Return Value

RtlUnicodeStringCbCatNEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, and the strings were concatenated without truncation.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the concatenation operation did not complete because of insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCbCatNEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of a **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in *dwFlags*.
- The destination buffer is already full.

- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified in dwFlags.
- The destination buffer pointer is **NULL**, but the buffer size is not zero.
- The destination buffer pointer is **NULL**, or its length is zero, but a nonzero length source string is present.
- The *cbToAppend* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCbCatNEx** function uses the destination buffer's size to ensure that the concatenation operation does not write past the end of the buffer. By default, the function does not terminate the resultant string with a null character value (that is, with zero). As an option, the caller can use the STRSAFE_FILL_BEHIND flag and a fill byte value of zero to null-terminate a resultant string that does not occupy the entire destination buffer.

RtlUnicodeStringCbCatNEx adds to the functionality of the RtlUnicodeStringCbCatN function by returning a UNICODE_STRING structure that identifies the end of the destination string and the number of bytes that are left unused in that string. You can pass flags to **RtlUnicodeStringCbCatNEx** for additional control.

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString* and *DestinationString* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both of these pointers can be **NULL**. If the *DestinationString* pointer is **NULL**, the *SourceString* pointer must be **NULL** or the **UNICODE_STRING** structure must specify an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

RtlUnicodeStringCbCatN

RtlUnicodeStringCchCatNEx

UNICODE_STRING

RtlUnicodeStringCbCatStringN function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringCbCatStringN** function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCbCatStringN(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszSrc,
  size_t           cbToAppend
);
```

Parameters

`DestinationString`

A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that, on input, contains a destination string to which the source string will be concatenated. On output, this buffer is the destination buffer that contains the entire resultant string. The source string (excluding the terminating null) is added to the end of the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

`pszSrc`

A caller-supplied pointer to a null-terminated string. This string will be concatenated to the end of the destination string that is contained in the **UNICODE_STRING** structure that *DestinationString* points to.

`cbToAppend`

The maximum number of bytes to append to the string that the *DestinationString* parameter describes.

Return Value

RtlUnicodeStringCbCatStringN returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the strings were concatenated without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means that the concatenation operation did not complete because of insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCbCatStringN returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure are invalid.
- The destination buffer is already full.
- A buffer pointer is **NULL**.
- The destination buffer's length is zero, but a nonzero length source string is present.
- The *cbToAppend* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCbCatStringN** function uses the destination buffer's size to ensure that the concatenation operation does not write past the end of the buffer. The function does not terminate the resultant string with a null character value (that is, with zero).

If the source and destination strings overlap, the behavior of the function is undefined.

The *pszSrc* and *DestinationString* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use the RtlUnicodeStringCbCatStringNEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)

Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlUnicodeStringCbCatStringNEx

RtlUnicodeStringCchCatStringN

UNICODE_STRING

RtlUnicodeStringCbCatStringNEx function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlUnicodeStringCbCatStringNEx** function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCbCatStringNEx(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszSrc,
  size_t           cbToAppend,
  PUNICODE_STRING  RemainingString,
  DWORD            dwFlags
);
```

Parameters

`DestinationString`

Optional. A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that, on input, contains a destination string to which the source string will be concatenated. On output, this buffer is the destination buffer that contains the entire resultant string. The source string (excluding the terminating null) is added to the end of the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR). *DestinationString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`pszSrc`

A caller-supplied pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the **UNICODE_STRING** structure that *DestinationString* points to. *pszSrc* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbToAppend`

The maximum number of bytes to append to the string that the *DestinationString* parameter describes.

`RemainingString`

Optional. If the caller supplies a non-**NULL** pointer to a **UNICODE_STRING** structure, the function sets this structure's **Buffer** member to the end of the concatenated string, sets the structure's **Length** member to zero, and sets the structure's **MaximumLength** member to the number of bytes that are remaining in the destination buffer. *RemainingString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the last character in the string.

STRSAFE_IGNORE_NULLS

If this flag is set, the source or destination pointer, or both, can be **NULL**. **RtlUnicodeStringCbCatStringNEx**

treats **NULL** source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer pointers cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

STRSAFE_ZERO_LENGTH_ON_FAILURE

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the destination string length is set to zero bytes.

Return Value

RtlUnicodeStringCbCatStringNEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, and the strings were concatenated without truncation.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the concatenated operation did not complete because of insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCbCatStringNEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of a **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in *dwFlags*.
- The destination buffer is already full.

- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified.
- The destination buffer pointer is **NULL**, but the buffer size is not zero.
- The destination buffer pointer is **NULL**, or its length is zero, but a nonzero length source string is present.
- The *cbToAppend* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCbCatStringNEx** function uses the destination buffer's size to ensure that the concatenation operation does not write past the end of the buffer. By default, the function does not terminate the resultant string with a null character value (that is, with zero). As an option, the caller can use the STRSAFE_FILL_BEHIND flag and a fill byte value of zero to null-terminate a resultant string that does not occupy the entire destination buffer.

RtlUnicodeStringCbCatStringNEx adds to the functionality of the RtlUnicodeStringCbCatStringN function by returning a **UNICODE_STRING** structure that identifies the end of the destination string and the number of bytes that are left unused in that string. You can pass flags to **RtlUnicodeStringCbCatStringNEx** for additional control.

If the source and destination strings overlap, the behavior of the function is undefined.

The *pszSrc* and *DestinationString* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both of these pointers can be **NULL**. If the *DestinationString* pointer is **NULL**, the *pszSrc* pointer must be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

RtlUnicodeStringCbCatStringN

RtlUnicodeStringCchCatStringNEx

UNICODE_STRING

RtlUnicodeStringCbCopyN function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringCbCopyN** function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCbCopyN(
  PUNICODE_STRING  DestinationString,
  PCUNICODE_STRING SourceString,
  size_t           cbToCopy
);
```

Parameters

`DestinationString`

A pointer to a **UNICODE_STRING** structure that receives the copied string. The string that the *SourceString* parameter's **UNICODE_STRING** structure points to is copied to the buffer that the *DestinationString* parameter's **UNICODE_STRING** structure points to. The maximum number of bytes in the *DestinationString*structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

`SourceString`

A pointer to a **UNICODE_STRING** structure that contains the string to be copied. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

`cbToCopy`

The number of bytes to be copied from the source to the destination.

Return Value

RtlUnicodeStringCbCopyN returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation.

STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient buffer space. The destination buffer contains a truncated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph.

RtlUnicodeStringCbCopyN returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure are invalid.
- The destination buffer is already full.
- A buffer pointer is **NULL**.
- The destination buffer's length is zero, but a nonzero length source string is present.
- The *cbToCopy* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCbCopyN** function uses the destination buffer's size to ensure that the copy operation does not write past the end of the buffer. The function does not terminate the resultant string with a null character value (that is, with zero).

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString* and *DestinationString* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use the RtlUnicodeStringCbCopyNEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)

Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlUnicodeStringCbCopyNEx

RtlUnicodeStringCchCopyN

UNICODE_STRING

RtlUnicodeStringCbCopyNEx function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlUnicodeStringCbCopyNEx** function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCbCopyNEx(
  PUNICODE_STRING  DestinationString,
  PCUNICODE_STRING SourceString,
  size_t           cbToCopy,
  PUNICODE_STRING  RemainingString,
  DWORD            dwFlags
);
```

Parameters

`DestinationString`

Optional. A pointer to a **UNICODE_STRING** structure that receives the copied string. The string that the *SourceString* parameter's **UNICODE_STRING** structure points to is copied to the buffer that the *DestinationString* parameter's **UNICODE_STRING** structure points to. The maximum number of bytes in the *DestinationString* structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).*DestinationString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`SourceString`

Optional. A pointer to a **UNICODE_STRING** structure that contains the string to be copied. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR). *SourceString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbToCopy`

The number of bytes to be copied from the source to the destination.

`RemainingString`

Optional. If the caller supplies a non-**NULL** pointer to a **UNICODE_STRING** structure, the function sets this structure's **Buffer** member to the end of the concatenated string, sets the structure's **Length** member to zero, and sets the structure's **MaximumLength** member to the number of bytes that are remaining in the destination buffer. *RemainingString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the last character in the string.

STRSAFE_IGNORE_NULLS

If this flag is set, the source or destination pointer, or both, can be **NULL**. **RtlUnicodeStringCbCopyNEx** treats **NULL** source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer pointers

cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

STRSAFE_ZERO_LENGTH_ON_FAILURE

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the destination string length is set to zero bytes.

Return Value

RtlUnicodeStringCbCopyNEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, and the strings were concatenated without truncation.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the copy operation did not complete because of insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCbCopyNEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of a **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in *dwFlags*.
- The destination buffer is already full.

- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified in dwFlags.
- The destination buffer pointer is **NULL**, but the buffer size is not zero.
- The destination buffer pointer is **NULL**, or its length is zero, but a nonzero length source string is present.
- The *cbToCopy* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCbCopyNEx** function uses the destination buffer's size to ensure that the copy operation does not write past the end of the buffer. By default, the function does not terminate the resultant string with a null character value (that is, with zero). As an option, the caller can use the STRSAFE_FILL_BEHIND flag and a fill byte value of zero to null-terminate a resultant string that does not occupy the entire destination buffer.

RtlUnicodeStringCbCopyNEx adds to the functionality of the RtlUnicodeStringCbCopyN function by returning a UNICODE_STRING structure that identifies the end of the destination string and the number of bytes that are left unused in that string. You can pass flags to **RtlUnicodeStringCbCopyNEx** for additional control.

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString* and *DestinationString* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both of these pointers can be **NULL**. If the *DestinationString* pointer is **NULL**, the *SourceString* pointer must be **NULL** or the **UNICODE_STRING** structure must contain an empty string.

For more information about the safe string functions, see Using Safe String Functions.

RtlUnicodeStringCbCopyN

RtlUnicodeStringCchCopyNEx

UNICODE_STRING

RtlUnicodeStringCbCopyStringN function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringCbCopyStringN** function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCbCopyStringN(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszSrc,
  size_t           cbToCopy
);
```

Parameters

`DestinationString`

A pointer to a **UNICODE_STRING** structure that receives the copied string. The string that the *pszSrc* parameter points to (excluding the terminating null) is copied into the buffer that the *DestinationString* parameter's **UNICODE_STRING** structure points to. The maximum number of bytes in the string is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

`pszSrc`

A pointer to the string to be copied.

`cbToCopy`

The number of bytes to be copied from the source to the destination.

Return Value

RtlUnicodeStringCbCopyN returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the copy operation did not complete because of insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.

STA TUS _IN VAL ID_ PAR AM ETE R	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCbCopyN returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure are invalid.
- The destination buffer is already full.
- A buffer pointer is **NULL**.
- The destination buffer's length is zero, but a nonzero length source string is present.
- The *cbToCopy* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCbCopyN** function uses the destination buffer's size to ensure that the copy operation does not write past the end of the buffer. The function does not terminate the resultant string with a null character value (that is, with zero).

If the source and destination strings overlap, the behavior of the function is undefined.

The *pszSrc* and *DestinationString* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use the RtlUnicodeStringCbCopyNEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)

Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlUnicodeStringCbCopyNEx

RtlUnicodeStringCchCopyN

UNICODE_STRING

RtlUnicodeStringCbCopyStringNEx function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlUnicodeStringCbCopyStringNEx** function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCbCopyStringNEx(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszSrc,
  size_t           cbToCopy,
  PUNICODE_STRING  RemainingString,
  DWORD            dwFlags
);
```

Parameters

`DestinationString`

Optional. A pointer to a **UNICODE_STRING** structure that receives the copied string. The string that the *pszSrc* parameter points to (excluding the terminating null) is copied into the buffer that the *DestinationString* parameter's **UNICODE_STRING** structure points to. The maximum number of bytes in the string is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR). *DestinationString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`pszSrc`

Optional. A pointer to the string to be copied. This pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cbToCopy`

The number of bytes to be copied from the source to the destination.

`RemainingString`

Optional. If the caller supplies a non-**NULL** pointer to a **UNICODE_STRING** structure, the function sets this structure's **Buffer** member to the end of the concatenated string, sets the structure's **Length** member to zero, and sets the structure's **MaximumLength** member to the number of bytes that are remaining in the destination buffer. *RemainingString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the last character in the string.

STRSAFE_IGNORE_NULLS

If this flag is set, the source or destination pointer, or both, can be **NULL**. **RtlUnicodeStringCbCopyStringNEx** treats **NULL** source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer pointers cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

STRSAFE_ZERO_LENGTH_ON_FAILURE

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the destination string length is set to zero bytes.

Return Value

RtlUnicodeStringCbCopyStringNEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, and the strings were concatenated without truncation.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the copy operation did not complete because of insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCbCopyStringNEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of a **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in *dwFlags*.
- The destination buffer is already full.
- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified in *dwFlags*.
- The destination buffer pointer is **NULL**, but the buffer size is not zero.

- The destination buffer pointer is **NULL**, or its length is zero, but a nonzero length source string is present.
- The *cbToCopy* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCbCopyStringNEx** function uses the destination buffer's size to ensure that the copy operation does not write past the end of the buffer. By default, the function does not terminate the resultant string with a null character value (that is, with zero). As an option, the caller can use the STRSAFE_FILL_BEHIND flag and a fill byte value of zero to null-terminate a resultant string that does not occupy the entire destination buffer.

RtlUnicodeStringCbCopyStringNEx adds to the functionality of the RtlUnicodeStringCbCopyStringN function by returning a UNICODE_STRING structure that identifies the end of the destination string and the number of bytes left unused in that string. You can pass flags **RtlUnicodeStringCbCopyStringNEx** for additional control.

If the source and destination strings overlap, the behavior of the function is undefined.

The *pszSrc* and *DestinationString* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both of these pointers can be **NULL**. If the *DestinationString* pointer is **NULL**, the *pszSrc* pointer must be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

RtlUnicodeStringCbCopyStringN

RtlUnicodeStringCchCopyStringNEx

UNICODE_STRING

RtlUnicodeStringCchCatN function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringCchCatN** function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCchCatN(
  PUNICODE_STRING  DestinationString,
  PCUNICODE_STRING SourceString,
  size_t           cchToAppend
);
```

Parameters

`DestinationString`

A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that, on input, contains a destination string to which the source string will be concatenated. On output, this buffer is the destination buffer that contains the entire resultant string. The source string is added to the end of the destination string. The maximum number of characters in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH.

`SourceString`

A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that contains the source string. This string will be added to the end of the destination string. The maximum number of characters in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH.

`cchToAppend`

The maximum number of characters to append to the string that the *DestinationString* parameter describes.

Return Value

RtlUnicodeStringCchCatN returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the strings were concatenated without truncation, and the resultant destination buffer is null-terminated.

STA TUS _BU FFE R_O VER FLO W	This *warning* status means that the concatenated operation did not complete because of insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.
STA TUS _IN VAL ID_ PAR AM ETE R	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCchCatN returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure are invalid.
- The destination buffer is already full.
- A buffer pointer is **NULL**.
- The destination buffer's length is zero, but a nonzero length source string is present.
- The *cchToAppend* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCchCatN** function uses the destination buffer's size to ensure that the concatenation operation does not write past the end of the buffer. The function does not terminate the resultant string with a null character value (that is, with zero).

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString* and *DestinationString* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use the RtlUnicodeStringCchCatNEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

RtlUnicodeStringCbCatN

RtlUnicodeStringCchCatNEx

UNICODE_STRING

RtlUnicodeStringCchCatNEx function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlUnicodeStringCchCatNEx** function concatenates two strings that are contained in UNICODE_STRING structures while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCchCatNEx(
  PUNICODE_STRING  DestinationString,
  PCUNICODE_STRING SourceString,
  size_t           cchToAppend,
  PUNICODE_STRING  RemainingString,
  DWORD            dwFlags
);
```

Parameters

`DestinationString`

Optional. A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that, on input, contains a string to which the source string will be concatenated. On output, this buffer is the destination buffer that contains the entire resultant string. The source string is added to the end of the destination string. The maximum number of characters in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH. *DestinationString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`SourceString`

Optional. A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that contains the source string. This string will be added to the end of the destination string. The maximum number of characters in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH. *SourceString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchToAppend`

The maximum number of characters to append to the string that the *DestinationString* parameter describes.

`RemainingString`

Optional. If the caller supplies a non-**NULL** pointer to a **UNICODE_STRING** structure, the function sets this structure's **Buffer** member to the end of the concatenated string, sets the structure's **Length** member to zero, and sets the structure's **MaximumLength** member to the number of bytes that are remaining in the destination buffer. *RemainingString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the last character in the string.

STRSAFE_IGNORE_NULLS

If this flag is set, the source or destination pointer, or both, can be **NULL**. **RtlUnicodeStringCchCatNEx** treats

NULL source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer pointers cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

STRSAFE_ZERO_LENGTH_ON_FAILURE

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the destination string length is set to zero bytes.

Return Value

RtlUnicodeStringCchCatNEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, and the strings were concatenated without truncation.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the concatenated operation did not complete because of insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCchCatNEx returns the STATUS_INVALID_PARAMETER value when:

- The contents of a **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in *dwFlags*.
- The destination buffer is already full.

- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified in *dwFlags*.
- The destination buffer pointer is **NULL**, but the buffer size is not zero.
- The destination buffer pointer is **NULL**, or its length is zero, but a nonzero length source string is present.
- The *cchToAppend* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCchCatNEx** function uses the destination buffer's size to ensure that the concatenation operation does not write past the end of the buffer. By default, the function does not terminate the resultant string with a null character value (that is, with zero). As an option, the caller can use the STRSAFE_FILL_BEHIND flag and a fill byte value of zero to null-terminate a resultant string that does not occupy the entire destination buffer.

RtlUnicodeStringCchCatNEx adds to the functionality of the RtlUnicodeStringCchCatN function by returning a UNICODE_STRING structure that identifies the end of the destination string and the number of bytes that are left unused in that string. You can pass flags to **RtlUnicodeStringCchCatNEx** for additional control.

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString* and *DestinationString* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both can be **NULL**. If the *DestinationString* pointer is **NULL**, the *SourceString* pointer must be **NULL** or the **UNICODE_STRING** structure must specify an empty string.

For more information about the safe string functions, see Using Safe String Functions.

RtlUnicodeStringCchCatN

UNICODE_STRING

RtlUnicodeStringCchCatStringN function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringCchCatStringN** function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCchCatStringN(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszSrc,
  size_t           cchToAppend
);
```

Parameters

`DestinationString`

A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that, on input, contains a string to which the source string will be concatenated. On output, this buffer is the destination buffer that contains the entire resultant string. The source string (excluding the terminating **NULL**) is added to the end of the destination string. The maximum number of characters in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH.

`pszSrc`

A caller-supplied pointer to a null-terminated string. This string will be concatenated to the end of the string that is contained in the *DestinationString* parameter's **UNICODE_STRING** structure.

`cchToAppend`

The maximum number of characters to append to the string that the *DestinationString* parameter describes.

Return Value

RtlUnicodeStringCchCatStringN returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the strings were concatenated without truncation, and the resultant destination buffer is null-terminated.

STATUS_BUFFER_OVERFLOW	This *warning* status means that the concatenated operation did not complete because of insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCchCatStringN returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure are invalid.
- The destination buffer is already full.
- A buffer pointer is **NULL**.
- The destination buffer's length is zero, but a nonzero length source string is present.
- The *cchToAppend* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCchCatStringN** function uses the destination buffer's size to ensure that the concatenation operation does not write past the end of the buffer. The function does not terminate the resultant string with a null character value (that is, with zero).

If the source and destination strings overlap, the behavior of the function is undefined.

The *pszSrc* and *DestinationString* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use the RtlUnicodeStringCchCatStringNEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

RtlUnicodeStringCbCatStringN

RtlUnicodeStringCchCatStringNEx

UNICODE_STRING

RtlUnicodeStringCchCatStringNEx function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlUnicodeStringCchCatStringNEx** function concatenates two strings when the destination string is contained in a UNICODE_STRING structure, while limiting the size of the appended string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCchCatStringNEx(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszSrc,
  size_t           cchToAppend,
  PUNICODE_STRING  RemainingString,
  DWORD            dwFlags
);
```

Parameters

`DestinationString`

Optional. A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that, on input, contains a string to which the source string will be concatenated. On output, this buffer is the destination buffer that contains the entire resultant string. The source string (excluding the terminating null) is added to the end of the destination string. The maximum number of characters in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH. *DestinationString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`pszSrc`

A caller-supplied pointer to a null-terminated string. This string will be concatenated to the end of the string that *DestinationString* describes. *pszSrc* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchToAppend`

The maximum number of characters to append to the string that the *DestinationString* parameter describes.

`RemainingString`

Optional. If the caller supplies a non-**NULL** pointer to a **UNICODE_STRING** structure, the function sets this structure's **Buffer** member to the end of the concatenated string, sets the structure's **Length** member to zero, and sets the structure's **MaximumLength** member to the number of bytes that are remaining in the destination buffer. *RemainingString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the last character in the string.

STRSAFE_IGNORE_NULLS

If this flag is set, the source or destination pointer, or both, can be **NULL**. **RtlUnicodeStringCchCatStringNEx** treats **NULL** source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer

pointers cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

STRSAFE_ZERO_LENGTH_ON_FAILURE

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the destination string length is set to zero bytes.

Return Value

RtlUnicodeStringCchCatStringNEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, and the strings were concatenated without truncation.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the concatenation operation did not complete because of insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the intended result.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCchCatStringNEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of a **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in *dwFlags*.
- The destination buffer is already full.

- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified in *dwFlags*.
- The destination buffer pointer is **NULL**, but the buffer size is not zero.
- The destination buffer pointer is **NULL**, or its length is zero, but a nonzero length source string is present.
- The *cchToAppend* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCchCatStringNEx** function uses the destination buffer's size to ensure that the concatenation operation does not write past the end of the buffer. By default, the function does not terminate the resultant string with a null character value (that is, with zero). As an option, the caller can use the STRSAFE_FILL_BEHIND flag and a fill byte value of zero to null-terminate a resultant string that does not occupy the entire destination buffer.

RtlUnicodeStringCchCatStringNEx adds to the functionality of the RtlUnicodeStringCchCatStringN function by returning a UNICODE_STRING structure that identifies the end of the destination string and the number of bytes that are left unused in that string. Flags can be passed to **RtlUnicodeStringCchCatStringNEx** for additional control.

If the source and destination strings overlap, the behavior of the function is undefined.

The *pszSrc* and *DestinationString* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both of these pointers can be **NULL**. If the *DestinationString* pointer is **NULL**, the *pszSrc* pointer must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

RtlUnicodeStringCchCatStringN

UNICODE_STRING

RtlUnicodeStringCchCopyN function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringCchCopyN** function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCchCopyN(
  PUNICODE_STRING  DestinationString,
  PCUNICODE_STRING SourceString,
  size_t           cchToCopy
);
```

Parameters

`DestinationString`

A pointer to a **UNICODE_STRING** structure that receives the copied string. The string that the *SourceString* parameter's **UNICODE_STRING** structure points to is copied to the buffer that the *DestinationString* parameter's **UNICODE_STRING** structure points to. The maximum number of characters in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH.

`SourceString`

A pointer to a **UNICODE_STRING** structure that contains the string to be copied. The maximum number of characters in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH.

`cchToCopy`

The number of characters to be copied from the source to the destination.

Return Value

RtlUnicodeStringCchCopyN returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.

STA TUS _BU FFE R_O VER FLO W	This *warning* status means that the copy operation did not complete because of insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.
STA TUS _IN VAL ID_ PAR AM ETE R	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCchCopyN returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure are invalid.
- The destination buffer is already full.
- A buffer pointer is **NULL**.
- The destination buffer's length is zero, but a nonzero length source string is present.
- The *cchToCopy* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCchCopyN** function uses the destination buffer's size to ensure that the copy operation does not write past the end of the buffer. The function does not terminate the resultant string with a null character.

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString* and *DestinationString* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use the RtlUnicodeStringCchCopyNEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop

RtlUnicodeStringCchCopyN

RtlUnicodeStringCchCopyNEx

UNICODE_STRING

RtlUnicodeStringCchCopyNEx function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlUnicodeStringCchCopyNEx** function copies a string from one UNICODE_STRING structure to another while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCchCopyNEx(
  PUNICODE_STRING  DestinationString,
  PCUNICODE_STRING SourceString,
  size_t           cchToCopy,
  PUNICODE_STRING  RemainingString,
  DWORD            dwFlags
);
```

Parameters

`DestinationString`

Optional. A pointer to a **UNICODE_STRING** structure that receives the copied string. The string that the *SourceString* parameter's **UNICODE_STRING** structure points to is copied to the buffer that the *DestinationString* parameter's **UNICODE_STRING** structure points to. The maximum number of characters in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH. *DestinationString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`SourceString`

Optional. A pointer to a **UNICODE_STRING** structure that contains the string to be copied. The maximum number of characters in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR). *SourceString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchToCopy`

The number of characters to be copied from the source to the destination.

`RemainingString`

Optional. If the caller supplies a non-**NULL** pointer to a **UNICODE_STRING** structure, the function sets this structure's **Buffer** member to the end of the concatenated string, sets the structure's **Length** member to zero, and sets the structure's **MaximumLength** member to the number of bytes that are remaining in the destination buffer. *RemainingString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the last character in the string.

STRSAFE_IGNORE_NULLS

If this flag is set, the source or destination pointer, or both, can be **NULL**. **RtlUnicodeStringCchCopyNEx** treats **NULL** source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer pointers

cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

STRSAFE_ZERO_LENGTH_ON_FAILURE

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the destination string length is set to zero bytes.

Return Value

RtlUnicodeStringCchCopyNEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, and the strings were concatenated without truncation.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the copy operation did not complete because of insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCchCopyNEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of a **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in *dwFlags*.
- The destination buffer is already full.

- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified in *dwFlags*.
- The destination buffer pointer is **NULL**, but the buffer size is not zero.
- The destination buffer pointer is **NULL**, or its length is zero, but a nonzero length source string is present.
- The *cchToCopy* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCchCopyNEx** function uses the destination buffer's size to ensure that the copy operation does not write past the end of the buffer. By default, the function does not terminate the resultant string with a null character value (that is, with zero). As an option, the caller can use the STRSAFE_FILL_BEHIND flag and a fill byte value of zero to null-terminate a resultant string that does not occupy the entire destination buffer.

RtlUnicodeStringCchCopyNEx adds to the functionality of the RtlUnicodeStringCchCopyN function by returning a UNICODE_STRING structure that identifies the end of the destination string and the number of bytes that are left unused in that string. You can pass flags to **RtlUnicodeStringCchCopyNEx** for additional control.

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString* and *DestinationString* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both of these pointers can be **NULL**. If the *DestinationString* pointer is **NULL**, the *SourceString* pointer must be **NULL** or the **UNICODE_STRING** structure must contain an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

RtlUnicodeStringCchCopyN

UNICODE_STRING

RtlUnicodeStringCchCopyStringN function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringCchCopyStringN** function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCchCopyStringN(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszSrc,
  size_t           cchToCopy
);
```

Parameters

`DestinationString`

A pointer to a **UNICODE_STRING** structure that receives the copied string. The string that the *pszSrc*parameter points to (excluding the terminating **NULL**) is copied into the buffer that the *DestinationString* parameter's **UNICODE_STRING** structure points to. The maximum number of characters in the string is NTSTRSAFE_UNICODE_STRING_MAX_CCH.

`pszSrc`

A pointer to the string to be copied.

`cchToCopy`

The number of characters to be copied from the source to the destination.

Return Value

RtlUnicodeStringCchCopyStringN returns one of the following NTSTATUS.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the copy operation did not complete because of insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.

STA TUS _IN VAL ID_ PAR AM ETE R	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCchCopyStringN returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure are invalid.
- The destination buffer is already full.
- A buffer pointer is **NULL**.
- The destination buffer's length is zero, but a nonzero length source string is present.
- The *cchToCopy* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCchCopyN** function uses the destination buffer's size to ensure that the copy operation does not write past the end of the buffer. The function does not terminate the resultant string with a null character.

If the source and destination strings overlap, the behavior of the function is undefined.

The *pszSrc*and *DestinationString* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use the RtlUnicodeStringCchCopyNEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib

RtlUnicodeStringCchCopyN

RtlUnicodeStringCchCopyNEx

UNICODE_STRING

RtlUnicodeStringCchCopyStringNEx function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlUnicodeStringCchCopyStringNEx** function copies a string into a UNICODE_STRING structure while limiting the size of the copied string.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCchCopyStringNEx(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszSrc,
  size_t           cchToCopy,
  PUNICODE_STRING  RemainingString,
  DWORD            dwFlags
);
```

Parameters

`DestinationString`

Optional. A pointer to a **UNICODE_STRING** structure that receives the copied string. The string that the *pszSrc* parameter points to (excluding the terminating null) is copied into the buffer that the *DestinationString* parameter's **UNICODE_STRING** structure points to. The maximum number of characters in the string is NTSTRSAFE_UNICODE_STRING_MAX_CCH. *DestinationString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`pszSrc`

Optional. A pointer to the string to be copied. This pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`cchToCopy`

The number of characters to be copied from the source to the destination.

`RemainingString`

Optional. If the caller supplies a non-**NULL** pointer to a **UNICODE_STRING** structure, the function sets this structure's **Buffer** member to the end of the concatenated string, sets the structure's **Length** member to zero, and sets the structure's **MaximumLength** member to the number of bytes that are remaining in the destination buffer. *RemainingString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the last character in the string.

STRSAFE_IGNORE_NULLS

If this flag is set, the source or destination pointer, or both, can be **NULL**. **RtlUnicodeStringCchCopyStringNEx** treats **NULL** source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer pointers cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

STRSAFE_ZERO_LENGTH_ON_FAILURE

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the destination string length is set to zero bytes.

Return Value

RtlUnicodeStringCchCopyStringNEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, and the strings were concatenated without truncation.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the copy operation did not complete because of insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCchCopyStringNEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of a **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in *dwFlags*.
- The destination buffer is already full.
- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified in *dwFlags*.
- The destination buffer pointer is **NULL**, but the buffer size is not zero.

- The destination buffer pointer is **NULL**, or its length is zero, but a nonzero length source string is present.
- The *cchToCopy* parameter's value is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCchCopyStringNEx** function uses the destination buffer's size to ensure that the copy operation does not write past the end of the buffer. By default, the function does not terminate the resultant string with a null character value (that is, with zero). As an option, the caller can use the STRSAFE_FILL_BEHIND flag and a fill byte value of zero to null-terminate a resultant string that does not occupy the entire destination buffer.

RtlUnicodeStringCchCopyStringNEx adds to the functionality of the RtlUnicodeStringCchCopyStringN function by returning a UNICODE_STRING structure that identifies the end of the destination string and the number of bytes that are left unused in that string. You can pass flags to **RtlUnicodeStringCchCopyStringNEx** for additional control.

If the source and destination strings overlap, the behavior of the function is undefined.

The *pszSrc* and *DestinationString* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both of these pointers can be **NULL**. If the *DestinationString* pointer is **NULL**, the *pszSrc* pointer must be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available starting with Windows XP with Service Pack 1 (SP1).
Target Platform	Desktop

RtlUnicodeStringCbCopyStringNEx

RtlUnicodeStringCchCopyStringN

UNICODE_STRING

RtlUnicodeStringCopy function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringCopy** function copies a string from one UNICODE_STRING structure to another.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCopy(
  PUNICODE_STRING  DestinationString,
  PCUNICODE_STRING SourceString
);
```

Parameters

`DestinationString`

A pointer to a **UNICODE_STRING** structure. The source string is copied to the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

`SourceString`

A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that contains the source string. This string will be copied to the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).

Return Value

RtlUnicodeStringCopy returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the copy operation did not complete because of insufficient buffer space. The destination buffer contains a truncated version of the source string.

STA TUS _IN VAL ID_ PAR AM ETE R	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCopy returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of a **UNICODE_STRING** structure are invalid.
- The destination buffer is already full.
- A buffer pointer is **NULL**.
- The destination buffer's length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCopy** function uses the destination buffer's size to ensure that the copy operation does not write past the end of the buffer. If the string must be truncated at the end of the destination buffer, the function does not terminate the resultant string with a null character.

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString* and *DestinationString* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use the RtlUnicodeStringCopyEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlUnicodeStringCopyEx

UNICODE_STRING

RtlUnicodeStringCopyEx function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlUnicodeStringCopyEx** function copies a string from one UNICODE_STRING structure to another.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCopyEx(
  PUNICODE_STRING  DestinationString,
  PCUNICODE_STRING SourceString,
  PUNICODE_STRING  RemainingString,
  DWORD            dwFlags
);
```

Parameters

`DestinationString`

Optional. A pointer to a **UNICODE_STRING** structure. The source string is copied to the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR). *DestinationString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`SourceString`

Optional. A pointer to a **UNICODE_STRING** structure. This structure includes a buffer that contains the source string. This string will be copied to the destination string. The maximum number of bytes in the structure's string buffer is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR). *SourceString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`RemainingString`

Optional. If the caller supplies a non-**NULL** pointer to a **UNICODE_STRING** structure, the function sets this structure's **Buffer** member to the end of the copied string, sets the structure's **Length** member to zero, and sets the structure's **MaximumLength** member to the number of bytes that are remaining in the destination buffer. *RemainingString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the last character in the string.

STRSAFE_IGNORE_NULLS

If this flag is set, the source or destination pointer, or both, can be **NULL**. **RtlUnicodeStringCopyEx** treats **NULL** source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer pointers cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

STRSAFE_ZERO_LENGTH_ON_FAILURE

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the destination string length is set to zero bytes.

Return Value

RtlUnicodeStringCopyEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, and the strings were concatenated without truncation.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the copy operation did not complete because of insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCopyEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of a **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in *dwFlags*.
- The destination buffer is already full.
- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified in *dwFlags*.
- The destination buffer pointer is **NULL**, but the buffer size is not zero.
- The destination buffer pointer is **NULL**, or its length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCopyEx** function uses the destination buffer's size to ensure that the concatenation operation does not write past the end of the buffer. By default, the function does not terminate the resultant string with a null character value (that is, with zero). As an option, the caller can use the STRSAFE_FILL_BEHIND flag and a fill byte value of zero to null-terminate a resultant string that does not occupy the entire destination buffer.

RtlUnicodeStringCopyEx adds to the functionality of the RtlUnicodeStringCopy function by returning a UNICODE_STRING structure that identifies the end of the destination string and the number of bytes that are left unused in that string. You can pass flags to **RtlUnicodeStringCopyEx** for additional control.

If the source and destination strings overlap, the behavior of the function is undefined.

The *SourceString* and *DestinationString* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both of these pointers can be **NULL**. If the *DestinationString* pointer is **NULL**, the *SourceString* pointer must be **NULL** or the **UNICODE_STRING** structure must describe an empty string.

For more information about the safe string functions, see Using Safe String Functions.

RtlUnicodeStringCopy

UNICODE_STRING

RtlUnicodeStringCopyString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringCopyString** function copies a string into a UNICODE_STRING structure.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCopyString(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszSrc
);
```

Parameters

`DestinationString`

A pointer to a **UNICODE_STRING** structure that receives the copied string. The string that the *pszSrc*parameter points to (excluding the terminating null) is copied into the buffer that the *DestinationString* parameter's **UNICODE_STRING** structure points to. The maximum number of bytes in the string is NTSTRSAFE_UNICODE_STRING_MAX_CCH * **sizeof**(WCHAR).

`pszSrc`

A pointer to a null-terminated string. This string will be copied into the buffer that the *DestinationString*parameter's **UNICODE_STRING** structure points to.

Return Value

RtlUnicodeStringCopyString returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the copy operation did not complete because of insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.

STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCopyString returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure are invalid.
- The destination buffer is already full.
- A buffer pointer is **NULL**.
- The destination buffer's length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCopyString** function uses the destination buffer's size to ensure that the concatenation operation does not write past the end of the buffer. The function does not terminate the resultant string with a null character.

If the source and destination strings overlap, the behavior of the function is undefined.

The *pszSrc* and *DestinationString* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use the RtlUnicodeStringCopyStringEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

RtlUnicodeStringCopyStringEx

UNICODE_STRING

RtlUnicodeStringCopyStringEx function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlUnicodeStringCopyStringEx** function copies a string into a UNICODE_STRING structure.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringCopyStringEx(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszSrc,
  PUNICODE_STRING  RemainingString,
  DWORD            dwFlags
);
```

Parameters

`DestinationString`

Optional. A pointer to a **UNICODE_STRING** structure that receives the copied string. The string that the *pszSrc* parameter points to (excluding the terminating null) is copied into the buffer that the *DestinationString* parameter's **UNICODE_STRING** structure points to. The maximum number of bytes in the string is NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR). *DestinationString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`pszSrc`

Optional. A pointer to a null-terminated string that will be copied into the buffer that the *DestinationString* parameter's **UNICODE_STRING** structure points to. *pszSrc* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`RemainingString`

Optional. If the caller supplies a non-**NULL** pointer to a **UNICODE_STRING** structure, the function sets this structure's **Buffer** member to the end of the concatenated string, sets the structure's **Length** member to zero, and sets the structure's **MaximumLength** member to the number of bytes that are remaining in the destination buffer. *RemainingString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the last character in the string.

STRSAFE_IGNORE_NULLS

If this flag is set, the source or destination pointer, or both, can be **NULL**. **RtlUnicodeStringCopyStringEx** treats **NULL** source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer pointers cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

STRSAFE_ZERO_LENGTH_ON_FAILURE

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the destination string length is set to zero bytes.

Return Value

RtlUnicodeStringCopyStringEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, and the strings were concatenated without truncation.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the copy operation did not complete because of insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringCopyStringEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of a **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in *dwFlags*.
- The destination buffer is already full.
- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified in *dwFlags*.
- The destination buffer pointer is **NULL**, but the buffer size is not zero.
- The destination buffer pointer is **NULL**, or its length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringCopyStringEx** function uses the destination buffer's size to ensure that the concatenation operation does not write past the end of the buffer. By default, the function does not terminate the resultant string with a null character value (that is, with zero). As an option, the caller can use the STRSAFE_FILL_BEHIND flag and a fill byte value of zero to null-terminate a resultant string that does not occupy the entire destination buffer.

RtlUnicodeStringCopyStringEx adds to the functionality of the RtlUnicodeStringCopyString function by returning a UNICODE_STRING structure that identifies the end of the destination string and the number of bytes that are left unused in that string. You can pass flags to **RtlUnicodeStringCopyStringEx** for additional control.

If the source and destination strings overlap, the behavior of the function is undefined.

The *pszSrc* and *DestinationString* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both of these pointers can be **NULL**. If the *DestinationString* pointer is **NULL**, the *pszSrc* pointer must be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

RtlUnicodeStringCopyString

UNICODE_STRING

RtlUnicodeStringInit function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringInit** function initializes a UNICODE_STRING structure.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringInit(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszSrc
);
```

Parameters

`DestinationString`

A pointer to a **UNICODE_STRING** structure to be initialized. The *pszSrc*pointer is copied into the *DestinationString* parameter's **UNICODE_STRING** structure. The maximum number of characters in the string that *pszSrc* points to is NTSTRSAFE_UNICODE_STRING_MAX_CCH.

`pszSrc`

Optional. A pointer to a null-terminated string constant. This string pointer will be copied to the **Buffer** member of the **UNICODE_STRING** structure pointed to by the *DestinationString* parameter. This string pointer can be **NULL**.

Return Value

RtlUnicodeStringInit returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringInit returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The length of the string that the *pszSrc* parameter points to is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH characters.

- The *DestinationString* pointer is **NULL**, but the *pszSrc* pointer is not **NULL**.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringInit** function does the following:

- Sets the **Length** member of the UNICODE_STRING structure that is pointed to by the *pszSrc* parameter to the length, in bytes, of the string that the *pszSrc* parameter points to.
- Sets the **MaximumLength** member of the **UNICODE_STRING** structure to the length, in bytes, of the string that the *pszSrc* parameter points to plus 2 bytes.
- Sets the **Buffer** member of the **UNICODE_STRING** structure to the address that the *pszSrc* parameter specifies.

The *DestinationString* pointer should not be **NULL**. If you need to specify **NULL** *DestinationString* pointer values, use the RtlUnicodeStringInitEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available starting with Windows XP with Service Pack 1 (SP1).
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlUnicodeStringInitEx

UNICODE_STRING

RtlUnicodeStringInitEx function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringInitEx** function initializes a UNICODE_STRING structure.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringInitEx(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszSrc,
  DWORD            dwFlags
);
```

Parameters

`DestinationString`

Optional. A pointer to a **UNICODE_STRING** structure to be initialized. The *pszSrc* pointer is copied into the *DestinationString* parameter's **UNICODE_STRING** structure. The maximum number of characters in the string that *pszSrc* points to is NTSTRSAFE_UNICODE_STRING_MAX_CCH. *DestinationString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`pszSrc`

Optional. A pointer to a null-terminated string constant. This string pointer will be copied to the **Buffer** member of the **UNICODE_STRING** structure pointed to by the *DestinationString* parameter. This string pointer can be **NULL**.

`dwFlags`

The following flag is defined:

STRSAFE_IGNORE_NULLS

If this flag is set, the source pointer can be **NULL**. **RtlUnicodeStringInitEx** treats **NULL** source buffer pointers like empty strings (TEXT("")), which can be copied.

Return Value

RtlUnicodeStringInitEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STA **TUS** **_SU** **CCE** **SS**	This *success* status means that source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.

STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringInitEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The length of the string that the *pszSrc* parameter points to is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH characters.
- The *DestinationString* pointer is **NULL**, but the *pszSrc* pointer is not **NULL**.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringInitEx** function does the following:

- Sets the **Length** member of the UNICODE_STRING structure to the length, in bytes, of the string that the *pszSrc* parameter points to.
- Sets the **MaximumLength** member of the **UNICODE_STRING** structure to the length, in bytes, of the string that the *pszSrc* parameter points to plus 2 bytes.
- Sets the **Buffer** member of the **UNICODE_STRING** structure to the address that the *pszSrc* parameter specifies.

The *DestinationString* pointer cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available starting with Windows XP with Service Pack 1 (SP1).
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)

RtlUnicodeStringInit

UNICODE_STRING

RtlUnicodeStringPrintf function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringPrintf** function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringPrintf(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszFormat,
  ...
);
```

Parameters

`DestinationString`

A pointer to a **UNICODE_STRING** structure that receives a formatted string. **RtlUnicodeStringPrintf** creates this string from the formatting string that *pszFormat* specifies and the function's argument list. The maximum number of characters in the string is NTSTRSAFE_UNICODE_STRING_MAX_CCH.

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives.

`arg3`

Return Value

RtlUnicodeStringPrintf returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the operation did not complete because of insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.

STA TUS _IN VAL ID_ PAR AM ETE R	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringPrintf returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure that the *DestinationString* parameter points to are invalid.
- The destination buffer is already full.
- A **NULL** pointer is present.
- The destination buffer's length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringPrintf** function uses the destination buffer's size to ensure that the string formatting operation does not write past the end of the buffer. The function does not terminate the resultant string with a null character.

If the format string and destination string overlap, the behavior of the function is undefined.

The *pszFormat* and *DestinationString* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use the RtlUnicodeStringPrintfEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlUnicodeStringPrintfEx

RtlUnicodeStringVPrintf

RtlUnicodeStringVPrintfEx

RtlUnicodeStringPrintfEx function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlUnicodeStringPrintfEx** function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringPrintfEx(
  PUNICODE_STRING  DestinationString,
  PUNICODE_STRING  RemainingString,
  DWORD            dwFlags,
  NTSTRSAFE_PCWSTR pszFormat,
  ...
);
```

Parameters

`DestinationString`

Optional. A pointer to a **UNICODE_STRING** structure that receives a formatted string. **RtlUnicodeStringPrintfEx** creates this string from both the formatting string that *pszFormat* specifies and the function's argument list. The maximum number of characters in the string is NTSTRSAFE_UNICODE_STRING_MAX_CCH. *DestinationString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`RemainingString`

Optional. If the caller supplies a non-**NULL** pointer to a **UNICODE_STRING** structure, **RtlUnicodeStringPrintfEx** sets this structure's **Buffer** member to the end of the formatted string, sets the structure's **Length** member to zero, and sets the structure's **MaximumLength** member to the number of bytes that are remaining in the destination buffer. *RemainingString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the last character in the string.

STRSAFE_IGNORE_NULLS

If this flag is set, the source or destination pointer, or both, can be **NULL**. **RtlUnicodeStringPrintfEx** treats **NULL** source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer pointers cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation

overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

STRSAFE_ZERO_LENGTH_ON_FAILURE

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the destination string length is set to zero bytes.

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives. This pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`arg5`

Return Value

RtlUnicodeStringPrintfEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, and the strings were concatenated without truncation.
STATUS_BUFFER_OVERFLOW	This *warning* status means that the operation did not complete because of insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringPrintfEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of a **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in *dwFlags*.
- The destination buffer is already full.
- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified in *dwFlags*.
- The destination buffer pointer is **NULL**, but the buffer size is not zero.

- The destination buffer pointer is **NULL**, or its length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringPrintfEx** function uses the destination buffer's size to ensure that the string formatting operation does not write past the end of the buffer. By default, the function does not terminate the resultant string with a null character value (that is, with zero). As an option, the caller can use the STRSAFE_FILL_BEHIND flag and a fill byte value of zero to null-terminate a resultant string that does not occupy the entire destination buffer.

RtlUnicodeStringPrintfEx adds to the functionality of the RtlUnicodeStringPrintf function by returning a UNICODE_STRING structure that identifies the end of the destination string and the number of bytes that are left unused in that string. You can pass flags to **RtlUnicodeStringPrintfEx** for additional control.

If the format string and the destination string overlap, the behavior of the function is undefined.

The *pszFormat* and *DestinationString* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both of these pointers can be **NULL**. If the *DestinationString* pointer is **NULL**, the *pszFormat* pointer must either be **NULL** or point to an empty string.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available starting with Windows XP with Service Pack 1 (SP1).
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlUnicodeStringVPrintfEx

UNICODE_STRING

RtlUnicodeStringValidate function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringValidate** function validates the contents of a UNICODE_STRING structure.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringValidate(
  PCUNICODE_STRING SourceString
);
```

Parameters

`SourceString`

A pointer to a **UNICODE_STRING** structure to be validated.

Return Value

RtlUnicodeStringValidate returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that the function completed successfully.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

RtlUnicodeStringValidate returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- *SourceString*->**Length** % sizeof(WCHAR) does not equal zero.
- *SourceString*->**MaximumLength** % sizeof(WCHAR) does not equal zero.
- *SourceString*->**Length** is greater than *SourceString*->**MaximumLength**.
- *SourceString*->**MaximumLength** is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).
- *SourceString*->**Buffer** equals **NULL** but *SourceString*->**Length** or *SourceString*->**MaximumLength** does not equal zero.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The *SourceString* pointer cannot be **NULL**. If you need to specify a **NULL** pointer value, use the RtlUnicodeStringValidateEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib
IRQL	PASSIVE_LEVEL

RtlUnicodeStringValidateEx

UNICODE_STRING

RtlUnicodeStringValidateEx function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringValidateEx** function validates the contents of a UNICODE_STRING structure.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringValidateEx(
  PCUNICODE_STRING SourceString,
  DWORD            dwFlags
);
```

Parameters

`SourceString`

Optional. A pointer to a **UNICODE_STRING** structure to be validated. This pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`dwFlags`

The following flag is defined:

STRSAFE_IGNORE_NULLS

If this flag is set, the source pointer can be **NULL**. **RtlUnicodeStringValidateEx** treats **NULL** source buffer pointers like empty strings (TEXT("")).

Return Value

RtlUnicodeStringValidateEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means that the function completed successfully.
STATUS_INVALID_PARAMETER	This *error* status means that the function received an invalid input parameter. For more information, see the following list.

If STRSAFE_IGNORE_NULLS is not set in dwFlags, **RtlUnicodeStringValidateEx** returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- *SourceString*->**Length** % sizeof(WCHAR) does not equal zero.
- *SourceString*->**MaximumLength** % sizeof(WCHAR) does not equal zero.
- *SourceString*->**Length** is greater than *SourceString*->**MaximumLength**.
- *SourceString*->**MaximumLength** is greater than NTSTRSAFE_UNICODE_STRING_MAX_CCH * sizeof(WCHAR).
- *SourceString*->**Buffer** equals **NULL** but *SourceString*->Length or *SourceString*->**MaximumLength** does not equal zero.
- An invalid flag is specified for *dwFlags*.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The *SourceString* pointer cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.

RtlUnicodeStringValidate

UNICODE_STRING

RtlUnicodeStringVPrintf function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringVPrintf** function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringVPrintf(
  PUNICODE_STRING  DestinationString,
  NTSTRSAFE_PCWSTR pszFormat,
  va_list          argList
);
```

Parameters

`DestinationString`

A pointer to a **UNICODE_STRING** structure that receives a formatted string. **RtlUnicodeStringVPrintf** creates this string from the formatting string that *pszFormat* specifies and the function's argument list. The maximum number of characters in the string is NTSTRSAFE_UNICODE_STRING_MAX_CCH.

`pszFormat`

A pointer to a null-terminated text string that contains **printf**-styled formatting directives.

`argList`

A **va_list**-typed argument list. Arguments in this argument list will be interpreted by using the formatting string that *pszFormat* specifies.

Return Value

RtlUnicodeStringVPrintf returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, the string was copied without truncation, and the resultant destination buffer is null-terminated.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient buffer space. The destination buffer contains a truncated, null-terminated version of the intended result.

STA TUS _IN VAL ID_ PAR AM ETE R	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph.

RtlUnicodeStringVPrintf returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of the **UNICODE_STRING** structure that *DestinationString* points to are invalid.
- The destination buffer is already full.
- A **NULL** pointer is present.
- The destination buffer's length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringVPrintf** function uses the destination buffer's size to ensure that the string formatting operation does not write past the end of the buffer. The function does not terminate the resultant string with a null character.

If the format string and destination string overlap, the behavior of the function is undefined.

The *pszFormat* and *DestinationString* pointers cannot be **NULL**. If you need to handle **NULL** pointer values, use the RtlUnicodeStringVPrintfEx function.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available in Windows XP with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Desktop
Header	ntstrsafe.h (include Ntstrsafe.h)
Library	Ntstrsafe.lib

IRQL	PASSIVE_LEVEL

RtlUnicodeStringPrintf

RtlUnicodeStringPrintfEx

RtlUnicodeStringVPrintfEx

UNICODE_STRING

RtlUnicodeStringVPrintfEx function

1/25/2019 • 4 minutes to read • Edit Online

The **RtlUnicodeStringVPrintfEx** function creates a text string, with formatting that is based on supplied formatting information, and stores the string in a UNICODE_STRING structure.

Syntax

```
NTSTRSAFEDDI RtlUnicodeStringVPrintfEx(
  PUNICODE_STRING  DestinationString,
  PUNICODE_STRING  RemainingString,
  DWORD            dwFlags,
  NTSTRSAFE_PCWSTR pszFormat,
  va_list          argList
);
```

Parameters

`DestinationString`

Optional. A pointer to a **UNICODE_STRING** structure that receives a formatted string. **RtlUnicodeStringVPrintfEx** creates this string from the formatting string that *pszFormat* supplies and the function's argument list. The maximum number of characters in the string is NTSTRSAFE_UNICODE_STRING_MAX_CCH. *DestinationString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`RemainingString`

Optional. If the caller supplies a non-**NULL** pointer to a **UNICODE_STRING** structure, **RtlUnicodeStringVPrintfE** sets this structure's **Buffer** member to the end of the formatted string, sets the structure's **Length** member to zero, and sets the structure's **MaximumLength** member to the number of bytes that are remaining in the destination buffer. *RemainingString* can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`dwFlags`

One or more flags and, optionally, a fill byte. The flags are defined as follows:

STRSAFE_FILL_BEHIND

If this flag is set and the function succeeds, the low byte of *dwFlags* is used to fill the portion of the destination buffer that follows the last character in the string.

STRSAFE_IGNORE_NULLS

If this flag is set, the source or destination pointer, or both, can be **NULL**. **RtlUnicodeStringVPrintfEx** treats **NULL** source buffer pointers like empty strings (TEXT("")), which can be copied. **NULL** destination buffer pointers cannot receive nonempty strings.

STRSAFE_FILL_ON_FAILURE

If this flag is set and the function fails, the low byte of *dwFlags* is used to fill the entire destination buffer. This operation overwrites any preexisting buffer contents.

STRSAFE_NULL_ON_FAILURE

If this flag is set and the function fails, the destination buffer is set to an empty string (TEXT("")). This operation

overwrites any preexisting buffer contents.

STRSAFE_NO_TRUNCATION

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the contents of the destination buffer are not modified.

STRSAFE_ZERO_LENGTH_ON_FAILURE

If this flag is set and the function returns STATUS_BUFFER_OVERFLOW, the destination string length is set to zero bytes.

`pszFormat`

A pointer to a nul-terminated text string that contains **printf**-styled formatting directives. This pointer can be **NULL**, but only if STRSAFE_IGNORE_NULLS is set in *dwFlags*.

`argList`

A **va_list**-typed argument list. Arguments in this argument list will be interpreted by the using formatting string that *pszFormat* supplies.

Return Value

RtlUnicodeStringVPrintfEx returns one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	This *success* status means source data was present, and the strings were concatenated without truncation.
STATUS_BUFFER_OVERFLOW	This *warning* status means the copy operation did not complete due to insufficient space in the destination buffer. If STRSAFE_NO_TRUNCATION is set in *dwFlags*, the destination buffer is not modified. If the flag is not set, the destination buffer contains a truncated version of the copied string.
STATUS_INVALID_PARAMETER	This *error* status means the function received an invalid input parameter. For more information, see the following paragraph.

RtlUnicodeStringVPrintfEx returns the STATUS_INVALID_PARAMETER value when one of the following occurs:

- The contents of a **UNICODE_STRING** structure are invalid.
- An invalid flag is specified in *dwFlags*.

- The destination buffer is already full.
- A buffer pointer is **NULL** and the STRSAFE_IGNORE_NULLS flag is not specified in *dwFlags*.
- The destination buffer pointer is **NULL**, but the buffer size is not zero.
- The destination buffer pointer is **NULL**, or its length is zero, but a nonzero length source string is present.

For information about how to test NTSTATUS values, see Using NTSTATUS Values.

Remarks

The **RtlUnicodeStringVPrintfEx** function uses the destination buffer's size to ensure that the string formatting operation does not write past the end of the buffer. By default, the function does not terminate the resultant string with a null character value (that is, with zero). As an option, the caller can use the STRSAFE_FILL_BEHIND flag and a fill byte value of zero to null-terminate a resultant string that does not occupy the entire destination buffer.

RtlUnicodeStringVPrintfEx adds to the functionality of the RtlUnicodeStringVPrintf function by returning a UNICODE_STRING structure that identifies the end of the destination string and the number of bytes that are left unused in that string. You can pass flags to **RtlUnicodeStringVPrintfEx** for additional control.

If the format string and the destination string overlap, the behavior of the function is undefined.

The *pszFormat* and *DestinationString* pointers cannot be **NULL** unless the STRSAFE_IGNORE_NULLS flag is set in *dwFlags*. If STRSAFE_IGNORE_NULLS is set, one or both of these pointers can be **NULL**. If the *DestinationString* pointer is **NULL**, the *pszFormat* pointer must be **NULL** or point to an empty string.

For more information about **va_list**-typed argument lists, see the Microsoft Windows SDK documentation.

For more information about the safe string functions, see Using Safe String Functions.

Requirements

Minimum supported client	Available starting with Windows XP with Service Pack 1 (SP1).

UNICODE_STRING

pcivirt.h header

1/8/2019 • 8 minutes to read • Edit Online

Reference guide for using interfaces used exposing VFs to a Virtual Machine.

Devices that conform to the PCI Express Single-Root I/O Virtualization (SR-IOV) specification can provide multiple interfaces to the device. These interfaces, known as Virtual Functions (VFs), are independent and are provided through the initial device interface, known as the Physical Function (PF). For example, an Ethernet NIC that supports SR-IOV can be designed to have a switch with one physical Ethernet port (connected to the physical wire) and many virtual Ethernet ports.

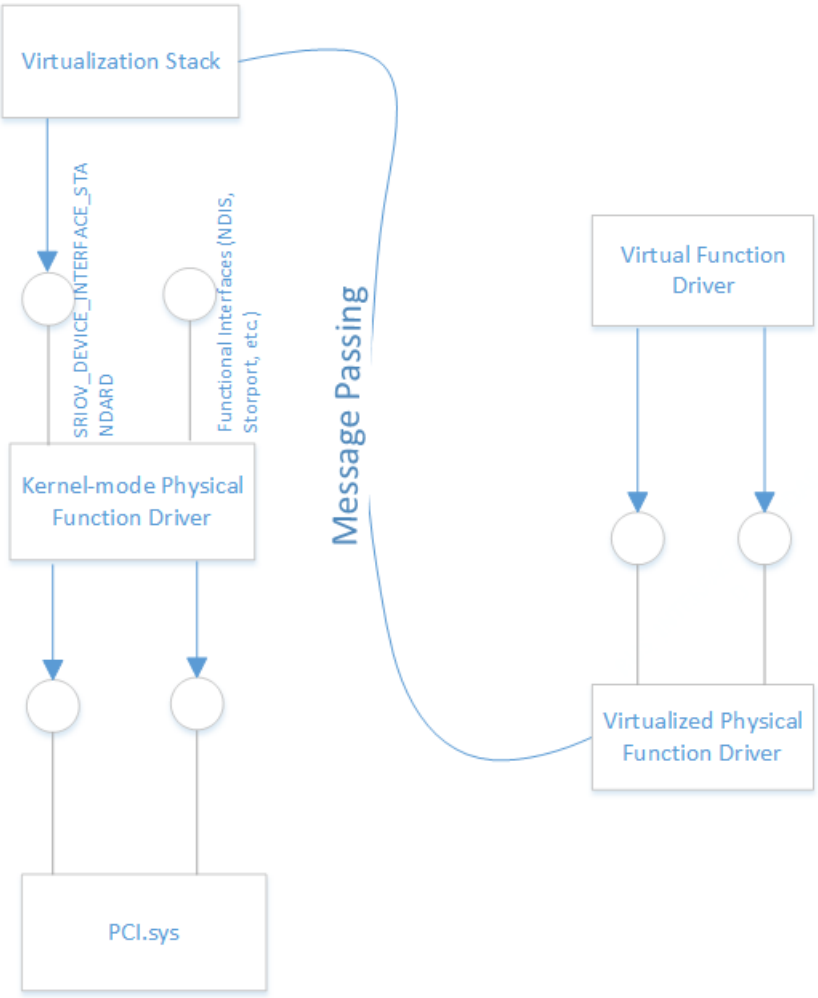
The PF's configuration space allows the PF driver to manage the VF's PCI resources, including memory-mapped I/O space and message-signaled interrupts. Since VFs are a subset of a complete device, they can be less expensive to expose in hardware than a traditional function in a multi-function package. This allows the device maker to build more interfaces, and to manage any shared resources centrally.

When Windows is running directly on the machine hardware, the device drivers participate in operations related to Plug and Play, power management, interrupt management and other tasks. A trusted Windows bus driver and Hardware Abstraction Layer (HAL) own bus configuration and configure the entire bus. The driver runs within the same privilege level and there are no trust boundaries in kernel mode.

When Windows is running on a virtual machine (VM), those assumptions do not apply. VFs can be put under the control of a non-privileged VM. However, the hardware must be security checked so that the security or performance of the system is not impacted.

When a driver running on the VF requests a configuration space read or write, the request is received by the virtualization stack and sent to the SR-IOV device's PF driver. It is the responsibility of the PF driver to respond to those requests and provide details for the VF. The PF driver may occasionally require that a configuration read or write request that is passed down to the hardware.

The stack uses an I/O MMU to differentiate traffic coming from the various interfaces that the device exposes, enforcing policy about which regions of memory a device can access and which interrupts it can generate.



Hardware requirements

The system to be used for SR-IOV device assignment must meet the requirements for SR-IOV networking and Direct Device Assignment. The system must have a IOMMU, that IOMMU must be configured to give control of devices over to the operating system, and PCIe ACS (Access Control Services) must be enabled and configured for use by the operating system. Finally, the device in question must not use line based interrupts, and must not require ATS (Address Translation Services).

More information here:

Everything you wanted to know about SR-IOV in Hyper-V. Part 1

Discrete Device Assignment — Description and background

To determine if a system supports device assignement, and if a particular PCI device will work for device assignment:

Discrete Device Assignment script

Querying for SR-IOV devices

GUID_DEVINTERFACE_VIRTUALIZABLE_DEVICE is a device class interface that is provided by drivers for SR-IOV devices. This GUID provides a way to query for all the device stacks which expose the various function tables that are used to manage the virtualization-related features of the device. After the driver registers the GUID, individual capabilities are discovered by sending IRP_MN_QUERY_INTERFACE. The driver must respond to that request with GUID_SRIOV_DEVICE_INTERFACE_STANDARD. Drivers must also handle IOCTL_SRIOV_NOTIFICATION and IOCTL_SRIOV_EVENT_COMPLETE.

A driver for an SR_IOV device, which runs in a privileged VM is the host OS. It owns Plug-and-Play and power

management for a entire machine, and exposes PCI Express SR-IOV Virtual Functions in non-privileged VMs, must provide the GUID_SRIOV_DEVICE_INTERFACE_STANDARD (defined in the header Pcivirt.h). That driver might be PCI Express SR-IOV Physical Function (PF) driver that creates the FDO, or it might be a lower filter on that device node in the case when the FDO is being managed by a port driver.

The device interface is required so that the driver can access the configuration space of the VFs.

In the PF driver's EVT_WDF_DRIVER_DEVICE_ADD implementation, perform these tasks:

- After calling WdfDeviceCreate to create the function device object (FDO), call WdfDeviceCreateDeviceInterface to register GUID_DEVINTERFACE_VIRTUALIZABLE_DEVICE. This allows the virtualization stack to retrieve a device handle to the SR-IOV device.
- Expose the GUID_SRIOV_DEVICE_INTERFACE_STANDARD.
    - Initialize a SRIOV_DEVICE_INTERFACE_STANDARD structure and set members to function pointers of the callback functions implemented by the PF driver.
    - Configure the structure by calling WDF_QUERY_INTERFACE_CONFIG_INIT.
    - Register the interface with the FDO by calling WdfDeviceAddQueryInterface.

