IRP, each driver performs any device-specific tasks required before the power state transition, then passes the IRP to the next-lower driver. When the IRP reaches the bus driver, that driver puts the device in the requested lower power state and completes the IRP.

PoRegisterDeviceForIdleDetection sets time-out values for both conservation and performance. The *ConservationIdleTime* value applies when the system power policy optimizes for conservation; the *PerformanceIdleTime* value applies when the system power policy optimizes for performance. Typically, the applicable policy depends upon the power source: when running with AC power, the system optimizes for performance, and when running off a battery, the system optimizes for conservation.

Certain devices can specify time-out values of -1 to use the standard power policy time-outs for their device class. The standard time-out values provide for better system integration for supported standard device classes. At present, WDM supports this feature for devices of type FILE_DEVICE_DISK and FILE_DEVICE_MASS_STORAGE. **PoRegisterDeviceForIdleDetection** returns **NULL** if -1 is specified for a device of an unsupported type. (For information about device types, see Specifying Device Types.)

Only one idle detection can be set per device. Subsequent calls to **PoRegisterDeviceForIdleDetection** change the idle detection values.

If both *ConservationIdleTime* and *PerformanceIdleTime* are zero, this routine cancels all idle detection for the device and returns **NULL**.

PoRegisterDeviceForIdleDetection can free a driver from the need to perform its own idle detection. However, drivers can also implement their own idle detection.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

IRP

IRP_MN_SET_POWER

PoSetDeviceBusy

PoRegisterPowerSettingCallback function

1/25/2019 • 4 minutes to read • Edit Online

The **PoRegisterPowerSettingCallback** routine registers a power-setting callback routine to receive notifications of changes in the specified power setting.

Syntax

```
NTSTATUS PoRegisterPowerSettingCallback(
  PDEVICE_OBJECT          DeviceObject,
  LPCGUID                 SettingGuid,
  PPOWER_SETTING_CALLBACK Callback,
  PVOID                   Context,
  PVOID                   *Handle
);
```

Parameters

`DeviceObject`

A pointer to a DEVICE_OBJECT structure that is associated with the caller of this routine. This parameter is optional. It is used internally only for debugging purposes. If this parameter is not supplied, it must be set to **NULL**.

`SettingGuid`

A pointer to the GUID that represents the power setting for this registration. When the specified power setting changes, the power manager calls the callback routine to notify the driver of the change and to supply the new value of the setting. For more information, see Remarks.

`Callback`

A pointer to a caller-implemented power-setting callback routine that the power manager calls when the specified power setting changes. For the functional prototype for the callback routine, see Power-Setting Callback, below.

`Context`

A pointer to the context for the callback routine. This parameter is optional. It is provided so that a driver or device context can be passed to the callback routine. If this parameter is not used, it must be set to **NULL**.

`Handle`

A handle that the power manager uses to represent the callback routine. A driver must subsequently supply this handle in a call to PoUnregisterPowerSettingCallback to unregister the callback routine.

Return Value

PoRegisterPowerSettingCallback returns one of the following:

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	The routine registered the callback routine.
STATUS_INSUFFICIENT_RESOURCES	The routine could not allocate the system resources that are required to register the callback routine.

Remarks

A driver calls **PoRegisterPowerSettingCallback** to register a callback routine with the power manager. The power manager subsequently calls this callback routine to notify the driver after there is a change to the specified power setting. In addition, the power manager initializes the power setting of the driver by immediately calling the callback routine and passing the current value of the power setting. The power manager initializes the power setting of the driver this way regardless of whether the power setting has actually changed.

A driver should call **PoRegisterPowerSettingCallback** for each power setting that the driver needs to monitor. Drivers should call this routine in their DriverEntry routine during initialization. Typically, most drivers pass a pointer to a device extension in the *Context* parameter.

To unregister a power-setting callback, call the PoUnregisterPowerSettingCallback routine.

Typically, Kernel-Mode Driver Framework (KMDF) drivers should call **PoRegisterPowerSettingCallback** from their EvtDeviceSelfManagedIoInit callback function, and should call **PoUnregisterPowerSettingCallback** from their EvtDeviceSelfManagedIoCleanup callback function. These drivers should not call **PoRegisterPowerSettingCallback** from their EvtDriverDeviceAdd callback function; otherwise, the power-setting callback routine might be called before the driver stack is completely built.

The callback routine that is registered for a particular power setting is called when a transition in power state occurs that changes the value of the setting, or when the power manager changes the value of the setting. For example, if *SettingGuid* points to the GUID value GUID_LIDSWITCH_STATE_CHANGE, the callback routine is called when the lid to a laptop computer clicks open or closed. The *Value* parameter passed to the callback routine in this example points to a ULONG value that is 1 if the state of the lid switch changed from closed to open, and is 0 if the state of the lid switch changed from open to closed. For more information, see the power-setting GUID definitions and extensive comments in the Wdm.h header file.

The initial call to a callback routine might occur immediately, before the **PoRegisterPowerSettingCallback** call that registers the routine returns.

PoRegisterPowerSettingCallback can be called only at IRQL = PASSIVE_LEVEL.

Power-Setting Callback

The function prototype of the power-setting callback routine is as follows:

```
NTSTATUS
POWER_SETTING_CALLBACK (
  _In_ LPCGUID SettingGuid,
  _In_ PVOID Value,
  _In_ ULONG ValueLength,
  _Inout_opt_ PVOID Context
);
```

The power-setting callback parameters are:

SettingGuid
A pointer to a GUID that represents the power setting that changed. Power settings and their corresponding GUIDs are defined in Wdm.h.

Value A pointer to the new value of the power setting that changed.

ValueLength A value of type ULONG that specifies the size, in bytes, of the new power setting value.

Context
The pointer to the context that a driver supplied in the call to **PoRegisterPowerSettingCallback** that registered the callback routine.

The power manager calls a power-setting callback at IRQL = PASSIVE_LEVEL. #### Examples To define a power-setting callback routine, you must first provide a function declaration that identifies the type of callback function you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system. For example, to define a power-setting callback routine that is named `MyPowerSettingCallback`, use the POWER_SETTING_CALLBACK type as shown in this code example:

```
POWER_SETTING_CALLBACK MyPowerSettingCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
NTSTATUS
  MyPowerSettingCallback(
    LPCGUID SettingGuid,
    PVOID Value,
    ULONG ValueLength,
    PVOID Context
    )
  {
      // Function body
  }
```

The POWER_SETTING_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the POWER_SETTING_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For

information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Available starting with Windows Vista.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)

PoUnregisterPowerSettingCallback

PoRegisterSystemState function

1/25/2019 • 2 minutes to read • Edit Online

The **PoRegisterSystemState** routine registers the system as busy due to certain activity.

Syntax

```
PVOID PoRegisterSystemState(
  PVOID           StateHandle,
  EXECUTION_STATE Flags
);
```

Parameters

`StateHandle`

A pointer to a caller-supplied buffer for a registration state handle. The size, in bytes, of the buffer is **sizeof**(ULONG). If **NULL**, this is a new registration. If non-**NULL**, this parameter points to a handle that was returned by a previous call to **PoRegisterSystemState**.

`Flags`

Indicates the type of activity, as specified by a bitwise OR of one or more of the following values:

ES_SYSTEM_REQUIRED

The system is not idle, regardless of apparent load.

ES_DISPLAY_REQUIRED

Use of the display is required.

ES_USER_PRESENT

A user is present.

ES_CONTINUOUS

The settings are continuous and should remain in effect until explicitly changed.

Return Value

PoRegisterSystemState returns a handle to be used later to change or unregister the system busy state. It returns **NULL** if the handle could not be allocated.

Remarks

PoRegisterSystemState registers the system busy state as indicated by the flags. The registration persists until the caller explicitly changes it with another call to **PoRegisterSystemState** or cancels it with a call to PoUnregisterSystemState.

The *Flags* parameter specifies the type of activity in progress. Drivers can specify any combination of the flags.

Setting ES_CONTINUOUS makes the busy state persist until a driver explicitly changes or cancels it by calling **PoRegisterSystemState** or **PoUnregisterSystemState**.

A driver can set the system busy state to request that the power manager avoid system power state transitions out

of the system working state (S0) while driver activity is occurring. Note, however, that under some circumstances (such as a critically low battery) the power manager may override this request and put the system to sleep anyway.

To set the system power state, call PoSetSystemState.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)

PoSetSystemState

PoUnregisterSystemState

PoSetDeviceBusyEx function

1/25/2019 • 2 minutes to read • Edit Online

The **PoSetDeviceBusyEx** routine notifies the power manager that the device associated with the specified idle counter is busy.

Syntax

```
void PoSetDeviceBusyEx(
  PULONG IdlePointer
);
```

Parameters

`IdlePointer`

A pointer to an idle counter. This is a pointer value that was previously returned by the PoRegisterDeviceForIdleDetection routine. Because **PoRegisterDeviceForIdleDetection** might return a **NULL** pointer, the caller must verify that the pointer is non-**NULL** before it calls **PoSetDeviceBusyEx**.

Return Value

None

Remarks

This routine is a direct replacement for the PoSetDeviceBusy macro. If you are writing new driver code for Windows Vista with Service Pack 1 (SP1) and later versions of Windows, call **PoSetDeviceBusyEx** instead of **PoSetDeviceBusy**.

A driver calls the **PoSetDeviceBusyEx** and **PoRegisterDeviceForIdleDetection** routines to enable system idle detection for its device. If a device that is registered for idle detection stays idle for the driver-specified time-out period, the power manager sends an IRP_MN_SET_POWER request to put the device in a requested sleep state.

PoSetDeviceBusyEx reports that the device is busy, so that the power manager can restart its idle countdown. If the device is in a sleep state, **PoSetDeviceBusyEx** does not change the state of the device. That is, it does not cause the system to send an **IRP_MN_SET_POWER** request to awaken the device.

PoSetDeviceBusyEx is designed for use with I/O operations that are relatively brief compared to the time-out period of the idle counter. For longer operations that might exceed this period, use the PoStartDeviceBusy and PoEndDeviceBusy routines instead.

A driver that makes multiple requests for brief I/O operations should call **PoSetDeviceBusyEx** for every I/O request that it makes.

Requirements

Minimum supported client	Available starting with Windows Vista with SP1.

Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

PoSetDeviceBusy

PoStartDeviceBusy

PoSetPowerRequest function

1/25/2019 • 2 minutes to read • Edit Online

The **PoSetPowerRequest** routine increments the count for the specified power request type.

Syntax

```
NTSTATUS PoSetPowerRequest(
  PVOID             PowerRequest,
  POWER_REQUEST_TYPE Type
);
```

Parameters

`PowerRequest`

A pointer to a power request object that was created by the PoCreatePowerRequest routine.

`Type`

The type of power request. Set this parameter to the following POWER_REQUEST_TYPE enumeration value:

- **PowerRequestSystemRequired**

Return Value

PoSetPowerRequest returns STATUS_SUCCESS if the call is successful. If the call fails, possible error return codes include the following:

RETURN CODE	DESCRIPTION
STATUS_UNSUPPORTED_TYPE	The *Type* parameter is set to an unsupported value.

Remarks

A driver can call the **PoSetPowerRequest** routine to request that the power manager override several types of default power behavior, which are specified as POWER_REQUEST_TYPE enumeration values. To restore the default behavior, the driver cancels the request by calling the PoClearPowerRequest routine.

The power manager maintains a count of the active requests for each power request type. The **PoSetPowerRequest** routine increments the count for the specified power request type by one. The **PoClearPowerRequest** routine decrements the count by one. A nonzero count indicates that requests from one or more components are active. After the count decrements to zero, the computer reverts to the default behavior for the specified power request type.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

POWER_REQUEST_TYPE

PoClearPowerRequest

PoCreatePowerRequest

PoSetPowerState function

1/25/2019 • 2 minutes to read • Edit Online

The **PoSetPowerState** routine notifies the system of a change in the device power state for a device.

Syntax

```
POWER_STATE PoSetPowerState(
  PDEVICE_OBJECT   DeviceObject,
  POWER_STATE_TYPE Type,
  POWER_STATE      State
);
```

Parameters

`DeviceObject`

A pointer to the target DEVICE_OBJECT.

`Type`

Indicates a POWER_STATE_TYPE value. Drivers must specify **DevicePowerState**.

`State`

Specifies the power state to be set. Drivers must specify a DEVICE_POWER_STATE value.

Return Value

On Windows 2000 and later versions of the operating system, **PoSetPowerState** returns the previous power state. On Windows 98/Me, **PoSetPowerState** returns the state passed in *State*.

Remarks

PoSetPowerState notifies the power manager of the new power state for a device. Each driver in a device stack (filter, function, and bus drivers) must call **PoSetPowerState** to inform the power manager of a change in the power state of its corresponding device object. For example:

- A driver calls this routine after receiving a device set-power request and before calling PoStartNextPowerIrp. When handling a PnP IRP_MN_START_DEVICE request, the driver should call **PoSetPowerState** to notify the power manager that the device is in the D0 state.
- If the device is powering down, the driver must call **PoSetPowerState** before leaving the D0 state. In addition, the driver must be able to process client requests before **PoSetPowerState** returns.
- If the device is powering up, the driver must call **PoSetPowerState** after the device is successfully put into the D0 state.

For more information about powering a device up and down, see Handling IRP_MN_SET_POWER for Device Power States.

Callers of **PoSetPowerState** must be running at IRQL <= APC_LEVEL except when setting state to D0. When setting state to D0, callers can be running at IRQL <= DISPATCH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	See Remarks section.

IRP_MN_START_DEVICE

PoStartNextPowerIrp

PoStartDeviceBusy function

1/25/2019 • 2 minutes to read • Edit Online

The **PoStartDeviceBusy** routine marks the start of a period of time in which the device is busy.

Syntax

```
void PoStartDeviceBusy(
  PULONG IdlePointer
);
```

Parameters

`IdlePointer`

A pointer to an idle counter. This is a pointer value that was previously returned by the PoRegisterDeviceForIdleDetection routine. Because **PoRegisterDeviceForIdleDetection** might return a **NULL** pointer, the caller must verify that the pointer is non-**NULL** before it calls **PoStartDeviceBusy**.

Return Value

None

Remarks

The **PoStartDeviceBusy** and PoEndDeviceBusy routines mark the start and end of a time period in which a device is busy. Each call to **PoStartDeviceBusy** must be followed by a corresponding call to **PoEndDeviceBusy**.

For each device, the power manager maintains a count of the number of outstanding **PoStartDeviceBusy** calls for which it has not yet received a corresponding **PoEndDeviceBusy** call. A **PoStartDeviceBusy** call increments the busy count by one. A **PoEndDeviceBusy** call decrements the busy count by one. A nonzero busy count disables the idle counter for the device. After the busy count reaches zero, the power manager resets the idle counter to the time-out period and enables the counter.

Rather than use the **PoStartDeviceBusy** and **PoEndDeviceBusy** routines to reset the idle counter, you can call the PoSetDeviceBusyEx routine (or the PoSetDeviceBusy macro). To disable the idle counter during an extended busy period, a driver can call the **PoRegisterDeviceForIdleDetection** routine to disable and enable idle notifications at the start and end of the busy period. However, **PoStartDeviceBusy** and **PoEndDeviceBusy** are typically more convenient to use for this purpose, and you should consider using these routines in new code that you write for Windows 7 and later versions of Windows.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal

Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

PoEndDeviceBusy

PoRegisterDeviceForIdleDetection

PoSetDeviceBusy

PoStartNextPowerIrp function

1/25/2019 • 2 minutes to read • Edit Online

The **PoStartNextPowerIrp** routine signals the power manager that the driver is ready to handle the next power IRP. (Windows Server 2003, Windows XP, and Windows 2000 only.)

Syntax

```
void PoStartNextPowerIrp(
  PIRP Irp
);
```

Parameters

`Irp`

A pointer to an IRP in which the major function code is IRP_MJ_POWER.

Return Value

None

Remarks

Starting with Windows Vista, the driver is not required to call **PoStartNextPowerIrp** and a call to this routine does not perform a power management operation. However, on Windows Server 2003, Windows XP, and Windows 2000, **PoStartNextPowerIrp** must be called by every driver in a device stack after the driver is finished with the previous power IRP, if any, and is ready to handle the next power IRP. It must be called once by each driver for every IRP_MN_QUERY_POWER or IRP_MN_SET_POWER request.

Although power IRPs are completed only once, typically by the bus driver for a device, each driver in the device stack must call **PoStartNextPowerIrp** as the IRP travels down or back up the stack. Even if a driver fails the IRP, the driver must nevertheless call **PoStartNextPowerIrp** to signal the power manager that it is ready to handle another power IRP.

The driver must call **PoStartNextPowerIrp** while the current IRP stack location points to the current driver. Therefore, this routine must be called before IoCompleteRequest, IoSkipCurrentIrpStackLocation, and PoCallDriver. As a general rule, a driver should call **PoStartNextPowerIrp** from its *IoCompletion* routine associated with the IRP or from the callback routine it passed to PoRequestPowerIrp.

Bus drivers must call **PoStartNextPowerIrp** before completing each IRP.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

PoUnregisterPowerSettingCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **PoUnregisterPowerSettingCallback** routine unregisters a power-setting callback routine that a driver previously registered by calling the PoRegisterPowerSettingCallback routine.

Syntax

```
NTSTATUS PoUnregisterPowerSettingCallback(
  PVOID Handle
);
```

Parameters

`Handle`

A handle to a callback routine that a driver registered by calling **PoRegisterPowerSettingCallback**.

Return Value

PoUnregisterPowerSettingCallback returns one of the following:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The callback routine was unregistered.
STATUS_INVALID_PARAMETER	The *Handle* value is not a valid handle to a power setting callback routine.

Remarks

A driver calls **PoUnregisterPowerSettingCallback** to unregister a power setting callback routine that the driver previously registered by calling **PoRegisterPowerSettingCallback**.

A driver must call **PoUnregisterPowerSettingCallback** to unregister each callback routine that it previously registered. All callback routines registered by a driver should be unregistered in the *Unload* routine of the driver.

Requirements

Minimum supported client	Available starting with Windows Vista.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

PoUnregisterSystemState function

1/25/2019 • 2 minutes to read • Edit Online

The **PoUnregisterSystemState** routine cancels a system state registration created by PoRegisterSystemState.

Syntax

```
void PoUnregisterSystemState(
  PVOID StateHandle
);
```

Parameters

`StateHandle`

A pointer to a handle previously returned by **PoRegisterSystemState**.

Return Value

None

Remarks

This routine cancels a system busy state registration established by **PoRegisterSystemState** and frees the associated *StateHandle*.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)

PsGetCurrentThread

RtlInitStringEx function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlInitStringEx** routine initializes a counted string of 8-bit characters.

Syntax

```
NTSYSAPI NTSTATUS RtlInitStringEx(
  PSTRING              DestinationString,
  __drv_aliasesMem PCSZ SourceString
);
```

Parameters

`DestinationString`

A pointer to the **STRING** structure to be initialized. The Ntdef.h header file defines this structure to be identical to the ANSI_STRING structure.

`SourceString`

A pointer to a null-terminated character string. This string is used to initialize the counted string pointed to by *DestinationString*.

Return Value

Returns STATUS_NAME_TOO_LONG if the SourceString is too long. Otherwise, this routine returns STATUS_SUCCESS.

Remarks

This routine initializes a counted character string.

The routine copies the *SourceString* pointer value to the **Buffer** member of the **STRING** structure pointed to by *DestinationString*. The **Length** member of this structure is set to the length, in bytes, of the source string, excluding the terminating null. The **MaximumLength** member of the structure is set to the length, in bytes, of the source string, including the terminating null. If *SourceString* is **NULL**, **Length** and **MaximumLength** are both set to zero.

RtlInitStringEx does not alter the source string pointed to by *SourceString*.

Callers of **RtlInitStringEx** can be running at IRQL <= DISPATCH_LEVEL if the *DestinationString* buffer is nonpageable. Usually, callers run at IRQL = PASSIVE_LEVEL because most other **Rtl*Xxx*String** routines cannot be called at IRQL > PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 10.
Target Platform	Universal

Header	ntifs.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	See Remarks section.

ANSI_STRING

RtlUnicodeToUTF8N function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlUnicodeToUTF8N** routine converts a Unicode string to a UTF-8 string.

Syntax

```
NTSYSAPI NTSTATUS RtlUnicodeToUTF8N(
  PCHAR  UTF8StringDestination,
  ULONG  UTF8StringMaxByteCount,
  PULONG UTF8StringActualByteCount,
  PCWCH  UnicodeStringSource,
  ULONG  UnicodeStringByteCount
);
```

Parameters

`UTF8StringDestination`

A pointer to a caller-allocated destination buffer into which the routine writes the UTF-8 output string. If this parameter is **NULL**, the routine writes the required size of the output buffer to **UTF8StringActualByteCount*.

`UTF8StringMaxByteCount`

Specifies the maximum number of bytes that the routine can write to the buffer that *UTF8StringDestination* points to. If *UTF8StringDestination* = **NULL**, set *UTF8StringMaxByteCount* = 0.

`UTF8StringActualByteCount`

A pointer to a location into which the routine writes the actual number of bytes that it has written to the buffer that *UTF8StringDestination* points to. If *UTF8StringDestination* is non-**NULL**, this count never exceeds the value of *UTF8StringMaxByteCount*. If *UTF8StringDestination* is **NULL**, this count is the number of bytes that are required to contain the entire output string.

`UnicodeStringSource`

A pointer to the Unicode source string.

`UnicodeStringByteCount`

Specifies the number of bytes in the Unicode source string that the *UnicodeStringSource* parameter points to.

Return Value

RtlUnicodeToUTF8N returns STATUS_SUCCESS if the call is successful and all Unicode character codes in the input string were converted to the corresponding UTF-8 character codes in the output string. It returns STATUS_SOME_NOT_MAPPED if the call is successful but one or more input characters were invalid and were replaced by the Unicode replacement character, U+FFFD, before they were converted to UTF-8. Possible error return values include the following error codes:

RETURN CODE	DESCRIPTION

STATUS_BUFFER_TOO_SMALL	The *UTF8StringMaxByteCount* parameter specifies a buffer size that is too small to contain the entire output string.
STATUS_INVALID_PARAMETER	The *UTF8StringDestination* and *UTF8StringActualByteCount* parameters are both **NULL**.
STATUS_INVALID_PARAMETER_4	The *UnicodeStringSource* parameter is **NULL**.
STATUS_INVALID_PARAMETER_5	*UnicodeStringByteCount* is not an integer multiple of **sizeof**(WCHAR).

Remarks

The UTF-8 output string is null-terminated only if the Unicode input string is null-terminated.

The routine returns STATUS_BUFFER_TOO_SMALL if the *UTF8StringMaxByteCount* parameter specifies a buffer size that is too small to contain the entire output string. In this case, the routine writes as many UTF-8 characters as will fit in the buffer, and the **UTF8StringActualByteCount* value specifies the number of valid bytes that the routine has written to the buffer. The partial string that is contained in the output buffer might not include a terminating null character.

You can make an initial call to **RtlUnicodeToUTF8N** to obtain the required output buffer size, and then call **RtlUnicodeToUTF8N** again to obtain the Unicode output string. In the initial call, set *UTF8StringDestination* = **NULL** and *UTF8StringMaxByteCount* = 0, and the routine will write the required buffer size to **UTF8StringActualByteCount*. Next, allocate a buffer of the required size and call **RtlUnicodeToUTF8N** a second time to obtain the UTF-8 output string.

RtlUnicodeToUTF8N supports Unicode surrogate pairs. However, a surrogate leading word value that is not followed by a trailing word value, or a trailing word value that is not preceded by a leading word value, is not recognized as a valid character code and is replaced by the Unicode replacement character, U+FFFD.

RtlUnicodeToUTF8N continues to convert the input string to an output string until it reaches the end of the source buffer or the end of the destination buffer, whichever occurs first. The routine converts any null characters in the input string to null characters in the output string. If the input string contains a terminating null character, but the null character is not located at the end of the source buffer, the routine continues past the terminating null character until it reaches the end of the available buffer space.

The RtlUTF8ToUnicodeN routine converts a UTF-8 string to a Unicode string.

You can use **RtlUnicodeToUTF8N** and **RtlUTF8ToUnicode** routines to perform a lossless conversion of valid text strings between the Unicode and UTF-8 formats. However, strings that have arbitrary data values are likely to violate the Unicode rules for encoding surrogate pairs, and any information that is contained in the invalid values in an input string is lost and cannot be recovered from the resulting output string.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	ntifs.h (include Ntifs.h, Wdm.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

RtlUTF8ToUnicodeN

RtlUTF8ToUnicodeN function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlUTF8ToUnicodeN** routine converts a UTF-8 string to a Unicode string.

Syntax

```
NTSYSAPI NTSTATUS RtlUTF8ToUnicodeN(
  PWSTR  UnicodeStringDestination,
  ULONG  UnicodeStringMaxByteCount,
  PULONG UnicodeStringActualByteCount,
  PCCH   UTF8StringSource,
  ULONG  UTF8StringByteCount
);
```

Parameters

`UnicodeStringDestination`

A pointer to a caller-allocated destination buffer into which the routine writes the Unicode output string. If this parameter is **NULL**, the routine writes the required size of the output buffer to **UnicodeStringActualByteCount*.

`UnicodeStringMaxByteCount`

Specifies the maximum number of bytes that the routine can write to the buffer that *UnicodeStringDestination* points to. If *UnicodeStringDestination* = **NULL**, set *UnicodeStringMaxByteCount* = 0.

`UnicodeStringActualByteCount`

A pointer to a location into which the routine writes the actual number of bytes that the routine has written to the buffer that *UnicodeStringDestination* points to. If *UnicodeStringDestination* is non-**NULL**, this count never exceeds the value of *UnicodeStringMaxByteCount*. If *UnicodeStringDestination* is **NULL**, this count is the number of bytes that are required to contain the entire output string.

`UTF8StringSource`

A pointer to the UTF-8 source string.

`UTF8StringByteCount`

Specifies the number of bytes in the UTF-8 source string that the *UTF8StringSource* parameter points to.

Return Value

RtlUTF8ToUnicodeN returns STATUS_SUCCESS if the call is successful and all UTF-8 character codes in the input string were converted to the corresponding Unicode character codes in the output string. It returns STATUS_SOME_NOT_MAPPED if the call is successful but one or more input characters were invalid and were converted to the Unicode replacement character, U+FFFD. Possible error return values include the following error codes:

RETURN CODE	DESCRIPTION

STATUS_BUFFER_TOO_SMALL	The *UnicodeStringMaxByteCount* parameter specifies a buffer size that is too small to contain the entire output string.
STATUS_INVALID_PARAMETER	The *UnicodeStringDestination* and *UnicodeStringActualByteCount* parameters are both **NULL**.
STATUS_INVALID_PARAMETER_4	The *UTF8StringSource* parameter is **NULL**.

Remarks

The Unicode output string is null-terminated only if the UTF-8 input string is null-terminated.

The routine returns STATUS_BUFFER_TOO_SMALL if the *UnicodeStringMaxByteCount* parameter specifies a buffer size that is too small to contain the entire output string. In this case, the routine writes as many Unicode characters as will fit in the buffer, and the **UnicodeStringActualByteCount* value specifies the number of valid bytes that the routine has written to the buffer. The partial string that is contained in the output buffer might not include a terminating null character.

You can make an initial call to **RtlUTF8ToUnicodeN** to obtain the required output buffer size, and then call **RtlUTF8ToUnicodeN** again to obtain the Unicode output string. In the initial call, set *UnicodeStringDestination* = **NULL** and *UnicodeStringMaxByteCount* = 0, and the routine will write the required buffer size to **UnicodeStringActualByteCount*. Next, allocate a buffer of the required size and call **RtlUTF8ToUnicodeN** a second time to obtain the Unicode output string.

RtlUTF8ToUnicodeN supports Unicode surrogate pairs. However, a surrogate leading word value that is not followed by a trailing word value, or a trailing word value that is not preceded by a leading word value, is not recognized as a valid character and is replaced by the Unicode replacement character, U+FFFD.

RtlUTF8ToUnicodeN continues to convert the input string to an output string until it reaches the end of the source buffer or the end of the destination buffer, whichever occurs first. The routine converts any null characters in the input string to null characters in the output string. If the input string contains a terminating null character, but the null character is not located at the end of the source buffer, the routine continues past the terminating null character until it reaches the end of the available buffer space.

The RtlUnicodeToUTF8N routine converts a Unicode string to a UTF-8 string.

You can use the **RtlUTF8ToUnicode** and **RtlUnicodeToUTF8N** routines to perform a lossless conversion of valid text strings between the UTF-8 and Unicode formats. However, strings that have arbitrary data values are likely to violate the Unicode rules for encoding surrogate pairs, and any information that is contained in the invalid values in an input string is lost and cannot be recovered from the resulting output string.

RtlIntPtrToUShort	Converts a value of type INT_PTR to a value of type USHORT.
RtlIntSub	Subtracts one value of type INT from another.
RtlIntToChar	Converts a value of type INT to a value of type CHAR.
RtlIntToInt8	Converts a value of type INT to a value of type INT8.
RtlIntToShort	Converts a value of type INT to a value of type SHORT.
RtlIntToUChar	Converts a value of type INT to a value of type UCHAR.
RtlIntToUInt	Converts a value of type INT to a value of type UINT.
RtlIntToUInt8	Converts a value of type INT to a value of type UINT8.
RtlIntToULong	Converts a value of type INT to a value of type ULONG.

TITLE	DESCRIPTION
RtlIntToULongLong	Converts a value of type INT to a value of type ULONGLONG.
RtlIntToUShort	Converts a value of type INT to a value of type USHORT.
RtlLongAdd	Adds two values of type LONG.
RtlLongLongAdd	Adds two values of type LONGLONG.
RtlLongLongMult	Multiplies one value of type LONGLONG by another.
RtlLongLongSub	Subtracts one value of type LONGLONG from another.
RtlLongLongToChar	Converts a value of type LONGLONG to a value of type CHAR.
RtlLongLongToInt	Converts a value of type LONGLONG to a value of type INT.
RtlLongLongToInt8	Converts a value of type LONGLONG to a value of type INT8.
RtlLongLongToIntPtr	Converts a value of type LONGLONG to a value of type INT_PTR.
RtlLongLongToLong	Converts a value of type LONGLONG to a value of type LONG.
RtlLongLongToLongPtr	Converts a value of type LONGLONG to a value of type LONG_PTR.
RtlLongLongToShort	Converts a value of type LONGLONG to a value of type SHORT.
RtlLongLongToUChar	Converts a value of type LONGLONG to a value of type UCHAR.
RtlLongLongToUInt	Converts a value of type LONGLONG to a value of type UINT.
RtlLongLongToUInt8	Converts a value of type LONGLONG to a value of type UNIT8.
RtlLongLongToULong	Converts a value of type LONGLONG to a value of type ULONG.
RtlLongLongToULongLong	Converts a value of type LONGLONG to a value of type LONGLONG.
RtlLongLongToUShort	Converts a value of type LONGLONG to a value of type USHORT.
RtlLongMult	Multiplies one value of type LONG by another.
RtlLongPtrAdd	Adds two values of type LONG_PTR.

TITLE	DESCRIPTION
RtlLongPtrMult	Multiplies one value of type LONG_PTR by another.
RtlLongPtrSub	Subtracts one value of type LONG_PTR from another.
RtlLongPtrToChar	Converts a value of type LONG_PTR to a value of type CHAR.
RtlLongPtrToInt	Converts a value of type LONG_PTR to a value of type INT.
RtlLongPtrToInt8	Converts a value of type LONG_PTR to a value of type INT8.
RtlLongPtrToIntPtr	Converts a value of type LONG_PTR to a value of type INT_PTR.
RtlLongPtrToLong	Converts a value of type LONG_PTR to a value of type LONG.
RtlLongPtrToShort	Converts a value of type LONG_PTR to a value of type SHORT.
RtlLongPtrToUChar	Converts a value of type LONG_PTR to a value of type UCHAR.
RtlLongPtrToUInt	Converts a value of type LONG_PTR to a value of type UINT.
RtlLongPtrToUInt8	Converts a value of type LONG_PTR to a value of type UINT8.
RtlLongPtrToUIntPtr	Converts a value of type LONG_PTR to a value of type UINT_PTR.
RtlLongPtrToULong	Converts a value of type LONG_PTR to a value of type ULONG.
RtlLongPtrToULongLong	Converts a value of type LONG_PTR to a value of type ULONGLONG.
RtlLongPtrToULongPtr	Converts a value of type LONG_PTR to a value of type ULONG_PTR.
RtlLongPtrToUShort	Converts a value of type LONG_PTR to a value of type USHORT.
RtlLongSub	Subtracts one value of type LONG from another.
RtlLongToChar	Converts a value of type LONG to a value of type CHAR.
RtlLongToInt	Converts a value of type LONG to a value of type INT.
RtlLongToInt8	Converts a value of type LONG to a value of type INT8.
RtlLongToIntPtr	Converts a value of type LONG to a value of type INT_PTR.
RtlLongToShort	Converts a value of type LONG to a value of type SHORT.