```
    // Make the device visible as an assignable device.
    //
    status = WdfDeviceCreateDeviceInterface(
        fdo,
        &GUID_DEVINTERFACE_VIRTUALIZABLE_DEVICE,
        NULL);
    if (!NT_SUCCESS(status))
    {
        TraceEvents(TRACE_LEVEL_ERROR, DBG_INIT,
                    "Failed to create interface: %!STATUS!",
                    status);
        goto Cleanup;
    }

    //
    // Expose SRIOV_DEVICE_INTERFACE_STANDARD
    //
    RtlZeroMemory(&sriovInterface, sizeof(sriovInterface));
    sriovInterface.Size = sizeof(sriovInterface);
    sriovInterface.Version = 1;
    sriovInterface.Context = deviceContext;
    sriovInterface.InterfaceReference = Virtualization_ReferenceInterface;
    sriovInterface.InterfaceDereference = Virtualization_DereferenceInterface;
    sriovInterface.ReadVfConfig = Virtualization_ReadConfig;
    sriovInterface.WriteVfConfig = Virtualization_WriteConfig;
    sriovInterface.ReadVfConfigBlock = Virtualization_ReadBlock;
    sriovInterface.WriteVfConfigBlock = Virtualization_WriteBlock;
    sriovInterface.ResetVf = Virtualization_ResetFunction;
    sriovInterface.SetVfPowerState = Virtualization_SetPowerState;
    sriovInterface.GetDeviceLocation = Virtualization_GetDeviceLocation;
    sriovInterface.GetVendorAndDevice = Virtualization_GetVendorAndDevice;
    sriovInterface.QueryProbedBars = Virtualization_QueryProbedBars;
    sriovInterface.QueryLuid = Virtualization_QueryLuid;

    WDF_QUERY_INTERFACE_CONFIG_INIT(&qiConfig,
                                    (PINTERFACE)&sriovInterface,
                                    &GUID_SRIOV_DEVICE_INTERFACE_STANDARD,
                                    NULL);

    status = WdfDeviceAddQueryInterface(fdo, &qiConfig);

    if (!NT_SUCCESS(status))
    {
        TraceEvents(TRACE_LEVEL_ERROR, DBG_INIT,
                    "WdfDeviceAddQueryInterface failed: %!STATUS!\n",
                    status);
        goto Cleanup;
    }
```

Handling Plug and Play events

The virtualization stack is responsible for sending the appropriate messages to the VM, waiting for the reply (with a timeout) and in case of non-responding VM, and applying appropriate action such as vetoing the PnP event, or surprise-removing the device from the non-privileged VM. PF drivers that implement GUID_DEVINTERFACE_VIRTUALIZABLE_DEVICE must also handle these I/O control requests that allow the virtualization stack to react to PnP events.

- The virtualization stack first sends IOCTL_SRIOV_ATTACH to the device. This notifies the device that the virtualization stack needs to be notified about certain PnP events.
- This is in effect until the virtualization stack sends IOCTL_SRIOV_DETACH.
- The virtualization stack queries the devices about PnP events by sending IOCTL_SRIOV_NOTIFICATION

requests. The PF driver can inform the virtualization stack of a PnP event by completing the IOCTL_SRIOV_NOTIFICATION request.

- The virtualization stack unblocks those events by sending IOCTL_SRIOV_EVENT_COMPLETE. pcivirt.h contains the following programming interfaces:

IOCTLs

TITLE	DESCRIPTION
IOCTL_SRIOV_ATTACH	The request indicates that the virtualization stack wants to register for Plug and Play events received by the SR-IOV device.
IOCTL_SRIOV_DETACH	The request indicates that the virtualization stack wants to unregister for Plug and Play events (previously registered through the IOCTL_SRIOV_ATTACH request).
IOCTL_SRIOV_EVENT_COMPLETE	The request indicates that the virtualization stack or the SR-IOV device received one of the events listed in SRIOV_PF_EVENT.
IOCTL_SRIOV_INVALIDATE_BLOCK	The IOCTL_SRIOV_INVALIDATE_BLOCK request indicates that the virtualization stack wants to reset the contents of the specified configuration block.
IOCTL_SRIOV_MITIGATED_RANGE_UPDATE	The IOCTL_SRIOV_MITIGATED_RANGE_UPDATE request indicates that the virtualization stack wants to update to the mitigation ranges.
IOCTL_SRIOV_NOTIFICATION	The request indicates that the virtualization stack wants to be notified when one of the events listed in SRIOV_PF_EVENT occurs.
IOCTL_SRIOV_PROXY_QUERY_LUID	This request supplies the local unique identifier of the SR_IOV device implementing the interface.
IOCTL_SRIOV_QUERY_MITIGATED_RANGE_COUNT	The request determines the ranges of memory-mapped I/O space that must mitigated.
IOCTL_SRIOV_QUERY_MITIGATED_RANGES	The request determines the specific ranges on which intercepts must be placed.

Callback functions

TITLE	DESCRIPTION
READ_WRITE_MITIGATED_REGISTER	Reads or writes to mitigated address spaces.
SRIOV_GET_DEVICE_LOCATION	Retrieves information about the current location of the PCI device on the bus, such as PCI Segment, Bus, Device and Function number.
SRIOV_GET_MMIO_REQUIREMENTS	This callback function is not supported.

TITLE	DESCRIPTION
SRIOV_GET_RESOURCE_FOR_BAR	Gets the translated resource for a specific Base Address Register (BAR).
SRIOV_GET_VENDOR_AND_DEVICE_IDS	Supplies the Vendor and Device ID for a PCI Express SR-IOV Virtual Function (VF) to be used for generating a more generic Plug and Play ID for the VF. These IDs cannot be read directly from the VF's configuration space.
SRIOV_QUERY_LUID	Gets the local unique identifier of the SR-IOV device.
SRIOV_QUERY_LUID_VF	Gets the PCI Express SR-IOV Virtual Function (VF) given a unique identifier.
SRIOV_QUERY_PROBED_BARS	Queries the data read from the physical function's (PF) base address registers (BARs) if the value -1 were written to them first.
SRIOV_QUERY_PROBED_BARS_2	Queries the data read from the specified PCI Express SR-IOV Virtual Function (VF) base address registers (BARs) if the value -1 were written to them first.
SRIOV_QUERY_VF_LUID	Gets the local unique identifier of the PCI Express SR-IOV Virtual Function (VF).
SRIOV_READ_BLOCK	Reads data from the specified configuration block of a PCI Express SR-IOV Virtual Function (VF).
SRIOV_READ_CONFIG	Reads data from the configuration space of the specified PCI Express SR-IOV Virtual Function (VF).
SRIOV_RESET_FUNCTION	Resets the specified PCI Express SR-IOV Virtual Function (VF).
SRIOV_SET_POWER_STATE	Sets the power state of the specified PCI Express SR-IOV Virtual Function (VF).
SRIOV_WRITE_BLOCK	Writes data to the specified configuration block of a PCI Express SR-IOV Virtual Function (VF).
SRIOV_WRITE_CONFIG	Writes configuration data to a PCI Express SR-IOV Virtual Function (VF).

Structures

TITLE	DESCRIPTION
MITIGABLE_DEVICE_INTERFACE	Stores function pointers to callback functions implemented by the physical function (PF) driver for the mitigable device interface.
SRIOV_DEVICE_INTERFACE_STANDARD	Stores function pointers to callback functions implemented by the physical function (PF) driver in the device stack for the of the SR-IOV device.

TITLE	DESCRIPTION
SRIOV_DEVICE_INTERFACE_STANDARD_2	Stores function pointers to callback functions implemented by the physical function (PF) driver in the device stack for the of the SR-IOV device. This is an extended version of SRIOV_DEVICE_INTERFACE_STANDARD.
SRIOV_INVALIDATE_BLOCK	Contains the configuration block information. This structure is used in a IOCTL_SRIOV_INVALIDATE_BLOCK request.
SRIOV_MITIGATED_RANGE_COUNT_INPUT	This structure is used as an input buffer to the IOCTL_SRIOV_QUERY_MITIGATED_RANGE_COUNT request to determine the ranges of memory-mapped I/O space that must be mitigated.
SRIOV_MITIGATED_RANGE_COUNT_OUTPUT	This structures is the output buffer received by the IOCTL_SRIOV_QUERY_MITIGATED_RANGE_COUNT request that contains an array of ranges of memory-mapped I/O space that must be mitigated.
SRIOV_MITIGATED_RANGE_UPDATE_INPUT	This structure is used as an input buffer to the IOCTL_SRIOV_MITIGATED_RANGE_UPDATE request to indicate the virtual function (VF) whose memory-mapped I/O space that must be mitigated.
SRIOV_MITIGATED_RANGE_UPDATE_OUTPUT	This structures is the output buffer received by the IOCTL_SRIOV_MITIGATED_RANGE_UPDATE request that indicates the virtual function (VF) whose memory-mapped I/O space was mitigated.
SRIOV_MITIGATED_RANGES_INPUT	This structure is the input buffer in the IOCTL_SRIOV_QUERY_MITIGATED_RANGES request to get the specific ranges on which intercepts must be placed.
SRIOV_MITIGATED_RANGES_OUTPUT	This structure is the output buffer received by the IOCTL_SRIOV_QUERY_MITIGATED_RANGES request to get the specific ranges on which intercepts must be placed.
SRIOV_PNP_EVENT_COMPLETE	Stores the status for an event that the SR-IOV Physical Function (PF) driver should set for Plug and Play even completion. This structure is used in the input buffer of the IOCTL_SRIOV_EVENT_COMPLETE request.
SRIOV_PROXY_QUERY_LUID_OUTPUT	Stores the local unique identifier of the SR_IOV device implementing the interface. This structure is the output buffer for the IOCTL_SRIOV_PROXY_QUERY_LUID request.

Enumerations

TITLE	DESCRIPTION
SRIOV_PF_EVENT	Defines event values for the SR-IOV device.

pep_x.h header

1/8/2019 • 15 minutes to read • Edit Online

This header contains programming interfaces used by the Power Engine Plugins (PEPs). For more information, see:

- Platform Extension Plug-ins (PEPs) pep_x.h contains the following programming interfaces:

Functions

TITLE	DESCRIPTION
PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE	The PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_EXTENDED_ADDRESS structure.
PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE	The PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_EXTENDED_ADDRESS structure.
PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE	The PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_GPIO_RESOURCE structure.
PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE	The PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_GPIO_RESOURCE structure.
PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE	The PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_INTERRUPT_RESOURCE structure.
PEP_ACPI_INITIALIZE_IOPORT_RESOURCE	The PEP_ACPI_INITIALIZE_IOPORT_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_IO_MEMORY_RESOURCE structure.
PEP_ACPI_INITIALIZE_MEMORY_RESOURCE	The PEP_ACPI_INITIALIZE_MEMORY_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_IO_MEMORY_RESOURCE structure.
PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE	The PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_I2C_RESOURCE structure.
PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE	The PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_SPI_RESOURCE structure.
PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE	The PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_UART_RESOURCE structure.

TITLE	DESCRIPTION
PoFxRegisterCoreDevice	The PoFxRegisterCoreDevice routine registers a new core system resource with the Windows power management framework (PoFx).
PoFxRegisterPlugin	The PoFxRegisterPlugin routine registers a platform extension plug-in (PEP) with the Windows power management framework (PoFx).
PoFxRegisterPluginEx	The PoFxRegisterPluginEx routine registers a platform extension plug-in (PEP) with the Windows power management framework (PoFx).

Callback functions

TITLE	DESCRIPTION
PEPCALLBACKNOTIFYACPI	An AcceptAcpiNotification event callback routine handles ACPI notifications from the Windows power management framework (PoFx).
PEPCALLBACKNOTIFYDPM	An AcceptDeviceNotification event callback routine handles device power management (DPM) notifications from the Windows power management framework (PoFx).
PEPCALLBACKNOTIFYPPM	An AcceptProcessorNotification event callback routine handles processor power management (PPM) notifications from the Windows power management framework (PoFx).
PEPCALLBACKPOWERONCRASHDUMPDEVICE	The PowerOnDumpDeviceCallback callback routine turns on the crash-dump device.
POFXCALLBACKCRITICALRESOURCE	The TransitionCriticalResource routine changes the active/inactive state of a core system component.
POFXCALLBACKENUMERATEUNMASKEDINTERRUPTS	The EnumerateUnmaskedInterrupts routine enumerates interrupt sources whose interrupts are unmasked and enabled.
POFXCALLBACKPLATFORMIDLEVETO	The PlatformIdleVeto routine increments or decrements the veto count for a veto code for a platform idle state.
POFXCALLBACKPROCESSORHALT	The ProcessorHalt routine prepares the processor to be halted.
POFXCALLBACKPROCESSORIDLEVETO	The ProcessorIdleVeto routine increments or decrements the veto count for a veto code for a processor idle state.
POFXCALLBACKREQUESTCOMMON	The RequestCommon routine is a generic request handler.
POFXCALLBACKREQUESTINTERRUPT	The RequestInterrupt routine requests that the operating system replay an edge-triggered interrupt that might have been lost while the hardware platform was in a low-power state.

TITLE	DESCRIPTION
POFXCALLBACKREQUESTWORKER	The RequestWorker routine is called by a platform extension plug-in (PEP) to inform the Windows power management framework (PoFx) that the platform extension plug-in (PEP) has a work request to submit on behalf of the specified device.
POFXCALLBACKUPDATEPLATFORMIDLESTATE	The UpdatePlatformIdleState routine is called by the platform extension plug-in (PEP) to update the properties of the specified platform idle state.
POFXCALLBACKUPDATEPROCESSORIDLESTATE	The UpdateProcessorIdleState routine is called by the platform extension plug-in (PEP) to update the properties of the specified processor idle state.
PPO_ENUMERATE_INTERRUPT_SOURCE_CALLBACK	An EnumerateInterruptSource callback routine supplies a platform extension plug-in (PEP) with information about an interrupt source.

Structures

TITLE	DESCRIPTION
PEP_ABANDON_DEVICE	The PEP_ABANDON_DEVICE structure identifies a device that has been abandoned and will no longer be used by the operating system.
PEP_ACPI_ABANDON_DEVICE	The PEP_ACPI_ABANDON_DEVICE structure indicates whether the platform extension plug-in (PEP) accepts ownership of an abandoned device.
PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE	The PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE structure contains an enumeration of the objects in the namespace of the device.
PEP_ACPI_EVALUATE_CONTROL_METHOD	The PEP_ACPI_EVALUATE_CONTROL_METHOD structure specifies an ACPI control method to evaluate, an input argument to supply to this method, and an output buffer for the result of the evaluation.
PEP_ACPI_EXTENDED_ADDRESS	The PEP_ACPI_EXTENDED_ADDRESS structure is used to report resource usage in the address space such as memory and IO.
PEP_ACPI_GPIO_RESOURCE	The PEP_ACPI_GPIO_RESOURCE structure describes the ACPI configuration for a general purpose input/output (GPIO) resource.
PEP_ACPI_INTERRUPT_RESOURCE	The PEP_ACPI_INTERRUPT_RESOURCE structure describes an ACPI interrupt resource.
PEP_ACPI_IO_MEMORY_RESOURCE	The PEP_ACPI_IO_MEMORY_RESOURCE structure describes an ACPI IO port descriptor resource.
PEP_ACPI_OBJECT_NAME	The PEP_ACPI_OBJECT_NAME union contains the four-character name of an ACPI object.

TITLE	DESCRIPTION
PEP_ACPI_OBJECT_NAME_WITH_TYPE	The PEP_ACPI_OBJECT_NAME_WITH_TYPE structure that specifies both the path-relative name of an ACPI object and the type of this object.
PEP_ACPI_PREPARE_DEVICE	The PEP_ACPI_PREPARE_DEVICE structure indicates whether a platform extension plug-in (PEP) is prepared to provide ACPI services for the specified device.
PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES	The PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES structure contains a list of raw resources that are needed to control power to the device.
PEP_ACPI_QUERY_OBJECT_INFORMATION	The PEP_ACPI_QUERY_OBJECT_INFORMATION structure contains information about an ACPI object.
PEP_ACPI_REGISTER_DEVICE	The PEP_ACPI_REGISTER_DEVICE structure contains registration information about a device for which the platform extension plug-in (PEP) is to provide ACPI services.
PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES	The PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES structure is used in the process of converting ACPI resources to BIOS resources by one of the PEP initialization functions.
PEP_ACPI_RESOURCE	The PEP_ACPI_RESOURCE structure contains hardware details for a specific ACPI resource.
PEP_ACPI_RESOURCE_FLAGS	The PEP_ACPI_RESOURCE_FLAGS structure contains flags describing an ACPI resource.
PEP_ACPI_SPB_I2C_RESOURCE	The PEP_ACPI_SPB_I2C_RESOURCE structure describes an ACPI I2C serial bus resource.
PEP_ACPI_SPB_RESOURCE	The PEP_ACPI_SPB_RESOURCE structure describes an ACPI serial bus connection resource.
PEP_ACPI_SPB_SPI_RESOURCE	The PEP_ACPI_SPB_SPI_RESOURCE structure describes an ACPI SPI serial bus resource.
PEP_ACPI_SPB_UART_RESOURCE	The PEP_ACPI_SPB_UART_RESOURCE structure describes an ACPI UART serial bus resource.
PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES	The PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES structure contains a list of translated power-control resources for the platform extension plug-in (PEP) to use.
PEP_ACPI_UNREGISTER_DEVICE	The PEP_ACPI_UNREGISTER_DEVICE structure contains information about a device that has been unregistered from ACPI services.
PEP_COMPONENT_ACTIVE	The PEP_COMPONENT_ACTIVE structure identifies a component that is making a transition between the idle condition and the active condition.
PEP_COMPONENT_PERF_INFO	The PEP_COMPONENT_PERF_INFO structure describes the performance states (P-states) of a component.

TITLE	DESCRIPTION
PEP_COMPONENT_PERF_SET	The PEP_COMPONENT_PERF_SET structure describes the performance states (P-states) in a P-state set.
PEP_COMPONENT_PERF_STATE_REQUEST	The PEP_COMPONENT_PERF_STATE_REQUEST structure specifies a performance state (P-state) set and a new performance level to assign to this set.
PEP_COMPONENT_PLATFORM_CONSTRAINTS	The PEP_COMPONENT_PLATFORM_CONSTRAINTS structure describes the lowest-powered Fx state of that a component can be in when the platform is in a particular idle state.
PEP_COMPONENT_V2	The PEP_COMPONENT_V2 structure specifies the power state attributes of a component in the device.
PEP_COORDINATED_DEPENDENCY_OPTION	The PEP_COORIDNATED_DEPENDENCY_OPTION structure describes a coordinated idle state's dependency to the OS.
PEP_COORDINATED_IDLE_STATE	The PEP_COORIDNATED_IDLE_STATE structure describes a coordinated idle state to the OS.
PEP_CRASHDUMP_INFORMATION	The PEP_CRASHDUMP_INFORMATION structure contains information about a crash-dump device.
PEP_DEBUGGER_TRANSITION_REQUIREMENTS	The PEP_DEBUGGER_TRANSITION_REQUIREMENTS structure indicates the platform idle states for which the debugger device must be turned on.
PEP_DEVICE_PLATFORM_CONSTRAINTS	The PEP_DEVICE_PLATFORM_CONSTRAINTS structure specifies the constraints for entry to the various Dx power states that are supported by a device.
PEP_DEVICE_POWER_STATE	The PEP_DEVICE_POWER_STATE structure indicates the status of a transition to a new Dx (device power) state.
PEP_DEVICE_REGISTER_V2	The PEP_DEVICE_REGISTER structure describes all the components in a particular device.
PEP_DEVICE_STARTED	The PEP_DEVICE_STARTED structure identifies a device whose driver has completed its registration with the Windows power management framework (PoFx).
PEP_INFORMATION	The PEP_INFORMATION structure specifies the interface that the platform extension plug-in (PEP) uses to receive notifications from the Windows power management framework (PoFx).
PEP_KERNEL_INFORMATION_STRUCT_V1	The PEP_KERNEL_INFORMATION structure specifies the interface that the power extension plug-in (PEP) uses to request services from the Windows power management framework (PoFx).

TITLE	DESCRIPTION
PEP_KERNEL_INFORMATION_STRUCT_V2	The PEP_KERNEL_INFORMATION structure specifies the interface that the power extension plug-in (PEP) uses to request services from the Windows power management framework (PoFx).
PEP_KERNEL_INFORMATION_STRUCT_V3	The PEP_KERNEL_INFORMATION structure specifies the interface that the power extension plug-in (PEP) uses to request services from the Windows power management framework (PoFx).
PEP_LOW_POWER_EPOCH	The PEP_LOW_POWER_EPOCH structure is used to provide data for a PEP_DPM_LOW_POWER_EPOCH notification (deprecated).
PEP_NOTIFY_COMPONENT_IDLE_STATE	The PEP_NOTIFY_COMPONENT_IDLE_STATE structure contains status information about a component's pending transition to a new Fx power state.
PEP_PERF_STATE	The PEP_PERF_STATE structure describes a performance state (P-state) in a P-state set in which the P-states are specified as a list of one or more discrete values.
PEP_PLATFORM_IDLE_STATE	The PEP_PLATFORM_IDLE_STATE structure specifies the properties of a platform idle state.
PEP_PLATFORM_IDLE_STATE_UPDATE	The PEP_PLATFORM_IDLE_STATE_UPDATE structure contains the updated properties of a platform idle state.
PEP_POWER_CONTROL_COMPLETE	The PEP_POWER_CONTROL_COMPLETE structure contains status information for a power control operation that the PEP previously requested and that the device driver has completed.
PEP_POWER_CONTROL_REQUEST	The PEP_POWER_CONTROL_REQUEST structure contains a request from a driver for a power control operation.
PEP_PPM_CONTEXT_QUERY_PARKING_PAGE	The PEP_PPM_CONTEXT_QUERY_PARKING_PAGE structure describes the parking page for a processor.
PEP_PPM_CST_STATE	The PEP_PPM_CST_STATE structure specifies the properties of a C state (ACPI processor power state).
PEP_PPM_CST_STATES	The PEP_PPM_CST_STATES structure specifies the properties of the C states (ACPI processor power states) that are supported for a processor.
PEP_PPM_ENTER_SYSTEM_STATE	Used in the PEP_NOTIFY_PPM_ENTER_SYSTEM_STATE notification to notify PEP that the system is about to enter a system power state. .
PEP_PPM_FEEDBACK_READ	The PEP_PPM_FEEDBACK_READ structure contains the value read from a processor performance feedback counter.
PEP_PPM_IDLE_CANCEL	The PEP_PPM_IDLE_CANCEL structure indicates why the processor could not enter the previously selected idle state.

TITLE	DESCRIPTION
PEP_PPM_IDLE_COMPLETE	The PEP_PPM_IDLE_COMPLETE structure describe the idle states from which the processor and hardware platform are waking.
PEP_PPM_IDLE_COMPLETE_V2	The PEP_PPM_IDLE_COMPLETE_V2 structure describe the idle states from which the processor and hardware platform are waking.
PEP_PPM_IDLE_EXECUTE	The PEP_PPM_IDLE_EXECUTE structure specifies the idle state that the processor is to enter.
PEP_PPM_IDLE_EXECUTE_V2	The PEP_PPM_IDLE_EXECUTE_V2 structure specifies the idle state that the processor is to enter.
PEP_PPM_IDLE_SELECT	The PEP_PPM_IDLE_SELECT structure describes the most energy-efficient idle state that the processor can enter and still satisfy the constraints specified by the operating system.
PEP_PPM_INITIATE_WAKE	The PEP_PPM_INITIATE_WAKE structure indicates whether a processor requires an interrupt to wake up from an idle state.
PEP_PPM_IS_PROCESSOR_HALTED	The PEP_PPM_IS_PROCESSOR_HALTED structure indicates whether the processor is currently halted in its selected idle state.
PEP_PPM_LPI_COMPLETE	The PEP_PPM_QUERY_FEEDBACK_COUNTERS structure describes all the processor performance counters that the platform extension plug-in (PEP) supports for a particular processor.
PEP_PPM_PARK_MASK	The PEP_PROCESSOR_PARK_MASK structure contains the current core parking mask.
PEP_PPM_PARK_SELECTION	The PEP_PPM_PARK_SELECTION structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding which processors in the platform should be parked to reduce power consumption.
PEP_PPM_PARK_SELECTION_V2	The PEP_PPM_PARK_SELECTION_V2 structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding which processors in the platform should be parked to reduce power consumption.
PEP_PPM_PERF_CHECK_COMPLETE	The PEP_PPM_PERF_CHECK_COMPLETE structure is used to inform the PEP of details regarding the completion of a periodic performance check evaluation.
PEP_PPM_PERF_CONSTRAINTS	The PEP_PPM_PERF_CONSTRAINTS structure describes the performance limits to apply to the processor.
PEP_PPM_PERF_SET	The PEP_PPM_PERF_SET structure specifies the new performance level that the operating system is requesting for the processor.

TITLE	DESCRIPTION
PEP_PPM_PERF_SET_STATE	Used in the PEP_NOTIFY_PPM_PERF_SET notification at runtime to set the current operating performance of the processor. .
PEP_PPM_PLATFORM_STATE_RESIDENCIES	The PEP_PPM_PLATFORM_STATE_RESIDENCIES structure contains the accumulated residency times and transition counts for the idle states that are supported by the hardware platform.
PEP_PPM_PLATFORM_STATE_RESIDENCY	The PEP_PPM_PLATFORM_STATE_RESIDENCY structure specifies the accumulated residency time and transition count for a particular platform idle state.
PEP_PPM_QUERY_CAPABILITIES	The PEP_PPM_QUERY_CAPABILITIES structure contains information about the processor power management (PPM) capabilities of the platform extension plug-in (PEP).
PEP_PPM_QUERY_COORDINATED_DEPENDENCY	The PEP_PPM_QUERY_COORDINATED_DEPENDENCY structure describes dependencies for coordinated idle states.
PEP_PPM_QUERY_COORDINATED_STATES	The PEP_PPM_QUERY_COORDINATED_STATES structure contains information about each coordinated idle state that the platform extension plug-in (PEP) supports.
PEP_PPM_QUERY_DISCRETE_PERF_STATES	Used in the PEP_NOTIFY_PPM_QUERY_DISCRETE_PERF_STATES notification that stores the list of discrete performance states that PEP supports, if the PEP_NOTIFY_PPM_QUERY_CAPABILITIES notification indicates support for discrete performance states. .
PEP_PPM_QUERY_DOMAIN_INFO	Used in the PEP_NOTIFY_PPM_QUERY_DOMAIN_INFO notification that queries for information about a performance domain. .
PEP_PPM_QUERY_FEEDBACK_COUNTERS	The PEP_PPM_QUERY_FEEDBACK_COUNTERS structure describes all the processor performance counters that the platform extension plug-in (PEP) supports for a particular processor.
PEP_PPM_QUERY_IDLE_STATES	The PEP_PPM_QUERY_IDLE_STATES structure describes the idle states of a particular processor.
PEP_PPM_QUERY_IDLE_STATES_V2	The PEP_PPM_QUERY_IDLE_STATES_V2 structure is used during processor initialization to query the platform extension plug-in (PEP) for a list of processor idle states that the processor supports.
PEP_PPM_QUERY_LP_SETTINGS	The PEP_PPM_QUERY_LP_SETTINGS structure contains a kernel handle to the registry key that contains the power optimization settings that the platform extension plug-in (PEP) has defined for each power scenario.
PEP_PPM_QUERY_PERF_CAPABILITIES	The PEP_PPM_QUERY_PERF_CAPABILITIES structure describes the performance capabilities of the processors in the specified processor performance domain.

TITLE	DESCRIPTION
PEP_PPM_QUERY_PLATFORM_STATE	The PEP_PPM_QUERY_PLATFORM_STATE structure contains information about a platform idle state.
PEP_PPM_QUERY_PLATFORM_STATES	The PEP_PPM_QUERY_PLATFORM_STATES structure specifies the number of platform idle states the hardware platform supports.
PEP_PPM_QUERY_STATE_NAME	The PEP_PPM_QUERY_STATE_NAME structure contains information about a specific coordinated or platform idle state.
PEP_PPM_QUERY_VETO_REASON	The PEP_PPM_QUERY_VETO_REASON structure supplies a wide-character, null-terminated string that contains a descriptive, human-readable name for a veto reason.
PEP_PPM_QUERY_VETO_REASONS	The PEP_PPM_QUERY_VETO_REASONS structure specifies the total number of veto reasons that the PEP uses in calls to the ProcessorIdleVeto and PlatformIdleVeto routines.
PEP_PPM_RESUME_FROM_SYSTEM_STATE	Used by the PEP_NOTIFY_PPM_RESUME_FROM_SYSTEM_STATE notification that notifies the PEP that the system has just resumed from a system power state.
PEP_PPM_TEST_IDLE_STATE	The PEP_PPM_TEST_IDLE_STATE structure contains information about whether the processor can immediately enter a processor idle state.
PEP_PREPARE_DEVICE	The PEP_PREPARE_DEVICE structure identifies a device that must be started up in preparation for its use by the operating system.
PEP_PROCESSOR_FEEDBACK_COUNTER	The PEP_PROCESSOR_FEEDBACK_COUNTER structure describes a feedback counter to the operating system.
PEP_PROCESSOR_IDLE_CONSTRAINTS	The PEP_PROCESSOR_IDLE_CONSTRAINTS structure specifies a set of constraints that the PEP uses to select a processor idle state.
PEP_PROCESSOR_IDLE_DEPENDENCY	The PEP_PROCESSOR_IDLE_DEPENDENCY structure specifies the dependencies of a platform idle state on the specified processor.
PEP_PROCESSOR_IDLE_STATE	The PEP_PROCESSOR_IDLE_STATE structure describes the capabilities of a processor idle state.
PEP_PROCESSOR_IDLE_STATE_UPDATE	The PEP_PROCESSOR_IDLE_STATE_UPDATE structure contains the updated properties of a processor idle state.
PEP_PROCESSOR_IDLE_STATE_V2	The PEP_PROCESSOR_IDLE_STATE_V2 structure describes a processor idle state that the platform extension plug-in (PEP) supports.

TITLE	DESCRIPTION
PEP_PROCESSOR_PARK_PREFERENCE	The PEP_PROCESSOR_PARK_PREFERENCE structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding whether the specified processor should be parked to reduce power consumption.
PEP_PROCESSOR_PARK_STATE	The PEP_PROCESSOR_PARK_STATE structure describes the parking state for a single processor.
PEP_PROCESSOR_PERF_STATE	Use in the PEP_NOTIFY_PPM_QUERY_DISCRETE_PERF_STATES notification. This structure describes the properties of a single performance state. .
PEP_QUERY_COMPONENT_PERF_CAPABILITIES	The PEP_QUERY_COMPONENT_PERF_CAPABILITIES structure specifies the number of performance state (P-state) sets that are defined for a component.
PEP_QUERY_COMPONENT_PERF_SET	The PEP_QUERY_COMPONENT_PERF_SET structure contains query information about a set of performance state values (P-state set) for a component.
PEP_QUERY_COMPONENT_PERF_SET_NAME	The PEP_QUERY_COMPONENT_PERF_SET_NAME structure contains query information about a set of performance state values (P-state set) for a component.
PEP_QUERY_COMPONENT_PERF_STATES	The PEP_QUERY_COMPONENT_PERF_STATES structure contains a list of discrete performance state (P-state) values for the specified P-state set.
PEP_QUERY_CURRENT_COMPONENT_PERF_STATE	The PEP_QUERY_CURRENT_COMPONENT_PERF_STATE structure contains information about the current P-state in the specified P-state set.
PEP_QUERY_SOC_SUBSYSTEM	The PEP_QUERY_SOC_SUBSYSTEM structure is used by the PEP_DPM_QUERY_SOC_SUBSYSTEM notification to gather basic information about a particular system on a chip (SoC) subsystem.
PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME	The PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME structure is used by the PEP_DPM_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME notification to collect details about the blocking duration for a particular system on a chip (SoC) subsystem.
PEP_QUERY_SOC_SUBSYSTEM_COUNT	The PEP_QUERY_SOC_SUBSYSTEM_COUNT structure is used to tell the OS whether the PEP supports system on a chip (SoC) subsystem accounting for a given platform idle state.
PEP_QUERY_SOC_SUBSYSTEM_METADATA	The PEP_QUERY_SOC_SUBSYSTEM_METADATA structure is used with the PEP_DPM_QUERY_SOC_SUBSYSTEM_METADATA notification to collect optional metadata about the system on a chip (SoC) subsystem whose blocking time has just been queried.
PEP_REGISTER_COMPONENT_PERF_STATES	The PEP_REGISTER_COMPONENT_PERF_STATES structure describes the performance states (P-states) of the specified component.

TITLE	DESCRIPTION
PEP_REGISTER_CRASHDUMP_DEVICE	The PEP_REGISTER_CRASHDUMP_DEVICE structure provides a callback routine to turn on a crash-dump device.
PEP_REGISTER_DEBUGGER	The PEP_REGISTER_DEBUGGER structure identifies a registered device that is a core system resource that provides debugger transport.
PEP_REGISTER_DEVICE_V2	The PEP_REGISTER_DEVICE_V2 structure describes a device whose driver stack has just registered with the Windows power management framework (PoFx).
PEP_REQUEST_COMPONENT_PERF_STATE	The PEP_REQUEST_COMPONENT_PERF_STATE structure contains a list of performance state (P-state) changes requested by the Windows power management framework (PoFx), plus status information about the handling of these requests by the platform extension plug-in (PEP).
PEP_RESET_SOC_SUBSYSTEM_ACCOUNTING	The PEP_RESET_SOC_SUBSYSTEM_ACCOUNTING structure is provided to the platform extension plug-in (PEP) as part of a PEP_DPM_RESET_SOC_SUBSYSTEM_ACCOUNTING notification.
PEP_SOC_SUBSYSTEM_METADATA	The PEP_SOC_SUBSYSTEM_METADATA structure contains key-value pairs that contain metadata for a system on a chip (SoC) subsystem. It is used in the context of a PEP_DPM_QUERY_SOC_SUBSYSTEM_METADATA notification sent to a platform extension plug-in (PEP).
PEP_SYSTEM_LATENCY	The PEP_SYSTEM_LATENCY structure specifies the new value for the system latency tolerance.
PEP_UNMASKED_INTERRUPT_FLAGS	The PEP_UNMASKED_INTERRUPT_FLAGS union indicates whether an unmasked interrupt source is a primary interrupt or a secondary interrupt.
PEP_UNMASKED_INTERRUPT_INFORMATION	The PEP_UNMASKED_INTERRUPT_INFORMATION structure contains information about an interrupt source.
PEP_UNREGISTER_DEVICE	The PEP_UNREGISTER_DEVICE structure identifies a device whose registration is being removed from the Windows power management framework (PoFx).
PEP_WORK	The PEP_WORK structure indicates whether the PEP has a work request to submit to the Windows power management framework (PoFx).
PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE	The PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE structure contains the results of an ACPI control method that was asynchronously evaluated by the platform extension plug-in (PEP).
PEP_WORK_ACPI_NOTIFY	The PEP_WORK_ACPI_NOTIFY structure contains the ACPI Notify code for a device that has generated a hardware event.

TITLE	DESCRIPTION
PEP_WORK_ACTIVE_COMPLETE	The PEP_WORK_ACTIVE_COMPLETE structure identifies a component that is now in the active condition.
PEP_WORK_COMPLETE_IDLE_STATE	The PEP_WORK_COMPLETE_IDLE_STATE structure identifies a component that the platform extension plug-in (PEP) has prepared for a transition to a new Fx power state.
PEP_WORK_COMPLETE_PERF_STATE	The PEP_WORK_COMPLETE_PERF_STATE structure describes the completion status of a previously requested update to the performance values assigned to a list of performance state (P-state) sets.
PEP_WORK_DEVICE_IDLE	The PEP_WORK_DEVICE_IDLE structure indicates whether to ignore the idle time-out for the specified device.
PEP_WORK_DEVICE_POWER	The PEP_WORK_DEVICE_POWER structure describes the new power requirements for the specified device.
PEP_WORK_IDLE_STATE	The PEP_WORK_IDLE_STATE structure contains a request to transition a component to an Fx power state.
PEP_WORK_INFORMATION	The PEP_WORK_INFORMATION structure describes a work item that the PEP is submitting to the Windows power management framework (PoFx).
PEP_WORK_POWER_CONTROL	The PEP_WORK_POWER_CONTROL structure contains the parameters for a power control request that the platform extension plug-in (PEP) sends directly to a processor driver.
PO_FX_CORE_DEVICE	The PO_FX_CORE_DEVICE structure contains information about the power-state attributes of the components in a core system resource, and provides a software interface for power-managing these components.

Enumerations

TITLE	DESCRIPTION
GPIO_PIN_CONFIG_TYPE	The GPIO_PIN_CONFIG_TYPE enumeration describes a connection IO resource.
GPIO_PIN_IORESTRICTION_TYPE	The GPIO_PIN_IORESTRICTION_TYPE enumeration describes the functions that a GPIO pin is limited to performing.
PEP_ACPI_OBJECT_TYPE	The PEP_ACPI_OBJECT_TYPE enumeration indicates the type of ACPI object.
PEP_ACPI_RESOURCE_TYPE	The PEP_ACPI_RESOURCE_TYPE enumeration is used to identify the type of ACPI resource that is contained in the PEP_ACPI_RESOURCE union.
PEP_DEVICE_ACCEPTANCE_TYPE	The PEP_DEVICE_ACCEPTANCE_TYPE enumeration indicates whether a PEP accepts ownership of a device.

TITLE	DESCRIPTION
PEP_PERF_STATE_TYPE	The PEP_PERF_STATE_TYPE enumeration indicates the type of performance information that is specified for a performance state (P-state) of a component.
PEP_PERF_STATE_UNIT	The PEP_PERF_STATE_UNIT enumeration indicates the measurement units in which the performance state (P-state) of a component is specified.
PEP_PROCESSOR_IDLE_CANCEL_CODE	The PEP_PROCESSOR_IDLE_CANCEL_CODE enumeration values indicate reasons why a processor cannot enter an idle state that was previously selected by the platform extension plug-in (PEP).
PEP_PROCESSOR_IDLE_TYPE	The PEP_PROCESSOR_IDLE_TYPE enumeration indicates whether idle constraints apply to just the current processor or to all processors in the hardware platform.
PEP_WORK_TYPE	The PEP_WORK_TYPE enumeration describes the type of work that the platform extension plug-in (PEP) is requesting.

PEP_PROCESSOR_IDLE_TYPE Enumeration

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_PROCESSOR_IDLE_TYPE** enumeration indicates whether idle constraints apply to just the current processor or to all processors in the hardware platform.

Syntax

```
typedef enum  {
  PepIdleTypeProcessor,
  PepIdleTypePlatform,
  PepIdleTypeMax
} PEP_PROCESSOR_IDLE_TYPE, *PPEP_PROCESSOR_IDLE_TYPE;
```

Constants

PepIdleTypeProcessor	Apply to current processor.
PepIdleTypePlatform	Apply to all processors.
PepIdleTypeMax	Reserved for use by operating system.

Remarks

The **Type** member of the PEP_PROCESSOR_IDLE_CONSTRAINTS structure is a **PEP_PROCESSOR_IDLE_TYPE** enumeration value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pepfx.h)

See Also

PEP_PROCESSOR_IDLE_CONSTRAINTS

PEP_PROCESSOR_IDLE_CANCEL_CODE Enumeration

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_PROCESSOR_IDLE_CANCEL_CODE** enumeration values indicate reasons why a processor cannot enter an idle state that was previously selected by the platform extension plug-in (PEP).

Syntax

```
typedef enum  {
  PepIdleCancelWorkPending,
  PepIdleCancelDependencyCheckFailed,
  PepIdleCancelNoCState,
  PepIdleCancelMax
} PEP_PROCESSOR_IDLE_CANCEL_CODE, *PPEP_PROCESSOR_IDLE_CANCEL_CODE;
```

Constants

PepIdleCancelWorkPending	The processor has pending work that prevents it from entering the selected idle state.
PepIdleCancelDependencyCheckFailed	The processor can enter the selected idle state only after one or more secondary processors have entered their corresponding idle states, but not all of these secondary processors have entered the correct idle states.
PepIdleCancelNoCState	The selected idle state corresponds to a C-state that is not supported. The PEP previously received a PEP_NOTIFY_PPM_CST_STATES notification that supplied a list of the supported C-states for this processor.
PepIdleCancelMax	Reserved for use by the operating system.

Remarks

The **CancelCode** member of the PEP_PPM_IDLE_CANCEL structure contains a **PEP_PROCESSOR_IDLE_CANCEL_CODE** enumeration value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pepfx.h)

See Also

PEP_NOTIFY_PPM_CST_STATES

PEP_PPM_IDLE_CANCEL

GPIO_PIN_CONFIG_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **GPIO_PIN_CONFIG_TYPE** enumeration describes a connection IO resource.

Syntax

```
typedef enum _GPIO_PIN_CONFIG_TYPE {
  PullDefault,
  PullUp,
  PullDown,
  PullNone
} GPIO_PIN_CONFIG_TYPE;
```

Constants

PullDefault	Indicates that no configuration is applied to this pin.
PullUp	Indicates that this pin is configured to use a pull-up resistor.
PullDown	Indicates that this pin is configured to use a pull-down resistor.
PullNone	Indicates that this pin is not configured to use a pull-up or pull-down resistor.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

GPIO_PIN_IORESTRICTION_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **GPIO_PIN_IORESTRICTION_TYPE** enumeration describes the functions that a GPIO pin is limited to performing.

Syntax

```
typedef enum _GPIO_PIN_IORESTRICTION_TYPE {
  IoRestrictionNone,
  IoRestrictionInputOnly,
  IoRestrictionOutputOnly,
  IoRestrictionNoneAndPreserve
} GPIO_PIN_IORESTRICTION_TYPE;
```

Constants

IoRestrictionNone	Indicates that the GPIO pin is not restricted to either input or output. When no IO restriction is described, it is assumed to be **IoRestrictionNone**.
IoRestrictionInputOnly	Indicates that the GPIO pin is restricted to input.
IoRestrictionOutputOnly	Indicates that the GPIO pin is restricted to output.
IoRestrictionNoneAndPreserve	Indicates that the GPIO pin is not restricted to either input or output and that the mode should be preserved when the driver is unloaded.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_ABANDON_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ABANDON_DEVICE** structure identifies a device that has been abandoned and will no longer be used by the operating system.

Syntax

```
typedef struct _PEP_ABANDON_DEVICE {
  PCUNICODE_STRING DeviceId;
  BOOLEAN          DeviceAccepted;
} PEP_ABANDON_DEVICE, *PPEP_ABANDON_DEVICE;
```

Members

`DeviceId`

[in] A string that uniquely identifies the device. This member is a pointer to a UNICODE_STRING structure that contains a device identification string.

`DeviceAccepted`

[out] Whether the PEP claims ownership of the device. The PEP sets this member to TRUE to claim ownership of the device, or to FALSE to indicate that it does not own the device.

Remarks

This structure is used by the PEP_DPM_ABANDON_DEVICE notification. The **DeviceId** member of the structure contains an input value that is supplied by the Windows power management framework (PoFx). The **DeviceAccepted** member contains an output value that the PEP writes to the structure in response to this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_DPM_ABANDON_DEVICE

UNICODE_STRING

PEP_ACPI_ABANDON_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_ABANDON_DEVICE** structure indicates whether the platform extension plug-in (PEP) accepts ownership of an abandoned device.

Syntax

```
typedef struct _PEP_ACPI_ABANDON_DEVICE {
  PCUNICODE_STRING AcpiDeviceName;
  BOOLEAN          DeviceAccepted;
} PEP_ACPI_ABANDON_DEVICE, *PPEP_ACPI_ABANDON_DEVICE;
```

Members

`AcpiDeviceName`

[in] A pointer to an ANSI_STRING structure that contains the fully qualified BIOS name for the device. This name specifies the the path and name of the device in the ACPI namespace. For more information, see Enumerating Child Devices and Control Methods.

`DeviceAccepted`

[out] Whether the PEP claims ownership of the device specified by the **AcpiDeviceName** member. Set to TRUE if the PEP claims ownership, and to FALSE if the PEP does not own the device.

Remarks

This structure is used by the PEP_NOTIFY_ACPI_ABANDON_DEVICE notification. This notification provides an opportunity for the PEP to clean up any remaining device state after the operating system has abandoned the device. The **AcpiDeviceName** member of the structure contains an input value that is supplied by the Windows power management framework (PoFx). The **DeviceAccepted** member contains an output value that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

ANSI_STRING

PEP_NOTIFY_ACPI_ABANDON_DEVICE

PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE** structure contains an enumeration of the objects in the namespace of the device.

Syntax

```
typedef struct _PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE {
  PEPHANDLE                       DeviceHandle;
  ULONG                           RequestFlags;
  NTSTATUS                        Status;
  ULONG                           ObjectCount;
  SIZE_T                          ObjectBufferSize;
  PEP_ACPI_OBJECT_NAME_WITH_TYPE Objects[ANYSIZE_ARRAY];
} PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE, *PPEP_ACPI_ENUMERATE_DEVICE_NAMESPACE;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device's registration for ACPI services. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_NOTIFY_ACPI_REGISTER_DEVICE notification.

`RequestFlags`

[in] A set of input flags. No flags are currently defined for this member, which is always set to PEP_ACPI_EDN_FLAG_NONE (0x0).

`Status`

[out] An NTSTATUS value that indicates the status of the requested device-namespace enumeration. Set this member to STATUS_SUCCESS if the PEP succeeds in enumerating the objects in the device namespace. Set to STATUS_BUFFER_TOO_SMALL if the input value in the **TotalBufferSize** member indicates that the allocated buffer is not large enough to contain the **PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE** structure and **Objects** array.

`ObjectCount`

[out] The number of elements in the **Objects** array.

`ObjectBufferSize`

`Objects`

[out] The first element in an array of PEP_ACPI_OBJECT_NAME_WITH_TYPE structures that describe the objects in the ACPI namespace of the device. If this array contains more than one element, the additional array elements follow the end of the **PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE** structure.

Remarks

This structure is used by the PEP_NOTIFY_ACPI_ENUMERATE_DEVICE_NAMESPACE notification. The

RequestFlags and **TotalBufferSize** members contain input values supplied by PoFx when the notification is sent. The PEP may overwrite the **TotalBufferSize** input value with an output value if the input value is less than the required output buffer size. The **Status**, **ObjectCount**, and **Objects** members contain output values that the PEP writes to the structure.

If N is the number of objects listed in the ACPI namespace under this device, the PEP should verify that the storage allocated by PoFx for the **Objects** array is large enough to contain N array elements. If N > 1, the additional N−1 array elements follow the end of the **PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE** structure. The buffer size required to contain the structure and additional array elements is calculated as follows:

sizeof PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE sizeof PEP_ACPI_OBJECT_NAME_WITH_TYPE If the input value specified in the **TotalBufferSize** member is less than the required size, the PEP overwrites the **TotalBufferSize** input value with the required size, and sets the **Status** member to STATUS_BUFFER_TOO_SMALL. In response, PoFx will allocate a buffer of the required size and send a second PEP_NOTIFY_ACPI_ENUMERATE_DEVICE_NAMESPACE notification to the PEP for this device.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_ACPI_EVALUATE_CONTROL_METHOD structure

2/5/2019 • 3 minutes to read • Edit Online

The **PEP_ACPI_EVALUATE_CONTROL_METHOD** structure specifies an ACPI control method to evaluate, an input argument to supply to this method, and an output buffer for the result of the evaluation.

Syntax

```
typedef struct _PEP_ACPI_EVALUATE_CONTROL_METHOD {
  PEPHANDLE              DeviceHandle;
  ULONG                  RequestFlags;
  union {
    ULONG       MethodName;
    ANSI_STRING MethodNameString;
  };
  NTSTATUS               MethodStatus;
  PVOID                  CompletionContext;
  ULONG                  InputArgumentCount;
  SIZE_T                 InputArgumentSize;
  PACPI_METHOD_ARGUMENT InputArguments;
  ULONG                  OutputArgumentCount;
  SIZE_T                 OutputArgumentSize;
  PACPI_METHOD_ARGUMENT OutputArguments;
} PEP_ACPI_EVALUATE_CONTROL_METHOD, *PPEP_ACPI_EVALUATE_CONTROL_METHOD;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device's registration for ACPI services. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_NOTIFY_ACPI_REGISTER_DEVICE notification.

`RequestFlags`

[in] A set of flags. This member contains one of the following values.

FLAG NAME	VALUE	MEANING
PEP_ACPI_ECM_FLAG_NONE	0x0	Not a valid control method name.
PEP_ACPI_ECM_FLAG_RELATIVE_NAME	0x1	The **MethodNameUlong** member contains a path-relative control method name.
PEP_ACPI_ECM_FLAG_FULLY_QUALIFIED_NAME	0x2	The **MethodNameString** member contains a fully qualified control method name.

`MethodName`

`MethodNameString`

`MethodStatus`

[out] An NTSTATUS value that indicates the status of the evaluation of the ACPI control method. Set this member

to STATUS_SUCCESS to indicate that the platform extension plug-in (PEP) successfully completed its evaluation of the method. Set to STATUS_NOT_SUPPORTED to indicate that the PEP does not recognize the control method. Set to STATUS_BUFFER_TOO_SMALL to indicate that the output buffer size specified by the **InputArgumentSize** member is not large enough to contain the method results.

If the PEP is to evaluate the method asychronously, set this member to STATUS_PENDING and return from the AcceptAcpiNotification callback. Later, when the evaluation is completed, the PEP calls the CompleteWork routine to notify the Windows power management framework (PoFx) that the evaluation of the control method is complete.

`CompletionContext`

[in] A pointer to a completion context value. The PEP uses this member only if the control method is evaluated asynchronously. In this case, the PEP supplies this completion context pointer in the call to the CompleteWork routine that notifies the Windows power management framework (PoFx) that the evaluation of the control method is complete. Included in the input parameters to this call is a pointer to a PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE structure to which the PEP has written the completion context pointer. The context is opaque to the PEP and contains data used internally by PoFx.

`InputArgumentCount`

[in] The number of input arguments in the input buffer pointed to by the **InputArguments** member. Each argument starts with an ACPI_METHOD_ARGUMENT structure that specifies the size of the argument. Currently, the maximum **InputArgumentCount** value is one.

`InputArgumentSize`

[in] The size, in bytes, of the input buffer pointed to by the **InputArguments** member.

`InputArguments`

[in] A pointer to an input buffer that contains an ACPI_METHOD_ARGUMENT structure that specifies the input argument for the specified ACPI control method.

`OutputArgumentCount`

[in] The number of output arguments in the output buffer pointed to by the **OutputArguments** member. Each argument starts with an ACPI_METHOD_ARGUMENT structure that specifies the size of the argument. Currently, the maximum allowed **OutputArgumentCount** value is one.

`OutputArgumentSize`

[in, out] On input, the size, in bytes, of the output buffer pointed to by the **OutputArguments** member. If this buffer is not large enough to contain the result of evaluating the method, the PEP overwrites the **OutputArgumentSize** input value with the required size, and sets the **MethodStatus** member to STATUS_BUFFER_TOO_SMALL.

`OutputArguments`

[in] A pointer to an output buffer to which the PEP writes an ACPI_METHOD_ARGUMENT structure that contains the result of evaluating the specified ACPI control method.

Remarks

This structure is used by the PEP_NOTIFY_ACPI_EVALUATE_CONTROL_METHOD notification. The **MethodStatus** member contains an output value that the PEP writes to the structure in response to this notification. The **OutputArgumentSize** member contains an input value supplied by PoFx when the notification is sent. The PEP may overwrite this input value with an output value if the input value is less than the required output buffer size. All other members of this structure contain input values that are supplied by PoFx when the notification

is sent.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_EXTENDED_ADDRESS structure

1/30/2019 • 5 minutes to read • Edit Online

The **PEP_ACPI_EXTENDED_ADDRESS** structure is used to report resource usage in the address space such as memory and IO.

Syntax

```
typedef struct _PEP_ACPI_EXTENDED_ADDRESS {
  PEP_ACPI_RESOURCE_TYPE  Type;
  PEP_ACPI_RESOURCE_FLAGS Flags;
  UCHAR                   ResourceFlags;
  UCHAR                   GeneralFlags;
  UCHAR                   TypeSpecificFlags;
  UCHAR                   RevisionId;
  UCHAR                   Reserved;
  ULONGLONG               Granularity;
  ULONGLONG               MinimumAddress;
  ULONGLONG               MaximumAddress;
  ULONGLONG               TranslationAddress;
  ULONGLONG               AddressLength;
  ULONGLONG               TypeAttribute;
  PUNICODE_STRING         DescriptorName;
} PEP_ACPI_EXTENDED_ADDRESS, *PPEP_ACPI_EXTENDED_ADDRESS;
```

Members

`Type`

A PEP_ACPI_RESOURCE_TYPE enumeration value describing this resource.

`Flags`

A PEP_ACPI_RESOURCE_FLAGS structure describing this resource.

`ResourceFlags`

Indicates the type of resource this structure describes.

VALUE	MEANING
0	Indicates that this resource is a memory range.
1	Indicates that this resource is an IO range.
2	Indicates that this resource is a bus number range.
3-191	These values are reserved for future use.

192 - 255	These values are reserved for use by the hardware vendor.

`GeneralFlags`

A value containing the bit flags that are common to all resource types.

BIT(S)	MEANING
0 - Consumer/ Producer flag	When set, this indicates that the device consumes this resource.
1 - Decode type	When set, indicates that this bridge subtractively decodes the address. This applies to top level bridges only. When not set, indicates that this bridge positively decodes this address.
2 - Minimum address fixed	When set, indicates that the minimum address is fixed.
3 - Max address fixed	When set, indicates that the maximum address is fixed.
4 to 7 - Reserved	These bits are reserved and must be set to zero.

`TypeSpecificFlags`

The value of this member is dependent on the value in **ResourceFlags** member. The flags for each resource type are described in the tables below.

Memory Resource (**ResourceFlags** = **0**)

BIT(S)	MEANING
0 - Write status	When set, indicates that this memory range is available for reading and writing. Otherwise, this indicates that this memory range is read-only.
1 to 2 - Memory attributes (MEM)	**0** - Indicates the memory is non-cacheable. **1** - Indicates the memory is cacheable. **2** - Indicates the memory is cacheable and supports write combining. **3** - The memory is cacheable and prefetchable.
3 to 4 - Memory attributes (MTP)	These bits are only defined if this memory resource describes system RAM. **0** - Address range memory: This range is available RAM usable by the operating system. **1** - Address range reserved: This range of addresses is in use or reserved by the system and is not to be included in the allocatable memory pool of the operating system's memory manager. **2** - Address range ACPI: ACPI Reclaim Memory. This range is available RAM usable by the OS after it reads the ACPI tables. **3** - Address Range NVS: ACPI NVS Memory. This range of addresses is in use or reserved by the system and must not be used by the operating system. This range is required to be saved and restored across an NVS sleep.
5 - Memory to IO translation	**0** - Type-static: This resource is memory on the primary and secondary sides of the bridge. **1** - Type-translation: This resource is memory on the secondary side of the bridge and IO on the primary side of the bridge.
6 to 7 - Reserved	These bits are reserved and must be set to zero.

IO Resource (**ResourceFlags** = **1**)

BIT(S)	MEANING

0 to 1 - Range	**0** - Reserved. **1** - Non-ISA ranges only. This flag is for bridges on systems with multiple bridges. Setting this bit means the memory window specified in this descriptor is limited to the non-ISA IO addresses that fall within the specified window. The non-ISA IO ranges are: n100-n3FF, n500-n7FF, n900-nBFF, nD00-nFFF. This bit can only be set for bridges entirely configured through the ACPI namespace. **2** - ISA ranges only. This flag is for bridges on systems with multiple bridges. Setting this bit means the memory window specified in this descriptor is limited to the ISA IO addresses that fall within the specified window. The ISA IO ranges are: n000-n0FF, n400-n4FF, n800-n8FF, nC00-nCFF. This bit can only be set for bridges entirely configured through the ACPI namespace. **3** - The memory window covers the entire range
2 to 3 - Reserved	These bits are reserved and must be set to zero.
4 - IO to memory translation	**0** - Type-static: This resource is IO on the primary and secondary sides of the bridge. **1** - Type-translation: This resource is IO on the secondary side of the bridge and memory on the primary side of the bridge.
5 - Sparse translation	This bit is only meaningful if bit 4 (IO to memory translation) is set. **0** - Dense translation: The primary-side memory address of any specific IO port within the secondary-side range can be found using the following function. *address = port + TranslationAddress* **1** - Sparse translation: The primary-side memory address of any specific IO port within the secondary-side range can be found using the following function. *address = (((port & 0xFFFc) << 10) || (port & 0xFFF)) + TranslationAddress* In the address used to access the IO port, bits 2 to 11 must be identical to bits 12 to 21, this gives four bytes of IO ports on each 4 KB page.
6 to 7 - Reserved	These bits are reserved and must be set to zero.

Bus Number Range Resource (**ResourceFlags** = **2**)

BIT(S)	MEANING

0 to 7 - Reserved	These bits are reserved and must be set to zero.

`RevisionId`

Indicates the revision of the extended address space descriptor detailed by this structure. For ACPI 3.0, this value is 1.

`Reserved`

`Granularity`

A bit mask indicating which bits have been decoded.

`MinimumAddress`

The minimum starting address. For bridges that translate addresses, this is the address space on the secondary side of the bridge.

`MaximumAddress`

The maximum starting address. For bridges that translate addresses, this is the address space on the secondary side of the bridge.

`TranslationAddress`

For bridges that translate addresses across the bridge, this is the address on the primary side.

`AddressLength`

The address length.

`TypeAttribute`

Indicates attributes that are specific to the resource type that is specified in the **ResourceFlags** member. If **ResourceFlags** is zero, this value is zero, otherwise the meaning of the value can be found in the *UEFI Specification* in the section titled **GetMemoryMap()**.

`DescriptorName`

The name of this resource descriptor.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_GPIO_RESOURCE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_GPIO_RESOURCE** structure describes the ACPI configuration for a general purpose input/output (GPIO) resource.

Syntax

```
typedef struct _PEP_ACPI_GPIO_RESOURCE {
  PEP_ACPI_RESOURCE_TYPE      Type;
  PEP_ACPI_RESOURCE_FLAGS     Flags;
  KINTERRUPT_MODE             InterruptType;
  KINTERRUPT_POLARITY         InterruptPolarity;
  GPIO_PIN_CONFIG_TYPE        PinConfig;
  GPIO_PIN_IORESTRICTION_TYPE IoRestrictionType;
  USHORT                      DriveStrength;
  USHORT                      DebounceTimeout;
  PUSHORT                     PinTable;
  USHORT                      PinCount;
  UCHAR                       ResourceSourceIndex;
  PUNICODE_STRING             ResourceSourceName;
  PUCHAR                      VendorData;
  USHORT                      VendorDataLength;
} PEP_ACPI_GPIO_RESOURCE, *PPEP_ACPI_GPIO_RESOURCE;
```

Members

`Type`

A PEP_ACPI_RESOURCE_TYPE enumeration value that identifies the resource type for this ACPI resource.

`Flags`

A PEP_ACPI_RESOURCE_FLAGS structure that describes the capabilities of this ACPI resource.

`InterruptType`

A KINTERRUPT_MODE enumeration value that identifies the interrupt type.

`InterruptPolarity`

A KINTERRUPT_POLARITY enumeration value that identifies how a device signals an interrupt request on an interrupt line.

`PinConfig`

A GPIO_PIN_CONFIG_TYPE enumeration value that identifies the GPIO pin configuration type.

`IoRestrictionType`

A GPIO_PIN_IORESTRICTION_TYPE enumeration value that identifies the type of IO that the pin supports.

`DriveStrength`

Specifies the output drive capability of the pin, in hundredths of milliamperes.

`DebounceTimeout`

Specifies the hardware debounce wait time, in hundredths of milliseconds.

`PinTable`

A list of pin numbers on the resource that are described by this descriptor.

`PinCount`

The number of pins in **PinTable**.

`ResourceSourceIndex`

This member is always zero.

`ResourceSourceName`

This member is always set to "ResourceConsumer."

`VendorData`

A pointer to a raw data buffer containing vendor-defined byte data to be decoded by the OS driver.

`VendorDataLength`

The size of the **VendorData** buffer.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_INTERRUPT_RESOURCE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INTERRUPT_RESOURCE** structure describes an ACPI interrupt resource.

Syntax

```
typedef struct _PEP_ACPI_INTERRUPT_RESOURCE {
  PEP_ACPI_RESOURCE_TYPE  Type;
  KINTERRUPT_MODE         InterruptType;
  KINTERRUPT_POLARITY     InterruptPolarity;
  PEP_ACPI_RESOURCE_FLAGS Flags;
  UCHAR                   Count;
  PULONG                  Pins;
} PEP_ACPI_INTERRUPT_RESOURCE, *PPEP_ACPI_INTERRUPT_RESOURCE;
```

Members

`Type`

A PEP_ACPI_RESOURCE_TYPE enumeration value describing this resource.

`InterruptType`

A KINTERRUPT_MODE enumeration value that identifies the interrupt type.

`InterruptPolarity`

A KINTERRUPT_POLARITY enumeration value that identifies how a device signals an interrupt request on an interrupt line.

`Flags`

A PEP_ACPI_RESOURCE_FLAGS structure that describes the capabilities of this ACPI resource.

`Count`

The count of items in the **Pins** array.

`Pins`

A list of pin numbers on the resource that are described by this descriptor.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_ACPI_RESOURCE_TYPE

PEP_ACPI_IO_MEMORY_RESOURCE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_IO_MEMORY_RESOURCE** structure describes an ACPI IO port descriptor resource.

Syntax

```
typedef struct _PEP_ACPI_IO_MEMORY_RESOURCE {
  PEP_ACPI_RESOURCE_TYPE Type;
  UCHAR                  Information;
  PHYSICAL_ADDRESS       MinimumAddress;
  PHYSICAL_ADDRESS       MaximumAddress;
  ULONG                  Alignment;
  ULONG                  Length;
} PEP_ACPI_IO_MEMORY_RESOURCE, *PPEP_ACPI_IO_MEMORY_RESOURCE;
```

Members

`Type`

A PEP_ACPI_RESOURCE_TYPE enumeration value that identifies the resource type for this ACPI resource.

`Information`

If bit 0 is a 1, this indicates that the logical device decodes 16-bit addresses. If bit 0 is 0, this indicates that the logical device only decodes the first 10 bits of the address.

Bits 1 to 7 of this member are reserved and must be set to zero.

`MinimumAddress`

Specifies the minimum acceptable starting address for the IO range.

`MaximumAddress`

Specifies the maximum acceptable starting address for the IO range.

`Alignment`

Specifies the alignment granularity for the IO address assigned.

`Length`

Specifies the number of bytes in the IO range.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_OBJECT_NAME

PEP_ACPI_OBJECT_TYPE

PEP_ACPI_OBJECT_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_OBJECT_TYPE** enumeration indicates the type of ACPI object.

Syntax

```
typedef enum _PEP_ACPI_OBJECT_TYPE {
  PepAcpiObjectTypeMethod,
  PepAcpiObjectTypeDevice,
  PepAcpiObjectTypeMaximum
} PEP_ACPI_OBJECT_TYPE, *PPEP_ACPI_OBJECT_TYPE;
```

Constants

PepAcpiObjectTypeMethod	The object is an ACPI control method.
PepAcpiObjectTypeDevice	
PepAcpiObjectTypeMaximum	Reserved for use by the operating system.

Remarks

The **Type** member of the PEP_ACPI_QUERY_OBJECT_INFORMATION structure is an **PEP_ACPI_OBJECT_TYPE** enumeration value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_PREPARE_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_PREPARE_DEVICE** structure indicates whether a platform extension plug-in (PEP) is prepared to provide ACPI services for the specified device.

Syntax

```
typedef struct _PEP_ACPI_PREPARE_DEVICE {
  PCUNICODE_STRING AcpiDeviceName;
  ULONG            InputFlags;
  BOOLEAN          DeviceAccepted;
  ULONG            OutputFlags;
} PEP_ACPI_PREPARE_DEVICE, *PPEP_ACPI_PREPARE_DEVICE;
```

Members

`AcpiDeviceName`

[in] A pointer to an ANSI_STRING structure that contains the fully qualified BIOS name for the device. This name specifies the path and name of the device in the ACPI namespace. For more information, see Enumerating Child Devices and Control Methods.

`InputFlags`

[in] A set of input flags. No flags are currently defined for this member, which is always set to PEP_ACPI_PREPARE_DEVICE_INPUT_FLAG_NONE (0x0).

`DeviceAccepted`

[out] Whether the PEP is prepared to provide ACPI services for the device. Set this member to TRUE if the PEP is prepared to be the sole provider of ACPI services for this device, and to FALSE if it is not.

`OutputFlags`

[out] A set of output flags. No flags are currently defined for this member. Set this member to PEP_ACPI_PREPARE_DEVICE_OUTPUT_FLAG_NONE (0x0).

Remarks

This structure is used by the PEP_NOTIFY_ACPI_PREPARE_DEVICE notification. The **AcpiDeviceName** and **InputFlags** members of the structure contain input values that are supplied by the Windows power management framework (PoFx) when this notification is sent to the PEP. The **DeviceAccepted** and **OutputFlags** members contain output values that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.

Header	pep_x.h (include Pep_x.h)

ANSI_STRING

PEP_NOTIFY_ACPI_PREPARE_DEVICE

PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES** structure contains a list of raw resources that are needed to control power to the device.

Syntax

```
typedef struct _PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES {
  PEPHANDLE            DeviceHandle;
  ULONG                RequestFlags;
  NTSTATUS             Status;
  SIZE_T               BiosResourcesSize;
  ACPI_METHOD_ARGUMENT BiosResources[ANYSIZE_ARRAY];
} PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES, *PPEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device's registration for ACPI services. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_NOTIFY_ACPI_REGISTER_DEVICE notification.