TITLE	DESCRIPTION
RtlLongToUChar	Converts a value of type LONG to a value of type UCHAR.
RtlLongToUInt	Converts a value of type LONG to a value of type UINT.
RtlLongToUInt8	Converts a value of type LONG to a value of type UINT8.
RtlLongToUIntPtr	Converts a value of type LONG to a value of type UINT_PTR.
RtlLongToULong	Converts a value of type LONG to a value of type ULONG.
RtlLongToULongLong	Converts a value of type LONG to a value of type ULONGLONG.
RtlLongToULongPtr	Converts a value of type LONG to a value of type ULONG_PTR.
RtlLongToUShort	Converts a value of type LONG to a value of type USHORT.
RtlPtrdiffTAdd	Adds two values of type PTRDIFF_T.
RtlPtrdiffTMult	Multiplies one value of type PTRDIFF_T by another.
RtlPtrdiffTSub	Subtracts one value of type PTRDIFF_T from another.
RtlShortAdd	Adds two values of type SHORT.
RtlShortMult	Multiplies one value of type SHORT by another.
RtlShortSub	Subtracts one value of type SHORT from another.
RtlShortToChar	Converts a value of type SHORT to a value of type CHAR.
RtlShortToDWordPtr	Converts a value of type SHORT to a value of type DWORD_PTR.
RtlShortToInt8	Converts a value of type SHORT to a value of type INT8.
RtlShortToUChar	Converts a value of type SHORT to a value of type UCHAR.
RtlShortToUInt	Converts a value of type SHORT to a value of type UINT.
RtlShortToUInt8	Converts a value of type SHORT to a value of type UINT8.
RtlShortToUIntPtr	Converts a value of type SHORT to a value of type UINT_PTR.
RtlShortToULong	Converts a value of type SHORT to a value of type ULONG.
RtlShortToULongLong	Converts a value of type SHORT to a value of type ULONGLONG.

TITLE	DESCRIPTION
RtlShortToULongPtr	Converts a value of type SHORT to a value of type ULONG_PTR.
RtlShortToUShort	Converts a value of type SHORT to a value of type USHORT.
RtlSizeTAdd	Adds two values of type SIZE_T.
RtlSizeTMult	Multiplies one value of type SIZE_T by another.
RtlSizeTSub	Subtracts one value of type SIZE_T from another.
RtlSSIZETAdd	Adds two values of type SSIZE_T.
RtlSSIZETMult	Multiplies one value of type SSIZE_T by another.
RtlSSIZETSub	Subtracts one value of type SSIZE_T from another.
RtlUInt8Add	Adds two values of type UINT8.
RtlUInt8Mult	Multiplies one value of type UINT8 by another.
RtlUInt8Sub	The RtlUInt8Sub routine subtracts one value of type UINT8 from another.
RtlUInt8ToChar	Converts a value of type UINT8 to a value of type CHAR.
RtlUInt8ToInt8	Converts a value of type UINT8 to a value of type INT8.
RtlUIntAdd	Adds two values of type UINT.
RtlUIntMult	Multiplies one value of type UINT by another.
RtlUIntPtrAdd	Adds two values of type UINT_PTR.
RtlUIntPtrMult	Multiplies one value of type UINT_PTR by another.
RtlUIntPtrSub	Subtracts one value of type UINT_PTR from another.
RtlUIntPtrToChar	Converts a value of type UINT_PTR to a value of type CHAR.
RtlUIntPtrToInt	Converts a value of type UINT_PTR to a value of type INT.
RtlUIntPtrToInt16	Converts a value of type UINT_PTR to a value of type INT16.
RtlUIntPtrToInt8	Converts a value of type UINT_PTR to a value of type INT8.
RtlUIntPtrToIntPtr	Converts a value of type UINT_PTR to a value of type INT_PTR.
RtlUIntPtrToLong	Converts a value of type UINT_PTR to a value of type LONG.

TITLE	DESCRIPTION
RtlUIntPtrToLongLong	Converts a value of type UINT_PTR to a value of type LONGLONG.
RtlUIntPtrToLongPtr	Converts a value of type UINT_PTR to a value of type LONG_PTR.
RtlUIntPtrToShort	Converts a value of type UINT_PTR to a value of type SHORT.
RtlUIntPtrToUChar	Converts a value of type UINT_PTR to a value of type UCHAR.
RtlUIntPtrToUInt	Converts a value of type UINT_PTR to a value of type UINT.
RtlUIntPtrToUInt16	Converts a value of type UINT_PTR to a value of type UINT16.
RtlUIntPtrToUInt8	Converts a value of type UINT_PTR to a value of type UINT8.
RtlUIntPtrToULong	Converts a value of type UINT_PTR to a value of type LONG.
RtlUIntPtrToUShort	Converts a value of type UINT_PTR to a value of type USHORT.
RtlUIntSub	Subtracts one value of type UINT from another.
RtlUIntToChar	Converts a value of type UINT to a value of type CHAR.
RtlUIntToInt	Converts a value of type UINT to a value of type INT.
RtlUIntToInt8	Converts a value of type UINT to a value of type INT8.
RtlUIntToIntPtr	Converts a value of type UINT to a value of type INT_PTR.
RtlUIntToLong	Converts a value of type UINT to a value of type LONG.
RtlUIntToLongPtr	Converts a value of type UINT to a value of type LONG_PTR.
RtlUIntToShort	Converts a value of type UINT to a value of type SHORT.
RtlUIntToUChar	Converts a value of type UINT to a value of type UCHAR.
RtlUIntToUInt8	Converts a value of type UINT to a value of type UINT8.
RtlUIntToUShort	Converts a value of type UINT to a value of type USHORT.
RtlULongAdd	Adds two values of type ULONG.
RtlULongLongAdd	Adds two values of type ULONGLONG.
RtlULongLongMult	Multiplies one value of type ULONGLONG by another.
RtlULongLongSub	Subtracts one value of type ULONGLONG from another.

TITLE	DESCRIPTION
RtlULongLongToChar	Converts a value of type ULONGLONG to a value of type CHAR.
RtlULongLongToInt	Converts a value of type ULONGLONG to a value of type INT.
RtlULongLongToInt8	Converts a value of type ULONGLONG to a value of type INT8.
RtlULongLongToLong	Converts a value of type ULONGLONG to a value of type LONG.
RtlULongLongToLongLong	Converts a value of type ULONGLONG to a value of type LONGLONG.
RtlULongLongToLongPtr	Converts a value of type ULONGLONG to a value of type LONG_PTR.
RtlULongLongToShort	Converts a value of type ULONGLONG to a value of type SHORT.
RtlULongLongToUChar	Converts a value of type ULONGLONG to a value of type UCHAR.
RtlULongLongToUInt	Converts a value of type ULONGLONG to a value of type UINT.
RtlULongLongToUInt8	Converts a value of type ULONGLONG to a value of type UINT8.
RtlULongLongToUIntPtr	Converts a value of type ULONGLONG to a value of type UINT_PTR.
RtlULongLongToULong	Converts a value of type ULONGLONG to a value of type ULONG.
RtlULongLongToULongPtr	Converts a value of type ULONGLONG to a value of type ULONG_PTR.
RtlULongLongToUShort	Converts a value of type ULONGLONG to a value of type USHORT.
RtlULongMult	Multiplies one value of type ULONG by another.
RtlULongPtrAdd	Adds two values of type ULONG_PTR.
RtlULongPtrMult	Multiplies one value of type ULONG_PTR by another.
RtlULongPtrSub	Subtracts one value of type ULONG_PTR from another.
RtlULongPtrToChar	Converts a value of type ULONG_PTR to a value of type CHAR.
RtlULongPtrToInt	Converts a value of type ULONG_PTR to a value of type INT.

TITLE	DESCRIPTION
RtlULongPtrToInt8	Converts a value of type ULONG_PTR to a value of type INT8.
RtlULongPtrToIntPtr	Converts a value of type ULONG_PTR to a value of type INT_PTR.
RtlULongPtrToLong	Converts a value of type ULONG_PTR to a value of type LONG.
RtlULongPtrToLongLong	Converts a value of type ULONG_PTR to a value of type LONGLONG.
RtlULongPtrToLongPtr	Converts a value of type ULONG_PTR to a value of type LONG_PTR.
RtlULongPtrToShort	Converts a value of type ULONG_PTR to a value of type SHORT.
RtlULongPtrToUChar	Converts a value of type ULONG_PTR to a value of type UCHAR.
RtlULongPtrToUInt	Converts a value of type ULONG_PTR to a value of type UINT.
RtlULongPtrToUInt8	Converts a value of type ULONG_PTR to a value of type UINT8.
RtlULongPtrToUIntPtr	Converts a value of type ULONG_PTR to a value of type UINT_PTR.
RtlULongPtrToULong	Converts a value of type ULONG_PTR to a value of type ULONG.
RtlULongPtrToUShort	Converts a value of type ULONG_PTR to a value of type USHORT.
RtlULongSub	Subtracts one value of type ULONG from another.
RtlULongToChar	Converts a value of type ULONG to a value of type CHAR.
RtlULongToInt	Converts a value of type ULONG to a value of type INT.
RtlULongToInt8	Converts a value of type ULONG to a value of type INT8.
RtlULongToIntPtr	Converts a value of type ULONG to a value of type INT_PTR.
RtlULongToLong	Converts a value of type ULONG to a value of type LONG.
RtlULongToLongPtr	Converts a value of type ULONG to a value of type LONG_PTR.
RtlULongToShort	Converts a value of type ULONG to a value of type SHORT.
RtlULongToUChar	Converts a value of type ULONG to a value of type UCHAR.

TITLE	DESCRIPTION
RtlULongToUInt	Converts a value of type ULONG to a value of type UINT.
RtlULongToUInt8	Converts a value of type ULONG_PTR to a value of type UINT8.
RtlULongToUIntPtr	Converts a value of type ULONG_PTR to a value of type UINT_PTR.
RtlULongToUShort	Converts a value of type ULONG to a value of type USHORT.
RtlUShortAdd	Adds two values of type USHORT.
RtlUShortMult	Multiplies one value of type USHORT by another.
RtlUShortSub	Subtracts one value of type USHORT from another.
RtlUShortToChar	Converts a value of type USHORT to a value of type CHAR.
RtlUShortToInt8	Converts a value of type USHORT to a value of type INT8.
RtlUShortToShort	Converts a value of type USHORT to a value of type SHORT.
RtlUShortToUChar	Converts a value of type USHORT to a value of type UCHAR.
RtlUShortToUInt8	Converts a value of type USHORT to a value of type UINT8.

RtlByteToChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **BYTE** to a value of type **CHAR**.

Syntax

```
NTSTATUS RtlByteToChar(
  BYTE bOperand,
  CHAR *pch
);
```

Parameters

`bOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlByteToInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **BYTE** to a value of type **INT8**.

Syntax

```
NTSTATUS RtlByteToInt8(
  BYTE bOperand,
  INT8 *pi8Result
);
```

Parameters

`bOperand`

The value to be converted.

`pi8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlDWordPtrAdd function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **DWORD_PTR**.

Syntax

```
NTSTATUS RtlDWordPtrAdd(
  DWORD_PTR dwAugend,
  DWORD_PTR dwAddend,
  DWORD_PTR *pdwResult
);
```

Parameters

`dwAugend`

The first value in the equation.

`dwAddend`

The value to add to *dwAugend*.

`pdwResult`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlDWordPtrMult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **DWORD_PTR** by another.

Syntax

```
NTSTATUS RtlDWordPtrMult(
  DWORD_PTR dwMultiplicand,
  DWORD_PTR dwMultiplier,
  DWORD_PTR *pdwResult
);
```

Parameters

`dwMultiplicand`

The value to be multiplied by *dwMultiplier*.

`dwMultiplier`

The value by which to multiply *dwMultiplicand*.

`pdwResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlDWordPtrSub function

1/25/2019 • 2 minutes to read • Edit Online

Subtracts one value of type **DWORD_PTR** from another.

Syntax

```
NTSTATUS RtlDWordPtrSub(
  DWORD_PTR dwMinuend,
  DWORD_PTR dwSubtrahend,
  DWORD_PTR *pdwResult
);
```

Parameters

`dwMinuend`

The value from which *dwSubtrahend* is subtracted.

`dwSubtrahend`

The value to subtract from *dwMinuend*.

`pdwResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlInt8Add function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **INT8**.

Syntax

```
NTSTATUS RtlInt8Add(
  INT8 i8Augend,
  INT8 i8Addend,
  INT8 *pi8Result
);
```

Parameters

`i8Augend`

The first value in the equation.

`i8Addend`

The value to add to *i8Augend*.

`pi8Result`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlInt8Mult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **INT8** by another.

Syntax

```
NTSTATUS RtlInt8Mult(
  INT8 i8Multiplicand,
  INT8 i8Multiplier,
  INT8 *pi8Result
);
```

Parameters

`i8Multiplicand`

The value to be multiplied by *i8Multiplier*.

`i8Multiplier`

The value by which to multiply *i8Multiplicand*.

`pi8Result`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlInt8Sub function

1/25/2019 • 2 minutes to read • Edit Online

Subtracts one value of type **INT8** from another.

Syntax

```
NTSTATUS RtlInt8Sub(
  INT8 i8Minuend,
  INT8 i8Subtrahend,
  INT8 *pi8Result
);
```

Parameters

`i8Minuend`

The value from which *i8Subtrahend* is subtracted.

`i8Subtrahend`

The value to subtract from *i8Minuend*.

`pi8Result`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlInt8ToUChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT8** to a value of type **UCHAR**.

Syntax

```
NTSTATUS RtlInt8ToUChar(
  INT8  i8Operand,
  UCHAR *pch
);
```

Parameters

`i8Operand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlInt8ToUInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT8** to a value of type **UINT**.

Syntax

```
NTSTATUS RtlInt8ToUInt(
  INT8 i8Operand,
  UINT *puResult
);
```

Parameters

`i8Operand`

The value to be converted.

`puResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt8ToUInt32

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlInt8ToUInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT8** to a value of type **UINT8**.

Syntax

```
NTSTATUS RtlInt8ToUInt8(
  INT8  i8Operand,
  UINT8 *pu8Result
);
```

Parameters

`i8Operand`

The value to be converted.

`pu8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt8ToByte

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlInt8ToUIntPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT8** to a value of type **UINT_PTR**.

Syntax

```
NTSTATUS RtlInt8ToUIntPtr(
  INT8     i8Operand,
  UINT_PTR *puResult
);
```

Parameters

`i8Operand`

The value to be converted.

`puResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt8ToSizeT

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlInt8ToULong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT8** to a value of type **ULONG**.

Syntax

```
NTSTATUS RtlInt8ToULong(
  INT8  i8Operand,
  ULONG *pulResult
);
```

Parameters

`i8Operand`

The value to be converted.

`pulResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt8ToDWord

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlInt8ToULongLong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT8** to a value of type **ULONGLONG**.

Syntax

```
NTSTATUS RtlInt8ToULongLong(
  INT8      i8Operand,
  ULONGLONG *pullResult
);
```

Parameters

`i8Operand`

The value to be converted.

`pullResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt8ToDWordLong
- RtlInt8ToULong64
- RtlInt8ToDWord64
- RtlInt8ToUInt64

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlInt8ToULongPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT8** to a value of type **ULONG_PTR**.

Syntax

```
NTSTATUS RtlInt8ToULongPtr(
  INT8      i8Operand,
  ULONG_PTR *pulResult
);
```

Parameters

`i8Operand`

The value to be converted.

`pulResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt8ToDWordPtr
- RtlInt8ToSIZET

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlInt8ToUShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT8** to a value of type **USHORT**.

Syntax

```
NTSTATUS RtlInt8ToUShort(
  INT8   i8Operand,
  USHORT *pusResult
);
```

Parameters

`i8Operand`

The value to be converted.

`pusResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt8ToUInt16
- RtlInt8ToWord

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntAdd function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **INT**.

Syntax

```
NTSTATUS RtlIntAdd(
  INT iAugend,
  INT iAddend,
  INT *piResult
);
```

Parameters

`iAugend`

The first value in the equation.

`iAddend`

The value to add to *iAugend*.

`piResult`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt32Add
- RtlLong32Add

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntMult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **INT** by another.

Syntax

```
NTSTATUS RtlIntMult(
  INT iMultiplicand,
  INT iMultiplier,
  INT *piResult
);
```

Parameters

`iMultiplicand`

The value to be multiplied by *iMultiplier*.

`iMultiplier`

The value by which to multiply *iMultiplicand*.

`piResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt32Mult
- RtlLong32Mult

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrAdd function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **INT_PTR**.

Syntax

```
NTSTATUS RtlIntPtrAdd(
  INT_PTR iAugend,
  INT_PTR iAddend,
  INT_PTR *piResult
);
```

Parameters

`iAugend`

The first value in the equation.

`iAddend`

The value to add to *iAugend*.

`piResult`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrMult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **INT_PTR** by another.

Syntax

```
NTSTATUS RtlIntPtrMult(
  INT_PTR iMultiplicand,
  INT_PTR iMultiplier,
  INT_PTR *piResult
);
```

Parameters

`iMultiplicand`

The value to be multiplied by *iMultiplier*.

`iMultiplier`

The value by which to multiply *iMultiplicand*.

`piResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrSub function

1/25/2019 • 2 minutes to read • Edit Online

Subtracts one value of type **INT_PTR** from another.

Syntax

```
NTSTATUS RtlIntPtrSub(
  INT_PTR iMinuend,
  INT_PTR iSubtrahend,
  INT_PTR *piResult
);
```

Parameters

`iMinuend`

The value from which *iSubtrahend* is subtracted.

`iSubtrahend`

The value to subtract from *iMinuend*.

`piResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrToChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT_PTR** to a value of type **CHAR**.

Syntax

```
NTSTATUS RtlIntPtrToChar(
  INT_PTR iOperand,
  CHAR    *pch
);
```

Parameters

`iOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlPtrdiffTToChar

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrToInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT_PTR** to a value of type **INT**.

Syntax

```
NTSTATUS RtlIntPtrToInt(
  INT_PTR iOperand,
  INT     *piResult
);
```

Parameters

`iOperand`

The value to be converted.

`piResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrToInt32
- RtlPtrdiffTToInt
- RtlPtrdiffTToInt32

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrToInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT_PTR** to a value of type **INT8**.

Syntax

```
NTSTATUS RtlIntPtrToInt8(
  INT_PTR iOperand,
  INT8    *pi8Result
);
```

Parameters

`iOperand`

The value to be converted.

`pi8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlPtrdiffTToInt8

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrToLong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT_PTR** to a value of type **LONG**.

Syntax

```
NTSTATUS RtlIntPtrToLong(
  INT_PTR iOperand,
  LONG    *plResult
);
```

Parameters

`iOperand`

The value to be converted.

`plResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlPtrdiffTToLong

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrToLongPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT_PTR** to a value of type **LONG_PTR**.

Syntax

```
NTSTATUS RtlIntPtrToLongPtr(
  INT_PTR  iOperand,
  LONG_PTR *plResult
);
```

Parameters

`iOperand`

The value to be converted.

`plResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlPtrdiffTToLongPtr

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrToShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT_PTR** to a value of type **SHORT**.

Syntax

```
NTSTATUS RtlIntPtrToShort(
  INT_PTR iOperand,
  SHORT   *psResult
);
```

Parameters

`iOperand`

The value to be converted.

`psResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrToInt16
- RtlPtrdiffTToShort
- RtlPtrdiffTToInt16

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrToUChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT_PTR** to a value of type **UCHAR**.

Syntax

```
NTSTATUS RtlIntPtrToUChar(
  INT_PTR iOperand,
  UCHAR   *pch
);
```

Parameters

`iOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlPtrdiffTToUChar

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrToUInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT_PTR** to a value of type **UINT**.

Syntax

```
NTSTATUS RtlIntPtrToUInt(
  INT_PTR iOperand,
  UINT    *puResult
);
```

Parameters

`iOperand`

The value to be converted.

`puResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrToUInt32
- RtlPtrdiffTToUInt
- RtlPtrdiffTToUInt32

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrToUInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT_PTR** to a value of type **UINT8**.

Syntax

```
NTSTATUS RtlIntPtrToUInt8(
  INT_PTR iOperand,
  UINT8   *pui8Result
);
```

Parameters

`iOperand`

The value to be converted.

`pui8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrToByte
- RtlPtrdiffTToUInt8
- RtlPtrdiffTToByte

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrToUIntPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT_PTR** to a value of type **UINT_PTR**.

Syntax

```
NTSTATUS RtlIntPtrToUIntPtr(
  INT_PTR  iOperand,
  UINT_PTR *puResult
);
```

Parameters

`iOperand`

The value to be converted.

`puResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrToSizeT
- RtlPtrdiffTToUIntPtr
- RtlPtrdiffTToSizeT

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrToULong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT_PTR** to a value of type **ULONG**.

Syntax

```
NTSTATUS RtlIntPtrToULong(
  INT_PTR iOperand,
  ULONG   *pulResult
);
```

Parameters

`iOperand`

The value to be converted.

`pulResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrToDWord
- RtlPtrdiffTToULong
- RtlPtrdiffTToDWord

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrToULongLong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT_PTR** to a value of type **ULONGLONG**.

Syntax

```
NTSTATUS RtlIntPtrToULongLong(
  INT_PTR   iOperand,
  ULONGLONG *pullResult
);
```

Parameters

`iOperand`

The value to be converted.

`pullResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrToDWordLong
- RtlIntPtrToULong64
- RtlIntPtrToDWord64
- RtlIntPtrToUInt64
- RtlPtrdiffTToULongLong
- RtlPtrdiffTToDWordLong
- RtlPtrdiffTToULong64
- RtlPtrdiffTToDWord64
- RtlPtrdiffTToUInt64

Requirements

Target Platform	Desktop

Header	ntintsafe.h

RtlIntPtrToULongPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT_PTR** to a value of type **ULONG_PTR**.

Syntax

```
NTSTATUS RtlIntPtrToULongPtr(
  INT_PTR   iOperand,
  ULONG_PTR *pulResult
);
```

Parameters

`iOperand`

The value to be converted.

`pulResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrToDWordPtr
- RtlIntPtrToSIZET
- RtlPtrdiffTToULongPtr
- RtlPtrdiffTToDWordPtr
- RtlPtrdiffTToSIZET

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntPtrToUShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT_PTR** to a value of type **USHORT**.

Syntax

```
NTSTATUS RtlIntPtrToUShort(
  INT_PTR iOperand,
  USHORT  *pusResult
);
```

Parameters

`iOperand`

The value to be converted.

`pusResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrToUInt16
- RtlIntPtrToWord
- RtlPtrdiffTToUShort
- RtlPtrdiffTToUInt16
- RtlPtrdiffTToWord

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntSub function

1/25/2019 • 2 minutes to read • Edit Online

Subtracts one value of type **INT** from another.

Syntax

```
NTSTATUS RtlIntSub(
  INT iMinuend,
  INT iSubtrahend,
  INT *piResult
);
```

Parameters

`iMinuend`

The value from which *iSubtrahend* is subtracted.

`iSubtrahend`

The value to subtract from *iMinuend*.

`piResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt32Sub
- RtlLong32Sub

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntToChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT** to a value of type **CHAR**.

Syntax

```
NTSTATUS RtlIntToChar(
  INT  iOperand,
  CHAR *pch
);
```

Parameters

`iOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt32ToChar

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntToInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT** to a value of type **INT8**.

Syntax

```
NTSTATUS RtlIntToInt8(
  INT  iOperand,
  INT8 *pi8Result
);
```

Parameters

`iOperand`

The value to be converted.

`pi8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt32ToInt8

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntToShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT** to a value of type **SHORT**.

Syntax

```
NTSTATUS RtlIntToShort(
  INT   iOperand,
  SHORT *psResult
);
```

Parameters

`iOperand`

The value to be converted.

`psResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntToInt16
- RtlInt32ToShort
- RtlInt32ToInt16

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlIntToUChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **INT** to a value of type **UCHAR**.

Syntax

```
NTSTATUS RtlIntToUChar(
  INT   iOperand,
  UCHAR *pch
);
```

Parameters

`iOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt32ToUChar

Requirements

RtlLongAdd function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **LONG**.

Syntax

```
NTSTATUS RtlLongAdd(
  LONG lAugend,
  LONG lAddend,
  LONG *plResult
);
```

Parameters

`lAugend`

The first value in the equation.

`lAddend`

The value to add to *lAugend*.

`plResult`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongLongAdd function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **LONGLONG**.

Syntax

```
NTSTATUS RtlLongLongAdd(
  LONGLONG llAugend,
  LONGLONG llAddend,
  LONGLONG *pllResult
);
```

Parameters

`llAugend`

The first value in the equation.

`llAddend`

The value to add to *llAugend*.

`pllResult`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrAdd
- RtlLongPtrAdd
- RtlLong64Add
- RtlInt64Add
- RtlPtrdiffTAdd
- RtlSSIZETAdd

Requirements

Target Platform	Desktop

Header	ntintsafe.h

RtlLongLongMult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **LONGLONG** by another.

Syntax

```
NTSTATUS RtlLongLongMult(
  LONGLONG llMultiplicand,
  LONGLONG llMultiplier,
  LONGLONG *pllResult
);
```

Parameters

`llMultiplicand`

The value to be multiplied by *llMultiplier*.

`llMultiplier`

The value by which to multiply *llMultiplicand*.

`pllResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrMult
- RtlLongPtrMult
- RtlLong64Mult
- RtlInt64Mult
- RtlPtrdiffTMult
- RtlSSIZETMult

Requirements

Target Platform	Desktop

RtlLongLongSub function

1/25/2019 • 2 minutes to read • Edit Online

Subtracts one value of type **LONGLONG** from another.

Syntax

```
NTSTATUS RtlLongLongSub(
  LONGLONG llMinuend,
  LONGLONG llSubtrahend,
  LONGLONG *pllResult
);
```

Parameters

`llMinuend`

The value from which *llSubtrahend* is subtracted.

`llSubtrahend`

The value to subtract from *llMinuend*.

`pllResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrSub
- RtlLongPtrSub
- RtlLong64Sub
- RtlInt64Sub
- RtlPtrdiffTSub
- RtlSSIZETSub

RtlLongLongToChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONGLONG** to a value of type **CHAR**.

Syntax

```
NTSTATUS RtlLongLongToChar(
  LONGLONG llOperand,
  CHAR     *pch
);
```

Parameters

`llOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLong64ToChar
- RtlInt64ToChar

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongLongToInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONGLONG** to a value of type **INT**.

Syntax

```
NTSTATUS RtlLongLongToInt(
  LONGLONG llOperand,
  INT      *piResult
);
```

Parameters

`llOperand`

The value to be converted.

`piResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrToInt
- RtlLongPtrToInt
- RtlLongLongToInt32
- RtlLongLongToIntPtr
- RtlLong64ToInt
- RtlLong64ToInt32
- RtlInt64ToInt
- RtlInt64ToInt32

Requirements

Target Platform	Desktop

Header	ntintsafe.h

RtlLongLongToInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONGLONG** to a value of type **INT8**.

Syntax

```
NTSTATUS RtlLongLongToInt8(
  LONGLONG llOperand,
  INT8     *pi8Result
);
```

Parameters

`llOperand`

The value to be converted.

`pi8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLong64ToInt8
- RtlInt64ToInt8

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongLongToIntPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONGLONG** to a value of type **INT_PTR**.

Syntax

```
NTSTATUS RtlLongLongToIntPtr(
  LONGLONG llOperand,
  INT_PTR  *piResult
);
```

Parameters

`llOperand`

The value to be converted.

`piResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLongLongToPtrdiffT
- RtlLong64ToIntPtr
- RtlLong64ToPtrdiffT
- RtlInt64ToIntPtr
- RtlInt64ToPtrdiffT

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongLongToLong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONGLONG** to a value of type **LONG**.

Syntax

```
NTSTATUS RtlLongLongToLong(
  LONGLONG llOperand,
  LONG     *plResult
);
```

Parameters

`llOperand`

The value to be converted.

`plResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrToLong
- RtlLongPtrToLong
- RtlLongLongToLongPtr
- RtlLong64ToLong
- RtlInt64ToLong

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongLongToLongPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONGLONG** to a value of type **LONG_PTR**.

Syntax

```
NTSTATUS RtlLongLongToLongPtr(
  LONGLONG llOperand,
  LONG_PTR *plResult
);
```

Parameters

`llOperand`

The value to be converted.

`plResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLongLongToSSIZET
- RtlLong64ToLongPtr
- RtlLong64ToSSIZET
- RtlInt64ToLongPtr
- RtlInt64ToSSIZET

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongLongToShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONGLONG** to a value of type **SHORT**.

Syntax

```
NTSTATUS RtlLongLongToShort(
  LONGLONG llOperand,
  SHORT    *psResult
);
```

Parameters

`llOperand`

The value to be converted.

`psResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLongLongToInt16
- RtlLong64ToShort
- RtlLong64ToInt16
- RtlInt64ToShort
- RtlInt64ToInt16

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongLongToUChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONGLONG** to a value of type **UCHAR**.

Syntax

```
NTSTATUS RtlLongLongToUChar(
  LONGLONG llOperand,
  UCHAR    *pch
);
```

Parameters

`llOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLong64ToUChar
- RtlInt64ToUChar

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongLongToUInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONGLONG** to a value of type **UINT**.

Syntax

```
NTSTATUS RtlLongLongToUInt(
  LONGLONG llOperand,
  UINT     *puResult
);
```

Parameters

`llOperand`

The value to be converted.

`puResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrToUInt
- RtlLongPtrToUInt
- RtlLongLongToUInt32
- RtlLongLongToUIntPtr
- RtlLong64ToUInt
- RtlLong64ToUInt32
- RtlInt64ToUInt
- RtlInt64ToUInt32
- RtlLongLongToSizeT
- RtlLong64ToUIntPtr
- RtlLong64ToSizeT
- RtlInt64ToUIntPtr
- RtlInt64ToSizeT

Requirements

Target Platform	Desktop

RtlLongLongToUInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONGLONG** to a value of type **UNIT8**.

Syntax

```
NTSTATUS RtlLongLongToUInt8(
  LONGLONG llOperand,
  UINT8    *pu8Result
);
```

Parameters

`llOperand`

The value to be converted.

`pu8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLongLongToByte
- RtlLong64ToUInt8
- RtlLong64ToByte
- RtlInt64ToUInt8
- RtlInt64ToByte

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongLongToULong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONGLONG** to a value of type **ULONG**.

Syntax

```
NTSTATUS RtlLongLongToULong(
  LONGLONG llOperand,
  ULONG    *pulResult
);
```

Parameters

`llOperand`

The value to be converted.

`pulResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrToULong
- RtlLongPtrToULong
- RtlLongLongToULongPtr
- RtlLongLongToDWord
- RtlLong64ToULong
- RtlLong64ToDWord
- RtlInt64ToULong
- RtlInt64ToDWord

Requirements

RtlLongLongToULongLong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONGLONG** to a value of type **LONGLONG**.

Syntax

```
NTSTATUS RtlLongLongToULongLong(
  LONGLONG  llOperand,
  ULONGLONG *pullResult
);
```

Parameters

`llOperand`

The value to be converted.

`pullResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlIntPtrToUIntPtr
- RtlIntPtrToULongPtr
- RtlIntPtrToULongLong
- RtlLongLongToUIntPtr
- RtlLongLongToULongPtr
- RtlLongLongToDWordLong
- RtlLongLongToULong64
- RtlLongLongToDWord64
- RtlLongLongToUInt64
- RtlLong64ToULongLong
- RtlInt64ToULongLong

RtlLongMult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **LONG** by another.

Syntax

```
NTSTATUS RtlLongMult(
  LONG lMultiplicand,
  LONG lMultiplier,
  LONG *plResult
);
```

Parameters

`lMultiplicand`

The value to be multiplied by *lMultiplier*.

`lMultiplier`

The value by which to multiply *lMultiplicand*.

`plResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongPtrAdd function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **LONG_PTR**.

Syntax

```
NTSTATUS RtlLongPtrAdd(
  LONG_PTR lAugend,
  LONG_PTR lAddend,
  LONG_PTR *plResult
);
```

Parameters

`lAugend`

The first value in the equation.

`lAddend`

The value to add to *u8Augend*.

`plResult`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongPtrMult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **LONG_PTR** by another.

Syntax

```
NTSTATUS RtlLongPtrMult(
  LONG_PTR lMultiplicand,
  LONG_PTR lMultiplier,
  LONG_PTR *plResult
);
```

Parameters

`lMultiplicand`

The value to be multiplied by *lMultiplier*.

`lMultiplier`

The value by which to multiply *lMultiplicand*.

`plResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongPtrSub function

1/25/2019 • 2 minutes to read • Edit Online

Subtracts one value of type **LONG_PTR** from another.

Syntax

```
NTSTATUS RtlLongPtrSub(
  LONG_PTR lMinuend,
  LONG_PTR lSubtrahend,
  LONG_PTR *plResult
);
```

Parameters

`lMinuend`

The value from which *lSubtrahend* is subtracted.

`lSubtrahend`

The value to subtract from *lMinuend*.

`plResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

RtlLongPtrToChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONG_PTR** to a value of type **CHAR**.

Syntax

```
NTSTATUS RtlLongPtrToChar(
  LONG_PTR lOperand,
  CHAR     *pch
);
```

Parameters

`lOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlSSIZETToChar

Requirements

Target Platform	Desktop

RtlLongPtrToInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONG_PTR** to a value of type **INT**.

Syntax

```
NTSTATUS RtlLongPtrToInt(
  LONG_PTR lOperand,
  INT      *piResult
);
```

Parameters

`lOperand`

The value to be converted.

`piResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLongPtrToInt32
- RtlSSIZETToInt
- RtlSSIZETToInt32

Requirements

RtlLongToChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONG** to a value of type **CHAR**.

Syntax

```
NTSTATUS RtlLongToChar(
  LONG lOperand,
  CHAR *pch
);
```

Parameters

`lOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongToInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONG** to a value of type **INT**.

Syntax

```
NTSTATUS RtlLongToInt(
  LONG lOperand,
  INT  *piResult
);
```

Parameters

`lOperand`

The value to be converted.

`piResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLongToInt32
- RtlLongToIntPtr

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongToInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONG** to a value of type **INT8**.

Syntax

```
NTSTATUS RtlLongToInt8(
  LONG lOperand,
  INT8 *pi8Result
);
```

Parameters

`lOperand`

The value to be converted.

`pi8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongToIntPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONG** to a value of type **INT_PTR**.

Syntax

```
NTSTATUS RtlLongToIntPtr(
  LONG    lOperand,
  INT_PTR *piResult
);
```

Parameters

`lOperand`

The value to be converted.

`piResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLongToPtrdiffT

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongToShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONG** to a value of type **SHORT**.

Syntax

```
NTSTATUS RtlLongToShort(
  LONG  lOperand,
  SHORT *psResult
);
```

Parameters

`lOperand`

The value to be converted.

`psResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLongToInt16

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongToUChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONG** to a value of type **UCHAR**.

Syntax

```
NTSTATUS RtlLongToUChar(
  LONG  lOperand,
  UCHAR *pch
);
```

Parameters

`lOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongToUInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONG** to a value of type **UINT**.

Syntax

```
NTSTATUS RtlLongToUInt(
  LONG lOperand,
  UINT *puResult
);
```

Parameters

`lOperand`

The value to be converted.

`puResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLongToUInt32
- RtlLongToUIntPtr

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongToUInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONG** to a value of type **UINT8**.

Syntax

```
NTSTATUS RtlLongToUInt8(
  LONG  lOperand,
  UINT8 *pui8Result
);
```

Parameters

`lOperand`

The value to be converted.

`pui8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLongToByte

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongToUIntPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONG** to a value of type **UINT_PTR**.

Syntax

```
NTSTATUS RtlLongToUIntPtr(
  LONG     lOperand,
  UINT_PTR *puResult
);
```

Parameters

`lOperand`

The value to be converted.

`puResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLongToSizeT

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongToULong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONG** to a value of type **ULONG**.

Syntax

```
NTSTATUS RtlLongToULong(
  LONG  lOperand,
  ULONG *pulResult
);
```

Parameters

`lOperand`

The value to be converted.

`pulResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLongToULongPtr
- RtlLongToDWord

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongToULongLong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONG** to a value of type **ULONGLONG**.

Syntax

```
NTSTATUS RtlLongToULongLong(
  LONG      lOperand,
  ULONGLONG *pullResult
);
```

Parameters

`lOperand`

The value to be converted.

`pullResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLongToDWordLong
- RtlLongToULong64
- RtlLongToDWord64
- RtlLongToUInt64

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongToULongPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONG** to a value of type **ULONG_PTR**.

Syntax

```
NTSTATUS RtlLongToULongPtr(
  LONG      lOperand,
  ULONG_PTR *pulResult
);
```

Parameters

`lOperand`

The value to be converted.

`pulResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLongToDWordPtr
- RtlLongToSIZET

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlLongToUShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **LONG** to a value of type **USHORT**.

Syntax

```
NTSTATUS RtlLongToUShort(
  LONG   lOperand,
  USHORT *pusResult
);
```

Parameters

`lOperand`

The value to be converted.

`pusResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlLongToUInt16
- RtlLongToWord

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlPtrdiffTAdd function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **PTRDIFF_T**.

Syntax

```
NTSTATUS RtlPtrdiffTAdd(
  ptrdiff_t Augend,
  ptrdiff_t Addend,
  ptrdiff_t *pResult
);
```

Parameters

`Augend`

The first value in the equation.

`Addend`

The value to add to *Augend*.

`pResult`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlPtrdiffTMult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **PTRDIFF_T** by another.

Syntax

```
NTSTATUS RtlPtrdiffTMult(
  ptrdiff_t Multiplicand,
  ptrdiff_t Multiplier,
  ptrdiff_t *pResult
);
```

Parameters

`Multiplicand`

The value to be multiplied by *Multiplier*.

`Multiplier`

The value by which to multiply *Multiplicand*.

`pResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlPtrdiffTSub function

1/25/2019 • 2 minutes to read • Edit Online

Subtracts one value of type **PTRDIFF_T** from another.

Syntax

```
NTSTATUS RtlPtrdiffTSub(
  ptrdiff_t Minuend,
  ptrdiff_t Subtrahend,
  ptrdiff_t *pResult
);
```

Parameters

`Minuend`

The value from which *Subtrahend* is subtracted.

`Subtrahend`

The value to subtract from *Minuend*.

`pResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlShortAdd function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **SHORT**.

Syntax

```
NTSTATUS RtlShortAdd(
  SHORT sAugend,
  SHORT sAddend,
  SHORT *psResult
);
```

Parameters

`sAugend`

The first value in the equation.

`sAddend`

The value to add to *sAugend*.

`psResult`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt16Add

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlShortMult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **SHORT** by another.

Syntax

```
NTSTATUS RtlShortMult(
  SHORT sMultiplicand,
  SHORT sMultiplier,
  SHORT *psResult
);
```

Parameters

`sMultiplicand`

The value to be multiplied by *sMultiplier*.

`sMultiplier`

The value by which to multiply *sMultiplicand*.

`psResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt16Mult

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlShortSub function

1/25/2019 • 2 minutes to read • Edit Online

Subtracts one value of type **SHORT** from another.

Syntax

```
NTSTATUS RtlShortSub(
  SHORT sMinuend,
  SHORT sSubtrahend,
  SHORT *psResult
);
```

Parameters

`sMinuend`

The value from which *sSubtrahend* is subtracted.

`sSubtrahend`

The value to subtract from *sMinuend*.

`psResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt16Sub

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlShortToChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **SHORT** to a value of type **CHAR**.

Syntax

```
NTSTATUS RtlShortToChar(
  SHORT sOperand,
  CHAR  *pch
);
```

Parameters

`sOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt16ToChar

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlShortToDWordPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **SHORT** to a value of type **DWORD_PTR**.

Syntax

```
NTSTATUS RtlShortToDWordPtr(
  SHORT     sOperand,
  DWORD_PTR *pdwResult
);
```

Parameters

`sOperand`

The value to be converted.

`pdwResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

-

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlShortToInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **SHORT** to a value of type **INT8**.

Syntax

```
NTSTATUS RtlShortToInt8(
  SHORT sOperand,
  INT8  *pi8Result
);
```

Parameters

`sOperand`

The value to be converted.

`pi8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt16ToInt8

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlShortToUChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **SHORT** to a value of type **UCHAR**.

Syntax

```
NTSTATUS RtlShortToUChar(
  SHORT sOperand,
  UCHAR *pch
);
```

Parameters

`sOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlInt16ToUChar

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlShortToUInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **SHORT** to a value of type **UINT**.

Syntax

```
NTSTATUS RtlShortToUInt(
  SHORT sOperand,
  UINT  *puResult
);
```

Parameters

`sOperand`

The value to be converted.

`puResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlShortToUInt32
- RtlInt16ToUInt
- RtlInt16ToUInt32

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlShortToUInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **SHORT** to a value of type **UINT8**.

Syntax

```
NTSTATUS RtlShortToUInt8(
  SHORT sOperand,
  UINT8 *pui8Result
);
```

Parameters

`sOperand`

The value to be converted.

`pui8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlShortToByte
- RtlInt16ToUInt8
- RtlInt16ToByte

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlShortToUIntPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **SHORT** to a value of type **UINT_PTR**.

Syntax

```
NTSTATUS RtlShortToUIntPtr(
  SHORT    sOperand,
  UINT_PTR *puResult
);
```

Parameters

`sOperand`

The value to be converted.

`puResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlShortToSizeT
- RtlInt16ToUIntPtr
- RtlInt16ToSizeT

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlShortToULong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **SHORT** to a value of type **ULONG**.

Syntax

```
NTSTATUS RtlShortToULong(
  SHORT sOperand,
  ULONG *pulResult
);
```

Parameters

`sOperand`

The value to be converted.

`pulResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlShortToDWord
- RtlInt16ToULong
- RtlInt16ToDWord

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlShortToULongLong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **SHORT** to a value of type **ULONGLONG**.

Syntax

```
NTSTATUS RtlShortToULongLong(
  SHORT     sOperand,
  ULONGLONG *pullResult
);
```

Parameters

`sOperand`

The value to be converted.

`pullResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlShortToDWordLong
- RtlShortToULong64
- RtlShortToDWord64
- RtlShortToUInt64
- RtlInt16ToULongLong
- RtlInt16ToDWordLong
- RtlInt16ToULong64
- RtlInt16ToDWord64

RtlSizeTAdd function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **SIZE_T**.

Syntax

```
NTSTATUS RtlSizeTAdd(
  size_t Augend,
  size_t Addend,
  size_t *pResult
);
```

Parameters

`Augend`

The first value in the equation.

`Addend`

The value to add to *Augend*.

`pResult`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

RtlSizeTMult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **SIZE_T** by another.

Syntax

```
NTSTATUS RtlSizeTMult(
  size_t Multiplicand,
  size_t Multiplier,
  size_t *pResult
);
```

Parameters

`Multiplicand`

The value to be multiplied by *Multiplier*.

`Multiplier`

The value by which to multiply *Multiplicand*.

`pResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

RtlSSIZETMult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **SSIZE_T** by another.

Syntax

```
NTSTATUS RtlSSIZETMult(
  SSIZE_T Multiplicand,
  SSIZE_T Multiplier,
  SSIZE_T *pResult
);
```

Parameters

`Multiplicand`

The value to be multiplied by *Multiplier*.

`Multiplier`

The value by which to multiply *Multiplicand*.

`pResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlSSIZETSub function

1/25/2019 • 2 minutes to read • Edit Online

Subtracts one value of type **SSIZE_T** from another.

Syntax

```
NTSTATUS RtlSSIZETSub(
  SSIZE_T Minuend,
  SSIZE_T Subtrahend,
  SSIZE_T *pResult
);
```

Parameters

`Minuend`

The value from which *Subtrahend* is subtracted.

`Subtrahend`

The value to subtract from *Minuend*.

`pResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUInt8Add function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **UINT8**.

Syntax

```
NTSTATUS RtlUInt8Add(
  UINT8 u8Augend,
  UINT8 u8Addend,
  UINT8 *pu8Result
);
```

Parameters

`u8Augend`

The first value in the equation.

`u8Addend`

The value to add to *u8Augend*.

`pu8Result`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUInt8Mult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **UINT8** by another.

Syntax

```
NTSTATUS RtlUInt8Mult(
  UINT8 u8Multiplicand,
  UINT8 u8Multiplier,
  UINT8 *pu8Result
);
```

Parameters

`u8Multiplicand`

The value to be multiplied by *u8Multiplier*.

`u8Multiplier`

The value by which to multiply *u8Multiplicand*.

`pu8Result`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUInt8Sub function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUInt8Sub** routine subtracts one value of type **UINT8** from another.

Syntax

```
NTSTATUS RtlUInt8Sub(
  UINT8 u8Minuend,
  UINT8 u8Subtrahend,
  UINT8 *pu8Result
);
```

Parameters

`u8Minuend`

The value from which *u8Subtrahend* is subtracted.

`u8Subtrahend`

The value to subtract from *u8Minuend*.

`pu8Result`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

RtlUInt8Sub returns STATUS_SUCCESS if the routine is successful. Possible error return values include the following status code.

RETURN CODE	DESCRIPTION
STA TUS _IN TEG ER_ OVE RFL OW	An arithmetic overflow occurred.

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUInt8ToChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT8** to a value of type **CHAR**.

Syntax

```
NTSTATUS RtlUInt8ToChar(
  UINT8 u8Operand,
  CHAR  *pch
);
```

Parameters

`u8Operand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUInt8ToInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT8** to a value of type **INT8**.

Syntax

```
NTSTATUS RtlUInt8ToInt8(
  UINT8 u8Operand,
  INT8  *pi8Result
);
```

Parameters

`u8Operand`

The value to be converted.

`pi8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntAdd function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **UINT**.

Syntax

```
NTSTATUS RtlUIntAdd(
  UINT uAugend,
  UINT uAddend,
  UINT *puResult
);
```

Parameters

`uAugend`

The first value in the equation.

`uAddend`

The value to add to *uAugend*.

`puResult`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUInt32Add

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntMult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **UINT** by another.

Syntax

```
NTSTATUS RtlUIntMult(
  UINT uMultiplicand,
  UINT uMultiplier,
  UINT *puResult
);
```

Parameters

`uMultiplicand`

The value to be multiplied by *uMultiplier*.

`uMultiplier`

The value by which to multiply *uMultiplicand*.

`puResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUInt32Mult

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrAdd function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **UINT_PTR**.

Syntax

```
NTSTATUS RtlUIntPtrAdd(
  UINT_PTR uAugend,
  UINT_PTR uAddend,
  UINT_PTR *puResult
);
```

Parameters

`uAugend`

The first value in the equation.

`uAddend`

The value to add to *uAugend*.

`puResult`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlDWordAdd
- RtlUIntPtrAdd
- RtlULongPtrAdd
- RtlDWordPtrAdd
- RtlSIZETAdd
- RtlDWordLongAdd
- RtlULong64Add
- RtlDWord64Add
- RtlUInt64Add

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrMult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **UINT_PTR** by another.

Syntax

```
NTSTATUS RtlUIntPtrMult(
  UINT_PTR uMultiplicand,
  UINT_PTR uMultiplier,
  UINT_PTR *puResult
);
```

Parameters

`uMultiplicand`

The value to be multiplied by *uMultiplier*.

`uMultiplier`

The value by which to multiply *uMultiplicand*.

`puResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntPtrMult
- RtlULongPtrMult
- RtlDWordPtrMult
- RtlSizeTMult
- RtlSIZETMult
- RtlDWordLongMult
- RtlULong64Mult
- RtlDWord64Mult
- RtlUInt64Mult

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrSub function

1/25/2019 • 2 minutes to read • Edit Online

Subtracts one value of type **UINT_PTR** from another.

Syntax

```
NTSTATUS RtlUIntPtrSub(
  UINT_PTR uMinuend,
  UINT_PTR uSubtrahend,
  UINT_PTR *puResult
);
```

Parameters

`uMinuend`

The value from which *uSubtrahend* is subtracted.

`uSubtrahend`

The value to subtract from *uMinuend*.

`puResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntPtrSub
- RtlULongPtrSub
- RtlDWordPtrSub
- RtlSIZETSub
- RtlDWordLongSub
- RtlULong64Sub
- RtlDWord64Sub
- RtlUInt64Sub

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrToChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT_PTR** to a value of type **CHAR**.

Syntax

```
NTSTATUS RtlUIntPtrToChar(
  UINT_PTR uOperand,
  CHAR     *pch
);
```

Parameters

`uOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlSizeTToChar

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrToInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT_PTR** to a value of type **INT**.

Syntax

```
NTSTATUS RtlUIntPtrToInt(
  UINT_PTR uOperand,
  INT      *piResult
);
```

Parameters

`uOperand`

The value to be converted.

`piResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntPtrToInt32
- RtlSizeTToInt
- RtlSizeTToInt32

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrToInt16 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT_PTR** to a value of type **INT16**.

Syntax

```
NTSTATUS RtlUIntPtrToInt16(
  UINT_PTR uOperand,
  INT16    *pi16Result
);
```

Parameters

`uOperand`

The value to be converted.

`pi16Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrToInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT_PTR** to a value of type **INT8**.

Syntax

```
NTSTATUS RtlUIntPtrToInt8(
  UINT_PTR uOperand,
  INT8     *pi8Result
);
```

Parameters

`uOperand`

The value to be converted.

`pi8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlSizeTToInt8

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrToIntPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT_PTR** to a value of type **INT_PTR**.

Syntax

```
NTSTATUS RtlUIntPtrToIntPtr(
  UINT_PTR uOperand,
  INT_PTR  *piResult
);
```

Parameters

`uOperand`

The value to be converted.

`piResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntPtrToPtrdiffT
- RtlSizeTToIntPtr
- RtlSizeTToPtrdiffT

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrToLong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT_PTR** to a value of type **LONG**.

Syntax

```
NTSTATUS RtlUIntPtrToLong(
  UINT_PTR uOperand,
  LONG     *plResult
);
```

Parameters

`uOperand`

The value to be converted.

`plResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlSizeTToLong

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrToLongLong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT_PTR** to a value of type **LONGLONG**.

Syntax

```
NTSTATUS RtlUIntPtrToLongLong(
  UINT_PTR uOperand,
  LONGLONG *pllResult
);
```

Parameters

`uOperand`

The value to be converted.

`pllResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntPtrToLong64
- RtlUIntPtrToInt64
- RtlSizeTToLongLong
- RtlSizeTToLong64
- RtlSizeTToInt64

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrToLongPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT_PTR** to a value of type **LONG_PTR**.

Syntax

```
NTSTATUS RtlUIntPtrToLongPtr(
  UINT_PTR uOperand,
  LONG_PTR *plResult
);
```

Parameters

`uOperand`

The value to be converted.

`plResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntPtrToSSIZET
- RtlSizeTToLongPtr
- RtlSizeTToSSIZET

Requirements

Target Platform	Desktop

RtlUIntPtrToShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT_PTR** to a value of type **SHORT**.

Syntax

```
NTSTATUS RtlUIntPtrToShort(
  UINT_PTR uOperand,
  SHORT    *psResult
);
```

Parameters

`uOperand`

The value to be converted.

`psResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlSizeTToShort
- RtlSizeTToInt16

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrToUChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT_PTR** to a value of type **UCHAR**.

Syntax

```
NTSTATUS RtlUIntPtrToUChar(
  UINT_PTR uOperand,
  UCHAR    *pch
);
```

Parameters

`uOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlSizeTToUChar

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrToUInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT_PTR** to a value of type **UINT**.

Syntax

```
NTSTATUS RtlUIntPtrToUInt(
  UINT_PTR uOperand,
  UINT     *puResult
);
```

Parameters

`uOperand`

The value to be converted.

`puResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntPtrToUInt32
- RtlSizeTToUInt
- RtlSizeTToUInt32

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrToUInt16 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT_PTR** to a value of type **UINT16**.

Syntax

```
NTSTATUS RtlUIntPtrToUInt16(
  UINT_PTR uOperand,
  UINT16   *pu16Result
);
```

Parameters

`uOperand`

The value to be converted.

`pu16Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrToUInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT_PTR** to a value of type **UINT8**.

Syntax

```
NTSTATUS RtlUIntPtrToUInt8(
  UINT_PTR uOperand,
  UINT8    *pu8Result
);
```

Parameters

`uOperand`

The value to be converted.

`pu8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntPtrToByte
- RtlSizeTToUInt8
- RtlSizeTToByte

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrToULong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT_PTR** to a value of type **LONG**.

Syntax

```
NTSTATUS RtlUIntPtrToULong(
  UINT_PTR uOperand,
  ULONG    *pulResult
);
```

Parameters

`uOperand`

The value to be converted.

`pulResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntPtrToDWord
- RtlSizeTToULong
- RtlSizeTToDWord

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntPtrToUShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT_PTR** to a value of type **USHORT**.

Syntax

```
NTSTATUS RtlUIntPtrToUShort(
  UINT_PTR uOperand,
  USHORT   *pusResult
);
```

Parameters

`uOperand`

The value to be converted.

`pusResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntPtrToWord
- RtlSizeTToUShort
- RtlSizeTToUInt16
- RtlSizeTToWord

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntSub function

1/25/2019 • 2 minutes to read • Edit Online

Subtracts one value of type **UINT** from another.

Syntax

```
NTSTATUS RtlUIntSub(
  UINT uMinuend,
  UINT uSubtrahend,
  UINT *puResult
);
```

Parameters

`uMinuend`

The value from which *u8Subtrahend* is subtracted.

`uSubtrahend`

The value to subtract from *u8Minuend*.

`puResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUInt32Sub

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntToChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT** to a value of type **CHAR**.

Syntax

```
NTSTATUS RtlUIntToChar(
  UINT uOperand,
  CHAR *pch
);
```

Parameters

`uOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntToInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT** to a value of type **INT**.

Syntax

```
NTSTATUS RtlUIntToInt(
  UINT uOperand,
  INT  *piResult
);
```

Parameters

`uOperand`

The value to be converted.

`piResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntToInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT** to a value of type **INT8**.

Syntax

```
NTSTATUS RtlUIntToInt8(
  UINT uOperand,
  INT8 *pi8Result
);
```

Parameters

`uOperand`

The value to be converted.

`pi8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntToIntPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT** to a value of type **INT_PTR**.

Syntax

```
NTSTATUS RtlUIntToIntPtr(
  UINT    uOperand,
  INT_PTR *piResult
);
```

Parameters

`uOperand`

The value to be converted.

`piResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntToLong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT** to a value of type **LONG**.

Syntax

```
NTSTATUS RtlUIntToLong(
  UINT uOperand,
  LONG *plResult
);
```

Parameters

`uOperand`

The value to be converted.

`plResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntToLongPtr
- RtlUInt32ToLong

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntToLongPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT** to a value of type **LONG_PTR**.

Syntax

```
NTSTATUS RtlUIntToLongPtr(
  UINT     uOperand,
  LONG_PTR *plResult
);
```

Parameters

`uOperand`

The value to be converted.

`plResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntToSSIZET
- RtlUInt32ToLongPtr

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntToShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT** to a value of type **SHORT**.

Syntax

```
NTSTATUS RtlUIntToShort(
  UINT  uOperand,
  SHORT *psResult
);
```

Parameters

`uOperand`

The value to be converted.

`psResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntToInt16
- RtlUInt32ToShort
- RtlUInt32ToInt16

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntToUChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT** to a value of type **UCHAR**.

Syntax

```
NTSTATUS RtlUIntToUChar(
  UINT  uOperand,
  UCHAR *pch
);
```

Parameters

`uOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUInt32ToChar

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntToUInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT** to a value of type **UINT8**.

Syntax

```
NTSTATUS RtlUIntToUInt8(
  UINT  uOperand,
  UINT8 *pui8Result
);
```

Parameters

`uOperand`

The value to be converted.

`pui8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntToByte
- RtlUInt32ToUInt8

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUIntToUShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **UINT** to a value of type **USHORT**.

Syntax

```
NTSTATUS RtlUIntToUShort(
  UINT   uOperand,
  USHORT *pusResult
);
```

Parameters

`uOperand`

The value to be converted.

`pusResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntToUInt16
- RtlUIntToWord
- RtlUInt32ToUShort
- RtlUInt32ToUInt16
- RtlUInt32ToWord

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongAdd function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **ULONG**.

Syntax

```
NTSTATUS RtlULongAdd(
  ULONG ulAugend,
  ULONG ulAddend,
  ULONG *pulResult
);
```

Parameters

`ulAugend`

The first value in the equation.

`ulAddend`

The value to add to *ulAugend*.

`pulResult`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongLongAdd function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **ULONGLONG**.

Syntax

```
NTSTATUS RtlULongLongAdd(
  ULONGLONG ullAugend,
  ULONGLONG ullAddend,
  ULONGLONG *pullResult
);
```

Parameters

`ullAugend`

The first value in the equation.

`ullAddend`

The value to add to *ullAugend*.

`pullResult`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongLongMult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **ULONGLONG** by another.

Syntax

```
NTSTATUS RtlULongLongMult(
  ULONGLONG ullMultiplicand,
  ULONGLONG ullMultiplier,
  ULONGLONG *pullResult
);
```

Parameters

`ullMultiplicand`

The value to be multiplied by *ullMultiplier*.

`ullMultiplier`

The value by which to multiply *ullMultiplicand*.

`pullResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongLongSub function

1/25/2019 • 2 minutes to read • Edit Online

Subtracts one value of type **ULONGLONG** from another.

Syntax

```
NTSTATUS RtlULongLongSub(
  ULONGLONG ullMinuend,
  ULONGLONG ullSubtrahend,
  ULONGLONG *pullResult
);
```

Parameters

`ullMinuend`

The value from which *ullSubtrahend* is subtracted.

`ullSubtrahend`

The value to subtract from *ullMinuend*.

`pullResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongLongToChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONGLONG** to a value of type **CHAR**.

Syntax

```
NTSTATUS RtlULongLongToChar(
  ULONGLONG ullOperand,
  CHAR      *pch
);
```

Parameters

`ullOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongLongToInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONGLONG** to a value of type **INT**.

Syntax

```
NTSTATUS RtlULongLongToInt(
  ULONGLONG ullOperand,
  INT       *piResult
);
```

Parameters

`ullOperand`

The value to be converted.

`piResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongLongToInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONGLONG** to a value of type **INT8**.

Syntax

```
NTSTATUS RtlULongLongToInt8(
  ULONGLONG ullOperand,
  INT8      *pi8Result
);
```

Parameters

`ullOperand`

The value to be converted.

`pi8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongLongToLong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONGLONG** to a value of type **LONG**.

Syntax

```
NTSTATUS RtlULongLongToLong(
  ULONGLONG ullOperand,
  LONG      *plResult
);
```

Parameters

`ullOperand`

The value to be converted.

`plResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongLongToLongLong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONGLONG** to a value of type **LONGLONG**.

Syntax

```
NTSTATUS RtlULongLongToLongLong(
  ULONGLONG ullOperand,
  LONGLONG  *pllResult
);
```

Parameters

`ullOperand`

The value to be converted.

`pllResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlUIntPtrToLongLong
- RtlULongPtrToLongLong
- RtlULongLongToIntPtr
- RtlULongLongToInt64
- RtlULongLongToLong64
- RtlDWordLongToLongLong
- RtlDWordLongToLong64
- RtlDWordLongToInt64
- RtlULong64ToLongLong
- RtlULong64ToLong64
- RtlULong64ToInt64
- RtlDWord64ToLongLong
- RtlDWord64ToLong64

RtlULongLongToLongPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONGLONG** to a value of type **LONG_PTR**.

Syntax

```
NTSTATUS RtlULongLongToLongPtr(
  ULONGLONG ullOperand,
  LONG_PTR  *plResult
);
```

Parameters

`ullOperand`

The value to be converted.

`plResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

This function uses the following alternate name:

- RtlULongLongToSSIZET
- RtlDWordLongToLongPtr
- RtlDWordLongToSSIZET
- RtlULong64ToLongPtr
- RtlULong64ToSSIZET
- RtlDWord64ToLongPtr

RtlULongLongToShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONGLONG** to a value of type **SHORT**.

Syntax

```
NTSTATUS RtlULongLongToShort(
  ULONGLONG ullOperand,
  SHORT     *psResult
);
```

Parameters

`ullOperand`

The value to be converted.

`psResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

RtlULongPtrToUInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG_PTR** to a value of type **UINT**.

Syntax

```
NTSTATUS RtlULongPtrToUInt(
  ULONG_PTR ulOperand,
  UINT      *puResult
);
```

Parameters

`ulOperand`

The value to be converted.

`puResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongPtrToUInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG_PTR** to a value of type **UINT8**.

Syntax

```
NTSTATUS RtlULongPtrToUInt8(
  ULONG_PTR ulOperand,
  UINT8     *pui8Result
);
```

Parameters

`ulOperand`

The value to be converted.

`pui8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongPtrToUIntPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG_PTR** to a value of type **UINT_PTR**.

Syntax

```
NTSTATUS RtlULongPtrToUIntPtr(
  ULONG_PTR ulOperand,
  UINT_PTR  *puResult
);
```

Parameters

`ulOperand`

The value to be converted.

`puResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongPtrToULong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG_PTR** to a value of type **ULONG**.

Syntax

```
NTSTATUS RtlULongPtrToULong(
  ULONG_PTR ulOperand,
  ULONG     *pulResult
);
```

Parameters

`ulOperand`

The value to be converted.

`pulResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongPtrToUShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG_PTR** to a value of type **USHORT**.

Syntax

```
NTSTATUS RtlULongPtrToUShort(
  ULONG_PTR ulOperand,
  USHORT    *pusResult
);
```

Parameters

`ulOperand`

The value to be converted.

`pusResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongSub function

1/25/2019 • 2 minutes to read • Edit Online

Subtracts one value of type **ULONG** from another.

Syntax

```
NTSTATUS RtlULongSub(
  ULONG ulMinuend,
  ULONG ulSubtrahend,
  ULONG *pulResult
);
```

Parameters

`ulMinuend`

The value from which *ulSubtrahend* is subtracted.

`ulSubtrahend`

The value to subtract from *ulMinuend*.

`pulResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongToChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG** to a value of type **CHAR**.

Syntax

```
NTSTATUS RtlULongToChar(
  ULONG ulOperand,
  CHAR  *pch
);
```

Parameters

`ulOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop

RtlULongToInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG** to a value of type **INT**.

Syntax

```
NTSTATUS RtlULongToInt(
  ULONG ulOperand,
  INT   *piResult
);
```

Parameters

`ulOperand`

The value to be converted.

`piResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongToInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG** to a value of type **INT8**.

Syntax

```
NTSTATUS RtlULongToInt8(
  ULONG ulOperand,
  INT8  *pi8Result
);
```

Parameters

`ulOperand`

The value to be converted.

`pi8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongToIntPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG** to a value of type **INT_PTR**.

Syntax

```
NTSTATUS RtlULongToIntPtr(
  ULONG   ulOperand,
  INT_PTR *piResult
);
```

Parameters

`ulOperand`

The value to be converted.

`piResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongToLong function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG** to a value of type **LONG**.

Syntax

```
NTSTATUS RtlULongToLong(
  ULONG ulOperand,
  LONG  *plResult
);
```

Parameters

`ulOperand`

The value to be converted.

`plResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongToLongPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG** to a value of type **LONG_PTR**.