`RequestFlags`

[in] A set of input flags. No flags are currently defined for this member, which is always set to PEP_ACPI_QDCR_FLAG_NONE (0x0).

`Status`

[out] An NTSTATUS value that indicates the status of this query. Set this member to STATUS_SUCCESS if the PEP succeeded in providing the requested list of resources. Set to STATUS_BUFFER_TOO_SMALL to indicate that the output buffer is not large enough to contain the resource list.

`BiosResourcesSize`

[in, out] On input, the size, in bytes, of the buffer allocated for the **BiosResources** member. This buffer size includes any associated data that might follow this member.

If this buffer is not large enough to contain the **ACPI_METHOD_ARGUMENT** structure and its associated data, the PEP overwrites the input value of **BiosResourcesSize** with the required size and sets the **Status** member to STATUS_BUFFER_TOO_SMALL.

`BiosResources`

[in] An output buffer to which the PEP writes an ACPI_METHOD_ARGUMENT structure that contains the requested resource list. The **Data** member of this structure is the first member in an array that might extend past the end of the structure. The buffer size specified by **BiosResourcesSize** includes both the **ACPI_METHOD_ARGUMENT** structure and any **Data** array elements that follow this structure. For more information, see TBD.

Remarks

This structure is used by the PEP_NOTIFY_ACPI_QUERY_DEVICE_CONTROL_RESOURCES notification. The **RequestFlags**, **BiosResourcesSize**, and **BiosResources** members of the structure contain input values supplied by the Windows power management framework (PoFx) when this notification is sent. If the **BiosResourcesSize** input value is too small, the PEP should overwrite this value. The **Status** member contains an output value that the PEP writes to this structure in response to the notification.

If the input value specified in the **BiosResourcesSize** member is less than the required size, the PEP overwrites the **BiosResourcesSize** input value with the required size, and sets the **Status** member to STATUS_BUFFER_TOO_SMALL. In response, PoFx will try to allocate a buffer of the required size and send a second **PEP_NOTIFY_ACPI_QUERY_DEVICE_CONTROL_RESOURCES** notification to the PEP for this device.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_QUERY_OBJECT_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_QUERY_OBJECT_INFORMATION** structure contains information about an ACPI object.

Syntax

```
typedef struct _PEP_ACPI_QUERY_OBJECT_INFORMATION {
  PEPHANDLE            DeviceHandle;
  PEP_ACPI_OBJECT_NAME Name;
  PEP_ACPI_OBJECT_TYPE Type;
  ULONG                ObjectFlags;
  union {
    struct {
      ULONG InputArgumentCount;
      ULONG OutputArgumentCount;
    } MethodObject;
  } DUMMYUNIONNAME;
} PEP_ACPI_QUERY_OBJECT_INFORMATION, *PPEP_ACPI_QUERY_OBJECT_INFORMATION;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device's registration for ACPI services. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_NOTIFY_ACPI_REGISTER_DEVICE notification.

`Name`

[in] A PEP_ACPI_OBJECT_NAME union that specifies the path-relative, four-character name of the object.

`Type`

[in] A PEP_ACPI_OBJECT_TYPE enumeration value that specifies the object type. Currently, a control method is the only object type that is defined for this member (**Type** = **PepAcpiObjectTypeMethod**).

`ObjectFlags`

[in] A set of input flags. No flags are currently defined for this member, which is always set to PEP_ACPI_OBJECT_FLAG_NONE (0x0).

`DUMMYUNIONNAME`

The query result. If the specified object is a control method, the platform extension plug-in (PEP) writes the query result to the **MethodObject** member of this union.

`DUMMYUNIONNAME.MethodObject`

`DUMMYUNIONNAME.MethodObject.InputArgumentCount`

The number of input arguments expected by the control method.

`DUMMYUNIONNAME.MethodObject.OutputArgumentCount`

The number of output arguments produced by the control method.

Remarks

This structure is used by the PEP_NOTIFY_ACPI_QUERY_OBJECT_INFORMATION notification. The **Name**, **Type**, and **Flags** members of the structure contain input values that the Windows power management framework (PoFx) supplies when this notification is sent. The **MethodObject** member contains an output value that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_ACPI_REGISTER_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_REGISTER_DEVICE** structure contains registration information about a device for which the platform extension plug-in (PEP) is to provide ACPI services.

Syntax

```
typedef struct _PEP_ACPI_REGISTER_DEVICE {
  PCUNICODE_STRING AcpiDeviceName;
  ULONG            InputFlags;
  POHANDLE         KernelHandle;
  PEPHANDLE        DeviceHandle;
  ULONG            OutputFlags;
} PEP_ACPI_REGISTER_DEVICE, *PPEP_ACPI_REGISTER_DEVICE;
```

Members

`AcpiDeviceName`

[in] An ANSI_STRING structure that contains the fully qualified BIOS name for the device. The same name was previously supplied as an input value in the PEP_ACPI_PREPARE_DEVICE notification for the device. This name specifies the path and name of the device in the ACPI namespace. For more information, see Enumerating Child Devices and Control Methods.

`InputFlags`

[in] A set of input flags. No flags are currently defined for this member, which is always set to PEP_ACPI_REGISTER_DEVICE_INPUT_FLAG_NONE (0x0).

`KernelHandle`

[in] A POHANDLE value that represents the registration of the device with the Windows power management framework (PoFx). The PEP can use this handle to identify the device in subsequent communications with PoFx.

`DeviceHandle`

[out] A PEPHANDLE value that identifies the registration of this device for ACPI services. This handle is created by the PEP. In subsequent ACPI service notifications, PoFx will use this handle to identify the device.

`OutputFlags`

[out] A set of output flags. No flags are currently defined for this member. Set this member to PEP_ACPI_REGISTER_DEVICE_OUTPUT_FLAG_NONE (0x0).

Remarks

This structure is used by the PEP_NOTIFY_ACPI_REGISTER_DEVICE notification. The **AcpiDeviceName**, **InputFlags**, and **KernelHandle** members of the structure contain input values that are supplied by PoFx when this notification is sent to the PEP. The **DeviceHandle** and **OutputFlags** members contains output values that the PEP writes to this structure in response to the notification.

PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES** structure is used in the process of converting ACPI resources to BIOS resources by one of the PEP initialization functions.

Syntax

```
typedef struct _PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES {
  NTSTATUS           TranslationStatus;
  PPEP_ACPI_RESOURCE InputBuffer;
  SIZE_T             InputBufferSize;
  PVOID              OutputBuffer;
  SIZE_T             OutputBufferSize;
  ULONG              Flags;
} PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES, *PPEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES;
```

Members

`TranslationStatus`

The result code from the resource translation call.

`InputBuffer`

A pointer to a PEP_ACPI_RESOURCE containing the input buffer.

`InputBufferSize`

The size of the input buffer.

`OutputBuffer`

A pointer to the output buffer containing the translated structure.

`OutputBufferSize`

The size of the output buffer.

`Flags`

The value contained in the PEP_ACPI_RESOURCE_FLAGS structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_RESOURCE

PEP_ACPI_RESOURCE_FLAGS

PEP_ACPI_RESOURCE union

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_RESOURCE** structure contains hardware details for a specific ACPI resource.

Syntax

```
typedef union _PEP_ACPI_RESOURCE {
  PEP_ACPI_RESOURCE_TYPE      Type;
  PEP_ACPI_IO_MEMORY_RESOURCE IoMemory;
  PEP_ACPI_INTERRUPT_RESOURCE Interrupt;
  PEP_ACPI_GPIO_RESOURCE      Gpio;
  PEP_ACPI_SPB_I2C_RESOURCE   SpbI2c;
  PEP_ACPI_SPB_SPI_RESOURCE   SpbSpi;
  PEP_ACPI_SPB_UART_RESOURCE  SpbUart;
  PEP_ACPI_EXTENDED_ADDRESS   ExtendedAddress;
} PEP_ACPI_RESOURCE, *PPEP_ACPI_RESOURCE;
```

Members

`Type`

The PEP_ACPI_RESOURCE_TYPE enumeration value that is applicable to this resource.

`IoMemory`

If **Type** is **PepAcpiMemory** or **PepAcpiIoPort**, this union contains a PEP_ACPI_IO_MEMORY_RESOURCE structure describing an ACPI IO or memory resource.

`Interrupt`

If **Type** is **PepAcpiInterrupt**, this union contains a PEP_ACPI_INTERRUPT_RESOURCE structure describing an ACPI interrupt resource.

`Gpio`

If **Type** is **PepAcpiGpioIo** or **PepAcpiGpioInt**, this union contains a PEP_ACPI_GPIO_RESOURCE structure describing an ACPI GPIO resource.

`SpbI2c`

If **Type** is **PepAcpiSpbI2c**, this union contains a PEP_ACPI_SPB_I2C_RESOURCE structure describing an ACPI I2C serial bus resource.

`SpbSpi`

If **Type** is **PepAcpiSpbSpi**, this union contains a PEP_ACPI_SPB_SPI_RESOURCE structure describing an ACPI SPI serial bus resource.

`SpbUart`

If **Type** is **PepAcpiSpbUart**, this union contains a PEP_ACPI_SPB_UART_RESOURCE structure describing an ACPI SPB serial bus resource.

`ExtendedAddress`

If **Type** is **PepAcpiExtendedMemory** or **PepAcpiExtendedIo**, this union contains a PEP_ACPI_EXTENDED_ADDRESS structure describing an ACPI extended memory or extended IO resource.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_RESOURCE_FLAGS union

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_RESOURCE_FLAGS** structure contains flags describing an ACPI resource.

Syntax

```
typedef union _PEP_ACPI_RESOURCE_FLAGS {
  ULONG  AsULong;
  struct {
    ULONG Shared : 1;
    ULONG Wake : 1;
    ULONG ResourceUsage : 1;
    ULONG SlaveMode : 1;
    ULONG AddressingMode : 1;
    ULONG SharedMode : 1;
    ULONG Reserved : 26;
  } DUMMYSTRUCTNAME;
} PEP_ACPI_RESOURCE_FLAGS, *PPEP_ACPI_RESOURCE_FLAGS;
```

Members

`AsULong`

The consolidated values of the flags in **DUMMYSTRUCTNAME**.

`DUMMYSTRUCTNAME`

A structure containing ACPI resource flags.

`DUMMYSTRUCTNAME.Shared`

When set, indicates that this is a shared device.

`DUMMYSTRUCTNAME.Wake`

When set, indicates that this device can be woken from a low-power state.

`DUMMYSTRUCTNAME.ResourceUsage`

When set, indicates that this device is in use.

`DUMMYSTRUCTNAME.SlaveMode`

When set, indicates that this device is in slave mode.

`DUMMYSTRUCTNAME.AddressingMode`

When set, indicates that this device is in addressing mode.

`DUMMYSTRUCTNAME.SharedMode`

When set, indicates that this device is in shared mode.

`DUMMYSTRUCTNAME.Reserved`

This member is reserved and should be set to zero.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_RESOURCE_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_RESOURCE_TYPE** enumeration is used to identify the type of ACPI resource that is contained in the PEP_ACPI_RESOURCE union.

Syntax

```
typedef enum _PEP_ACPI_RESOURCE_TYPE {
  PepAcpiMemory,
  PepAcpiIoPort,
  PepAcpiInterrupt,
  PepAcpiGpioIo,
  PepAcpiGpioInt,
  PepAcpiSpbI2c,
  PepAcpiSpbSpi,
  PepAcpiSpbUart,
  PepAcpiExtendedMemory,
  PepAcpiExtendedIo
} PEP_ACPI_RESOURCE_TYPE;
```

Constants

PepAcpiMemory	Indicates that the resource is an ACPI memory resource.
PepAcpiIoPort	Indicates that the resource is an ACPI IO port resource.
PepAcpiInterrupt	Indicates that the resource is an ACPI interrupt resource.
PepAcpiGpioIo	Indicates that the resource is an ACPI GPIO resource.
PepAcpiGpioInt	Indicates that the resource is an ACPI GPIO interrupt resource.
PepAcpiSpbI2c	Indicates that the resource is an ACPI I2C serial bus resource.
PepAcpiSpbSpi	Indicates that the resource is an ACPI SPI serial bus resource.
PepAcpiSpbUart	Indicates that the resource is an ACPI UART serial bus resource.
PepAcpiExtendedMemory	Indicates that the resource is an ACPI extended memory resource.
PepAcpiExtendedIo	Indicates that the resource is an ACPI extended IO resource.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_RESOURCE

PEP_ACPI_SPB_I2C_RESOURCE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_SPB_I2C_RESOURCE** structure describes an ACPI I2C serial bus resource.

Syntax

```
typedef struct _PEP_ACPI_SPB_I2C_RESOURCE {
  PEP_ACPI_SPB_RESOURCE SpbCommon;
  ULONG                 ConnectionSpeed;
  USHORT                SlaveAddress;
} PEP_ACPI_SPB_I2C_RESOURCE, *PPEP_ACPI_SPB_I2C_RESOURCE;
```

Members

`SpbCommon`

A PEP_ACPI_SPB_RESOURCE structure describing this resource.

`ConnectionSpeed`

The maximum speed, in hertz, supported by this connection.

`SlaveAddress`

The I2C bus address for this connection.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_SPB_RESOURCE

PEP_ACPI_SPB_RESOURCE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_SPB_RESOURCE** structure describes an ACPI serial bus connection resource.

Syntax

```
typedef struct _PEP_ACPI_SPB_RESOURCE {
  PEP_ACPI_RESOURCE_TYPE  Type;
  PEP_ACPI_RESOURCE_FLAGS Flags;
  USHORT                  TypeSpecificFlags;
  UCHAR                   ResourceSourceIndex;
  PUNICODE_STRING         ResourceSourceName;
  PCHAR                   VendorData;
  USHORT                  VendorDataLength;
} PEP_ACPI_SPB_RESOURCE, *PPEP_ACPI_SPB_RESOURCE;
```

Members

`Type`

A PEP_ACPI_RESOURCE_TYPE enumeration value describing this resource.

`Flags`

A PEP_ACPI_RESOURCE_FLAGS structure that describes the capabilities of this ACPI resource.

`TypeSpecificFlags`

Specifies the bit flags that are common to all serial bus connection types.

BIT(S)	MEANING
0 - Slave mode	**0x0** - Indicates that communication over this connection is initiated by the controller. **0x1** - Indicates that communication over this connection is initiated by the device.
1 - Consumer/producer mode	**0x0** - Indicates that this device produces and consumes this resource. **0x1** - Indicates that this device consumes this resource.

2 to 7 - Reserved	These bits are reserved and must be set to zero.

`ResourceSourceIndex`

`ResourceSourceName`

The name of the serial bus controller device to which this connection descriptor applies. The name can be a fully qualified path, a relative path, or a simple name segment that utilizes the namespace search rules.

`VendorData`

A pointer to optional data that is specific to the serial bus connection type.

`VendorDataLength`

The length of the buffer pointed to by **VendorData**.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_SPB_SPI_RESOURCE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_SPB_SPI_RESOURCE** structure describes an ACPI SPI serial bus resource.

Syntax

```
typedef struct _PEP_ACPI_SPB_SPI_RESOURCE {
  PEP_ACPI_SPB_RESOURCE SpbCommon;
  ULONG                 ConnectionSpeed;
  UCHAR                 DataBitLength;
  UCHAR                 Phase;
  UCHAR                 Polarity;
  USHORT                DeviceSelection;
} PEP_ACPI_SPB_SPI_RESOURCE, *PPEP_ACPI_SPB_SPI_RESOURCE;
```

Members

`SpbCommon`

A PEP_ACPI_SPB_RESOURCE structure describing this resource.

`ConnectionSpeed`

The maximum speed, in hertz, supported by this connection.

`DataBitLength`

The size, in bits, of the smallest unit of transfer.

`Phase`

The phase of the clock pulse on which to capture data.

`Polarity`

The polarity of the clock. If zero, this indicates the clock is low during the first phase. If 1, this indicates the clock is high during the first phase.

`DeviceSelection`

The device selection value. This value is specific to the device and may refer to a chip-select line, GPIO line, or other line selection mechanism.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_SPB_UART_RESOURCE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_SPB_UART_RESOURCE** structure describes an ACPI UART serial bus resource.

Syntax

```
typedef struct _PEP_ACPI_SPB_UART_RESOURCE {
  PEP_ACPI_SPB_RESOURCE SpbCommon;
  ULONG                 BaudRate;
  USHORT                RxBufferSize;
  USHORT                TxBufferSize;
  UCHAR                 Parity;
  UCHAR                 LinesInUse;
} PEP_ACPI_SPB_UART_RESOURCE, *PPEP_ACPI_SPB_UART_RESOURCE;
```

Members

`SpbCommon`

A PEP_ACPI_SPB_RESOURCE structure describing this resource.

`BaudRate`

The baud rate of the connection.

`RxBufferSize`

The maximum receive buffer size, in bytes, that is supported by this connection.

`TxBufferSize`

The maximum transmit buffer size, in bytes, that is supported by this connection.

`Parity`

Indicates the parity of the connection.

VALUE	MEANING
0x0 0	None
0x0 1	Even
0x0 2	Odd

0x03	Mark
0x04	Space

`LinesInUse`

Flag indicating the serial lines that are enabled. A value of 1 in the bit positions indicates that the line is enabled.

BIT	MEANING
0	This bit is reserved and must be set to zero.
1	This bit is reserved and must be set to zero.
2	Data Carrier Detect (DTD)
3	Ring Indicator (RI)
4	Data Set Ready (DSR)
5	Data Terminal Ready (DTR)
6	Clear to Send (CTS)
7	Request to Send (RTS)

PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES** structure contains a list of translated power-control resources for the platform extension plug-in (PEP) to use.

Syntax

```
typedef struct _PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES {
  PEPHANDLE         DeviceHandle;
  ULONG             RequestFlags;
  NTSTATUS          Status;
  SIZE_T            TranslatedResourcesSize;
  PCM_RESOURCE_LIST TranslatedResources;
} PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES, *PPEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device's registration for ACPI services. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_NOTIFY_ACPI_REGISTER_DEVICE notification.

`RequestFlags`

[in] A set of input flags. No flags are currently defined for this member, which is always set to PEP_ACPI_TDCR_FLAG_NONE (0x0).

`Status`

[out] An NTSTATUS value that indicates the status of the resource translation. The PEP sets this member to STATUS_SUCCESS to indicate that the PEP successfully received the translated resources. Otherwise, the PEP sets this member to an appropriate error status code.

`TranslatedResourcesSize`

`TranslatedResources`

[in] A CM_RESOURCE_LIST structure that serves as the header for the resource list. The remainder of the resource list immediately follows this header.

Remarks

This structure is used by the PEP_NOTIFY_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES notification to provide the PEP with a list of translated power control resources. The **RequestFlags**, **ResourceBufferSize**, and **TranslatedResources** members of the structure contain input values that the Windows power management framework (PoFx) supplies when this notification is sent. The **Status** member contains an output value that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_UNREGISTER_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_UNREGISTER_DEVICE** structure contains information about a device that has been unregistered from ACPI services.

Syntax

```
typedef struct _PEP_ACPI_UNREGISTER_DEVICE {
  PEPHANDLE DeviceHandle;
  ULONG     InputFlags;
} PEP_ACPI_UNREGISTER_DEVICE, *PPEP_ACPI_UNREGISTER_DEVICE;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device's registration for ACPI services. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_NOTIFY_ACPI_REGISTER_DEVICE notification.

`InputFlags`

[in] A set of input flags. No flags are currently defined for this member, which is always set to PEP_ACPI_UNREGISTER_DEVICE_INPUT_FLAG_NONE (0x0).

Remarks

This structure is used by the PEP_NOTIFY_ACPI_UNREGISTER_DEVICE notification. The **DeviceHandle** and **InputFlags** members contain input values that are supplied by the Windows power management framework when this notification is sent.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_COMPONENT_ACTIVE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_COMPONENT_ACTIVE** structure identifies a component that is making a transition between the idle condition and the active condition.

Syntax

```
typedef struct _PEP_COMPONENT_ACTIVE {
  PEPHANDLE             DeviceHandle;
  ULONG                 Component;
  BOOLEAN               Active;
  PPEP_WORK_INFORMATION WorkInformation;
  BOOLEAN               NeedWork;
} PEP_COMPONENT_ACTIVE, *PPEP_COMPONENT_ACTIVE;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Active`

[in] Whether the component is making a transition to the active condition. If TRUE, the component is making a transition from the idle condition to the active condition. If FALSE, the component is making a transition from the active condition to the idle condition.

`WorkInformation`

[out] A pointer to a PEP_WORK_INFORMATION structure that describes the work that the PEP requests in response to this notification. If **NeedWork** is TRUE, **WorkInformation** must point to a valid **PEP_WORK_INFORMATION** structure. If **NeedWork** is FALSE, **WorkInformation** must be NULL.

`NeedWork`

[out] Whether the PEP has a work request to submit in response to this notification. Set to TRUE if the PEP has work to request, or to FALSE if the PEP has no work to request.

Remarks

This structure is used by the PEP_DPM_COMPONENT_ACTIVE notification. The first three members of the structure contain input values that are supplied by the Windows power management framework (PoFx). The last two members contain output values that the PEP writes to the structure in response to this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_DPM_REGISTER_DEVICE

PEP_WORK_INFORMATION

PEP_COMPONENT_PERF_INFO structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_COMPONENT_PERF_INFO** structure describes the performance states (P-states) of a component.

Syntax

```
typedef struct _PEP_COMPONENT_PERF_INFO {
  ULONG                  SetCount;
  PEP_COMPONENT_PERF_SET PerfStateSets[ANYSIZE_ARRAY];
} PEP_COMPONENT_PERF_INFO, *PPEP_COMPONENT_PERF_INFO;
```

Members

`SetCount`

The number of elements in the **PerfStateSets** array.

`PerfStateSets`

The first element in an array of PEP_COMPONENT_PERF_SET structures. Each array element describes a P-state of the component. If the array contains more than one element, the additional elements immediately follow the end of the **PEP_COMPONENT_PERF_INFO** structure.

Remarks

This structure is used in conjunction with the PEP_DPM_REGISTER_COMPONENT_PERF_STATES notification. The **PerfStateSets** member of the PEP_REGISTER_COMPONENT_PERF_STATES structure is a **PEP_COMPONENT_PERF_INFO** structure.

The **PEP_COMPONENT_PERF_INFO** structure contains input values that are supplied by the Windows power management framework (PoFx). The platform extension plug-in (PEP) must not write to this structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_REGISTER_COMPONENT_PERF_STATES

PEP_COMPONENT_PERF_SET structure

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_COMPONENT_PERF_SET** structure describes the performance states (P-states) in a P-state set.

Syntax

```
typedef struct _PEP_COMPONENT_PERF_SET {
  UNICODE_STRING      Name;
  ULONGLONG           Flags;
  PEP_PERF_STATE_UNIT Unit;
  PEP_PERF_STATE_TYPE Type;
  union {
    struct {
      ULONG           Count;
      PPEP_PERF_STATE States;
    } Discrete;
    struct {
      ULONGLONG Minimum;
      ULONGLONG Maximum;
    } Range;
  };
} PEP_COMPONENT_PERF_SET, *PPEP_COMPONENT_PERF_SET;
```

Members

`Name`

An optional string that describes the device property controlled by this P-state set. For example, this string might be "Clock frequency" or "Memory bandwidth". If no such string is available for this P-state, the **Name** member is set to NULL. Otherwise, this member contains a pointer to a UNICODE_STRING structure that contains the string.

`Flags`

Set to zero. No flag bits are currently defined for this member.

`Unit`

A PEP_PERF_STATE_UNIT structure that specifies the units in which the performance values for this P-state set are expressed. Component performance can be expressed in hertz (frequency) or in bits per second (bandwidth).

`Type`

A PEP_PERF_STATE_TYPE enumeration value that indicates the type of performance information that is specified for this component. This member indicates whether the performance values for this P-state set are specified as a list of discrete values or as a continuous range of values.

`Discrete`

`Discrete.Count`

`Discrete.States`

`Range`

`Range.Minimum`

`Range.Maximum`

Remarks

The **PerfStateSets** member of the PEP_COMPONENT_PERF_INFO is the first element in an array of **PEP_COMPONENT_PERF_SET** structures. All members of the **PEP_COMPONENT_PERF_SET** structure contain input values that are supplied by the Windows power management framework (PoFx). The platform extension plug-in (PEP) must not write to this structure.

Device drivers use the PO_FX_COMPONENT_PERF_SET structure, which is similar to the **PEP_COMPONENT_PERF_SET** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

UNICODE_STRING

PEP_COMPONENT_PERF_STATE_REQUEST structure

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_COMPONENT_PERF_STATE_REQUEST** structure specifies a performance state (P-state) set and a new performance level to assign to this set.

Syntax

```
typedef struct _PEP_COMPONENT_PERF_STATE_REQUEST {
  ULONG Set;
  union {
    ULONG     StateIndex;
    ULONGLONG StateValue;
  };
} PEP_COMPONENT_PERF_STATE_REQUEST, *PPEP_COMPONENT_PERF_STATE_REQUEST;
```

Members

`Set`

The index of the P-state set to which to assign the new performance level. If N is the number of P-state sets specified for this component, P-state set indexes range from 0 to N−1. The PEP previously specified the number of P-state sets in response to a PEP_DPM_QUERY_COMPONENT_PERF_CAPABILITIES notification.

`StateIndex`

`StateValue`

Remarks

The **PerfRequests** member of the PEP_REQUEST_COMPONENT_PERF_STATE structure is a pointer to an array of **PEP_COMPONENT_PERF_STATE_REQUEST** structures.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_REQUEST_COMPONENT_PERF_STATE

PEP_COMPONENT_PLATFORM_CONSTRAINTS structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_COMPONENT_PLATFORM_CONSTRAINTS** structure describes the lowest-powered F*x* state of that a component can be in when the platform is in a particular idle state.

Syntax

```
typedef struct _PEP_COMPONENT_PLATFORM_CONSTRAINTS {
  PEPHANDLE DeviceHandle;
  ULONG     Component;
  PULONG    MinimumFStates;
  ULONG     PlatformStateCount;
} PEP_COMPONENT_PLATFORM_CONSTRAINTS, *PPEP_COMPONENT_PLATFORM_CONSTRAINTS;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N−1.

`MinimumFStates`

[in] A pointer to an output buffer. The PEP writes a ULONG array to this buffer that specifies the lowest-powered F*x* state that the component can be in for each platform idle state. An element with a value of 0 indicates F0, a value of 1 indicates F1, and so on. If the platform supports M idle states, array elements 0 to M−1 specify the F*x* states corresponding to platform idle states 0 to M−1.

`PlatformStateCount`

[in] The number of elements in the **MinimumFStates** array. The array contains one element for each platform idle state. The Windows power management framework (PoFx) previously sent a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification to the PEP to determine the number of supported platform idle states.

Remarks

This structure is used by the PEP_DPM_COMPONENT_IDLE_CONSTRAINTS notification. All four members of the structure contain input values that PoFx supplies when this notification is sent. PoFx allocates the buffer pointed to by the **MinimumFStates** member, and the PEP writes to this buffer in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_DPM_REGISTER_DEVICE

PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES

PEP_COMPONENT_V2 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_COMPONENT_V2** structure specifies the power state attributes of a component in the device.

Syntax

```
typedef struct _PEP_COMPONENT_V2 {
  GUID                          Id;
  ULONGLONG                     Flags;
  ULONG                         DeepestWakeableIdleState;
  ULONG                         IdleStateCount;
  PPO_FX_COMPONENT_IDLE_STATE IdleStates;
} PEP_COMPONENT_V2, *PPEP_COMPONENT_V2;
```

Members

`Id`

A component ID that uniquely identifies this component with respect to the other components in the device. The PEP should specify a nonzero value for this member if the Windows power management framework (PoFx) requires a component ID to distinguish this component from other, similar components in the same device. This member is optional. If this member is not used, it must be set to all zeros.

`Flags`

A set of component-power-state flags. No flags are currently defined for this member, which is always zero.

`DeepestWakeableIdleState`

The index of the deepest F*x* state from which the component can wake. Specify 0 for F0, 1 for F1, and so on. This index must be less than **IdleStateCount**.

`IdleStateCount`

The number of elements in the array that is pointed to by the **IdleStates** member. Additionally, this member specifies the number of F*x* power states that the component supports. A component must support at least one F*x* state (F0).

`IdleStates`

A pointer to an array of PO_FX_COMPONENT_IDLE_STATE structures. The length of this array is specified by the **IdleStateCount** member. Each array element specifies the attributes of an F*x* power state that is supported by the component. Element 0 describes F0, element 1 describes F1, and so on.

Remarks

This structure

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_COORDINATED_DEPENDENCY_OPTION structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_COORIDNATED_DEPENDENCY_OPTION** structure describes a coordinated idle state's dependency to the OS.

Syntax

```
typedef struct _PEP_COORDINATED_DEPENDENCY_OPTION {
  UCHAR   ExpectedStateIndex;
  BOOLEAN LooseDependency;
  BOOLEAN InitiatingState;
  BOOLEAN DependentState;
} PEP_COORDINATED_DEPENDENCY_OPTION, *PPEP_COORDINATED_DEPENDENCY_OPTION;
```

Members

`ExpectedStateIndex`

Supplies the index of the idle state (coordinated idle state or processor idle state) that must have already been entered/be entered by this idle transition.

`LooseDependency`

When **FALSE**, the OS must use synchronization to guarantee that the state referred to by this dependency has already been entered. When **TRUE**, the OS may perform best-effort coordination that the target state is entered. The PEP must set **LooseDependency** to **TRUE** if the **ExpectedState** is a processor state and has the **WakesSpuriously** flag set.

`InitiatingState`

Indicates if the OS may simultaneously enter the state referred to by this dependency. If **FALSE**, this state is only valid when another processor has previously entered it.

`DependentState`

Indicates if this state is a valid state for a dependent processor to be in.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_QUERY_COORDINATED_DEPENDENCY notification

PEP_COORDINATED_IDLE_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_COORIDNATED_IDLE_STATE** structure describes a coordinated idle state to the OS.

Syntax

```
typedef struct _PEP_COORDINATED_IDLE_STATE {
  ULONG Latency;
  ULONG BreakEvenDuration;
  ULONG DependencyCount;
  ULONG MaximumDependencySize;
} PEP_COORDINATED_IDLE_STATE, *PPEP_COORDINATED_IDLE_STATE;
```

Members

`Latency`

The latency of waking from this idle state, in 100ns units.

`BreakEvenDuration`

Supplies the minimum time the state must be entered to amortize the cost of entering/exiting the state. Idle durations longer than this period should save power when compared to entering a lighter state for the same period.

`DependencyCount`

Supplies the number of dependencies this coordinated state has on other coordinated states or on processors.

`MaximumDependencySize`

Supplies the maximum size of a single dependency.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_COORDINATED_IDLE_STATE structure

PEP_NOTIFY_PPM_QUERY_COORDINATED_STATES notification

PEP_CRASHDUMP_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_CRASHDUMP_INFORMATION** structure contains information about a crash-dump device.

Syntax

```
typedef struct _PEP_CRASHDUMP_INFORMATION {
  PEPHANDLE DeviceHandle;
  PVOID     DeviceContext;
} PEP_CRASHDUMP_INFORMATION, *PPEP_CRASHDUMP_INFORMATION;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the crash-dump device. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`DeviceContext`

[in] A pointer to a device-specific context. This pointer is the *Context* parameter value that the device driver previously passed to the PoFxPowerOnCrashdumpDevice routine. The context contains information in a format that is defined by the device driver and is understood by the PEP. The context is opaque to the operating system. This member value can be NULL if the PEP does not require a context.

Remarks

The *CrashdumpInformation* parameter to the PowerOnDumpDeviceCallback routine is a pointer to a **PEP_CRASHDUMP_INFORMATION** structure.

When a fatal system error occurs, the devices in the crash-dump device chain (storage controller, PCI controller, and so on) need to be turned on so that the Windows kernel can write a crash-dump file to disk.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PoFxPowerOnCrashdumpDevice

PowerOnDumpDeviceCallback

PEP_DEBUGGER_TRANSITION_REQUIREMENTS structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_DEBUGGER_TRANSITION_REQUIREMENTS** structure indicates the platform idle states for which the debugger device must be turned on.

Syntax

```
typedef struct _PEP_DEBUGGER_TRANSITION_REQUIREMENTS {
  PEPHANDLE DeviceHandle;
  ULONG     PlatformStateCount;
  PBOOLEAN  PowerTransitionRequired;
} PEP_DEBUGGER_TRANSITION_REQUIREMENTS, *PPEP_DEBUGGER_TRANSITION_REQUIREMENTS;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the debugger device. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`PlatformStateCount`

[in] The number of entries in the array pointed to by the **PowerTransitionRequired** member. This number is the same as the number of supported platform idle states that the PEP specified in response to a previous PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification.

`PowerTransitionRequired`

[in] An output buffer to which the PEP writes a BOOLEAN array that indicates the platform idle states for which power to the debugger device must be turned on. This buffer is allocated by the Windows power management framework (PoFx) and is guaranteed to be large enough to contain the number of array elements specified by the **PlatformStateCount** member. Set an array element to TRUE if the debugger device must be turned on in the corresponding platform idle state. Set to FALSE to indicate that the device is not required to be turned on in this state. If the platform supports N idle states, the array contains N elements, and idle states are numbered 0 to N–1 in the order in which they are represented in the array.

Remarks

This structure is used by the PEP_DPM_QUERY_DEBUGGER_TRANSITION_REQUIREMENTS notification. All three members of the structure contain input values that are supplied by PoFx when this notification is sent to the PEP.

During a debugging session, the debugger component that runs on the target computer communicates with the host computer through a debugger device such as a USB host controller, UART, or networking device.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_DEVICE_ACCEPTANCE_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_DEVICE_ACCEPTANCE_TYPE** enumeration indicates whether a PEP accepts ownership of a device.

Syntax

```
typedef enum _PEP_DEVICE_ACCEPTANCE_TYPE {
  PepDeviceNotAccepted,
  PepDeviceAccepted,
  PepDeviceAceptedMax
} PEP_DEVICE_ACCEPTANCE_TYPE, *PPEP_DEVICE_ACCEPTANCE_TYPE;
```

Constants

PepDeviceNotAccepted	The PEP does not claim ownership of this device.
PepDeviceAccepted	The PEP claims ownership of this device.
PepDeviceAceptedMax	

Remarks

This enumeration is used by **DeviceAccepted** member of the PEP_REGISTER_DEVICE_V2 structure to indicate whether a PEP accepts ownership of a device.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_REGISTER_DEVICE_V2

PEP_DEVICE_PLATFORM_CONSTRAINTS structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_DEVICE_PLATFORM_CONSTRAINTS** structure specifies the constraints for entry to the various D*x* power states that are supported by a device.

Syntax

```
typedef struct _PEP_DEVICE_PLATFORM_CONSTRAINTS {
  PEPHANDLE           DeviceHandle;
  PDEVICE_POWER_STATE MinimumDStates;
  ULONG               PlatformStateCount;
} PEP_DEVICE_PLATFORM_CONSTRAINTS, *PPEP_DEVICE_PLATFORM_CONSTRAINTS;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`MinimumDStates`

[in] A pointer to an array of DEVICE_POWER_STATE enumeration values that indicate the lowest-powered D*x* (device power) state the device can enter for each platform idle state.

`PlatformStateCount`

[in] The number of elements in the array pointed to by the **MinimumDStates** member. This member contains the platform state count that the PEP supplied in response to a previous PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification.

Remarks

This structure is used by the PEP_DPM_DEVICE_IDLE_CONSTRAINTS notification. All three members of this structure contain input values that are supplied by the Windows power management framework (PoFx). In response to this notification, the PEP writes DEVICE_POWER_STATE enumeration values to the elements of the array pointed to by the **MinimumDStates** member. PoFx allocates the storage for this array before sending the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

DEVICE_POWER_STATE

PEP_DPM_DEVICE_IDLE_CONSTRAINTS

PEP_DPM_REGISTER_DEVICE

PEP_DEVICE_POWER_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_DEVICE_POWER_STATE** structure indicates the status of a transition to a new D*x* (device power) state.

Syntax

```
typedef struct _PEP_DEVICE_POWER_STATE {
  PEPHANDLE          DeviceHandle;
  DEVICE_POWER_STATE PowerState;
  BOOLEAN            Complete;
  BOOLEAN            SystemTransition;
} PEP_DEVICE_POWER_STATE, *PPEP_DEVICE_POWER_STATE;
```

Members

`DeviceHandle`

[in] The PEPHANDLE value that identifies this device. The PEP previously created this handle in response to a PEP_DPM_REGISTER_DEVICE notification from the Windows power management framework (PoFx).

`PowerState`

[in] A DEVICE_POWER_STATE enumeration value that specifies the new device power state.

`Complete`

[in] Whether the transition to the new device power state has just been initiated or has just completed. If TRUE, the transition to the target device power state has completed. If FALSE, the power policy owner (PPO) has initiated the transition by calling the PoRequestPowerIrp routine, but the Windows power manager has not yet issued the D*x* IRP (an IRP_MN_SET_POWER request of type **DevicePowerState**) to the device's driver stack.

`SystemTransition`

[in] Always set to FALSE.

Remarks

This structure is used by the PEP_DPM_DEVICE_POWER_STATE notification. All four members of the structure contain input values that are supplied by PoFx. The PEP does not write to this structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_DEVICE_REGISTER_V2 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_DEVICE_REGISTER** structure describes all the components in a particular device.

Syntax

```
typedef struct _PEP_DEVICE_REGISTER_V2 {
  ULONGLONG         Flags;
  ULONG             ComponentCount;
  PPEP_COMPONENT_V2 Components[ANYSIZE_ARRAY];
} PEP_DEVICE_REGISTER_V2, *PPEP_DEVICE_REGISTER_V2;
```

Members

`Flags`

TBD

`ComponentCount`

The number of components in this device, which is also the number of elements in the **Components** array. The **ComponentCount** value must be greater than or equal to one.

`Components`

The first element in an array of pointers to PEP_COMPONENT_V2 structures. Each element in the array points to a structure that describes a component in the device. If this array contains more than one element, the additional elements immediately follow the end of the **PEP_DEVICE_REGISTER** structure.

Remarks

The PEP_REGISTER_DEVICE structure contains a **Register** member that points to a **PEP_DEVICE_REGISTER** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_REGISTER_DEVICE

PEP_DEVICE_STARTED structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_DEVICE_STARTED** structure identifies a device whose driver has completed its registration with the Windows power management framework (PoFx).

Syntax

```
typedef struct _PEP_DEVICE_STARTED {
  PEPHANDLE DeviceHandle;
} PEP_DEVICE_STARTED, *PPEP_DEVICE_STARTED;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

Remarks

This structure is used by the PEP_DPM_DEVICE_STARTED notification. The **DeviceHandle** member of this structure contains an input value that is supplied by PoFx.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_INFORMATION** structure specifies the interface that the platform extension plug-in (PEP) uses to receive notifications from the Windows power management framework (PoFx).

Syntax

```
typedef struct _PEP_INFORMATION {
  USHORT                 Version;
  USHORT                 Size;
  PPEPCALLBACKNOTIFYDPM  AcceptDeviceNotification;
  PPEPCALLBACKNOTIFYPPM  AcceptProcessorNotification;
  PPEPCALLBACKNOTIFYACPI AcceptAcpiNotification;
} PEP_INFORMATION, *PPEP_INFORMATION;
```

Members

`Version`

The current version number for this structure. Set this member to PEP_INFORMATION_VERSION.

`Size`

The size, in bytes, of this structure. Set this member to **sizeof**(**PEP_INFORMATION**).

`AcceptDeviceNotification`

A pointer to an AcceptDeviceNotification callback routine. This member is required to point to a valid callback routine.

`AcceptProcessorNotification`

A pointer to an AcceptProcessorNotification callback routine. This member is optional and can be NULL if the PEP is not prepared to handle PPM notifications from PoFx.

`AcceptAcpiNotification`

A pointer to an AcceptAcpiNotification callback routine. This member is optional and can be NULL if the PEP is not prepared to handle ACPI notifications from PoFx.

Remarks

This structure contains pointers to several callback routines that are implemented by the PEP. PoFx calls these routines to send notifications to the PEP.

The *PepInformation* parameter to the PoFxRegisterPlugin and PoFxRegisterPluginEx routines is a pointer to a **PEP_INFORMATION** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_KERNEL_INFORMATION_STRUCT_V1 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_KERNEL_INFORMATION** structure specifies the interface that the power extension plug-in (PEP) uses to request services from the Windows power management framework (PoFx).

Syntax

```
typedef struct _PEP_KERNEL_INFORMATION_STRUCT_V1 {
  USHORT                                  Version;
  USHORT                                  Size;
  POHANDLE                                Plugin;
  PPOFXCALLBACKREQUESTWORKER              RequestWorker;
  PPOFXCALLBACKENUMERATEUNMASKEDINTERRUPTS EnumerateUnmaskedInterrupts;
  PPOFXCALLBACKPROCESSORHALT              ProcessorHalt;
  PPOFXCALLBACKREQUESTINTERRUPT           RequestInterrupt;
  PPOFXCALLBACKCRITICALRESOURCE           TransitionCriticalResource;
} PEP_KERNEL_INFORMATION_STRUCT_V1, *PPEP_KERNEL_INFORMATION_STRUCT_V1;
```

Members

`Version`

The current version number for this structure. Set this member to PEP_KERNEL_INFORMATION_VERSION.

`Size`

The size, in bytes, of this structure. Set this member to **sizeof**(**PEP_KERNEL_INFORMATION**).

`Plugin`

The handle assigned to the PEP's registration with PoFx. PoFx sets the value of this member. The PEP uses this handle in calls to the RequestWorker routine.

`RequestWorker`

A pointer to a RequestWorker routine. PoFx sets the value of this member. The **RequestWorker** routine is implemented by PoFx. The PEP calls this routine to request the use of a worker thread from the operating system.

`EnumerateUnmaskedInterrupts`

A pointer to an EnumerateUnmaskedInterrupts routine. PoFx sets the value of this member. The **EnumerateUnmaskedInterrupts** routine is implemented by PoFx. The PEP calls this routine to request information about the unmasked interrupts.

`ProcessorHalt`

A pointer to a ProcessorHalt routine. PoFx sets the value of this member. The **ProcessorHalt** routine is implemented by PoFx. The PEP calls this routine to prepare the current processor to enter the halted state.

`RequestInterrupt`

A pointer to a RequestInterrupt routine. PoFx sets the value of this member. The **RequestInterrupt** routine is implemented by PoFx. The PEP calls this routine to replay an edge-triggered interrupt that might have been lost after the hardware platform entered a low-power system state.

`TransitionCriticalResource`

A pointer to a TransitionCriticalResource routine. PoFx sets the value of this member. The **TransitionCriticalResource** routine is implemented by PoFx. The PEP calls this routine to transition critical system resources to the idle condition.

Remarks

The **KernelInformation** parameter to the PoFxRegisterPlugin or PoFxRegisterPluginEx routine is a pointer to a **PEP_KERNEL_INFORMATION** structure. The PEP allocates this structure and sets the values of the **Version** and **Size** members of this structure before calling **PoFxRegisterPlugin** or **PoFxRegisterPluginEx**. During the call to this routine, PoFx fills in the remaining members of the structure.

} PEP_KERNEL_INFORMATION_STRUCT_V2, *PPEP_KERNEL_INFORMATION_STRUCT_V2;
```

Members

`Version`

The current version number for this structure. Set this member to PEP_KERNEL_INFORMATION_VERSION.

`Size`

The size, in bytes, of this structure. Set this member to **sizeof**(**PEP_KERNEL_INFORMATION**).

`Plugin`

The handle assigned to the PEP's registration with PoFx. PoFx sets the value of this member. The PEP uses this handle in calls to the RequestWorker routine.

`RequestWorker`

A pointer to a RequestWorker routine. PoFx sets the value of this member. The **RequestWorker** routine is implemented by PoFx. The PEP calls this routine to request the use of a worker thread from the operating system.

`EnumerateUnmaskedInterrupts`

A pointer to an EnumerateUnmaskedInterrupts routine. PoFx sets the value of this member. The **EnumerateUnmaskedInterrupts** routine is implemented by PoFx. The PEP calls this routine to request information about the unmasked interrupts.

`ProcessorHalt`

A pointer to a ProcessorHalt routine. PoFx sets the value of this member. The **ProcessorHalt** routine is implemented by PoFx. The PEP calls this routine to prepare the current processor to enter the halted state.

`RequestInterrupt`

A pointer to a RequestInterrupt routine. PoFx sets the value of this member. The **RequestInterrupt** routine is implemented by PoFx. The PEP calls this routine to replay an edge-triggered interrupt that might have been lost after the hardware platform entered a low-power system state.

`TransitionCriticalResource`

A pointer to a TransitionCriticalResource routine. PoFx sets the value of this member. The **TransitionCriticalResource** routine is implemented by PoFx. The PEP calls this routine to transition critical system resources to the idle condition.

`ProcessorIdleVeto`

A pointer to a ProcessorIdleVeto routine. PoFx sets the value of this member. The **ProcessorIdleVeto** routine is implemented by PoFx. The PEP calls this routine to increment or decrement the veto count for a pending transition to a processor idle state.

`PlatformIdleVeto`

A pointer to a PlatformIdleVeto routine. PoFx sets the value of this member. The **PlatformIdleVeto** routine is implemented by PoFx. The PEP calls this routine to increment or decrement the veto count for a pending transition to a platform idle state.

`UpdateProcessorIdleState`

A pointer to an UpdateProcessorIdleState routine. PoFx sets the value of this member. The **UpdateProcessorIdleState** routine is implemented by PoFx. The PEP calls this routine to update the properties of the specified processor idle state.

`UpdatePlatformIdleState`

A pointer to an UpdatePlatformIdleState routine. PoFx sets the value of this member. The **UpdatePlatformIdleState** routine is implemented by PoFx. The PEP calls this routine to update the properties of the specified platform idle state.

Remarks

The **KernelInformation** parameter to the PoFxRegisterPlugin or PoFxRegisterPluginEx routine is a pointer to a **PEP_KERNEL_INFORMATION** structure. The PEP allocates this structure and sets the values of the **Version** and **Size** members of this structure before calling **PoFxRegisterPlugin** or **PoFxRegisterPluginEx**. During the call to this routine, PoFx fills in the remaining members of the structure.

PEP_KERNEL_INFORMATION_STRUCT_V3 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_KERNEL_INFORMATION** structure specifies the interface that the power extension plug-in (PEP) uses to request services from the Windows power management framework (PoFx).

Syntax

```
typedef struct _PEP_KERNEL_INFORMATION_STRUCT_V3 {
  USHORT                                  Version;
  USHORT                                  Size;
  POHANDLE                                Plugin;
  PPOFXCALLBACKREQUESTWORKER              RequestWorker;
  PPOFXCALLBACKENUMERATEUNMASKEDINTERRUPTS EnumerateUnmaskedInterrupts;
  PPOFXCALLBACKPROCESSORHALT              ProcessorHalt;
  PPOFXCALLBACKREQUESTINTERRUPT           RequestInterrupt;
  PPOFXCALLBACKCRITICALRESOURCE           TransitionCriticalResource;
  PPOFXCALLBACKPROCESSORIDLEVETO          ProcessorIdleVeto;
  PPOFXCALLBACKPLATFORMIDLEVETO           PlatformIdleVeto;
  PPOFXCALLBACKUPDATEPROCESSORIDLESTATE   UpdateProcessorIdleState;
  PPOFXCALLBACKUPDATEPLATFORMIDLESTATE    UpdatePlatformIdleState;
  PPOFXCALLBACKREQUESTCOMMON              RequestCommon;
} PEP_KERNEL_INFORMATION_STRUCT_V3, *PPEP_KERNEL_INFORMATION_STRUCT_V3;
```

Members

`Version`

The current version number for this structure. Set this member to PEP_KERNEL_INFORMATION_VERSION.

`Size`

The size, in bytes, of this structure. Set this member to **sizeof**(**PEP_KERNEL_INFORMATION**).

`Plugin`

The handle assigned to the PEP's registration with PoFx. PoFx sets the value of this member. The PEP uses this handle in calls to the RequestWorker routine.

`RequestWorker`

A pointer to a RequestWorker routine. PoFx sets the value of this member. The **RequestWorker** routine is implemented by PoFx. The PEP calls this routine to request the use of a worker thread from the operating system.

`EnumerateUnmaskedInterrupts`

A pointer to an EnumerateUnmaskedInterrupts routine. PoFx sets the value of this member. The **EnumerateUnmaskedInterrupts** routine is implemented by PoFx. The PEP calls this routine to request information about the unmasked interrupts.

`ProcessorHalt`

A pointer to a ProcessorHalt routine. PoFx sets the value of this member. The **ProcessorHalt** routine is implemented by PoFx. The PEP calls this routine to prepare the current processor to enter the halted state.

`RequestInterrupt`

A pointer to a RequestInterrupt routine. PoFx sets the value of this member. The **RequestInterrupt** routine is implemented by PoFx. The PEP calls this routine to replay an edge-triggered interrupt that might have been lost after the hardware platform entered a low-power system state.

`TransitionCriticalResource`

A pointer to a TransitionCriticalResource routine. PoFx sets the value of this member. The **TransitionCriticalResource** routine is implemented by PoFx. The PEP calls this routine to transition critical system resources to the idle condition.

`ProcessorIdleVeto`

A pointer to a ProcessorIdleVeto routine. PoFx sets the value of this member. The **ProcessorIdleVeto** routine is implemented by PoFx. The PEP calls this routine to increment or decrement the veto count for a pending transition to a processor idle state.

`PlatformIdleVeto`

A pointer to a PlatformIdleVeto routine. PoFx sets the value of this member. The **PlatformIdleVeto** routine is implemented by PoFx. The PEP calls this routine to increment or decrement the veto count for a pending transition to a platform idle state.

`UpdateProcessorIdleState`

A pointer to an UpdateProcessorIdleState routine. PoFx sets the value of this member. The **UpdateProcessorIdleState** routine is implemented by PoFx. The PEP calls this routine to update the properties of the specified processor idle state.

`UpdatePlatformIdleState`

A pointer to an UpdatePlatformIdleState routine. PoFx sets the value of this member. The **UpdatePlatformIdleState** routine is implemented by PoFx. The PEP calls this routine to update the properties of the specified platform idle state.

`RequestCommon`

A pointer to an RequestCommon routine. PoFx sets the value of this member. The **RequestCommon** routine is implemented by PoFx. The PEP calls this routine to perform a processing operation that is specified by a request ID.

Remarks

The **KernelInformation** parameter to the PoFxRegisterPlugin or PoFxRegisterPluginEx routine is a pointer to a **PEP_KERNEL_INFORMATION** structure. The PEP allocates this structure and sets the values of the **Version** and **Size** members of this structure before calling **PoFxRegisterPlugin** or **PoFxRegisterPluginEx**. During the call to this routine, PoFx fills in the remaining members of the structure.

PEP_LOW_POWER_EPOCH structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_LOW_POWER_EPOCH** structure is used to provide data for a PEP_DPM_LOW_POWER_EPOCH notification (deprecated).

Syntax

```
typedef struct _PEP_LOW_POWER_EPOCH {
  BOOLEAN LowPowerEpoch;
} PEP_LOW_POWER_EPOCH, *PPEP_LOW_POWER_EPOCH;
```

Members

`LowPowerEpoch`

When **TRUE**, indicates that the low power epoch is on.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_DPM_LOW_POWER_EPOCH notification

PEP_NOTIFY_COMPONENT_IDLE_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_NOTIFY_COMPONENT_IDLE_STATE** structure contains status information about a component's pending transition to a new F*x* power state.