Syntax

```
NTSTATUS RtlULongToLongPtr(
  ULONG    ulOperand,
  LONG_PTR *plResult
);
```

Parameters

`ulOperand`

The value to be converted.

`plResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongToShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG** to a value of type **SHORT**.

Syntax

```
NTSTATUS RtlULongToShort(
  ULONG ulOperand,
  SHORT *psResult
);
```

Parameters

`ulOperand`

The value to be converted.

`psResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongToUChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG** to a value of type **UCHAR**.

Syntax

```
NTSTATUS RtlULongToUChar(
  ULONG ulOperand,
  UCHAR *pch
);
```

Parameters

`ulOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

RtlULongToUInt function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG** to a value of type **UINT**.

Syntax

```
NTSTATUS RtlULongToUInt(
  ULONG ulOperand,
  UINT  *puResult
);
```

Parameters

`ulOperand`

The value to be converted.

`puResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongToUInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG_PTR** to a value of type **UINT8**.

Syntax

```
NTSTATUS RtlULongToUInt8(
  ULONG ulOperand,
  UINT8 *pui8Result
);
```

Parameters

`ulOperand`

The value to be converted.

`pui8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongToUIntPtr function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG_PTR** to a value of type **UINT_PTR**.

Syntax

```
NTSTATUS RtlULongToUIntPtr(
  ULONG    ulOperand,
  UINT_PTR *puiResult
);
```

Parameters

`ulOperand`

The value to be converted.

`puiResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlULongToUShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **ULONG** to a value of type **USHORT**.

Syntax

```
NTSTATUS RtlULongToUShort(
  ULONG  ulOperand,
  USHORT *pusResult
);
```

Parameters

`ulOperand`

The value to be converted.

`pusResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUShortAdd function

1/25/2019 • 2 minutes to read • Edit Online

Adds two values of type **USHORT**.

Syntax

```
NTSTATUS RtlUShortAdd(
  USHORT usAugend,
  USHORT usAddend,
  USHORT *pusResult
);
```

Parameters

`usAugend`

The first value in the equation.

`usAddend`

The value to add to *usAugend*.

`pusResult`

A pointer to the sum. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUShortMult function

1/25/2019 • 2 minutes to read • Edit Online

Multiplies one value of type **USHORT** by another.

Syntax

```
NTSTATUS RtlUShortMult(
  USHORT usMultiplicand,
  USHORT usMultiplier,
  USHORT *pusResult
);
```

Parameters

`usMultiplicand`

The value to be multiplied by *usMultiplier*.

`usMultiplier`

The value by which to multiply *usMultiplicand*.

`pusResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUShortSub function

1/25/2019 • 2 minutes to read • Edit Online

Subtracts one value of type **USHORT** from another.

Syntax

```
NTSTATUS RtlUShortSub(
  USHORT usMinuend,
  USHORT usSubtrahend,
  USHORT *pusResult
);
```

Parameters

`usMinuend`

The value from which *usSubtrahend* is subtracted.

`usSubtrahend`

The value to subtract from *usMinuend*.

`pusResult`

A pointer to the result. If the operation results in a value that overflows or underflows the capacity of the type, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide arithmetic operations and perform validity checks with minimal impact on performance.

Requirements

Header	ntintsafe.h

RtlUShortToChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **USHORT** to a value of type **CHAR**.

Syntax

```
NTSTATUS RtlUShortToChar(
  USHORT usOperand,
  CHAR   *pch
);
```

Parameters

`usOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUShortToInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **USHORT** to a value of type **INT8**.

Syntax

```
NTSTATUS RtlUShortToInt8(
  USHORT usOperand,
  INT8   *pi8Result
);
```

Parameters

`usOperand`

The value to be converted.

`pi8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Header	ntintsafe.h

RtlUShortToShort function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **USHORT** to a value of type **SHORT**.

Syntax

```
NTSTATUS RtlUShortToShort(
  USHORT usOperand,
  SHORT  *psResult
);
```

Parameters

`usOperand`

The value to be converted.

`psResult`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUShortToUChar function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **USHORT** to a value of type **UCHAR**.

Syntax

```
NTSTATUS RtlUShortToUChar(
  USHORT usOperand,
  UCHAR  *pch
);
```

Parameters

`usOperand`

The value to be converted.

`pch`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

Requirements

Target Platform	Desktop
Header	ntintsafe.h

RtlUShortToUInt8 function

1/25/2019 • 2 minutes to read • Edit Online

Converts a value of type **USHORT** to a value of type **UINT8**.

Syntax

```
NTSTATUS RtlUShortToUInt8(
  USHORT usOperand,
  UINT8  *pui8Result
);
```

Parameters

`usOperand`

The value to be converted.

`pui8Result`

A pointer to the converted value. In the case where the conversion causes a truncation of the original value, the function returns STATUS_INTEGER_OVERFLOW and this parameter is not valid.

Return Value

None

Remarks

This is one of a set of inline functions designed to provide type conversions and perform validity checks with minimal impact on performance.

ntpoapi.h header

1/8/2019 • 2 minutes to read • Edit Online

This header contains functions and data structures that an application can use power management. For more information, see:

- About Power Management ntpoapi.h contains the following programming interfaces:

Functions

TITLE	DESCRIPTION
NtPowerInformation	The ZwPowerInformation routine sets or retrieves system power information.

Structures

TITLE	DESCRIPTION
CM_POWER_DATA	The CM_POWER_DATA structure contains information about a device's power management state and capabilities.
COUNTED_REASON_CONTEXT	The COUNTED_REASON_CONTEXT structure contains one or more strings that give reasons for a power request.
PO_SPR_ACTIVE_SESSION_DATA	Allow drivers to register/unregister for SPR Active session start and end notifications.
POWER_PLATFORM_INFORMATION	The POWER_PLATFORM_INFORMATION structure contains information about the power capabilities of the system.
POWER_STATE	The POWER_STATE union specifies a system power state value or a device power state value.
SYSTEM_POWER_STATE_CONTEXT	The SYSTEM_POWER_STATE_CONTEXT structure is a partially opaque system structure that contains information about the previous system power states of a computer.

Enumerations

TITLE	DESCRIPTION
DEVICE_POWER_STATE	The DEVICE_POWER_STATE enumeration type indicates a device power state.
MONITOR_DISPLAY_STATE	Indicates the power state of the monitor being displayed on.
POWER_ACTION	The POWER_ACTION enumeration identifies the system power actions that can occur on a computer.

TITLE	DESCRIPTION
POWER_INFORMATION_LEVEL	Indicates power level information.
POWER_MONITOR_REQUEST_REASON	Defines values for power transitions reasons for a monitor.
POWER_REQUEST_TYPE	The POWER_REQUEST_TYPE enumeration indicates the power request type.
POWER_STATE_TYPE	The POWER_STATE_TYPE enumeration type indicates that a power state value is a system power state or a device power state.
SYSTEM_POWER_STATE	The SYSTEM_POWER_STATE enumeration type is used to indicate a system power state.

1/30/2019 • 2 minutes to read • Edit Online

POWER_ACTION Enumeration

[**Warning:** UMDF 2 is the latest version of UMDF and supersedes UMDF 1. All new UMDF drivers should be written using UMDF 2. No new features are being added to UMDF 1 and there is limited support for UMDF 1 on newer versions of Windows 10. Universal Windows drivers must use UMDF 2. For more info, see Getting Started with UMDF.]

The **POWER_ACTION** enumeration identifies the system power actions that can occur on a computer.

Syntax

```
typedef enum  {
  PowerActionNone           = 0,
  PowerActionReserved       = ( PowerActionNone + 1 ),
  PowerActionSleep          = ( PowerActionReserved + 1 ),
  PowerActionHibernate      = ( PowerActionSleep + 1 ),
  PowerActionShutdown       = ( PowerActionHibernate + 1 ),
  PowerActionShutdownReset  = ( PowerActionShutdown + 1 ),
  PowerActionShutdownOff    = ( PowerActionShutdownReset + 1 ),
  PowerActionWarmEject      = ( PowerActionShutdownOff + 1 )
} POWER_ACTION, *PPOWER_ACTION;
```

Constants

PowerActionNone	No power action is taking place.
PowerActionReserved	Reserved for system use.
PowerActionSleep	The computer is entering a system sleeping (S1, S2, or S3) state.
PowerActionHibernate	The computer is entering its hibernation (S4) state.
PowerActionShutdown	The computer is entering its shutdown (S5) state. After all devices have entered their off (D3) state, the computer remains powered on until an administrator presses the power button.
PowerActionShutdownReset	The computer is entering its shutdown (S5) state. After all devices have entered their off (D3) state, the computer automatically powers off and then immediately restarts and returns to its working (S0) state.
PowerActionShutdownOff	The computer is entering its shutdown (S5) state. After all devices have entered their off (D3) state, the computer automatically powers off.
PowerActionWarmEject	The computer is being ejected from an ACPI-compatible dock device. Typically, the computer's power state does not change.
PowerActionDisplayOff	

Remarks

The **POWER_ACTION** enumeration is used as the return value for IWDFDevice2::GetSystemPowerAction.

Requirements

Minimum UMDF version	1.9
Header	ntpoapi.h (include Wudfddi.h, Ntpoapi.h, Wdm.h)

Constants

SystemPowerPolicyAc	Indicates SystemPowerPolicyAc.
SystemPowerPolicyDc	Indicates SystemPowerPolicyDc.
VerifySystemPolicyAc	Indicates VerifySystemPolicyAc.
VerifySystemPolicyDc	Indicates VerifySystemPolicyDc.
SystemPowerCapabilities	Indicates the power capabilities of the system.
SystemBatteryState	Indicates the system's battery state.
SystemPowerStateHandler	Indicates the system's power state handler.

ProcessorStateHandler	Indicates the processor state handler.
SystemPowerPolicyCurrent	Indicates the system's current power policy.
AdministratorPowerPolicy	Indicates the administrator's power policy.
SystemReserveHiberFile	Indicates the SystemReserveHiberFile.
ProcessorInformation	Indicates the processor information.
SystemPowerInformation	Indicates the system power information.
ProcessorStateHandler2	Indicates the processor state handler.
LastWakeTime	Indicates the last wake time.
LastSleepTime	Indicates the last sleep time.
SystemExecutionState	Indicates the system execution state.
SystemPowerStateNotifyHandler	Indicates the system power state notify handler.
ProcessorPowerPolicyAc	Indicates ProcessorPowerPolicyAc.
ProcessorPowerPolicyDc	Indicates ProcessorPowerPolicyDc.
VerifyProcessorPowerPolicyAc	Indicates VerifyProcessorPowerPolicyAc.
VerifyProcessorPowerPolicyDc	Indicates VerifyProcessorPowerPolicyDc.
ProcessorPowerPolicyCurrent	Indicates the current processor power policy.
SystemPowerStateLogging	Indicates SystemPowerStateLogging.
SystemPowerLoggingEntry	Indicates SystemPowerLoggingEntry.
SetPowerSettingValue	Indicates that the power setting value is set.
NotifyUserPowerSetting	Indicates that the user should be notified of the power setting.
PowerInformationLevelUnused0	Indicates that the power information level is unused.
SystemMonitorHiberBootPowerOff	Indicates that the system monitor boot power is off.
SystemVideoState	Indicates the system video state.
TraceApplicationPowerMessage	Indicates the trace application power message.
TraceApplicationPowerMessageEnd	Indicates the end of the trace application power message.
ProcessorPerfStates	Indicates the processor performance states.

ProcessorIdleStates	Indicates the processor idle states.
ProcessorCap	Indicates the processor cap.
SystemWakeSource	Indicates the system wake source.
SystemHiberFileInformation	Indicates the system's hibernation file information.
TraceServicePowerMessage	Indicates the trace service power message.
ProcessorLoad	Indicates the processor load.
PowerShutdownNotification	Indicates the power shutdown notification.
MonitorCapabilities	Indicates the monitor's capabilities.
SessionPowerInit	Indicates the session power has been initialized.
SessionDisplayState	Indicates the session display state.
PowerRequestCreate	Indicates that a power request has been created.
PowerRequestAction	Indicates the action of the power request.
GetPowerRequestList	Indicates that the power request list should be queued.
ProcessorInformationEx	Indicates ProcessorInformationEx.
NotifyUserModeLegacyPowerEvent	Indicates that a notification should be created for the user mode legacy power event.
GroupPark	Indicates the group park.
ProcessorIdleDomains	Indicates the processor's idle domains.
WakeTimerList	Indicates the wake timer list.
SystemHiberFileSize	Indicates the system's hibernation file size.
ProcessorIdleStatesHv	Indicates the processor's idle states.
ProcessorPerfStatesHv	Indicates the processor's performance states.
ProcessorPerfCapHv	Indicates the processor's performance capabilities.
ProcessorSetIdle	Indicates that the processor has been set to idle.
LogicalProcessorIdling	Indicates that the processor is idling.
UserPresence	Indicates the user presence.
PowerSettingNotificationName	Indicates the power setting notification name.

GetPowerSettingValue	Indicates that the power setting value should be queued.
IdleResiliency	Indicates the idle resiliency.
SessionRITState	Indicates the session's RIT state.
SessionConnectNotification	Indicates the session's connect notification.
SessionPowerCleanup	Indicates the session's power cleanup.
SessionLockState	Indicates the session's lock state.
SystemHiberbootState	Indicates the system's hibernation boot state.
PlatformInformation	Indicates the platform information.
PdcInvocation	Indicates the pdc invocation.
MonitorInvocation	Indicates the monitor invocation.
FirmwareTableInformationRegistered	Indicates the registered firmware table information.
SetShutdownSelectedTime	Indicates that the shutdown time should be set.
SuspendResumeInvocation	Indicates SuspendResumeInvocation.
PlmPowerRequestCreate	Indicates that the power request has been created.
ScreenOff	Indicates that the screen is off.
CsDeviceNotification	Indicates the device notification.
PlatformRole	Indicates the platform role.
LastResumePerformance	Indicates the last time performance was resumed.
DisplayBurst	Indicates display burst.
ExitLatencySamplingPercentage	Indicates the latency sampling percentage.
RegisterSpmPowerSettings	Indicates that the power settings are registered.
PlatformIdleStates	Indicates the platform's idle states.
ProcessorIdleVeto	Indicates the processor's idle veto.
PlatformIdleVeto	Indicates the platform's idle veto.
SystemBatteryStatePrecise	Indicates the system's battery state.
ThermalEvent	Indicates the thermal event.

PowerRequestActionInternal	Indicates the internal power request action.
BatteryDeviceState	Indicates the battery's device state.
PowerInformationInternal	Indicates the internal power information.
ThermalStandby	Indicates thermal standby.
SystemHiberFileType	Indicates the system's hibernation file type.
PhysicalPowerButtonPress	Indicates a physical power button press.
QueryPotentialDripsConstraint	Indicates the potential drips constraint.
EnergyTrackerCreate	Indicates that the energy tracker is created.
EnergyTrackerQuery	Indicates that the energy tracker is queried.
UpdateBlackBoxRecorder	Indicates that the black box recorder is updated.
PowerInformationLevelMaximum	Indicates the maximum power level.

POWER_MONITOR_REQUEST_REASON Enumeration

1/25/2019 • 2 minutes to read • Edit Online

Defines values for power transitions reasons for a monitor.

Syntax

```
typedef enum  {
  MonitorRequestReasonUnknown,
  MonitorRequestReasonPowerButton,
  MonitorRequestReasonRemoteConnection,
  MonitorRequestReasonScMonitorpower,
  MonitorRequestReasonUserInput,
  MonitorRequestReasonAcDcDisplayBurst,
  MonitorRequestReasonUserDisplayBurst,
  MonitorRequestReasonPoSetSystemState,
  MonitorRequestReasonSetThreadExecutionState,
  MonitorRequestReasonFullWake,
  MonitorRequestReasonSessionUnlock,
  MonitorRequestReasonScreenOffRequest,
  MonitorRequestReasonIdleTimeout,
  MonitorRequestReasonPolicyChange,
  MonitorRequestReasonSleepButton,
  MonitorRequestReasonLid,
  MonitorRequestReasonBatteryCountChange,
  MonitorRequestReasonGracePeriod,
  MonitorRequestReasonPnP,
  MonitorRequestReasonDP,
  MonitorRequestReasonSxTransition,
  MonitorRequestReasonSystemIdle,
  MonitorRequestReasonNearProximity,
  MonitorRequestReasonThermalStandby,
  MonitorRequestReasonResumePdc,
  MonitorRequestReasonResumeS4,
  MonitorRequestReasonTerminal,
  MonitorRequestReasonPdcSignal,
  MonitorRequestReasonAcDcDisplayBurstSuppressed,
  MonitorRequestReasonSystemStateEntered,
  MonitorRequestReasonWinrt,
  MonitorRequestReasonUserInputKeyboard,
  MonitorRequestReasonUserInputMouse,
  MonitorRequestReasonUserInputTouch,
  MonitorRequestReasonUserInputPen,
  MonitorRequestReasonUserInputAccelerometer,
  MonitorRequestReasonUserInputHid,
  MonitorRequestReasonUserInputPoUserPresent,
  MonitorRequestReasonUserInputSessionSwitch,
  MonitorRequestReasonUserInputInitialization,
  MonitorRequestReasonPdcSignalWindowsMobilePwrNotif,
  MonitorRequestReasonPdcSignalWindowsMobileShell,
  MonitorRequestReasonPdcSignalHeyCortana,
  MonitorRequestReasonPdcSignalHolographicShell,
  MonitorRequestReasonPdcSignalFingerprint,
  MonitorRequestReasonDirectedDrips,
  MonitorRequestReasonMax
} POWER_MONITOR_REQUEST_REASON;
```

COUNTED_REASON_CONTEXT structure

1/30/2019 • 2 minutes to read • Edit Online

The **COUNTED_REASON_CONTEXT** structure contains one or more strings that give reasons for a power request.

Syntax

```
typedef struct _COUNTED_REASON_CONTEXT {
  ULONG Version;
  ULONG Flags;
  union {
    struct {
      UNICODE_STRING  ResourceFileName;
      USHORT          ResourceReasonId;
      ULONG           StringCount;
      PUNICODE_STRING ReasonStrings;
    } DUMMYSTRUCTNAME;
    UNICODE_STRING SimpleString;
  } DUMMYUNIONNAME;
} COUNTED_REASON_CONTEXT, *PCOUNTED_REASON_CONTEXT;
```

Members

`Version`

The version number of the structure. Set this member to DIAGNOSTIC_REASON_VERSION.

`Flags`

Indicates whether the structure contains a simple reason string or a detailed set of reason strings. Set this member to one of the following constants:

- DIAGNOSTIC_REASON_SIMPLE_STRING
- DIAGNOSTIC_REASON_DETAILED_STRING

If **Flags** = DIAGNOSTIC_REASON_SIMPLE_STRING, the **SimpleString** member of the union is valid. If **Flags** = DIAGNOSTIC_REASON_DETAILED_STRING, the **ResourceFileName**, **ResourceReasonId**, **StringCount**, and **ReasonStrings** members are valid (and the **SimpleString** member is not valid).

`DUMMYUNIONNAME`

`DUMMYUNIONNAME.DUMMYSTRUCTNAME`

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.ResourceFileName`

A pointer to a wide-character, null-terminated string that contains the pathname of a resource file. This resource file contains one or more localized strings that give reasons for a power request. This member is optional and can be specified as **NULL** or as an empty string if no resource file is required. This member is valid only if **Flags** = DIAGNOSTIC_REASON_DETAILED_STRING.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.ResourceReasonId`

The resource ID assigned to the first reason string in the resource file that is specified by **ResourceFileName**. This

member is valid only if **Flags** = DIAGNOSTIC_REASON_DETAILED_STRING.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.StringCount`

The number of reason strings in the **ReasonStrings** array or in the resource file that is specified by **ResourceFileName**. This member is valid only if **Flags** = DIAGNOSTIC_REASON_DETAILED_STRING.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.ReasonStrings`

A pointer to an array of string pointers. Each array element is a pointer to a wide-character, null-terminated string. The number of array elements is specified by **StringCount**. This member is valid only if **Flags** = DIAGNOSTIC_REASON_DETAILED_STRING.

`DUMMYUNIONNAME.SimpleString`

A pointer to a wide-character, null-terminated string that explains the reason for a power request. This member is valid only if **Flags** = DIAGNOSTIC_REASON_SIMPLE_STRING.

Remarks

This structure is used by the PoCreatePowerRequest routine.

The power manager uses the reason string or strings contained in this structure as a diagnostic aid during functional and performance testing.

The **COUNTED_REASON_CONTEXT** structure can contain either a simple reason string or a set of detailed reason strings. If **Flags** = DIAGNOSTIC_REASON_SIMPLE_STRING, the **SimpleString** member points to a string that explains the reason for the power request. If **Flags** = DIAGNOSTIC_REASON_DETAILED_STRING, the **ResourceFileName**, **ResourceReasonId**, **StringCount**, and **ReasonStrings** members can give a detailed set of reasons for the power request.

The DIAGNOSTIC_REASON_DETAILED_STRING flag supports localization. If the localized resource file specified by **ResourceFileName** exists, the power manager retrieves a set of resource strings from the file and uses these strings in place of the strings contained in the **ReasonStrings** array. **ResourceId** specifies the resource index of the first string in the file to use as a reason string, and **StringCount** specifies the number of resource strings to use as reason strings. The resource strings must have consecutive resource indexes.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of the Windows operating system.
Header	ntpoapi.h (include Wdm.h, Ntddk.h, Ntifs.h, Ntpoapi.h)

See Also

PoCreatePowerRequest

DEVICE_POWER_STATE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **DEVICE_POWER_STATE** enumeration type indicates a device power state.

Syntax

```
typedef enum _DEVICE_POWER_STATE {
  PowerDeviceUnspecified,
  PowerDeviceD0,
  PowerDeviceD1,
  PowerDeviceD2,
  PowerDeviceD3,
  PowerDeviceMaximum
} DEVICE_POWER_STATE, *PDEVICE_POWER_STATE;
```

Constants

PowerDeviceUnspecified	Indicates an unspecified device power state.
PowerDeviceD0	Indicates a maximum device power state, which corresponds to device working state D0.
PowerDeviceD1	Indicates a device sleeping state less than **PowerDeviceD0** and greater than **PowerDeviceD2**, which corresponds to device power state D1.
PowerDeviceD2	Indicates a device sleeping state less than **PowerDeviceD1** and greater than **PowerDeviceD3**, which corresponds to device power state D2.
PowerDeviceD3	Indicates the lowest-powered device sleeping state, which corresponds to device power state D3.
PowerDeviceMaximum	The number of device power state values for this enumeration type that represent actual power states. The value of the other device power states is less than this value.

Remarks

A power state indicates the level of power consumption—and thus the extent of computing activity—by the system or by a single device. The power manager sets the power state of the system as a whole, where the system power state is indicated by one of the values of the SYSTEM_POWER_STATE enumeration type. Device drivers set the power state of their individual devices, where the device power state is indicated by one of the values of the **DEVICE_POWER_STATE** enumeration type.

For more information about system power states, see Handling System Power State Requests. For more information about device power states, see Managing Power for Individual Devices. For more information about power management in general, see Introduction to Power Management.

Requirements

Header	ntpoapi.h (include Wdm.h, Ntpoapi.h)

See Also

SYSTEM_POWER_STATE

MONITOR_DISPLAY_STATE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

Indicates the power state of the monitor being displayed on.

Syntax

```
typedef enum _MONITOR_DISPLAY_STATE {
  PowerMonitorOff,
  PowerMonitorOn,
  PowerMonitorDim
} MONITOR_DISPLAY_STATE, *PMONITOR_DISPLAY_STATE;
```

Constants

PowerMonitorOff	This indicates that the monitor is off.
PowerMonitorOn	This indicates that the monitor is on.
PowerMonitorDim	This indicates that the monitor is dim.

Requirements

Header	ntpoapi.h (include Ntpoapi.h)

PO_SPR_ACTIVE_SESSION_DATA structure

1/25/2019 • 2 minutes to read • Edit Online

Stores information that indicates whether a System Power Report's Active Session is starting or ending.

Syntax

```
typedef struct _PO_SPR_ACTIVE_SESSION_DATA {
  BOOLEAN Start;
  GUID    ActiveSessionGuid;
} PO_SPR_ACTIVE_SESSION_DATA, *PPO_SPR_ACTIVE_SESSION_DATA;
```

Members

`Start`

A boolean value that indicates whether the session is starting or ending.

`ActiveSessionGuid`

The Active session GUID for the session.

Remarks

To register for System Power Report's Active Session notifications, you must call **PowerSettingRegisterNotification** function with these these values:

- *SettingGuid*: Pass GUID_SPR_ACTIVE_SESSION_CHANGE.
- *Flags*: Set to DEVICE_NOTIFY_CALLBACK.
- *Recipient*: A **DEVICE_NOTIFY_SUBSCRIBE_PARAMETERS** structure, in which the **Callback** member is set to your implementation of the DEVICE_NOTIFY_CALLBACK_ROUTINE callback routine that gets called when the session starts or ends.

If the registration is successful, the DEVICE_NOTIFY_CALLBACK_ROUTINE callback is invoked with these value:

- *Type*: PBT_POWERSETTINGCHANGE to indicate a power setting change.
- *UpdateSetting*: Is a **POWERBROADCAST_SETTING** structure; the **PowerSetting** member is set to GUID_SPR_ACTIVE_SESSION_CHANGE, the **DataLength** member is a **_PO_SPR_ACTIVE_SESSION_DATA** structure.

Requirements

Header	ntpoapi.h

See Also

PowerSettingRegisterNotification

POWERBROADCAST_SETTING

POWER_PLATFORM_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **POWER_PLATFORM_INFORMATION** structure contains information about the power capabilities of the system.

Syntax

```
typedef struct _POWER_PLATFORM_INFORMATION {
  BOOLEAN AoAc;
} POWER_PLATFORM_INFORMATION, *PPOWER_PLATFORM_INFORMATION;
```

Members

`AoAc`

Indicates whether the system supports the connected standby power model.

Requirements

Minimum supported client	Windows 8
Minimum supported server	Windows Server 2012
Header	ntpoapi.h (include Ntpoapi.h)

POWER_REQUEST_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **POWER_REQUEST_TYPE** enumeration indicates the power request type.

Syntax

```
typedef enum _POWER_REQUEST_TYPE {
  PowerRequestDisplayRequired,
  PowerRequestSystemRequired,
  PowerRequestAwayModeRequired,
  PowerRequestExecutionRequired
} POWER_REQUEST_TYPE, *PPOWER_REQUEST_TYPE;
```

Constants

PowerRequestDisplayRequired	Not used by drivers. For more information, see Remarks.
PowerRequestSystemRequired	Prevents the computer from automatically entering sleep mode after a period of user inactivity.
PowerRequestAwayModeRequired	Not used by drivers. For more information, see Remarks.
PowerRequestExecutionRequired	Not used by drivers. For more information, see Remarks.

Remarks

This enumeration is used by the kernel-mode PoClearPowerRequest and PoSetPowerRequest routines. Drivers that call these routines must specify the **PowerRequestSystemRequired** enumeration value.

The other three enumeration values—**PowerRequestDisplayRequired**, **PowerRequestAwayModeRequired**, and **PowerRequestExecutionRequired**—are not used by drivers. Applications specify these power request types in calls to the PowerSetRequest and PowerClearRequest functions.

A **PowerRequestDisplayRequired** power request has the following effects:

- After a period of user inactivity, the session display stays on and will not automatically turn off. If the display is already turned off, the power request turns the display on.
- A screensaver will not automatically start after a period of user inactivity. If a screensaver is already running, the power request stops the screensaver.
- The session will not be automatically locked after a period of user inactivity. If the session is already locked when the driver sends the power request, the session remains locked.

While a **PowerRequestAwayModeRequired** power request is in effect, if the user tries to put the computer into sleep mode (for example, by clicking **Start** and then clicking **Sleep**), the power manager turns off audio and video so that the computer appears to be in sleep mode, but the computer continues to run.

While a **PowerRequestExecutionRequired** power request is in effect, the calling process continues to run instead of being suspended or terminated by process lifetime management (PLM) mechanisms. When and how long the

process is allowed to run depends on the operating system and power policy settings. This type of power request is supported starting with Windows 8.

Requirements

Minimum supported client	Supported starting with Windows 7.
Header	ntpoapi.h (include Wdm.h, Ntddk.h, Ntifs.h, Ntpoapi.h)

POWER_STATE union

1/30/2019 • 2 minutes to read • Edit Online

The **POWER_STATE** union specifies a system power state value or a device power state value.

Syntax

```
typedef union _POWER_STATE {
  SYSTEM_POWER_STATE SystemState;
  DEVICE_POWER_STATE DeviceState;
} POWER_STATE, *PPOWER_STATE;
```

Members

`SystemState`

A system power state value of type SYSTEM_POWER_STATE.

`DeviceState`

A device power state value of type DEVICE_POWER_STATE.

Remarks

The **POWER_STATE** union is used in conjunction with the POWER_STATE_TYPE enumeration type to specify a system power state value or a device power state value. This union is also used in cases where the power state type is implicitly determined by the context in which it is used. For example, see PoRequestPowerIrp and PoSetPowerState.

For more information about power management, see Introduction to Power Management.

SYSTEM_POWER_STATE

POWER_STATE_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **POWER_STATE_TYPE** enumeration type indicates that a power state value is a system power state or a device power state.

Syntax

```
typedef enum _POWER_STATE_TYPE {
  SystemPowerState,
  DevicePowerState
} POWER_STATE_TYPE, *PPOWER_STATE_TYPE;
```

Constants

SystemPowerState	Indicates a SYSTEM_POWER_STATE value.
DevicePowerState	Indicates a DEVICE_POWER_STATE value.

Remarks

The **POWER_STATE_TYPE** enumeration type is used in conjunction with a value of type POWER_STATE to indicate that the power state value is a system power state value or a device power state value. For an example, see PoSetPowerState.

POWER_STATE

PoSetPowerState

SYSTEM_POWER_STATE

SYSTEM_POWER_STATE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **SYSTEM_POWER_STATE** enumeration type is used to indicate a system power state.

Syntax

```
typedef enum _SYSTEM_POWER_STATE {
  PowerSystemUnspecified,
  PowerSystemWorking,
  PowerSystemSleeping1,
  PowerSystemSleeping2,
  PowerSystemSleeping3,
  PowerSystemHibernate,
  PowerSystemShutdown,
  PowerSystemMaximum
} SYSTEM_POWER_STATE, *PSYSTEM_POWER_STATE;
```

Constants

PowerSystemUnspecified	Indicates an unspecified system power state.
PowerSystemWorking	Indicates maximum system power, which corresponds to system working state S0.
PowerSystemSleeping1	Indicates a system sleeping state less than **PowerSystemWorking** and greater than **PowerSystemSleeping2**, which corresponds to system power state S1.
PowerSystemSleeping2	Indicates a system sleeping state less than **PowerSystemSleeping1** and greater than **PowerSystemSleeping3**, which corresponds to system power state S2.
PowerSystemSleeping3	Indicates a system sleeping state less than **PowerSystemSleeping2** and greater than **PowerSystemHibernate**, which corresponds to system power state S3.
PowerSystemHibernate	Indicates the lowest-powered sleeping state, which corresponds to system power state S4.
PowerSystemShutdown	Indicates the system is turned off, which corresponds to system shutdown state S5.
PowerSystemMaximum	The number of system power state values for this enumeration type that represents actual power states. This value is the number of elements in the **DeviceState** member of the DEVICE_CAPABILITIES structure for a device. The other system power state values are less than this value.

Remarks

A power state indicates the level of power consumption—and thus the extent of computing activity—by the system or by a single device. The power manager sets the power state of the system as a whole, where the system power state is indicated by one of the values of the **SYSTEM_POWER_STATE** enumeration type. Device drivers set the power state of their individual devices, where the device power state is indicated by one of the values of the DEVICE_POWER_STATE enumeration type.

For more information about system power states, see Handling System Power State Requests and for more information about device power states, see Managing Power for Individual Devices.

For more information about power management in general, see Introduction to Power Management.

Requirements

DEVICE_POWER_STATE

SYSTEM_POWER_STATE_CONTEXT structure

1/30/2019 • 2 minutes to read • Edit Online

The **SYSTEM_POWER_STATE_CONTEXT** structure is a partially opaque system structure that contains information about the previous system power states of a computer.

Syntax

```
typedef struct _SYSTEM_POWER_STATE_CONTEXT {
  union {
    struct {
      ULONG Reserved1 : 8;
      ULONG TargetSystemState : 4;
      ULONG EffectiveSystemState : 4;
      ULONG CurrentSystemState : 4;
      ULONG IgnoreHibernationPath : 1;
      ULONG PseudoTransition : 1;
      ULONG KernelSoftReboot : 1;
      ULONG DirectedDripsTransition : 1;
      ULONG Reserved2 : 8;
    } DUMMYSTRUCTNAME;
    ULONG ContextAsUlong;
  } DUMMYUNIONNAME;
} SYSTEM_POWER_STATE_CONTEXT, *PSYSTEM_POWER_STATE_CONTEXT;
```

Members

`DUMMYUNIONNAME`

Unnamed union.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME`

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.Reserved1`

Opaque member. Reserved for system use.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.TargetSystemState`

The target system power state of the previous system power IRP that the driver received. This member is set to a SYSTEM_POWER_STATE enumeration value. Drivers should treat this member as read-only.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.EffectiveSystemState`

The effective previous system power state, as perceived by the user. This member is set to a **SYSTEM_POWER_STATE** enumeration value. Drivers should treat this member as read-only. This member value might not match the **TargetSystemState** member if, for example, the previous system power IRP indicated that the computer was about to enter hibernation, but a hybrid shutdown instead occurred to prepare the computer for a fast startup. For more information, see Remarks.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.CurrentSystemState`

Opaque member. Reserved for system use.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.IgnoreHibernationPath`

Opaque member. Reserved for system use.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.PseudoTransition`

Opaque member. Reserved for system use.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.KernelSoftReboot`

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.DirectedDripsTransition`

a Directed DRIPS transition.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.Reserved2`

Opaque member. Reserved for system use.

`DUMMYUNIONNAME.ContextAsUlong`

Opaque member. Reserved for system use.

Remarks

Starting with Windows Vista, the I/O stack location in a system power IRP contains a **SYSTEM_POWER_STATE_CONTEXT** structure. The **Power** member of the **IO_STACK_LOCATION** structure contains a **SystemPowerStateContext** member, which is a **SYSTEM_POWER_STATE_CONTEXT** structure. For more information, see IO_STACK_LOCATION.

The size of the **SYSTEM_POWER_STATE_CONTEXT** structure is four bytes. This structure is divided into bit fields, most of which are opaque to drivers and reserved exclusively for use by the operating system. However, two of these bit fields, **TargetSystemState** and **EffectiveSystemState**, can be read by kernel-mode drivers to distinguish a fast startup from a wake-from-hibernation startup. For more information, see Distinguishing Fast Startup from Wake-from-Hibernation.

Requirements

Minimum supported client	Available starting with Windows Vista.
Header	ntpoapi.h (include Ntpoapi.h)

See Also

IO_STACK_LOCATION

SYSTEM_POWER_STATE

CM_POWER_DATA structure

1/25/2019 • 2 minutes to read • Edit Online

The **CM_POWER_DATA** structure contains information about a device's power management state and capabilities.

Syntax

```
typedef struct CM_Power_Data_s {
  ULONG              PD_Size;
  DEVICE_POWER_STATE PD_MostRecentPowerState;
  ULONG              PD_Capabilities;
  ULONG              PD_D1Latency;
  ULONG              PD_D2Latency;
  ULONG              PD_D3Latency;
  DEVICE_POWER_STATE PD_PowerStateMapping[POWER_SYSTEM_MAXIMUM];
  SYSTEM_POWER_STATE PD_DeepestSystemWake;
} CM_POWER_DATA, *PCM_POWER_DATA;
```

Members

`PD_Size`

The size, in bytes, of this structure.

`PD_MostRecentPowerState`

A DEVICE_POWER_STATE value representing the device's most recent power state.

`PD_Capabilities`

The device's power capabilities, represented by a combination of the following bit flags:

PDCAP_D0_SUPPORTED

PDCAP_D1_SUPPORTED

PDCAP_D2_SUPPORTED

PDCAP_D3_SUPPORTED

PDCAP_WAKE_FROM_D0_SUPPORTED

PDCAP_WAKE_FROM_D1_SUPPORTED

PDCAP_WAKE_FROM_D2_SUPPORTED

PDCAP_WAKE_FROM_D3_SUPPORTED

PDCAP_WARM_EJECT_SUPPORTED

`PD_D1Latency`

The device's latency when returning the D0 state from the D1 state. For more information, see the **D1Latency** member of DEVICE_CAPABILITIES.

`PD_D2Latency`

The device's latency when returning the D0 state from the D2 state. For more information, see the **D2Latency** member of **DEVICE_CAPABILITIES**.

`PD_D3Latency`

The device's latency when returning the D0 state from the D3 state. For more information, see the **D3Latency** member of **DEVICE_CAPABILITIES**.

`PD_PowerStateMapping`

An array of **DEVICE_POWER_STATE** values representing the maximum device power state achievable for each system power state. For more information, see the **DeviceState** member of DEVICE_CAPABILITIES.

`PD_DeepestSystemWake`

Specifies the least-powered system state from which the device can wake the system. **PD_DeepestSystemWake** typically indicates one of the system sleeping states, S1, S2, or S3 (as specified by **PowerSystemSleeping1**, **PowerSystemSleeping2**, and **PowerSystemSleeping3**, respectively). Note, however, that some devices might be able to wake the system from the system hibernate state, S4 (as specified by **PowerSystemHibernate**), or even from the system shutdown state, S5 (as specified by **PowerSystemShutdown**).

Requirements

Minimum supported client	Available in Microsoft Windows XP and later versions of the Windows operating system.

DEVICE_POWER_STATE

SetupDiGetDeviceRegistryProperty

NtPowerInformation function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwPowerInformation** routine sets or retrieves system power information.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtPowerInformation(
  POWER_INFORMATION_LEVEL InformationLevel,
  PVOID                   InputBuffer,
  ULONG                   InputBufferLength,
  PVOID                   OutputBuffer,
  ULONG                   OutputBufferLength
);
```

Parameters

`InformationLevel`

Specifies the requested information level, which indicates the specific power information to be set or retrieved. Currently, the only supported *POWER_INFORMATION_LEVEL* value is **PlatformInformation**.

VALUE	MEANING
PlatformInformation	Information represents the currently supported power capabilities of the system. Information may change as drivers are installed. For example, the installation of legacy device drivers that do not support power management might modify the capabilities of the system.

`InputBuffer`

Pointer to a caller-allocated input buffer. This parameter must be **NULL**, otherwise **ERROR_INVALID_PARAMETER** is returned.

`InputBufferLength`

Size, in bytes, of the buffer at *InputBuffer*. The parameter must be set to zero.

`OutputBuffer`

A pointer to an output buffer. The data type of this buffer depends on the information level requested in the *InformationLevel* parameter. For the **PlatformInformation** level, the only currently supported value, the *OutputBuffer* parameter is required and should be of the POWER_PLATFORM_INFORMATION type.

`OutputBufferLength`

Size, in bytes, of the output buffer. Depending on the information level requested, the buffer may be variably sized. *PlatformInformation*, the only currently supported value, requires a buffer that is the size of a POWER_PLATFORM_INFORMATION structure.

Return Value

Returns STATUS_SUCCESS if the call is successful. If the call fails, possible error codes include the following:

RETURN CODE	DESCRIPTION
STATUS_BUFFER_TOO_SMALL	The output buffer is of insufficient size to contain the data being returned.
STATUS_INVALID_PARAMETER	The **PlatformInformation** information level, which is the only currently supported value, requires no input buffer and must contain an output buffer. The caller either supplied an input buffer or no output buffer.
STATUS_ACCESS_DENIED	The caller had insufficient access rights to perform the requested action.

Remarks

NtPowerInformation and **ZwPowerInformation** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Examples

This example illustrates a valid function call.

C++

```
POWER_PLATFORM_INFORMATION PlatformInfo = {0};
NTSTATUS Result = NtPowerInformation(PlatformInformation, NULL, 0, &PlatformInfo, sizeof(PlatformInfo));
```

Requirements

Minimum supported client	Windows 8
Minimum supported server	Windows Server 2012
Target Platform	Universal
Header	ntpoapi.h (include Wdm.h, Ntddk.h, Ntpoapi.h)
Library	Ntoskrnl.lib
DLL	Ntoskrnl.lib
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

ntstrsafe.h header

1/8/2019 • 8 minutes to read • Edit Online

If you use the safe string functions instead of the string manipulation functions that are provided by C-language run-time libraries, you protect your code from buffer overrun errors that can make code untrustworthy. This header declares functions that copy, concatenate, and format strings in a manner that prevents buffer overrun errors.

To manipulate Unicode and ANSI strings, each function is available in two versions:

- A W-suffixed version that supports two-byte Unicode characters.
- An A-suffixed version that supports one-byte ANSI characters.

Unicode strings are specified within **UNICODE_STRING** structures in kernel-mode drivers.

For more information, see:

- Using Safe String Functions ntstrsafe.h contains the following programming interfaces:

Functions

TITLE	DESCRIPTION
RtlStringCbCatA	The RtlStringCbCatW and RtlStringCbCatA functions concatenate two byte-counted strings.
RtlStringCbCatExA	The RtlStringCbCatExW and RtlStringCbCatExA functions concatenate two byte-counted strings.
RtlStringCbCatExW	The RtlStringCbCatExW and RtlStringCbCatExA functions concatenate two byte-counted strings.
RtlStringCbCatNA	The RtlStringCbCatNW and RtlStringCbCatNA functions concatenate two byte-counted strings while limiting the size of the appended string.
RtlStringCbCatNExA	The RtlStringCbCatNExW and RtlStringCbCatNExA functions concatenate two byte-counted strings while limiting the size of the appended string.
RtlStringCbCatNExW	The RtlStringCbCatNExW and RtlStringCbCatNExA functions concatenate two byte-counted strings while limiting the size of the appended string.
RtlStringCbCatNW	The RtlStringCbCatNW and RtlStringCbCatNA functions concatenate two byte-counted strings while limiting the size of the appended string.
RtlStringCbCatW	The RtlStringCbCatW and RtlStringCbCatA functions concatenate two byte-counted strings.
RtlStringCbCopyA	The RtlStringCbCopyW and RtlStringCbCopyA functions copy a byte-counted string into a buffer.

TITLE	DESCRIPTION
RtlStringCbCopyExA	The RtlStringCbCopyExW and RtlStringCbCopyExA functions copy a byte-counted string into a buffer.
RtlStringCbCopyExW	The RtlStringCbCopyExW and RtlStringCbCopyExA functions copy a byte-counted string into a buffer.
RtlStringCbCopyNA	The RtlStringCbCopyNW and RtlStringCbCopyNA functions copy a byte-counted string to a buffer while limiting the size of the copied string.
RtlStringCbCopyNExA	The RtlStringCbCopyNExW and RtlStringCbCopyNExA functions copy a byte-counted string to a buffer while limiting the size of the copied string.
RtlStringCbCopyNExW	The RtlStringCbCopyNExW and RtlStringCbCopyNExA functions copy a byte-counted string to a buffer while limiting the size of the copied string.
RtlStringCbCopyNW	The RtlStringCbCopyNW and RtlStringCbCopyNA functions copy a byte-counted string to a buffer while limiting the size of the copied string.
RtlStringCbCopyUnicodeString	The RtlStringCbCopyUnicodeString function copies the contents of a UNICODE_STRING structure to a specified destination.
RtlStringCbCopyUnicodeStringEx	The RtlStringCbCopyUnicodeStringEx function copies the contents of a UNICODE_STRING structure to a specified destination.
RtlStringCbCopyW	The RtlStringCbCopyW and RtlStringCbCopyA functions copy a byte-counted string into a buffer.
RtlStringCbLengthA	The RtlStringCbLengthW and RtlStringCbLengthA functions determine the length, in bytes, of a supplied string.
RtlStringCbLengthW	The RtlStringCbLengthW and RtlStringCbLengthA functions determine the length, in bytes, of a supplied string.
RtlStringCbPrintfA	The RtlStringCbPrintfW and RtlStringCbPrintfA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCbPrintfExA	The RtlStringCbPrintfExW and RtlStringCbPrintfExA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCbPrintfExW	The RtlStringCbPrintfExW and RtlStringCbPrintfExA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCbPrintfW	The RtlStringCbPrintfW and RtlStringCbPrintfA functions create a byte-counted text string, with formatting that is based on supplied formatting information.

TITLE	DESCRIPTION
RtlStringCbVPrintfA	The RtlStringCbVPrintfW and RtlStringCbVPrintfA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCbVPrintfExA	The RtlStringCbVPrintfExW and RtlStringCbVPrintfExA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCbVPrintfExW	The RtlStringCbVPrintfExW and RtlStringCbVPrintfExA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCbVPrintfW	The RtlStringCbVPrintfW and RtlStringCbVPrintfA functions create a byte-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchCatA	The RtlStringCchCatW and RtlStringCchCatA functions concatenate two character-counted strings.
RtlStringCchCatExA	The RtlStringCchCatExW and RtlStringCchCatExA functions concatenate two character-counted strings.
RtlStringCchCatExW	The RtlStringCchCatExW and RtlStringCchCatExA functions concatenate two character-counted strings.
RtlStringCchCatNA	The RtlStringCchCatNW and RtlStringCchCatNA functions concatenate two character-counted strings while limiting the size of the appended string.
RtlStringCchCatNExA	The RtlStringCchCatNExW and RtlStringCchCatNExA functions concatenate two character-counted strings while limiting the size of the appended string.
RtlStringCchCatNExW	The RtlStringCchCatNExW and RtlStringCchCatNExA functions concatenate two character-counted strings while limiting the size of the appended string.
RtlStringCchCatNW	The RtlStringCchCatNW and RtlStringCchCatNA functions concatenate two character-counted strings while limiting the size of the appended string.
RtlStringCchCatW	The RtlStringCchCatW and RtlStringCchCatA functions concatenate two character-counted strings.
RtlStringCchCopyA	The RtlStringCchCopyW and RtlStringCchCopyA functions copy a null-terminated source string into a destination buffer of specified length.
RtlStringCchCopyExA	The RtlStringCchCopyExW and RtlStringCchCopyExA functions copy a character-counted string into a buffer.
RtlStringCchCopyExW	The RtlStringCchCopyExW and RtlStringCchCopyExA functions copy a character-counted string into a buffer.

TITLE	DESCRIPTION
RtlStringCchCopyNA	The RtlStringCchCopyNW and RtlStringCchCopyNA functions copy a character-counted string to a buffer while limiting the size of the copied string.
RtlStringCchCopyNExA	The RtlStringCchCopyNExW and RtlStringCchCopyNExA functions copy a character-counted string to a buffer while limiting the size of the copied string.
RtlStringCchCopyNExW	The RtlStringCchCopyNExW and RtlStringCchCopyNExA functions copy a character-counted string to a buffer while limiting the size of the copied string.
RtlStringCchCopyNW	The RtlStringCchCopyNW and RtlStringCchCopyNA functions copy a character-counted string to a buffer while limiting the size of the copied string.
RtlStringCchCopyUnicodeString	The RtlStringCchCopyUnicodeString function copies the contents of a UNICODE_STRING structure to a specified destination.
RtlStringCchCopyUnicodeStringEx	The RtlStringCchCopyUnicodeStringEx function copies the contents of a UNICODE_STRING structure to a specified destination.
RtlStringCchCopyW	The RtlStringCchCopyW and RtlStringCchCopyA functions copy a null-terminated source string into a destination buffer of specified length.
RtlStringCchLengthA	The RtlStringCchLengthW and RtlStringCchLengthA functions determine the length, in characters, of a supplied string.
RtlStringCchLengthW	The RtlStringCchLengthW and RtlStringCchLengthA functions determine the length, in characters, of a supplied string.
RtlStringCchPrintfA	The RtlStringCchPrintfW and RtlStringCchPrintfA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchPrintfExA	The RtlStringCchPrintfExW and RtlStringCchPrintfExA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchPrintfExW	The RtlStringCchPrintfExW and RtlStringCchPrintfExA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchPrintfW	The RtlStringCchPrintfW and RtlStringCchPrintfA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchVPrintfA	The RtlStringCchVPrintfW and RtlStringCchVPrintfA functions create a character-counted text string, with formatting that is based on supplied formatting information.

TITLE	DESCRIPTION
RtlStringCchVPrintfExA	The RtlStringCchVPrintfExW and RtlStringCchVPrintfExA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchVPrintfExW	The RtlStringCchVPrintfExW and RtlStringCchVPrintfExA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlStringCchVPrintfW	The RtlStringCchVPrintfW and RtlStringCchVPrintfA functions create a character-counted text string, with formatting that is based on supplied formatting information.
RtlUnalignedStringCbLengthW	The RtlUnalignedStringCbLengthW function is a version of the RtlStringCbLength function that accepts an unaligned pointer to a string of Unicode characters.
RtlUnalignedStringCchLengthW	The RtlUnalignedStringCchLengthW function is a version of the RtlStringCchLength function that accepts an unaligned pointer to a string of Unicode characters.
RtlUnicodeStringCat	The RtlUnicodeStringCat function concatenates two strings that are contained in UNICODE_STRING structures.
RtlUnicodeStringCatEx	The RtlUnicodeStringCatEx function concatenates two strings that are contained in UNICODE_STRING structures.
RtlUnicodeStringCatString	The RtlUnicodeStringCatString function concatenates two strings when the destination string is contained in a UNICODE_STRING structure.
RtlUnicodeStringCatStringEx	The RtlUnicodeStringCatStringEx function concatenates two strings when the destination string is contained in a UNICODE_STRING structure.
RtlUnicodeStringCbCatN	The RtlUnicodeStringCbCatN function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.
RtlUnicodeStringCbCatNEx	The RtlUnicodeStringCbCatNEx function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.
RtlUnicodeStringCbCatStringN	The RtlUnicodeStringCbCatStringN function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.
RtlUnicodeStringCbCatStringNEx	The RtlUnicodeStringCbCatStringNEx function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.
RtlUnicodeStringCbCopyN	The RtlUnicodeStringCbCopyN function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.

TITLE	DESCRIPTION
RtlUnicodeStringCbCopyNEx	The RtlUnicodeStringCbCopyNEx function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.
RtlUnicodeStringCbCopyStringN	The RtlUnicodeStringCbCopyStringN function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.
RtlUnicodeStringCbCopyStringNEx	The RtlUnicodeStringCbCopyStringNEx function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.
RtlUnicodeStringCchCatN	The RtlUnicodeStringCchCatN function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.
RtlUnicodeStringCchCatNEx	The RtlUnicodeStringCchCatNEx function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.
RtlUnicodeStringCchCatStringN	The RtlUnicodeStringCchCatStringN function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.
RtlUnicodeStringCchCatStringNEx	The RtlUnicodeStringCchCatStringNEx function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.
RtlUnicodeStringCchCopyN	The RtlUnicodeStringCchCopyN function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.
RtlUnicodeStringCchCopyNEx	The RtlUnicodeStringCchCopyNEx function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.
RtlUnicodeStringCchCopyStringN	The RtlUnicodeStringCchCopyStringN function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.
RtlUnicodeStringCchCopyStringNEx	The RtlUnicodeStringCchCopyStringNEx function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.
RtlUnicodeStringCopy	The RtlUnicodeStringCopy function copies a string from one UNICODE_STRING structure to another.
RtlUnicodeStringCopyEx	The RtlUnicodeStringCopyEx function copies a string from one UNICODE_STRING structure to another.
RtlUnicodeStringCopyString	The RtlUnicodeStringCopyString function copies a string into a UNICODE_STRING structure.

TITLE	DESCRIPTION
RtlUnicodeStringCopyStringEx	The RtlUnicodeStringCopyStringEx function copies a string into a UNICODE_STRING structure.
RtlUnicodeStringInit	The RtlUnicodeStringInit function initializes a UNICODE_STRING structure.
RtlUnicodeStringInitEx	The RtlUnicodeStringInitEx function initializes a UNICODE_STRING structure.
RtlUnicodeStringPrintf	The RtlUnicodeStringPrintf function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.
RtlUnicodeStringPrintfEx	The RtlUnicodeStringPrintfEx function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.
RtlUnicodeStringValidate	The RtlUnicodeStringValidate function validates the contents of a UNICODE_STRING structure.
RtlUnicodeStringValidateEx	The RtlUnicodeStringValidateEx function validates the contents of a UNICODE_STRING structure.
RtlUnicodeStringVPrintf	The RtlUnicodeStringVPrintf function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.
RtlUnicodeStringVPrintfEx	The RtlUnicodeStringVPrintfEx function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.

RtlStringCbCatA function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCbCatW** and **RtlStringCbCatA** functions concatenate two byte-counted strings.

Syntax

```
NTSTRSAFEDDI RtlStringCbCatA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cbDest,
  NTSTRSAFE_PCSTR pszSrc
);
```

Parameters

`pszDest`

A pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc* is added to the end of the string at *pszDest* and terminated with a null character.

`cbDest`

The size of the destination buffer, in bytes. The destination buffer must be large enough to include the concatenated strings and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

`pszSrc`

A pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the strings were concatenated without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the concatenation operation did not complete due to insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The STATUS_INVALID_PARAMETER return value means that one of the following occurred: • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCatW and **RtlStringCbCatA** should be used instead of the following functions:

- **strcat**
- **wcscat**

Because **RtlStringCbCatW** and **RtlStringCbCatA** receive the size of the destination buffer as input, they will not write past the end of the buffer.

Use **RtlStringCbCatW** to handle Unicode strings and **RtlStringCbCatA** to handle ANSI strings. The form to use is determined by your data as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCatW**
char	"string"	**RtlStringCbCatA**

If *pszSrc* and *pszDest* point to strings that overlap, the behavior of the functions is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCbCatNEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop

Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

See Also

RtlStringCbCatEx

RtlStringCbCatNEx

RtlStringCchCatEx

RtlStringCbCatExA function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCbCatExW** and **RtlStringCbCatExA** functions concatenate two byte-counted strings.

Syntax

```
NTSTRSAFEDDI RtlStringCbCatExA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cbDest,
  NTSTRSAFE_PCSTR pszSrc,
  NTSTRSAFE_PSTR  *ppszDestEnd,
  size_t          *pcbRemaining,
  DWORD           dwFlags
);
```

Parameters

`pszDest`

A pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc* is added to the end of the string at *pszDest* and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbDest`

The size of the destination buffer, in bytes. The buffer must be large enough to include both strings and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

`pszSrc`

A pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*. The *pszSrc* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer, then after the concatenation operation completes, the function loads that address with a pointer to the destination buffer's resulting **NULL** string terminator.

`pcbRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused bytes that are in the buffer pointed to by *pszDest*, including bytes used for the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	This *success* status means source data was present, the strings were fully concatenated without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the concatenated string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER when: • An invalid flag was specified. • The value in cbDest is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCatExW and **RtlStringCbCatExA** should be used instead of the following functions:

- **strcat**
- **wcscat**

Because **RtlStringCbCatExW** and **RtlStringCbCatExA** receive the size of the destination buffer as input, they will not write past the end of the buffer.

RtlStringCbCatEx adds to the functionality of RtlStringCbCat by returning a pointer to the end of the destination string, as well as the number of bytes left unused in that string. Flags can also be passed to the function for additional control.

Use **RtlStringCbCatExW** to handle Unicode strings and **RtlStringCbCatExA** to handle ANSI strings. The form to use is determined by your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCatExW**
char	"string"	**RtlStringCbCatExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbCat

RtlStringCbCatNEx

RtlStringCchCatEx

RtlStringCbCatExW function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCbCatExW** and **RtlStringCbCatExA** functions concatenate two byte-counted strings.

Syntax

```
NTSTRSAFEDDI RtlStringCbCatExW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cbDest,
  NTSTRSAFE_PCWSTR pszSrc,
  NTSTRSAFE_PWSTR  *ppszDestEnd,
  size_t           *pcbRemaining,
  DWORD            dwFlags
);
```

Parameters

`pszDest`

A pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc* is added to the end of the string at *pszDest* and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbDest`

The size of the destination buffer, in bytes. The buffer must be large enough to include both strings and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

`pszSrc`

A pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*. The *pszSrc* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer, then after the concatenation operation completes, the function loads that address with a pointer to the destination buffer's resulting **NULL** string terminator.

`pcbRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused bytes that are in the buffer pointed to by *pszDest*, including bytes used for the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	This *success* status means source data was present, the strings were fully concatenated without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the concatenated string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER when: • An invalid flag was specified. • The value in cbDest is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCatExW and **RtlStringCbCatExA** should be used instead of the following functions:

- **strcat**
- **wcscat**

Because **RtlStringCbCatExW** and **RtlStringCbCatExA** receive the size of the destination buffer as input, they will not write past the end of the buffer.

RtlStringCbCatEx adds to the functionality of RtlStringCbCat by returning a pointer to the end of the destination string, as well as the number of bytes left unused in that string. Flags can also be passed to the function for additional control.

Use **RtlStringCbCatExW** to handle Unicode strings and **RtlStringCbCatExA** to handle ANSI strings. The form to use is determined by your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCatExW**
char	"string"	**RtlStringCbCatExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbCat

RtlStringCbCatNEx

RtlStringCchCatEx

RtlStringCbCatNA function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCbCatNW** and **RtlStringCbCatNA** functions concatenate two byte-counted strings while limiting the size of the appended string.

Syntax

```
NTSTRSAFEDDI RtlStringCbCatNA(
  NTSTRSAFE_PSTR pszDest,
  size_t         cbDest,
  STRSAFE_PCNZCH pszSrc,
  size_t         cbToAppend
);
```

Parameters

`pszDest`

Pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc*, up to *cbMaxAppend* bytes, is added to the end of the string at *pszDest* and terminated with a null character.

`cbDest`

The size of the destination buffer, in bytes. The buffer must be large enough to include both strings and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

`pszSrc`

Pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*.

`cbToAppend`

The maximum number of bytes to append to the string that is contained in the buffer at *pszDest*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	This *success* status means source data was present, the strings were concatenated without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the concatenation operation did not complete due to insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer's length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCatNW and **RtlStringCbCatNA** should be used instead of the following functions:

- **strncat**
- **wcsncat**

The size, in bytes, of the destination buffer is provided to **RtlStringCbCatNW** and **RtlStringCbCatNA** to ensure that they do not write past the end of the buffer.

Use **RtlStringCbCatNW** to handle Unicode strings and **RtlStringCbCatNA** to handle ANSI strings. The form you use depends on your data, as shown in the following table

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCatNW**
char	"string"	**RtlStringCbCatNA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCbCatNEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbCat

RtlStringCbCatNEx

RtlStringCchCatN

RtlStringCbCatNExA function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCbCatNExW** and **RtlStringCbCatNExA** functions concatenate two byte-counted strings while limiting the size of the appended string.

Syntax

```
NTSTRSAFEDDI RtlStringCbCatNExA(
  NTSTRSAFE_PSTR pszDest,
  size_t         cbDest,
  STRSAFE_PCNZCH pszSrc,
  size_t         cbToAppend,
  NTSTRSAFE_PSTR *ppszDestEnd,
  size_t         *pcbRemaining,
  DWORD          dwFlags
);
```

Parameters

`pszDest`

A pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc*, up to *cbMaxAppend* bytes, is added to the end of the string at *pszDest*, and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbDest`

The size of the destination buffer, in bytes. The buffer must be large enough to include both strings and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

If *pszDest* is **NULL**, *cbDest* must be zero.

`pszSrc`

A pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*. The *pszSrc* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbToAppend`

The maximum number of bytes to append to *pszDest*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer, then after the concatenation operation completes, the function loads that address with a pointer to the destination buffer's resulting **NULL** string terminator.

`pcbRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused bytes

that are in the buffer pointed to by *pszDest*, including bytes used for the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING
STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how

to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the strings were fully concatenated without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the concatenated string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCatNExW and **RtlStringCbCatNExA** should be used instead of the following functions:

- **strncat**
- **wcsncat**

The size, in bytes, of the destination buffer is provided to **RtlStringCbCatNExW** and **RtlStringCbCatNExA** to ensure that they do not write past the end of the buffer.

RtlStringCbCatNEx adds to the functionality of RtlStringCbCatN by returning a pointer to the end of the destination string as well as the number of bytes left unused in that string. Flags can be passed to the function for additional control.

Use **RtlStringCbCatNExW** to handle Unicode strings and **RtlStringCbCatNExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCatNExW**

char	"string"	**RtlStringCbCatNExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

RtlStringCbCatEx

RtlStringCbCatN

RtlStringCchCatNEx

RtlStringCbCatNExW function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCbCatNExW** and **RtlStringCbCatNExA** functions concatenate two byte-counted strings while limiting the size of the appended string.

Syntax

```
NTSTRSAFEDDI RtlStringCbCatNExW(
  NTSTRSAFE_PWSTR pszDest,
  size_t          cbDest,
  STRSAFE_PCNZWCH pszSrc,
  size_t          cbToAppend,
  NTSTRSAFE_PWSTR *ppszDestEnd,
  size_t          *pcbRemaining,
  DWORD           dwFlags
);
```

Parameters

`pszDest`

A pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc*, up to *cbMaxAppend* bytes, is added to the end of the string at *pszDest*, and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbDest`

The size of the destination buffer, in bytes. The buffer must be large enough to include both strings and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

If *pszDest* is **NULL**, *cbDest* must be zero.

`pszSrc`

A pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*. The *pszSrc* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbToAppend`

The maximum number of bytes to append to *pszDest*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer, then after the concatenation operation completes, the function loads that address with a pointer to the destination buffer's resulting **NULL** string terminator.

`pcbRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused bytes

that are in the buffer pointed to by *pszDest*, including bytes used for the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING
STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how

to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the strings were fully concatenated without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the concatenated string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCatNExW and **RtlStringCbCatNExA** should be used instead of the following functions:

- **strncat**
- **wcsncat**

The size, in bytes, of the destination buffer is provided to **RtlStringCbCatNExW** and **RtlStringCbCatNExA** to ensure that they do not write past the end of the buffer.

RtlStringCbCatNEx adds to the functionality of RtlStringCbCatN by returning a pointer to the end of the destination string as well as the number of bytes left unused in that string. Flags can be passed to the function for additional control.

Use **RtlStringCbCatNExW** to handle Unicode strings and **RtlStringCbCatNExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCatNExW**

char	"string"	**RtlStringCbCatNExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

RtlStringCbCatEx

RtlStringCbCatN

RtlStringCchCatNEx

RtlStringCbCatNW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCbCatNW** and **RtlStringCbCatNA** functions concatenate two byte-counted strings while limiting the size of the appended string.

Syntax

```
NTSTRSAFEDDI RtlStringCbCatNW(
  NTSTRSAFE_PWSTR pszDest,
  size_t          cbDest,
  STRSAFE_PCNZWCH pszSrc,
  size_t          cbToAppend
);
```

Parameters

`pszDest`

Pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc*, up to *cbMaxAppend* bytes, is added to the end of the string at *pszDest* and terminated with a null character.

`cbDest`

The size of the destination buffer, in bytes. The buffer must be large enough to include both strings and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

`pszSrc`

Pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*.

`cbToAppend`

The maximum number of bytes to append to the string that is contained in the buffer at *pszDest*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	This *success* status means source data was present, the strings were concatenated without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the concatenation operation did not complete due to insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer's length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCatNW and **RtlStringCbCatNA** should be used instead of the following functions:

- **strncat**
- **wcsncat**

The size, in bytes, of the destination buffer is provided to **RtlStringCbCatNW** and **RtlStringCbCatNA** to ensure that they do not write past the end of the buffer.

Use **RtlStringCbCatNW** to handle Unicode strings and **RtlStringCbCatNA** to handle ANSI strings. The form you use depends on your data, as shown in the following table

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCatNW**
char	"string"	**RtlStringCbCatNA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCbCatNEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbCat

RtlStringCbCatNEx

RtlStringCchCatN

RtlStringCbCatW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCbCatW** and **RtlStringCbCatA** functions concatenate two byte-counted strings.

Syntax

```
NTSTRSAFEDDI RtlStringCbCatW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cbDest,
  NTSTRSAFE_PCWSTR pszSrc
);
```

Parameters

`pszDest`

A pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc* is added to the end of the string at *pszDest* and terminated with a null character.

`cbDest`

The size of the destination buffer, in bytes. The destination buffer must be large enough to include the concatenated strings and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

`pszSrc`

A pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the strings were concatenated without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the concatenation operation did not complete due to insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The STATUS_INVALID_PARAMETER return value means that one of the following occurred: • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCatW and **RtlStringCbCatA** should be used instead of the following functions:

- **strcat**
- **wcscat**

Because **RtlStringCbCatW** and **RtlStringCbCatA** receive the size of the destination buffer as input, they will not write past the end of the buffer.

Use **RtlStringCbCatW** to handle Unicode strings and **RtlStringCbCatA** to handle ANSI strings. The form to use is determined by your data as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCatW**
char	"string"	**RtlStringCbCatA**

If *pszSrc* and *pszDest* point to strings that overlap, the behavior of the functions is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCbCatNEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

RtlStringCbCatEx

RtlStringCbCatNEx

RtlStringCchCatEx

RtlStringCbCopyA function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCbCopyW** and **RtlStringCbCopyA** functions copy a byte-counted string into a buffer.

Syntax

```
NTSTRSAFEDDI RtlStringCbCopyA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cbDest,
  NTSTRSAFE_PCSTR pszSrc
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc* is copied to the buffer at *pszDest* and terminated with a null character.