Syntax

```
typedef struct _PEP_NOTIFY_COMPONENT_IDLE_STATE {
  PEPHANDLE DeviceHandle;
  ULONG     Component;
  ULONG     IdleState;
  BOOLEAN   DriverNotified;
  BOOLEAN   Completed;
} PEP_NOTIFY_COMPONENT_IDLE_STATE, *PPEP_NOTIFY_COMPONENT_IDLE_STATE;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`IdleState`

[in] The new F*x* power state that the component will transition to. If this parameter is zero, the new state is F0; if this parameter is one, the new state is F1; and so on.

`DriverNotified`

[in] Whether the driver for the device has already been notified of the pending transition to the new F*x* state. If TRUE, the power management framework (PoFx) already notified the driver by calling the driver's ComponentIdleStateCallback callback routine. If FALSE, PoFx has not yet notified the driver.

`Completed`

[out] Whether the PEP has completed all necessary preparations for the specified component to enter the new F*x* state. Set to TRUE to indicate that the PEP has completed all necessary preparations, or to FALSE to indicate that is has not.

If FALSE, the PEP must complete the necessary preparations at a later time and then inform PoFx when the preparations have been completed. To do so, the PEP calls the RequestWorker routine to request a work item, and then responds to the ensuing PEP_DPM_WORK notification by submitting a work request of type **PepWorkCompleteIdleState** to inform PoFx that the preparations are complete.

Remarks

This structure is used by the PEP_DPM_NOTIFY_COMPONENT_IDLE_STATE notification. The first four members of this structure contain input values that are supplied by PoFx. The **Completed** member contains an output value that the PEP writes to the structure in response to this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_PERF_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PERF_STATE** structure describes a performance state (P-state) in a P-state set in which the P-states are specified as a list of one or more discrete values.

Syntax

```
typedef struct _PEP_PERF_STATE {
  ULONGLONG Value;
  PVOID     Context;
} PEP_PERF_STATE, *PPEP_PERF_STATE;
```

Members

`Value`

The discrete value represented by this P-state. For more information, see Remarks.

`Context`

A pointer to PEP-defined context data. The PEP uses this context to contain additional information about the discrete performance level that cannot be expressed in the **Value** member. This context is opaque to the Windows power management framework (PoFx). The **Context** member is optional and can be set to NULL.

Remarks

The **Discrete.States** member of the PEP_COMPONENT_PERF_SET structure is a pointer to an array of **PEP_PERF_STATE** structures. The **Unit** member of the **PEP_COMPONENT_PERF_SET** structure specifies the units in which the **Value** member in each array element is expressed. Component performance can be expressed in hertz (frequency) or in bits per second (bandwidth). For example, if **Value** = 100,000,000 and **Unit** = **PepPerfStateUnitFrequency**, this performance state represents a frequency of 100 megahertz.

Device drivers use the PO_FX_PERF_STATE structure, which is similar to the **PEP_PERF_STATE** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_COMPONENT_PERF_SET

PO_FX_PERF_STATE

PEP_PERF_STATE_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PERF_STATE_TYPE** enumeration indicates the type of performance information that is specified for a performance state (P-state) of a component.

Syntax

```
typedef enum _PEP_PERF_STATE_TYPE {
  PepPerfStateTypeDiscrete,
  PepPerfStateTypeRange,
  PepPerfStateTypeMax
} PEP_PERF_STATE_TYPE, *PPEP_PERF_STATE_TYPE;
```

Constants

PepPerfStateTypeDiscrete	The performance information is specified as a set of discrete values.
PepPerfStateTypeRange	The performance information is specified as a range of values.
PepPerfStateTypeMax	Reserved for use by operating system.

Remarks

The **Type** member of the PEP_COMPONENT_PERF_SET structure is a **PEP_PERF_STATE_TYPE** enumeration value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_COMPONENT_PERF_SET

PEP_PERF_STATE_UNIT Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PERF_STATE_UNIT** enumeration indicates the measurement units in which the performance state (P-state) of a component is specified.

Syntax

```
typedef enum _PEP_PERF_STATE_UNIT {
  PepPerfStateUnitOther,
  PepPerfStateUnitFrequency,
  PepPerfStateUnitBandwidth,
  PepPerfStateUnitMax
} PEP_PERF_STATE_UNIT, *PPEP_PERF_STATE_UNIT;
```

Constants

PepPerfStateUnitOther	Some other type of measurement units not explicitly described by this enumeration.
PepPerfStateUnitFrequency	Hertz (frequency units).
PepPerfStateUnitBandwidth	Bits per second (bandwidth units).
PepPerfStateUnitMax	Reserved for use by operating system.

Remarks

The **Type** member of the PEP_COMPONENT_PERF_SET structure is a **PEP_PERF_STATE_UNIT** enumeration value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_COMPONENT_PERF_SET

PEP_PLATFORM_IDLE_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PLATFORM_IDLE_STATE** structure specifies the properties of a platform idle state.

Syntax

```
typedef struct _PEP_PLATFORM_IDLE_STATE {
  POHANDLE                      InitiatingProcessor;
  UCHAR                         InitiatingState;
  ULONG                         Latency;
  ULONG                         BreakEvenDuration;
  ULONG                         DependencyArrayUsed;
  ULONG                         DependencyArrayCount;
  PEP_PROCESSOR_IDLE_DEPENDENCY DependencyArray[ANYSIZE_ARRAY];
} PEP_PLATFORM_IDLE_STATE, *PPEP_PLATFORM_IDLE_STATE;
```

Members

`InitiatingProcessor`

A **POHANDLE** value that identifies the processor that initiates the transition to this platform idle state, or **NULL** if any processor can initiate the transition. If non-NULL, this handle represents the registration of the processor (as a device) with the Windows power management framework (PoFx).

`InitiatingState`

The index of the processor idle state that the processor enters to initiate the platform's entry to the specified platform idle state. If the **IdleStates** array in the PEP_PPM_QUERY_IDLE_STATES_V2 structure contains N elements, the idle states are numbered 0 to N-1 in the order in which they appear in the array.

`Latency`

The worst-case latency, in 100-nanosecond units, that the platform requires to wake from this idle state in response to a wake event.

`BreakEvenDuration`

The minimum amount of time, specified in 100-nanosecond units, that the platform must spend in this idle state to make a transition to this state worthwhile. PoFx uses this member value as a hint to avoid switching the platform to an idle state unless the platform is likely to remain in this state for at least the amount of time specified by **BreakEvenDuration**.

`DependencyArrayUsed`

The number of items in **DependencyArray** which were filled in by the PEP.

`DependencyArrayCount`

The number of elements in the **DependencyArray** array. The array contains one element for each processor in the hardware platform.

`DependencyArray`

The first element in an array of PEP_PROCESSOR_IDLE_DEPENDENCY structures. This array specifies the set of

dependencies that the platform idle state has on each processor. If the platform contains N processors, the array contains N elements, and processors are numbered 0 to N-1 in the order in which they are represented in the array.

Remarks

This structure is used in conjunction with the PEP_NOTIFY_PPM_QUERY_PLATFORM_STATE notification. The **State** member of a PEP_PPM_QUERY_PLATFORM_STATE structure is a **PEP_PLATFORM_IDLE_STATE** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_PLATFORM_IDLE_STATE_UPDATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PLATFORM_IDLE_STATE_UPDATE** structure contains the updated properties of a platform idle state.

Syntax

```
typedef struct _PEP_PLATFORM_IDLE_STATE_UPDATE {
  ULONG Version;
  ULONG Latency;
  ULONG BreakEvenDuration;
} PEP_PLATFORM_IDLE_STATE_UPDATE, *PPEP_PLATFORM_IDLE_STATE_UPDATE;
```

Members

`Version`

The current version number of this structure. Set this member to PEP_PLATFORM_IDLE_STATE_UPDATE_VERSION.

`Latency`

The worst-case latency, in 100-nanosecond units, for the platform to wake from this idle state in response to a wake event.

`BreakEvenDuration`

The minimum amount of time, specified in 100-nanosecond units, that the platform must spend in this idle state to make a transition to this state worthwhile. The Windows power management framework (PoFx) uses this member value as a hint to avoid switching the platform to an idle state unless the platform is likely to remain in this state for at least the amount of time specified by **BreakEvenDuration**.

Remarks

The *Update* parameter of the UpdatePlatformIdleState routine is a pointer to a **PEP_PLATFORM_IDLE_STATE_UPDATE** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

UpdatePlatformIdleState

PEP_POWER_CONTROL_COMPLETE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_POWER_CONTROL_COMPLETE** structure contains status information for a power control operation that the PEP previously requested and that the device driver has completed.

Syntax

```
typedef struct _PEP_POWER_CONTROL_COMPLETE {
  PEPHANDLE DeviceHandle;
  LPCGUID   PowerControlCode;
  PVOID     RequestContext;
  SIZE_T    BytesReturned;
  NTSTATUS  Status;
} PEP_POWER_CONTROL_COMPLETE, *PPEP_POWER_CONTROL_COMPLETE;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`PowerControlCode`

[in] A pointer to a GUID value that specifies the power control operation that was performed. This is the same value that the PEP supplied in response to the PEP_DPM_WORK notification to initiate the power control operation.

`RequestContext`

[in] A pointer to the request context that was sent by the PEP in the PEP_WORK_INFORMATION structure that the PEP supplied in the original work request. Typically, this member points to a structure that contains a pointer to an output buffer to contain the results of the power control operation that was requested by the PEP.

`BytesReturned`

[in] The size, in bytes, of the result data stored by the driver in the output buffer. For more information about this buffer, see the description of the **RequestContext** member.

`Status`

[in] The status of the power control operation. If the operation was successful, the PEP sets this member to STATUS_SUCCESS. Otherwise, the PEP sets this member to an appropriate error status code.

Remarks

This structure is used by the PEP_DPM_POWER_CONTROL_COMPLETE notification. All five members of the structure contain input values that are supplied by

If the output buffer is too small to receive all of the result data from the operation, the PEP sets the **Status** member of the structure to STATUS_INSUFFICIENT_RESOURCES, sets the **BytesReturned** member to the required size of the output buffer, and (typically) writes no data to the output buffer.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

GUID

PEP_POWER_CONTROL_REQUEST structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_POWER_CONTROL_REQUEST** structure contains a request from a driver for a power control operation.

Syntax

```
typedef struct _PEP_POWER_CONTROL_REQUEST {
  PEPHANDLE DeviceHandle;
  LPCGUID   PowerControlCode;
  PVOID     InBuffer;
  SIZE_T    InBufferSize;
  PVOID     OutBuffer;
  SIZE_T    OutBufferSize;
  SIZE_T    BytesReturned;
  NTSTATUS  Status;
} PEP_POWER_CONTROL_REQUEST, *PPEP_POWER_CONTROL_REQUEST;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`PowerControlCode`

[in] A pointer to a GUID value that specifies the power control operation to perform. This is the same value that the requesting driver supplied as the *PowerControlCode* parameter to the PoFxPowerControl routine.

`InBuffer`

[in] A pointer to a driver-allocated input buffer that contains the input parameters for this power control operation. This is the same value that the requesting driver supplied as the *InBuffer* parameter to the **PoFxPowerControl** routine.

`InBufferSize`

[in] The size in bytes of the buffer pointed to by **InBuffer**. This is the same value that the requesting driver supplied as the *InBufferSize* parameter to the **PoFxPowerControl** routine.

`OutBuffer`

[in] A pointer to a driver-allocated output buffer to which the PEP writes the results of this power control operation. This is the same value that the requesting driver supplied as the *OutBuffer* parameter to the **PoFxPowerControl** routine.

`OutBufferSize`

[in] The size in bytes of the buffer pointed to by **OutBuffer**.

`BytesReturned`

[out] The number of bytes that the PEP wrote to the output buffer pointed to by **OutBuffer**.

`Status`

[out] The status of the requested power control operation. If the operation is successful, the PEP sets this member to STATUS_SUCCESS. Otherwise, the PEP sets this member to an appropriate error status code.

Remarks

This structure is used by the PEP_DPM_POWER_CONTROL_REQUEST notification. The first six members of the structure contain input values that are supplied by the Windows power management Framework (PoFx). The last two members contain values that the PEP writes to the structure in response to this notification. In addition, the PEP writes to the output buffer pointed to by the **OutBuffer** member.

If the output buffer is too small to receive all of the result data from the operation, the PEP sets the **Status** member of the structure to STATUS_INSUFFICIENT_RESOURCES, sets the **BytesReturned** member to the required size of the output buffer, and (typically) writes no data to the output buffer.

The driver for a device can call the PoFxPowerControl routine to request a power control operation on the device. During this call, PoFx delegates the handling of this request to the PEP that owns the device. The **PowerControlCode** member of the **PEP_POWER_CONTROL_REQUEST** structure contains a custom control code whose meaning is understood by both the driver and the PEP for the device.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_PPM_CONTEXT_QUERY_PARKING_PAGE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_CONTEXT_QUERY_PARKING_PAGE** structure describes the parking page for a processor.

Syntax

```
typedef struct _PEP_PPM_CONTEXT_QUERY_PARKING_PAGE {
  PHYSICAL_ADDRESS PhysicalPageAddress;
  PVOID            VirtualPageAddress;
} PEP_PPM_CONTEXT_QUERY_PARKING_PAGE, *PPEP_PPM_CONTEXT_QUERY_PARKING_PAGE;
```

Members

`PhysicalPageAddress`

The physical memory address of the parking page.

`VirtualPageAddress`

The virtual memory address of the parking page.

Remarks

The output buffer for a PEP_PPM_POWER_CONTROL_QUERY_PARKING_PAGE power control request is a **PEP_PPM_CONTEXT_QUERY_PARKING_PAGE** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_PPM_POWER_CONTROL_QUERY_PARKING_PAGE

PEP_PPM_CST_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_CST_STATE** structure specifies the properties of a C state (ACPI processor power state).

Syntax

```
typedef struct _PEP_PPM_CST_STATE {
  UCHAR            Type;
  USHORT           Latency;
  ULONG            Power;
  UCHAR            AddressSpaceId;
  UCHAR            BitWidth;
  UCHAR            BitOffset;
  UCHAR            AccessSize;
  PHYSICAL_ADDRESS Address;
} PEP_PPM_CST_STATE, *PPEP_PPM_CST_STATE;
```

Members

`Type`

The C-state type (0 = C0, 1 = C1, 2 = C2, and so on).

`Latency`

The worst-case latency, in microseconds, to enter and exit this C state. There are no restrictions on latency size.

`Power`

The average power consumption, in milliwatts, of the processor when in this C state.

`AddressSpaceId`

The register address space ID (_ASI) for this C state. This member specifies the address space in which the register for this C state is located. The following IDs are defined for this member.

ID	MEANING
0x00	System memory space
0x01	System I/O space
0x02	PCI configuration space
0x03	Embedded controller
0x04	SMBus address
0x0A	Platform communications channel (PCC)
0x7F	Functional fixed hardware

`BitWidth`

The register bit width (_RBW) for this C state. This member specifies the width, in bits, of the register for this C state.

`BitOffset`

The register bit offset (_RBO) for this C state. This member specifies the offset, in bits, from the register address specified in the **Address** member to the start of the register for this C state.

`AccessSize`

The register access size (_ASZ) code for this C state. This member specifies the number of bytes to read during an access of the register for this C state. Valid access size codes are shown in the following table.

ACCESS SIZE CODE	MEANING
0	Undefined
1	BYTE (1 byte)
2	WORD (2 bytes)
3	DWORD (4 bytes)
4	QWORD (8 bytes)

`Address`

The register address (_ADR) for this C state.

Remarks

This structure is used in conjunction with the PEP_NOTIFY_PPM_CST_STATES notification. The **IdleStates** member of the PEP_PPM_CST_STATES structure is a pointer to an array of **PEP_PPM_CST_STATE** structures. The **Type** member in each element of the array should equal the array index of this member.

The values in the **PEP_PPM_CST_STATE** structure are obtained from the parameters that are specified for this C state in the _CST object in the ACPI namespace for the processor.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_CST_STATES

PEP_PPM_CST_STATES

PEP_PPM_CST_STATES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_CST_STATES** structure specifies the properties of the C states (ACPI processor power states) that are supported for a processor.

Syntax

```
typedef struct _PEP_PPM_CST_STATES {
  ULONG              Count;
  PPEP_PPM_CST_STATE IdleStates;
} PEP_PPM_CST_STATES, *PPEP_PPM_CST_STATES;
```

Members

`Count`

The number of elements in the **IdleStates** array.

`IdleStates`

A pointer to an array of PEP_PPM_CST_STATE structures.

Remarks

This structure is used by the PEP_NOTIFY_PPM_CST_STATES notification. The contents of this structure are obtained from the _CST object that is located in the ACPI namespace for the processor.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_CST_STATES

PEP_PPM_CST_STATE

PEP_PPM_ENTER_SYSTEM_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

Used in the **PEP_NOTIFY_PPM_ENTER_SYSTEM_STATE** notification to notify PEP that the system is about to enter a system power state.

Syntax

```
typedef struct _PEP_PPM_ENTER_SYSTEM_STATE {
  SYSTEM_POWER_STATE TargetState;
} PEP_PPM_ENTER_SYSTEM_STATE, *PPEP_PPM_ENTER_SYSTEM_STATE;
```

Members

`TargetState`

On input, a SYSTEM_POWER_STATE-type value that indicates the power state that the system is entering.

Remarks

This notification is sent to all processors simultaneously after the system has completed all passive level work transitioning the processor to the system power state. This notification is sent at DISPATCH_LEVEL, with all processors at dispatch. This notification is always executed on the target processor. PEP must not queue any work from this notification. The processors will not process work items, DPCs, etc. after this notification has been sent.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Header	pep_x.h (include Pep_x.h)

See Also

Processor power management (PPM) notifications

PEP_PPM_FEEDBACK_READ structure

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_FEEDBACK_READ** structure contains the value read from a processor performance feedback counter.

Syntax

```
typedef struct _PEP_PPM_FEEDBACK_READ {
  ULONG CounterIndex;
  union {
    ULONG64 InstantaneousValue;
    struct {
      ULONG64 NominalCount;
      ULONG64 ActualCount;
    };
  };
} PEP_PPM_FEEDBACK_READ, *PPEP_PPM_FEEDBACK_READ;
```

Members

`CounterIndex`

[in] The index that identifies which processor performance feedback counter to read. If the platform extension plug-in (PEP) supports N counters for this processor, counter indexes range from 0 to N-1. The PEP previously supplied the number of supported counters in response to a PEP_NOTIFY_PPM_QUERY_CAPABILITIES notification.

`InstantaneousValue`

`NominalCount`

`ActualCount`

Remarks

This structure is used by the PEP_NOTIFY_PPM_FEEDBACK_READ notification. The **CounterIndex** member of the structure contains an input value supplied by the Windows power management framework (PoFx) when this notification is set. The other members contain output values that the PEP writes to the structure in response to the notification. The PEP writes to the **InstantaneousValue** member if the counter generates an instantaneous value, or to the **NominalCount** and **ActualCount** members if the counter generates a relative value.

Both an instantaneous counter and a relative counter are reset to zero when power is first turned on, but reading a relative counter causes the count to reset to zero, whereas reading an instantaneous counter does not reset the count. The PEP previously indicated whether the counter is instantaneous or relative in response to a PEP_NOTIFY_PPM_QUERY_FEEDBACK_COUNTERS notification.

Requirements

Minimum supported client	Supported starting with Windows 10.

Header	pep_x.h (include Pep_x.h)

PEP_PPM_IDLE_CANCEL structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_IDLE_CANCEL** structure indicates why the processor could not enter the previously selected idle state.

Syntax

```
typedef struct _PEP_PPM_IDLE_CANCEL {
  PEP_PROCESSOR_IDLE_CANCEL_CODE CancelCode;
} PEP_PPM_IDLE_CANCEL, *PPEP_PPM_IDLE_CANCEL;
```

Members

`CancelCode`

[in] A PEP_PROCESSOR_IDLE_CANCEL_CODE enumeration value that indicates why the processor could not enter the idle state selected by the platform extension plug-in (PEP).

Remarks

This structure is used by the PEP_NOTIFY_PPM_IDLE_CANCEL notification. The **CancelCode** member of the structure contains an input value that the Windows power management framework (PoFx) supplies before this notification is sent.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pepfx.h)

See Also

PEP_PROCESSOR_IDLE_CANCEL_CODE

PEP_PPM_IDLE_COMPLETE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_IDLE_COMPLETE** structure describe the idle states from which the processor and hardware platform are waking.

Syntax

```
typedef struct _PEP_PPM_IDLE_COMPLETE {
  ULONG ProcessorState;
  ULONG PlatformState;
} PEP_PPM_IDLE_COMPLETE, *PPEP_PPM_IDLE_COMPLETE;
```

Members

`ProcessorState`

[in] An index that identifies the idle state from which the processor is waking. The platform extension plug-in (PEP) previously specified the supported processor idle states in response to a PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification. If the PEP specified N processor idle states, valid processor-idle-state indexes range from 0 to N-1. When the hypervisor is enabled and the platform wakes from an idle state, this member is set to **PEP_PROCESSOR_IDLE_STATE_UNKNOWN** (0xffffffff). For more information, see PEP_NOTIFY_PPM_IDLE_COMPLETE.

`PlatformState`

[in] An index that identifies the idle state from which the platform is waking. The PEP previously specified the supported platform idle states in response to a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification. If the PEP specified M platform idle states, valid platform-idle-state indexes range from 0 to M-1. If the transition from the processor idle state does not involve a transition from an platform idle state, this member will contain the value **PEP_PLATFORM_IDLE_STATE_NONE** (0xffffffff).

Remarks

This structure is used by the PEP_NOTIFY_PPM_IDLE_COMPLETE notification. The **ProcessorState** and **PlatformState** members contain input values that are supplied by the Windows power management framework (PoFx) when this notification is sent to the PEP.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_PPM_IDLE_COMPLETE_V2 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_IDLE_COMPLETE_V2** structure describe the idle states from which the processor and hardware platform are waking.

Syntax

```
typedef struct _PEP_PPM_IDLE_COMPLETE_V2 {
  ULONG  ProcessorState;
  ULONG  PlatformState;
  ULONG  CoordinatedStateCount;
  PULONG CoordinatedStates;
} PEP_PPM_IDLE_COMPLETE_V2, *PPEP_PPM_IDLE_COMPLETE_V2;
```

Members

`ProcessorState`

[in] An index that identifies the idle state from which the processor is waking. The platform extension plug-in (PEP) previously specified the supported processor idle states in response to a PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification. If the PEP specified N processor idle states, valid processor-idle-state indexes range from 0 to N-1. When the hypervisor is enabled and the platform wakes from an idle state, this member is set to **PEP_PROCESSOR_IDLE_STATE_UNKNOWN** (0xffffffff). For more information, see PEP_NOTIFY_PPM_IDLE_COMPLETE.

`PlatformState`

[in] An index that identifies the idle state from which the platform is waking. The PEP previously specified the supported platform idle states in response to a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification. If the PEP specified M platform idle states, valid platform-idle-state indexes range from 0 to M-1. If the transition from the processor idle state does not involve a transition from an platform idle state, this member will contain the value **PEP_PLATFORM_IDLE_STATE_NONE** (0xffffffff).

`CoordinatedStateCount`

`CoordinatedStates`

Remarks

This structure is used by the PEP_NOTIFY_PPM_IDLE_COMPLETE notification. The **ProcessorState** and **PlatformState** members contain input values that are supplied by the Windows power management framework (PoFx) when this notification is sent to the PEP.

Requirements

Minimum supported client	Supported starting with Windows 10.

Header	pep_x.h (include Pep_x.h)

PEP_PPM_IDLE_EXECUTE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_IDLE_EXECUTE** structure specifies the idle state that the processor is to enter.

Syntax

```
typedef struct _PEP_PPM_IDLE_EXECUTE {
  NTSTATUS Status;
  ULONG    ProcessorState;
  ULONG    PlatformState;
} PEP_PPM_IDLE_EXECUTE, *PPEP_PPM_IDLE_EXECUTE;
```

Members

`Status`

[out] An **NTSTATUS** value that indicates whether the processor idle state transition was successful. The platform extension plug-in (PEP) sets this member to **STATUS_SUCCESSFUL** if the transition succeeded. Otherwise, this member is set to an appropriate error status code.

`ProcessorState`

[in] The index of the processor idle state that the processor is to enter. The PEP previously specified the supported processor idle states in response to a PEP_NOTIFY_PPM_QUERY_IDLE_STATES notification. If the PEP specified N processor idle states, valid processor-idle-state indexes range from 0 to N-1.

`PlatformState`

[in] The index of the platform idle state that the hardware platform will enter when the processor enters the processor idle state specified by **ProcessorState**. The PEP previously specified the supported platform idle states in response to a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification. If the PEP specified M platform idle states, valid platform-idle-state indexes range from 0 to M-1. If no change in platform idle state will occur, this member will contain the value P**EP_PLATFORM_IDLE_STATE_NONE** (0xffffffff).

Remarks

This structure is used by the PEP_NOTIFY_PPM_IDLE_EXECUTE notification. The **ProcessorState** and **PlatformState** members contain input values that are supplied by the Windows power management framework (PoFx). The **Status** member contains an output value that the PEP writes to this member.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_PPM_IDLE_EXECUTE_V2 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_IDLE_EXECUTE_V2** structure specifies the idle state that the processor is to enter.

Syntax

```
typedef struct _PEP_PPM_IDLE_EXECUTE_V2 {
  NTSTATUS Status;
  ULONG    ProcessorState;
  ULONG    PlatformState;
  ULONG    CoordinatedStateCount;
  PULONG   CoordinatedStates;
} PEP_PPM_IDLE_EXECUTE_V2, *PPEP_PPM_IDLE_EXECUTE_V2;
```

Members

`Status`

[out] An **NTSTATUS** value that indicates whether the processor idle state transition was successful. The platform extension plug-in (PEP) sets this member to **STATUS_SUCCESSFUL** if the transition succeeded. Otherwise, this member is set to an appropriate error status code.

`ProcessorState`

[in] The index of the processor idle state that the processor is to enter. The PEP previously specified the supported processor idle states in response to a PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification. If the PEP specified N processor idle states, valid processor-idle-state indexes range from 0 to N-1.

`PlatformState`

[in] The index of the platform idle state that the hardware platform will enter when the processor enters the processor idle state specified by **ProcessorState**. The PEP previously specified the supported platform idle states in response to a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification. If the PEP specified M platform idle states, valid platform-idle-state indexes range from 0 to M-1. If no change in platform idle state will occur, this member will contain the value **PEP_PLATFORM_IDLE_STATE_NONE** (0xffffffff).

`CoordinatedStateCount`

Supplies the number of coordinated idle states being entered by this transition.

`CoordinatedStates`

Supplies a pointer to an array of coordinated idle states that are being entered by this transition.

Remarks

This structure is used by the PEP_NOTIFY_PPM_IDLE_EXECUTE notification. The **ProcessorState** and **PlatformState** members contain input values that are supplied by the Windows power management framework (PoFx). The **Status** member contains an output value that the PEP writes to this member.

Requirements

PEP_PPM_IDLE_SELECT structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_IDLE_SELECT** structure describes the most energy-efficient idle state that the processor can enter and still satisfy the constraints specified by the operating system.

Syntax

```
typedef struct _PEP_PPM_IDLE_SELECT {
  PPEP_PROCESSOR_IDLE_CONSTRAINTS Constraints;
  BOOLEAN                         AbortTransition;
  ULONG                           IdleStateIndex;
  ULONG                           DependencyArrayUsed;
  ULONG                           DependencyArrayCount;
  PPEP_PROCESSOR_IDLE_DEPENDENCY  DependencyArray;
  ULONG                           PlatformIdleStateIndex;
} PEP_PPM_IDLE_SELECT, *PPEP_PPM_IDLE_SELECT;
```

Members

`Constraints`

[in] A pointer to a PEP_PROCESSOR_IDLE_CONSTRAINTS structure that specifies the constraints that the selected processor idle state must satisfy. The operating system sets the values in this structure. The platform extension plug-in (PEP) must select a processor idle state that satisfies these constraints.

`AbortTransition`

[out] Whether to cancel the pending transition to a processor idle state. Set this member to TRUE if the PEP requires the operating system to cancel the pending transition, and to FALSE otherwise. The PEP selects this option if it wants to queue work and have the Windows kernel process this work before the processor enters idle.

`IdleStateIndex`

[out] The index that identifies the idle state that the processor is to enter. This member is ignored if **AbortTransition** = TRUE. If the processor supports N idle states, idle state indexes range from 0 to N–1. The PEP supplied the number of supported idle states for this processor in response to a previous PEP_NOTIFY_PPM_QUERY_IDLE_STATES notification.

`DependencyArrayUsed`

[out] The number of array elements that the PEP has actually written to the output buffer pointed to the **DependencyArray** member.

`DependencyArrayCount`

[in] The maximum number of elements in the array pointed to by the **DependencyArray** member. The **DependencyArrayCount** member value is equal to the **MaximumCoordinatedProcessors** value that the PEP previously supplied in response to the PEP_NOTIFY_PPM_QUERY_IDLE_STATES notification.

`DependencyArray`

[in] A pointer to an output buffer to which the PEP writes an array of PEP_PROCESSOR_IDLE_DEPENDENCY structures. The elements of this array specify processor idle dependencies or wake dependencies that must be met

for this idle transition to succeed. The PEP sets the **DependencyArrayUsed** member to the actual number of array elements that the PEP writes to the buffer. The output buffer is allocated by the Windows power management framework (PoFx) and is guaranteed to be large enough to contain the number of array elements specified by the **DependencyArrayCount** member.

`PlatformIdleStateIndex`

[out] The index of the platform idle state that the platform is to enter when the processor enters the selected processor idle state. The PEP should set this member only if the platform enters an idle state at the same time as the processor. This member is ignored if **AbortTransition** is TRUE.

Remarks

This structure is used by the PEP_NOTIFY_PPM_IDLE_SELECT notification. The **Constraints**, **DependencyArrayCount**, and **DependencyArray** members of the structure contain input values supplied by PoFx when this notification is sent. The remaining members contain output values that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pepfx.h)

PEP_PPM_INITIATE_WAKE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_INITIATE_WAKE** structure indicates whether a processor requires an interrupt to wake up from an idle state.

Syntax

```
typedef struct _PEP_PPM_INITIATE_WAKE {
  BOOLEAN NeedInterruptForCompletion;
} PEP_PPM_INITIATE_WAKE, *PPEP_PPM_INITIATE_WAKE;
```

Members

`NeedInterruptForCompletion`

[out] Whether the processor requires an interrupt finish waking up from an idle state. Set to **TRUE** if the processor requires an interrupt, or to **FALSE** if it does not.

Remarks

This structure is used by the PEP_NOTIFY_PPM_INITIATE_WAKE notification. The **NeedInterruptForCompletion** member contains an output value that the platform extension plug-in (PEP) writes to the structure in response to this notification.

If the PEP sets the **NeedInterruptForCompletion** member to TRUE, the PEP must ensure that the processor is enabled to be interrupted before the AcceptProcessorNotification callback routine returns.

The PEP should set the **NeedInterruptForCompletion** member to **FALSE** if the processor is already running and/or will eventually exit the idle state (and is in the process of doing so) without requiring a software-generated interrupt.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

AcceptProcessorNotification

PEP_NOTIFY_PPM_INITIATE_WAKE

PEP_PPM_IS_PROCESSOR_HALTED structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_IS_PROCESSOR_HALTED** structure indicates whether the processor is currently halted in its selected idle state.

Syntax

```
typedef struct _PEP_PPM_IS_PROCESSOR_HALTED {
  BOOLEAN Halted;
} PEP_PPM_IS_PROCESSOR_HALTED, *PPEP_PPM_IS_PROCESSOR_HALTED;
```

Members

`Halted`

[out] Whether the processor is halted. Set to **TRUE** if the processor is halted, or to **FALSE** if it is not halted.

Remarks

This structure is used by the PEP_NOTIFY_PPM_IS_PROCESSOR_HALTED notification. The **Halted** member contains an output value that the platform extension plug-in (PEP) writes to the structure in response to this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_PPM_LPI_COMPLETE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_FEEDBACK_COUNTERS** structure describes all the processor performance counters that the platform extension plug-in (PEP) supports for a particular processor.

Syntax

```
typedef struct _PEP_PPM_LPI_COMPLETE {
  ULONG  CoordinatedStateCount;
  PULONG CoordinatedStates;
} PEP_PPM_LPI_COMPLETE, *PPEP_PPM_LPI_COMPLETE;
```

Members

`CoordinatedStateCount`

`CoordinatedStates`

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_FEEDBACK_COUNTERS notification. The **Count** member of the structure contains an input value that PoFx supplies when this notification is sent. The **Counters** member contains an output value that the PEP writes in response to the notification. The PEP writes any additional **Counters** array elements to the output buffer area that follows the **PEP_PPM_QUERY_FEEDBACK_COUNTERS** structure. The buffer that PoFx allocated for this structure is guaranteed to be large enough to contain any array elements that follow the structure.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_PPM_PARK_MASK structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PROCESSOR_PARK_MASK** structure contains the current core parking mask.

Syntax

```
typedef struct _PEP_PPM_PARK_MASK {
  ULONG                     Count;
  ULONGLONG                 EvaluationTime;
  PPEP_PROCESSOR_PARK_STATE Processors;
} PEP_PPM_PARK_MASK, *PPEP_PPM_PARK_MASK;
```

Members

`Count`

[in] Indicates the number of processors in the **Processors** array.

`EvaluationTime`

[in] The interrupt time of the performance check evaluation that initiated this notification.

`Processors`

[in/out] An array of processors in the core parking domain.

On input

Indicates the OS parking preference for each processor.

On output

Returns the PEP parking preference for each processor.

The Processors array is guaranteed to contain the processors in increasing order by processor index.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_PROCESSOR_PARK_STATE

PEP_PPM_PARK_SELECTION structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_PARK_SELECTION** structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding which processors in the platform should be parked to reduce power consumption.

Syntax

```
typedef struct _PEP_PPM_PARK_SELECTION {
  ULONG                          AdditionalUnparkedProcessors;
  ULONG                          Count;
  PPEP_PROCESSOR_PARK_PREFERENCE Processors;
} PEP_PPM_PARK_SELECTION, *PPEP_PPM_PARK_SELECTION;
```

Members

`AdditionalUnparkedProcessors`

[in] The number of additional processors that need to be parked.

This number includes all processors in the **Processors** array for which the PEP sets **PepPreference** to PROCESSOR_PARK_PREFERENCE_PARKED but the operating system sets **PoPreference** to either PROCESSOR_PARK_PREFERENCE_UNPARKED or PROCESSOR_PARK_PREFERENCE_NONE. For more information about these values, see PEP_PROCESSOR_PARK_PREFERENCE.

This number does not include processors in the **Processors** array for which the operating system sets the **PoPreference** value to PROCESSOR_PARK_PREFERENCE_PARKED.

`Count`

[in] The number of elements in the array pointed to by the **Processors** member.

`Processors`

[in/out] A pointer to an array of PEP_PROCESSOR_PARK_PREFERENCE structures. The **Count** member specifies the number of elements in the array.

On input

Each array element indicates the parking preferences for a particular processor.

On output

Returns the PEP parking preference for each processor.

The Processors array is guaranteed to contain the processors in increasing order by processor index.

Remarks

This structure is used by the PEP_NOTIFY_PPM_PARK_SELECTION notification. All three members of the structure contain input values that are set by the Windows power management framework (PoFx) before this notification is sent to the PEP.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_PPM_PARK_SELECTION_V2 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_PARK_SELECTION_V2** structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding which processors in the platform should be parked to reduce power consumption.

Syntax

```
typedef struct _PEP_PPM_PARK_SELECTION_V2 {
  ULONG                          AdditionalUnparkedProcessors;
  ULONG                          Count;
  PPEP_PROCESSOR_PARK_PREFERENCE Processors;
  ULONGLONG                      EvaluationTime;
  UCHAR                          EvaluationType;
} PEP_PPM_PARK_SELECTION_V2, *PPEP_PPM_PARK_SELECTION_V2;
```

Members

`AdditionalUnparkedProcessors`

[in] The number of additional processors that need to be unparked.

This number includes all processors in the **Processors** array for which the PEP sets **PepPreference** to PROCESSOR_PARK_PREFERENCE_PARKED but the operating system sets **PoPreference** to either PROCESSOR_PARK_PREFERENCE_UNPARKED or PROCESSOR_PARK_PREFERENCE_NONE. For more information about these values, see PEP_PROCESSOR_PARK_PREFERENCE.

This number does not include processors in the **Processors** array for which the operating system sets the **PoPreference** value to PROCESSOR_PARK_PREFERENCE_PARKED.

`Count`

[in] The number of elements in the array pointed to by the **Processors** member.

`Processors`

[in/out] A pointer to an array of PEP_PROCESSOR_PARK_PREFERENCE structures. Each array element indicates the parking preferences for a particular processor. The **Count** member specifies the number of elements in the array.

`EvaluationTime`

The interrupt time of the performance check evaluation that initiated this notification.

`EvaluationType`

The type of evaluation being performed. This can be one of the following values:

VALUE	MEANING

PR OCE SSO R_P ARK _TY PE_ CO RE_ PAR KIN G 0x0 0	The processor should be parked.
PR OCE SSO R_P ARK _TY PE_I NTE RRU PT_ STE ERI NG 0x0 1	Interrupts should be steered away from the processor.

Remarks

This structure is used by the PEP_NOTIFY_PPM_PARK_SELECTION_V2 notification notification. All three members of the structure contain input values that are set by the Windows power management framework (PoFx) before this notification is sent to the PEP.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_PPM_PERF_CHECK_COMPLETE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_PERF_CHECK_COMPLETE** structure is used to inform the PEP of details regarding the completion of a periodic performance check evaluation.

Syntax

```
typedef struct _PEP_PPM_PERF_CHECK_COMPLETE {
  ULONGLONG EvaluationTime;
} PEP_PPM_PERF_CHECK_COMPLETE, *PPEP_PPM_PERF_CHECK_COMPLETE;
```

Members

`EvaluationTime`

[in] The interrupt time of the performance check evaluation that initiated this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_PERF_CHECK_COMPLETE notification

PEP_PPM_PERF_SET structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_PERF_SET** structure specifies the new performance level that the operating system is requesting for the processor.

Syntax

```
typedef struct _PEP_PPM_PERF_SET {
  ULONG MinimumPerformance;
  ULONG MaximumPerformance;
  ULONG DesiredPerformance;
  ULONG TimeWindow;
  ULONG PerformanceTolerance;
} PEP_PPM_PERF_SET, *PPEP_PPM_PERF_SET;
```

Members

`MinimumPerformance`

[in] The new minimum performance level in platform-specific units. This member indicates the absolute minimum performance level that the processor can run at.

`MaximumPerformance`

[in] The new maximum performance level in platform-specific units. This member indicates the absolute maximum performance level that the processor can run at.

`DesiredPerformance`

[in] The new desired performance level in platform-specific units. This member is set to a value in the range **MinimumPerformance** to **MaximumPerformance**.

`TimeWindow`

[in] The width, in milliseconds, of the new time window over which the platform must provide the required average performance. If this time window is nonzero, the instantaneous performance provided by the platform does not need to match the desired performance level, and only needs to fall within the constraints specified by the minimum and maximum performance level.

`PerformanceTolerance`

[in] The new performance tolerance in platform-specific units. This member contains the minimum performance level that the platform can deliver and still meet the operating system's performance requirements.

Remarks

This structure is used by the PEP_NOTIFY_PPM_PERF_SET notification. All five members of this structure contain input values that PoFx supplies when this notification is sent to the PEP.

Processor performance levels are specified in platform-specific units. For example, a hardware platform might use a metric such as the processor clock frequency to provide a rough approximation to the amount of processing work that is being done. For more information, see Platform Performance Thresholds.

Requirements

Minimum supported client	Supported starting with Windows 10.

Platform Performance Thresholds

PEP_PPM_PERF_SET_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

Used in the **PEP_NOTIFY_PPM_PERF_SET** notification at runtime to set the current operating performance of the processor.

Syntax

```
typedef struct _PEP_PPM_PERF_SET_STATE {
  UCHAR MinimumPerformanceState;
  UCHAR MaximumPerformanceState;
  UCHAR DesiredPerformanceState;
} PEP_PPM_PERF_SET_STATE, *PPEP_PPM_PERF_SET_STATE;
```

Members

`MinimumPerformanceState`

On input, the new requested minimum performance state. This state is defined as the absolute minimum instantaneous performance level at which the processor may run. The operating system may set this value to any performance value in the range [Lowest Performance, Guaranteed Performance], inclusive. Minimum performance must never be set to a value higher than maximum performance.

`MaximumPerformanceState`

On input, the new requested maximum performance state. This state is defined as the absolute maximum instantaneous performance level at which the processor may run. The OS may set Maximum performance to any performance value in the range [Lowest Performance, Highest Performance], inclusive.

`DesiredPerformanceState`

On input, the new requested desired performance state. This state is defined as the performance level power manager is requesting from the processor. Desired performance may be set to any performance value in the range [Minimum Performance, Maximum Performance], inclusive. Desired performance may take one of two meanings, depending on whether the desired performance is above or below the guaranteed performance level.

- Below the guaranteed performance level, desired performance expresses the average performance level the platform must provide.
- Above the guaranteed performance level, the platform must provide the guaranteed performance level. The platform should attempt to provide up to the desired performance level, if current operating conditions allow for it, but it is not required to do so.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016

Header	pep_x.h (include Pep_x.h)

See Also

Processor power management (PPM) notifications

PEP_PPM_PLATFORM_STATE_RESIDENCIES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_PLATFORM_STATE_RESIDENCIES** structure contains the accumulated residency times and transition counts for the idle states that are supported by the hardware platform.

Syntax

```
typedef struct _PEP_PPM_PLATFORM_STATE_RESIDENCIES {
  ULONG                              Count;
  PPEP_PPM_PLATFORM_STATE_RESIDENCY States;
} PEP_PPM_PLATFORM_STATE_RESIDENCIES, *PPEP_PPM_PLATFORM_STATE_RESIDENCIES;
```

Members

`Count`

[in] The number of elements in the array pointed to by the **States** member. The number of array elements equals the number of platform idle states that the PEP previously provided in response to a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification.

`States`

[in] A pointer to an output buffer to which the PEP writes an array of PEP_PPM_PLATFORM_STATE_RESIDENCY structures. Each structure contains the accumulated residency and transition count information for a particular platform idle state. This buffer is guaranteed to be large enough to contain the number of array elements specified by the **Count** member. Each idle state is identified by its array index. If the array contains N elements, idle state indexes range from 0 to N-1.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_PLATFORM_STATE_RESIDENCIES notification. Both members of the structure contain input values that the Windows power management framework (PoFx) supplies when this notification is sent to the PEP. PoFx allocates the output buffer pointed to by the **States** member, and the PEP writes to this buffer.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES

PEP_NOTIFY_PPM_QUERY_PLATFORM_STATE_RESIDENCIES

PEP_PPM_PLATFORM_STATE_RESIDENCY structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_PLATFORM_STATE_RESIDENCY** structure specifies the accumulated residency time and transition count for a particular platform idle state.

Syntax

```
typedef struct _PEP_PPM_PLATFORM_STATE_RESIDENCY {
  ULONG64 Residency;
  ULONG64 TransitionCount;
} PEP_PPM_PLATFORM_STATE_RESIDENCY, *PPEP_PPM_PLATFORM_STATE_RESIDENCY;
```

Members

`Residency`

The accumulated residency time, in 100-nanosecond units. This is the total amount of time that the hardware platform has spent in this idle state since system startup.

`TransitionCount`

The total number of times that the platform has entered this idle state since system startup.

Remarks

The **States** member of the PEP_PPM_PLATFORM_STATE_RESIDENCIES structure is a pointer to an array of **PEP_PPM_PLATFORM_STATE_RESIDENCY** structures.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_PPM_PLATFORM_STATE_RESIDENCIES

PEP_PPM_QUERY_CAPABILITIES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_CAPABILITIES** structure contains information about the processor power management (PPM) capabilities of the platform extension plug-in (PEP).

Syntax

```
typedef struct _PEP_PPM_QUERY_CAPABILITIES {
  ULONG   FeedbackCounterCount;
  ULONG   IdleStateCount;
  BOOLEAN PerformanceStatesSupported;
  BOOLEAN ParkingSupported;
  UCHAR   DiscretePerformanceStateCount;
} PEP_PPM_QUERY_CAPABILITIES, *PPEP_PPM_QUERY_CAPABILITIES;
```

Members

`FeedbackCounterCount`

[out] The number of processor performance feedback counters supported by the PEP for this processor. On x86/AMD64 platforms, this must be zero.

`IdleStateCount`

[out] The number of processor idle states that the PEP supports. The PEP is not required to support the same number of idle states for all processors. The PEP can set **IdleStateCount** = 0 to indicate that it doesn't support any idle states, in which case the PEP doesn't need to implement any other notifications that deal with processor idle states.

`PerformanceStatesSupported`

[out] Whether the PEP supports performance state controls. Set to TRUE if the PEP supports performance states, or to FALSE if it does not.

`ParkingSupported`

[out] Whether the PEP supports supplying core parking hints. Set to TRUE if the PEP can indicate which cores to park, or to FALSE if it cannot.

`DiscretePerformanceStateCount`

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_CAPABILITIES notification. All four members contain output values that the PEP writes to the structure in response to this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.

Header	pep_x.h (include Pep_x.h)

PEP_NOTIFY_PPM_QUERY_CAPABILITIES

PEP_PPM_QUERY_COORDINATED_DEPENDENCY structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_COORDINATED_DEPENDENCY** structure describes dependencies for coordinated idle states.

Syntax

```
typedef struct _PEP_PPM_QUERY_COORDINATED_DEPENDENCY {
  ULONG                              StateIndex;
  ULONG                              DependencyIndex;
  ULONG                              DependencySize;
  ULONG                              DependencySizeUsed;
  POHANDLE                           TargetProcessor;
  PEP_COORDINATED_DEPENDENCY_OPTION Options[ANYSIZE_ARRAY];
} PEP_PPM_QUERY_COORDINATED_DEPENDENCY, *PPEP_PPM_QUERY_COORDINATED_DEPENDENCY;
```

Members

`StateIndex`

[in] The index of the coordinated idle state which is having its dependencies queried.

`DependencyIndex`

[in] The index of the dependency being queried.

`DependencySize`

[in] The size of the **Dependencies** array.

`DependencySizeUsed`

[out] The number of elements of the **Dependencies** array filled in by the PEP.

`TargetProcessor`

[out] The **POHANDLE** corresponding to the processor being targeted by this dependency, or **NULL** if this is a coordinated state dependency.

`Options`

[out] A list of PEP_COORDINATED_DEPENDENCY_OPTION structures describing dependency options, one of which must be satisfied for this coordinated state to be entered.

Requirements

Minimum supported client	Supported starting with Windows 10.

Header	pep_x.h (include Pep_x.h)

PEP_NOTIFY_PPM_QUERY_COORDINATED_DEPENDENCY notification

PEP_PPM_QUERY_COORDINATED_STATES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_COORDINATED_STATES** structure contains information about each coordinated idle state that the platform extension plug-in (PEP) supports.

Syntax

```
typedef struct _PEP_PPM_QUERY_COORDINATED_STATES {
  ULONG                      Count;
  PEP_COORDINATED_IDLE_STATE States[ANYSIZE_ARRAY];
} PEP_PPM_QUERY_COORDINATED_STATES, *PPEP_PPM_QUERY_COORDINATED_STATES;
```

Members

`Count`

[in] The size of the **States** array. This will be equal to the **PlatformStateCount** returned from the query platform states notification.

`States`

[out] An array of PEP_COORDINATED_IDLE_STATE structures that contains information about each coordinated idle state that the PEP supports.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_QUERY_COORDINATED_STATES notification

PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification

PEP_PPM_QUERY_DISCRETE_PERF_STATES structure

1/30/2019 • 2 minutes to read • Edit Online

Used in the **PEP_NOTIFY_PPM_QUERY_DISCRETE_PERF_STATES** notification that stores the list of discrete performance states that PEP supports, if the **PEP_NOTIFY_PPM_QUERY_CAPABILITIES** notification indicates support for discrete performance states.

Syntax

```
typedef struct _PEP_PPM_QUERY_DISCRETE_PERF_STATES {
  ULONG                     Count;
  PPEP_PROCESSOR_PERF_STATE States;
} PEP_PPM_QUERY_DISCRETE_PERF_STATES, *PPEP_PPM_QUERY_DISCRETE_PERF_STATES;
```

Members

`Count`

On input, the size of the array pointed to by *States*.

`States`

On output, an array of PEP_PROCESSOR_PERF_STATE structures that indicates performance states that is filled by PEP.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Header	pep_x.h (include Pep_x.h)

See Also

PEP_PPM_QUERY_CAPABILITIES

Processor power management (PPM) notifications

PEP_PPM_QUERY_DOMAIN_INFO structure

1/30/2019 • 2 minutes to read • Edit Online

Used in the **PEP_NOTIFY_PPM_QUERY_DOMAIN_INFO** notification that queries for information about a performance domain.

Syntax

```
typedef struct _PEP_PPM_QUERY_DOMAIN_INFO {
  ULONG   DomainId;
  UCHAR   CoordinationType;
  BOOLEAN IdleProcessorsDiscounted;
  BOOLEAN SchedulerDirectedTransitionsSupported;
  BOOLEAN AffinitizePerfSet;
  ULONG   WorstCaseTransitionLatency;
  ULONG   WorstCaseTransitionOverhead;
} PEP_PPM_QUERY_DOMAIN_INFO, *PPEP_PPM_QUERY_DOMAIN_INFO;
```

Members

`DomainId`

On input, the domain ID of the domain being queried.

`CoordinationType`

On output, indicates the coordination type of the performance domain. The possible values are:

- PROCESSOR_DOMAIN_COORDIANTION_SW_ALL (0x00)
- PROCESSOR_DOMAIN_COORDIANTION_SW_ANY (0x01)
- PROCESSOR_DOMAIN_COORDIANTION_HW_ALL (0x02)

If this notification is not supported, PROCESSOR_DOMAIN_COORDIANTION_SW_ALL coordination is used.

`IdleProcessorsDiscounted`

On output, and if HW-ALL coordination is used, this value is TRUE if the platform automatically ignores requests from idle processors as it determines the resolved performance level of the domain, FALSE if requests from idle processors continue to be honored.
If PROCESSOR_DOMAIN_COORDIANTION_HW_ALL coordination is not used: this field is ignored.

`SchedulerDirectedTransitionsSupported`

On output, this value is TRUE if the PEP supports the requirements of scheduler directed performance transitions for this domain, FALSE otherwise.

`AffinitizePerfSet`

`WorstCaseTransitionLatency`

On output, this value indicates the worst case latency for the processor to transition to a new performance state, measured from the time the OS issues the notification to the PEP to transition to a new performance level, to the time the processor is running at the new performance level, in 100ns units.

`WorstCaseTransitionOverhead`

On output, this value indicates the worst case overhead (PEP code execution time plus time the processor is not executing instructions) measured from the time the OS issues the notification to the PEP to transition to a new performance level, to the time the processor is running at the new performance level, in 100ns units.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Header	pep_x.h (include Pep_x.h)

See Also

Processor power management (PPM) notifications

PEP_PPM_QUERY_FEEDBACK_COUNTERS structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_FEEDBACK_COUNTERS** structure describes all the processor performance counters that the platform extension plug-in (PEP) supports for a particular processor.

Syntax

```
typedef struct _PEP_PPM_QUERY_FEEDBACK_COUNTERS {
  ULONG                          Count;
  PEP_PROCESSOR_FEEDBACK_COUNTER Counters[ANYSIZE_ARRAY];
} PEP_PPM_QUERY_FEEDBACK_COUNTERS, *PPEP_PPM_QUERY_FEEDBACK_COUNTERS;
```

Members

`Count`

[in] The number of processor performance feedback counters supported by the PEP. The PEP previously supplied this count in response to a PEP_NOTIFY_PPM_QUERY_CAPABILITIES notification.

`Counters`

[out] The first element in an array of PEP_PROCESSOR_FEEDBACK_COUNTER structures. If this array contains more than one element, the additional elements immediately follow the end of the **PEP_PPM_QUERY_FEEDBACK_COUNTERS** structure. The **Count** member specifies the number of elements in this array. For more information, see Remarks.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_FEEDBACK_COUNTERS notification. The **Count** member of the structure contains an input value that PoFx supplies when this notification is sent. The **Counters** member contains an output value that the PEP writes in response to the notification. The PEP writes any additional **Counters** array elements to the output buffer area that follows the **PEP_PPM_QUERY_FEEDBACK_COUNTERS** structure. The buffer that PoFx allocated for this structure is guaranteed to be large enough to contain any array elements that follow the structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h, Pep_x.h)

PEP_PROCESSOR_FEEDBACK_COUNTER

PEP_PPM_QUERY_IDLE_STATES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_IDLE_STATES** structure describes the idle states of a particular processor.

Syntax

```
typedef struct _PEP_PPM_QUERY_IDLE_STATES {
  ULONG                    Count;
  ULONG                    MaximumCoordinatedProcessors;
  PEP_PROCESSOR_IDLE_STATE IdleStates[ANYSIZE_ARRAY];
} PEP_PPM_QUERY_IDLE_STATES, *PPEP_PPM_QUERY_IDLE_STATES;
```

Members

`Count`

[in] The number of elements in the **IdleStates** array. This member is set to the **IdleStateCount** value that the PEP previously supplied for this processor in response to the PEP_NOTIFY_PPM_QUERY_CAPABILITIES notification.

`MaximumCoordinatedProcessors`

[out] The maximum number of secondary processors that are subordinate to this processor for any transitions to idle states. A primary processor can enter the selected idle state only after the secondary processors have entered their corresponding idle states. The PEP must set the **MaximumCoordinatedProcessors** member to a number that is less than the total number of processors in the hardware platform.

`IdleStates`

[in] The first element in an array of PEP_PROCESSOR_IDLE_STATE structures. Each array element describes one of the idle states of this processor. If the array contains more than one element, the additional elements immediately follow the end of the **PEP_PPM_QUERY_IDLE_STATES** structure. The number of array elements is specified by the **Count** member. The buffer that PoFx allocates to hold this structure is guaranteed to be large enough to contain the **PEP_PPM_QUERY_IDLE_STATES** structure plus any array elements that follow this structure. Each idle state is identified by its array index. If the array contains N elements, idle state indexes range from 0 to N−1.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_IDLE_STATES notification. The **Count** member of the structure contains an input value that PoFx supplies when this notification is sent. The other two members contain output values that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pepfx.h)

PEP_NOTIFY_PPM_QUERY_IDLE_STATES

PEP_PROCESSOR_IDLE_STATE

PEP_PPM_QUERY_IDLE_STATES_V2 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_IDLE_STATES_V2** structure is used during processor initialization to query the platform extension plug-in (PEP) for a list of processor idle states that the processor supports.

Syntax

```
typedef struct _PEP_PPM_QUERY_IDLE_STATES_V2 {
  ULONG                       Count;
  PEP_PROCESSOR_IDLE_STATE_V2 IdleStates[ANYSIZE_ARRAY];
} PEP_PPM_QUERY_IDLE_STATES_V2, *PPEP_PPM_QUERY_IDLE_STATES_V2;
```

Members

`Count`

[in] The number of elements in the **IdleStates** array. The Windows power management framework (PoFx) previously sent the PEP a PEP_NOTIFY_PPM_QUERY_CAPABILITIES notification to determine this number.

`IdleStates`

[out] The first element in an array of PEP_PROCESSOR_IDLE_STATE_V2 structures that describe the processor idle states. If this array contains more than one element, the addition array elements follow the end of the **PEP_PPM_QUERY_IDLE_STATES_V2** structure.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification. The **Count** member of the **PEP_PPM_QUERY_IDLE_STATES_V2** structure contains an input value that is supplied by the Windows power management framework (PoFx). The **IdleStates** array elements contain output values that the PEP writes to the structure in response to this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_PROCESSOR_IDLE_STATE_V2

PEP_PPM_QUERY_LP_SETTINGS structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_LP_SETTINGS** structure contains a kernel handle to the registry key that contains the power optimization settings that the platform extension plug-in (PEP) has defined for each power scenario.

Syntax

```
typedef struct _PEP_PPM_QUERY_LP_SETTINGS {
  HANDLE RegistryRoot;
} PEP_PPM_QUERY_LP_SETTINGS, *PPEP_PPM_QUERY_LP_SETTINGS;
```

Members

`RegistryRoot`

[out] The kernel handle to the registry root that contains the settings for a platform power scenario. For more information, see Remarks.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_LP_SETTINGS notification. The **RegistryRoot** member contains an output value that the PEP writes to the structure in response to this notification.

The PEP can provide settings for certain key power scenarios such as full-screen video playback and connected standby that have unique characteristics that can benefit from specially tuned power policies that are different from the default settings used by Windows. The PEP loads the settings for such a power scenario into the registry and passes the registry key for these settings to the operating system.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pepfx.h)

See Also

PEP_NOTIFY_PPM_QUERY_LP_SETTINGS

PEP_PPM_QUERY_PERF_CAPABILITIES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_PERF_CAPABILITIES** structure describes the performance capabilities of the processors in the specified processor performance domain.

Syntax

```
typedef struct _PEP_PPM_QUERY_PERF_CAPABILITIES {
  ULONG HighestPerformance;
  ULONG NominalPerformance;
  ULONG LowestNonlinearPerformance;
  ULONG LowestPerformance;
  ULONG DomainId;
  ULONG DomainMembers;
} PEP_PPM_QUERY_PERF_CAPABILITIES, *PPEP_PPM_QUERY_PERF_CAPABILITIES;
```

Members

`HighestPerformance`

[out] The highest performance level in platform-specific units. For more information, see Remarks.

`NominalPerformance`

[out] The nominal performance level in platform-specific units. For more information, see Remarks.

`LowestNonlinearPerformance`

[out] The lowest nonlinear performance level in platform-specific units. For more information, see Remarks.

`LowestPerformance`

[out] The lowest performance level in platform-specific units. For more information, see Remarks.

`DomainId`

[out] The domain ID of the processor performance domain.

`DomainMembers`

[out] The number of processors in this performance domain.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_PERF_CAPABILITIES notification. All six members contain output values that the platform extension plug-in (PEP) writes to the structure in response to this notification.

Processor performance levels are specified in platform-specific units. For example, a hardware platform might use a metric such as the processor clock frequency to provide a rough approximation to the amount of processing work that is being done. For more information, see Platform Performance Thresholds.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_QUERY_PERF_CAPABILITIES

Platform Performance Thresholds

PEP_PPM_PERF_CONSTRAINTS structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_PERF_CONSTRAINTS** structure describes the performance limits to apply to the processor.

Syntax

```
typedef struct _PEP_PPM_QUERY_PERF_CONSTRAINTS {
  ULONG GuaranteedPerformanceLimit;
  ULONG LimitReasons;
} PEP_PPM_PERF_CONSTRAINTS, *PPEP_PPM_PERF_CONSTRAINTS;
```

Members

`GuaranteedPerformanceLimit`

[out] The guaranteed performance threshold in platform-specific units. If nonzero, this value specifies the maximum sustained performance level of the processor, taking into account all known external constraints (power budgeting, thermal constraints, power source, and so on). All processors are expected to be able to simultaneously sustain their guaranteed performance levels. For more information, see Platform Performance Thresholds.

`LimitReasons`

[out] The reasons for which the processor's performance can be limited. Set this member to zero or to the bitwise-OR of one or more of the following values:

LIMIT REASON	MEANING
PERFORMANCE_LIMIT_THERMAL 0x1	The processor performance can be limited due to an out-of-band (that is, non-ACPI Thermal Zone) thermal condition.
PERFORMANCE_LIMIT_POWER 0x2	The processor performance can be limited to keep power consumption of the processor within hardware safety limits.

PER FOR MA NCE _LI MIT _DO MAI N_D EPE NDE NC Y 0x4	The processor performance can be limited because of a voltage or frequency dependency between this processor and another, non-processor device.

Remarks

This structure is used by the PEP_NOTIFY_PPM_PERF_CONSTRAINTS notification. The **GuaranteedPerformanceLimit** and **LimitReasons** members contain output values that the platform extension plug-in (PEP) writes to the structure in response to this notification.

The **GuaranteedPerformanceLimit** member value is specified in platform-specific units. For example, a hardware platform might use a metric such as the processor clock frequency to provide a rough approximation to the amount of processing work that is being done.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_NOTIFY_PPM_PERF_CONSTRAINTS

PEP_PPM_QUERY_PLATFORM_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_PLATFORM_STATE** structure contains information about a platform idle state.

Syntax

```
typedef struct _PEP_PPM_QUERY_PLATFORM_STATE {
  ULONG                  StateIndex;
  PEP_PLATFORM_IDLE_STATE State;
} PEP_PPM_QUERY_PLATFORM_STATE, *PPEP_PPM_QUERY_PLATFORM_STATE;
```

Members

`StateIndex`

[in] The index of this platform idle state. If the hardware platform supports N platform idle states, the states are numbered 0 to N-1. The Windows power management framework (PoFx) previously sent a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification to the platform extension plug-in (PEP) to determine the number of supported platform idle states.

`State`

[out] A PEP_PLATFORM_IDLE_STATE structure that describes the platform idle state.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_PLATFORM_STATE notification. The **StateIndex** member of the **PEP_PPM_QUERY_PLATFORM_STATE** structure contains an input value that is supplied by the Windows power management framework (PoFx) when this notification is sent to the PEP. The **State** member contains an output value that the PEP writes to the structure in response to the notification.

The buffer that PoFx allocates to hold the **PEP_PPM_QUERY_PLATFORM_STATE** structure is guaranteed to be large enough to contain this structure plus any elements of the **State.DependencyArray** array that follow this structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES

PEP_PLATFORM_IDLE_STATE

PEP_PPM_QUERY_PLATFORM_STATES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_PLATFORM_STATES** structure specifies the number of platform idle states the hardware platform supports.

Syntax

```
typedef struct _PEP_PPM_QUERY_PLATFORM_STATES {
  ULONG PlatformStateCount;
} PEP_PPM_QUERY_PLATFORM_STATES, *PPEP_PPM_QUERY_PLATFORM_STATES;
```

Members

`PlatformStateCount`

The number of platform idle states supported by the platform.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES

PEP_PPM_QUERY_STATE_NAME structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_STATE_NAME** structure contains information about a specific coordinated or platform idle state.

Syntax

```
typedef struct _PEP_PPM_QUERY_STATE_NAME {
  ULONG  StateIndex;
  USHORT NameSize;
  PWSTR  Name;
} PEP_PPM_QUERY_STATE_NAME, *PPEP_PPM_QUERY_STATE_NAME;
```

Members

`StateIndex`

[in] The index of the state that the OS is querying about.

`NameSize`

[in/out] If **Name** is **NULL**, returns the size of the buffer required to hold **Name** (including the trailing **UNICODE_NULL** character), in WCHARs. If **Name** is not **NULL**, supplies the size of the **Name** buffer, in WCHARs.

`Name`

[in] A pointer to a buffer to copy the name of the state to, or **NULL**.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_QUERY_COORDINATED_STATE_NAME notification

PEP_NOTIFY_PPM_QUERY_PROCESSOR_STATE_NAME notification

PEP_PPM_QUERY_VETO_REASON structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_VETO_REASON** structure supplies a wide-character, null-terminated string that contains a descriptive, human-readable name for a veto reason.

Syntax

```
typedef struct _PEP_PPM_QUERY_VETO_REASON {
  ULONG  VetoReason;
  USHORT NameSize;
  PWSTR  Name;
} PEP_PPM_QUERY_VETO_REASON, *PPEP_PPM_QUERY_VETO_REASON;
```

Members

`VetoReason`

[in] The index that identifies this veto reason. If the platform extension plug-in (PEP) supports N veto reasons, valid veto reason indexes range from 1 to N. The PEP previously specified the number of supported veto reasons in response to a PEP_NOTIFY_PPM_QUERY_VETO_REASONS notification.

`NameSize`

[out] The size, in bytes, of the string buffer pointed to by the **Name** member. This string size includes the storage space for the null character that terminates the wide-character string.

`Name`

[in] A pointer to a PoFx-allocated string buffer. If this buffer pointer is non-**NULL**, the PEP writes a wide-character, null-terminated string to the buffer (and writes nothing to the **NameSize** member). Otherwise, the PEP writes nothing to this buffer and instead writes the required string size to the **NameSize** member.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_VETO_REASON notification. The **VetoReason** and **Name** members contain input values that are supplied by the Windows power management framework (PoFx). If the input value of the **Name** member is **NULL**, the PEP writes an output value (the required string buffer size) to the **NameSize** member.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_NOTIFY_PPM_QUERY_VETO_REASON

PEP_NOTIFY_PPM_QUERY_VETO_REASONS

PEP_PPM_QUERY_VETO_REASONS structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_VETO_REASONS** structure specifies the total number of veto reasons that the PEP uses in calls to the ProcessorIdleVeto and PlatformIdleVeto routines.

Syntax

```
typedef struct _PEP_PPM_QUERY_VETO_REASONS {
  ULONG VetoReasonCount;
} PEP_PPM_QUERY_VETO_REASONS, *PPEP_PPM_QUERY_VETO_REASONS;
```

Members

`VetoReasonCount`

[out] The number of veto codes used by the PEP.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_VETO_REASONS notification. The **VetoReasonCount** member contains an output value that the PEP writes to this member in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_QUERY_VETO_REASONS

PEP_PPM_RESUME_FROM_SYSTEM_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

Used by the **PEP_NOTIFY_PPM_RESUME_FROM_SYSTEM_STATE** notification that notifies the PEP that the system has just resumed from a system power state.

Syntax