`cbDest`

The size, in bytes, of the destination buffer. The buffer must be large enough for the string and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

`pszSrc`

A pointer to a caller-supplied, null-terminated string.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer's length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCopyA and **RtlStringCbCopyW** should be used instead of the following functions:

- **strcpy**
- **wcscpy**

RtlStringCbCopyA and **RtlStringCbCopyW** are not replacements for **strncpy**. To replace **strncpy**, use RtlStringCbCopyN or RtlStringCbCopyNEx.

The size of the destination buffer is provided to the function to ensure that **RtlStringCbCopy** does not write past the end of the buffer.

Use **RtlStringCbCopyW** to handle Unicode strings and **RtlStringCbCopyA** to handle ANSI strings. The form you use depends on your data as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCopyW**
char	"string"	**RtlStringCbCopyA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCbCopyEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

RtlStringCbCopyEx

RtlStringCchCopy

RtlStringCbCopyExA function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlStringCbCopyExW** and **RtlStringCbCopyExA** functions copy a byte-counted string into a buffer.

Syntax

```
NTSTRSAFEDDI RtlStringCbCopyExA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cbDest,
  NTSTRSAFE_PCSTR pszSrc,
  NTSTRSAFE_PSTR  *ppszDestEnd,
  size_t          *pcbRemaining,
  DWORD           dwFlags
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc* is copied to the buffer at *pszDest* and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbDest`

The size, in bytes, of the destination buffer. The buffer must be large enough for the string and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

If *pszDest* is **NULL**, *cbDest* must be zero.

`pszSrc`

A pointer to a caller-supplied, null-terminated string. The *pszSrc* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer, then after the copy operation completes, the function loads that address with a pointer to the destination buffer's resulting **NULL** string terminator.

`pcbRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused bytes that are in the buffer pointed to by *pszDest*, including bytes used for the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCopyExA and **RtlStringCbCopyExW** should be used instead of the following functions:

- **strcpy**
- **wcscpy**

The size, in bytes, of the destination buffer is provided to **RtlStringCbCopyExA** and **RtlStringCbCopyExW** to ensure that they do not write past the end of the buffer.

RtlStringCbCopyEx adds to the functionality of RtlStringCbCopy by returning a pointer to the end of the destination string as well as the number of bytes left unused in that string. Flags can be passed to the function for additional control.

Use **RtlStringCbCopyExW** to handle Unicode strings and **RtlStringCbCopyExA** to handle ANSI strings. The form you use depends on your data as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCopyExW**
char	"string"	**RtlStringCbCopyExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbCopy

RtlStringCchCopyEx

RtlStringCbCopyExW function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlStringCbCopyExW** and **RtlStringCbCopyExA** functions copy a byte-counted string into a buffer.

Syntax

```
NTSTRSAFEDDI RtlStringCbCopyExW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cbDest,
  NTSTRSAFE_PCWSTR pszSrc,
  NTSTRSAFE_PWSTR  *ppszDestEnd,
  size_t           *pcbRemaining,
  DWORD            dwFlags
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc* is copied to the buffer at *pszDest* and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbDest`

The size, in bytes, of the destination buffer. The buffer must be large enough for the string and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

If *pszDest* is **NULL**, *cbDest* must be zero.

`pszSrc`

A pointer to a caller-supplied, null-terminated string. The *pszSrc* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer, then after the copy operation completes, the function loads that address with a pointer to the destination buffer's resulting **NULL** string terminator.

`pcbRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused bytes that are in the buffer pointed to by *pszDest*, including bytes used for the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCopyExA and **RtlStringCbCopyExW** should be used instead of the following functions:

- **strcpy**
- **wcscpy**

The size, in bytes, of the destination buffer is provided to **RtlStringCbCopyExA** and **RtlStringCbCopyExW** to ensure that they do not write past the end of the buffer.

RtlStringCbCopyEx adds to the functionality of RtlStringCbCopy by returning a pointer to the end of the destination string as well as the number of bytes left unused in that string. Flags can be passed to the function for additional control.

Use **RtlStringCbCopyExW** to handle Unicode strings and **RtlStringCbCopyExA** to handle ANSI strings. The form you use depends on your data as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCopyExW**
char	"string"	**RtlStringCbCopyExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop

RtlStringCbCopy

RtlStringCchCopyEx

RtlStringCbCopyNA function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCbCopyNW** and **RtlStringCbCopyNA** functions copy a byte-counted string to a buffer while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlStringCbCopyNA(
  NTSTRSAFE_PSTR pszDest,
  size_t         cbDest,
  STRSAFE_PCNZCH pszSrc,
  size_t         cbToCopy
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc*, up to *cbSrc* bytes, is copied to the buffer at *pszDest* and terminated with a null character.

`cbDest`

The size, in bytes, of the destination buffer. The buffer must be large enough for both the string and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * **sizeof**(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * **sizeof**(**char**).

`pszSrc`

A pointer to a caller-supplied, null-terminated string.

`cbToCopy`

The maximum number of bytes to copy from *pszSrc* to *pszDest*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. The destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer's length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCopyNW and **RtlStringCbCopyNA** should be used instead of **strncpy**. However, these functions differ in behavior. If *cbSrc* is larger than the number of bytes in *pszSrc*, the **RtlStringCbCopyN** functions—unlike **strncpy**—do not fill *pszDest* with null characters until *cbSrc* bytes have been copied.

RtlStringCbCopyN copies a given number of bytes from a source string. The size, in bytes, of the destination buffer is provided to the function to ensure that **RtlStringCbCopyN** does not write past the end of this buffer.

Use **RtlStringCbCopyNW** to handle Unicode strings and **RtlStringCbCopyNA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCopyNW**
char	"string"	**RtlStringCbCopyNA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, see RtlStringCbCopyNEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop

Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbCopy

RtlStringCbCopyNEx

RtlStringCchCopyN

RtlStringCbCopyNExA function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCbCopyNExW** and **RtlStringCbCopyNExA** functions copy a byte-counted string to a buffer while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlStringCbCopyNExA(
  NTSTRSAFE_PSTR pszDest,
  size_t         cbDest,
  STRSAFE_PCNZCH pszSrc,
  size_t         cbToCopy,
  NTSTRSAFE_PSTR *ppszDestEnd,
  size_t         *pcbRemaining,
  DWORD          dwFlags
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc* is copied to the buffer at *pszDest* and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbDest`

The size, in bytes, of the destination buffer. The buffer must be large enough for the string and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

If *pszDest* is **NULL**, *cbDest* must be zero.

`pszSrc`

A pointer to a caller-supplied, null-terminated string. The *pszSrc* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbToCopy`

The maximum number of bytes to copy from *pszSrc* to *pszDest*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer then, after the copy operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcbRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused bytes that are in the buffer pointed to by *pszDest*, including those bytes used for the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING
STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCopyNExW and **RtlStringCbCopyNExA** should be used instead of **strncpy**. However, these functions differ in behavior. If *cbSrc* is larger than the number of bytes in *pszSrc*, the **RtlStringCbCopyNEx** functions, unlike **strncpy**, do not fill *pszDest* with null characters until *cbSrc* bytes have been copied.

The size, in bytes, of the destination buffer is provided to **RtlStringCbCopyNExW** and **RtlStringCbCopyNExA** to ensure that they do not write past the end of this buffer.

RtlStringCbCopyNEx adds to the functionality of RtlStringCbCopyN by returning a pointer to the end of the destination string as well as the number of bytes left unused in that string. Flags may also be passed to the function for additional control.

Use **RtlStringCbCopyNExW** to handle Unicode strings and **RtlStringCbCopyNExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCopyNExW**
char	"string"	**RtlStringCbCopyNExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

RtlStringCbCopyN

RtlStringCchCopyNEx

RtlStringCbCopyNExW function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCbCopyNExW** and **RtlStringCbCopyNExA** functions copy a byte-counted string to a buffer while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlStringCbCopyNExW(
  NTSTRSAFE_PWSTR pszDest,
  size_t          cbDest,
  STRSAFE_PCNZWCH pszSrc,
  size_t          cbToCopy,
  NTSTRSAFE_PWSTR *ppszDestEnd,
  size_t          *pcbRemaining,
  DWORD           dwFlags
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc* is copied to the buffer at *pszDest* and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbDest`

The size, in bytes, of the destination buffer. The buffer must be large enough for the string and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

If *pszDest* is **NULL**, *cbDest* must be zero.

`pszSrc`

A pointer to a caller-supplied, null-terminated string. The *pszSrc* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbToCopy`

The maximum number of bytes to copy from *pszSrc* to *pszDest*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer then, after the copy operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcbRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused bytes that are in the buffer pointed to by *pszDest*, including those bytes used for the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING
STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCopyNExW and **RtlStringCbCopyNExA** should be used instead of **strncpy**. However, these functions differ in behavior. If *cbSrc* is larger than the number of bytes in *pszSrc*, the **RtlStringCbCopyNEx** functions, unlike **strncpy**, do not fill *pszDest* with null characters until *cbSrc* bytes have been copied.

The size, in bytes, of the destination buffer is provided to **RtlStringCbCopyNExW** and **RtlStringCbCopyNExA** to ensure that they do not write past the end of this buffer.

RtlStringCbCopyNEx adds to the functionality of RtlStringCbCopyN by returning a pointer to the end of the destination string as well as the number of bytes left unused in that string. Flags may also be passed to the function for additional control.

Use **RtlStringCbCopyNExW** to handle Unicode strings and **RtlStringCbCopyNExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCopyNExW**
char	"string"	**RtlStringCbCopyNExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

RtlStringCbCopyN

RtlStringCchCopyNEx

RtlStringCbCopyNW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCbCopyNW** and **RtlStringCbCopyNA** functions copy a byte-counted string to a buffer while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlStringCbCopyNW(
  NTSTRSAFE_PWSTR pszDest,
  size_t          cbDest,
  STRSAFE_PCNZWCH pszSrc,
  size_t          cbToCopy
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc*, up to *cbSrc* bytes, is copied to the buffer at *pszDest* and terminated with a null character.

`cbDest`

The size, in bytes, of the destination buffer. The buffer must be large enough for both the string and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * **sizeof**(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * **sizeof**(**char**).

`pszSrc`

A pointer to a caller-supplied, null-terminated string.

`cbToCopy`

The maximum number of bytes to copy from *pszSrc* to *pszDest*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. The destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer's length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCopyNW and **RtlStringCbCopyNA** should be used instead of **strncpy**. However, these functions differ in behavior. If *cbSrc* is larger than the number of bytes in *pszSrc*, the **RtlStringCbCopyN** functions—unlike **strncpy**—do not fill *pszDest* with null characters until *cbSrc* bytes have been copied.

RtlStringCbCopyN copies a given number of bytes from a source string. The size, in bytes, of the destination buffer is provided to the function to ensure that **RtlStringCbCopyN** does not write past the end of this buffer.

Use **RtlStringCbCopyNW** to handle Unicode strings and **RtlStringCbCopyNA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCopyNW**
char	"string"	**RtlStringCbCopyNA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, see RtlStringCbCopyNEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop

Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbCopy

RtlStringCbCopyNEx

RtlStringCchCopyN

RtlStringCbCopyUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCbCopyUnicodeString** function copies the contents of a UNICODE_STRING structure to a specified destination.

Syntax

```
NTSTRSAFEDDI RtlStringCbCopyUnicodeString(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cbDest,
  PCUNICODE_STRING SourceString
);
```

Parameters

`pszDest`

A pointer to a buffer that receives the copied string. The string that the *SourceString* parameter's **UNICODE_STRING** structure points to is copied to the buffer at *pszDest* and terminated with a null character.

`cbDest`

The size, in bytes, of the destination buffer that *pszDest* points to. The buffer must be large enough to contain the string and the terminating null character. The maximum number of bytes in the buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * **sizeof**(WCHAR).

`SourceString`

A pointer to a **UNICODE_STRING** structure that contains the string to be copied. The maximum number of bytes in the string is NTSTRSAFE_UNICODE_STRING_MAX_CCH * **sizeof**(WCHAR).

Return Value

RtlStringCbCopyUnicodeString returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.

STA TUS _BU FFE R_O VER FLO W	This *warning* status means that the copy operation did not complete because of insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.
STA TUS _IN VAL ID_ PAR AM ETE R	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlStringCbCopyUnicodeString returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure are invalid.
- The value in *cbDest* is larger than the maximum buffer size.
- The destination buffer (which *pszDest* points to) is already full.
- A buffer pointer is **NULL**.
- The destination buffer's length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlStringCbCopyUnicodeString** function uses the destination buffer's size (which the *cbDest* parameter specifies) to ensure that the copy operation does not write past the end of the buffer.

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString*and *pszDest* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use the RtlStringCbCopyUnicodeStringEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available starting with Windows XP with Service Pack 1 (SP1).
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib

IRQL	PASSIVE_LEVEL

RtlStringCbCopyUnicodeStringEx function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlStringCbCopyUnicodeStringEx** function copies the contents of a UNICODE_STRING structure to a specified destination.

Syntax

```
NTSTRSAFEDDI RtlStringCbCopyUnicodeStringEx(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cbDest,
  PCUNICODE_STRING SourceString,
  NTSTRSAFE_PWSTR  *ppszDestEnd,
  size_t           *pcbRemaining,
  DWORD            dwFlags
);
```

Parameters

`pszDest`

Optional. A pointer to a buffer that receives the copied string. The string that the *SourceString* parameter's **UNICODE_STRING** structure points to is copied to the buffer at *pszDest* and terminated with a null character. This pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbDest`

The size, in bytes, of the destination buffer. The buffer must be large enough for the string and the terminating null character. The maximum number of bytes in the buffer is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

`SourceString`

Optional. A pointer to a **UNICODE_STRING** structure that contains the string to be copied. The maximum number of bytes in the string is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR). This pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`ppszDestEnd`

Optional. If the caller supplies a non-**NULL** address pointer, then after the copy operation completes, the function loads that address with a pointer to the destination buffer's resulting **NULL** string terminator.

`pcbRemaining`

Optional. If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused bytes that are in the buffer that *pszDest* points to, including bytes that are used for the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND_NULL

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.

STRSAFE_IGNORE_NULLS

If this flag is set, either the source or destination pointer, or both, can be **NULL**.
RtlStringCbCopyUnicodeStringEx treats **NULL** source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer pointers cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

RtlStringCbCopyUnicodeStringEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the copy operation did not complete because of insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlStringCbCopyUnicodeStringEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in dwFlags.
- The value in *cbDest* is larger than the maximum buffer size.
- The destination buffer (which *pszDest* points to) is already full.

- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified.
- The destination buffer pointer is **NULL**, but the buffer size is not zero.
- The destination buffer pointer is **NULL** or its length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlStringCbCopyUnicodeStringEx** function uses the destination buffer's size (which the *cbDest* parameter specifies) to ensure that the copy operation does not write past the end of the buffer.

RtlStringCbCopyUnicodeStringEx adds to the functionality of the RtlStringCbCopyUnicodeString function by returning a pointer to the end of the destination string and the number of bytes that are left unused in that string. You can pass flags to the function for additional control.

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString*and *pszDest* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both of these pointers can be **NULL**. If the *pszDest* pointer is **NULL**, the *SourceString*pointer must be **NULL** or the UNICODE_STRING structure must describe an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbCopyUnicodeString

RtlStringCchCopyUnicodeStringEx

UNICODE_STRING

RtlStringCbCopyW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCbCopyW** and **RtlStringCbCopyA** functions copy a byte-counted string into a buffer.

Syntax

```
NTSTRSAFEDDI RtlStringCbCopyW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cbDest,
  NTSTRSAFE_PCWSTR pszSrc
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc* is copied to the buffer at *pszDest* and terminated with a null character.

`cbDest`

The size, in bytes, of the destination buffer. The buffer must be large enough for the string and the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

`pszSrc`

A pointer to a caller-supplied, null-terminated string.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer's length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbCopyA and **RtlStringCbCopyW** should be used instead of the following functions:

- **strcpy**
- **wcscpy**

RtlStringCbCopyA and **RtlStringCbCopyW** are not replacements for **strncpy**. To replace **strncpy**, use RtlStringCbCopyN or RtlStringCbCopyNEx.

The size of the destination buffer is provided to the function to ensure that **RtlStringCbCopy** does not write past the end of the buffer.

Use **RtlStringCbCopyW** to handle Unicode strings and **RtlStringCbCopyA** to handle ANSI strings. The form you use depends on your data as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbCopyW**
char	"string"	**RtlStringCbCopyA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCbCopyEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbCopyEx

RtlStringCchCopy

RtlStringCbLengthA function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCbLengthW** and **RtlStringCbLengthA** functions determine the length, in bytes, of a supplied string.

Syntax

```
NTSTRSAFEDDI RtlStringCbLengthA(
  STRSAFE_PCNZCH psz,
  size_t         cbMax,
  size_t         *pcbLength
);
```

Parameters

`psz`

A pointer to a buffer that contains a null-terminated string, the length of which will be checked.

`cbMax`

The maximum number of bytes allowed in the buffer that is pointed to by *psz*, including the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

`pcbLength`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the length, in bytes, of the string that is contained in the buffer. The length does not include the string's terminating null character.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means the string at *psz* was not **NULL**, and the length of the string (including the terminating null character) is less than or equal to *cbMax* characters.

STA TUS _IN VAL ID_ PAR AM ETE R	This *error* status means the value in *psz* is **NULL**, *cbMax* is larger than NTSTRSAFE_MAX_CCH * sizeof(TCHAR), or *psz* is longer than *cbMax*.

Remarks

RtlStringCbLengthW and **RtlStringCbLengthA** should be used instead of **strlen**. Use these functions to ensure that a string is not larger than a given length, in bytes. If that condition is met, **RtlStringCbLengthW** and **RtlStringCbLengthA** return the current length of the string in bytes, not including those bytes used for the terminating null character.

Use **RtlStringCbLengthW** to handle Unicode strings and **RtlStringCbLengthA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbLengthW**
char	"string"	**RtlStringCbLengthA**

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCchLength

RtlStringCbLengthW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCbLengthW** and **RtlStringCbLengthA** functions determine the length, in bytes, of a supplied string.

Syntax

```
NTSTRSAFEDDI RtlStringCbLengthW(
  STRSAFE_PCNZWCH psz,
  size_t          cbMax,
  size_t          *pcbLength
);
```

Parameters

`psz`

A pointer to a buffer that contains a null-terminated string, the length of which will be checked.

`cbMax`

The maximum number of bytes allowed in the buffer that is pointed to by *psz*, including the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

`pcbLength`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the length, in bytes, of the string that is contained in the buffer. The length does not include the string's terminating null character.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means the string at *psz* was not **NULL**, and the length of the string (including the terminating null character) is less than or equal to *cbMax* characters.

STA TUS _IN VAL ID_ PAR AM ETE R	This *error* status means the value in *psz* is **NULL**, *cbMax* is larger than NTSTRSAFE_MAX_CCH * sizeof(TCHAR), or *psz* is longer than *cbMax*.

Remarks

RtlStringCbLengthW and **RtlStringCbLengthA** should be used instead of **strlen**. Use these functions to ensure that a string is not larger than a given length, in bytes. If that condition is met, **RtlStringCbLengthW** and **RtlStringCbLengthA** return the current length of the string in bytes, not including those bytes used for the terminating null character.

Use **RtlStringCbLengthW** to handle Unicode strings and **RtlStringCbLengthA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbLengthW**
char	"string"	**RtlStringCbLengthA**

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCchLength

RtlStringCbPrintfA function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCbPrintfW** and **RtlStringCbPrintfA** functions create a byte-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCbPrintfA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cbDest,
  NTSTRSAFE_PCSTR pszFormat,
  ...
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the function's argument list.

`cbDest`

The size of the destination buffer, in bytes. The buffer must be large enough to contain the formatted string plus the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives.

`arg4`

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was created without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. The destination buffer contains a truncated version of the output string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer's length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbPrintfW and **RtlStringCbPrintfA** should be used instead of the following functions:

- **sprintf**
- **swprintf**
- **_snprintf**
- **_snwprintf**

All of these functions accept a format string and a list of arguments, interpret them, and create a formatted string. The size, in bytes, of the destination buffer is provided to **RtlStringCbPrintfW** and **RtlStringCbPrintfA** to ensure that they do not write past the end of the buffer.

Use **RtlStringCbPrintfW** to handle Unicode strings and **RtlStringCbPrintfA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbPrintfW**
char	"string"	**RtlStringCbPrintfA**

If *pszDest* and *pszFormat* point to overlapping string or if any argument strings overlap, the behavior of the function is undefined.

Neither *pszFormat* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCbPrintfEx.

For more information about the safe string functions, see Using Safe String Functions.

Examples

The following example shows a basic use of **RtlStringCbPrintfW** using four arguments.

```
int const arraysize = 30;
WCHAR pszDest[arraysize];
size_t cbDest = arraysize * sizeof(WCHAR);

LPCWSTR pszFormat = L"%s %d + %d = %d.";
WCHAR* pszTxt = L"The answer is";

NTSTATUS status = RtlStringCbPrintfW(pszDest, cbDest, pszFormat, pszTxt, 1, 2, 3);
```

The resultant string is "The answer is 1 + 2 = 3." It is contained in the buffer at *pszDest*.

Requirements

Minimum supported client	Available starting with Windows XP with Service Pack 1 (SP1).
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbPrintfEx

RtlStringCbVPrintf

RtlStringCchPrintf

RtlStringCbPrintfExA function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCbPrintfExW** and **RtlStringCbPrintfExA** functions create a byte-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCbPrintfExA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cbDest,
  NTSTRSAFE_PSTR  *ppszDestEnd,
  size_t          *pcbRemaining,
  DWORD           dwFlags,
  NTSTRSAFE_PCSTR pszFormat,
  ...
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the function's argument list. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbDest`

The size of the destination buffer, in bytes. The buffer must be large enough to contain the formatted string plus the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

If *pszDest* is **NULL**, *cbDest* must be zero.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer then, after the operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcbRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused bytes that are in the buffer pointed to by *pszDest*, including bytes used for the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL***pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives. The *pszFormat* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`arg7`

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbPrintfExW and **RtlStringCbPrintfExA** should be used instead of the following functions:

- **sprintf**
- **swprintf**
- **_snprintf**
- **_snwprintf**

All of these functions accept a format string and a list of arguments, interpret them, and create a formatted string. The size, in bytes, of the destination buffer is provided to **RtlStringCbPrintfExW** and **RtlStringCbPrintfExA** to ensure that they do not write past the end of the buffer.

RtlStringCbPrintfExW and **RtlStringCbPrintfExA** add to the functionality of RtlStringCbPrintf by returning a pointer to the end of the destination string, as well as the number of bytes left unused in that string. Flags can be passed to the function for additional control.

Use **RtlStringCbPrintfExW** to handle Unicode strings and **RtlStringCbPrintfExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbPrintfExW**
char	"string"	**RtlStringCbPrintfExA**

If *pszDest* and *pszFormat*point to overlapping strings or if any argument strings overlap, the behavior of the function is undefined.

Neither *pszFormat* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszFormat* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

RtlStringCbVPrintfEx

RtlStringCchPrintf

RtlStringCchPrintfEx

RtlStringCbPrintfExW function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCbPrintfExW** and **RtlStringCbPrintfExA** functions create a byte-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCbPrintfExW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cbDest,
  NTSTRSAFE_PWSTR  *ppszDestEnd,
  size_t           *pcbRemaining,
  DWORD            dwFlags,
  NTSTRSAFE_PCWSTR pszFormat,
  ...
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the function's argument list. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbDest`

The size of the destination buffer, in bytes. The buffer must be large enough to contain the formatted string plus the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

If *pszDest* is **NULL**, *cbDest* must be zero.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer then, after the operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcbRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused bytes that are in the buffer pointed to by *pszDest*, including bytes used for the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL***pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives. The *pszFormat* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`arg7`

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbPrintfExW and **RtlStringCbPrintfExA** should be used instead of the following functions:

- **sprintf**
- **swprintf**
- **_snprintf**
- **_snwprintf**

All of these functions accept a format string and a list of arguments, interpret them, and create a formatted string. The size, in bytes, of the destination buffer is provided to **RtlStringCbPrintfExW** and **RtlStringCbPrintfExA** to ensure that they do not write past the end of the buffer.

RtlStringCbPrintfExW and **RtlStringCbPrintfExA** add to the functionality of RtlStringCbPrintf by returning a pointer to the end of the destination string, as well as the number of bytes left unused in that string. Flags can be passed to the function for additional control.

Use **RtlStringCbPrintfExW** to handle Unicode strings and **RtlStringCbPrintfExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbPrintfExW**
char	"string"	**RtlStringCbPrintfExA**

If *pszDest* and *pszFormat*point to overlapping strings or if any argument strings overlap, the behavior of the function is undefined.

Neither *pszFormat* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszFormat* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

RtlStringCchPrintfEx

RtlStringCbPrintfW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCbPrintfW** and **RtlStringCbPrintfA** functions create a byte-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCbPrintfW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cbDest,
  NTSTRSAFE_PCWSTR pszFormat,
  ...
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the function's argument list.

`cbDest`

The size of the destination buffer, in bytes. The buffer must be large enough to contain the formatted string plus the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives.

`arg4`

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was created without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. The destination buffer contains a truncated version of the output string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer's length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbPrintfW and **RtlStringCbPrintfA** should be used instead of the following functions:

- **sprintf**
- **swprintf**
- **_snprintf**
- **_snwprintf**

All of these functions accept a format string and a list of arguments, interpret them, and create a formatted string. The size, in bytes, of the destination buffer is provided to **RtlStringCbPrintfW** and **RtlStringCbPrintfA** to ensure that they do not write past the end of the buffer.

Use **RtlStringCbPrintfW** to handle Unicode strings and **RtlStringCbPrintfA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbPrintfW**
char	"string"	**RtlStringCbPrintfA**

If *pszDest* and *pszFormat* point to overlapping string or if any argument strings overlap, the behavior of the function is undefined.

Neither *pszFormat* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCbPrintfEx.

For more information about the safe string functions, see Using Safe String Functions.

Examples

The following example shows a basic use of **RtlStringCbPrintfW** using four arguments.

```
int const arraysize = 30;
WCHAR pszDest[arraysize];
size_t cbDest = arraysize * sizeof(WCHAR);

LPCWSTR pszFormat = L"%s %d + %d = %d.";
WCHAR* pszTxt = L"The answer is";

NTSTATUS status = RtlStringCbPrintfW(pszDest, cbDest, pszFormat, pszTxt, 1, 2, 3);
```

The resultant string is "The answer is 1 + 2 = 3." It is contained in the buffer at *pszDest*.

Requirements

Minimum supported client	Available starting with Windows XP with Service Pack 1 (SP1).
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbPrintfEx

RtlStringCbVPrintf

RtlStringCchPrintf

RtlStringCbVPrintfA function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCbVPrintfW** and **RtlStringCbVPrintfA** functions create a byte-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCbVPrintfA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cbDest,
  NTSTRSAFE_PCSTR pszFormat,
  va_list         argList
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the arguments supplied by *argList*.

`cbDest`

The size of the destination buffer, in bytes. The buffer must be large enough to contain the formatted string plus the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives.

`argList`

A **va_list**-typed argument list. Arguments contained in the argument list will be interpreted by using the formatting string that is supplied by *pszFormat*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. The destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbVPrintfW and **RtlStringCbVPrintfA** should be used instead of the following functions:

- **vsprintf**
- **vswprintf**
- **_vsnprintf**
- **_vsnwprintf**

All of these functions accept a format string, along with a set of arguments in a **va_list**-typed argument list, and return a formatted string. The size, in bytes, of the destination buffer is provided to **RtlStringCbVPrintfW** and **RtlStringCbVPrintfA** to ensure that they do not write past the end of the buffer.

For more information about **va_list**-typed argument lists, see the Microsoft Windows SDK documentation.

Use **RtlStringCbVPrintfW** to handle Unicode strings and **RtlStringCbVPrintfA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbVPrintfW**
char	"string"	**RtlStringCbVPrintfA**

If *pszDest* and *pszFormat*point to overlapping strings or if any argument strings overlap, the behavior of the function is undefined..

Neither *pszFormat* nor *pszDest* should be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCbVPrintfEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available starting with Windows XP with Service Pack 1 (SP1).
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbPrintf

RtlStringCbVPrintfEx

RtlStringCchVPrintf

RtlStringCbVPrintfExA function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCbVPrintfExW** and **RtlStringCbVPrintfExA** functions create a byte-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCbVPrintfExA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cbDest,
  NTSTRSAFE_PSTR  *ppszDestEnd,
  size_t          *pcbRemaining,
  DWORD           dwFlags,
  NTSTRSAFE_PCSTR pszFormat,
  va_list         argList
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the arguments supplied by *argList*. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbDest`

The size of the destination buffer, in bytes. The buffer must be large enough to contain the formatted string plus the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

If *pszDest* is **NULL**, *cbDest* must be zero.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer then, after the operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcbRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused bytes that are in the buffer pointed to by *pszDest*, including bytes used for the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives. The *pszFormat* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`argList`

A **va_list**-typed argument list. Arguments contained in the argument list will be interpreted by using the formatting string that is supplied by *pszFormat*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbVPrintfExW and **RtlStringCbVPrintfExA** should be used instead of the following functions:

- **vsprintf**
- **vswprintf**
- **_vsnprintf**
- **_vsnwprintf**

All of these functions accept a format string, along with a set of arguments in a **va_list**-typed argument list, and return a formatted string. The size, in bytes, of the destination buffer is provided to **RtlStringCbVPrintfExW** and **RtlStringCbVPrintfExA** to ensure that they do not write past the end of the buffer.

RtlStringCbVPrintfExW and **RtlStringCbVPrintfExA** add to the functionality of RtlStringCbVPrintf by returning a pointer to the end of the destination string, as well as the number of bytes left unused in that string. Flags can be passed to the function for additional control.

For more information about **va_list**-typed argument lists, see the Microsoft Windows SDK documentation.

Use **RtlStringCbVPrintfExW** to handle Unicode strings and **RtlStringCbVPrintfExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbVPrintfExW**
char	"string"	**RtlStringCbVPrintfExA**

If *pszDest* and *pszFormat* point to overlapping strings, or if any argument strings overlap, behavior of the function is undefined.

Neither *pszFormat* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszFormat* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbPrintfEx

RtlStringCbVPrintf

RtlStringCchVPrintfEx

RtlStringCbVPrintfExW function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCbVPrintfExW** and **RtlStringCbVPrintfExA** functions create a byte-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCbVPrintfExW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cbDest,
  NTSTRSAFE_PWSTR  *ppszDestEnd,
  size_t           *pcbRemaining,
  DWORD            dwFlags,
  NTSTRSAFE_PCWSTR pszFormat,
  va_list          argList
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the arguments supplied by *argList*. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbDest`

The size of the destination buffer, in bytes. The buffer must be large enough to contain the formatted string plus the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

If *pszDest* is **NULL**, *cbDest* must be zero.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer then, after the operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcbRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused bytes that are in the buffer pointed to by *pszDest*, including bytes used for the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives. The *pszFormat* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`argList`

A **va_list**-typed argument list. Arguments contained in the argument list will be interpreted by using the formatting string that is supplied by *pszFormat*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbVPrintfExW and **RtlStringCbVPrintfExA** should be used instead of the following functions:

- **vsprintf**
- **vswprintf**
- **_vsnprintf**
- **_vsnwprintf**

All of these functions accept a format string, along with a set of arguments in a **va_list**-typed argument list, and return a formatted string. The size, in bytes, of the destination buffer is provided to **RtlStringCbVPrintfExW** and **RtlStringCbVPrintfExA** to ensure that they do not write past the end of the buffer.

RtlStringCbVPrintfExW and **RtlStringCbVPrintfExA** add to the functionality of RtlStringCbVPrintf by returning a pointer to the end of the destination string, as well as the number of bytes left unused in that string. Flags can be passed to the function for additional control.

For more information about **va_list**-typed argument lists, see the Microsoft Windows SDK documentation.

Use **RtlStringCbVPrintfExW** to handle Unicode strings and **RtlStringCbVPrintfExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbVPrintfExW**
char	"string"	**RtlStringCbVPrintfExA**

If *pszDest* and *pszFormat* point to overlapping strings, or if any argument strings overlap, behavior of the function is undefined.

Neither *pszFormat* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszFormat* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

RtlStringCbPrintfEx

RtlStringCbVPrintf

RtlStringCchVPrintfEx

RtlStringCbVPrintfW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCbVPrintfW** and **RtlStringCbVPrintfA** functions create a byte-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCbVPrintfW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cbDest,
  NTSTRSAFE_PCWSTR pszFormat,
  va_list          argList
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the arguments supplied by *argList*.

`cbDest`

The size of the destination buffer, in bytes. The buffer must be large enough to contain the formatted string plus the terminating null character.

For Unicode strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

For ANSI strings, the maximum number of bytes is NTSTRSAFE_MAX_CCH * sizeof(char).

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives.

`argList`

A **va_list**-typed argument list. Arguments contained in the argument list will be interpreted by using the formatting string that is supplied by *pszFormat*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. The destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cbDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer length was zero, but a nonzero length source string was present.

Remarks

RtlStringCbVPrintfW and **RtlStringCbVPrintfA** should be used instead of the following functions:

- **vsprintf**
- **vswprintf**
- **_vsnprintf**
- **_vsnwprintf**

All of these functions accept a format string, along with a set of arguments in a **va_list**-typed argument list, and return a formatted string. The size, in bytes, of the destination buffer is provided to **RtlStringCbVPrintfW** and **RtlStringCbVPrintfA** to ensure that they do not write past the end of the buffer.

For more information about **va_list**-typed argument lists, see the Microsoft Windows SDK documentation.

Use **RtlStringCbVPrintfW** to handle Unicode strings and **RtlStringCbVPrintfA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCbVPrintfW**
char	"string"	**RtlStringCbVPrintfA**

If *pszDest* and *pszFormat*point to overlapping strings or if any argument strings overlap, the behavior of the function is undefined..

Neither *pszFormat* nor *pszDest* should be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCbVPrintfEx.

For more information about the safe string functions, see Using Safe String Functions.

RtlStringCbPrintf

RtlStringCbVPrintfEx

RtlStringCchVPrintf

RtlStringCchCatA function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCchCatW** and **RtlStringCchCatA** functions concatenate two character-counted strings.

Syntax

```
NTSTRSAFEDDI RtlStringCchCatA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cchDest,
  NTSTRSAFE_PCSTR pszSrc
);
```

Parameters

`pszDest`

A pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc* is added to the end of the string at *pszDest* and terminated with a null character.

`cchDest`

The size, in characters, of the destination buffer. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH.

`pszSrc`

A pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. The destination buffer contains a truncated, null-terminated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchCatW and **RtlStringCchCatA** should be used instead of the following functions:

- **strcat**
- **wcscat**

The size, in characters, of the destination buffer is provided to ensure that **RtlStringCchCatW** and **RtlStringCchCatA** do not write past the end of the buffer.

Use **RtlStringCchCatW** to handle Unicode strings and **RtlStringCchCatA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCatW**
char	"string"	**RtlStringCchCatA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCchCatEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbCat

RtlStringCchCatEx

RtlStringCchCatN

RtlStringCchCatExA function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlStringCchCatExW** and **RtlStringCchCatExA** functions concatenate two character-counted strings.

Syntax

```
NTSTRSAFEDDI RtlStringCchCatExA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cchDest,
  NTSTRSAFE_PCSTR pszSrc,
  NTSTRSAFE_PSTR  *ppszDestEnd,
  size_t          *pcchRemaining,
  DWORD           dwFlags
);
```

Parameters

`pszDest`

A pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc* is added to the end of the string at *pszDest* and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchDest`

The size of the destination buffer, in characters. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH. If *pszDest* is **NULL**, *cchDest* must be zero.

`pszSrc`

A pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*. The *pszSrc* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer, then after the concatenation operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcchRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused characters that are in the buffer pointed to by *pszDest*, including the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchCatExW and **RtlStringCchCatExA** should be used instead of the following functions:

- **strcat**
- **wcscat**

The size, in characters, of the destination buffer is provided to ensure that **RtlStringCchCatExW** and **RtlStringCchCatExA** do not write past the end of the buffer.

RtlStringCchCatExW and **RtlStringCchCatExA** add to the functionality of RtlStringCchCat by returning a pointer to the end of the destination string, as well as the number of characters left unused in the destination buffer. Flags can be passed to the function for additional control.

Use **RtlStringCchCatExW** to handle Unicode strings and **RtlStringCchCatExA** to handle ANSI strings. The form you use depends on your data.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCatExW**
char	"string"	**RtlStringCchCatExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

RtlStringCchCat

RtlStringCchCatNEx

RtlStringCchCatExW function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlStringCchCatExW** and **RtlStringCchCatExA** functions concatenate two character-counted strings.

Syntax

```
NTSTRSAFEDDI RtlStringCchCatExW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cchDest,
  NTSTRSAFE_PCWSTR pszSrc,
  NTSTRSAFE_PWSTR  *ppszDestEnd,
  size_t           *pcchRemaining,
  DWORD            dwFlags
);
```

Parameters

`pszDest`

A pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc* is added to the end of the string at *pszDest* and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchDest`

The size of the destination buffer, in characters. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH. If *pszDest* is **NULL**, *cchDest* must be zero.

`pszSrc`

A pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*. The *pszSrc* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer, then after the concatenation operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcchRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused characters that are in the buffer pointed to by *pszDest*, including the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchCatExW and **RtlStringCchCatExA** should be used instead of the following functions:

- **strcat**
- **wcscat**

The size, in characters, of the destination buffer is provided to ensure that **RtlStringCchCatExW** and **RtlStringCchCatExA** do not write past the end of the buffer.

RtlStringCchCatExW and **RtlStringCchCatExA** add to the functionality of RtlStringCchCat by returning a pointer to the end of the destination string, as well as the number of characters left unused in the destination buffer. Flags can be passed to the function for additional control.

Use **RtlStringCchCatExW** to handle Unicode strings and **RtlStringCchCatExA** to handle ANSI strings. The form you use depends on your data.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCatExW**
char	"string"	**RtlStringCchCatExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

RtlStringCchCat

RtlStringCchCatNEx

RtlStringCchCatNA function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCchCatNW** and **RtlStringCchCatNA** functions concatenate two character-counted strings while limiting the size of the appended string.

Syntax

```
NTSTRSAFEDDI RtlStringCchCatNA(
  NTSTRSAFE_PSTR pszDest,
  size_t         cchDest,
  STRSAFE_PCNZCH pszSrc,
  size_t         cchToAppend
);
```

Parameters

`pszDest`

A pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc*, up to *cchMaxAppend* characters, is added to the end of the string at *pszDest* and terminated with a null character.

`cchDest`

The size of the destination buffer, in characters. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH.

`pszSrc`

A pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*.

`cchToAppend`

The maximum number of characters to append to the string that is contained in the buffer at *pszDest*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the strings were concatenated without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the concatenation operation did not complete due to insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer's length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchCatNW and **RtlStringCchCatNA** should be used instead of the following functions:

- **strncat**
- **wcsncat**

The size, in characters, of the destination buffer is provided to the function to ensure that **RtlStringCchCatNW** and **RtlStringCchCatNA** do not write past the end of the buffer.

Use **RtlStringCchCatNW** to handle Unicode strings and **RtlStringCchCatNA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCatNW**
char	"string"	**RtlStringCchCatNA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCchCatNEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

RtlStringCchCat

RtlStringCchCatNEx

RtlStringCchCatNExA function

1/25/2019 • 4 minutes to read • Edit Online

The RtlStringCchCatNExW and **RtlStringCchCatNExA** functions concatenate two character-counted strings while limiting the size of the appended string.

Syntax

```
NTSTRSAFEDDI RtlStringCchCatNExA(
  NTSTRSAFE_PSTR pszDest,
  size_t         cchDest,
  STRSAFE_PCNZCH pszSrc,
  size_t         cchToAppend,
  NTSTRSAFE_PSTR *ppszDestEnd,
  size_t         *pcchRemaining,
  DWORD          dwFlags
);
```

Parameters

`pszDest`

A pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc*, up to *cchMaxAppend* characters, is added to the end of the string at *pszDest* and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchDest`

The size of the destination buffer, in characters. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH. If *pszDest* is **NULL**, *cchDest* must be zero.

`pszSrc`

A pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*. The *pszSrc* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchToAppend`

The maximum number of characters to append to the string that is contained in the buffer at *pszDest*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer, then after the concatenation operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcchRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused characters in the buffer pointed to by *pszDest*, including the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING
STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the concatenated string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchCatNExW and **RtlStringCchCatNExA** should be used instead of the following functions:

- **strncat**
- **wcsncat**

The size, in characters, of the destination buffer is provided to **RtlStringCchCatNExW** and **RtlStringCchCatNExA** to ensure that the functions do not write past the end of the buffer.

RtlStringCchCatNExW and **RtlStringCchCatNExA** add to the functionality of RtlStringCchCatN by returning a pointer to the end of the destination string, as well as the number of characters left unused in that string. Flags can be passed to the function for additional control.

Use **RtlStringCchCatNExW** to handle Unicode strings and **RtlStringCchCatNExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCatNExW**
char	"string"	**RtlStringCchCatNExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

RtlStringCchCatEx

RtlStringCchCatN

RtlStringCchCatNExW function

1/25/2019 • 4 minutes to read • Edit Online

The RtlStringCchCatNExW and **RtlStringCchCatNExA** functions concatenate two character-counted strings while limiting the size of the appended string.

Syntax

```
NTSTRSAFEDDI RtlStringCchCatNExW(
  NTSTRSAFE_PWSTR pszDest,
  size_t          cchDest,
  STRSAFE_PCNZWCH pszSrc,
  size_t          cchToAppend,
  NTSTRSAFE_PWSTR *ppszDestEnd,
  size_t          *pcchRemaining,
  DWORD           dwFlags
);
```

Parameters

`pszDest`

A pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc*, up to *cchMaxAppend* characters, is added to the end of the string at *pszDest* and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchDest`

The size of the destination buffer, in characters. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH. If *pszDest* is **NULL**, *cchDest* must be zero.

`pszSrc`

A pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*. The *pszSrc* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchToAppend`

The maximum number of characters to append to the string that is contained in the buffer at *pszDest*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer, then after the concatenation operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcchRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused characters in the buffer pointed to by *pszDest*, including the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING
STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the concatenated string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchCatNExW and **RtlStringCchCatNExA** should be used instead of the following functions:

- **strncat**
- **wcsncat**

The size, in characters, of the destination buffer is provided to **RtlStringCchCatNExW** and **RtlStringCchCatNExA** to ensure that the functions do not write past the end of the buffer.

RtlStringCchCatNExW and **RtlStringCchCatNExA** add to the functionality of RtlStringCchCatN by returning a pointer to the end of the destination string, as well as the number of characters left unused in that string. Flags can be passed to the function for additional control.

Use **RtlStringCchCatNExW** to handle Unicode strings and **RtlStringCchCatNExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCatNExW**
char	"string"	**RtlStringCchCatNExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

RtlStringCchCatEx

RtlStringCchCatN

RtlStringCchCatNW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCchCatNW** and **RtlStringCchCatNA** functions concatenate two character-counted strings while limiting the size of the appended string.

Syntax

```
NTSTRSAFEDDI RtlStringCchCatNW(
  NTSTRSAFE_PWSTR pszDest,
  size_t          cchDest,
  STRSAFE_PCNZWCH pszSrc,
  size_t          cchToAppend
);
```

Parameters

`pszDest`

A pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc*, up to *cchMaxAppend* characters, is added to the end of the string at *pszDest* and terminated with a null character.

`cchDest`

The size of the destination buffer, in characters. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH.

`pszSrc`

A pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*.

`cchToAppend`

The maximum number of characters to append to the string that is contained in the buffer at *pszDest*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the strings were concatenated without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the concatenation operation did not complete due to insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer's length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchCatNW and **RtlStringCchCatNA** should be used instead of the following functions:

- **strncat**
- **wcsncat**

The size, in characters, of the destination buffer is provided to the function to ensure that **RtlStringCchCatNW** and **RtlStringCchCatNA** do not write past the end of the buffer.

Use **RtlStringCchCatNW** to handle Unicode strings and **RtlStringCchCatNA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCatNW**
char	"string"	**RtlStringCchCatNA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCchCatNEx.

For more information about the safe string functions, see Using Safe String Functions.

RtlStringCchCat

RtlStringCchCatNEx

RtlStringCchCatW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCchCatW** and **RtlStringCchCatA** functions concatenate two character-counted strings.

Syntax

```
NTSTRSAFEDDI RtlStringCchCatW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cchDest,
  NTSTRSAFE_PCWSTR pszSrc
);
```

Parameters

`pszDest`

A pointer to a buffer which, on input, contains a null-terminated string to which *pszSrc* will be concatenated. On output, this is the destination buffer that contains the entire resultant string. The string at *pszSrc* is added to the end of the string at *pszDest* and terminated with a null character.

`cchDest`

The size, in characters, of the destination buffer. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH.

`pszSrc`

A pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer at *pszDest*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. The destination buffer contains a truncated, null-terminated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchCatW and **RtlStringCchCatA** should be used instead of the following functions:

- **strcat**
- **wcscat**

The size, in characters, of the destination buffer is provided to ensure that **RtlStringCchCatW** and **RtlStringCchCatA** do not write past the end of the buffer.

Use **RtlStringCchCatW** to handle Unicode strings and **RtlStringCchCatA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCatW**
char	"string"	**RtlStringCchCatA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCchCatEx.

For more information about the safe string functions, see Using Safe String Functions.

RtlStringCchCatEx

RtlStringCchCatN

RtlStringCchCopyA function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCchCopyW** and **RtlStringCchCopyA** functions copy a null-terminated source string into a destination buffer of specified length.

Syntax

```
NTSTRSAFEDDI RtlStringCchCopyA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cchDest,
  NTSTRSAFE_PCSTR pszSrc
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc* is copied to the buffer at *pszDest* and terminated with a null character.

`cchDest`

The size, in characters, of the destination buffer. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH.

`pszSrc`

A pointer to a caller-supplied, null-terminated string.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.

STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cchDest* is larger than the maximum buffer size. • A **NULL** pointer was present. • The destination buffer length was zero at entry.

Remarks

RtlStringCchCopyW and **RtlStringCchCopyA** should be used instead of the following functions:

- **strcpy**
- **wcscpy**

These functions are not replacements for **strncpy**. Use RtlStringCchCopyN or RtlStringCchCopyNEx to replace **strncpy**.

The size, in characters, of the destination buffer is provided to **RtlStringCchCopyW** and **RtlStringCchCopyA** to ensure that they do not write past the end of the buffer.

Use **RtlStringCchCopyW** to handle Unicode strings and **RtlStringCchCopyA** to handle ANSI strings. The form you use depends your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCopyW**
char	"string"	**RtlStringCchCopyA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCchCopyEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbCopy

RtlStringCchCopyEx

RtlStringCchCopyExA function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlStringCchCopyExW** and **RtlStringCchCopyExA** functions copy a character-counted string into a buffer.

Syntax

```
NTSTRSAFEDDI RtlStringCchCopyExA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cchDest,
  NTSTRSAFE_PCSTR pszSrc,
  NTSTRSAFE_PSTR  *ppszDestEnd,
  size_t          *pcchRemaining,
  DWORD           dwFlags
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc* is copied to the buffer at *pszDest* and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchDest`

The size of the destination buffer, in characters. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH. If *pszDest* is **NULL**, *cchDest* must be zero.

`pszSrc`

A pointer to a caller-supplied, null-terminated string. The *pszSrc* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer, then after the copy operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcchRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused characters that are in the buffer pointed to by *pszDest*, including the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchCopyExW and **RtlStringCchCopyExA** should be used instead of the following functions:

- **strcpy**
- **wcscpy**

The size, in characters, of the destination buffer is provided to **RtlStringCchCopyExW** and **RtlStringCchCopyExA** to ensure that they do not write past the end of the buffer.

RtlStringCchCopyExW and **RtlStringCchCopyExA** add to the functionality of RtlStringCchCopy by returning a pointer to the end of the destination string, as well as the number of characters left unused in that string. Flags can be passed to the function for additional control. Use **RtlStringCchCopyExW** to handle Unicode strings and **RtlStringCchCopyExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCopyExW**
char	"string"	**RtlStringCchCopyExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)

RtlStringCbCopyEx

RtlStringCchCopy

RtlStringCchCopyExW function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlStringCchCopyExW** and **RtlStringCchCopyExA** functions copy a character-counted string into a buffer.

Syntax

```
NTSTRSAFEDDI RtlStringCchCopyExW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cchDest,
  NTSTRSAFE_PCWSTR pszSrc,
  NTSTRSAFE_PWSTR  *ppszDestEnd,
  size_t           *pcchRemaining,
  DWORD            dwFlags
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc* is copied to the buffer at *pszDest* and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchDest`

The size of the destination buffer, in characters. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH. If *pszDest* is **NULL**, *cchDest* must be zero.

`pszSrc`

A pointer to a caller-supplied, null-terminated string. The *pszSrc* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer, then after the copy operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcchRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused characters that are in the buffer pointed to by *pszDest*, including the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchCopyExW and **RtlStringCchCopyExA** should be used instead of the following functions:

- **strcpy**
- **wcscpy**

The size, in characters, of the destination buffer is provided to **RtlStringCchCopyExW** and **RtlStringCchCopyExA** to ensure that they do not write past the end of the buffer.

RtlStringCchCopyExW and **RtlStringCchCopyExA** add to the functionality of RtlStringCchCopy by returning a pointer to the end of the destination string, as well as the number of characters left unused in that string. Flags can be passed to the function for additional control. Use **RtlStringCchCopyExW** to handle Unicode strings and **RtlStringCchCopyExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCopyExW**
char	"string"	**RtlStringCchCopyExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

RtlStringCbCopyEx

RtlStringCchCopy

RtlStringCchCopyNA function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCchCopyNW** and **RtlStringCchCopyNA** functions copy a character-counted string to a buffer while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlStringCchCopyNA(
  NTSTRSAFE_PSTR pszDest,
  size_t         cchDest,
  STRSAFE_PCNZCH pszSrc,
  size_t         cchToCopy
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc*, up to *cchSrc* characters, is copied to the buffer at *pszDest* and terminated with a null character.

`cchDest`

The size of the destination buffer, in characters. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH.

`pszSrc`

A pointer to a caller-supplied, null-terminated string.

`cchToCopy`

The maximum number of characters to copy from *pszSrc* to the buffer that is supplied by *pszDest*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. The destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer's length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchCopyNW and **RtlStringCchCopyNA** should be used instead of **strncpy**.

The functions copy a given number of characters from a source string. **RtlStringCchCopyNW** and **RtlStringCchCopyNA** receive the size, in characters, of the destination buffer to ensure that the functions do not write past the end of the buffer.

Note that these functions behave differently from **strncpy** in one respect. If *cchSrc* is larger than the number of characters in *pszSrc*, **RtlStringCchCopyNW** and **RtlStringCchCopyNA**—unlike **strncpy**—do not continue to pad *pszDest* with null characters until *cchSrc* characters have been copied.

Use **RtlStringCchCopyNW** to handle Unicode strings and **RtlStringCchCopyNA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCopyNW**
char	"string"	**RtlStringCchCopyNA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCchCopyNEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbCopyN

RtlStringCchCopy

RtlStringCchCopyNEx

RtlStringCchCopyNExA function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCchCopyNExW** and **RtlStringCchCopyNExA** functions copy a character-counted string to a buffer while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlStringCchCopyNExA(
  NTSTRSAFE_PSTR pszDest,
  size_t         cchDest,
  STRSAFE_PCNZCH pszSrc,
  size_t         cchToCopy,
  NTSTRSAFE_PSTR *ppszDestEnd,
  size_t         *pcchRemaining,
  DWORD          dwFlags
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc* is copied to the buffer at *pszDest* and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchDest`

The size, in characters, of the destination buffer. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH. If *pszDest* is **NULL**, *cchDest* must be zero.

`pszSrc`

A pointer to a caller-supplied, null-terminated string.

`cchToCopy`

The maximum number of characters to copy from *pszSrc* to the buffer that is supplied by *pszDest*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer then, after the copy operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcchRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused characters that are in the buffer pointed to by *pszDest*, including the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchCopyNExW and **RtlStringCchCopyNExA** should be used instead of **strncpy**.

The functions copy a given number of characters from a source string. The size, in characters, of the destination buffer is provided to **RtlStringCchCopyNExW** and **RtlStringCchCopyNExA** to ensure that they do not write past the end of the buffer.

Note that these functions behave differently from **strncpy** in one respect. If *cchSrc* is larger than the number of characters in *pszSrc*, **RtlStringCchCopyNExW** and **RtlStringCchCopyNExA**—unlike **strncpy**—do not continue to pad *pszDest* with null characters until *cchSrc* characters have been copied.

RtlStringCchCopyNExW and **RtlStringCchCopyNExA** add to the functionality of RtlStringCchCopyN by returning a pointer to the end of the destination string, as well as the number of characters left unused in that string. Flags can be passed to the function for additional control.

Use **RtlStringCchCopyNExW** to handle Unicode strings and **RtlStringCchCopyNExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCopyNExW**
char	"string"	**RtlStringCchCopyNExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

RtlStringCbCopyNEx

RtlStringCchCopyN

RtlStringCchCopyNExW function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCchCopyNExW** and **RtlStringCchCopyNExA** functions copy a character-counted string to a buffer while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlStringCchCopyNExW(
  NTSTRSAFE_PWSTR pszDest,
  size_t          cchDest,
  STRSAFE_PCNZWCH pszSrc,
  size_t          cchToCopy,
  NTSTRSAFE_PWSTR *ppszDestEnd,
  size_t          *pcchRemaining,
  DWORD           dwFlags
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc* is copied to the buffer at *pszDest* and terminated with a null character. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchDest`

The size, in characters, of the destination buffer. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH. If *pszDest* is **NULL**, *cchDest* must be zero.

`pszSrc`

A pointer to a caller-supplied, null-terminated string.

`cchToCopy`

The maximum number of characters to copy from *pszSrc* to the buffer that is supplied by *pszDest*.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer then, after the copy operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcchRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused characters that are in the buffer pointed to by *pszDest*, including the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchCopyNExW and **RtlStringCchCopyNExA** should be used instead of **strncpy**.

The functions copy a given number of characters from a source string. The size, in characters, of the destination buffer is provided to **RtlStringCchCopyNExW** and **RtlStringCchCopyNExA** to ensure that they do not write past the end of the buffer.

Note that these functions behave differently from **strncpy** in one respect. If *cchSrc* is larger than the number of characters in *pszSrc*, **RtlStringCchCopyNExW** and **RtlStringCchCopyNExA**—unlike **strncpy**—do not continue to pad *pszDest* with null characters until *cchSrc* characters have been copied.

RtlStringCchCopyNExW and **RtlStringCchCopyNExA** add to the functionality of RtlStringCchCopyN by returning a pointer to the end of the destination string, as well as the number of characters left unused in that string. Flags can be passed to the function for additional control.

Use **RtlStringCchCopyNExW** to handle Unicode strings and **RtlStringCchCopyNExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCopyNExW**
char	"string"	**RtlStringCchCopyNExA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

RtlStringCbCopyNEx

RtlStringCchCopyN

RtlStringCchCopyNW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCchCopyNW** and **RtlStringCchCopyNA** functions copy a character-counted string to a buffer while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlStringCchCopyNW(
  NTSTRSAFE_PWSTR pszDest,
  size_t          cchDest,
  STRSAFE_PCNZWCH pszSrc,
  size_t          cchToCopy
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc*, up to *cchSrc* characters, is copied to the buffer at *pszDest* and terminated with a null character.

`cchDest`

The size of the destination buffer, in characters. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH.

`pszSrc`

A pointer to a caller-supplied, null-terminated string.

`cchToCopy`

The maximum number of characters to copy from *pszSrc* to the buffer that is supplied by *pszDest*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. The destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer's length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchCopyNW and **RtlStringCchCopyNA** should be used instead of **strncpy**.

The functions copy a given number of characters from a source string. **RtlStringCchCopyNW** and **RtlStringCchCopyNA** receive the size, in characters, of the destination buffer to ensure that the functions do not write past the end of the buffer.

Note that these functions behave differently from **strncpy** in one respect. If *cchSrc* is larger than the number of characters in *pszSrc*, **RtlStringCchCopyNW** and **RtlStringCchCopyNA**—unlike **strncpy**—do not continue to pad *pszDest* with null characters until *cchSrc* characters have been copied.

Use **RtlStringCchCopyNW** to handle Unicode strings and **RtlStringCchCopyNA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCopyNW**
char	"string"	**RtlStringCchCopyNA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCchCopyNEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbCopyN

RtlStringCchCopy

RtlStringCchCopyNEx

RtlStringCchCopyUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCchCopyUnicodeString** function copies the contents of a UNICODE_STRING structure to a specified destination.

Syntax

```
NTSTRSAFEDDI RtlStringCchCopyUnicodeString(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cchDest,
  PCUNICODE_STRING SourceString
);
```

Parameters

`pszDest`

A pointer to a buffer that receives the copied string. The string that the *SourceString* parameter's **UNICODE_STRING** structure points to is copied to the buffer at *pszDest* and terminated with a null character.

`cchDest`

The size, in characters, of the destination buffer. The buffer must be large enough for the string and the terminating null character. The maximum number of characters is NTSTRSAFE_MAX_CCH.

`SourceString`

A pointer to a **UNICODE_STRING** structure that contains the string to be copied. The maximum number of characters in the string is NTSTRSAFE_UNICODE_STRING_MAX_CCH.

Return Value

RtlStringCchCopyUnicodeString returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the copy operation did not complete because of insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.

STA TUS _IN VAL ID_ PAR AM ETE R	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlStringCchCopyUnicodeString returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure are invalid.
- The value in *cbDest* is larger than the maximum buffer size.
- The destination buffer (which *pszDest* points to) is already full.
- A buffer pointer is **NULL**.
- The destination buffer's length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlStringCchCopyUnicodeString** function uses the destination buffer's size (which *cchDest* specifies) to ensure that the copy operation does not write past the end of the buffer.

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString*and *pszDest* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use the RtlStringCchCopyUnicodeStringEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib

IRQL	PASSIVE_LEVEL

RtlStringCbCopyUnicodeString

RtlStringCchCopyUnicodeStringEx

UNICODE_STRING

RtlStringCchCopyUnicodeStringEx function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlStringCchCopyUnicodeStringEx** function copies the contents of a UNICODE_STRING structure to a specified destination.

Syntax

```
NTSTRSAFEDDI RtlStringCchCopyUnicodeStringEx(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cchDest,
  PCUNICODE_STRING SourceString,
  NTSTRSAFE_PWSTR  *ppszDestEnd,
  size_t           *pcchRemaining,
  DWORD            dwFlags
);
```

Parameters

`pszDest`

Optional. A pointer to a buffer that receives the copied string. The string that the *SourceString* parameter's **UNICODE_STRING** structure points to is copied to the buffer at *pszDest* and terminated with a null character. This pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchDest`

The size, in characters, of the destination buffer. The buffer must be large enough for the string and the terminating null character. The maximum number of characters in the buffer is NTSTRSAFE_MAX_CCH.

`SourceString`

Optional. A pointer to a **UNICODE_STRING** structure that contains the string to be copied. The maximum number of characters in the string is NTSTRSAFE_UNICODE_STRING_MAX_CCH. This pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`ppszDestEnd`

Optional. If the caller supplies a non-**NULL** address pointer, then after the copy operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcchRemaining`

Optional. If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused characters that are in the buffer that *pszDest* points to, including the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND_NULL

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.

STRSAFE_IGNORE_NULLS

If this flag is set, either the source or destination pointer, or both, can be **NULL**.
RtlStringCchCopyUnicodeStringEx treats **NULL** source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer pointers cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

Return Value

RtlStringCchCopyUnicodeStringEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the copy operation did not complete because of insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlStringCchCopyUnicodeStringEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in *dwFlags*.
- The value in *cchDest* is larger than the maximum buffer size.
- The destination buffer (which *pszDest* points to) is already full.
- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified.

- The destination buffer pointer is **NULL**, but the buffer size is not zero.
- The destination buffer pointer is **NULL** or its length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlStringCchCopyUnicodeStringEx** function uses the destination buffer's size (which the *cchDest* parameter specifies) to ensure that the copy operation does not write past the end of the buffer.

RtlStringCchCopyUnicodeStringEx adds to the functionality of the RtlStringCchCopyUnicodeString function by returning a pointer to the end of the destination string and the number of bytes that are left unused in that string. You can pass flags to the function for additional control.

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString*and *pszDest* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both of these points can be **NULL**. If the *pszDest* pointer is **NULL**, the *SourceString*pointer must be **NULL** or the UNICODE_STRING structure must describe an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbCopyUnicodeStringEx

RtlStringCchCopyUnicodeString

UNICODE_STRING

RtlStringCchCopyW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCchCopyW** and **RtlStringCchCopyA** functions copy a null-terminated source string into a destination buffer of specified length.