```
typedef struct _PEP_PPM_RESUME_FROM_SYSTEM_STATE {
  SYSTEM_POWER_STATE TargetState;
} PEP_PPM_RESUME_FROM_SYSTEM_STATE, *PPEP_PPM_RESUME_FROM_SYSTEM_STATE;
```

Members

`TargetState`

On input, a SYSTEM_POWER_STATE-type value that indicates the power state that the system is entering.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Header	pep_x.h (include Pep_x.h)

See Also

Processor power management (PPM) notifications

PEP_PPM_TEST_IDLE_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_TEST_IDLE_STATE** structure contains information about whether the processor can immediately enter a processor idle state.

Syntax

```
typedef struct _PEP_PPM_TEST_IDLE_STATE {
  ULONG ProcessorState;
  ULONG PlatformState;
  ULONG VetoReason;
} PEP_PPM_TEST_IDLE_STATE, *PPEP_PPM_TEST_IDLE_STATE;
```

Members

`ProcessorState`

(input) The index of the processor idle state that is to be entered. The platform extension plug-in (PEP) previously specified the supported processor idle states in response to a PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification. If the PEP specified N processor idle states, valid processor-idle-state indexes range from 0 to N-1.

`PlatformState`

[in] The index of the platform idle state that the hardware platform will enter when the processor enters the processor idle state specified by **ProcessorState**. The PEP previously specified the supported platform idle states in response to a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification. If the PEP specified M platform idle states, valid platform-idle-state indexes range from 0 to M-1. If no change in platform idle state will occur, this member will contain the value **PEP_PLATFORM_IDLE_STATE_NONE** (0xffffffff).

`VetoReason`

[out] The nonzero index value that identifies reason the PEP needs to veto this idle state transition, or **PEP_IDLE_VETO_NONE** (0) if the PEP is prepared to immediately make this transition. If the PEP supports N veto reasons, valid veto reason indexes range from 1 to N. The PEP previously specified the number of supported veto reasons in response to a PEP_NOTIFY_PPM_QUERY_VETO_REASONS notification.

Remarks

This structure is used by the PEP_NOTIFY_PPM_TEST_IDLE_STATE notification. The **ProcessorState** and **PlatformState** members contain input values that are supplied by the Windows power management framework (PoFx). The PEP writes an output value to the **VetoReason** member of this structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_PREPARE_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PREPARE_DEVICE** structure identifies a device that must be started up in preparation for its use by the operating system.

Syntax

```
typedef struct _PEP_PREPARE_DEVICE {
  PCUNICODE_STRING DeviceId;
  BOOLEAN          DeviceAccepted;
} PEP_PREPARE_DEVICE, *PPEP_PREPARE_DEVICE;
```

Members

`DeviceId`

[in] A string that uniquely identifies the device. This member is a pointer to a UNICODE_STRING structure that contains a device identification string.

`DeviceAccepted`

[out] Whether the PEP claims ownership of the device. The PEP sets this member to TRUE to claim ownership of the device, or to FALSE to indicate that it does not own the device. The PEP that claims ownership is responsible for handling device power management (DPM) notifications for the device.

Remarks

This structure is used by the PEP_DPM_PREPARE_DEVICE notification. The **DeviceId** member of the structure contains an input value that is supplied by the Windows power management framework (PoFx). The **DeviceAccepted** member contains an output value that the PEP writes to the structure in response to this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_DPM_PREPARE_DEVICE

UNICODE_STRING

PEP_PROCESSOR_FEEDBACK_COUNTER structure

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_PROCESSOR_FEEDBACK_COUNTER** structure describes a feedback counter to the operating system.

Syntax

```
typedef struct _PEP_PROCESSOR_FEEDBACK_COUNTER {
  struct {
    ULONG Affinitized : 1;
    ULONG Type : 2;
    ULONG Counter : 4;
    ULONG DiscountIdle : 1;
    ULONG Reserved : 24;
  };
  ULONG  NominalRate;
} PEP_PROCESSOR_FEEDBACK_COUNTER, *PPEP_PROCESSOR_FEEDBACK_COUNTER;
```

Members

`Affinitized`

Identifies the counter process affinity. If set to 1, the counter must be read while executing on the target processor, otherwise, it will be set to 0.

`Type`

Specifies the data type of the counter.

The processor feedback counter data types are:

VALUE	MEANING
PR **OCE** **SSO** **R_F** **EED** **BAC** **K_T** **YPE** **_IN** **STA** **NT** **ANE** **OU** **S** 0x0 0	The feedback counter returns the instantaneous value of the property being counted.

PR **OCE** **SSO** **R_F** **EED** **BAC** **K_T** **YPE** **_RE** **LAT** **IVE** 0x0 1	The feedback counter returns two incrementing values: the nominal count, and the actual count. Nominal count increments at a fixed nominal rate. Actual count increments at a variable rate relative to the property being counted. When the property is incrementing at its nominal rate, the two values should increment at the same rate. To compute an average rate over a time period, the OS reads the counter once and the beginning of the period and once at the end and computes:

`Counter`

Specifies the data the counter is providing.

The processor feedback counter types are:

VALUE	MEANING
PR **OCE** **SSO** **R_F** **EED** **BAC** **K_C** **OU** **NTE** **R_F** **REQ** **UEN** **CY** 0x0 0	The feedback counter returns the clock speed of the processor. The nominal rate is the nominal clock speed, in MHz.
PR **OCE** **SSO** **R_F** **EED** **BAC** **K_C** **OU** **NTE** **R_P** **ERF** **OR** **MA** **NCE** 0x0 1	The feedback counter returns the current processor performance. The nominal rate is equivalent to the processor's **NominalPerformance** (see PEP_NOTIFY_PPM_QUERY_PERF_CAPABILITIES notification).

`DiscountIdle`

`Reserved`

This member is reserved and should be set to zero.

`NominalRate`

Specifies the nominal rate of the counter.

Remarks

This structure

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP structures

PEP_NOTIFY_PPM_QUERY_PERF_CAPABILITIES notification

PEP_PROCESSOR_IDLE_CONSTRAINTS structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PROCESSOR_IDLE_CONSTRAINTS** structure specifies a set of constraints that the PEP uses to select a processor idle state.

Syntax

```
typedef struct _PEP_PROCESSOR_IDLE_CONSTRAINTS {
  ULONGLONG               IdleDuration;
  BOOLEAN                 Interruptible;
  PEP_PROCESSOR_IDLE_TYPE Type;
} PEP_PROCESSOR_IDLE_CONSTRAINTS, *PPEP_PROCESSOR_IDLE_CONSTRAINTS;
```

Members

`IdleDuration`

The length of time, in 100-nanosecond units, for which the processor is expected to stay in the selected idle state. This is the operating system's current best estimate and might vary over time without further notification.

`Interruptible`

Whether the processor must be able to respond to interrupts in the selected idle state. A value of TRUE indicates that the processor must be interruptible in this idle state. A value of FALSE indicates that the processor is not required to be interruptible in this idle state.

`Type`

A PEP_PROCESSOR_IDLE_TYPE enumeration value that indicates whether these idle constraints apply to just the current processor (**Type** = **PepIdleTypeProcessor**) or to all processors in the hardware platform (**Type** = **PepIdleTypePlatform**).

Remarks

The **Constraints** member of the PEP_PPM_IDLE_SELECT structure is a pointer to a **PEP_PROCESSOR_IDLE_CONSTRAINTS** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pepfx.h)

See Also

PEP_PPM_IDLE_SELECT

PEP_PROCESSOR_IDLE_TYPE

PEP_PROCESSOR_IDLE_DEPENDENCY structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PROCESSOR_IDLE_DEPENDENCY** structure specifies the dependencies of a platform idle state on the specified processor.

Syntax

```
typedef struct _PEP_PROCESSOR_IDLE_DEPENDENCY {
  POHANDLE TargetProcessor;
  UCHAR    ExpectedState;
  BOOLEAN  AllowDeeperStates;
  BOOLEAN  LooseDependency;
} PEP_PROCESSOR_IDLE_DEPENDENCY, *PPEP_PROCESSOR_IDLE_DEPENDENCY;
```

Members

`TargetProcessor`

A **POHANDLE** value that identifies the processor. The platform extension plug-in (PEP) received this handle in a previous PEP_DPM_REGISTER_DEVICE notification.

`ExpectedState`

The index of the processor idle state that this processor must enter to initiate the platform's transition to this platform idle state. If the **IdleStates** array in the PEP_PPM_QUERY_IDLE_STATES_V2 structure contains N elements, the idle states are numbered 0 to N-1 in the order in which they appear in the array.

`AllowDeeperStates`

Whether a secondary (subordinate) processor can be in a deeper processor idle state than **ExpectedState** and still satisfy the constraints of the transition to the platform idle state. Set this member to **TRUE** if a secondary processor in a deeper idle state can still satisfy the constraints, and to **FALSE** if it cannot. A primary processor (identified by the **TargetProcessor** member) can enter the selected idle state only after its secondary processors have entered their corresponding idle states.

`LooseDependency`

Whether the platform idle state has a loose dependency on the idle state of this processor. Set this member to **TRUE** to indicate a loose dependency in which a best effort to synchronize the idle state transitions of the platform and processor is sufficient. Set to **FALSE** to indicate a dependency in which the operating system is required to strictly synchronize these transitions. If **LooseDependency** is **FALSE**, the **WakesSpuriously** bit in the PEP_PROCESSOR_IDLE_STATE_V2 structure for this processor must be **FALSE**.

Remarks

The **DependencyArray** member of the PEP_PPM_IDLE_SELECT structure is a pointer to an array of **PEP_PROCESSOR_IDLE_DEPENDENCY** structures. The **DependencyArray** member of the PEP_PLATFORM_IDLE_STATE structure is the first element in an array of **PEP_PROCESSOR_IDLE_DEPENDENCY** structures.

Requirements

PEP_PROCESSOR_IDLE_STATE_UPDATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PROCESSOR_IDLE_STATE_UPDATE** structure contains the updated properties of a processor idle state.

Syntax

```
typedef struct _PEP_PROCESSOR_IDLE_STATE_UPDATE {
  ULONG Version;
  ULONG Latency;
  ULONG BreakEvenDuration;
} PEP_PROCESSOR_IDLE_STATE_UPDATE, *PPEP_PROCESSOR_IDLE_STATE_UPDATE;
```

Members

`Version`

The version number of this structure. Set this member to PEP_PROCESSOR_IDLE_STATE_UPDATE_VERSION.

`Latency`

The worst-case latency, in 100-nanosecond units, that the platform requires to wake from this platform idle state in response to a wake event.

`BreakEvenDuration`

The minimum amount of time, specified in 100-nanosecond units, that the platform must spend in this idle state to make a transition to this state worthwhile. PoFx uses this member value as a hint to avoid switching the platform to an idle state unless the platform is likely to remain in this state for at least the amount of time specified by **BreakEvenDuration**.

Remarks

The *Update* parameter to the UpdateProcessorIdleState routine is a pointer to a **PEP_PROCESSOR_IDLE_STATE_UPDATE** structure. This routine updates the properties of the specified idle state for a processor. The PEP must not call this routine until it has responded to a PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification for this processor.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_PROCESSOR_PARK_PREFERENCE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PROCESSOR_PARK_PREFERENCE** structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding whether the specified processor should be parked to reduce power consumption.

Syntax

```
typedef struct _PEP_PROCESSOR_PARK_PREFERENCE {
  PEPHANDLE Processor;
  UCHAR     PoPreference;
  UCHAR     PepPreference;
} PEP_PROCESSOR_PARK_PREFERENCE, *PPEP_PROCESSOR_PARK_PREFERENCE;
```

Members

`Processor`

A **PEPHANDLE** value that identifies the processor. The PEP supplied this handle in a previous PEP_DPM_REGISTER_DEVICE notification.

`PoPreference`

The operating system's parking preference for this processor. For more information, see Remarks.

`PepPreference`

The PEP's parking preference for this processor. For more information, see Remarks.

Remarks

The **Processors** member of the PEP_PPM_PARK_SELECTION structure is a pointer to an array of **PEP_PROCESSOR_PARK_PREFERENCE** structures.

The **Processor** and **PoPreference** members of the **PEP_PROCESSOR_PARK_PREFERENCE** structure contain input values that are supplied by the Windows power management framework when a PEP_NOTIFY_PPM_PARK_SELECTION notification is sent to the PEP. The **PepPreference** member contains an output value that the PEP writes to the structure in response to this notification.

The following table lists the three values that are defined for the **PoPreference** and **PepPreference** members.

PARKING PREFERENCE	VALUE	MEANING
PROCESSOR_PARK_PREFERENCE_NONE	0x0	No preference. Either parked or unparked is okay.
PROCESSOR_PARK_PREFERENCE_PARKED	0x1	The operating system or PEP specifies that the processor should be parked.

PROCESSOR_PARK_PREFERENCE_UNPARKED	0x2	The operating system or PEP specifies that the processor should not be parked.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_PROCESSOR_PERF_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

Use in the **PEP_NOTIFY_PPM_QUERY_DISCRETE_PERF_STATES** notification. This structure describes the properties of a single performance state.

Syntax

```
typedef struct _PEP_PROCESSOR_PERF_STATE {
  ULONG Performance;
  ULONG Frequency;
  ULONG Reserved[4];
} PEP_PROCESSOR_PERF_STATE, *PPEP_PROCESSOR_PERF_STATE;
```

Members

`Performance`

On output, the performance level (on the scale returned by the PEP_QUERY_COMPONENT_PERF_CAPABILITIES notification) of this performance state.

`Frequency`

On output, the frequency (in MHz) of this performance state.

`Reserved`

Reserved.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Header	pep_x.h (include Pep_x.h)

PEP_QUERY_COMPONENT_PERF_CAPABILITIES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_COMPONENT_PERF_CAPABILITIES** structure specifies the number of performance state (P-state) sets that are defined for a component.

Syntax

```
typedef struct _PEP_QUERY_COMPONENT_PERF_CAPABILITIES {
  PEPHANDLE DeviceHandle;
  ULONG     Component;
  ULONG     SetCount;
} PEP_QUERY_COMPONENT_PERF_CAPABILITIES, *PPEP_QUERY_COMPONENT_PERF_CAPABILITIES;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`SetCount`

[out] The number of P-state sets that are defined for this component.

Remarks

This structure is used by the PEP_DPM_QUERY_COMPONENT_PERF_CAPABILITIES notification. The **DeviceHandle** and **Component** members contain input values that are supplied by the Windows power management framework (PoFx) when this notification is sent. The **SetCount** member contains an output value that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_QUERY_COMPONENT_PERF_SET structure

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_COMPONENT_PERF_SET** structure contains query information about a set of performance state values (P-state set) for a component.

Syntax

```
typedef struct _PEP_QUERY_COMPONENT_PERF_SET {
  PEPHANDLE           DeviceHandle;
  ULONG               Component;
  ULONG               Set;
  ULONGLONG           Flags;
  PEP_PERF_STATE_UNIT Unit;
  PEP_PERF_STATE_TYPE Type;
  union {
    struct {
      ULONG Count;
    } Discrete;
    struct {
      ULONGLONG Minimum;
      ULONGLONG Maximum;
    } Range;
  };
} PEP_QUERY_COMPONENT_PERF_SET, *PPEP_QUERY_COMPONENT_PERF_SET;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Set`

[in] The index that identifies this P-state set. If this component has M P-state sets, P-state set indexes range from 0 to M–1. The PEP previously specified the number of P-state sets in response to a PEP_DPM_QUERY_COMPONENT_PERF_CAPABILITIES notification.

`Flags`

[in] A set of input flags. No flag bits are currently defined for this member, which is always zero.

`Unit`

[out] A PEP_PERF_STATE_UNIT enumeration value that indicates whether the values for this P-state set are expressed in hertz (frequency units) or bits per second (bandwidth units).

`Type`

[out] A PEP_PERF_STATE_TYPE enumeration value that indicates whether the performance values for this P-state set are expressed as a list of discrete values or as a continuous range of values.

`Discrete`

`Discrete.Count`

`Range`

`Range.Minimum`

`Range.Maximum`

Remarks

This structure is used by the PEP_DPM_QUERY_COMPONENT_PERF_SET notification. The **DeviceHandle**, **Component**, **Set**, and **Flags** members contain input values that are supplied by the Windows power management framework (PoFx) when this notification is sent. The **Discrete** member or **Range** member contains an output value that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_PERF_STATE_UNIT

PEP_QUERY_COMPONENT_PERF_SET_NAME structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_COMPONENT_PERF_SET_NAME** structure contains query information about a set of performance state values (P-state set) for a component.

Syntax

```
typedef struct _PEP_QUERY_COMPONENT_PERF_SET_NAME {
  PEPHANDLE DeviceHandle;
  ULONG     Component;
  ULONG     Set;
  USHORT    NameSize;
  PWCHAR    Name;
} PEP_QUERY_COMPONENT_PERF_SET_NAME, *PPEP_QUERY_COMPONENT_PERF_SET_NAME;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Set`

[in] The index that identifies this P-state set. If this component has M P-state sets, P-state set indexes range from 0 to M–1. The PEP previously specified the number of P-state sets in response to a PEP_DPM_QUERY_COMPONENT_PERF_CAPABILITIES notification.

`NameSize`

[in, out] On input, the size, in bytes, of the buffer pointed to by the **Name** member. If **Name** is NULL, the PEP overwrites the input value of **NameSize** with the buffer size required for the name string.

`Name`

[in] A pointer to an output buffer. The PEP writes the name of the P-state to this buffer. The name is stored as a wide-character, null-terminated string. The **Name** member is NULL if the Windows power management framework (PoFx) needs to determine how large a buffer to allocate for the name string. If **Name** is non-NULL, the buffer must be large enough to contain the entire string, including the terminating null character.

Remarks

This structure is used by the PEP_DPM_QUERY_COMPONENT_PERF_SET_NAME notification. The

DeviceHandle, **Component**, and **Set** members of the structure contain input values supplied by PoFx when this notification is sent. If the **Name** member is non-NULL, the PEP writes a string to the buffer pointed to by **Name**. If **Name** is NULL, PEP writes the required buffer size to the **NameSize** member.

The string that the PEP writes to the output buffer should contain a descriptive name for the P-state set. This name is intended to make log entries and diagnostic messages easier to understand.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_QUERY_COMPONENT_PERF_STATES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_COMPONENT_PERF_STATES** structure contains a list of discrete performance state (P-state) values for the specified P-state set.

Syntax

```
typedef struct _PEP_QUERY_COMPONENT_PERF_STATES {
  PEPHANDLE       DeviceHandle;
  ULONG           Component;
  ULONG           Set;
  PPEP_PERF_STATE States;
} PEP_QUERY_COMPONENT_PERF_STATES, *PPEP_QUERY_COMPONENT_PERF_STATES;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Set`

[in] The index that identifies this P-state set. If M is the number of P-state sets for this component, P-state set indexes range from 0 to M–1. The PEP previously specified the number of P-state sets in response to a PEP_DPM_QUERY_COMPONENT_PERF_CAPABILITIES notification.

`States`

[in] A pointer to an output buffer. The PEP writes an array of PEP_PERF_STATE structures to this buffer. Each array element describes one P-state in the P-state set specified by the **Set** member. The Windows power management framework (PoFx) allocated this buffer, which is guaranteed to be large enough to contain an array of the length that the PEP previously wrote to the **Discrete.Count** member of the PEP_QUERY_COMPONENT_PERF_SET structure in response to a PEP_DPM_QUERY_COMPONENT_PERF_SET notification.

Remarks

This structure is used by the PEP_DPM_QUERY_COMPONENT_PERF_STATES notification. All four members of this structure contain input values that are supplied by PoFx when this notification is sent.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_PERF_STATE

PEP_QUERY_CURRENT_COMPONENT_PERF_STATE structure

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_CURRENT_COMPONENT_PERF_STATE** structure contains information about the current P-state in the specified P-state set.

Syntax

```
typedef struct _PEP_QUERY_CURRENT_COMPONENT_PERF_STATE {
  PEPHANDLE DeviceHandle;
  ULONG     Component;
  ULONG     Set;
  union {
    ULONG     StateIndex;
    ULONGLONG StateValue;
  };
} PEP_QUERY_CURRENT_COMPONENT_PERF_STATE, *PPEP_QUERY_CURRENT_COMPONENT_PERF_STATE;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Set`

[in] The index that identifies this P-state set. If M is the number of P-state sets for this component, P-state set indexes range from 0 to M–1. The PEP previously specified the number of P-state sets in response to a PEP_DPM_QUERY_COMPONENT_PERF_CAPABILITIES notification.

`StateIndex`

`StateValue`

Remarks

This structure is used by the PEP_DPM_QUERY_CURRENT_COMPONENT_PERF_STATE notification. The **DeviceHandle**, **Component**, and **Set** members contain input values supplied by the Windows power management framework (PoFx) when this notification is sent. The **StateIndex** member or **StateValue** member contains an output value that the PEP writes to the structure in response to the notification.

PEP_QUERY_SOC_SUBSYSTEM structure

1/30/2019 • 3 minutes to read • Edit Online

The **PEP_QUERY_SOC_SUBSYSTEM** structure is used by the PEP_DPM_QUERY_SOC_SUBSYSTEM notification to gather basic information about a particular system on a chip (SoC) subsystem.

Syntax

```
typedef struct _PEP_QUERY_SOC_SUBSYSTEM {
  ULONG          PlatformIdleStateIndex;
  ULONG          SubsystemIndex;
  PVOID          SubsystemHandle;
  UNICODE_STRING ParentName;
  UNICODE_STRING SubsystemName;
  ULONG          MetadataCount;
  ULONG          Flags;
} PEP_QUERY_SOC_SUBSYSTEM, *PPEP_QUERY_SOC_SUBSYSTEM;
```

Members

`PlatformIdleStateIndex`

[in] The platform idle state index that is being queried by the kernel.

`SubsystemIndex`

[in] The subsystem index, which is a unique index assigned by the OS to each subsystem within the context of a given **PlatformIdleStateIndex**.

The kernel initializes this value to zero and increments it for each subsequent subsystem static info notification. A value of 0 means it's the first such notification for the given **PlatformIdleStateIndex**. This field is intended to give the PEP context between instances of this notification. It is the only field whose input value varies across instances of this notification for a given **PlatformIdleStateIndex** and a PEP might use this value to look up a subsystem.

The PEP can ignore this value.

`SubsystemHandle`

[out] A context pointer that the PEP can optionally assign a value to. It will receive the pointer on subsequent notifications for this particular subsystem. In subsequent notifications, a PEP uses **PlatformIdleStateIndex** along with **SubsystemName** and/or **SubsystemHandle** to look up a particular subsystem's accounting data.

By default the value if this member is zero. This value is ignored by the OS and used only in notifications.

The PEP is not required to fill this member.

`ParentName`

[in/out] A buffer for holding the parent name of the corresponding subsystem. Each subsystem has a parent and subsystems with the same value for **ParentName** are considered siblings. Subsystem sibling hierarchies are optional. In the absence of any hierarchy, all subsystems are top level subsystems and specify a common value for **ParentName**. To indicate a hierarchy, top level subsystems specify a common **ParentName** while each non-top-level subsystem specifies its parent subsystem's **SubsystemName** for **ParentName**.

Prior to entry, the kernel will:

- Pre-allocate 64 **WCHARs** for **ParentName.Buffer[]**
- Zero the buffer
- Set **ParentName.MaximumLength** to the size of the buffer in bytes, and
- Set **ParentName.Length** = **0**

Prior to exit, the PEP must copy a null-terminated string into **ParentName.Buffer** and update **ParentName.Length** with a byte count that is **sizeof(WCHAR)** times the number of UNICODE characters copied, not including the terminating **UNICODE_NULL**.

The PEP must use the allocated memory that is pointed to by the address in **ParentName.Buffer** to provide the parent name. Since this memory is pre-allocated, its size cannot be changed. The PEP is responsible for truncating the parent name, if necessary, so that it does not exceed the length specified in **ParentName.MaximumLength** (including the terminating **UNICODE_NULL** character).

`SubsystemName`

[in/out] A buffer for holding this subsystem's name. Every subsystem has a subsystem name and **SubsystemName** must be unique among all subsystems within the context of a given platform idle state. A subsystem's **SubsystemName** cannot be the same as **ParentName**.

Prior to entry, the kernel will:

- Pre-allocate 64 **WCHARs** for **SubsystemName.Buffer[]**
- Zero the buffer
- Set **SubsystemName.MaximumLength** to the size of the buffer in bytes, and
- Set **SubsystemName.Length** = **0**

Prior to exit, the PEP must copy a null-terminated string into **SubsystemName.Buffer** and update **SubsystemName.Length** with a byte count that is **sizeof(WCHAR)** times the number of UNICODE characters copied, not including the terminating **UNICODE_NULL**.

The PEP must use the allocated memory that is pointed to by the address in **SubsystemName.Buffer** to provide the subsystem name. Since this memory is pre-allocated, its size cannot be changed. The PEP is responsible for truncating the subsystem name, if necessary, so that it does not exceed the length specified in **SubsystemName.MaximumLength** (including the terminating **UNICODE_NULL** character).

`MetadataCount`

[out] The number of metadata key/value string pairs tallied by this SoC subsystem.

Metadata is optional. The PEP returns zero if it does not report any metadata for this SoC subsystem.

`Flags`

This member is reserved and should be set to zero.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME** structure is used by the PEP_DPM_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME notification to collect details about the blocking duration for a particular system on a chip (SoC) subsystem.

Syntax

```
typedef struct _PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME {
  ULONG            PlatformIdleStateIndex;
  PVOID            SubsystemHandle;
  PCUNICODE_STRING SubsystemName;
  ULONG64          BlockingTime;
  ULONG            Flags;
} PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME, *PPEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME;
```

Members

`PlatformIdleStateIndex`

[in] The platform idle state index for the SoC subsystem that the OS is querying.

`SubsystemHandle`

[in] A context pointer that the PEP previously provided on subsystem initialization. The context pointer is optional, so if none was provided then the value will be zero. The PEP is free to ignore this field.

`SubsystemName`

[in] The name of the subsystem whose blocking time is being queried. This name was provided by the PEP on subsystem initialization.

`BlockingTime`

[out] The blocking time tallied for this subsystem in 100 nanosecond units since the previous PEP_DPM_RESET_SOC_SUBSYSTEM_ACCOUNTING notification.

`Flags`

This member is reserved and should be set to zero.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_QUERY_SOC_SUBSYSTEM_COUNT structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_SOC_SUBSYSTEM_COUNT** structure is used to tell the OS whether the PEP supports system on a chip (SoC) subsystem accounting for a given platform idle state.

Syntax

```
typedef struct _PEP_QUERY_SOC_SUBSYSTEM_COUNT {
  ULONG PlatformIdleStateIndex;
  ULONG SubsystemCount;
  ULONG Flags;
} PEP_QUERY_SOC_SUBSYSTEM_COUNT, *PPEP_QUERY_SOC_SUBSYSTEM_COUNT;
```

Members

`PlatformIdleStateIndex`

[in] The platform idle state index for which the kernel is querying about.

`SubsystemCount`

[out] The number of SoC subsystems tallied by the PEP for the specified platform idle state. The PEP cannot return 0 in this parameter; instead the PEP should return **FALSE** to the PEP_DPM_QUERY_SOC_SUBSYSTEM_COUNT notification that provided this structure.

`Flags`

This member is reserved and should be set to zero.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_QUERY_SOC_SUBSYSTEM_METADATA structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_SOC_SUBSYSTEM_METADATA** structure is used with the **PEP_DPM_QUERY_SOC_SUBSYSTEM_METADATA** notification to collect optional metadata about the system on a chip (SoC) subsystem whose blocking time has just been queried.

Syntax

```
typedef struct _PEP_QUERY_SOC_SUBSYSTEM_METADATA {
  ULONG                       PlatformIdleStateIndex;
  PVOID                       SubsystemHandle;
  PCUNICODE_STRING            SubsystemName;
  ULONG                       Flags;
  ULONG                       MetadataCount;
  PPEP_SOC_SUBSYSTEM_METADATA Metadata[ANYSIZE_ARRAY];
} PEP_QUERY_SOC_SUBSYSTEM_METADATA, *PPEP_QUERY_SOC_SUBSYSTEM_METADATA;
```

Members

`PlatformIdleStateIndex`

[in] The platform idle state index for for the SoC subsystem that the OS is querying.

`SubsystemHandle`

[in] A context pointer that the PEP previously provided on subsystem initialization. The context pointer is optional, so if none was provided then the value will be zero. The PEP is free to ignore this field.

`SubsystemName`

[in] The name of the subsystem whose metadata is being queried.

`Flags`

This member is reserved and should be set to zero.

`MetadataCount`

[in] The number of entries in the **Metadata** array. The PEP previously provided this value as **PEP_QUERY_SOC_SUBSYSTEM.MetadataCount**.

`Metadata`

[in/out] An array of pointers to PEP_SOC_SUBSYSTEM_METADATA structures. Each entry holds one key/value metadata string-pair.

Requirements

Minimum supported client	Supported starting with Windows 10.

Header	pep_x.h (include Pep_x.h)

PEP_REGISTER_COMPONENT_PERF_STATES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_REGISTER_COMPONENT_PERF_STATES** structure describes the performance states (P-states) of the specified component.

Syntax

```
typedef struct _PEP_REGISTER_COMPONENT_PERF_STATES {
  PEPHANDLE                DeviceHandle;
  ULONG                    Component;
  ULONGLONG                Flags;
  PPEP_COMPONENT_PERF_INFO PerfStateInfo;
} PEP_REGISTER_COMPONENT_PERF_STATES, *PPEP_REGISTER_COMPONENT_PERF_STATES;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N−1.

`Flags`

[in] A set of input flags. No flag bits are currently defined for this member, which is always zero.

`PerfStateInfo`

[in] A pointer to a PEP_COMPONENT_PERF_INFO structure that contains the performance information for this component's P-states. If this member is non-NULL, it points to P-state information that was supplied by the device driver.

Remarks

This structure is used by the PEP_DPM_REGISTER_COMPONENT_PERF_STATES notification. The values of all members of the **PEP_REGISTER_COMPONENT_PERF_STATES** structure are supplied by the Windows power management framework (PoFx) when the notification is sent. The PEP must not write to this structure.

If the **PerfStateInfo** member is not NULL, the device driver has provided P-state information and requires the PEP to use it.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_REGISTER_CRASHDUMP_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_REGISTER_CRASHDUMP_DEVICE** structure provides a callback routine to turn on a crash-dump device.

Syntax

```
typedef struct _PEP_REGISTER_CRASHDUMP_DEVICE {
  PPEPCALLBACKPOWERONCRASHDUMPDEVICE PowerOnDumpDeviceCallback;
  PEPHANDLE                          DeviceHandle;
} PEP_REGISTER_CRASHDUMP_DEVICE, *PPEP_REGISTER_CRASHDUMP_DEVICE;
```

Members

`PowerOnDumpDeviceCallback`

[out] A pointer to a PowerOnDumpDeviceCallback callback routine that is implemented by the platform extension plug-in (PEP). This routine handles requests from the Windows kernel to turn on the crash-dump device so that a crash dump can be saved. For more information, see Kernel-Mode Dump Files.

`DeviceHandle`

[in] A PEPHANDLE value that identifies the crash-dump device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

Remarks

This structure is used by the PEP_DPM_REGISTER_CRASHDUMP_DEVICE notification. The **DeviceHandle** member of the structure contains an input value that is supplied by the Windows power management framework (PoFx) when this notification is sent to the PEP. The **PowerOnDumpDeviceCallbackmember** contains an output value that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_DPM_REGISTER_DEVICE

PowerOnDumpDeviceCallback

PEP_REGISTER_DEBUGGER structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_REGISTER_DEBUGGER** structure identifies a registered device that is a core system resource that provides debugger transport.

Syntax

```
typedef struct _PEP_REGISTER_DEBUGGER {
  PEPHANDLE DeviceHandle;
} PEP_REGISTER_DEBUGGER, *PPEP_REGISTER_DEBUGGER;
```

Members

`DeviceHandle`

[in] A **PEPHANDLE** value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

Remarks

This structure is used by the PEP_DPM_REGISTER_DEBUGGER notification. The **DeviceHandle** member contains an input value that is supplied by the Windows power management framework (PoFx).

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_DPM_REGISTER_DEBUGGER

PEP_DPM_REGISTER_DEVICE

PEP_REGISTER_DEVICE_V2 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_REGISTER_DEVICE_V2** structure describes a device whose driver stack has just registered with the Windows power management framework (PoFx).

Syntax

```
typedef struct _PEP_REGISTER_DEVICE_V2 {
  PCUNICODE_STRING           DeviceId;
  POHANDLE                   KernelHandle;
  PPEP_DEVICE_REGISTER_V2    Register;
  PEPHANDLE                  DeviceHandle;
  PEP_DEVICE_ACCEPTANCE_TYPE DeviceAccepted;
} PEP_REGISTER_DEVICE_V2, *PPEP_REGISTER_DEVICE_V2;
```

Members

`DeviceId`

[in] A string that uniquely identifies the device. This member is a pointer to a UNICODE_STRING structure that contains a device identification string.

`KernelHandle`

[in] A POHANDLE value that represents the registration of the device with PoFx. The platform extension plug-in (PEP) previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the device's driver stack registered the device with PoFx.

`Register`

[in] A pointer to a PEP_DEVICE_REGISTER_V2 structure that describes the power management attributes of all the components in the device. For more information, see Remarks.

`DeviceHandle`

[out] A PEPHANDLE value that the PEP creates to identify this device. PoFx will use this handle to identify the device in future device power management (DPM) notifications.

`DeviceAccepted`

[out] A PEP_DEVICE_ACCEPTANCE_TYPE enumeration value that indicates whether the PEP claims ownership of the device. The PEP that claims ownership is responsible for handling DPM notifications for the device.

Remarks

This structure is used by the PEP_DPM_REGISTER_DEVICE notification. The first three members of this structure contain input values supplied by PoFx. The last two members contain output values that the PEP writes to the structure in response to this notification.

The **Register** member contains a pointer to an input buffer allocated by PoFx. PoFx writes the PEP_DEVICE_REGISTER_V2 structure and associated data to this structure before sending the PEP_DPM_REGISTER_DEVICE notification to the PEP. The contents of this buffer remain valid only until the PEP

finishes handling the notification and returns from the AcceptDeviceNotification callback.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_REQUEST_COMPONENT_PERF_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_REQUEST_COMPONENT_PERF_STATE** structure contains a list of performance state (P-state) changes requested by the Windows power management framework (PoFx), plus status information about the handling of these requests by the platform extension plug-in (PEP).

Syntax

```
typedef struct _PEP_REQUEST_COMPONENT_PERF_STATE {
  PEPHANDLE                          DeviceHandle;
  ULONG                              Component;
  BOOLEAN                            Completed;
  BOOLEAN                            Succeeded;
  ULONG                              PerfRequestsCount;
  PPEP_COMPONENT_PERF_STATE_REQUEST PerfRequests;
} PEP_REQUEST_COMPONENT_PERF_STATE, *PPEP_REQUEST_COMPONENT_PERF_STATE;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Completed`

[out] Whether the PEP has completed the requested P-state changes. Set to TRUE to indicate that the P-state changes completed synchronously. Set to FALSE to indicate that the requested P-state changes are pending and will be completed asynchronously by a PEP worker thread. For more information, see Remarks.

`Succeeded`

[out] Whether the requested P-state changes successfully completed. Set to TRUE if the PEP successfully completed all P-state changes requested in the **PerfRequests** array. Set to FALSE if the PEP was unable to perform all the requested P-state changes, in which case the P-states in the hardware were left unchanged. The **Succeeded** member is used only for *synchronous* P-state changes. If the PEP sets **Completed** to FALSE, PoFx ignores the value in the **Succeeded** member.

`PerfRequestsCount`

[in] The number of P-state changes requested in the array pointed to by the **PerfRequests** member.

`PerfRequests`

[in] A pointer to an array of PEP_COMPONENT_PERF_STATE_REQUEST structures. Each element in the array specifies a new performance level to assign to a P-state set. The number of array elements is specified by the

PerfRequestsCount member.

Remarks

This structure is used by the PEP_DPM_REQUEST_COMPONENT_PERF_STATE notification. The **DeviceHandle**, **Component**, **PerfRequestsCount**, and **PerfRequests** members of the structure contain input values that are supplied by PoFx when this notification is sent. The **Completed** and **Succeeded** members contain output values that the PEP writes to the structure in response to the notification.

The PEP can complete the requested P-state changes either synchronously or asynchronously. The PEP can set the **Completed** member to TRUE to indicate that all the requests in the **PEP_DPM_REQUEST_COMPONENT_PERF_STATE** notification have been completed synchronously—that is, before the return from the PEP's AcceptDeviceNotification callback routine. Or, the PEP can set **Completed** to FALSE to indicate that the requests will be completed asynchronously. To complete the requests asynchronously, the PEP should call the RequestWorker routine to inform PoFx that the PEP has a work request to submit, and PoFx will respond by sending a PEP_DPM_WORK notification to the PEP.

PoFx writes the requested P-state changes to the **PerfRequests** array before the **PEP_DPM_REQUEST_COMPONENT_PERF_STATE** notification is sent. If the PEP handles the requested P-state changes *synchronously*, the contents of the **PerfRequests** array remain valid only until the return from the *AcceptDeviceNotification* callback routine. If the requests are completed *asynchronously*, the array contents remain valid until the PEP calls the CompleteWork routine to notify PoFx that the PEP has completed the pending requests.

Requirements

PEP_DPM_RESET_SOC_SUBSYSTEM_ACCOUNTING notification

PEP_SOC_SUBSYSTEM_METADATA structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_SOC_SUBSYSTEM_METADATA** structure contains key-value pairs that contain metadata for a system on a chip (SoC) subsystem. It is used in the context of a PEP_DPM_QUERY_SOC_SUBSYSTEM_METADATA notification sent to a platform extension plug-in (PEP).

Syntax

```
typedef struct _PEP_SOC_SUBSYSTEM_METADATA {
  UNICODE_STRING Key;
  UNICODE_STRING Value;
} PEP_SOC_SUBSYSTEM_METADATA, *PPEP_SOC_SUBSYSTEM_METADATA;
```

Members

`Key`

[in/out] A buffer for the PEP to write the key portion of the metadata string-pair. **Key** must be unique among all **Key** values reported by this subsystem.

Prior to entry into the notification callback routine, the kernel will:

- Pre-allocate 64 **WCHARs** for **Key.Buffer[]**
- Zero the buffer
- Set **Key.MaximumLength** to the size of the buffer in bytes, and
- Set **Key.Length** = **0**

Prior to exit from the callback routine, the PEP must copy a null-terminated string into **Key.Buffer** and update **Key.Length** with a byte count that is **sizeof(WCHAR)** times the number of UNICODE characters copied, not including the terminating **UNICODE_NULL**.

The PEP must use the allocated memory that is pointed to by the address in **Key.Buffer** to provide the key. Since this memory is pre-allocated, its size cannot be changed. The PEP is responsible for truncating the key string, if necessary, so that it does not exceed the length specified in **Key.MaximumLength** (including the terminating **UNICODE_NULL** character).

`Value`

[in/out] A buffer for the PEP to write the value portion of the metadata string-pair.

Prior to entry into the notification callback routine, the kernel will:

- Pre-allocate 64 **WCHARs** for **Value.Buffer[]**
- Zero the buffer
- Set **Value.MaximumLength** to the size of the buffer in bytes, and
- Set **Value.Length** = **0**

Prior to exit from the callback routine, the PEP must copy a null-terminated string into **Value.Buffer** and update **Value.Length** with a byte count that is **sizeof(WCHAR)** times the number of UNICODE characters copied, not including the terminating **UNICODE_NULL**.

The PEP must use the allocated memory that is pointed to by the address in **Value.Buffer** to provide the metadata value. Since this memory is pre-allocated, its size cannot be changed. The PEP is responsible for truncating the value string, if necessary, so that it does not exceed the length specified in **Value.MaximumLength** (including the terminating **UNICODE_NULL** character).

Requirements

PEP_SYSTEM_LATENCY structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_SYSTEM_LATENCY** structure specifies the new value for the system latency tolerance.

Syntax

```
typedef struct _PEP_SYSTEM_LATENCY {
  ULONGLONG Latency;
} PEP_SYSTEM_LATENCY, *PPEP_SYSTEM_LATENCY;
```

Members

`Latency`

[in] The overall system latency tolerance, in 100-nanosecond units. This member specifies the maximum latency that the operating system can tolerate in the time required to move a component from a low-power F*x* state to F0.

Remarks

This structure is used by the PEP_DPM_SYSTEM_LATENCY_UPDATE notification. The **Latency** member of the structure contains an input value that is supplied by the Windows power management framework (PoFx).

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_DPM_SYSTEM_LATENCY_UPDATE

PEP_UNMASKED_INTERRUPT_FLAGS union

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_UNMASKED_INTERRUPT_FLAGS** union indicates whether an unmasked interrupt source is a primary interrupt or a secondary interrupt.

Syntax

```
typedef union _PEP_UNMASKED_INTERRUPT_FLAGS {
  struct {
    USHORT SecondaryInterrupt : 1;
    USHORT Reserved : 15;
  };
  USHORT AsUSHORT;
} PEP_UNMASKED_INTERRUPT_FLAGS, *PPEP_UNMASKED_INTERRUPT_FLAGS;
```

Members

`SecondaryInterrupt`

`Reserved`

`AsUSHORT`

A USHORT value that contains all of the unmasked interrupt flags.

Remarks

The **Flags** member of the PEP_UNMASKED_INTERRUPT_INFORMATION structure is a **PEP_UNMASKED_INTERRUPT_FLAGS** union.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_UNMASKED_INTERRUPT_INFORMATION

PEP_UNMASKED_INTERRUPT_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_UNMASKED_INTERRUPT_INFORMATION** structure contains information about an interrupt source.

Syntax

```
typedef struct _PEP_UNMASKED_INTERRUPT_INFORMATION {
  USHORT                       Version;
  USHORT                       Size;
  PEP_UNMASKED_INTERRUPT_FLAGS Flags;
  KINTERRUPT_MODE              Mode;
  KINTERRUPT_POLARITY          Polarity;
  ULONG                        Gsiv;
  USHORT                       PinNumber;
  PEPHANDLE                    DeviceHandle;
} PEP_UNMASKED_INTERRUPT_INFORMATION, *PPEP_UNMASKED_INTERRUPT_INFORMATION;
```

Members

`Version`

The version of this structure.

`Size`

The size, in bytes, of this structure.

`Flags`

A PEP_UNMASKED_INTERRUPT_FLAGS union that indicates whether the interrupt is a primary or secondary interrupt. For more information, see Primary and Secondary Interrupts.

`Mode`

A KINTERRUPT_MODE enumeration value. This member indicates whether the interrupt is edge-triggered or level-triggered.

`Polarity`

A KINTERRUPT_POLARITY enumeration value. This member indicates which edge or level of the interrupt signal triggers the interrupt.

`Gsiv`

The global system interrupt vector (GSIV) number that identifies this interrupt. The ACPI firmware assigns GSIV numbers to all primary interrupt lines. For secondary (GPIO) interrupt lines, the GSIV number is dynamically assigned by the operating system.

`PinNumber`

For secondary interrupt sources, this member identifies the number of the pin on the general-purpose I/O (GPIO) controller that is connected to the interrupt signal line from the interrupting device. For primary interrupt sources,

this member is undefined.

If a GPIO controller has N GPIO pins, the pins are numbered 0 to N−1. One or more of these GPIO pins might be configured as interrupt inputs.

`DeviceHandle`

For secondary interrupt sources, this member contains the PEP device handle for the GPIO controller that is the source for this interrupt. For primary interrupt sources, this field is undefined.

Remarks

This structure is used by the EnumerateInterruptSource callback routine.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

EnumerateInterruptSource

KINTERRUPT_MODE

KINTERRUPT_POLARITY

PEP_UNMASKED_INTERRUPT_FLAGS

PEP_UNREGISTER_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_UNREGISTER_DEVICE** structure identifies a device whose registration is being removed from the Windows power management framework (PoFx).

Syntax

```
typedef struct _PEP_UNREGISTER_DEVICE {
  PEPHANDLE DeviceHandle;
} PEP_UNREGISTER_DEVICE, *PPEP_UNREGISTER_DEVICE;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

Remarks

This structure is used by the PEP_DPM_UNREGISTER_DEVICE notification. The **DeviceHandle** member contains an input value that is supplied by the Windows power management framework (PoFx).

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_DPM_REGISTER_DEVICE

PEP_DPM_UNREGISTER_DEVICE

PEP_WORK structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK** structure indicates whether the PEP has a work request to submit to the Windows power management framework (PoFx).

Syntax

```
typedef struct _PEP_WORK {
  PPEP_WORK_INFORMATION WorkInformation;
  BOOLEAN               NeedWork;
} PEP_WORK, *PPEP_WORK;
```

Members

`WorkInformation`

[out] A pointer to a PEP-allocated PEP_WORK_INFORMATION structure that describes the work that the PEP is requesting. If **NeedWork** is TRUE, **WorkInformation** must point to a valid **PEP_WORK_INFORMATION** structure. If **NeedWork** is FALSE, **WorkInformation** must be NULL.

`NeedWork`

[out] Whether the PEP has a work request to submit. Set this member to TRUE if the PEP has a work request, or to FALSE if the PEP has no work to request.

Remarks

This structure is used by the PEP_DPM_WORK notification. Both members of the structure contain values that the PEP writes to the structure in response to this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_DPM_WORK

PEP_WORK_INFORMATION

PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE** structure contains the results of an ACPI control method that was asynchronously evaluated by the platform extension plug-in (PEP).

Syntax

```
typedef struct _PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE {
  POHANDLE              DeviceHandle;
  ULONG                 CompletionFlags;
  NTSTATUS              MethodStatus;
  PVOID                 CompletionContext;
  SIZE_T                OutputArgumentSize;
  PACPI_METHOD_ARGUMENT OutputArguments;
} PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE, *PPEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE;
```

Members

`DeviceHandle`

A POHANDLE value that represents the registration of the device with the Windows power management framework (PoFx). The PEP previously received this handle from PoFx during the PEP_NOTIFY_ACPI_REGISTER_DEVICE notification in which the PEP elected to provide ACPI services for the device.

`CompletionFlags`

A set of completion flags. No flags are currently defined for this member, which is always set to PEP_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE_FLAG_NONE (0x0).

`MethodStatus`

`CompletionContext`

A pointer to a completion context value. This is the same pointer that PoFx passed to the PEP in the PEP_NOTIFY_ACPI_EVALUATE_CONTROL_METHOD notification that initiated the asynchronous evaluation of the ACPI control method.

`OutputArgumentSize`

The size, in bytes, of the buffer pointed to by the **OutputArguments** member.

`OutputArguments`

A pointer to a buffer to which the PEP has written the result of evaluating the ACPI control method. This buffer starts with a ACPI_METHOD_ARGUMENT structure, which might be followed by additional output data. PoFx allocated this buffer and passed the buffer pointer to the PEP in the PEP_NOTIFY_ACPI_EVALUATE_CONTROL_METHOD notification that initiated the asynchronous evaluation of the ACPI control method.

Remarks

The **ControlMethodComplete** member of the PEP_WORK_INFORMATION structure is a **PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE** structure.

A **PEP_WORK_INFORMATION** structure is included in the input parameters to the CompleteWork routine. The PEP writes the control method results to the **ControlMethodComplete** member of this structure before calling the routine. Evaluation of the control method was initiated by a previous PEP_NOTIFY_ACPI_EVALUATE_CONTROL_METHOD notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_WORK_ACPI_NOTIFY structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_ACPI_NOTIFY** structure contains the ACPI Notify code for a device that has generated a hardware event.

Syntax

```
typedef struct _PEP_WORK_ACPI_NOTIFY {
  POHANDLE DeviceHandle;
  ULONG    NotifyCode;
} PEP_WORK_ACPI_NOTIFY, *PPEP_WORK_ACPI_NOTIFY;
```

Members

`DeviceHandle`

A POHANDLE value that represents the registration of the device with PoFx. The platform extension plug-in (PEP) previously received this handle from the Windows power management framework (PoFx) during the PEP_NOTIFY_ACPI_REGISTER_DEVICE notification in which the PEP elected to provide ACPI services for the device.

`NotifyCode`

The Notify code. For a list of Notify codes and their meanings, see section 5.6.6, "Device Object Notifications", of the ACPI 5.0 specification.

Remarks

The **AcpiNotify** member of the PEP_WORK_INFORMATION structure is a **PEP_WORK_ACPI_NOTIFY** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

See Also

PEP_WORK_INFORMATION

PEP_WORK_ACTIVE_COMPLETE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_ACTIVE_COMPLETE** structure identifies a component that is now in the *active* condition.

Syntax

```
typedef struct _PEP_WORK_ACTIVE_COMPLETE {
  POHANDLE DeviceHandle;
  ULONG    Component;
} PEP_WORK_ACTIVE_COMPLETE, *PPEP_WORK_ACTIVE_COMPLETE;
```

Members

`DeviceHandle`

A handle that represents the registration of the device with the Windows power management framework (PoFx). A POHANDLE value that represents the registration of the device with PoFx. The platform extension plug-in (PEP) previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the device's driver stack registered the device with PoFx.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

Remarks

The **ActiveComplete** member of the PEP_WORK_INFORMATION structure is a **PEP_WORK_ACTIVE_COMPLETE** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pepfx.h)

PEP_WORK_COMPLETE_IDLE_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_COMPLETE_IDLE_STATE** structure identifies a component that the platform extension plug-in (PEP) has prepared for a transition to a new F*x* power state.

Syntax

```
typedef struct _PEP_WORK_COMPLETE_IDLE_STATE {
  POHANDLE DeviceHandle;
  ULONG    Component;
} PEP_WORK_COMPLETE_IDLE_STATE, *PPEP_WORK_COMPLETE_IDLE_STATE;
```

Members

`DeviceHandle`

A handle that represents the registration of the device with the Windows power management framework (PoFx). A POHANDLE value that represents the registration of the device with PoFx. The PEP previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the device's driver stack registered the device with PoFx.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

Remarks

The **CompleteIdleState** member of the PEP_WORK_INFORMATION structure is a **PEP_WORK_COMPLETE_IDLE_STATE** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_DEVICE_REGISTER_V2

PEP_DPM_REGISTER_DEVICE

PEP_WORK_INFORMATION

PEP_WORK_COMPLETE_PERF_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_COMPLETE_PERF_STATE** structure describes the completion status of a previously requested update to the performance values assigned to a list of performance state (P-state) sets.

Syntax

```
typedef struct _PEP_WORK_COMPLETE_PERF_STATE {
  POHANDLE DeviceHandle;
  ULONG    Component;
  BOOLEAN  Succeeded;
} PEP_WORK_COMPLETE_PERF_STATE, *PPEP_WORK_COMPLETE_PERF_STATE;
```

Members

`DeviceHandle`

A handle that represents the registration of the device with the Windows power management framework (PoFx). The PEP received this handle in a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Succeeded`

Whether the requested P-state changes successfully completed. Set to TRUE if the PEP successfully completed all P-state changes requested in a previous PEP_DPM_REQUEST_COMPONENT_PERF_STATE notification. Set to FALSE if the PEP was unable to perform all the requested P-state changes, in which case the P-states in the hardware were left unchanged.

Remarks

The **CompletePerfState** member of the PEP_WORK_INFORMATION structure is a **PEP_WORK_COMPLETE_PERF_STATE** structure. If PoFx sends a PEP_DPM_REQUEST_COMPONENT_PERF_STATE notification to request performance level changes to one or more P-state sets, and the PEP chooses to handle this request asynchronously, the PEP uses a **PEP_WORK_COMPLETE_PERF_STATE** structure to describe the completion status of the request.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pep_x.h)

PEP_WORK_DEVICE_IDLE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_DEVICE_IDLE** structure indicates whether to ignore the idle time-out for the specified device.

Syntax

```
typedef struct _PEP_WORK_DEVICE_IDLE {
  POHANDLE DeviceHandle;
  BOOLEAN  IgnoreIdleTimeout;
} PEP_WORK_DEVICE_IDLE, *PPEP_WORK_DEVICE_IDLE;
```

Members

`DeviceHandle`

A handle that represents the registration of the device with the Windows power management framework (PoFx). A POHANDLE value that represents the registration of the device with PoFx. The platform extension plug-in (PEP) previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the device's driver stack registered the device with PoFx.

`IgnoreIdleTimeout`

Whether to ignore the idle time-out. Set to TRUE to tell the operating system to ignore the idle time-out for this device. Set to FALSE to tell the operating system to call the device driver's DevicePowerNotRequiredCallback callback routine after the device remains idle for the designated time-out interval. For more information, see PoFxSetDeviceIdleTimeout.

Remarks

The **DeviceIdle** member of the PEP_WORK_INFORMATION structure is a **PEP_WORK_DEVICE_IDLE** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_WORK_DEVICE_POWER structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_DEVICE_POWER** structure describes the new power requirements for the specified device.

Syntax

```
typedef struct _PEP_WORK_DEVICE_POWER {
  POHANDLE DeviceHandle;
  BOOLEAN  PowerRequired;
} PEP_WORK_DEVICE_POWER, *PPEP_WORK_DEVICE_POWER;
```

Members

`DeviceHandle`

A handle that represents the registration of the device with the Windows power management framework (PoFx). A POHANDLE value that represents the registration of the device with PoFx. The platform extension plug-in (PEP) previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the device's driver stack registered the device with PoFx.

`PowerRequired`

Whether the device requires power. Set to TRUE if the device requires power and the device driver must bring the device back to the D0 power state. Set to FALSE if the device is not required to stay turned on and the driver is permitted to transition the device from D0 to a low-power state.

Remarks

The **DevicePower** member of the PEP_WORK_INFORMATION structure is a **PEP_WORK_DEVICE_POWER** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_WORK_IDLE_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_IDLE_STATE** structure contains a request to transition a component to an F*x* power state.

Syntax

```
typedef struct _PEP_WORK_IDLE_STATE {
  POHANDLE DeviceHandle;
  ULONG    Component;
  ULONG    State;
} PEP_WORK_IDLE_STATE, *PPEP_WORK_IDLE_STATE;
```

Members

`DeviceHandle`

A handle that represents the registration of the device with the Windows power management framework (PoFx). A POHANDLE value that represents the registration of the device with PoFx. The platform extension plug-in (PEP) previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the device's driver stack registered the device with PoFx.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`State`

The target F*x* power state to transition the component to. If this parameter is 0, the target state is F0; if this parameter is 1, the target state is F1; and so on. For more information about F*x* power states, see Component-Level Power Management.

Remarks

The **IdleState** member of the PEP_WORK_INFORMATION structure is a **PEP_WORK_IDLE_STATE** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pep_x.h (include Pepfx.h)

PEP_WORK_INFORMATION

PEP_WORK_INFORMATION structure

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_INFORMATION** structure describes a work item that the PEP is submitting to the Windows power management framework (PoFx).

Syntax

```
typedef struct _PEP_WORK_INFORMATION {
  PEP_WORK_TYPE WorkType;
  union {
    PEP_WORK_POWER_CONTROL                          PowerControl;
    PEP_WORK_COMPLETE_IDLE_STATE                    CompleteIdleState;
    PEP_WORK_COMPLETE_PERF_STATE                    CompletePerfState;
    PEP_WORK_ACPI_NOTIFY                            AcpiNotify;
    PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE ControlMethodComplete;
  };
} PEP_WORK_INFORMATION, *PPEP_WORK_INFORMATION;
```

Members

`WorkType`

A PEP_WORK_TYPE enumeration value. This member indicates the type of work requested by the PEP, which also determines the type of structure that is contained in the unnamed union in the **PEP_WORK_INFORMATION** structure.

`PowerControl`

`CompleteIdleState`

`CompletePerfState`

`AcpiNotify`

`ControlMethodComplete`

Remarks

The **WorkInformation** member of the PEP_WORK structure is a pointer to a **PEP_WORK_INFORMATION** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_WORK_POWER_CONTROL

PEP_WORK_TYPE

PEP_WORK_POWER_CONTROL structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_POWER_CONTROL** structure contains the parameters for a power control request that the platform extension plug-in (PEP) sends directly to a processor driver.

Syntax

```
typedef struct _PEP_WORK_POWER_CONTROL {
  POHANDLE DeviceHandle;
  LPCGUID  PowerControlCode;
  PVOID    RequestContext;
  PVOID    InBuffer;
  SIZE_T   InBufferSize;
  PVOID    OutBuffer;
  SIZE_T   OutBufferSize;
} PEP_WORK_POWER_CONTROL, *PPEP_WORK_POWER_CONTROL;
```

Members

`DeviceHandle`

A POHANDLE value that identifies the processor. The PEP received this handle in a previous PEP_DPM_REGISTER_DEVICE notification.

`PowerControlCode`

[in] A pointer to a GUID value that specifies the power control operation to perform.

`RequestContext`

A pointer to a PEP-defined context value. The PEP might use this value to uniquely identify a power control request message (in case the PEP issues multiple requests with the same control code to the same device).

`InBuffer`

[in] A pointer to a driver-allocated input buffer that contains the input parameters for this power control operation.

`InBufferSize`

[in] The size in bytes of the buffer pointed to by **InBuffer**.

`OutBuffer`

[in] A pointer to a driver-allocated output buffer to which the PEP writes the results of this power control operation.

`OutBufferSize`

[in] The size in bytes of the buffer pointed to by **OutBuffer**.

Remarks

The **PowerControl** member of the PEP_WORK_INFORMATION structure is a pointer to a **PEP_WORK_POWER_CONTROL** structure.

The PEP issues a power control request from a worker thread. The Windows power management framework (PoFx) forwards this request by calling the processor driver's PowerControlCallback routine, if the driver implements this routine.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_WORK_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_TYPE** enumeration describes the type of work that the platform extension plug-in (PEP) is requesting.

Syntax

```
typedef enum _PEP_WORK_TYPE {
  PepWorkRequestPowerControl,
  PepWorkCompleteIdleState,
  PepWorkCompletePerfState,
  PepWorkAcpiNotify,
  PepWorkAcpiEvaluateControlMethodComplete,
  PepWorkMax
} PEP_WORK_TYPE, *PPEP_WORK_TYPE;
```

Constants

PepWorkRequestPowerControl	A request for the device driver to perform a custom power-control operation that uses a device-specific context that the PEP provides for the operation. The driver handles this request in its PowerControlCallback routine.
PepWorkCompleteIdleState	A notification to PoFx that the PEP has asynchronously completed the transition of a component to an idle state. PoFx previously initiated this transition by sending a PEP_DPM_NOTIFY_COMPONENT_IDLE_STATE notification to the PEP.
PepWorkCompletePerfState	A notification to PoFx that the PEP has asynchronously completed the transition of a component to a P-state. PoFx previously initiated this transition by sending a PEP_DPM_REQUEST_COMPONENT_PERF_STATE notification to the PEP.
PepWorkAcpiNotify	An ACPI Notify code to describe to PoFx a hardware event that the specified device has generated.
PepWorkAcpiEvaluateControlMethodComplete	A notification to PoFx that the PEP has asynchronously finished evaluating an ACPI control method. PoFx previously initiated the evaluation of this method by sending a PEP_NOTIFY_ACPI_EVALUATE_CONTROL_METHOD notification to the PEP.
PepWorkMax	Reserved for use by operating system.

Remarks

This enumeration is used by the PEP_WORK_INFORMATION structure to describe the type of work item that the PEP is requesting.

Requirements

Minimum supported client	Supported starting with Windows 10.

PowerControlCallback

PO_FX_CORE_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_CORE_DEVICE** structure contains information about the power-state attributes of the components in a core system resource, and provides a software interface for power-managing these components.

Syntax

```
typedef struct _PO_FX_CORE_DEVICE {
  ULONG                                        Version;
  ULONG                                        ComponentCount;
  PPO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK    ComponentActiveConditionCallback;
  PPO_FX_COMPONENT_IDLE_CONDITION_CALLBACK      ComponentIdleConditionCallback;
  PPO_FX_COMPONENT_CRITICAL_TRANSITION_CALLBACK ComponentCriticalTransitionCallback;
  PPO_FX_COMPONENT_IDLE_STATE_CALLBACK          ComponentIdleStateCallback;
  PVOID                                        DeviceContext;
  PO_FX_COMPONENT                              Components[ANYSIZE_ARRAY];
} PO_FX_CORE_DEVICE, *PPO_FX_CORE_DEVICE;
```

Members

`Version`

The version number of this structure.

`ComponentCount`

The number of elements in the **Components** array at the end of this structure. This count includes all elements of the array, and includes both the first element, which is a member of this structure, and any additional elements that follow the end of this structure.

`ComponentActiveConditionCallback`

A pointer to a ComponentActiveConditionCallback callback routine. PoFx calls this routine to notify the driver that the specified component completed a transition from the idle condition to the active condition.

`ComponentIdleConditionCallback`

A pointer to a ComponentIdleConditionCallback callback routine. PoFx calls this routine to notify the driver that the specified component completed a transition from the active condition to the idle condition.

`ComponentCriticalTransitionCallback`

A pointer to a ComponentCriticalTransitionCallback callback routine. PoFx calls this routine to notify the driver that the specified component is about to make a transition between the idle condition and the active condition.

`ComponentIdleStateCallback`

A pointer to a ComponentIdleStateCallback callback routine. PoFx calls this routine to notify the driver of a pending change to the F*x* power state of the specified component.

`DeviceContext`

A pointer to a PEP-defined device context. PoFx supplies this pointer as the first parameter in calls to the *ComponentActiveConditionCallback*, *ComponentIdleConditionCallback*, *ComponentCriticalTransitionCallback*, and

ComponentIdleStateCallback routines. This context is opaque to PoFx.

`Components`

The first element in an array of PO_FX_COMPONENT structures. Each element in the array describes the power attributes of a component in the device. If the array contains more than one element, the additional elements immediately follow the end of the **PO_FX_CORE_DEVICE** structure. The number of elements in the array is specified in the **ComponentCount** member of the **PO_FX_CORE_DEVICE** structure.

Remarks

This structure is used by the PoFxRegisterCoreDevice routine.

A *core system resource* is a hardware device, such as a timer or an interrupt controller, that is managed by the Windows hardware abstraction layer (HAL).

For more information about component transitions between the active condition and the idle condition, see Component-Level Power Management.

PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_EXTENDED_ADDRESS structure.

Syntax

```
void PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE(
  BOOLEAN            ResourceUsage,
  UCHAR              Decode,
  BOOLEAN            IsMinFixed,
  BOOLEAN            IsMaxFixed,
  UCHAR              ISARanges,
  ULONGLONG          AddressGranularity,
  ULONGLONG          AddressMinimum,
  ULONGLONG          AddressMaximum,
  ULONGLONG          AddressTranslation,
  ULONGLONG          RangeLength,
  ULONGLONG          TypeSpecificAttributes,
  PUNICODE_STRING    DescriptorName,
  BOOLEAN            TranslationTypeNonStatic,
  BOOLEAN            TanslationSparseDensity,
  PPEP_ACPI_RESOURCE Resource
);
```

Parameters

`ResourceUsage`

This parameter is copied into the **GeneralFlags** member of the initialized PEP_ACPI_EXTENDED_ADDRESS structure.

`Decode`

When set, indicates that this bridge subtractively decodes the address. This applies to top level bridges only.

When not set, indicates that this bridge positively decodes this address.

`IsMinFixed`

When set, indicates that the minimum address is fixed.

`IsMaxFixed`

When set, indicates that the maximum address is fixed.

`ISARanges`

This parameter is copied into the **TypeSpecificFlags** member of the initialized PEP_ACPI_EXTENDED_ADDRESS structure.

`AddressGranularity`

A bit mask indicating which bits have been decoded.

`AddressMinimum`

For bridges that translate addresses, this indicates the minimum starting address on the secondary side of the bridge.

`AddressMaximum`

For bridges that translate addresses, this indicates the maximum starting address on the secondary side of the bridge.

`AddressTranslation`

For bridges that translate addresses across the bridge, this is the address on the primary side.

`RangeLength`

The length of the address range.

`TypeSpecificAttributes`

The type-specific attributes for this resource.

`DescriptorName`

The name of the resource descriptor.

`TranslationTypeNonStatic`

When true, indicates that the resource uses type translation. Otherwise, it uses type-static translation.

`TanslationSparseDensity`

When false, indicates that this is a dense translation. Otherwise, it is sparse.

`Resource`

This is cast to *PEP_ACPI_EXTENDED_ADDRESS.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_EXTENDED_ADDRESS structure.

Syntax

```
void PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE(
  BOOLEAN            ResourceUsage,
  UCHAR              Decode,
  BOOLEAN            IsMinFixed,
  BOOLEAN            IsMaxFixed,
  UCHAR              Cacheable,
  BOOLEAN            ReadWrite,
  ULONGLONG          AddressGranularity,
  ULONGLONG          AddressMinimum,
  ULONGLONG          AddressMaximum,
  ULONGLONG          AddressTranslation,
  ULONGLONG          RangeLength,
  ULONGLONG          TypeSpecificAttributes,
  PUNICODE_STRING    DescriptorName,
  UCHAR              MemoryRangeType,
  BOOLEAN            TranslationTypeNonStatic,
  PPEP_ACPI_RESOURCE Resource
);
```

Parameters

`ResourceUsage`

This parameter is copied into the **GeneralFlags** member of the initialized PEP_ACPI_EXTENDED_ADDRESS structure.

`Decode`

When set, indicates that this bridge subtractively decodes the address. This applies to top level bridges only.

When not set, indicates that this bridge positively decodes this address.

`IsMinFixed`

When set, indicates that the minimum address is fixed.

`IsMaxFixed`

When set, indicates that the maximum address is fixed.

`Cacheable`

The caching flag for the resource.

VALUE	MEANING

0	Indicates the memory is non-cacheable.
1	Indicates the memory is cacheable.
2	Indicates the memory is cacheable and supports write combining.
3	The memory is cacheable and prefetchable.

`ReadWrite`

When true, indicates that the resource is available for read/write access. Otherwise, it's read-only.

`AddressGranularity`

A bit mask indicating which bits have been decoded.

`AddressMinimum`

For bridges that translate addresses, this indicates the minimum starting address on the secondary side of the bridge.

`AddressMaximum`

For bridges that translate addresses, this indicates the maximum starting address on the secondary side of the bridge.

`AddressTranslation`

For bridges that translate addresses across the bridge, this is the address on the primary side.

`RangeLength`

The length of the address range.

`TypeSpecificAttributes`

The type-specific attributes for this resource.

`DescriptorName`

The name of the resource descriptor.

`MemoryRangeType`

This parameter identifies the type of memory range provided by this resource.

VALUE	MEANING
0	Address range memory: This range is available RAM usable by the operating system.
1	Address range reserved: This range of addresses is in use or reserved by the system and is not to be included in the allocatable memory pool of the operating system's memory manager.
2	Address range ACPI: ACPI Reclaim Memory. This range is available RAM usable by the OS after it reads the ACPI tables.

3	Address Range NVS: ACPI NVS Memory. This range of addresses is in use or reserved by the system and must not be used by the operating system. This range is required to be saved and restored across an NVS sleep.

`TranslationTypeNonStatic`

When true, indicates that the resource uses type translation. Otherwise, it uses type-static translation.

`Resource`

This is cast to *PEP_ACPI_EXTENDED_ADDRESS.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_GPIO_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE(
  KINTERRUPT_MODE      InterruptType,
  KINTERRUPT_POLARITY  LevelType,
  BOOLEAN              Shareable,
  BOOLEAN              CanWake,
  GPIO_PIN_CONFIG_TYPE PinConfig,
  USHORT               DebounceTimeout,
  UCHAR                ResourceSourceIndex,
  PUNICODE_STRING      ResourceSourceName,
  BOOLEAN              ResourceUsage,
  PUCHAR               VendorData,
  USHORT               VendorDataLength,
  PUSHORT              PinTable,
  UCHAR                PinCount,
  PPEP_ACPI_RESOURCE   Resource
);
```

Parameters

`InterruptType`

A KINTERRUPT_MODE enumeration value that identifies the interrupt type.