Syntax

```
NTSTRSAFEDDI RtlStringCchCopyW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cchDest,
  NTSTRSAFE_PCWSTR pszSrc
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives the copied string. The string at *pszSrc* is copied to the buffer at *pszDest* and terminated with a null character.

`cchDest`

The size, in characters, of the destination buffer. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH.

`pszSrc`

A pointer to a caller-supplied, null-terminated string.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.

STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cchDest* is larger than the maximum buffer size. • A **NULL** pointer was present. • The destination buffer length was zero at entry.

Remarks

RtlStringCchCopyW and **RtlStringCchCopyA** should be used instead of the following functions:

- **strcpy**
- **wcscpy**

These functions are not replacements for **strncpy**. Use RtlStringCchCopyN or RtlStringCchCopyNEx to replace **strncpy**.

The size, in characters, of the destination buffer is provided to **RtlStringCchCopyW** and **RtlStringCchCopyA** to ensure that they do not write past the end of the buffer.

Use **RtlStringCchCopyW** to handle Unicode strings and **RtlStringCchCopyA** to handle ANSI strings. The form you use depends your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchCopyW**
char	"string"	**RtlStringCchCopyA**

If *pszSrc* and *pszDest* point to overlapping strings, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCchCopyEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbCopy

RtlStringCchCopyEx

RtlStringCchLengthA function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCchLengthW** and **RtlStringCchLengthA** functions determine the length, in characters, of a supplied string.

Syntax

```
NTSTRSAFEDDI RtlStringCchLengthA(
  STRSAFE_PCNZCH psz,
  size_t         cchMax,
  size_t         *pcchLength
);
```

Parameters

`psz`

A pointer to a buffer that contains a null-terminated string, the length of which will be checked.

`cchMax`

The maximum number of characters allowed in the buffer pointed to by *psz*, including the terminating null character. This value cannot exceed NTSTRSAFE_MAX_CCH.

`pcchLength`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the length, in characters, of the string that is contained in the buffer. The length does not include the string's terminating null character.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	This success status means the string at *psz* was not **NULL**, and the length of the string (including the terminating null character) is less than or equal to *cchMax* characters.

STA TUS _IN VAL ID_ PAR AM ETE R	This error status means the value in *psz* is **NULL**, *cchMax* is larger than NTSTRSAFE_MAX_CCH, or *psz* is longer than *cchMax*.

Remarks

RtlStringCchLengthW and **RtlStringCchLengthA** should be used instead of **strlen**. They are used to ensure that a string is not larger than a given length, in characters. If that condition is met, **RtlStringCchLengthW** and **RtlStringCchLengthA** return the current length of the string in characters, not including the terminating null character.

Use **RtlStringCchLengthW** to handle Unicode strings and **RtlStringCchLengthA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchLengthW**
char	"string"	**RtlStringCchLengthA**

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbLength

RtlStringCchLengthW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCchLengthW** and **RtlStringCchLengthA** functions determine the length, in characters, of a supplied string.

Syntax

```
NTSTRSAFEDDI RtlStringCchLengthW(
  STRSAFE_PCNZWCH psz,
  size_t          cchMax,
  size_t          *pcchLength
);
```

Parameters

`psz`

A pointer to a buffer that contains a null-terminated string, the length of which will be checked.

`cchMax`

The maximum number of characters allowed in the buffer pointed to by *psz*, including the terminating null character. This value cannot exceed NTSTRSAFE_MAX_CCH.

`pcchLength`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the length, in characters, of the string that is contained in the buffer. The length does not include the string's terminating null character.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	This success status means the string at *psz* was not **NULL**, and the length of the string (including the terminating null character) is less than or equal to *cchMax* characters.

STA TUS _IN VAL ID_ PAR AM ETE R	This error status means the value in *psz* is **NULL**, *cchMax* is larger than NTSTRSAFE_MAX_CCH, or *psz* is longer than *cchMax*.

Remarks

RtlStringCchLengthW and **RtlStringCchLengthA** should be used instead of **strlen**. They are used to ensure that a string is not larger than a given length, in characters. If that condition is met, **RtlStringCchLengthW** and **RtlStringCchLengthA** return the current length of the string in characters, not including the terminating null character.

Use **RtlStringCchLengthW** to handle Unicode strings and **RtlStringCchLengthA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchLengthW**
char	"string"	**RtlStringCchLengthA**

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbLength

RtlStringCchPrintfA function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCchPrintfW** and **RtlStringCchPrintfA** functions create a character-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCchPrintfA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cchDest,
  NTSTRSAFE_PCSTR pszFormat,
  ...
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the function's argument list.

`cchDest`

The size of the destination buffer, in characters. The buffer must be large enough to contain the formatted string plus the terminating null character. The maximum number of characters allowed is **NTSTRSAFE_MAX_CCH**.

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives.

`arg4`

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was created without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. The destination buffer contains a truncated version of the output string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer's length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchPrintfW and **RtlStringCchPrintfA** should be used instead of the following functions:

- **sprintf**
- **swprintf**
- **_snprintf**
- **_snwprintf**

All of these functions accept a format string and a list of arguments and return a formatted string. **RtlStringCchPrintfW** and **RtlStringCchPrintfA** accept the size, in characters, of the destination buffer to ensure that the functions do not write past the end of the buffer.

Use **RtlStringCchPrintfW** to handle Unicode strings and **RtlStringCchPrintfA** to handle ANSI strings. The form you use depends on your data.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchPrintfW**
char	"string"	**RtlStringCchPrintfA**

If *pszDest*and *pszFormat* point to overlapping strings, or if any argument strings overlap, behavior of the function is undefined.

Neither *pszFormat* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCchPrintfEx.

Examples

The following example shows a simple use of **RtlStringCchPrintfW** using four arguments.

```
WCHAR pszDest[30];
size_t cchDest = 30;

LPCWSTR pszFormat = L"%s %d + %d = %d.";
WCHAR* pszTxt = L"The answer is";

NTSTATUS status =
    RtlStringCchPrintfW(pszDest, cchDest, pszFormat, pszTxt, 1, 2, 3);
```

The resultant string is "The answer is 1 + 2 = 3." It is contained in the buffer at *pszDest*. For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available starting with Windows XP with Service Pack 1 (SP1).
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbPrintf

RtlStringCchPrintfEx

RtlStringCchVPrintf

RtlStringCchPrintfExA function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCchPrintfExW** and **RtlStringCchPrintfExA** functions create a character-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCchPrintfExA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cchDest,
  NTSTRSAFE_PSTR  *ppszDestEnd,
  size_t          *pcchRemaining,
  DWORD           dwFlags,
  NTSTRSAFE_PCSTR pszFormat,
  ...
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the function's argument list. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchDest`

The size of the destination buffer, in characters. The buffer must be large enough to contain the formatted string plus the terminating null character. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH. If *pszDest* is **NULL**, *cchDest* must be zero.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer then, after the operation completes, the function loads that address with a pointer to the destination buffer's resulting **NULL** string terminator.

`pcchRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused characters in the buffer pointed to by *pszDest*, including the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives. The *pszFormat* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`arg7`

Return Value

The function returns one of the **NTSTATUS** values that are listed in the following table. For information about how to test **NTSTATUS** values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchPrintfExW and **RtlStringCchPrintfExA** should be used instead of the following functions:

- **sprintf**
- **swprintf**
- **_snprintf**
- **_snwprintf**

All of these functions accept a format string and a list of arguments and return a formatted string. **RtlStringCchPrintfExW** and **RtlStringCchPrintfExA** accept the size, in characters, of the destination buffer to ensure that they do not write past the end of this buffer.

RtlStringCchPrintfExW and **RtlStringCchPrintfExA** add to the functionality of RtlStringCchPrintf by returning a pointer to the end of the destination string, as well as the number of characters left unused in that string. Flags can be passed to the function for additional control.

Use **RtlStringCchPrintfExW** to handle Unicode strings and **RtlStringCchPrintfExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchPrintfExW**
char	"string"	**RtlStringCchPrintfExA**

If *pszDest* and *pszFormat* point to overlapping strings, or any argument strings overlap, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop

RtlStringCbPrintfEx

RtlStringCchPrintf

RtlStringCchVPrintfEx

RtlStringCchPrintfExW function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCchPrintfExW** and **RtlStringCchPrintfExA** functions create a character-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCchPrintfExW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cchDest,
  NTSTRSAFE_PWSTR  *ppszDestEnd,
  size_t           *pcchRemaining,
  DWORD            dwFlags,
  NTSTRSAFE_PCWSTR pszFormat,
  ...
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the function's argument list. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchDest`

The size of the destination buffer, in characters. The buffer must be large enough to contain the formatted string plus the terminating null character. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH. If *pszDest* is **NULL**, *cchDest* must be zero.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer then, after the operation completes, the function loads that address with a pointer to the destination buffer's resulting **NULL** string terminator.

`pcchRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused characters in the buffer pointed to by *pszDest*, including the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives. The *pszFormat* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`arg7`

Return Value

The function returns one of the **NTSTATUS** values that are listed in the following table. For information about how to test **NTSTATUS** values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchPrintfExW and **RtlStringCchPrintfExA** should be used instead of the following functions:

- **sprintf**
- **swprintf**
- **_snprintf**
- **_snwprintf**

All of these functions accept a format string and a list of arguments and return a formatted string. **RtlStringCchPrintfExW** and **RtlStringCchPrintfExA** accept the size, in characters, of the destination buffer to ensure that they do not write past the end of this buffer.

RtlStringCchPrintfExW and **RtlStringCchPrintfExA** add to the functionality of RtlStringCchPrintf by returning a pointer to the end of the destination string, as well as the number of characters left unused in that string. Flags can be passed to the function for additional control.

Use **RtlStringCchPrintfExW** to handle Unicode strings and **RtlStringCchPrintfExA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchPrintfExW**
char	"string"	**RtlStringCchPrintfExA**

If *pszDest* and *pszFormat* point to overlapping strings, or any argument strings overlap, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbPrintfEx

RtlStringCchPrintf

RtlStringCchVPrintfEx

RtlStringCchPrintfW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCchPrintfW** and **RtlStringCchPrintfA** functions create a character-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCchPrintfW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cchDest,
  NTSTRSAFE_PCWSTR pszFormat,
  ...
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the function's argument list.

`cchDest`

The size of the destination buffer, in characters. The buffer must be large enough to contain the formatted string plus the terminating null character. The maximum number of characters allowed is **NTSTRSAFE_MAX_CCH**.

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives.

`arg4`

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was created without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. The destination buffer contains a truncated version of the output string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer's length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchPrintfW and **RtlStringCchPrintfA** should be used instead of the following functions:

- **sprintf**
- **swprintf**
- **_snprintf**
- **_snwprintf**

All of these functions accept a format string and a list of arguments and return a formatted string. **RtlStringCchPrintfW** and **RtlStringCchPrintfA** accept the size, in characters, of the destination buffer to ensure that the functions do not write past the end of the buffer.

Use **RtlStringCchPrintfW** to handle Unicode strings and **RtlStringCchPrintfA** to handle ANSI strings. The form you use depends on your data.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchPrintfW**
char	"string"	**RtlStringCchPrintfA**

If *pszDest*and *pszFormat* point to overlapping strings, or if any argument strings overlap, behavior of the function is undefined.

Neither *pszFormat* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCchPrintfEx.

Examples

The following example shows a simple use of **RtlStringCchPrintfW** using four arguments.

```
WCHAR pszDest[30];
size_t cchDest = 30;

LPCWSTR pszFormat = L"%s %d + %d = %d.";
WCHAR* pszTxt = L"The answer is";

NTSTATUS status =
    RtlStringCchPrintfW(pszDest, cchDest, pszFormat, pszTxt, 1, 2, 3);
```

The resultant string is "The answer is 1 + 2 = 3." It is contained in the buffer at *pszDest*. For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available starting with Windows XP with Service Pack 1 (SP1).
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCbPrintf

RtlStringCchPrintfEx

RtlStringCchVPrintf

RtlStringCchVPrintfA function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCchVPrintfW** and **RtlStringCchVPrintfA** functions create a character-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCchVPrintfA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cchDest,
  NTSTRSAFE_PCSTR pszFormat,
  va_list         argList
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the arguments supplied by *argList*.

`cchDest`

The size of the destination buffer, in characters. The buffer must be large enough to contain the formatted string plus the terminating null character. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH.

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives.

`argList`

A **va_list**-typed argument list. Arguments contained in the argument list will be interpreted by using the formatting string that is supplied by *pszFormat*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. The destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchVPrintfW and **RtlStringCchVPrintfA** should be used instead of the following functions:

- **vsprintf**
- **vswprintf**
- **_vsnprintf**
- **_vsnwprintf**

All of these functions accept a format string and its arguments, which are provided as a **va_list**-typed argument list, and return a formatted string. **RtlStringCchVPrintfW** and **RtlStringCchVPrintfA** receive the size, in characters, of the destination buffer to ensure that the functions do not write past the end of the buffer.

For more information about **va_list**-typed argument lists, see the Microsoft Windows SDK documentation.

Use **RtlStringCchVPrintfW** to handle Unicode strings and **RtlStringCchVPrintfA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchVPrintfW**
char	"string"	**RtlStringCchVPrintfA**

If *pszDest* and *pszFormat* point to overlapping strings, or if any argument strings overlap, the behavior of the function is undefined.

Neither *pszFormat* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCchVPrintfEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

RtlStringCbVPrintf

RtlStringCchPrintf

RtlStringCchVPrintfEx

RtlStringCchVPrintfExA function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCchVPrintfExW** and **RtlStringCchVPrintfExA** functions create a character-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCchVPrintfExA(
  NTSTRSAFE_PSTR  pszDest,
  size_t          cchDest,
  NTSTRSAFE_PSTR  *ppszDestEnd,
  size_t          *pcchRemaining,
  DWORD           dwFlags,
  NTSTRSAFE_PCSTR pszFormat,
  va_list         argList
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the arguments supplied by *argList*. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchDest`

The size of the destination buffer, in characters. The buffer must be large enough to contain the formatted string plus the terminating null character. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH. If *pszDest* is **NULL**, *cchDest* must be zero.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer then, after the operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcchRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused bytes that are in the buffer pointed to by *pszDest*, including those bytes used for the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows.

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

`pszFormat`

Pointer to a null-terminated text string that contains **printf**-styled formatting directives. The *pszFormat* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`argList`

A **va_list**-typed argument list. Arguments contained in the argument list will be interpreted by using the formatting string that is supplied by *pszFormat*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchVPrintfExW and **RtlStringCchVPrintfExA** should be used instead of the following functions:

- **vsprintf**
- **vswprintf**
- **_vsnprintf**
- **_vsnwprintf**

All of these functions accept a format string and its arguments, provided as a **va_list**-typed argument list, and return a formatted string. **RtlStringCchVPrintfExW** and **RtlStringCchVPrintfExA** receive the size, in characters, of the destination buffer to ensure that they do not write past the end of the buffer.

RtlStringCchVPrintfExW and **RtlStringCchVPrintfExA** add to the functionality of RtlStringCchVPrintf by returning a pointer to the end of the destination string, as well as the number of characters left unused in that string. Flags can be passed to the function for additional control.

For more information about **va_list**-typed argument lists, see the Microsoft Windows SDK documentation.

Use **RtlStringCchVPrintfExW** to handle Unicode strings and **RtlStringCchVPrintfExA** to handle ANSI strings. The form you use depends on your data.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchVPrintfExW**
char	"string"	**RtlStringCchVPrintfExA**

If *pszDest* and *pszFormat* point to overlapping strings or if any argument strings overlap, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

RtlStringCchPrintfEx

RtlStringCchVPrintf

RtlStringCchVPrintfExW function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlStringCchVPrintfExW** and **RtlStringCchVPrintfExA** functions create a character-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCchVPrintfExW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cchDest,
  NTSTRSAFE_PWSTR  *ppszDestEnd,
  size_t           *pcchRemaining,
  DWORD            dwFlags,
  NTSTRSAFE_PCWSTR pszFormat,
  va_list          argList
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the arguments supplied by *argList*. The *pszDest* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchDest`

The size of the destination buffer, in characters. The buffer must be large enough to contain the formatted string plus the terminating null character. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH. If *pszDest* is **NULL**, *cchDest* must be zero.

`ppszDestEnd`

If the caller supplies a non-**NULL** address pointer then, after the operation completes, the function loads that address with a pointer to the destination buffer's resulting null string terminator.

`pcchRemaining`

If the caller supplies a non-**NULL** address pointer, the function loads the address with the number of unused bytes that are in the buffer pointed to by *pszDest*, including those bytes used for the terminating null character.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows.

VALUE	MEANING

STRSAFE_FILL_BEHIND_NULL	If set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the terminating null character.
STRSAFE_IGNORE_NULLS	If set, either *pszDest*or*pszSrc*, or both, can be **NULL**. **NULL** *pszSrc* pointers are treated like empty strings (TEXT("")), which can be copied. **NULL** *pszDest* pointers cannot receive nonempty strings.
STRSAFE_FILL_ON_FAILURE	If set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer, and the buffer is null-terminated. This operation overwrites any preexisting buffer contents.
STRSAFE_NULL_ON_FAILURE	If set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.
STRSAFE_NO_TRUNCATION	If set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

`pszFormat`

Pointer to a null-terminated text string that contains **printf**-styled formatting directives. The *pszFormat* pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`argList`

A **va_list**-typed argument list. Arguments contained in the argument list will be interpreted by using the formatting string that is supplied by *pszFormat*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • An invalid flag was specified. • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present without the STRSAFE_IGNORE_NULLS flag. • The destination buffer pointer was **NULL**, but the buffer size was not zero. • The destination buffer pointer was **NULL**, or its length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchVPrintfExW and **RtlStringCchVPrintfExA** should be used instead of the following functions:

- **vsprintf**
- **vswprintf**
- **_vsnprintf**
- **_vsnwprintf**

All of these functions accept a format string and its arguments, provided as a **va_list**-typed argument list, and return a formatted string. **RtlStringCchVPrintfExW** and **RtlStringCchVPrintfExA** receive the size, in characters, of the destination buffer to ensure that they do not write past the end of the buffer.

RtlStringCchVPrintfExW and **RtlStringCchVPrintfExA** add to the functionality of RtlStringCchVPrintf by returning a pointer to the end of the destination string, as well as the number of characters left unused in that string. Flags can be passed to the function for additional control.

For more information about **va_list**-typed argument lists, see the Microsoft Windows SDK documentation.

Use **RtlStringCchVPrintfExW** to handle Unicode strings and **RtlStringCchVPrintfExA** to handle ANSI strings. The form you use depends on your data.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchVPrintfExW**
char	"string"	**RtlStringCchVPrintfExA**

If *pszDest* and *pszFormat* point to overlapping strings or if any argument strings overlap, the behavior of the function is undefined.

Neither *pszSrc* nor *pszDest* can be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set, in which case either or both can be **NULL**. If *pszDest* is **NULL**, *pszSrc* must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

RtlStringCbVPrintfEx

RtlStringCchPrintfEx

RtlStringCchVPrintf

RtlStringCchVPrintfW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringCchVPrintfW** and **RtlStringCchVPrintfA** functions create a character-counted text string, with formatting that is based on supplied formatting information.

Syntax

```
NTSTRSAFEDDI RtlStringCchVPrintfW(
  NTSTRSAFE_PWSTR  pszDest,
  size_t           cchDest,
  NTSTRSAFE_PCWSTR pszFormat,
  va_list          argList
);
```

Parameters

`pszDest`

A pointer to a caller-supplied buffer that receives a formatted, null-terminated string. The function creates this string from both the formatting string that is supplied by *pszFormat* and the arguments supplied by *argList*.

`cchDest`

The size of the destination buffer, in characters. The buffer must be large enough to contain the formatted string plus the terminating null character. The maximum number of characters allowed is NTSTRSAFE_MAX_CCH.

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives.

`argList`

A **va_list**-typed argument list. Arguments contained in the argument list will be interpreted by using the formatting string that is supplied by *pszFormat*.

Return Value

The function returns one of the NTSTATUS values that are listed in the following table. For information about how to test NTSTATUS values, see Using NTSTATUS Values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the output string was created without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means the operation did not complete due to insufficient space in the destination buffer. The destination buffer contains a truncated version of the created string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph. The function returns the STATUS_INVALID_PARAMETER value when: • The value in *cchDest* is larger than the maximum buffer size. • The destination buffer was already full. • A **NULL** pointer was present. • The destination buffer length was zero, but a nonzero length source string was present.

Remarks

RtlStringCchVPrintfW and **RtlStringCchVPrintfA** should be used instead of the following functions:

- **vsprintf**
- **vswprintf**
- **_vsnprintf**
- **_vsnwprintf**

All of these functions accept a format string and its arguments, which are provided as a **va_list**-typed argument list, and return a formatted string. **RtlStringCchVPrintfW** and **RtlStringCchVPrintfA** receive the size, in characters, of the destination buffer to ensure that the functions do not write past the end of the buffer.

For more information about **va_list**-typed argument lists, see the Microsoft Windows SDK documentation.

Use **RtlStringCchVPrintfW** to handle Unicode strings and **RtlStringCchVPrintfA** to handle ANSI strings. The form you use depends on your data, as shown in the following table.

STRING DATA TYPE	STRING LITERAL	FUNCTION
WCHAR	L"string"	**RtlStringCchVPrintfW**
char	"string"	**RtlStringCchVPrintfA**

If *pszDest* and *pszFormat* point to overlapping strings, or if any argument strings overlap, the behavior of the function is undefined.

Neither *pszFormat* nor *pszDest* can be **NULL**. If you need to handle **NULL** string pointer values, use RtlStringCchVPrintfEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

RtlStringCbVPrintf

RtlStringCchPrintf

RtlStringCchVPrintfEx

RtlUnalignedStringCbLengthW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnalignedStringCbLengthW** function is a version of the RtlStringCbLength function that accepts an unaligned pointer to a string of Unicode characters.

Syntax

```
NTSTRSAFEDDI RtlUnalignedStringCbLengthW(
  STRSAFE_PCUNZWCH psz,
  size_t           cbMax,
  size_t           *pcbLength
);
```

Parameters

`psz`

Supplies a pointer to a buffer that contains a null-terminated string whose length **RtlUnalignedStringCbLengthW** will check.

`cbMax`

Supplies the maximum number of bytes that are allowed in the buffer that *psz* points to, including the terminating NULL character. This value cannot exceed NTSTRSAFE_MAX_CCH * sizeof(WCHAR).

`pcbLength`

Optional. If the caller supplies a non-**NULL** address pointer, the function loads the address with the length, in bytes, of the string that is contained in the buffer that *psz* points to. The length does not include the string's terminating NULL character.

Return Value

RtlUnalignedStringCbLengthW returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	This *success* status means the string that the *psz* parameter specified was not **NULL**, and the length of the string (including the terminating NULL character) was less than or equal to *cbMax* bytes.

STA TUS _IN VAL ID_ PAR AM ETE R	This *error* status means the value in *psz* is **NULL**, *cbMax* is larger than NTSTRSAFE_MAX_CCH * sizeof(WCHAR, or *psz* is longer than *cbMax*.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnalignedStringCbLengthW** function is available for processor architectures, such as Itanium-based and x64-based, that cause alignment exceptions when software attempts to access unaligned data. On those processors, you can use **RtlUnalignedStringCbLengthW** instead of the RtlStringCbLength function to avoid alignment exceptions. (For processors that do not cause alignment exceptions, **RtlUnalignedStringCbLengthW** is equivalent to **RtlStringCbLength**.)

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)

RtlStringCbLength

RtlUnalignedStringCchLengthW function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnalignedStringCchLengthW** function is a version of the RtlStringCchLength function that accepts an unaligned pointer to a string of Unicode characters.

Syntax

```
NTSTRSAFEDDI RtlUnalignedStringCchLengthW(
  STRSAFE_PCUNZWCH psz,
  size_t           cchMax,
  size_t           *pcchLength
);
```

Parameters

`psz`

Supplies a pointer to a buffer that contains a null-terminated string whose length **RtlUnalignedStringCchLengthW** will check.

`cchMax`

Supplies the maximum number of characters that are allowed in the buffer that *psz* points to, including the terminating NULL character. This value cannot exceed NTSTRSAFE_MAX_CCH.

`pcchLength`

Optional. If the caller supplies a non-**NULL** address pointer, the function loads the address with the length, in characters, of the string that is contained in the buffer that *psz* points to. The length does not include the string's terminating NULL character.

Return Value

RtlUnalignedStringCchLengthW returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means the string that the *psz* parameter was not **NULL**, and the length of the string (including the terminating NULL character) was less than or equal to *cchMax* characters.

STATUS_INVALID_PARAMETER	This *error* status means the value in *psz* is **NULL**, *cchMax* is larger than NTSTRSAFE_MAX_CCH, or *psz* is longer than *cchMax*.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnalignedStringCchLengthW** function is available for processor architectures, such as Itanium-based and x64-based, that cause alignment exceptions when software attempts to access unaligned data. On those processors, you can use **RtlUnalignedStringCchLengthW** instead of RtlStringCchLength to avoid alignment exceptions. (For processors that do not cause alignment exceptions, **RtlUnalignedStringCchLengthW** is equivalent to **RtlStringCchLength**.)

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlStringCchLength

RtlUnicodeStringCat function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringCat** function concatenates two strings that are contained in UNICODE_STRING structures.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCat(
  PUNICODE_STRING  DestinationString,
  PCUNICODE_STRING SourceString
);
```

Parameters

`DestinationString`

A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that, on input, contains a destination string to which the source string will be concatenated. On output, this buffer is the destination buffer that contains the entire resultant string. The source string is added to the end of the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

`SourceString`

A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that contains the source string. This string will be added to the end of the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

Return Value

RtlUnicodeStringCat returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the strings were concatenated without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the concatenation operation did not complete because of insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.

STA TUS _IN VAL ID_ PAR AM ETE R	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCat returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of a **UNICODE_STRING** structure are invalid.
- The destination buffer is already full.
- A buffer pointer is **NULL**.
- The destination buffer's length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCat** function uses the destination buffer's size to ensure that the concatenation operation does not write past the end of the buffer. The function does not terminate the resultant string with a null character value (that is, with zero).

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString* and *DestinationString* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use RtlUnicodeStringCatEx.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlUnicodeStringCatEx

UNICODE_STRING

RtlUnicodeStringCatEx function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlUnicodeStringCatEx** function concatenates two strings that are contained in UNICODE_STRING structures.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCatEx(
  PUNICODE_STRING  DestinationString,
  PCUNICODE_STRING SourceString,
  PUNICODE_STRING  RemainingString,
  DWORD            dwFlags
);
```

Parameters

`DestinationString`

Optional. A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that, on input, contains a destination string to which the source string will be concatenated. On output, this buffer is the destination buffer that contains the entire resultant string. The source string is added to the end of the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR). *DestinationString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`SourceString`

Optional. A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that contains the source string. This string will be added to the end of the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR). *SourceString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`RemainingString`

Optional. If the caller supplies a non-**NULL** pointer to a **UNICODE_STRING** structure, the function sets this structure's **Buffer** member to the end of the concatenated string, sets the structure's **Length** member to zero, and sets the structure's **MaximumLength** member to the number of bytes that are remaining in the destination buffer. *RemainingString*can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the last character in the string.

STRSAFE_IGNORE_NULLS

If this flag is set, the source or destination pointer, or both, can be **NULL**. **RtlUnicodeStringCatEx** treats **NULL** source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer pointers cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

STRSAFE_ZERO_LENGTH_ON_FAILURE

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the destination string length is set to zero bytes.

Return Value

RtlUnicodeStringCatEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, and the strings were concatenated without truncation.
STATUS_BUFFER_OVERFLOW	This *warning* status means the concatenation operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCatEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of a **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in *dwFlags*.
- The destination buffer is already full.
- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified.
- The destination buffer pointer is **NULL**, but the buffer size is not zero.
- The destination buffer pointer is **NULL**, or its length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCatEx** function uses the destination buffer's size to ensure that the concatenation operation does not write past the end of the buffer. By default, the function does not terminate the resultant string with a null character value (that is, with zero). As an option, the caller can use the STRSAFE_FILL_BEHIND flag and a fill byte value of zero to null-terminate a resultant string that does not occupy the entire destination buffer.

RtlUnicodeStringCatEx adds to the functionality of the RtlUnicodeStringCat function by returning a UNICODE_STRING structure that identifies the end of the destination string and the number of bytes that are left unused in that string. You can pass flags to **RtlUnicodeStringCatEx** for additional control.

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString* and *DestinationString* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both of these pointers can be **NULL**. If the *DestinationString* pointer is **NULL**, the *SourceString* pointer must be **NULL** or the **UNICODE_STRING** structure must describe an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available starting with Windows XP with Service Pack 1 (SP1).
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib

RtlUnicodeStringCat

UNICODE_STRING

RtlUnicodeStringCatString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringCatString** function concatenates two strings when the destination string is contained in a UNICODE_STRING structure.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCatString(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszSrc
);
```

Parameters

`DestinationString`

A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that, on input, contains a destination string to which the source string will be concatenated. On output, this buffer is the destination buffer that contains the entire resultant string. The source string (excluding the terminating null) is added to the end of the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

`pszSrc`

A pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the buffer that the **UNICODE_STRING** structure points to.

Return Value

RtlUnicodeStringCatString returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the strings were concatenated without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the concatenation operation did not complete because of insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.

STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCatString returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure are invalid.
- The destination buffer is already full.
- A buffer pointer is **NULL**.
- The destination buffer's length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCatString** function uses the destination buffer's size to ensure that the concatenation operation does not write past the end of the buffer. The function does not terminate the resultant string with a null character value (that is, with zero).

If the source and destination strings overlap, the behavior of the function is undefined.

The *pszSrc* and *DestinationString* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use the RtlUnicodeStringCatStringEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlUnicodeStringCatStringEx

UNICODE_STRING

RtlUnicodeStringCatStringEx function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlUnicodeStringCatStringEx** function concatenates two strings when the destination string is contained in a UNICODE_STRING structure.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCatStringEx(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszSrc,
  PUNICODE_STRING  RemainingString,
  DWORD            dwFlags
);
```

Parameters

`DestinationString`

Optional. A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that, on input, contains a destination string to which the source string will be concatenated. On output, this buffer is the destination buffer that contains the entire resultant string. The source string (excluding the terminating null) is added to the end of the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR). *DestinationString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`pszSrc`

Optional. A caller-supplied pointer to a null-terminated source string. This string will be concatenated to the end of the string that is contained in the **UNICODE_STRING** structure that *DestinationString* specifies. *pszSrc* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`RemainingString`

Optional. If the caller supplies a non-**NULL** pointer to a **UNICODE_STRING** structure, the function sets this structure's **Buffer** member to the end of the concatenated string, sets the structure's **Length** member to zero, and sets the structure's **MaximumLength** member to the number of bytes that are remaining in the destination buffer. This pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the last character in the string.

STRSAFE_IGNORE_NULLS

If this flag is set, the source or destination pointer, or both, can be **NULL**. **RtlUnicodeStringCatStringEx** treats **NULL** source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer pointers cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

STRSAFE_ZERO_LENGTH_ON_FAILURE

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the destination string length is set to zero bytes.

Return Value

RtlUnicodeStringCatStringEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, and the strings were concatenated without truncation.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the copy operation did not complete because of insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCatStringEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of a **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in *dwFlags*.
- The destination buffer is already full.
- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified in *dwFlags*.
- The destination buffer pointer is **NULL**, but the buffer size is not zero.
- The destination buffer pointer is **NULL**, or its length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCatStringEx** function uses the destination buffer's size to ensure that the concatenation operation does not write past the end of the buffer. By default, the function does not terminate the resultant string with a null character value (that is, with zero). As an option, the caller can use the STRSAFE_FILL_BEHIND flag and a fill byte value of zero to null-terminate a resultant string that does not occupy the entire destination buffer.

RtlUnicodeStringCatStringEx adds to the functionality of the RtlUnicodeStringCatString function by returning a UNICODE_STRING structure that identifies the end of the destination string and the number of bytes that are left unused in that string. You can pass flags to **RtlUnicodeStringCatStringEx** for additional control.

If the source and destination strings overlap, the behavior of the function is undefined.

The *pszSrc* and *DestinationString* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both of these pointers can be **NULL**. If the *DestinationString* pointer is **NULL**, the *pszSrc* pointer must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

RtlUnicodeStringCatString

UNICODE_STRING

RtlUnicodeStringCbCatN function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringCbCatN** function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCbCatN(
  PUNICODE_STRING  DestinationString,
  PCUNICODE_STRING SourceString,
  size_t           cbToAppend
);
```

Parameters

`DestinationString`

A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that, on input, contains a destination string to which the source string will be concatenated. On output, this buffer is the destination buffer that contains the entire resultant string. The source string is added to the end of the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

`SourceString`

A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that contains the source string. This string will be added to the end of the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

`cbToAppend`

The maximum number of bytes to append to the string that the *DestinationString* parameter describes.

Return Value

RtlUnicodeStringCbCatN returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the strings were concatenated without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means that the concatenation operation did not complete because of insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCbCatN returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure are invalid.
- The destination buffer is already full.
- A buffer pointer is **NULL**.
- The destination buffer's length is zero, but a nonzero length source string is present.
- The *cbToAppend* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCbCatN** function uses the destination buffer's size to ensure that the concatenation operation does not write past the end of the buffer. The function does not terminate the resultant string with a null character value (that is, with zero).

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString* and *DestinationString* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use the RtlUnicodeStringCbCatNEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)

Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlUnicodeStringCbCatNEx

RtlUnicodeStringCchCatN

UNICODE_STRING

RtlUnicodeStringCbCatNEx function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlUnicodeStringCbCatNEx** function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCbCatNEx(
  PUNICODE_STRING  DestinationString,
  PCUNICODE_STRING SourceString,
  size_t           cbToAppend,
  PUNICODE_STRING  RemainingString,
  DWORD            dwFlags
);
```

Parameters

`DestinationString`

Optional. A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that, on input, contains a destination string to which the source string will be concatenated. On output, this buffer is the destination buffer that contains the entire resultant string. The source string is added to the end of the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR). *DestinationString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`SourceString`

Optional. A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that contains the source string. This string will be added to the end of the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR). *SourceString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbToAppend`

The maximum number of bytes to append to the string that the *DestinationString* parameter describes.

`RemainingString`

Optional. If the caller supplies a non-**NULL** pointer to a **UNICODE_STRING** structure, the function sets this structure's **Buffer** member to the end of the concatenated string, sets the structure's **Length** member to zero, and sets the structure's **MaximumLength** member to the number of bytes that are remaining in the destination buffer. *RemainingString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the last character in the string.

STRSAFE_IGNORE_NULLS

If this flag is set, the source or destination pointer, or both, can be **NULL**. **RtlUnicodeStringCbCatNEx** treats

NULL source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer pointers cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

STRSAFE_ZERO_LENGTH_ON_FAILURE

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the destination string length is set to zero bytes.