`LevelType`

A KINTERRUPT_POLARITY enumeration value that identifies how a device signals an interrupt request on an interrupt line.

`Shareable`

Indicates if the device can be shared.

`CanWake`

Indicates if the device can be woken from a low-power state.

`PinConfig`

A GPIO_PIN_CONFIG_TYPE enumeration value that identifies the GPIO pin configuration type.

`DebounceTimeout`

Specifies the hardware debounce wait time, in hundredths of milliseconds.

`ResourceSourceIndex`

This parameter should always be zero.

`ResourceSourceName`

This parameter should always be "ResourceConsumer."

`ResourceUsage`

Indicates if this device is in use.

`VendorData`

A pointer to a raw data buffer containing vendor-defined byte data to be decoded by the OS driver.

`VendorDataLength`

The size of the buffer in the *VendorData* partameter.

`PinTable`

A list of pin numbers on the resource.

`PinCount`

The number of pins described by the *PinTable* parameter.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_GPIO_RESOURCE.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_GPIO_RESOURCE

PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_GPIO_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE(
  BOOLEAN                     Shareable,
  BOOLEAN                     CanWake,
  GPIO_PIN_CONFIG_TYPE        PinConfig,
  USHORT                      DebounceTimeout,
  USHORT                      DriveStrength,
  GPIO_PIN_IORESTRICTION_TYPE IoRestriction,
  UCHAR                       ResourceSourceIndex,
  PUNICODE_STRING             ResourceSourceName,
  BOOLEAN                     ResourceUsage,
  PUCHAR                      VendorData,
  USHORT                      VendorDataLength,
  PUSHORT                     PinTable,
  USHORT                      PinCount,
  PPEP_ACPI_RESOURCE          Resource
);
```

Parameters

`Shareable`

Indicates if the device can be shared.

`CanWake`

Indicates if the device can be woken from a low-power state.

`PinConfig`

A GPIO_PIN_CONFIG_TYPE enumeration value that identifies the GPIO pin configuration type.

`DebounceTimeout`

Specifies the hardware debounce wait time, in hundredths of milliseconds.

`DriveStrength`

`IoRestriction`

`ResourceSourceIndex`

This parameter should always be zero.

`ResourceSourceName`

This parameter should always be "ResourceConsumer."

`ResourceUsage`

Indicates if this device is in use.

`VendorData`

A pointer to a raw data buffer containing vendor-defined byte data to be decoded by the OS driver.

`VendorDataLength`

The size of the buffer in the *VendorData* partameter.

`PinTable`

A list of pin numbers on the resource.

`PinCount`

The number of pins described by the *PinTable* parameter.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_GPIO_RESOURCE.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_GPIO_RESOURCE

PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_INTERRUPT_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE(
  BOOLEAN             ResourceUsage,
  KINTERRUPT_MODE     EdgeLevel,
  KINTERRUPT_POLARITY InterruptLevel,
  BOOLEAN             ShareType,
  BOOLEAN             Wake,
  PULONG              PinTable,
  UCHAR               PinCount,
  PPEP_ACPI_RESOURCE  Resource
);
```

Parameters

`ResourceUsage`

Indicates if this device is in use.

`EdgeLevel`

A KINTERRUPT_MODE enumeration value that identifies the interrupt type.

`InterruptLevel`

A KINTERRUPT_POLARITY enumeration value that identifies how a device signals an interrupt request on an interrupt line.

`ShareType`

Indicates if the device can be shared.

`Wake`

Indicates if the device can be woken from a low-power state.

`PinTable`

A list of pin numbers on the resource.

`PinCount`

The number of pins described by the *PinTable* parameter.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_INTERRUPT_RESOURCE.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_INTERRUPT_RESOURCE

PEP_ACPI_INITIALIZE_IOPORT_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_IOPORT_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_IO_MEMORY_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_IOPORT_RESOURCE(
  UCHAR               Decode,
  USHORT              MinimumAddress,
  USHORT              MaximumAddress,
  UCHAR               Alignment,
  UCHAR               PortLength,
  PPEP_ACPI_RESOURCE Resource
);
```

Parameters

`Decode`

Specifies how to decode the resource address. If bit 0 is a 1, this indicates that the logical device decodes 16-bit addresses. If bit 0 is 0, this indicates that the logical device only decodes the first 10 bits of the address.

Bits 1 to 7 of this parameter are reserved and must be set to zero.

`MinimumAddress`

Specifies the minimum acceptable starting address for the IO range.

`MaximumAddress`

Specifies the maximum acceptable starting address for the IO range.

`Alignment`

Specifies the alignment granularity for the IO address assigned.

`PortLength`

Specifies the number of bytes in the IO range.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_IO_MEMORY_RESOURCE.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_INITIALIZE_MEMORY_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_MEMORY_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_IO_MEMORY_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_MEMORY_RESOURCE(
  UCHAR              ReadWrite,
  ULONG              MinimumAddress,
  ULONG              MaximumAddress,
  ULONG              Alignment,
  ULONG              MemorySize,
  PPEP_ACPI_RESOURCE Resource
);
```

Parameters

`ReadWrite`

If true, indicates that the resource is read/write. Otherwise, it's read-only.

`MinimumAddress`

Specifies the minimum acceptable starting address for the IO range.

`MaximumAddress`

Specifies the maximum acceptable starting address for the IO range.

`Alignment`

Specifies the alignment granularity for the memory address assigned.

`MemorySize`

Specifies the number of bytes in the memory range.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_IO_MEMORY_RESOURCE.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.

Target Platform	Windows

PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_I2C_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE(
  USHORT              SlaveAddress,
  BOOLEAN             DeviceInitiated,
  ULONG               ConnectionSpeed,
  BOOLEAN             AddressingMode,
  PUNICODE_STRING     ResourceSource,
  UCHAR               ResourceSourceIndex,
  BOOLEAN             ResourceUsage,
  BOOLEAN             SharedMode,
  PCHAR               VendorData,
  USHORT              VendorDataLength,
  PPEP_ACPI_RESOURCE Resource
);
```

Parameters

`SlaveAddress`

The I2C bus address for this connection.

`DeviceInitiated`

If true, indicates that communication over this connection is initiated by the device.

`ConnectionSpeed`

The maximum speed, in hertz, supported by this connection.

`AddressingMode`

Indicates that this device is in addressing mode.

`ResourceSource`

The name of the serial bus controller device to which this connection descriptor applies. The name can be a fully qualified path, a relative path, or a simple name segment that utilizes the namespace search rules.

`ResourceSourceIndex`

This parameter should always be set to zero.

`ResourceUsage`

Indicates if the resource is in use.

`SharedMode`

Indicates if the resource is shared.

`VendorData`

A pointer to optional data that is specific to the serial bus connection type.

`VendorDataLength`

The length of the buffer pointed to by the *VendorData* parameter.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_SPB_I2C_RESOURCE.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_SPI_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE(
  USHORT              DeviceSelection,
  UCHAR               DeviceSelectionPolarity,
  UCHAR               WireMode,
  UCHAR               DataBitLength,
  BOOLEAN             SlaveMode,
  ULONG               ConnectionSpeed,
  UCHAR               ClockPolarity,
  UCHAR               ClockPhase,
  PUNICODE_STRING     ResourceSource,
  UCHAR               ResourceSourceIndex,
  BOOLEAN             ResourceUsage,
  BOOLEAN             SharedMode,
  PCHAR               VendorData,
  USHORT              VendorDataLength,
  PPEP_ACPI_RESOURCE Resource
);
```

Parameters

`DeviceSelection`

The device selection value. This value is specific to the device and may refer to a chip-select line, GPIO line, or other line selection mechanism.

`DeviceSelectionPolarity`

The polarity of the clock. If zero, this indicates the clock is low during the first phase. If 1, this indicates the clock is high during the first phase.

`WireMode`

When zero, indicates that this device produces and consumes this resource. Otherwise, this device only consumes this resource.

`DataBitLength`

The size, in bits, of the smallest unit of transfer.

`SlaveMode`

Indicates if the resource is operating in slave mode.

`ConnectionSpeed`

The maximum speed, in hertz, supported by this connection.

`ClockPolarity`

The polarity of the clock. If zero, this indicates the clock is low during the first phase. If 1, this indicates the clock is high during the first phase.

`ClockPhase`

The phase of the clock pulse on which to capture data.

`ResourceSource`

The name of the serial bus controller device to which this connection descriptor applies. The name can be a fully qualified path, a relative path, or a simple name segment that utilizes the namespace search rules.

`ResourceSourceIndex`

This parameter should always be set to zero.

`ResourceUsage`

Indicates if the resource is in use.

`SharedMode`

Indicates if the resource is shared.

`VendorData`

A pointer to optional data that is specific to the serial bus connection type.

`VendorDataLength`

The length of the buffer pointed to by the *VendorData* parameter.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_SPB_SPI_RESOURCE.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_UART_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE(
  ULONG              BaudRate,
  UCHAR              BitsPerByte,
  UCHAR              StopBits,
  UCHAR              LinesInUse,
  UCHAR              IsBigEndian,
  UCHAR              Parity,
  UCHAR              FlowControl,
  USHORT             RxSize,
  USHORT             TxSize,
  PUNICODE_STRING    ResourceSource,
  UCHAR              ResourceSourceIndex,
  BOOLEAN            ResourceUsage,
  BOOLEAN            SharedMode,
  PCHAR              VendorData,
  USHORT             VendorDataLength,
  PPEP_ACPI_RESOURCE Resource
);
```

Parameters

`BaudRate`

Specifies the baud rate of the connection.

`BitsPerByte`

Specifies the number of bits per byte of data.

`StopBits`

Specifies the stop bits used in the connection.

`LinesInUse`

Flag indicating the serial lines that are enabled. A value of 1 in the bit positions indicates that the line is enabled.

BIT	MEANING
0	This bit is reserved and must be set to zero.
1	This bit is reserved and must be set to zero.

2	Data Carrier Detect (DTD)
3	Ring Indicator (RI)
4	Data Set Ready (DSR)
5	Data Terminal Ready (DTR)
6	Clear to Send (CTS)
7	Request to Send (RTS)

`IsBigEndian`

Indicates if the most significant bits of data are in the lowest address.

`Parity`

Specifies the parity of the connection.

VALUE	MEANING
0x0 0	None
0x0 1	Even
0x0 2	Odd
0x0 3	Mark
0x0 4	Space

`FlowControl`

Specifies the type of flow control used by the connection.

`RxSize`

Specifies the maximum receive buffer size, in bytes, that is supported by this connection.

`TxSize`

Specifies the maximum transmit buffer size, in bytes, that is supported by this connection.

`ResourceSource`

The name of the serial bus controller device to which this connection descriptor applies. The name can be a fully qualified path, a relative path, or a simple name segment that utilizes the namespace search rules.

`ResourceSourceIndex`

This parameter should always be zero.

`ResourceUsage`

Indicates if this resource is in use.

`SharedMode`

Indicates if this resource is shared.

`VendorData`

A pointer to optional data that is specific to the serial bus connection type.

`VendorDataLength`

The length of the buffer pointed to by the *VendorData* parameter.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_SPB_UART_RESOURCE.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)

PEP_ACPI_SPB_UART_RESOURCE

PEPCALLBACKNOTIFYACPI callback function

1/25/2019 • 2 minutes to read • Edit Online

An *AcceptAcpiNotification* event callback routine handles ACPI notifications from the Windows power management framework (PoFx).

Syntax

```
PEPCALLBACKNOTIFYACPI Pepcallbacknotifyacpi;

BOOLEAN Pepcallbacknotifyacpi(
  ULONG Notification,
  PVOID Data
)
{...}
```

Parameters

`Notification`

The ACPI notification ID. This parameter specifies the type of ACPI notification that PoFx is sending. For a list of ACPI notification IDs, see ACPI notifications.

`Data`

A pointer to a PoFx-allocated structure that contains the input and/or output data for this notification. The type of this structure depends on the notification ID specified by *Notification*. For a list of the structure types that are defined for the various ACPI notification IDs, see ACPI notifications.

Return Value

The *AcceptAcpiNotification* routine must return TRUE if it handles the notification, or FALSE if it does not.

Remarks

This routine is implemented by the platform extension plug-in (PEP) for a device. The **AcceptAcpiNotification** member of the PEP_INFORMATION structure is a pointer to an *AcceptAcpiNotification* routine. The PEP calls the PoFxRegisterPlugin or PoFxRegisterPluginEx routine to register the PEP's *AcceptAcpiNotification* routine with PoFx.

The IRQL at which the PEP's *AcceptAcpiNotification* routine is called varies according to the type of notification that is being sent. The notification type is specified by the *Notification* parameter. For more information about the IRQL at which each notification type is sent, see the individual reference pages under ACPI notifications.

Requirements

Minimum supported client	Supported starting with Windows 10.

Target Platform	Windows
Header	pep_x.h (include Pep_x.h)
IRQL	"<= HIGH_LEVEL"

PEPCALLBACKNOTIFYDPM callback function

1/25/2019 • 2 minutes to read • Edit Online

An *AcceptDeviceNotification* event callback routine handles device power management (DPM) notifications from the Windows power management framework (PoFx).

Syntax

```
PEPCALLBACKNOTIFYDPM Pepcallbacknotifydpm;

BOOLEAN Pepcallbacknotifydpm(
  ULONG Notification,
  PVOID Data
)
{...}
```

Parameters

`Notification`

The DPM notification ID. This parameter specifies the type of DPM notification that PoFx is sending. For a list of DPM notification IDs, see Device power management (DPM) notifications.

`Data`

A pointer to a PoFx-allocated structure that contains the input and/or output data for this notification. The type of this structure depends on the notification ID specified by *Notification*. For a list of the structure types that are defined for the various DPM notification IDs, see Device power management (DPM) notifications.

Return Value

The *AcceptDeviceNotification* routine must return TRUE if it handles the notification, or FALSE if it does not.

Remarks

This routine is implemented by the platform extension plug-in (PEP) for a device. The **AcceptDeviceNotification** member of the PEP_INFORMATION structure is a pointer to an *AcceptDeviceNotification* routine. The PEP calls the PoFxRegisterPlugin or PoFxRegisterPluginEx routine to register the PEP's *AcceptDeviceNotification* routine with PoFx.

PoFx calls this routine to send a DPM notification to the PEP. In this call, the *Notification* parameter specifies the type of notification, and the *Data* parameter points to a data structure of the type that is associated with this notification. For a list of DPM notification IDs and their associated structure types, see Device power management (DPM) notifications.

DPM notifications inform the PEP about various system, device, or componentÂ–-level events, or pass requests from the device driver to the PEP.

The *AcceptDeviceNotification* routine does not have to accept every request from the device driver—for example, it can ignore idle residency hints. However, the PEP must understand and accept most device power management notifications even if the PEP chooses not to act on them. The PEP must refuse to handle (by returning FALSE) every notification that it does not recognize.

The *AcceptDeviceNotification* routine can be called at IRQL <= DISPATCH_LEVEL. The IRQL at which the PEP's *AcceptAcpiNotification* routine is called varies according to the type of notification that is being sent. The notification type is specified by the *Notification* parameter. For more information, see the individual reference pages under Device power management (DPM) notifications.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)
IRQL	"<= DISPATCH_LEVEL"

PoFxRegisterPluginEx

PEPCALLBACKNOTIFYPPM callback function

1/25/2019 • 2 minutes to read • Edit Online

An *AcceptProcessorNotification* event callback routine handles processor power management (PPM) notifications from the Windows power management framework (PoFx).

Syntax

```
PEPCALLBACKNOTIFYPPM Pepcallbacknotifyppm;

BOOLEAN Pepcallbacknotifyppm(
  PEPHANDLE Handle,
  ULONG Notification,
  PVOID Data
)
{...}
```

Parameters

`Handle`

The device handle for the PEP for the target processor. If **NULL**, the notification does not target a specific processor.

`Notification`

The PPM notification ID. This parameter specifies the type of PPM notification that PoFx is sending. For a list of PPM notification IDs, see Processor power management (PPM) notifications.

`Data`

A pointer to a PoFx-allocated structure that contains the input and/or output data for this notification. The type of this structure depends on the notification ID specified by *Notification*. For a list of the structure types that are defined for the various PPM notification IDs, see Processor power management (PPM) notifications.

Return Value

The *AcceptProcessorNotification* routine must return TRUE if it handles the notification, or FALSE if it does not.

Remarks

This routine is implemented by the platform extension plug-in (PEP) for a processor. The **AcceptProcessorNotification** member of the PEP_INFORMATION structure is a pointer to an *AcceptProcessorNotification* routine. The PEP calls the PoFxRegisterPlugin or PoFxRegisterPluginEx routine to register the PEP's *AcceptProcessorNotification* routine with PoFx.

The IRQL at which the PEP's *AcceptProcessorNotification* routine is called varies according to the type of notification that is being sent. The context in which this interface is called ranges from PASSIVE_LEVEL to HIGH_LEVEL with interrupts disabled. For more information about the IRQL at which each notification type is sent, see the individual reference pages under Processor power management (PPM) notifications.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)
IRQL	PASSIVE_LEVEL to HIGH_LEVEL

PoFxRegisterPluginEx

PEPCALLBACKPOWERONCRASHDUMPDEVICE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *PowerOnDumpDeviceCallback* callback routine turns on the crash-dump device.

Syntax

```
PEPCALLBACKPOWERONCRASHDUMPDEVICE Pepcallbackpoweroncrashdumpdevice;

BOOLEAN Pepcallbackpoweroncrashdumpdevice(
  PPEP_CRASHDUMP_INFORMATION CrashdumpInformation
)
{...}
```

Parameters

`CrashdumpInformation`

A pointer to a PEP_CRASHDUMP_INFORMATION structure that contains information about the crash-dump device.

Return Value

This routine returns TRUE if it succeeds in turning on power to the crash-dump device. Otherwise, it returns FALSE.

Remarks

This routine is implemented by the platform extension plug-in (PEP). The routine handles requests from the Windows kernel to turn on the crash-dump device so that a crash dump can be saved to disk.

The PEP registers its *PowerOnDumpDeviceCallback* routine in response to a PEP_DPM_REGISTER_CRASHDUMP_DEVICE notification from the Windows power management framework (PoFx).

The *PowerOnDumpDeviceCallback* routine is called at IRQL = HIGH_LEVEL with interrupts disabled. Thus, this routine cannot use timers, events, or any synchronization primitives other than spin locks.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)

IRQL	Called at HIGH_LEVEL.

POFXCALLBACKCRITICALRESOURCE callback function

1/25/2019 • 2 minutes to read • Edit Online

The **TransitionCriticalResource** routine changes the active/inactive state of a core system component.

Syntax

```
POFXCALLBACKCRITICALRESOURCE Pofxcallbackcriticalresource;

void Pofxcallbackcriticalresource(
  POHANDLE DeviceHandle,
  ULONG Component,
  BOOLEAN Active
)
{...}
```

Parameters

`DeviceHandle`

A POHANDLE value that represents the registration of the device with PoFx. The PEP previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the device's driver stack registered the device with PoFx.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N−1.

`Active`

Whether to transition the device from inactive to active, or vice versa. Set to TRUE to transition the device from inactive to active, or to FALSE to transition the device from active to inactive.

Return Value

None

Remarks

This routine is implemented by the power management framework (PoFx) and is called by the platform extension plug-in (PEP). The **TransitionCriticalResource** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to an **TransitionCriticalResource** routine.

A PEP can call this routine at IRQL <= HIGH_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)
IRQL	"<= HIGH_LEVEL"

POFXCALLBACKENUMERATEUNMASKEDINTERRUPTS callback function

1/25/2019 • 2 minutes to read • Edit Online

The **EnumerateUnmaskedInterrupts** routine enumerates interrupt sources whose interrupts are unmasked and enabled.

Syntax

```
POFXCALLBACKENUMERATEUNMASKEDINTERRUPTS Pofxcallbackenumerateunmaskedinterrupts;

NTSTATUS Pofxcallbackenumerateunmaskedinterrupts(
  POHANDLE PluginHandle,
  ULONG EnumerateFlags,
  PPO_ENUMERATE_INTERRUPT_SOURCE_CALLBACK Callback,
  PVOID CallbackContext,
  PPEP_UNMASKED_INTERRUPT_INFORMATION InterruptInformation
)
{...}
```

Parameters

`PluginHandle`

A POHANDLE value. If non-NULL, this parameter is a handle that identifies the platform extension plug-in (PEP), in which case **EnumerateUnmaskedInterrupts** enumerates only interrupts that are managed by this PEP. If this parameter is NULL, **EnumerateUnmaskedInterrupts** enumerates *all* interrupts in the hardware platform that are unmasked and enabled.

`EnumerateFlags`

No flags are currently defined. Set this parameter to PEP_ENUMERATE_UNMASKED_INTERRUPT_FLAGS_NONE (0x0).

`Callback`

A pointer to a caller-implemented EnumerateInterruptSource callback routine. This callback routine is called once for each interrupt source whose interrupt is unmasked. These callbacks occur synchronously before the **EnumerateUnmaskedInterrupts** routine returns.

`CallbackContext`

A pointer to a callback context. This pointer is passed as a parameter to the *EnumerateInterruptSource* callback routine pointed to by the *Callback* parameter. The contents of the callback context are PEP-defined, and are opaque to the power management framework (PoFx).

`InterruptInformation`

A pointer to a caller-allocated buffer whose size is at least **sizeof**(PEP_UNMASKED_INTERRUPT_INFORMATION) bytes. **EnumerateUnmaskedInterrupts** will use this buffer to transfer interrupt information to the PEP during calls to the PEP's *EnumerateInterruptSource* callback routine.

Return Value

EnumerateUnmaskedInterrupts returns STATUS_SUCCESS if the call successfully enumerates the interrupts. Possible error return values include the following status code.

RETURN VALUE	DESCRIPTION
STA TUS _IN VAL ID_P ARA MET ER	The **Size** or **Version** member of the **PEP_UNMASKED_INTERRUPT_INFORMATION** structure contains an invalid value.

Remarks

This routine is implemented by PoFx and is called by the PEP. The **EnumerateUnmaskedInterrupts** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to an **EnumerateUnmaskedInterrupts** routine.

Before the platform enters a system power state in which the interrupt controllers are power-gated, the PEP can call **EnumerateUnmaskedInterrupts** to get the information it needs to properly configure wake-up controllers for interrupts that are to remain unmasked.

The PEP can call this routine at IRQL <= HIGH_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)
IRQL	"<= HIGH_LEVEL"

PEP_UNMASKED_INTERRUPT_INFORMATION

POFXCALLBACKPLATFORMIDLEVETO callback function

1/25/2019 • 2 minutes to read • Edit Online

The **PlatformIdleVeto** routine increments or decrements the veto count for a veto code for a platform idle state.

Syntax

```
POFXCALLBACKPLATFORMIDLEVETO Pofxcallbackplatformidleveto;

NTSTATUS Pofxcallbackplatformidleveto(
  POHANDLE ProcessorHandle,
  ULONG PlatformState,
  ULONG VetoReason,
  BOOLEAN Increment
)
{...}
```

Parameters

`ProcessorHandle`

A POHANDLE value that represents the registration of the processor (as a device) with power management framework (PoFx). The platform extension plug-in (PEP) previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the processor had been registered with PoFx.

`PlatformState`

The index of the platform idle state whose veto count is being incremented or decremented. The PEP previously specified the supported platform idle states in response to a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification. If the PEP specified N platform idle states, valid platform idle state indexes range from 0 to N–1.

`VetoReason`

A PEP-defined veto code that indicates why the platform idle state cannot be entered. The PEP previously specified the number of supported veto reasons in response to a PEP_NOTIFY_PPM_QUERY_VETO_REASONS notification. If the PEP specified M veto reasons, valid veto codes range from 1 to M.

`Increment`

Whether to increment or decrement the veto count. Set to TRUE to increment the veto count for this veto reason, or to FALSE to decrement the count.

Return Value

PlatformIdleVeto returns STATUS_SUCCESS if the call successfully increments or decrements the veto count. Possible error return values include the following status code.

RETURN VALUE	DESCRIPTION

STA TUS _NO T_I MPL EME NTE D	Indicates that the **PlatformIdleVeto** routine is not implemented for this processor.

Remarks

This routine is implemented by the PoFx and is called by the PEP. The **PlatformIdleVeto** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to a **PlatformIdleVeto** routine.

After the PEP handles the PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification, each platform idle state starts with a veto count of zero for all veto codes. The PEP can increment the veto count of a veto code to prevent the operating system from transitioning the platform to this idle state. The PEP decrements the veto count when the veto reason that caused the count to be incremented is no longer in effect. Only after the count for all veto codes has decremented to zero is the operating system allowed to transition the platform to this idle state.

This routine must be called at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)
IRQL	PASSIVE_LEVEL

PEP_NOTIFY_PPM_QUERY_VETO_REASONS

POFXCALLBACKPROCESSORHALT callback function

1/25/2019 • 3 minutes to read • Edit Online

The **ProcessorHalt** routine prepares the processor to be halted.

Syntax

```
POFXCALLBACKPROCESSORHALT Pofxcallbackprocessorhalt;

NTSTATUS Pofxcallbackprocessorhalt(
  ULONG Flags,
  PVOID Context,
  PPROCESSOR_HALT_ROUTINE Halt
)
{...}
```

Parameters

`Flags`

Flags that indicate the properties of the idle state that the processor will enter. The *Flags* parameter is set to zero or to the bitwise-OR of one or more of the following flag bits.

FLAG NAME	VALUE	DESCRIPTION
PROCESSOR_HALT_CACHE_FLUSH_OVERRIDE	0x01	The PEP's *Halt* callback routine is responsible for flushing the processor's caches. If this flag is not set, **ProcessorHalt** will flush the caches on entry to the processor idle state, and will invalidate the caches on exit from this state.
PROCESSOR_HALT_CACHE_COHERENT	0x02	Prepare the processor to enter an idle state in which the processor's caches will remain coherent.
PROCESSOR_HALT_CONTEXT_RETAINED	0x04	Prepare the processor to enter an idle state in which the processor's thread context will be preserved.
PROCESSOR_HALT_RETURN_NOT_SAFE	0x08	The PEP's *Halt* callback routine is guaranteed to not return. Set this flag if the *Halt* callback transitions the processor to a context-losing, power-gated state that cannot be canceled by hardware. When this flag is set, the operating system will treat a return from the *Halt* callback as a fatal error.
PROCESSOR_HALT_VIA_PSCI_CPU_SUSPEND	0x16	

`Context`

A pointer to a PEP-defined processor-halt context. This pointer is passed as a parameter to the *Halt* callback routine. This context is opaque to the Windows power management framework (PoFx).

`Halt`

A pointer to a PEP-implemented *Halt* callback routine. PoFx calls this routine after preparations to halt the processor have been completed. During this callback, the PEP is expected to transition the processor to the *halted* state.

Return Value

ProcessorHalt returns STATUS_SUCCESS if the processor is successfully prepared to be halted. Possible error return values include the following status code.

RETURN VALUE	DESCRIPTION
STA TUS _IN VAL ID_P ARA MET ER	The *Halt* parameter is NULL; or an invalid flag value was specified in *Flags*; or *Flags* contains an illegal combination of flag bits. For more information, see Remarks.
STA TUS _UN SUC CES SFU L	The PEP's *Halt* callback routine unexpectedly returned from an idle state in which the processor's hardware context was not preserved.

Remarks

This routine is implemented by the power management framework (PoFx) and is called by the platform extension plug-in (PEP). The **ProcessorHalt** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to a **ProcessorHalt** routine.

Before halting the processor, the PEP calls the **ProcessorHalt** routine to give PoFx an opportunity to save the processor's hardware context. If necessary, **ProcessorHalt** saves this state internally in PoFx so that the state can later be restored when the processor exits the idle state. After preparing the processor to enter the idle state, **ProcessorHalt** calls the PEP's *Halt* callback routine to halt the processor.

As part of the PEP's handling of a PEP_NOTIFY_PPM_IDLE_EXECUTE notification, the PEP must transition the processor to the idle state that the PEP has selected. The following are the two ways to enter the processor idle state:

- For a processor idle state in which the processor's caches remain coherent so that all system and processor state is maintained, the PEP can enter the idle state directly without first calling **ProcessorHalt**.
- For a processor idle state in which the processor's caches might not remain coherent, or an idle state in which the processor hardware context is not preserved, the PEP must call **ProcessorHalt** before transitioning the processor to the idle state.

The following combinations of flag bits are illegal:

- PROCESSOR_HALT_CONTEXT_RETAINED = 1 and PROCESSOR_HALT_RETURN_NOT_SAFE = 1

  The PEP's *Halt* callback routine must return from any state in which context is retained.

- PROCESSOR_HALT_CACHE_FLUSH_OVERRIDE = 1 and PROCESSOR_HALT_CACHE_COHERENT = 1

  The cache-flush-override flag should be set only if entering an idle state that is not cache coherent.

- PROCESSOR_HALT_CACHE_FLUSH_OVERRIDE = 0 and PROCESSOR_HALT_CACHE_COHERENT = 0

  The cache-flush-override flag must be set for any non-cache coherent halt.

- PROCESSOR_HALT_CONTEXT_RETAINED = 0 and PROCESSOR_HALT_CACHE_COHERENT = 1

  Any idle states that lose processor hardware context (and therefore use the multiprocessor parking protocol to exit the idle state and return control to the operating system) are not cache-coherent states.

If the *Flags* parameter contains an illegal combination of flag bits, **ProcessorHalt** fails and returns STATUS_INVALID_PARAMETER.

The PEP can call this routine at IRQL <= HIGH_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)
IRQL	"<= HIGH_LEVEL"

POFXCALLBACKPROCESSORIDLEVETO callback function

1/25/2019 • 2 minutes to read • Edit Online

The **ProcessorIdleVeto** routine increments or decrements the veto count for a veto code for a processor idle state.

Syntax

```
POFXCALLBACKPROCESSORIDLEVETO Pofxcallbackprocessoridleveto;

NTSTATUS Pofxcallbackprocessoridleveto(
  POHANDLE ProcessorHandle,
  ULONG ProcessorState,
  ULONG VetoReason,
  BOOLEAN Increment
)
{...}
```

Parameters

`ProcessorHandle`

A POHANDLE value that represents the registration of the processor (as a device) with power management framework (PoFx). The platform extension plug-in (PEP) previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the processor had been registered with PoFx.

`ProcessorState`

The index of the processor idle state whose veto count is being incremented or decremented. The PEP previously specified the supported processor idle states in response to a PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification. If the PEP specified N processor idle states, valid processor idle state indexes range from 0 to N–1.

`VetoReason`

A PEP-defined veto code that indicates why the processor idle state cannot be entered. The PEP previously specified the supported veto reasons in response to a PEP_NOTIFY_PPM_QUERY_VETO_REASONS notification. If the PEP specified M veto reasons, valid veto codes range from 1 to M.

`Increment`

Whether to increment or decrement the veto count. Set to TRUE to increment the veto count for this veto reason, or to FALSE to decrement the count.

Whether to increment or decrement the veto count. Set to TRUE to increment the veto count for this veto reason, or to FALSE to decrement the count.

Return Value

This routine does not return a value.

Remarks

This routine is implemented by the power management framework (PoFx) and is called by the platform extension plug-in (PEP). The **ProcessorIdleVeto** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to an **ProcessorIdleVeto** routine.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)

PEP_KERNEL_INFORMATION_STRUCT_V3

POFXCALLBACKREQUESTCOMMON callback function

1/25/2019 • 2 minutes to read • Edit Online

The **RequestCommon** routine is a generic request handler.

Syntax

```
POFXCALLBACKREQUESTCOMMON Pofxcallbackrequestcommon;

NTSTATUS Pofxcallbackrequestcommon(
  ULONG RequestId,
  PVOID Data
)
{...}
```

Parameters

`RequestId`

A request ID that specifies the operation being requested.

`Data`

A pointer to a data structure that contains the input data and/or result data for the request specified by the *RequestId* parameter.

Return Value

RequestCommon returns STATUS_SUCCESS if the request is successfully handled. Otherwise, it returns an appropriate error status code.

Remarks

This routine is implemented by the power management framework (PoFx) and is called by the platform extension plug-in (PEP). The **RequestCommon** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to an **RequestCommon** routine.

A PEP can call this routine at IRQL <= HIGH_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)

IRQL	"<= HIGH_LEVEL"

PEP_KERNEL_INFORMATION_STRUCT_V3

POFXCALLBACKREQUESTINTERRUPT callback function

1/25/2019 • 2 minutes to read • Edit Online

The **RequestInterrupt** routine requests that the operating system replay an edge-triggered interrupt that might have been lost while the hardware platform was in a low-power state.

Syntax

```
POFXCALLBACKREQUESTINTERRUPT Pofxcallbackrequestinterrupt;

NTSTATUS Pofxcallbackrequestinterrupt(
  ULONG Gsiv
)
{...}
```

Parameters

`Gsiv`

The global system interrupt vector (GSIV) number that identifies this interrupt. The ACPI firmware assigns GSIV numbers to all primary interrupt lines. For secondary (GPIO) interrupt lines, the GSIV number is dynamically assigned by the operating system.

Return Value

RequestInterrupt returns STATUS_SUCCESS if the specified interrupt is successfully replayed. Possible error return values include the following status code.

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	Not a valid GSIV number.

Remarks

This routine is implemented by the power management framework (PoFx) and is called by the platform extension plug-in (PEP). The **RequestInterrupt** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to an **RequestInterrupt** routine.

Assertion of an edge-triggered interrupt signal is transient in nature and can be lost if the power to a primary interrupt controller is gated off when the interrupt occurs. In contrast, a level-triggered interrupt signal is expected

to remain asserted until it can be serviced.

A PEP can call this routine at IRQL <= HIGH_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)
IRQL	"<= HIGH_LEVEL"

POFXCALLBACKREQUESTWORKER callback function

1/25/2019 • 2 minutes to read • Edit Online

The **RequestWorker** routine is called by a platform extension plug-in (PEP) to inform the Windows power management framework (PoFx) that the platform extension plug-in (PEP) has a work request to submit on behalf of the specified device.

Syntax

```
POFXCALLBACKREQUESTWORKER Pofxcallbackrequestworker;

void Pofxcallbackrequestworker(
  POHANDLE PluginHandle
)
{...}
```

Parameters

`PluginHandle`

A POHANDLE value that represents the registration of the device with PoFx. The PEP previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the device's driver stack registered the device with PoFx.

Return Value

None.

Remarks

This routine is implemented by PoFx and is called by the PEP. The **RequestWorker** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to a **RequestWorker** routine.

Each time the PEP calls this routine, PoFx responds by sending a PEP_DPM_WORK notification to the PEP. This notification might be delayed if a worker thread is not immediately available to process the work request.

A PEP can call this routine at IRQL <= DISPATCH_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)
IRQL	"<= DISPATCH_LEVEL"

POFXCALLBACKUPDATEPLATFORMIDLESTATE callback function

1/25/2019 • 2 minutes to read • Edit Online

The **UpdatePlatformIdleState** routine is called by the platform extension plug-in (PEP) to update the properties of the specified platform idle state.

Syntax

```
POFXCALLBACKUPDATEPLATFORMIDLESTATE Pofxcallbackupdateplatformidlestate;

NTSTATUS Pofxcallbackupdateplatformidlestate(
  POHANDLE ProcessorHandle,
  ULONG PlatformState,
  PPEP_PLATFORM_IDLE_STATE_UPDATE Update
)
{...}
```

Parameters

`ProcessorHandle`

A POHANDLE value that represents the registration of the processor (as a device) with the Windows power management framework (PoFx). The PEP previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the processor had been registered with PoFx.

`PlatformState`

An index that identifies the platform idle state whose properties are to be updated. In response to a previous PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification, the PEP specified the number of supported platform idle states. If the PEP specified N platform idle states, valid platform idle state indexes range from 0 to N-1. In response to a previous PEP_NOTIFY_PPM_QUERY_PLATFORM_STATE notification, the PEP specified the properties of this platform idle state.

`Update`

A pointer to a PEP_PLATFORM_IDLE_STATE_UPDATE structure that contains the updated properties of the platform idle state.

Return Value

UpdatePlatformIdleState returns STATUS_SUCCESS if it successfully updates the properties of the platform idle state. Possible error return values include the following status codes.

RETURN VALUE	DESCRIPTION

STA TUS _NO T_S UPP ORT ED	The version number in the **PEP_PLATFORM_IDLE_STATE_UPDATE** structure is not a supported value.
STA TUS _NO T_I MPL EME NTE D	The **UpdatePlatformIdleState** routine is not implemented for this processor.

Remarks

This routine is implemented by PoFx and is called by the PEP. The **UpdatePlatformIdleState** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to an **UpdatePlatformIdleState** routine.

The PEP must wait until after it has completed all PEP_NOTIFY_PPM_QUERY_PLATFORM_STATE notifications to call the **UpdatePlatformIdleState** routine.

The **UpdatePlatformIdleState** routine must be called at IRQL = PASSIVE_LEVEL.

Requirements

POFXCALLBACKUPDATEPROCESSORIDLESTATE callback function

1/25/2019 • 2 minutes to read • Edit Online

The **UpdateProcessorIdleState** routine is called by the platform extension plug-in (PEP) to update the properties of the specified processor idle state.

Syntax

```
POFXCALLBACKUPDATEPROCESSORIDLESTATE Pofxcallbackupdateprocessoridlestate;

NTSTATUS Pofxcallbackupdateprocessoridlestate(
  POHANDLE ProcessorHandle,
  ULONG ProcessorState,
  PPEP_PROCESSOR_IDLE_STATE_UPDATE Update
)
{...}
```

Parameters

`ProcessorHandle`

A POHANDLE value that represents the registration of the processor (as a device) with the Windows power management framework (PoFx). The PEP previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the processor had been registered with PoFx.

`ProcessorState`

An index that identifies the processor idle state whose properties are to be updated. In response to a previous PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification, the PEP specified the number of supported processor idle states and the properties of these states. If the PEP specified N processor idle states, valid processor idle state indexes range from 0 to N-1.

`Update`

A pointer to a PEP_PROCESSOR_IDLE_STATE_UPDATE structure that contains the updated properties of the processor idle state.

Return Value

UpdateProcessorIdleState returns STATUS_SUCCESS if it successfully updates the properties of the processor idle state. Possible error return values include the following status codes.

RETURN VALUE	DESCRIPTION

STA TUS _NO T_S UPP ORT ED	The version number in the **PEP_PROCESSOR_IDLE_STATE_UPDATE** structure is not a supported value.
STA TUS _NO T_I MPL EME NTE D	The **UpdateProcessorIdleState** routine is not implemented for this processor.

Remarks

This routine is implemented by PoFx and is called by the PEP. The **UpdateProcessorIdleState** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to an **UpdateProcessorIdleState** routine.

The **UpdateProcessorIdleState** routine must be called at IRQL = PASSIVE_LEVEL.

PoFxRegisterCoreDevice function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxRegisterCoreDevice** routine registers a new core system resource with the Windows power management framework (PoFx).

Syntax

```
NTSTATUS PoFxRegisterCoreDevice(
  PCUNICODE_STRING   Id,
  PPO_FX_CORE_DEVICE Device,
  POHANDLE           *Handle
);
```

Parameters

`Id`

A string that uniquely identifies the core system resource. This member is a pointer to a UNICODE_STRING structure that contains a device identification string.

`Device`

A pointer to a PO_FX_CORE_DEVICE structure that describes the power characteristics of the core system resource.

`Handle`

A pointer to a location to which the routine writes a POHANDLE value. This handle represents the registration of the core system resource with PoFx.

Return Value

PoFxRegisterCoreDevice returns STATUS_SUCCESS if the call successfully registers the PEP. Possible error return values include the following status codes.

RETURN VALUE	DESCRIPTION
STA TUS _IN VAL ID_P ARA MET ER	The component count for this device is zero, or the **PO_FX_CORE_DEVICE** structure contains an invalid version number, or the **ComponentCriticalTransitionCallback** member of this structure contains an invalid function pointer.

STA TUS _INS UFFI CIE NT_ RES OU RCE S	Unable to allocate the resources required to complete the requested registration.

Remarks

This routine registers a core system resource so that this resource can be power-managed by PoFx.

Core system resources are hardware devices, such as timers and interrupt controllers, that are managed by the Windows hardware abstraction layer (HAL). These devices provide basic functions that are required by the operating system. Due to the close relationship between core system resources and processors, the power management of these resources needs to be coordinated with processor idle state management.

The **PoFxRegisterCoreDevice** routine should be called at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)
Library	Ntoskrnl.lib
IRQL	PASSIVE_LEVEL

PO_FX_CORE_DEVICE

UNICODE_STRING

PoFxRegisterPlugin function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxRegisterPlugin** routine registers a platform extension plug-in (PEP) with the Windows power management framework (PoFx).

Syntax

```
NTSTATUS PoFxRegisterPlugin(
  PPEP_INFORMATION        PepInformation,
  PPEP_KERNEL_INFORMATION KernelInformation
);
```

Parameters

`PepInformation`

A pointer to a PEP_INFORMATION structure.

`KernelInformation`

A pointer to a PEP_KERNEL_INFORMATION_STRUCT_V3 structure.

Return Value

PoFxRegisterPlugin returns STATUS_SUCCESS if the call successfully registers the PEP. Possible error return values include the following status codes.

RETURN VALUE	DESCRIPTION
STA TUS _IN VAL ID_P ARA MET ER	The **Version** or **Size** member of the **PEP_KERNEL_INFORMATION** structure is set to an invalid value; or the **AcceptDeviceNotification** member of this structure is set to NULL.
STA TUS _IN VAL ID_P EP_I NFO _VE RSI ON	The **Version** member of the **PEP_INFORMATION** structure is set to an invalid value.

STA TUS _INS UFFI CIE NT_ RES OU RCE S	Unable to allocate the resources required to complete the requested registration.

Remarks

A PEP calls this routine to register itself with PoFx.

A PEP cannot unregister, and cannot register twice. If the PEP must be serviced, the operating system must restart.

The PoFxRegisterPluginEx routine is similar to **PoFxRegisterPlugin**, except that it takes an additional parameter, *Flags*.

The PEP must call **PoFxRegisterPlugin** at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)
Library	Ntoskrnl.lib
IRQL	PASSIVE_LEVEL

PEP_INFORMATION

PEP_KERNEL_INFORMATION_STRUCT_V3

PoFxRegisterPluginEx

PoFxRegisterPluginEx function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxRegisterPluginEx** routine registers a platform extension plug-in (PEP) with the Windows power management framework (PoFx).

Syntax

```
NTSTATUS PoFxRegisterPluginEx(
  PPEP_INFORMATION        PepInformation,
  ULONGLONG               Flags,
  PPEP_KERNEL_INFORMATION KernelInformation
);
```

Parameters

`PepInformation`

A pointer to a PEP_INFORMATION structure that contains pointers to one or more callback routines that are implemented by the PEP. These routines handle notifications that are sent to the PEP by PoFx.

`Flags`

A set of flag bits for configuring the PEP interface. Set this member to zero or to the following value.

FLAG BIT	DESCRIPTION
PEP_FLAG_WORKER_CONCURRENCY	

`KernelInformation`

A pointer to a PEP_KERNEL_INFORMATION structure.

Return Value

PoFxRegisterPluginEx returns STATUS_SUCCESS if the call successfully registers the PEP. Possible error return values include the following status codes.

RETURN VALUE	DESCRIPTION
STA TUS _IN VAL ID_P ARA MET ER	The **Version** or **Size** member of the **PEP_KERNEL_INFORMATION** structure is set to an invalid value; or the **AcceptDeviceNotification** member of this structure is set to NULL.

STA TUS _IN VAL ID_P EP_I NFO _VE RSI ON	The **Version** member of the **PEP_INFORMATION** structure is set to an invalid value.
STA TUS _INS UFFI CIE NT_ RES OU RCE S	Unable to allocate the resources required to complete the requested registration.

Remarks

A PEP calls this routine to register itself with PoFx.

A PEP cannot unregister, and cannot register twice. If the PEP must be serviced, the operating system must restart.

The PoFxRegisterPlugin routine is similar to **PoFxRegisterPluginEx**, except that it does not take a *Flags* parameter.

The PEP must call **PoFxRegisterPluginEx** at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 10.
Target Platform	Windows
Header	pep_x.h (include Pep_x.h)
Library	Ntoskrnl.lib
IRQL	PASSIVE_LEVEL

PEP_INFORMATION

PEP_KERNEL_INFORMATION

PoFxRegisterPlugin

PPO_ENUMERATE_INTERRUPT_SOURCE_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

An *EnumerateInterruptSource* callback routine supplies a platform extension plug-in (PEP) with information about an interrupt source.

Syntax

```
PPO_ENUMERATE_INTERRUPT_SOURCE_CALLBACK PpoEnumerateInterruptSourceCallback;

BOOLEAN PpoEnumerateInterruptSourceCallback(
  PVOID CallbackContext,
  PPEP_UNMASKED_INTERRUPT_INFORMATION InterruptInformation
)
{...}
```

Parameters

`CallbackContext`

A pointer to a callback context. The PEP specified this pointer value as a parameter in the EnumerateUnmaskedInterrupts call that initiated the enumeration of interrupt sources.

`InterruptInformation`

A pointer to a PEP_UNMASKED_INTERRUPT_INFORMATION structure that contains information about the interrupt source.

Return Value

If the *EnumerateInterruptSource* callback routine returns TRUE, **EnumerateUnmaskedInterrupts** will continue to call the *EnumerateInterruptSource* callback routine while more interrupts are available to be enumerated. If the *EnumerateInterruptSource* callback routine returns FALSE, **EnumerateUnmaskedInterrupts** returns without enumerating any more interrupts.

Remarks

This callback routine is implemented by a PEP, and is called by the Windows power management framework (PoFx). The *Callback* parameter of the EnumerateUnmaskedInterrupts routine is a pointer to an *EnumerateInterruptSource* callback routine.

After a PEP calls **EnumerateUnmaskedInterrupts** to enumerate the unmasked interrupt sources, PoFx calls the PEP's *EnumerateInterruptSource* callback routine once for each unmasked interrupt source. **EnumerateUnmaskedInterrupts** returns only after the last call to the *EnumerateInterruptSource* callback routine completes.

An *EnumerateInterruptSource* callback routine is called at the same IRQL as the PEP's call to **EnumerateUnmaskedInterrupts** that initiates the enumeration callbacks.

Requirements

Target Platform	Windows
Header	pep_x.h (include Pep_x.h)
IRQL	See Remarks.

pepfx.h header

1/8/2019 • 13 minutes to read • Edit Online

This header contains programming interfaces used by the Power Engine Plugins (PEPs). For more information, see:

- Platform Extension Plug-ins (PEPs) pepfx.h contains the following programming interfaces:

Functions

TITLE	DESCRIPTION
PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE	The PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_EXTENDED_ADDRESS structure.
PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE	The PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_EXTENDED_ADDRESS structure.
PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE	The PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_GPIO_RESOURCE structure.
PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE	The PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_GPIO_RESOURCE structure.
PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE	The PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_INTERRUPT_RESOURCE structure.
PEP_ACPI_INITIALIZE_IOPORT_RESOURCE	The PEP_ACPI_INITIALIZE_IOPORT_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_IO_MEMORY_RESOURCE structure.
PEP_ACPI_INITIALIZE_MEMORY_RESOURCE	The PEP_ACPI_INITIALIZE_MEMORY_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_IO_MEMORY_RESOURCE structure.
PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE	The PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_I2C_RESOURCE structure.
PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE	The PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_SPI_RESOURCE structure.
PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE	The PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_UART_RESOURCE structure.

TITLE	DESCRIPTION
PoFxRegisterCoreDevice	The PoFxRegisterCoreDevice routine registers a new core system resource with the Windows power management framework (PoFx).
PoFxRegisterPlugin	The PoFxRegisterPlugin routine registers a platform extension plug-in (PEP) with the Windows power management framework (PoFx).
PoFxRegisterPluginEx	The PoFxRegisterPluginEx routine registers a platform extension plug-in (PEP) with the Windows power management framework (PoFx).

Callback functions

TITLE	DESCRIPTION
PEPCALLBACKNOTIFYACPI	An AcceptAcpiNotification event callback routine handles ACPI notifications from the Windows power management framework (PoFx).
PEPCALLBACKNOTIFYDPM	An AcceptDeviceNotification event callback routine handles device power management (DPM) notifications from the Windows power management framework (PoFx).
PEPCALLBACKNOTIFYPPM	An AcceptProcessorNotification event callback routine handles processor power management (PPM) notifications from the Windows power management framework (PoFx).
PEPCALLBACKPOWERONCRASHDUMPDEVICE	The PowerOnDumpDeviceCallback callback routine turns on the crash-dump device.
POFXCALLBACKCRITICALRESOURCE	The TransitionCriticalResource routine changes the active/inactive state of a core system component.
POFXCALLBACKENUMERATEUNMASKEDINTERRUPTS	The EnumerateUnmaskedInterrupts routine enumerates interrupt sources whose interrupts are unmasked and enabled.
POFXCALLBACKPLATFORMIDLEVETO	The PlatformIdleVeto routine increments or decrements the veto count for a veto code for a platform idle state.
POFXCALLBACKPROCESSORHALT	The ProcessorHalt routine prepares the processor to be halted.
POFXCALLBACKPROCESSORIDLEVETO	The ProcessorIdleVeto routine increments or decrements the veto count for a veto code for a processor idle state.
POFXCALLBACKREQUESTCOMMON	The RequestCommon routine is a generic request handler.
POFXCALLBACKREQUESTINTERRUPT	The RequestInterrupt routine requests that the operating system replay an edge-triggered interrupt that might have been lost while the hardware platform was in a low-power state.

TITLE	DESCRIPTION
POFXCALLBACKREQUESTWORKER	The RequestWorker routine is called by a platform extension plug-in (PEP) to inform the Windows power management framework (PoFx) that the platform extension plug-in (PEP) has a work request to submit on behalf of the specified device.
POFXCALLBACKUPDATEPLATFORMIDLESTATE	The UpdatePlatformIdleState routine is called by the platform extension plug-in (PEP) to update the properties of the specified platform idle state.
POFXCALLBACKUPDATEPROCESSORIDLESTATE	The UpdateProcessorIdleState routine is called by the platform extension plug-in (PEP) to update the properties of the specified processor idle state.
PPO_ENUMERATE_INTERRUPT_SOURCE_CALLBACK	An EnumerateInterruptSource callback routine supplies a platform extension plug-in (PEP) with information about an interrupt source.

Structures

TITLE	DESCRIPTION
PEP_ABANDON_DEVICE	The PEP_ABANDON_DEVICE structure identifies a device that has been abandoned and will no longer be used by the operating system.
PEP_ACPI_ABANDON_DEVICE	The PEP_ACPI_ABANDON_DEVICE structure indicates whether the platform extension plug-in (PEP) accepts ownership of an abandoned device.
PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE	The PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE structure contains an enumeration of the objects in the namespace of the device.
PEP_ACPI_EVALUATE_CONTROL_METHOD	The PEP_ACPI_EVALUATE_CONTROL_METHOD structure specifies an ACPI control method to evaluate, an input argument to supply to this method, and an output buffer for the result of the evaluation.
PEP_ACPI_EXTENDED_ADDRESS	The PEP_ACPI_EXTENDED_ADDRESS structure is used to report resource usage in the address space such as memory and IO.
PEP_ACPI_GPIO_RESOURCE	The PEP_ACPI_GPIO_RESOURCE structure describes the ACPI configuration for a general purpose input/output (GPIO) resource.
PEP_ACPI_INTERRUPT_RESOURCE	The PEP_ACPI_INTERRUPT_RESOURCE structure describes an ACPI interrupt resource.
PEP_ACPI_IO_MEMORY_RESOURCE	The PEP_ACPI_IO_MEMORY_RESOURCE structure describes an ACPI IO port descriptor resource.
PEP_ACPI_OBJECT_NAME	The PEP_ACPI_OBJECT_NAME union contains the four-character name of an ACPI object.

TITLE	DESCRIPTION
PEP_ACPI_OBJECT_NAME_WITH_TYPE	The PEP_ACPI_OBJECT_NAME_WITH_TYPE structure that specifies both the path-relative name of an ACPI object and the type of this object.
PEP_ACPI_PREPARE_DEVICE	The PEP_ACPI_PREPARE_DEVICE structure indicates whether a platform extension plug-in (PEP) is prepared to provide ACPI services for the specified device.
PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES	The PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES structure contains a list of raw resources that are needed to control power to the device.
PEP_ACPI_QUERY_OBJECT_INFORMATION	The PEP_ACPI_QUERY_OBJECT_INFORMATION structure contains information about an ACPI object.
PEP_ACPI_REGISTER_DEVICE	The PEP_ACPI_REGISTER_DEVICE structure contains registration information about a device for which the platform extension plug-in (PEP) is to provide ACPI services.
PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES	The PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES structure is used in the process of converting ACPI resources to BIOS resources by one of the PEP initialization functions.
PEP_ACPI_RESOURCE	The PEP_ACPI_RESOURCE structure contains hardware details for a specific ACPI resource.
PEP_ACPI_RESOURCE_FLAGS	The PEP_ACPI_RESOURCE_FLAGS structure contains flags describing an ACPI resource.
PEP_ACPI_SPB_I2C_RESOURCE	The PEP_ACPI_SPB_I2C_RESOURCE structure describes an ACPI I2C serial bus resource.
PEP_ACPI_SPB_RESOURCE	The PEP_ACPI_SPB_RESOURCE structure describes an ACPI serial bus connection resource.
PEP_ACPI_SPB_SPI_RESOURCE	The PEP_ACPI_SPB_SPI_RESOURCE structure describes an ACPI SPI serial bus resource.
PEP_ACPI_SPB_UART_RESOURCE	The PEP_ACPI_SPB_UART_RESOURCE structure describes an ACPI UART serial bus resource.
PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES	The PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES structure contains a list of translated power-control resources for the platform extension plug-in (PEP) to use.
PEP_ACPI_UNREGISTER_DEVICE	The PEP_ACPI_UNREGISTER_DEVICE structure contains information about a device that has been unregistered from ACPI services.
PEP_COMPONENT_PERF_INFO	The PEP_COMPONENT_PERF_INFO structure describes the performance states (P-states) of a component.
PEP_COMPONENT_PERF_SET	The PEP_COMPONENT_PERF_SET structure describes the performance states (P-states) in a P-state set.

TITLE	DESCRIPTION
PEP_COMPONENT_PERF_STATE_REQUEST	The PEP_COMPONENT_PERF_STATE_REQUEST structure specifies a performance state (P-state) set and a new performance level to assign to this set.
PEP_COMPONENT_PLATFORM_CONSTRAINTS	The PEP_COMPONENT_PLATFORM_CONSTRAINTS structure describes the lowest-powered Fx state of that a component can be in when the platform is in a particular idle state.
PEP_COMPONENT_V2	The PEP_COMPONENT_V2 structure specifies the power state attributes of a component in the device.
PEP_COORDINATED_DEPENDENCY_OPTION	The PEP_COORIDNATED_DEPENDENCY_OPTION structure describes a coordinated idle state's dependency to the OS.
PEP_COORDINATED_IDLE_STATE	The PEP_COORIDNATED_IDLE_STATE structure describes a coordinated idle state to the OS.
PEP_CRASHDUMP_INFORMATION	The PEP_CRASHDUMP_INFORMATION structure contains information about a crash-dump device.
PEP_DEBUGGER_TRANSITION_REQUIREMENTS	The PEP_DEBUGGER_TRANSITION_REQUIREMENTS structure indicates the platform idle states for which the debugger device must be turned on.
PEP_DEVICE_PLATFORM_CONSTRAINTS	The PEP_DEVICE_PLATFORM_CONSTRAINTS structure specifies the constraints for entry to the various Dx power states that are supported by a device.
PEP_DEVICE_POWER_STATE	The PEP_DEVICE_POWER_STATE structure indicates the status of a transition to a new Dx (device power) state.
PEP_DEVICE_REGISTER_V2	The PEP_DEVICE_REGISTER structure describes all the components in a particular device.
PEP_DEVICE_STARTED	The PEP_DEVICE_STARTED structure identifies a device whose driver has completed its registration with the Windows power management framework (PoFx).
PEP_INFORMATION	The PEP_INFORMATION structure specifies the interface that the platform extension plug-in (PEP) uses to receive notifications from the Windows power management framework (PoFx).
PEP_KERNEL_INFORMATION_STRUCT_V3	The PEP_KERNEL_INFORMATION_STRUCT_V3 structure specifies the interface that the power extension plug-in (PEP) uses to request services from the Windows power management framework (PoFx).
PEP_LOW_POWER_EPOCH	The PEP_LOW_POWER_EPOCH structure is used to provide data for a PEP_DPM_LOW_POWER_EPOCH notification (deprecated).
PEP_NOTIFY_COMPONENT_IDLE_STATE	The PEP_NOTIFY_COMPONENT_IDLE_STATE structure contains status information about a component's pending transition to a new Fx power state.

TITLE	DESCRIPTION
PEP_PERF_STATE	The PEP_PERF_STATE structure describes a performance state (P-state) in a P-state set in which the P-states are specified as a list of one or more discrete values.
PEP_PLATFORM_IDLE_STATE	The PEP_PLATFORM_IDLE_STATE structure specifies the properties of a platform idle state.
PEP_PLATFORM_IDLE_STATE_UPDATE	The PEP_PLATFORM_IDLE_STATE_UPDATE structure contains the updated properties of a platform idle state.
PEP_POWER_CONTROL_COMPLETE	The PEP_POWER_CONTROL_COMPLETE structure contains status information for a power control operation that the PEP previously requested and that the device driver has completed.
PEP_POWER_CONTROL_REQUEST	The PEP_POWER_CONTROL_REQUEST structure contains a request from a driver for a power control operation.
PEP_PPM_CONTEXT_QUERY_PARKING_PAGE	The PEP_PPM_CONTEXT_QUERY_PARKING_PAGE structure describes the parking page for a processor.
PEP_PPM_CST_STATE	The PEP_PPM_CST_STATE structure specifies the properties of a C state (ACPI processor power state).
PEP_PPM_CST_STATES	The PEP_PPM_CST_STATES structure specifies the properties of the C states (ACPI processor power states) that are supported for a processor.
PEP_PPM_ENTER_SYSTEM_STATE	Used in the PEP_NOTIFY_PPM_ENTER_SYSTEM_STATE notification to notify PEP that the system is about to enter a system power state. .
PEP_PPM_FEEDBACK_READ	The PEP_PPM_FEEDBACK_READ structure contains the value read from a processor performance feedback counter.
PEP_PPM_IDLE_COMPLETE	The PEP_PPM_IDLE_COMPLETE structure describe the idle states from which the processor and hardware platform are waking.
PEP_PPM_IDLE_COMPLETE_V2	The PEP_PPM_IDLE_COMPLETE_V2 structure describe the idle states from which the processor and hardware platform are waking.
PEP_PPM_IDLE_EXECUTE	The PEP_PPM_IDLE_EXECUTE structure specifies the idle state that the processor is to enter.
PEP_PPM_IDLE_EXECUTE_V2	The PEP_PPM_IDLE_EXECUTE_V2 structure specifies the idle state that the processor is to enter.
PEP_PPM_INITIATE_WAKE	The PEP_PPM_INITIATE_WAKE structure indicates whether a processor requires an interrupt to wake up from an idle state.
PEP_PPM_IS_PROCESSOR_HALTED	The PEP_PPM_IS_PROCESSOR_HALTED structure indicates whether the processor is currently halted in its selected idle state.

TITLE	DESCRIPTION
PEP_PPM_PARK_MASK	The PEP_PROCESSOR_PARK_MASK structure contains the current core parking mask.
PEP_PPM_PARK_SELECTION	The PEP_PPM_PARK_SELECTION structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding which processors in the platform should be parked to reduce power consumption.
PEP_PPM_PARK_SELECTION_V2	The PEP_PPM_PARK_SELECTION_V2 structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding which processors in the platform should be parked to reduce power consumption.
PEP_PPM_PERF_CHECK_COMPLETE	The PEP_PPM_PERF_CHECK_COMPLETE structure is used to inform the PEP of details regarding the completion of a periodic performance check evaluation.
PEP_PPM_PERF_CONSTRAINTS	The PEP_PPM_PERF_CONSTRAINTS structure describes the performance limits to apply to the processor.
PEP_PPM_PERF_SET	The PEP_PPM_PERF_SET structure specifies the new performance level that the operating system is requesting for the processor.
PEP_PPM_PERF_SET_STATE	Used in the PEP_NOTIFY_PPM_PERF_SET notification at runtime to set the current operating performance of the processor. .
PEP_PPM_PLATFORM_STATE_RESIDENCIES	The PEP_PPM_PLATFORM_STATE_RESIDENCIES structure contains the accumulated residency times and transition counts for the idle states that are supported by the hardware platform.
PEP_PPM_PLATFORM_STATE_RESIDENCY	The PEP_PPM_PLATFORM_STATE_RESIDENCY structure specifies the accumulated residency time and transition count for a particular platform idle state.
PEP_PPM_QUERY_CAPABILITIES	The PEP_PPM_QUERY_CAPABILITIES structure contains information about the processor power management (PPM) capabilities of the platform extension plug-in (PEP).
PEP_PPM_QUERY_COORDINATED_DEPENDENCY	The PEP_PPM_QUERY_COORDINATED_DEPENDENCY structure describes dependencies for coordinated idle states.
PEP_PPM_QUERY_COORDINATED_STATES	The PEP_PPM_QUERY_COORDINATED_STATES structure contains information about each coordinated idle state that the platform extension plug-in (PEP) supports.

TITLE	DESCRIPTION
PEP_PPM_QUERY_DISCRETE_PERF_STATES	Used in the PEP_NOTIFY_PPM_QUERY_DISCRETE_PERF_STATES notification that stores the list of discrete performance states that PEP supports, if the PEP_NOTIFY_PPM_QUERY_CAPABILITIES notification indicates support for discrete performance states. .
PEP_PPM_QUERY_DOMAIN_INFO	Used in the PEP_NOTIFY_PPM_QUERY_DOMAIN_INFO notification that queries for information about a performance domain. .
PEP_PPM_QUERY_FEEDBACK_COUNTERS	The PEP_PPM_QUERY_FEEDBACK_COUNTERS structure describes all the processor performance counters that the platform extension plug-in (PEP) supports for a particular processor.
PEP_PPM_QUERY_IDLE_STATES_V2	The PEP_PPM_QUERY_IDLE_STATES_V2 structure is used during processor initialization to query the platform extension plug-in (PEP) for a list of processor idle states that the processor supports.
PEP_PPM_QUERY_PERF_CAPABILITIES	The PEP_PPM_QUERY_PERF_CAPABILITIES structure describes the performance capabilities of the processors in the specified processor performance domain.
PEP_PPM_QUERY_PLATFORM_STATE	The PEP_PPM_QUERY_PLATFORM_STATE structure contains information about a platform idle state.
PEP_PPM_QUERY_PLATFORM_STATES	The PEP_PPM_QUERY_PLATFORM_STATES structure specifies the number of platform idle states the hardware platform supports.
PEP_PPM_QUERY_STATE_NAME	The PEP_PPM_QUERY_STATE_NAME structure contains information about a specific coordinated or platform idle state.
PEP_PPM_QUERY_VETO_REASON	The PEP_PPM_QUERY_VETO_REASON structure supplies a wide-character, null-terminated string that contains a descriptive, human-readable name for a veto reason.
PEP_PPM_QUERY_VETO_REASONS	The PEP_PPM_QUERY_VETO_REASONS structure specifies the total number of veto reasons that the PEP uses in calls to the ProcessorIdleVeto and PlatformIdleVeto routines.
PEP_PPM_RESUME_FROM_SYSTEM_STATE	Used by the PEP_NOTIFY_PPM_RESUME_FROM_SYSTEM_STATE notification that notifies the PEP that the system has just resumed from a system power state.
PEP_PPM_TEST_IDLE_STATE	The PEP_PPM_TEST_IDLE_STATE structure contains information about whether the processor can immediately enter a processor idle state.
PEP_PREPARE_DEVICE	The PEP_PREPARE_DEVICE structure identifies a device that must be started up in preparation for its use by the operating system.

TITLE	DESCRIPTION
PEP_PROCESSOR_FEEDBACK_COUNTER	The PEP_PROCESSOR_FEEDBACK_COUNTER structure describes a feedback counter to the operating system.
PEP_PROCESSOR_IDLE_DEPENDENCY	The PEP_PROCESSOR_IDLE_DEPENDENCY structure specifies the dependencies of a platform idle state on the specified processor.
PEP_PROCESSOR_IDLE_STATE_UPDATE	The PEP_PROCESSOR_IDLE_STATE_UPDATE structure contains the updated properties of a processor idle state.
PEP_PROCESSOR_IDLE_STATE_V2	The PEP_PROCESSOR_IDLE_STATE_V2 structure describes a processor idle state that the platform extension plug-in (PEP) supports.
PEP_PROCESSOR_PARK_PREFERENCE	The PEP_PROCESSOR_PARK_PREFERENCE structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding whether the specified processor should be parked to reduce power consumption.
PEP_PROCESSOR_PARK_STATE	The PEP_PROCESSOR_PARK_STATE structure describes the parking state for a single processor.
PEP_PROCESSOR_PERF_STATE	Use in the PEP_NOTIFY_PPM_QUERY_DISCRETE_PERF_STATES notification. This structure describes the properties of a single performance state. .
PEP_QUERY_COMPONENT_PERF_CAPABILITIES	The PEP_QUERY_COMPONENT_PERF_CAPABILITIES structure specifies the number of performance state (P-state) sets that are defined for a component.
PEP_QUERY_COMPONENT_PERF_SET	The PEP_QUERY_COMPONENT_PERF_SET structure contains query information about a set of performance state values (P-state set) for a component.
PEP_QUERY_COMPONENT_PERF_SET_NAME	The PEP_QUERY_COMPONENT_PERF_SET_NAME structure contains query information about a set of performance state values (P-state set) for a component.
PEP_QUERY_COMPONENT_PERF_STATES	The PEP_QUERY_COMPONENT_PERF_STATES structure contains a list of discrete performance state (P-state) values for the specified P-state set.
PEP_QUERY_CURRENT_COMPONENT_PERF_STATE	The PEP_QUERY_CURRENT_COMPONENT_PERF_STATE structure contains information about the current P-state in the specified P-state set.
PEP_QUERY_SOC_SUBSYSTEM	The PEP_QUERY_SOC_SUBSYSTEM structure is used by the PEP_DPM_QUERY_SOC_SUBSYSTEM notification to gather basic information about a particular system on a chip (SoC) subsystem.

TITLE	DESCRIPTION
PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME	The PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME structure is used by the PEP_DPM_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME notification to collect details about the blocking duration for a particular system on a chip (SoC) subsystem.
PEP_QUERY_SOC_SUBSYSTEM_COUNT	The PEP_QUERY_SOC_SUBSYSTEM_COUNT structure is used to tell the OS whether the PEP supports system on a chip (SoC) subsystem accounting for a given platform idle state.
PEP_QUERY_SOC_SUBSYSTEM_METADATA	The PEP_QUERY_SOC_SUBSYSTEM_METADATA structure is used with the PEP_DPM_QUERY_SOC_SUBSYSTEM_METADATA notification to collect optional metadata about the system on a chip (SoC) subsystem whose blocking time has just been queried.
PEP_REGISTER_COMPONENT_PERF_STATES	The PEP_REGISTER_COMPONENT_PERF_STATES structure describes the performance states (P-states) of the specified component.
PEP_REGISTER_CRASHDUMP_DEVICE	The PEP_REGISTER_CRASHDUMP_DEVICE structure provides a callback routine to turn on a crash-dump device.
PEP_REGISTER_DEBUGGER	The PEP_REGISTER_DEBUGGER structure identifies a registered device that is a core system resource that provides debugger transport.
PEP_REGISTER_DEVICE_V2	The PEP_REGISTER_DEVICE_V2 structure describes a device whose driver stack has just registered with the Windows power management framework (PoFx).
PEP_REQUEST_COMPONENT_PERF_STATE	The PEP_REQUEST_COMPONENT_PERF_STATE structure contains a list of performance state (P-state) changes requested by the Windows power management framework (PoFx), plus status information about the handling of these requests by the platform extension plug-in (PEP).
PEP_RESET_SOC_SUBSYSTEM_ACCOUNTING	The PEP_RESET_SOC_SUBSYSTEM_ACCOUNTING structure is provided to the platform extension plug-in (PEP) as part of a PEP_DPM_RESET_SOC_SUBSYSTEM_ACCOUNTING notification.
PEP_SOC_SUBSYSTEM_METADATA	The PEP_SOC_SUBSYSTEM_METADATA structure contains key-value pairs that contain metadata for a system on a chip (SoC) subsystem. It is used in the context of a PEP_DPM_QUERY_SOC_SUBSYSTEM_METADATA notification sent to a platform extension plug-in (PEP).
PEP_SYSTEM_LATENCY	The PEP_SYSTEM_LATENCY structure specifies the new value for the system latency tolerance.
PEP_UNMASKED_INTERRUPT_FLAGS	The PEP_UNMASKED_INTERRUPT_FLAGS union indicates whether an unmasked interrupt source is a primary interrupt or a secondary interrupt.

TITLE	DESCRIPTION
PEP_UNMASKED_INTERRUPT_INFORMATION	The PEP_UNMASKED_INTERRUPT_INFORMATION structure contains information about an interrupt source.
PEP_UNREGISTER_DEVICE	The PEP_UNREGISTER_DEVICE structure identifies a device whose registration is being removed from the Windows power management framework (PoFx).
PEP_WORK	The PEP_WORK structure indicates whether the PEP has a work request to submit to the Windows power management framework (PoFx).
PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE	The PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE structure contains the results of an ACPI control method that was asynchronously evaluated by the platform extension plug-in (PEP).
PEP_WORK_ACPI_NOTIFY	The PEP_WORK_ACPI_NOTIFY structure contains the ACPI Notify code for a device that has generated a hardware event.
PEP_WORK_COMPLETE_IDLE_STATE	The PEP_WORK_COMPLETE_IDLE_STATE structure identifies a component that the platform extension plug-in (PEP) has prepared for a transition to a new Fx power state.
PEP_WORK_COMPLETE_PERF_STATE	The PEP_WORK_COMPLETE_PERF_STATE structure describes the completion status of a previously requested update to the performance values assigned to a list of performance state (P-state) sets.
PEP_WORK_INFORMATION	The PEP_WORK_INFORMATION structure describes a work item that the PEP is submitting to the Windows power management framework (PoFx).
PEP_WORK_POWER_CONTROL	The PEP_WORK_POWER_CONTROL structure contains the parameters for a power control request that the platform extension plug-in (PEP) sends directly to a processor driver.
PO_FX_CORE_DEVICE	The PO_FX_CORE_DEVICE structure contains information about the power-state attributes of the components in a core system resource, and provides a software interface for power-managing these components.

Enumerations

TITLE	DESCRIPTION
GPIO_PIN_CONFIG_TYPE	The GPIO_PIN_CONFIG_TYPE enumeration describes a connection IO resource.
GPIO_PIN_IORESTRICTION_TYPE	The GPIO_PIN_IORESTRICTION_TYPE enumeration describes the functions that a GPIO pin is limited to performing.
PEP_ACPI_OBJECT_TYPE	The PEP_ACPI_OBJECT_TYPE enumeration indicates the type of ACPI object.

TITLE	DESCRIPTION
PEP_ACPI_RESOURCE_TYPE	The PEP_ACPI_RESOURCE_TYPE enumeration is used to identify the type of ACPI resource that is contained in the PEP_ACPI_RESOURCE union.
PEP_DEVICE_ACCEPTANCE_TYPE	The PEP_DEVICE_ACCEPTANCE_TYPE enumeration indicates whether a PEP accepts ownership of a device.
PEP_PERF_STATE_TYPE	The PEP_PERF_STATE_TYPE enumeration indicates the type of performance information that is specified for a performance state (P-state) of a component.
PEP_PERF_STATE_UNIT	The PEP_PERF_STATE_UNIT enumeration indicates the measurement units in which the performance state (P-state) of a component is specified.
PEP_WORK_TYPE	The PEP_WORK_TYPE enumeration describes the type of work that the platform extension plug-in (PEP) is requesting.

GPIO_PIN_CONFIG_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **GPIO_PIN_CONFIG_TYPE** enumeration describes a connection IO resource.

Syntax

```
typedef enum _GPIO_PIN_CONFIG_TYPE {
  PullDefault,
  PullUp,
  PullDown,
  PullNone
} GPIO_PIN_CONFIG_TYPE;
```

Constants

PullDefault	Indicates that no configuration is applied to this pin.
PullUp	Indicates that this pin is configured to use a pull-up resistor.
PullDown	Indicates that this pin is configured to use a pull-down resistor.
PullNone	Indicates that this pin is not configured to use a pull-up or pull-down resistor.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

GPIO_PIN_IORESTRICTION_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **GPIO_PIN_IORESTRICTION_TYPE** enumeration describes the functions that a GPIO pin is limited to performing.

Syntax

```
typedef enum _GPIO_PIN_IORESTRICTION_TYPE {
  IoRestrictionNone,
  IoRestrictionInputOnly,
  IoRestrictionOutputOnly,
  IoRestrictionNoneAndPreserve
} GPIO_PIN_IORESTRICTION_TYPE;
```

Constants

IoRestrictionNone	Indicates that the GPIO pin is not restricted to either input or output. When no IO restriction is described, it is assumed to be **IoRestrictionNone**.
IoRestrictionInputOnly	Indicates that the GPIO pin is restricted to input.
IoRestrictionOutputOnly	Indicates that the GPIO pin is restricted to output.
IoRestrictionNoneAndPreserve	Indicates that the GPIO pin is not restricted to either input or output and that the mode should be preserved when the driver is unloaded.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_ABANDON_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ABANDON_DEVICE** structure identifies a device that has been abandoned and will no longer be used by the operating system.

Syntax

```
typedef struct _PEP_ABANDON_DEVICE {
  PCUNICODE_STRING DeviceId;
  BOOLEAN          DeviceAccepted;
} PEP_ABANDON_DEVICE, *PPEP_ABANDON_DEVICE;
```

Members

`DeviceId`

[in] A string that uniquely identifies the device. This member is a pointer to a UNICODE_STRING structure that contains a device identification string.

`DeviceAccepted`

[out] Whether the PEP claims ownership of the device. The PEP sets this member to TRUE to claim ownership of the device, or to FALSE to indicate that it does not own the device.

Remarks

This structure is used by the PEP_DPM_ABANDON_DEVICE notification. The **DeviceId** member of the structure contains an input value that is supplied by the Windows power management framework (PoFx). The **DeviceAccepted** member contains an output value that the PEP writes to the structure in response to this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_DPM_ABANDON_DEVICE

UNICODE_STRING

PEP_ACPI_ABANDON_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_ABANDON_DEVICE** structure indicates whether the platform extension plug-in (PEP) accepts ownership of an abandoned device.

Syntax

```
typedef struct _PEP_ACPI_ABANDON_DEVICE {
  PCUNICODE_STRING AcpiDeviceName;
  BOOLEAN          DeviceAccepted;
} PEP_ACPI_ABANDON_DEVICE, *PPEP_ACPI_ABANDON_DEVICE;
```

Members

`AcpiDeviceName`

[in] A pointer to an ANSI_STRING structure that contains the fully qualified BIOS name for the device. This name specifies the the path and name of the device in the ACPI namespace. For more information, see Enumerating Child Devices and Control Methods.

`DeviceAccepted`

[out] Whether the PEP claims ownership of the device specified by the **AcpiDeviceName** member. Set to TRUE if the PEP claims ownership, and to FALSE if the PEP does not own the device.

Remarks

This structure is used by the PEP_NOTIFY_ACPI_ABANDON_DEVICE notification. This notification provides an opportunity for the PEP to clean up any remaining device state after the operating system has abandoned the device. The **AcpiDeviceName** member of the structure contains an input value that is supplied by the Windows power management framework (PoFx). The **DeviceAccepted** member contains an output value that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

ANSI_STRING

PEP_NOTIFY_ACPI_ABANDON_DEVICE

PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE** structure contains an enumeration of the objects in the namespace of the device.

Syntax

```
typedef struct _PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE {
  PEPHANDLE                       DeviceHandle;
  ULONG                           RequestFlags;
  NTSTATUS                        Status;
  ULONG                           ObjectCount;
  SIZE_T                          ObjectBufferSize;
  PEP_ACPI_OBJECT_NAME_WITH_TYPE Objects[ANYSIZE_ARRAY];
} PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE, *PPEP_ACPI_ENUMERATE_DEVICE_NAMESPACE;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device's registration for ACPI services. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_NOTIFY_ACPI_REGISTER_DEVICE notification.

`RequestFlags`

[in] A set of input flags. No flags are currently defined for this member, which is always set to PEP_ACPI_EDN_FLAG_NONE (0x0).

`Status`

[out] An NTSTATUS value that indicates the status of the requested device-namespace enumeration. Set this member to STATUS_SUCCESS if the PEP succeeds in enumerating the objects in the device namespace. Set to STATUS_BUFFER_TOO_SMALL if the input value in the **TotalBufferSize** member indicates that the allocated buffer is not large enough to contain the **PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE** structure and **Objects** array.

`ObjectCount`

[out] The number of elements in the **Objects** array.

`ObjectBufferSize`

`Objects`

[out] The first element in an array of PEP_ACPI_OBJECT_NAME_WITH_TYPE structures that describe the objects in the ACPI namespace of the device. If this array contains more than one element, the additional array elements follow the end of the **PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE** structure.

Remarks

This structure is used by the PEP_NOTIFY_ACPI_ENUMERATE_DEVICE_NAMESPACE notification. The

RequestFlags and **TotalBufferSize** members contain input values supplied by PoFx when the notification is sent. The PEP may overwrite the **TotalBufferSize** input value with an output value if the input value is less than the required output buffer size. The **Status**, **ObjectCount**, and **Objects** members contain output values that the PEP writes to the structure.

If N is the number of objects listed in the ACPI namespace under this device, the PEP should verify that the storage allocated by PoFx for the **Objects** array is large enough to contain N array elements. If N > 1, the additional N−1 array elements follow the end of the **PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE** structure. The buffer size required to contain the structure and additional array elements is calculated as follows:

sizeof PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE sizeof PEP_ACPI_OBJECT_NAME_WITH_TYPE If the input value specified in the **TotalBufferSize** member is less than the required size, the PEP overwrites the **TotalBufferSize** input value with the required size, and sets the **Status** member to STATUS_BUFFER_TOO_SMALL. In response, PoFx will allocate a buffer of the required size and send a second PEP_NOTIFY_ACPI_ENUMERATE_DEVICE_NAMESPACE notification to the PEP for this device.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_ACPI_ENUMERATE_DEVICE_NAMESPACE

PEP_NOTIFY_ACPI_REGISTER_DEVICE

PEP_ACPI_EVALUATE_CONTROL_METHOD structure

2/5/2019 • 3 minutes to read • Edit Online

The **PEP_ACPI_EVALUATE_CONTROL_METHOD** structure specifies an ACPI control method to evaluate, an input argument to supply to this method, and an output buffer for the result of the evaluation.

Syntax

```
typedef struct _PEP_ACPI_EVALUATE_CONTROL_METHOD {
  PEPHANDLE              DeviceHandle;
  ULONG                  RequestFlags;
  union {
    ULONG       MethodName;
    ANSI_STRING MethodNameString;
  };
  NTSTATUS               MethodStatus;
  PVOID                  CompletionContext;
  ULONG                  InputArgumentCount;
  SIZE_T                 InputArgumentSize;
  PACPI_METHOD_ARGUMENT InputArguments;
  ULONG                  OutputArgumentCount;
  SIZE_T                 OutputArgumentSize;
  PACPI_METHOD_ARGUMENT OutputArguments;
} PEP_ACPI_EVALUATE_CONTROL_METHOD, *PPEP_ACPI_EVALUATE_CONTROL_METHOD;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device's registration for ACPI services. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_NOTIFY_ACPI_REGISTER_DEVICE notification.

`RequestFlags`

[in] A set of flags. This member contains one of the following values.

FLAG NAME	VALUE	MEANING
PEP_ACPI_ECM_FLAG_NONE	0x0	Not a valid control method name.
PEP_ACPI_ECM_FLAG_RELATIVE_NAME	0x1	The **MethodNameUlong** member contains a path-relative control method name.
PEP_ACPI_ECM_FLAG_FULLY_QUALIFIED_NAME	0x2	The **MethodNameString** member contains a fully qualified control method name.

`MethodName`

`MethodNameString`

`MethodStatus`

[out] An NTSTATUS value that indicates the status of the evaluation of the ACPI control method. Set this member

to STATUS_SUCCESS to indicate that the platform extension plug-in (PEP) successfully completed its evaluation of the method. Set to STATUS_NOT_SUPPORTED to indicate that the PEP does not recognize the control method. Set to STATUS_BUFFER_TOO_SMALL to indicate that the output buffer size specified by the **InputArgumentSize** member is not large enough to contain the method results.

If the PEP is to evaluate the method asychronously, set this member to STATUS_PENDING and return from the AcceptAcpiNotification callback. Later, when the evaluation is completed, the PEP calls the CompleteWork routine to notify the Windows power management framework (PoFx) that the evaluation of the control method is complete.

`CompletionContext`

[in] A pointer to a completion context value. The PEP uses this member only if the control method is evaluated asynchronously. In this case, the PEP supplies this completion context pointer in the call to the CompleteWork routine that notifies the Windows power management framework (PoFx) that the evaluation of the control method is complete. Included in the input parameters to this call is a pointer to a PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE structure to which the PEP has written the completion context pointer. The context is opaque to the PEP and contains data used internally by PoFx.

`InputArgumentCount`

[in] The number of input arguments in the input buffer pointed to by the **InputArguments** member. Each argument starts with an ACPI_METHOD_ARGUMENT structure that specifies the size of the argument. Currently, the maximum **InputArgumentCount** value is one.

`InputArgumentSize`

[in] The size, in bytes, of the input buffer pointed to by the **InputArguments** member.

`InputArguments`

[in] A pointer to an input buffer that contains an ACPI_METHOD_ARGUMENT structure that specifies the input argument for the specified ACPI control method.

`OutputArgumentCount`

[in] The number of output arguments in the output buffer pointed to by the **OutputArguments** member. Each argument starts with an ACPI_METHOD_ARGUMENT structure that specifies the size of the argument. Currently, the maximum allowed **OutputArgumentCount** value is one.

`OutputArgumentSize`

[in, out] On input, the size, in bytes, of the output buffer pointed to by the **OutputArguments** member. If this buffer is not large enough to contain the result of evaluating the method, the PEP overwrites the **OutputArgumentSize** input value with the required size, and sets the **MethodStatus** member to STATUS_BUFFER_TOO_SMALL.

`OutputArguments`

[in] A pointer to an output buffer to which the PEP writes an ACPI_METHOD_ARGUMENT structure that contains the result of evaluating the specified ACPI control method.

Remarks

This structure is used by the PEP_NOTIFY_ACPI_EVALUATE_CONTROL_METHOD notification. The **MethodStatus** member contains an output value that the PEP writes to the structure in response to this notification. The **OutputArgumentSize** member contains an input value supplied by PoFx when the notification is sent. The PEP may overwrite this input value with an output value if the input value is less than the required output buffer size. All other members of this structure contain input values that are supplied by PoFx when the notification

is sent.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_ACPI_EXTENDED_ADDRESS structure

1/30/2019 • 5 minutes to read • Edit Online

The **PEP_ACPI_EXTENDED_ADDRESS** structure is used to report resource usage in the address space such as memory and IO.

Syntax

```
typedef struct _PEP_ACPI_EXTENDED_ADDRESS {
  PEP_ACPI_RESOURCE_TYPE  Type;
  PEP_ACPI_RESOURCE_FLAGS Flags;
  UCHAR                   ResourceFlags;
  UCHAR                   GeneralFlags;
  UCHAR                   TypeSpecificFlags;
  UCHAR                   RevisionId;
  UCHAR                   Reserved;
  ULONGLONG               Granularity;
  ULONGLONG               MinimumAddress;
  ULONGLONG               MaximumAddress;
  ULONGLONG               TranslationAddress;
  ULONGLONG               AddressLength;
  ULONGLONG               TypeAttribute;
  PUNICODE_STRING         DescriptorName;
} PEP_ACPI_EXTENDED_ADDRESS, *PPEP_ACPI_EXTENDED_ADDRESS;
```

Members

`Type`

A PEP_ACPI_RESOURCE_TYPE enumeration value describing this resource.

`Flags`

A PEP_ACPI_RESOURCE_FLAGS structure describing this resource.

`ResourceFlags`

Indicates the type of resource this structure describes.

VALUE	MEANING
0	Indicates that this resource is a memory range.
1	Indicates that this resource is an IO range.
2	Indicates that this resource is a bus number range.
3-191	These values are reserved for future use.

192 - 255	These values are reserved for use by the hardware vendor.

`GeneralFlags`

A value containing the bit flags that are common to all resource types.

BIT(S)	MEANING
0 - Consumer/ Producer flag	When set, this indicates that the device consumes this resource.
1 - Decode type	When set, indicates that this bridge subtractively decodes the address. This applies to top level bridges only. When not set, indicates that this bridge positively decodes this address.
2 - Minimum address fixed	When set, indicates that the minimum address is fixed.
3 - Max address fixed	When set, indicates that the maximum address is fixed.
4 to 7 - Reserved	These bits are reserved and must be set to zero.

`TypeSpecificFlags`

The value of this member is dependent on the value in **ResourceFlags** member. The flags for each resource type are described in the tables below.

Memory Resource (**ResourceFlags** = **0**)

BIT(S)	MEANING
0 - Write status	When set, indicates that this memory range is available for reading and writing. Otherwise, this indicates that this memory range is read-only.
1 to 2 - Memory attributes (MEM)	**0** - Indicates the memory is non-cacheable. **1** - Indicates the memory is cacheable. **2** - Indicates the memory is cacheable and supports write combining. **3** - The memory is cacheable and prefetchable.
3 to 4 - Memory attributes (MTP)	These bits are only defined if this memory resource describes system RAM. **0** - Address range memory: This range is available RAM usable by the operating system. **1** - Address range reserved: This range of addresses is in use or reserved by the system and is not to be included in the allocatable memory pool of the operating system's memory manager. **2** - Address range ACPI: ACPI Reclaim Memory. This range is available RAM usable by the OS after it reads the ACPI tables. **3** - Address Range NVS: ACPI NVS Memory. This range of addresses is in use or reserved by the system and must not be used by the operating system. This range is required to be saved and restored across an NVS sleep.
5 - Memory to IO translation	**0** - Type-static: This resource is memory on the primary and secondary sides of the bridge. **1** - Type-translation: This resource is memory on the secondary side of the bridge and IO on the primary side of the bridge.
6 to 7 - Reserved	These bits are reserved and must be set to zero.

IO Resource (**ResourceFlags** = **1**)

BIT(S)	MEANING

0 to 1 - Range	**0** - Reserved. **1** - Non-ISA ranges only. This flag is for bridges on systems with multiple bridges. Setting this bit means the memory window specified in this descriptor is limited to the non-ISA IO addresses that fall within the specified window. The non-ISA IO ranges are: n100-n3FF, n500-n7FF, n900-nBFF, nD00-nFFF. This bit can only be set for bridges entirely configured through the ACPI namespace. **2** - ISA ranges only. This flag is for bridges on systems with multiple bridges. Setting this bit means the memory window specified in this descriptor is limited to the ISA IO addresses that fall within the specified window. The ISA IO ranges are: n000-n0FF, n400-n4FF, n800-n8FF, nC00-nCFF. This bit can only be set for bridges entirely configured through the ACPI namespace. **3** - The memory window covers the entire range
2 to 3 - Reserved	These bits are reserved and must be set to zero.
4 - IO to memory translation	**0** - Type-static: This resource is IO on the primary and secondary sides of the bridge. **1** - Type-translation: This resource is IO on the secondary side of the bridge and memory on the primary side of the bridge.
5 - Sparse translation	This bit is only meaningful if bit 4 (IO to memory translation) is set. **0** - Dense translation: The primary-side memory address of any specific IO port within the secondary-side range can be found using the following function. *address = port + TranslationAddress* **1** - Sparse translation: The primary-side memory address of any specific IO port within the secondary-side range can be found using the following function. *address = (((port & 0xFFFc) << 10) || (port & 0xFFF)) + TranslationAddress* In the address used to access the IO port, bits 2 to 11 must be identical to bits 12 to 21, this gives four bytes of IO ports on each 4 KB page.
6 to 7 - Reserved	These bits are reserved and must be set to zero.

Bus Number Range Resource (**ResourceFlags** = **2**)

BIT(S)	MEANING

0 to 7 - Reserved	These bits are reserved and must be set to zero.

`RevisionId`

Indicates the revision of the extended address space descriptor detailed by this structure. For ACPI 3.0, this value is 1.

`Reserved`

`Granularity`

A bit mask indicating which bits have been decoded.

`MinimumAddress`

The minimum starting address. For bridges that translate addresses, this is the address space on the secondary side of the bridge.

`MaximumAddress`

The maximum starting address. For bridges that translate addresses, this is the address space on the secondary side of the bridge.

`TranslationAddress`

For bridges that translate addresses across the bridge, this is the address on the primary side.

`AddressLength`

The address length.

`TypeAttribute`

Indicates attributes that are specific to the resource type that is specified in the **ResourceFlags** member. If **ResourceFlags** is zero, this value is zero, otherwise the meaning of the value can be found in the *UEFI Specification* in the section titled **GetMemoryMap()**.

`DescriptorName`

The name of this resource descriptor.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_GPIO_RESOURCE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_GPIO_RESOURCE** structure describes the ACPI configuration for a general purpose input/output (GPIO) resource.

Syntax

```
typedef struct _PEP_ACPI_GPIO_RESOURCE {
  PEP_ACPI_RESOURCE_TYPE      Type;
  PEP_ACPI_RESOURCE_FLAGS     Flags;
  KINTERRUPT_MODE             InterruptType;
  KINTERRUPT_POLARITY         InterruptPolarity;
  GPIO_PIN_CONFIG_TYPE        PinConfig;
  GPIO_PIN_IORESTRICTION_TYPE IoRestrictionType;
  USHORT                      DriveStrength;
  USHORT                      DebounceTimeout;
  PUSHORT                     PinTable;
  USHORT                      PinCount;
  UCHAR                       ResourceSourceIndex;
  PUNICODE_STRING             ResourceSourceName;
  PUCHAR                      VendorData;
  USHORT                      VendorDataLength;
} PEP_ACPI_GPIO_RESOURCE, *PPEP_ACPI_GPIO_RESOURCE;
```

Members

`Type`

A PEP_ACPI_RESOURCE_TYPE enumeration value that identifies the resource type for this ACPI resource.

`Flags`

A PEP_ACPI_RESOURCE_FLAGS structure that describes the capabilities of this ACPI resource.

`InterruptType`

A KINTERRUPT_MODE enumeration value that identifies the interrupt type.

`InterruptPolarity`

A KINTERRUPT_POLARITY enumeration value that identifies how a device signals an interrupt request on an interrupt line.

`PinConfig`

A GPIO_PIN_CONFIG_TYPE enumeration value that identifies the GPIO pin configuration type.

`IoRestrictionType`

A GPIO_PIN_IORESTRICTION_TYPE enumeration value that identifies the type of IO that the pin supports.

`DriveStrength`

Specifies the output drive capability of the pin, in hundredths of milliamperes.

`DebounceTimeout`

Specifies the hardware debounce wait time, in hundredths of milliseconds.

`PinTable`

A list of pin numbers on the resource that are described by this descriptor.

`PinCount`

The number of pins in **PinTable**.

`ResourceSourceIndex`

This member is always zero.

`ResourceSourceName`

This member is always set to "ResourceConsumer."

`VendorData`

A pointer to a raw data buffer containing vendor-defined byte data to be decoded by the OS driver.

`VendorDataLength`

The size of the **VendorData** buffer.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_RESOURCE_TYPE

PEP_ACPI_IO_MEMORY_RESOURCE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_IO_MEMORY_RESOURCE** structure describes an ACPI IO port descriptor resource.

Syntax

```
typedef struct _PEP_ACPI_IO_MEMORY_RESOURCE {
  PEP_ACPI_RESOURCE_TYPE Type;
  UCHAR                  Information;
  PHYSICAL_ADDRESS       MinimumAddress;
  PHYSICAL_ADDRESS       MaximumAddress;
  ULONG                  Alignment;
  ULONG                  Length;
} PEP_ACPI_IO_MEMORY_RESOURCE, *PPEP_ACPI_IO_MEMORY_RESOURCE;
```

Members

`Type`

A PEP_ACPI_RESOURCE_TYPE enumeration value that identifies the resource type for this ACPI resource.

`Information`

If bit 0 is a 1, this indicates that the logical device decodes 16-bit addresses. If bit 0 is 0, this indicates that the logical device only decodes the first 10 bits of the address.

Bits 1 to 7 of this member are reserved and must be set to zero.

`MinimumAddress`

Specifies the minimum acceptable starting address for the IO range.

`MaximumAddress`

Specifies the maximum acceptable starting address for the IO range.

`Alignment`

Specifies the alignment granularity for the IO address assigned.

`Length`

Specifies the number of bytes in the IO range.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

Syntax

```
typedef struct _PEP_ACPI_OBJECT_NAME_WITH_TYPE {
  PEP_ACPI_OBJECT_NAME Name;
  PEP_ACPI_OBJECT_TYPE Type;
} PEP_ACPI_OBJECT_NAME_WITH_TYPE, *PPEP_ACPI_OBJECT_NAME_WITH_TYPE;
```

Members

`Name`

A PEP_ACPI_OBJECT_NAME structure that contains the four-character name of the ACPI object.

`Type`

A PEP_ACPI_OBJECT_TYPE enumeration value that indicates the type of ACPI object. Currently, the only supported object type is a control method.

Remarks

The **Objects** member of the PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE structure is the first element in an array of **PEP_ACPI_OBJECT_NAME_WITH_TYPE** structures.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_ACPI_ENUMERATE_DEVICE_NAMESPACE

PEP_ACPI_OBJECT_NAME

PEP_ACPI_OBJECT_TYPE

PEP_ACPI_OBJECT_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_OBJECT_TYPE** enumeration indicates the type of ACPI object.

Syntax

```
typedef enum _PEP_ACPI_OBJECT_TYPE {
  PepAcpiObjectTypeMethod,
  PepAcpiObjectTypeDevice,
  PepAcpiObjectTypeMaximum
} PEP_ACPI_OBJECT_TYPE, *PPEP_ACPI_OBJECT_TYPE;
```

Constants

PepAcpiObjectTypeMethod	The object is an ACPI control method.
PepAcpiObjectTypeDevice	
PepAcpiObjectTypeMaximum	Reserved for use by the operating system.

Remarks

The **Type** member of the PEP_ACPI_QUERY_OBJECT_INFORMATION structure is an **PEP_ACPI_OBJECT_TYPE** enumeration value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_ACPI_QUERY_OBJECT_INFORMATION

PEP_ACPI_PREPARE_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_PREPARE_DEVICE** structure indicates whether a platform extension plug-in (PEP) is prepared to provide ACPI services for the specified device.

Syntax

```
typedef struct _PEP_ACPI_PREPARE_DEVICE {
  PCUNICODE_STRING AcpiDeviceName;
  ULONG            InputFlags;
  BOOLEAN          DeviceAccepted;
  ULONG            OutputFlags;
} PEP_ACPI_PREPARE_DEVICE, *PPEP_ACPI_PREPARE_DEVICE;
```

Members

`AcpiDeviceName`

[in] A pointer to an ANSI_STRING structure that contains the fully qualified BIOS name for the device. This name specifies the path and name of the device in the ACPI namespace. For more information, see Enumerating Child Devices and Control Methods.

`InputFlags`

[in] A set of input flags. No flags are currently defined for this member, which is always set to PEP_ACPI_PREPARE_DEVICE_INPUT_FLAG_NONE (0x0).

`DeviceAccepted`

[out] Whether the PEP is prepared to provide ACPI services for the device. Set this member to TRUE if the PEP is prepared to be the sole provider of ACPI services for this device, and to FALSE if it is not.

`OutputFlags`

[out] A set of output flags. No flags are currently defined for this member. Set this member to PEP_ACPI_PREPARE_DEVICE_OUTPUT_FLAG_NONE (0x0).

Remarks

This structure is used by the PEP_NOTIFY_ACPI_PREPARE_DEVICE notification. The **AcpiDeviceName** and **InputFlags** members of the structure contain input values that are supplied by the Windows power management framework (PoFx) when this notification is sent to the PEP. The **DeviceAccepted** and **OutputFlags** members contain output values that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.

Header	pepfx.h (include Pep_x.h)

ANSI_STRING

PEP_NOTIFY_ACPI_PREPARE_DEVICE

PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES** structure contains a list of raw resources that are needed to control power to the device.

Syntax

```
typedef struct _PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES {
  PEPHANDLE            DeviceHandle;
  ULONG                RequestFlags;
  NTSTATUS             Status;
  SIZE_T               BiosResourcesSize;
  ACPI_METHOD_ARGUMENT BiosResources[ANYSIZE_ARRAY];
} PEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES, *PPEP_ACPI_QUERY_DEVICE_CONTROL_RESOURCES;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device's registration for ACPI services. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_NOTIFY_ACPI_REGISTER_DEVICE notification.

`RequestFlags`

[in] A set of input flags. No flags are currently defined for this member, which is always set to PEP_ACPI_QDCR_FLAG_NONE (0x0).

`Status`

[out] An NTSTATUS value that indicates the status of this query. Set this member to STATUS_SUCCESS if the PEP succeeded in providing the requested list of resources. Set to STATUS_BUFFER_TOO_SMALL to indicate that the output buffer is not large enough to contain the resource list.

`BiosResourcesSize`

[in, out] On input, the size, in bytes, of the buffer allocated for the **BiosResources** member. This buffer size includes any associated data that might follow this member.

If this buffer is not large enough to contain the **ACPI_METHOD_ARGUMENT** structure and its associated data, the PEP overwrites the input value of **BiosResourcesSize** with the required size and sets the **Status** member to STATUS_BUFFER_TOO_SMALL.

`BiosResources`

[in] An output buffer to which the PEP writes an ACPI_METHOD_ARGUMENT structure that contains the requested resource list. The **Data** member of this structure is the first member in an array that might extend past the end of the structure. The buffer size specified by **BiosResourcesSize** includes both the **ACPI_METHOD_ARGUMENT** structure and any **Data** array elements that follow this structure. For more information, see TBD.

Remarks

This structure is used by the PEP_NOTIFY_ACPI_QUERY_DEVICE_CONTROL_RESOURCES notification. The **RequestFlags**, **BiosResourcesSize**, and **BiosResources** members of the structure contain input values supplied by the Windows power management framework (PoFx) when this notification is sent. If the **BiosResourcesSize** input value is too small, the PEP should overwrite this value. The **Status** member contains an output value that the PEP writes to this structure in response to the notification.

If the input value specified in the **BiosResourcesSize** member is less than the required size, the PEP overwrites the **BiosResourcesSize** input value with the required size, and sets the **Status** member to STATUS_BUFFER_TOO_SMALL. In response, PoFx will try to allocate a buffer of the required size and send a second **PEP_NOTIFY_ACPI_QUERY_DEVICE_CONTROL_RESOURCES** notification to the PEP for this device.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_ACPI_REGISTER_DEVICE

PEP_ACPI_QUERY_OBJECT_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_QUERY_OBJECT_INFORMATION** structure contains information about an ACPI object.

Syntax

```
typedef struct _PEP_ACPI_QUERY_OBJECT_INFORMATION {
  PEPHANDLE            DeviceHandle;
  PEP_ACPI_OBJECT_NAME Name;
  PEP_ACPI_OBJECT_TYPE Type;
  ULONG                ObjectFlags;
  union {
    struct {
      ULONG InputArgumentCount;
      ULONG OutputArgumentCount;
    } MethodObject;
  } DUMMYUNIONNAME;
} PEP_ACPI_QUERY_OBJECT_INFORMATION, *PPEP_ACPI_QUERY_OBJECT_INFORMATION;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device's registration for ACPI services. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_NOTIFY_ACPI_REGISTER_DEVICE notification.

`Name`

[in] A PEP_ACPI_OBJECT_NAME union that specifies the path-relative, four-character name of the object.

`Type`

[in] A PEP_ACPI_OBJECT_TYPE enumeration value that specifies the object type. Currently, a control method is the only object type that is defined for this member (**Type** = **PepAcpiObjectTypeMethod**).

`ObjectFlags`

[in] A set of input flags. No flags are currently defined for this member, which is always set to PEP_ACPI_OBJECT_FLAG_NONE (0x0).

`DUMMYUNIONNAME`

The query result. If the specified object is a control method, the platform extension plug-in (PEP) writes the query result to the **MethodObject** member of this union.

`DUMMYUNIONNAME.MethodObject`

`DUMMYUNIONNAME.MethodObject.InputArgumentCount`

The number of input arguments expected by the control method.

`DUMMYUNIONNAME.MethodObject.OutputArgumentCount`

The number of output arguments produced by the control method.

Remarks

This structure is used by the PEP_NOTIFY_ACPI_QUERY_OBJECT_INFORMATION notification. The **Name**, **Type**, and **Flags** members of the structure contain input values that the Windows power management framework (PoFx) supplies when this notification is sent. The **MethodObject** member contains an output value that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_REGISTER_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_REGISTER_DEVICE** structure contains registration information about a device for which the platform extension plug-in (PEP) is to provide ACPI services.

Syntax

```
typedef struct _PEP_ACPI_REGISTER_DEVICE {
  PCUNICODE_STRING AcpiDeviceName;
  ULONG            InputFlags;
  POHANDLE         KernelHandle;
  PEPHANDLE        DeviceHandle;
  ULONG            OutputFlags;
} PEP_ACPI_REGISTER_DEVICE, *PPEP_ACPI_REGISTER_DEVICE;
```

Members

`AcpiDeviceName`

[in] An ANSI_STRING structure that contains the fully qualified BIOS name for the device. The same name was previously supplied as an input value in the PEP_ACPI_PREPARE_DEVICE notification for the device. This name specifies the path and name of the device in the ACPI namespace. For more information, see Enumerating Child Devices and Control Methods.

`InputFlags`

[in] A set of input flags. No flags are currently defined for this member, which is always set to PEP_ACPI_REGISTER_DEVICE_INPUT_FLAG_NONE (0x0).

`KernelHandle`

[in] A POHANDLE value that represents the registration of the device with the Windows power management framework (PoFx). The PEP can use this handle to identify the device in subsequent communications with PoFx.

`DeviceHandle`

[out] A PEPHANDLE value that identifies the registration of this device for ACPI services. This handle is created by the PEP. In subsequent ACPI service notifications, PoFx will use this handle to identify the device.

`OutputFlags`

[out] A set of output flags. No flags are currently defined for this member. Set this member to PEP_ACPI_REGISTER_DEVICE_OUTPUT_FLAG_NONE (0x0).

Remarks

This structure is used by the PEP_NOTIFY_ACPI_REGISTER_DEVICE notification. The **AcpiDeviceName**, **InputFlags**, and **KernelHandle** members of the structure contain input values that are supplied by PoFx when this notification is sent to the PEP. The **DeviceHandle** and **OutputFlags** members contains output values that the PEP writes to this structure in response to the notification.

PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES** structure is used in the process of converting ACPI resources to BIOS resources by one of the PEP initialization functions.

Syntax

```
typedef struct _PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES {
  NTSTATUS           TranslationStatus;
  PPEP_ACPI_RESOURCE InputBuffer;
  SIZE_T             InputBufferSize;
  PVOID              OutputBuffer;
  SIZE_T             OutputBufferSize;
  ULONG              Flags;
} PEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES, *PPEP_ACPI_REQUEST_CONVERT_TO_BIOS_RESOURCES;
```

Members

`TranslationStatus`

The result code from the resource translation call.

`InputBuffer`

A pointer to a PEP_ACPI_RESOURCE containing the input buffer.

`InputBufferSize`

The size of the input buffer.

`OutputBuffer`

A pointer to the output buffer containing the translated structure.

`OutputBufferSize`

The size of the output buffer.

`Flags`

The value contained in the PEP_ACPI_RESOURCE_FLAGS structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_RESOURCE

PEP_ACPI_RESOURCE_FLAGS

PEP_ACPI_RESOURCE union

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_RESOURCE** structure contains hardware details for a specific ACPI resource.

Syntax

```
typedef union _PEP_ACPI_RESOURCE {
  PEP_ACPI_RESOURCE_TYPE      Type;
  PEP_ACPI_IO_MEMORY_RESOURCE IoMemory;
  PEP_ACPI_INTERRUPT_RESOURCE Interrupt;
  PEP_ACPI_GPIO_RESOURCE      Gpio;
  PEP_ACPI_SPB_I2C_RESOURCE   SpbI2c;
  PEP_ACPI_SPB_SPI_RESOURCE   SpbSpi;
  PEP_ACPI_SPB_UART_RESOURCE  SpbUart;
  PEP_ACPI_EXTENDED_ADDRESS   ExtendedAddress;
} PEP_ACPI_RESOURCE, *PPEP_ACPI_RESOURCE;
```

Members

`Type`

The PEP_ACPI_RESOURCE_TYPE enumeration value that is applicable to this resource.

`IoMemory`

If **Type** is **PepAcpiMemory** or **PepAcpiIoPort**, this union contains a PEP_ACPI_IO_MEMORY_RESOURCE structure describing an ACPI IO or memory resource.

`Interrupt`

If **Type** is **PepAcpiInterrupt**, this union contains a PEP_ACPI_INTERRUPT_RESOURCE structure describing an ACPI interrupt resource.

`Gpio`

If **Type** is **PepAcpiGpioIo** or **PepAcpiGpioInt**, this union contains a PEP_ACPI_GPIO_RESOURCE structure describing an ACPI GPIO resource.

`SpbI2c`

If **Type** is **PepAcpiSpbI2c**, this union contains a PEP_ACPI_SPB_I2C_RESOURCE structure describing an ACPI I2C serial bus resource.

`SpbSpi`

If **Type** is **PepAcpiSpbSpi**, this union contains a PEP_ACPI_SPB_SPI_RESOURCE structure describing an ACPI SPI serial bus resource.

`SpbUart`

If **Type** is **PepAcpiSpbUart**, this union contains a PEP_ACPI_SPB_UART_RESOURCE structure describing an ACPI SPB serial bus resource.

`ExtendedAddress`

If **Type** is **PepAcpiExtendedMemory** or **PepAcpiExtendedIo**, this union contains a PEP_ACPI_EXTENDED_ADDRESS structure describing an ACPI extended memory or extended IO resource.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_RESOURCE_FLAGS union

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_RESOURCE_FLAGS** structure contains flags describing an ACPI resource.

Syntax

```
typedef union _PEP_ACPI_RESOURCE_FLAGS {
  ULONG  AsULong;
  struct {
    ULONG Shared : 1;
    ULONG Wake : 1;
    ULONG ResourceUsage : 1;
    ULONG SlaveMode : 1;
    ULONG AddressingMode : 1;
    ULONG SharedMode : 1;
    ULONG Reserved : 26;
  } DUMMYSTRUCTNAME;
} PEP_ACPI_RESOURCE_FLAGS, *PPEP_ACPI_RESOURCE_FLAGS;
```

Members

`AsULong`

The consolidated values of the flags in **DUMMYSTRUCTNAME**.

`DUMMYSTRUCTNAME`

A structure containing ACPI resource flags.

`DUMMYSTRUCTNAME.Shared`

When set, indicates that this is a shared device.

`DUMMYSTRUCTNAME.Wake`

When set, indicates that this device can be woken from a low-power state.

`DUMMYSTRUCTNAME.ResourceUsage`

When set, indicates that this device is in use.

`DUMMYSTRUCTNAME.SlaveMode`

When set, indicates that this device is in slave mode.

`DUMMYSTRUCTNAME.AddressingMode`

When set, indicates that this device is in addressing mode.

`DUMMYSTRUCTNAME.SharedMode`

When set, indicates that this device is in shared mode.

`DUMMYSTRUCTNAME.Reserved`

This member is reserved and should be set to zero.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_RESOURCE_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_RESOURCE_TYPE** enumeration is used to identify the type of ACPI resource that is contained in the PEP_ACPI_RESOURCE union.

Syntax

```
typedef enum _PEP_ACPI_RESOURCE_TYPE {
  PepAcpiMemory,
  PepAcpiIoPort,
  PepAcpiInterrupt,
  PepAcpiGpioIo,
  PepAcpiGpioInt,
  PepAcpiSpbI2c,
  PepAcpiSpbSpi,
  PepAcpiSpbUart,
  PepAcpiExtendedMemory,
  PepAcpiExtendedIo
} PEP_ACPI_RESOURCE_TYPE;
```

Constants

PepAcpiMemory	Indicates that the resource is an ACPI memory resource.
PepAcpiIoPort	Indicates that the resource is an ACPI IO port resource.
PepAcpiInterrupt	Indicates that the resource is an ACPI interrupt resource.
PepAcpiGpioIo	Indicates that the resource is an ACPI GPIO resource.
PepAcpiGpioInt	Indicates that the resource is an ACPI GPIO interrupt resource.
PepAcpiSpbI2c	Indicates that the resource is an ACPI I2C serial bus resource.
PepAcpiSpbSpi	Indicates that the resource is an ACPI SPI serial bus resource.
PepAcpiSpbUart	Indicates that the resource is an ACPI UART serial bus resource.
PepAcpiExtendedMemory	Indicates that the resource is an ACPI extended memory resource.
PepAcpiExtendedIo	Indicates that the resource is an ACPI extended IO resource.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_RESOURCE

PEP_ACPI_SPB_I2C_RESOURCE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_SPB_I2C_RESOURCE** structure describes an ACPI I2C serial bus resource.

Syntax

```
typedef struct _PEP_ACPI_SPB_I2C_RESOURCE {
  PEP_ACPI_SPB_RESOURCE SpbCommon;
  ULONG                 ConnectionSpeed;
  USHORT                SlaveAddress;
} PEP_ACPI_SPB_I2C_RESOURCE, *PPEP_ACPI_SPB_I2C_RESOURCE;
```

Members

`SpbCommon`

A PEP_ACPI_SPB_RESOURCE structure describing this resource.

`ConnectionSpeed`

The maximum speed, in hertz, supported by this connection.

`SlaveAddress`

The I2C bus address for this connection.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_SPB_RESOURCE

PEP_ACPI_SPB_RESOURCE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_SPB_RESOURCE** structure describes an ACPI serial bus connection resource.

Syntax

```
typedef struct _PEP_ACPI_SPB_RESOURCE {
  PEP_ACPI_RESOURCE_TYPE  Type;
  PEP_ACPI_RESOURCE_FLAGS Flags;
  USHORT                  TypeSpecificFlags;
  UCHAR                   ResourceSourceIndex;
  PUNICODE_STRING         ResourceSourceName;
  PCHAR                   VendorData;
  USHORT                  VendorDataLength;
} PEP_ACPI_SPB_RESOURCE, *PPEP_ACPI_SPB_RESOURCE;
```

Members

`Type`

A PEP_ACPI_RESOURCE_TYPE enumeration value describing this resource.

`Flags`

A PEP_ACPI_RESOURCE_FLAGS structure that describes the capabilities of this ACPI resource.

`TypeSpecificFlags`

Specifies the bit flags that are common to all serial bus connection types.

BIT(S)	MEANING
0 - Slave mode	**0x0** - Indicates that communication over this connection is initiated by the controller. **0x1** - Indicates that communication over this connection is initiated by the device.
1 - Consumer/producer mode	**0x0** - Indicates that this device produces and consumes this resource. **0x1** - Indicates that this device consumes this resource.

2 to 7 - Reserved	These bits are reserved and must be set to zero.

`ResourceSourceIndex`

`ResourceSourceName`

The name of the serial bus controller device to which this connection descriptor applies. The name can be a fully qualified path, a relative path, or a simple name segment that utilizes the namespace search rules.

`VendorData`

A pointer to optional data that is specific to the serial bus connection type.

`VendorDataLength`

The length of the buffer pointed to by **VendorData**.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_SPB_SPI_RESOURCE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_SPB_SPI_RESOURCE** structure describes an ACPI SPI serial bus resource.

Syntax

```
typedef struct _PEP_ACPI_SPB_SPI_RESOURCE {
  PEP_ACPI_SPB_RESOURCE SpbCommon;
  ULONG                 ConnectionSpeed;
  UCHAR                 DataBitLength;
  UCHAR                 Phase;
  UCHAR                 Polarity;
  USHORT                DeviceSelection;
} PEP_ACPI_SPB_SPI_RESOURCE, *PPEP_ACPI_SPB_SPI_RESOURCE;
```

Members

`SpbCommon`

A PEP_ACPI_SPB_RESOURCE structure describing this resource.

`ConnectionSpeed`

The maximum speed, in hertz, supported by this connection.

`DataBitLength`

The size, in bits, of the smallest unit of transfer.

`Phase`

The phase of the clock pulse on which to capture data.

`Polarity`

The polarity of the clock. If zero, this indicates the clock is low during the first phase. If 1, this indicates the clock is high during the first phase.

`DeviceSelection`

The device selection value. This value is specific to the device and may refer to a chip-select line, GPIO line, or other line selection mechanism.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_SPB_UART_RESOURCE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_SPB_UART_RESOURCE** structure describes an ACPI UART serial bus resource.

Syntax

```
typedef struct _PEP_ACPI_SPB_UART_RESOURCE {
  PEP_ACPI_SPB_RESOURCE SpbCommon;
  ULONG                 BaudRate;
  USHORT                RxBufferSize;
  USHORT                TxBufferSize;
  UCHAR                 Parity;
  UCHAR                 LinesInUse;
} PEP_ACPI_SPB_UART_RESOURCE, *PPEP_ACPI_SPB_UART_RESOURCE;
```

Members

`SpbCommon`

A PEP_ACPI_SPB_RESOURCE structure describing this resource.

`BaudRate`

The baud rate of the connection.

`RxBufferSize`

The maximum receive buffer size, in bytes, that is supported by this connection.

`TxBufferSize`

The maximum transmit buffer size, in bytes, that is supported by this connection.

`Parity`

Indicates the parity of the connection.

VALUE	MEANING
0x0 0	None
0x0 1	Even
0x0 2	Odd

0x03	Mark
0x04	Space

`LinesInUse`

Flag indicating the serial lines that are enabled. A value of 1 in the bit positions indicates that the line is enabled.

BIT	MEANING
0	This bit is reserved and must be set to zero.
1	This bit is reserved and must be set to zero.
2	Data Carrier Detect (DTD)
3	Ring Indicator (RI)
4	Data Set Ready (DSR)
5	Data Terminal Ready (DTR)
6	Clear to Send (CTS)
7	Request to Send (RTS)

PEP_ACPI_SPB_RESOURCE

PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES** structure contains a list of translated power-control resources for the platform extension plug-in (PEP) to use.

Syntax

```
typedef struct _PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES {
  PEPHANDLE         DeviceHandle;
  ULONG             RequestFlags;
  NTSTATUS          Status;
  SIZE_T            TranslatedResourcesSize;
  PCM_RESOURCE_LIST TranslatedResources;
} PEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES, *PPEP_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device's registration for ACPI services. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_NOTIFY_ACPI_REGISTER_DEVICE notification.

`RequestFlags`

[in] A set of input flags. No flags are currently defined for this member, which is always set to PEP_ACPI_TDCR_FLAG_NONE (0x0).

`Status`

[out] An NTSTATUS value that indicates the status of the resource translation. The PEP sets this member to STATUS_SUCCESS to indicate that the PEP successfully received the translated resources. Otherwise, the PEP sets this member to an appropriate error status code.

`TranslatedResourcesSize`

`TranslatedResources`

[in] A CM_RESOURCE_LIST structure that serves as the header for the resource list. The remainder of the resource list immediately follows this header.

Remarks

This structure is used by the PEP_NOTIFY_ACPI_TRANSLATED_DEVICE_CONTROL_RESOURCES notification to provide the PEP with a list of translated power control resources. The **RequestFlags**, **ResourceBufferSize**, and **TranslatedResources** members of the structure contain input values that the Windows power management framework (PoFx) supplies when this notification is sent. The **Status** member contains an output value that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_UNREGISTER_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_UNREGISTER_DEVICE** structure contains information about a device that has been unregistered from ACPI services.

Syntax

```
typedef struct _PEP_ACPI_UNREGISTER_DEVICE {
  PEPHANDLE DeviceHandle;
  ULONG     InputFlags;
} PEP_ACPI_UNREGISTER_DEVICE, *PPEP_ACPI_UNREGISTER_DEVICE;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device's registration for ACPI services. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_NOTIFY_ACPI_REGISTER_DEVICE notification.

`InputFlags`

[in] A set of input flags. No flags are currently defined for this member, which is always set to PEP_ACPI_UNREGISTER_DEVICE_INPUT_FLAG_NONE (0x0).

Remarks

This structure is used by the PEP_NOTIFY_ACPI_UNREGISTER_DEVICE notification. The **DeviceHandle** and **InputFlags** members contain input values that are supplied by the Windows power management framework when this notification is sent.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_ACPI_REGISTER_DEVICE

PEP_NOTIFY_ACPI_UNREGISTER_DEVICE

PEP_COMPONENT_PERF_INFO structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_COMPONENT_PERF_INFO** structure describes the performance states (P-states) of a component.

Syntax

```
typedef struct _PEP_COMPONENT_PERF_INFO {
  ULONG                  SetCount;
  PEP_COMPONENT_PERF_SET PerfStateSets[ANYSIZE_ARRAY];
} PEP_COMPONENT_PERF_INFO, *PPEP_COMPONENT_PERF_INFO;
```

Members

`SetCount`

The number of elements in the **PerfStateSets** array.

`PerfStateSets`

The first element in an array of PEP_COMPONENT_PERF_SET structures. Each array element describes a P-state of the component. If the array contains more than one element, the additional elements immediately follow the end of the **PEP_COMPONENT_PERF_INFO** structure.

Remarks

This structure is used in conjunction with the PEP_DPM_REGISTER_COMPONENT_PERF_STATES notification. The **PerfStateSets** member of the PEP_REGISTER_COMPONENT_PERF_STATES structure is a **PEP_COMPONENT_PERF_INFO** structure.

The **PEP_COMPONENT_PERF_INFO** structure contains input values that are supplied by the Windows power management framework (PoFx). The platform extension plug-in (PEP) must not write to this structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_REGISTER_COMPONENT_PERF_STATES

PEP_COMPONENT_PERF_SET structure

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_COMPONENT_PERF_SET** structure describes the performance states (P-states) in a P-state set.

Syntax

```
typedef struct _PEP_COMPONENT_PERF_SET {
  UNICODE_STRING      Name;
  ULONGLONG           Flags;
  PEP_PERF_STATE_UNIT Unit;
  PEP_PERF_STATE_TYPE Type;
  union {
    struct {
      ULONG           Count;
      PPEP_PERF_STATE States;
    } Discrete;
    struct {
      ULONGLONG Minimum;
      ULONGLONG Maximum;
    } Range;
  };
} PEP_COMPONENT_PERF_SET, *PPEP_COMPONENT_PERF_SET;
```

Members

`Name`

An optional string that describes the device property controlled by this P-state set. For example, this string might be "Clock frequency" or "Memory bandwidth". If no such string is available for this P-state, the **Name** member is set to NULL. Otherwise, this member contains a pointer to a UNICODE_STRING structure that contains the string.

`Flags`

Set to zero. No flag bits are currently defined for this member.

`Unit`

A PEP_PERF_STATE_UNIT structure that specifies the units in which the performance values for this P-state set are expressed. Component performance can be expressed in hertz (frequency) or in bits per second (bandwidth).

`Type`

A PEP_PERF_STATE_TYPE enumeration value that indicates the type of performance information that is specified for this component. This member indicates whether the performance values for this P-state set are specified as a list of discrete values or as a continuous range of values.

`Discrete`

`Discrete.Count`

`Discrete.States`

`Range`

`Range.Minimum`

`Range.Maximum`

Remarks

The **PerfStateSets** member of the PEP_COMPONENT_PERF_INFO is the first element in an array of **PEP_COMPONENT_PERF_SET** structures. All members of the **PEP_COMPONENT_PERF_SET** structure contain input values that are supplied by the Windows power management framework (PoFx). The platform extension plug-in (PEP) must not write to this structure.

Device drivers use the PO_FX_COMPONENT_PERF_SET structure, which is similar to the **PEP_COMPONENT_PERF_SET** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_COMPONENT_PERF_STATE_REQUEST structure

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_COMPONENT_PERF_STATE_REQUEST** structure specifies a performance state (P-state) set and a new performance level to assign to this set.

Syntax

```
typedef struct _PEP_COMPONENT_PERF_STATE_REQUEST {
  ULONG Set;
  union {
    ULONG     StateIndex;
    ULONGLONG StateValue;
  };
} PEP_COMPONENT_PERF_STATE_REQUEST, *PPEP_COMPONENT_PERF_STATE_REQUEST;
```

Members

`Set`

The index of the P-state set to which to assign the new performance level. If N is the number of P-state sets specified for this component, P-state set indexes range from 0 to N−1. The PEP previously specified the number of P-state sets in response to a PEP_DPM_QUERY_COMPONENT_PERF_CAPABILITIES notification.

`StateIndex`

`StateValue`

Remarks

The **PerfRequests** member of the PEP_REQUEST_COMPONENT_PERF_STATE structure is a pointer to an array of **PEP_COMPONENT_PERF_STATE_REQUEST** structures.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_REQUEST_COMPONENT_PERF_STATE

PEP_COMPONENT_PLATFORM_CONSTRAINTS structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_COMPONENT_PLATFORM_CONSTRAINTS** structure describes the lowest-powered F*x* state of that a component can be in when the platform is in a particular idle state.

Syntax

```
typedef struct _PEP_COMPONENT_PLATFORM_CONSTRAINTS {
  PEPHANDLE DeviceHandle;
  ULONG     Component;
  PULONG    MinimumFStates;
  ULONG     PlatformStateCount;
} PEP_COMPONENT_PLATFORM_CONSTRAINTS, *PPEP_COMPONENT_PLATFORM_CONSTRAINTS;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N−1.

`MinimumFStates`

[in] A pointer to an output buffer. The PEP writes a ULONG array to this buffer that specifies the lowest-powered F*x* state that the component can be in for each platform idle state. An element with a value of 0 indicates F0, a value of 1 indicates F1, and so on. If the platform supports M idle states, array elements 0 to M−1 specify the F*x* states corresponding to platform idle states 0 to M−1.

`PlatformStateCount`

[in] The number of elements in the **MinimumFStates** array. The array contains one element for each platform idle state. The Windows power management framework (PoFx) previously sent a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification to the PEP to determine the number of supported platform idle states.

Remarks

This structure is used by the PEP_DPM_COMPONENT_IDLE_CONSTRAINTS notification. All four members of the structure contain input values that PoFx supplies when this notification is sent. PoFx allocates the buffer pointed to by the **MinimumFStates** member, and the PEP writes to this buffer in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_DPM_REGISTER_DEVICE

PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES

PEP_COMPONENT_V2 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_COMPONENT_V2** structure specifies the power state attributes of a component in the device.

Syntax

```
typedef struct _PEP_COMPONENT_V2 {
  GUID                          Id;
  ULONGLONG                     Flags;
  ULONG                         DeepestWakeableIdleState;
  ULONG                         IdleStateCount;
  PPO_FX_COMPONENT_IDLE_STATE IdleStates;
} PEP_COMPONENT_V2, *PPEP_COMPONENT_V2;
```

Members

`Id`

A component ID that uniquely identifies this component with respect to the other components in the device. The PEP should specify a nonzero value for this member if the Windows power management framework (PoFx) requires a component ID to distinguish this component from other, similar components in the same device. This member is optional. If this member is not used, it must be set to all zeros.

`Flags`

A set of component-power-state flags. No flags are currently defined for this member, which is always zero.

`DeepestWakeableIdleState`

The index of the deepest F*x* state from which the component can wake. Specify 0 for F0, 1 for F1, and so on. This index must be less than **IdleStateCount**.

`IdleStateCount`

The number of elements in the array that is pointed to by the **IdleStates** member. Additionally, this member specifies the number of F*x* power states that the component supports. A component must support at least one F*x* state (F0).

`IdleStates`

A pointer to an array of PO_FX_COMPONENT_IDLE_STATE structures. The length of this array is specified by the **IdleStateCount** member. Each array element specifies the attributes of an F*x* power state that is supported by the component. Element 0 describes F0, element 1 describes F1, and so on.

Remarks

This structure

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_COORDINATED_DEPENDENCY_OPTION structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_COORIDNATED_DEPENDENCY_OPTION** structure describes a coordinated idle state's dependency to the OS.

Syntax

```
typedef struct _PEP_COORDINATED_DEPENDENCY_OPTION {
  UCHAR   ExpectedStateIndex;
  BOOLEAN LooseDependency;
  BOOLEAN InitiatingState;
  BOOLEAN DependentState;
} PEP_COORDINATED_DEPENDENCY_OPTION, *PPEP_COORDINATED_DEPENDENCY_OPTION;
```

Members

`ExpectedStateIndex`

Supplies the index of the idle state (coordinated idle state or processor idle state) that must have already been entered/be entered by this idle transition.

`LooseDependency`

When **FALSE**, the OS must use synchronization to guarantee that the state referred to by this dependency has already been entered. When **TRUE**, the OS may perform best-effort coordination that the target state is entered. The PEP must set **LooseDependency** to **TRUE** if the **ExpectedState** is a processor state and has the **WakesSpuriously** flag set.

`InitiatingState`

Indicates if the OS may simultaneously enter the state referred to by this dependency. If **FALSE**, this state is only valid when another processor has previously entered it.

`DependentState`

Indicates if this state is a valid state for a dependent processor to be in.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_QUERY_COORDINATED_DEPENDENCY notification

PEP_COORDINATED_IDLE_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_COORIDNATED_IDLE_STATE** structure describes a coordinated idle state to the OS.

Syntax

```
typedef struct _PEP_COORDINATED_IDLE_STATE {
  ULONG Latency;
  ULONG BreakEvenDuration;
  ULONG DependencyCount;
  ULONG MaximumDependencySize;
} PEP_COORDINATED_IDLE_STATE, *PPEP_COORDINATED_IDLE_STATE;
```

Members

`Latency`

The latency of waking from this idle state, in 100ns units.

`BreakEvenDuration`

Supplies the minimum time the state must be entered to amortize the cost of entering/exiting the state. Idle durations longer than this period should save power when compared to entering a lighter state for the same period.

`DependencyCount`

Supplies the number of dependencies this coordinated state has on other coordinated states or on processors.

`MaximumDependencySize`

Supplies the maximum size of a single dependency.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_COORDINATED_IDLE_STATE structure

PEP_NOTIFY_PPM_QUERY_COORDINATED_STATES notification

PEP_CRASHDUMP_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_CRASHDUMP_INFORMATION** structure contains information about a crash-dump device.

Syntax

```
typedef struct _PEP_CRASHDUMP_INFORMATION {
  PEPHANDLE DeviceHandle;
  PVOID     DeviceContext;
} PEP_CRASHDUMP_INFORMATION, *PPEP_CRASHDUMP_INFORMATION;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the crash-dump device. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`DeviceContext`

[in] A pointer to a device-specific context. This pointer is the *Context* parameter value that the device driver previously passed to the PoFxPowerOnCrashdumpDevice routine. The context contains information in a format that is defined by the device driver and is understood by the PEP. The context is opaque to the operating system. This member value can be NULL if the PEP does not require a context.

Remarks

The *CrashdumpInformation* parameter to the PowerOnDumpDeviceCallback routine is a pointer to a **PEP_CRASHDUMP_INFORMATION** structure.

When a fatal system error occurs, the devices in the crash-dump device chain (storage controller, PCI controller, and so on) need to be turned on so that the Windows kernel can write a crash-dump file to disk.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PowerOnDumpDeviceCallback

PEP_DEBUGGER_TRANSITION_REQUIREMENTS structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_DEBUGGER_TRANSITION_REQUIREMENTS** structure indicates the platform idle states for which the debugger device must be turned on.

Syntax

```
typedef struct _PEP_DEBUGGER_TRANSITION_REQUIREMENTS {
  PEPHANDLE DeviceHandle;
  ULONG     PlatformStateCount;
  PBOOLEAN  PowerTransitionRequired;
} PEP_DEBUGGER_TRANSITION_REQUIREMENTS, *PPEP_DEBUGGER_TRANSITION_REQUIREMENTS;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the debugger device. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`PlatformStateCount`

[in] The number of entries in the array pointed to by the **PowerTransitionRequired** member. This number is the same as the number of supported platform idle states that the PEP specified in response to a previous PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification.

`PowerTransitionRequired`

[in] An output buffer to which the PEP writes a BOOLEAN array that indicates the platform idle states for which power to the debugger device must be turned on. This buffer is allocated by the Windows power management framework (PoFx) and is guaranteed to be large enough to contain the number of array elements specified by the **PlatformStateCount** member. Set an array element to TRUE if the debugger device must be turned on in the corresponding platform idle state. Set to FALSE to indicate that the device is not required to be turned on in this state. If the platform supports N idle states, the array contains N elements, and idle states are numbered 0 to N–1 in the order in which they are represented in the array.

Remarks

This structure is used by the PEP_DPM_QUERY_DEBUGGER_TRANSITION_REQUIREMENTS notification. All three members of the structure contain input values that are supplied by PoFx when this notification is sent to the PEP.

During a debugging session, the debugger component that runs on the target computer communicates with the host computer through a debugger device such as a USB host controller, UART, or networking device.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_DEVICE_ACCEPTANCE_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_DEVICE_ACCEPTANCE_TYPE** enumeration indicates whether a PEP accepts ownership of a device.

Syntax

```
typedef enum _PEP_DEVICE_ACCEPTANCE_TYPE {
  PepDeviceNotAccepted,
  PepDeviceAccepted,
  PepDeviceAceptedMax
} PEP_DEVICE_ACCEPTANCE_TYPE, *PPEP_DEVICE_ACCEPTANCE_TYPE;
```

Constants

PepDeviceNotAccepted	The PEP does not claim ownership of this device.
PepDeviceAccepted	The PEP claims ownership of this device.
PepDeviceAceptedMax	

Remarks

This enumeration is used by **DeviceAccepted** member of the PEP_REGISTER_DEVICE_V2 structure to indicate whether a PEP accepts ownership of a device.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_REGISTER_DEVICE_V2

PEP_DEVICE_PLATFORM_CONSTRAINTS structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_DEVICE_PLATFORM_CONSTRAINTS** structure specifies the constraints for entry to the various D*x* power states that are supported by a device.

Syntax

```
typedef struct _PEP_DEVICE_PLATFORM_CONSTRAINTS {
  PEPHANDLE           DeviceHandle;
  PDEVICE_POWER_STATE MinimumDStates;
  ULONG               PlatformStateCount;
} PEP_DEVICE_PLATFORM_CONSTRAINTS, *PPEP_DEVICE_PLATFORM_CONSTRAINTS;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`MinimumDStates`

[in] A pointer to an array of DEVICE_POWER_STATE enumeration values that indicate the lowest-powered D*x* (device power) state the device can enter for each platform idle state.

`PlatformStateCount`

[in] The number of elements in the array pointed to by the **MinimumDStates** member. This member contains the platform state count that the PEP supplied in response to a previous PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification.

Remarks

This structure is used by the PEP_DPM_DEVICE_IDLE_CONSTRAINTS notification. All three members of this structure contain input values that are supplied by the Windows power management framework (PoFx). In response to this notification, the PEP writes DEVICE_POWER_STATE enumeration values to the elements of the array pointed to by the **MinimumDStates** member. PoFx allocates the storage for this array before sending the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_DPM_REGISTER_DEVICE

PEP_DEVICE_POWER_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_DEVICE_POWER_STATE** structure indicates the status of a transition to a new D*x* (device power) state.

Syntax

```
typedef struct _PEP_DEVICE_POWER_STATE {
  PEPHANDLE          DeviceHandle;
  DEVICE_POWER_STATE PowerState;
  BOOLEAN            Complete;
  BOOLEAN            SystemTransition;
} PEP_DEVICE_POWER_STATE, *PPEP_DEVICE_POWER_STATE;
```

Members

`DeviceHandle`

[in] The PEPHANDLE value that identifies this device. The PEP previously created this handle in response to a PEP_DPM_REGISTER_DEVICE notification from the Windows power management framework (PoFx).

`PowerState`

[in] A DEVICE_POWER_STATE enumeration value that specifies the new device power state.

`Complete`

[in] Whether the transition to the new device power state has just been initiated or has just completed. If TRUE, the transition to the target device power state has completed. If FALSE, the power policy owner (PPO) has initiated the transition by calling the PoRequestPowerIrp routine, but the Windows power manager has not yet issued the D*x* IRP (an IRP_MN_SET_POWER request of type **DevicePowerState**) to the device's driver stack.

`SystemTransition`

[in] Always set to FALSE.

Remarks

This structure is used by the PEP_DPM_DEVICE_POWER_STATE notification. All four members of the structure contain input values that are supplied by PoFx. The PEP does not write to this structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_DEVICE_REGISTER_V2 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_DEVICE_REGISTER** structure describes all the components in a particular device.

Syntax

```
typedef struct _PEP_DEVICE_REGISTER_V2 {
  ULONGLONG         Flags;
  ULONG             ComponentCount;
  PPEP_COMPONENT_V2 Components[ANYSIZE_ARRAY];
} PEP_DEVICE_REGISTER_V2, *PPEP_DEVICE_REGISTER_V2;
```

Members

`Flags`

TBD

`ComponentCount`

The number of components in this device, which is also the number of elements in the **Components** array. The **ComponentCount** value must be greater than or equal to one.

`Components`

The first element in an array of pointers to PEP_COMPONENT_V2 structures. Each element in the array points to a structure that describes a component in the device. If this array contains more than one element, the additional elements immediately follow the end of the **PEP_DEVICE_REGISTER** structure.

Remarks

The PEP_REGISTER_DEVICE structure contains a **Register** member that points to a **PEP_DEVICE_REGISTER** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_DEVICE_STARTED structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_DEVICE_STARTED** structure identifies a device whose driver has completed its registration with the Windows power management framework (PoFx).

Syntax

```
typedef struct _PEP_DEVICE_STARTED {
  PEPHANDLE DeviceHandle;
} PEP_DEVICE_STARTED, *PPEP_DEVICE_STARTED;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

Remarks

This structure is used by the PEP_DPM_DEVICE_STARTED notification. The **DeviceHandle** member of this structure contains an input value that is supplied by PoFx.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_DPM_DEVICE_STARTED

PEP_DPM_REGISTER_DEVICE

PEP_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_INFORMATION** structure specifies the interface that the platform extension plug-in (PEP) uses to receive notifications from the Windows power management framework (PoFx).

Syntax

```
typedef struct _PEP_INFORMATION {
  USHORT                 Version;
  USHORT                 Size;
  PPEPCALLBACKNOTIFYDPM  AcceptDeviceNotification;
  PPEPCALLBACKNOTIFYPPM  AcceptProcessorNotification;
  PPEPCALLBACKNOTIFYACPI AcceptAcpiNotification;
} PEP_INFORMATION, *PPEP_INFORMATION;
```

Members

`Version`

The current version number for this structure. Set this member to PEP_INFORMATION_VERSION.

`Size`

The size, in bytes, of this structure. Set this member to **sizeof**(**PEP_INFORMATION**).

`AcceptDeviceNotification`

A pointer to an AcceptDeviceNotification callback routine. This member is required to point to a valid callback routine.

`AcceptProcessorNotification`

A pointer to an AcceptProcessorNotification callback routine. This member is optional and can be NULL if the PEP is not prepared to handle PPM notifications from PoFx.

`AcceptAcpiNotification`

A pointer to an AcceptAcpiNotification callback routine. This member is optional and can be NULL if the PEP is not prepared to handle ACPI notifications from PoFx.

Remarks

This structure contains pointers to several callback routines that are implemented by the PEP. PoFx calls these routines to send notifications to the PEP.

The *PepInformation* parameter to the PoFxRegisterPlugin and PoFxRegisterPluginEx routines is a pointer to a **PEP_INFORMATION** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_KERNEL_INFORMATION_STRUCT_V3 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_KERNEL_INFORMATION_STRUCT_V3** structure specifies the interface that the power extension plug-in (PEP) uses to request services from the Windows power management framework (PoFx).

Syntax

```
typedef struct _PEP_KERNEL_INFORMATION_STRUCT_V3 {
  USHORT                                  Version;
  USHORT                                  Size;
  POHANDLE                                Plugin;
  PPOFXCALLBACKREQUESTWORKER              RequestWorker;
  PPOFXCALLBACKENUMERATEUNMASKEDINTERRUPTS EnumerateUnmaskedInterrupts;
  PPOFXCALLBACKPROCESSORHALT              ProcessorHalt;
  PPOFXCALLBACKREQUESTINTERRUPT           RequestInterrupt;
  PPOFXCALLBACKCRITICALRESOURCE           TransitionCriticalResource;
  PPOFXCALLBACKPROCESSORIDLEVETO          ProcessorIdleVeto;
  PPOFXCALLBACKPLATFORMIDLEVETO           PlatformIdleVeto;
  PPOFXCALLBACKUPDATEPROCESSORIDLESTATE   UpdateProcessorIdleState;
  PPOFXCALLBACKUPDATEPLATFORMIDLESTATE    UpdatePlatformIdleState;
  PPOFXCALLBACKREQUESTCOMMON              RequestCommon;
} PEP_KERNEL_INFORMATION_STRUCT_V3, *PPEP_KERNEL_INFORMATION_STRUCT_V3;
```

Members

`Version`

The current version number for this structure. Set this member to **PEP_KERNEL_INFORMATION_VERSION**.

`Size`

The size, in bytes, of this structure. Set this member to **sizeof**(**PEP_KERNEL_INFORMATION**).

`Plugin`

The handle assigned to the PEP's registration with PoFx. PoFx sets the value of this member. The PEP uses this handle in calls to the RequestWorker routine.

`RequestWorker`

A pointer to a RequestWorker routine. PoFx sets the value of this member. The **RequestWorker** routine is implemented by PoFx. The PEP calls this routine to request the use of a worker thread from the operating system.

`EnumerateUnmaskedInterrupts`

A pointer to an EnumerateUnmaskedInterrupts routine. PoFx sets the value of this member. The **EnumerateUnmaskedInterrupts** routine is implemented by PoFx. The PEP calls this routine to request information about the unmasked interrupts.

`ProcessorHalt`

A pointer to a ProcessorHalt routine. PoFx sets the value of this member. The **ProcessorHalt** routine is implemented by PoFx. The PEP calls this routine to prepare the current processor to enter the halted state.

`RequestInterrupt`

A pointer to a RequestInterrupt routine. PoFx sets the value of this member. The **RequestInterrupt** routine is implemented by PoFx. The PEP calls this routine to replay an edge-triggered interrupt that might have been lost after the hardware platform entered a low-power system state.

`TransitionCriticalResource`

A pointer to a TransitionCriticalResource routine. PoFx sets the value of this member. The **TransitionCriticalResource** routine is implemented by PoFx. The PEP calls this routine to transition critical system resources to the idle condition.

`ProcessorIdleVeto`

A pointer to a ProcessorIdleVeto routine. PoFx sets the value of this member. The **ProcessorIdleVeto** routine is implemented by PoFx. The PEP calls this routine to increment or decrement the veto count for a pending transition to a processor idle state.

`PlatformIdleVeto`

A pointer to a PlatformIdleVeto routine. PoFx sets the value of this member. The **PlatformIdleVeto** routine is implemented by PoFx. The PEP calls this routine to increment or decrement the veto count for a pending transition to a platform idle state.

`UpdateProcessorIdleState`

A pointer to an UpdateProcessorIdleState routine. PoFx sets the value of this member. The **UpdateProcessorIdleState** routine is implemented by PoFx. The PEP calls this routine to update the properties of the specified processor idle state.

`UpdatePlatformIdleState`

A pointer to an UpdatePlatformIdleState routine. PoFx sets the value of this member. The **UpdatePlatformIdleState** routine is implemented by PoFx. The PEP calls this routine to update the properties of the specified platform idle state.

`RequestCommon`

A pointer to an RequestCommon routine. PoFx sets the value of this member. The **RequestCommon** routine is implemented by PoFx. The PEP calls this routine to perform a processing operation that is specified by a request ID.

Remarks

The **KernelInformation** parameter to the PoFxRegisterPlugin or PoFxRegisterPluginEx routine is a pointer to a **PEP_KERNEL_INFORMATION** structure. The PEP allocates this structure and sets the values of the **Version** and **Size** members of this structure before calling **PoFxRegisterPlugin** or **PoFxRegisterPluginEx**. During the call to this routine, PoFx fills in the remaining members of the structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_LOW_POWER_EPOCH structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_LOW_POWER_EPOCH** structure is used to provide data for a PEP_DPM_LOW_POWER_EPOCH notification (deprecated).

Syntax

```
typedef struct _PEP_LOW_POWER_EPOCH {
  BOOLEAN LowPowerEpoch;
} PEP_LOW_POWER_EPOCH, *PPEP_LOW_POWER_EPOCH;
```

Members

`LowPowerEpoch`

When **TRUE**, indicates that the low power epoch is on.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_DPM_LOW_POWER_EPOCH notification

PEP_NOTIFY_COMPONENT_IDLE_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_NOTIFY_COMPONENT_IDLE_STATE** structure contains status information about a component's pending transition to a new F*x* power state.

Syntax

```
typedef struct _PEP_NOTIFY_COMPONENT_IDLE_STATE {
  PEPHANDLE DeviceHandle;
  ULONG     Component;
  ULONG     IdleState;
  BOOLEAN   DriverNotified;
  BOOLEAN   Completed;
} PEP_NOTIFY_COMPONENT_IDLE_STATE, *PPEP_NOTIFY_COMPONENT_IDLE_STATE;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`IdleState`

[in] The new F*x* power state that the component will transition to. If this parameter is zero, the new state is F0; if this parameter is one, the new state is F1; and so on.

`DriverNotified`

[in] Whether the driver for the device has already been notified of the pending transition to the new F*x* state. If TRUE, the power management framework (PoFx) already notified the driver by calling the driver's ComponentIdleStateCallback callback routine. If FALSE, PoFx has not yet notified the driver.

`Completed`

[out] Whether the PEP has completed all necessary preparations for the specified component to enter the new F*x* state. Set to TRUE to indicate that the PEP has completed all necessary preparations, or to FALSE to indicate that is has not.

If FALSE, the PEP must complete the necessary preparations at a later time and then inform PoFx when the preparations have been completed. To do so, the PEP calls the RequestWorker routine to request a work item, and then responds to the ensuing PEP_DPM_WORK notification by submitting a work request of type **PepWorkCompleteIdleState** to inform PoFx that the preparations are complete.

Remarks

This structure is used by the PEP_DPM_NOTIFY_COMPONENT_IDLE_STATE notification. The first four members of this structure contain input values that are supplied by PoFx. The **Completed** member contains an output value that the PEP writes to the structure in response to this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_PERF_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PERF_STATE** structure describes a performance state (P-state) in a P-state set in which the P-states are specified as a list of one or more discrete values.

Syntax

```
typedef struct _PEP_PERF_STATE {
  ULONGLONG Value;
  PVOID     Context;
} PEP_PERF_STATE, *PPEP_PERF_STATE;
```

Members

`Value`

The discrete value represented by this P-state. For more information, see Remarks.

`Context`

A pointer to PEP-defined context data. The PEP uses this context to contain additional information about the discrete performance level that cannot be expressed in the **Value** member. This context is opaque to the Windows power management framework (PoFx). The **Context** member is optional and can be set to NULL.

Remarks

The **Discrete.States** member of the PEP_COMPONENT_PERF_SET structure is a pointer to an array of **PEP_PERF_STATE** structures. The **Unit** member of the **PEP_COMPONENT_PERF_SET** structure specifies the units in which the **Value** member in each array element is expressed. Component performance can be expressed in hertz (frequency) or in bits per second (bandwidth). For example, if **Value** = 100,000,000 and **Unit** = **PepPerfStateUnitFrequency**, this performance state represents a frequency of 100 megahertz.

Device drivers use the PO_FX_PERF_STATE structure, which is similar to the **PEP_PERF_STATE** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_COMPONENT_PERF_SET

PO_FX_PERF_STATE

PEP_PERF_STATE_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PERF_STATE_TYPE** enumeration indicates the type of performance information that is specified for a performance state (P-state) of a component.

Syntax

```
typedef enum _PEP_PERF_STATE_TYPE {
  PepPerfStateTypeDiscrete,
  PepPerfStateTypeRange,
  PepPerfStateTypeMax
} PEP_PERF_STATE_TYPE, *PPEP_PERF_STATE_TYPE;
```

Constants

PepPerfStateTypeDiscrete	The performance information is specified as a set of discrete values.
PepPerfStateTypeRange	The performance information is specified as a range of values.
PepPerfStateTypeMax	Reserved for use by operating system.

Remarks

The **Type** member of the PEP_COMPONENT_PERF_SET structure is a **PEP_PERF_STATE_TYPE** enumeration value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_COMPONENT_PERF_SET

PEP_PERF_STATE_UNIT Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PERF_STATE_UNIT** enumeration indicates the measurement units in which the performance state (P-state) of a component is specified.

Syntax

```
typedef enum _PEP_PERF_STATE_UNIT {
  PepPerfStateUnitOther,
  PepPerfStateUnitFrequency,
  PepPerfStateUnitBandwidth,
  PepPerfStateUnitMax
} PEP_PERF_STATE_UNIT, *PPEP_PERF_STATE_UNIT;
```

Constants

PepPerfStateUnitOther	Some other type of measurement units not explicitly described by this enumeration.
PepPerfStateUnitFrequency	Hertz (frequency units).
PepPerfStateUnitBandwidth	Bits per second (bandwidth units).
PepPerfStateUnitMax	Reserved for use by operating system.

Remarks

The **Type** member of the PEP_COMPONENT_PERF_SET structure is a **PEP_PERF_STATE_UNIT** enumeration value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_COMPONENT_PERF_SET

PEP_PLATFORM_IDLE_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PLATFORM_IDLE_STATE** structure specifies the properties of a platform idle state.

Syntax

```
typedef struct _PEP_PLATFORM_IDLE_STATE {
  POHANDLE                      InitiatingProcessor;
  UCHAR                         InitiatingState;
  ULONG                         Latency;
  ULONG                         BreakEvenDuration;
  ULONG                         DependencyArrayUsed;
  ULONG                         DependencyArrayCount;
  PEP_PROCESSOR_IDLE_DEPENDENCY DependencyArray[ANYSIZE_ARRAY];
} PEP_PLATFORM_IDLE_STATE, *PPEP_PLATFORM_IDLE_STATE;
```

Members

`InitiatingProcessor`

A **POHANDLE** value that identifies the processor that initiates the transition to this platform idle state, or **NULL** if any processor can initiate the transition. If non-NULL, this handle represents the registration of the processor (as a device) with the Windows power management framework (PoFx).

`InitiatingState`

The index of the processor idle state that the processor enters to initiate the platform's entry to the specified platform idle state. If the **IdleStates** array in the PEP_PPM_QUERY_IDLE_STATES_V2 structure contains N elements, the idle states are numbered 0 to N-1 in the order in which they appear in the array.

`Latency`

The worst-case latency, in 100-nanosecond units, that the platform requires to wake from this idle state in response to a wake event.

`BreakEvenDuration`

The minimum amount of time, specified in 100-nanosecond units, that the platform must spend in this idle state to make a transition to this state worthwhile. PoFx uses this member value as a hint to avoid switching the platform to an idle state unless the platform is likely to remain in this state for at least the amount of time specified by **BreakEvenDuration**.

`DependencyArrayUsed`

The number of items in **DependencyArray** which were filled in by the PEP.

`DependencyArrayCount`

The number of elements in the **DependencyArray** array. The array contains one element for each processor in the hardware platform.

`DependencyArray`

The first element in an array of PEP_PROCESSOR_IDLE_DEPENDENCY structures. This array specifies the set of

dependencies that the platform idle state has on each processor. If the platform contains N processors, the array contains N elements, and processors are numbered 0 to N-1 in the order in which they are represented in the array.

Remarks

This structure is used in conjunction with the PEP_NOTIFY_PPM_QUERY_PLATFORM_STATE notification. The **State** member of a PEP_PPM_QUERY_PLATFORM_STATE structure is a **PEP_PLATFORM_IDLE_STATE** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_PROCESSOR_IDLE_DEPENDENCY

PEP_PLATFORM_IDLE_STATE_UPDATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PLATFORM_IDLE_STATE_UPDATE** structure contains the updated properties of a platform idle state.

Syntax

```
typedef struct _PEP_PLATFORM_IDLE_STATE_UPDATE {
  ULONG Version;
  ULONG Latency;
  ULONG BreakEvenDuration;
} PEP_PLATFORM_IDLE_STATE_UPDATE, *PPEP_PLATFORM_IDLE_STATE_UPDATE;
```

Members

`Version`

The current version number of this structure. Set this member to PEP_PLATFORM_IDLE_STATE_UPDATE_VERSION.

`Latency`

The worst-case latency, in 100-nanosecond units, for the platform to wake from this idle state in response to a wake event.

`BreakEvenDuration`

The minimum amount of time, specified in 100-nanosecond units, that the platform must spend in this idle state to make a transition to this state worthwhile. The Windows power management framework (PoFx) uses this member value as a hint to avoid switching the platform to an idle state unless the platform is likely to remain in this state for at least the amount of time specified by **BreakEvenDuration**.

Remarks

The *Update* parameter of the UpdatePlatformIdleState routine is a pointer to a **PEP_PLATFORM_IDLE_STATE_UPDATE** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

UpdatePlatformIdleState

PEP_POWER_CONTROL_COMPLETE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_POWER_CONTROL_COMPLETE** structure contains status information for a power control operation that the PEP previously requested and that the device driver has completed.

Syntax

```
typedef struct _PEP_POWER_CONTROL_COMPLETE {
  PEPHANDLE DeviceHandle;
  LPCGUID   PowerControlCode;
  PVOID     RequestContext;
  SIZE_T    BytesReturned;
  NTSTATUS  Status;
} PEP_POWER_CONTROL_COMPLETE, *PPEP_POWER_CONTROL_COMPLETE;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`PowerControlCode`

[in] A pointer to a GUID value that specifies the power control operation that was performed. This is the same value that the PEP supplied in response to the PEP_DPM_WORK notification to initiate the power control operation.

`RequestContext`

[in] A pointer to the request context that was sent by the PEP in the PEP_WORK_INFORMATION structure that the PEP supplied in the original work request. Typically, this member points to a structure that contains a pointer to an output buffer to contain the results of the power control operation that was requested by the PEP.

`BytesReturned`

[in] The size, in bytes, of the result data stored by the driver in the output buffer. For more information about this buffer, see the description of the **RequestContext** member.

`Status`

[in] The status of the power control operation. If the operation was successful, the PEP sets this member to STATUS_SUCCESS. Otherwise, the PEP sets this member to an appropriate error status code.

Remarks

This structure is used by the PEP_DPM_POWER_CONTROL_COMPLETE notification. All five members of the structure contain input values that are supplied by

If the output buffer is too small to receive all of the result data from the operation, the PEP sets the **Status** member of the structure to STATUS_INSUFFICIENT_RESOURCES, sets the **BytesReturned** member to the required size of the output buffer, and (typically) writes no data to the output buffer.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

GUID

PEP_POWER_CONTROL_REQUEST structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_POWER_CONTROL_REQUEST** structure contains a request from a driver for a power control operation.

Syntax

```
typedef struct _PEP_POWER_CONTROL_REQUEST {
  PEPHANDLE DeviceHandle;
  LPCGUID   PowerControlCode;
  PVOID     InBuffer;
  SIZE_T    InBufferSize;
  PVOID     OutBuffer;
  SIZE_T    OutBufferSize;
  SIZE_T    BytesReturned;
  NTSTATUS  Status;
} PEP_POWER_CONTROL_REQUEST, *PPEP_POWER_CONTROL_REQUEST;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`PowerControlCode`

[in] A pointer to a GUID value that specifies the power control operation to perform. This is the same value that the requesting driver supplied as the *PowerControlCode* parameter to the PoFxPowerControl routine.

`InBuffer`

[in] A pointer to a driver-allocated input buffer that contains the input parameters for this power control operation. This is the same value that the requesting driver supplied as the *InBuffer* parameter to the **PoFxPowerControl** routine.

`InBufferSize`

[in] The size in bytes of the buffer pointed to by **InBuffer**. This is the same value that the requesting driver supplied as the *InBufferSize* parameter to the **PoFxPowerControl** routine.

`OutBuffer`

[in] A pointer to a driver-allocated output buffer to which the PEP writes the results of this power control operation. This is the same value that the requesting driver supplied as the *OutBuffer* parameter to the **PoFxPowerControl** routine.

`OutBufferSize`

[in] The size in bytes of the buffer pointed to by **OutBuffer**.

`BytesReturned`

[out] The number of bytes that the PEP wrote to the output buffer pointed to by **OutBuffer**.

`Status`

[out] The status of the requested power control operation. If the operation is successful, the PEP sets this member to STATUS_SUCCESS. Otherwise, the PEP sets this member to an appropriate error status code.

Remarks

This structure is used by the PEP_DPM_POWER_CONTROL_REQUEST notification. The first six members of the structure contain input values that are supplied by the Windows power management Framework (PoFx). The last two members contain values that the PEP writes to the structure in response to this notification. In addition, the PEP writes to the output buffer pointed to by the **OutBuffer** member.

If the output buffer is too small to receive all of the result data from the operation, the PEP sets the **Status** member of the structure to STATUS_INSUFFICIENT_RESOURCES, sets the **BytesReturned** member to the required size of the output buffer, and (typically) writes no data to the output buffer.

The driver for a device can call the PoFxPowerControl routine to request a power control operation on the device. During this call, PoFx delegates the handling of this request to the PEP that owns the device. The **PowerControlCode** member of the **PEP_POWER_CONTROL_REQUEST** structure contains a custom control code whose meaning is understood by both the driver and the PEP for the device.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_PPM_CONTEXT_QUERY_PARKING_PAGE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_CONTEXT_QUERY_PARKING_PAGE** structure describes the parking page for a processor.

Syntax

```
typedef struct _PEP_PPM_CONTEXT_QUERY_PARKING_PAGE {
  PHYSICAL_ADDRESS PhysicalPageAddress;
  PVOID            VirtualPageAddress;
} PEP_PPM_CONTEXT_QUERY_PARKING_PAGE, *PPEP_PPM_CONTEXT_QUERY_PARKING_PAGE;
```

Members

`PhysicalPageAddress`

The physical memory address of the parking page.

`VirtualPageAddress`

The virtual memory address of the parking page.

Remarks

The output buffer for a PEP_PPM_POWER_CONTROL_QUERY_PARKING_PAGE power control request is a **PEP_PPM_CONTEXT_QUERY_PARKING_PAGE** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_PPM_POWER_CONTROL_QUERY_PARKING_PAGE

PEP_PPM_CST_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_CST_STATE** structure specifies the properties of a C state (ACPI processor power state).

Syntax

```
typedef struct _PEP_PPM_CST_STATE {
  UCHAR            Type;
  USHORT           Latency;
  ULONG            Power;
  UCHAR            AddressSpaceId;
  UCHAR            BitWidth;
  UCHAR            BitOffset;
  UCHAR            AccessSize;
  PHYSICAL_ADDRESS Address;
} PEP_PPM_CST_STATE, *PPEP_PPM_CST_STATE;
```

Members

`Type`

The C-state type (0 = C0, 1 = C1, 2 = C2, and so on).

`Latency`

The worst-case latency, in microseconds, to enter and exit this C state. There are no restrictions on latency size.

`Power`

The average power consumption, in milliwatts, of the processor when in this C state.

`AddressSpaceId`

The register address space ID (_ASI) for this C state. This member specifies the address space in which the register for this C state is located. The following IDs are defined for this member.

ID	MEANING
0x00	System memory space
0x01	System I/O space
0x02	PCI configuration space
0x03	Embedded controller
0x04	SMBus address
0x0A	Platform communications channel (PCC)
0x7F	Functional fixed hardware

`BitWidth`

The register bit width (_RBW) for this C state. This member specifies the width, in bits, of the register for this C state.

`BitOffset`

The register bit offset (_RBO) for this C state. This member specifies the offset, in bits, from the register address specified in the **Address** member to the start of the register for this C state.

`AccessSize`

The register access size (_ASZ) code for this C state. This member specifies the number of bytes to read during an access of the register for this C state. Valid access size codes are shown in the following table.

ACCESS SIZE CODE	MEANING
0	Undefined
1	BYTE (1 byte)
2	WORD (2 bytes)
3	DWORD (4 bytes)
4	QWORD (8 bytes)

`Address`

The register address (_ADR) for this C state.

Remarks

This structure is used in conjunction with the PEP_NOTIFY_PPM_CST_STATES notification. The **IdleStates** member of the PEP_PPM_CST_STATES structure is a pointer to an array of **PEP_PPM_CST_STATE** structures. The **Type** member in each element of the array should equal the array index of this member.

The values in the **PEP_PPM_CST_STATE** structure are obtained from the parameters that are specified for this C state in the _CST object in the ACPI namespace for the processor.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_CST_STATES

PEP_PPM_CST_STATES

PEP_PPM_CST_STATES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_CST_STATES** structure specifies the properties of the C states (ACPI processor power states) that are supported for a processor.

Syntax

```
typedef struct _PEP_PPM_CST_STATES {
  ULONG              Count;
  PPEP_PPM_CST_STATE IdleStates;
} PEP_PPM_CST_STATES, *PPEP_PPM_CST_STATES;
```

Members

`Count`

The number of elements in the **IdleStates** array.

`IdleStates`

A pointer to an array of PEP_PPM_CST_STATE structures.

Remarks

This structure is used by the PEP_NOTIFY_PPM_CST_STATES notification. The contents of this structure are obtained from the _CST object that is located in the ACPI namespace for the processor.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_CST_STATES

PEP_PPM_CST_STATE

PEP_PPM_ENTER_SYSTEM_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

Used in the **PEP_NOTIFY_PPM_ENTER_SYSTEM_STATE** notification to notify PEP that the system is about to enter a system power state.

Syntax

```
typedef struct _PEP_PPM_ENTER_SYSTEM_STATE {
  SYSTEM_POWER_STATE TargetState;
} PEP_PPM_ENTER_SYSTEM_STATE, *PPEP_PPM_ENTER_SYSTEM_STATE;
```

Members

`TargetState`

On input, a SYSTEM_POWER_STATE-type value that indicates the power state that the system is entering.

Remarks

This notification is sent to all processors simultaneously after the system has completed all passive level work transitioning the processor to the system power state. This notification is sent at DISPATCH_LEVEL, with all processors at dispatch. This notification is always executed on the target processor. PEP must not queue any work from this notification. The processors will not process work items, DPCs, etc. after this notification has been sent.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Header	pepfx.h (include Pep_x.h)

See Also

Processor power management (PPM) notifications

PEP_PPM_FEEDBACK_READ structure

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_FEEDBACK_READ** structure contains the value read from a processor performance feedback counter.

Syntax

```
typedef struct _PEP_PPM_FEEDBACK_READ {
  ULONG CounterIndex;
  union {
    ULONG64 InstantaneousValue;
    struct {
      ULONG64 NominalCount;
      ULONG64 ActualCount;
    };
  };
} PEP_PPM_FEEDBACK_READ, *PPEP_PPM_FEEDBACK_READ;
```

Members

`CounterIndex`

[in] The index that identifies which processor performance feedback counter to read. If the platform extension plug-in (PEP) supports N counters for this processor, counter indexes range from 0 to N-1. The PEP previously supplied the number of supported counters in response to a PEP_NOTIFY_PPM_QUERY_CAPABILITIES notification.

`InstantaneousValue`

`NominalCount`

`ActualCount`

Remarks

This structure is used by the PEP_NOTIFY_PPM_FEEDBACK_READ notification. The **CounterIndex** member of the structure contains an input value supplied by the Windows power management framework (PoFx) when this notification is set. The other members contain output values that the PEP writes to the structure in response to the notification. The PEP writes to the **InstantaneousValue** member if the counter generates an instantaneous value, or to the **NominalCount** and **ActualCount** members if the counter generates a relative value.

Both an instantaneous counter and a relative counter are reset to zero when power is first turned on, but reading a relative counter causes the count to reset to zero, whereas reading an instantaneous counter does not reset the count. The PEP previously indicated whether the counter is instantaneous or relative in response to a PEP_NOTIFY_PPM_QUERY_FEEDBACK_COUNTERS notification.

Requirements

Minimum supported client	Supported starting with Windows 10.

Header	pepfx.h (include Pep_x.h)

See Also

PEP_PPM_IDLE_COMPLETE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_IDLE_COMPLETE** structure describe the idle states from which the processor and hardware platform are waking.

Syntax

```
typedef struct _PEP_PPM_IDLE_COMPLETE {
  ULONG ProcessorState;
  ULONG PlatformState;
} PEP_PPM_IDLE_COMPLETE, *PPEP_PPM_IDLE_COMPLETE;
```

Members

`ProcessorState`

[in] An index that identifies the idle state from which the processor is waking. The platform extension plug-in (PEP) previously specified the supported processor idle states in response to a PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification. If the PEP specified N processor idle states, valid processor-idle-state indexes range from 0 to N-1. When the hypervisor is enabled and the platform wakes from an idle state, this member is set to **PEP_PROCESSOR_IDLE_STATE_UNKNOWN** (0xffffffff). For more information, see PEP_NOTIFY_PPM_IDLE_COMPLETE.

`PlatformState`

[in] An index that identifies the idle state from which the platform is waking. The PEP previously specified the supported platform idle states in response to a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification. If the PEP specified M platform idle states, valid platform-idle-state indexes range from 0 to M-1. If the transition from the processor idle state does not involve a transition from an platform idle state, this member will contain the value **PEP_PLATFORM_IDLE_STATE_NONE** (0xffffffff).

Remarks

This structure is used by the PEP_NOTIFY_PPM_IDLE_COMPLETE notification. The **ProcessorState** and **PlatformState** members contain input values that are supplied by the Windows power management framework (PoFx) when this notification is sent to the PEP.

Requirements

Minimum supported client	Supported starting with Windows 10.

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_IDLE_COMPLETE_V2** structure describe the idle states from which the processor and hardware platform are waking.

Syntax

```
typedef struct _PEP_PPM_IDLE_COMPLETE_V2 {
  ULONG  ProcessorState;
  ULONG  PlatformState;
  ULONG  CoordinatedStateCount;
  PULONG CoordinatedStates;
} PEP_PPM_IDLE_COMPLETE_V2, *PPEP_PPM_IDLE_COMPLETE_V2;
```

Members

`ProcessorState`

[in] An index that identifies the idle state from which the processor is waking. The platform extension plug-in (PEP) previously specified the supported processor idle states in response to a PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification. If the PEP specified N processor idle states, valid processor-idle-state indexes range from 0 to N-1. When the hypervisor is enabled and the platform wakes from an idle state, this member is set to **PEP_PROCESSOR_IDLE_STATE_UNKNOWN** (0xffffffff). For more information, see PEP_NOTIFY_PPM_IDLE_COMPLETE.

`PlatformState`

[in] An index that identifies the idle state from which the platform is waking. The PEP previously specified the supported platform idle states in response to a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification. If the PEP specified M platform idle states, valid platform-idle-state indexes range from 0 to M-1. If the transition from the processor idle state does not involve a transition from an platform idle state, this member will contain the value **PEP_PLATFORM_IDLE_STATE_NONE** (0xffffffff).

`CoordinatedStateCount`

`CoordinatedStates`

Remarks

This structure is used by the PEP_NOTIFY_PPM_IDLE_COMPLETE notification. The **ProcessorState** and **PlatformState** members contain input values that are supplied by the Windows power management framework (PoFx) when this notification is sent to the PEP.

Requirements

Minimum supported client	Supported starting with Windows 10.

Header	pepfx.h (include Pep_x.h)

PEP_PPM_IDLE_EXECUTE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_IDLE_EXECUTE** structure specifies the idle state that the processor is to enter.

Syntax

```
typedef struct _PEP_PPM_IDLE_EXECUTE {
  NTSTATUS Status;
  ULONG    ProcessorState;
  ULONG    PlatformState;
} PEP_PPM_IDLE_EXECUTE, *PPEP_PPM_IDLE_EXECUTE;
```

Members

`Status`

[out] An **NTSTATUS** value that indicates whether the processor idle state transition was successful. The platform extension plug-in (PEP) sets this member to **STATUS_SUCCESSFUL** if the transition succeeded. Otherwise, this member is set to an appropriate error status code.

`ProcessorState`

[in] The index of the processor idle state that the processor is to enter. The PEP previously specified the supported processor idle states in response to a PEP_NOTIFY_PPM_QUERY_IDLE_STATES notification. If the PEP specified N processor idle states, valid processor-idle-state indexes range from 0 to N-1.

`PlatformState`

[in] The index of the platform idle state that the hardware platform will enter when the processor enters the processor idle state specified by **ProcessorState**. The PEP previously specified the supported platform idle states in response to a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification. If the PEP specified M platform idle states, valid platform-idle-state indexes range from 0 to M-1. If no change in platform idle state will occur, this member will contain the value P**EP_PLATFORM_IDLE_STATE_NONE** (0xffffffff).

Remarks

This structure is used by the PEP_NOTIFY_PPM_IDLE_EXECUTE notification. The **ProcessorState** and **PlatformState** members contain input values that are supplied by the Windows power management framework (PoFx). The **Status** member contains an output value that the PEP writes to this member.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES

PEP_PPM_IDLE_EXECUTE_V2 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_IDLE_EXECUTE_V2** structure specifies the idle state that the processor is to enter.

Syntax

```
typedef struct _PEP_PPM_IDLE_EXECUTE_V2 {
  NTSTATUS Status;
  ULONG    ProcessorState;
  ULONG    PlatformState;
  ULONG    CoordinatedStateCount;
  PULONG   CoordinatedStates;
} PEP_PPM_IDLE_EXECUTE_V2, *PPEP_PPM_IDLE_EXECUTE_V2;
```

Members

`Status`

[out] An **NTSTATUS** value that indicates whether the processor idle state transition was successful. The platform extension plug-in (PEP) sets this member to **STATUS_SUCCESSFUL** if the transition succeeded. Otherwise, this member is set to an appropriate error status code.

`ProcessorState`

[in] The index of the processor idle state that the processor is to enter. The PEP previously specified the supported processor idle states in response to a PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification. If the PEP specified N processor idle states, valid processor-idle-state indexes range from 0 to N-1.

`PlatformState`

[in] The index of the platform idle state that the hardware platform will enter when the processor enters the processor idle state specified by **ProcessorState**. The PEP previously specified the supported platform idle states in response to a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification. If the PEP specified M platform idle states, valid platform-idle-state indexes range from 0 to M-1. If no change in platform idle state will occur, this member will contain the value **PEP_PLATFORM_IDLE_STATE_NONE** (0xffffffff).

`CoordinatedStateCount`

Supplies the number of coordinated idle states being entered by this transition.

`CoordinatedStates`

Supplies a pointer to an array of coordinated idle states that are being entered by this transition.

Remarks

This structure is used by the PEP_NOTIFY_PPM_IDLE_EXECUTE notification. The **ProcessorState** and **PlatformState** members contain input values that are supplied by the Windows power management framework (PoFx). The **Status** member contains an output value that the PEP writes to this member.

Requirements

PEP_PPM_INITIATE_WAKE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_INITIATE_WAKE** structure indicates whether a processor requires an interrupt to wake up from an idle state.

Syntax

```
typedef struct _PEP_PPM_INITIATE_WAKE {
  BOOLEAN NeedInterruptForCompletion;
} PEP_PPM_INITIATE_WAKE, *PPEP_PPM_INITIATE_WAKE;
```

Members

`NeedInterruptForCompletion`

[out] Whether the processor requires an interrupt finish waking up from an idle state. Set to **TRUE** if the processor requires an interrupt, or to **FALSE** if it does not.

Remarks

This structure is used by the PEP_NOTIFY_PPM_INITIATE_WAKE notification. The **NeedInterruptForCompletion** member contains an output value that the platform extension plug-in (PEP) writes to the structure in response to this notification.

If the PEP sets the **NeedInterruptForCompletion** member to TRUE, the PEP must ensure that the processor is enabled to be interrupted before the AcceptProcessorNotification callback routine returns.

The PEP should set the **NeedInterruptForCompletion** member to **FALSE** if the processor is already running and/or will eventually exit the idle state (and is in the process of doing so) without requiring a software-generated interrupt.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

AcceptProcessorNotification

PEP_NOTIFY_PPM_INITIATE_WAKE

PEP_PPM_IS_PROCESSOR_HALTED structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_IS_PROCESSOR_HALTED** structure indicates whether the processor is currently halted in its selected idle state.

Syntax

```
typedef struct _PEP_PPM_IS_PROCESSOR_HALTED {
  BOOLEAN Halted;
} PEP_PPM_IS_PROCESSOR_HALTED, *PPEP_PPM_IS_PROCESSOR_HALTED;
```

Members

`Halted`

[out] Whether the processor is halted. Set to **TRUE** if the processor is halted, or to **FALSE** if it is not halted.

Remarks

This structure is used by the PEP_NOTIFY_PPM_IS_PROCESSOR_HALTED notification. The **Halted** member contains an output value that the platform extension plug-in (PEP) writes to the structure in response to this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_NOTIFY_PPM_IS_PROCESSOR_HALTED

PEP_PPM_PARK_MASK structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PROCESSOR_PARK_MASK** structure contains the current core parking mask.

Syntax

```
typedef struct _PEP_PPM_PARK_MASK {
  ULONG                     Count;
  ULONGLONG                 EvaluationTime;
  PPEP_PROCESSOR_PARK_STATE Processors;
} PEP_PPM_PARK_MASK, *PPEP_PPM_PARK_MASK;
```

Members

`Count`

[in] Indicates the number of processors in the **Processors** array.

`EvaluationTime`

[in] The interrupt time of the performance check evaluation that initiated this notification.

`Processors`

[in/out] An array of processors in the core parking domain.

On input

Indicates the OS parking preference for each processor.

On output

Returns the PEP parking preference for each processor.

The Processors array is guaranteed to contain the processors in increasing order by processor index.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_PROCESSOR_PARK_STATE

PEP_PPM_PARK_SELECTION structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_PARK_SELECTION** structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding which processors in the platform should be parked to reduce power consumption.

Syntax

```
typedef struct _PEP_PPM_PARK_SELECTION {
  ULONG                          AdditionalUnparkedProcessors;
  ULONG                          Count;
  PPEP_PROCESSOR_PARK_PREFERENCE Processors;
} PEP_PPM_PARK_SELECTION, *PPEP_PPM_PARK_SELECTION;
```

Members

`AdditionalUnparkedProcessors`

[in] The number of additional processors that need to be parked.

This number includes all processors in the **Processors** array for which the PEP sets **PepPreference** to PROCESSOR_PARK_PREFERENCE_PARKED but the operating system sets **PoPreference** to either PROCESSOR_PARK_PREFERENCE_UNPARKED or PROCESSOR_PARK_PREFERENCE_NONE. For more information about these values, see PEP_PROCESSOR_PARK_PREFERENCE.

This number does not include processors in the **Processors** array for which the operating system sets the **PoPreference** value to PROCESSOR_PARK_PREFERENCE_PARKED.

`Count`

[in] The number of elements in the array pointed to by the **Processors** member.

`Processors`

[in/out] A pointer to an array of PEP_PROCESSOR_PARK_PREFERENCE structures. The **Count** member specifies the number of elements in the array.

On input

Each array element indicates the parking preferences for a particular processor.

On output

Returns the PEP parking preference for each processor.

The Processors array is guaranteed to contain the processors in increasing order by processor index.

Remarks

This structure is used by the PEP_NOTIFY_PPM_PARK_SELECTION notification. All three members of the structure contain input values that are set by the Windows power management framework (PoFx) before this notification is sent to the PEP.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_PARK_SELECTION

PEP_PROCESSOR_PARK_PREFERENCE

PEP_PPM_PARK_SELECTION_V2 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_PARK_SELECTION_V2** structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding which processors in the platform should be parked to reduce power consumption.

Syntax

```
typedef struct _PEP_PPM_PARK_SELECTION_V2 {
  ULONG                          AdditionalUnparkedProcessors;
  ULONG                          Count;
  PPEP_PROCESSOR_PARK_PREFERENCE Processors;
  ULONGLONG                      EvaluationTime;
  UCHAR                          EvaluationType;
} PEP_PPM_PARK_SELECTION_V2, *PPEP_PPM_PARK_SELECTION_V2;
```

Members

`AdditionalUnparkedProcessors`

[in] The number of additional processors that need to be unparked.

This number includes all processors in the **Processors** array for which the PEP sets **PepPreference** to PROCESSOR_PARK_PREFERENCE_PARKED but the operating system sets **PoPreference** to either PROCESSOR_PARK_PREFERENCE_UNPARKED or PROCESSOR_PARK_PREFERENCE_NONE. For more information about these values, see PEP_PROCESSOR_PARK_PREFERENCE.

This number does not include processors in the **Processors** array for which the operating system sets the **PoPreference** value to PROCESSOR_PARK_PREFERENCE_PARKED.

`Count`

[in] The number of elements in the array pointed to by the **Processors** member.

`Processors`

[in/out] A pointer to an array of PEP_PROCESSOR_PARK_PREFERENCE structures. Each array element indicates the parking preferences for a particular processor. The **Count** member specifies the number of elements in the array.

`EvaluationTime`

The interrupt time of the performance check evaluation that initiated this notification.

`EvaluationType`

The type of evaluation being performed. This can be one of the following values:

VALUE	MEANING

PROCESSOR_PARKING_TYPE_CORE_PARKING 0x00	The processor should be parked.
PROCESSOR_PARKING_TYPE_INTERRUPT_STEERING 0x01	Interrupts should be steered away from the processor.

Remarks

This structure is used by the PEP_NOTIFY_PPM_PARK_SELECTION_V2 notification notification. All three members of the structure contain input values that are set by the Windows power management framework (PoFx) before this notification is sent to the PEP.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_PPM_PERF_CHECK_COMPLETE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_PERF_CHECK_COMPLETE** structure is used to inform the PEP of details regarding the completion of a periodic performance check evaluation.

Syntax

```
typedef struct _PEP_PPM_PERF_CHECK_COMPLETE {
  ULONGLONG EvaluationTime;
} PEP_PPM_PERF_CHECK_COMPLETE, *PPEP_PPM_PERF_CHECK_COMPLETE;
```

Members

`EvaluationTime`

[in] The interrupt time of the performance check evaluation that initiated this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_PERF_CHECK_COMPLETE notification

PEP_PPM_PERF_SET structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_PERF_SET** structure specifies the new performance level that the operating system is requesting for the processor.

Syntax

```
typedef struct _PEP_PPM_PERF_SET {
  ULONG MinimumPerformance;
  ULONG MaximumPerformance;
  ULONG DesiredPerformance;
  ULONG TimeWindow;
  ULONG PerformanceTolerance;
} PEP_PPM_PERF_SET, *PPEP_PPM_PERF_SET;
```

Members

`MinimumPerformance`

[in] The new minimum performance level in platform-specific units. This member indicates the absolute minimum performance level that the processor can run at.

`MaximumPerformance`

[in] The new maximum performance level in platform-specific units. This member indicates the absolute maximum performance level that the processor can run at.

`DesiredPerformance`

[in] The new desired performance level in platform-specific units. This member is set to a value in the range **MinimumPerformance** to **MaximumPerformance**.

`TimeWindow`

[in] The width, in milliseconds, of the new time window over which the platform must provide the required average performance. If this time window is nonzero, the instantaneous performance provided by the platform does not need to match the desired performance level, and only needs to fall within the constraints specified by the minimum and maximum performance level.

`PerformanceTolerance`

[in] The new performance tolerance in platform-specific units. This member contains the minimum performance level that the platform can deliver and still meet the operating system's performance requirements.

Remarks

This structure is used by the PEP_NOTIFY_PPM_PERF_SET notification. All five members of this structure contain input values that PoFx supplies when this notification is sent to the PEP.

Processor performance levels are specified in platform-specific units. For example, a hardware platform might use a metric such as the processor clock frequency to provide a rough approximation to the amount of processing work that is being done. For more information, see Platform Performance Thresholds.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_PERF_SET

Platform Performance Thresholds

PEP_PPM_PERF_SET_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

Used in the **PEP_NOTIFY_PPM_PERF_SET** notification at runtime to set the current operating performance of the processor.

Syntax

```
typedef struct _PEP_PPM_PERF_SET_STATE {
  UCHAR MinimumPerformanceState;
  UCHAR MaximumPerformanceState;
  UCHAR DesiredPerformanceState;
} PEP_PPM_PERF_SET_STATE, *PPEP_PPM_PERF_SET_STATE;
```

Members

`MinimumPerformanceState`

On input, the new requested minimum performance state. This state is defined as the absolute minimum instantaneous performance level at which the processor may run. The operating system may set this value to any performance value in the range [Lowest Performance, Guaranteed Performance], inclusive. Minimum performance must never be set to a value higher than maximum performance.

`MaximumPerformanceState`

On input, the new requested maximum performance state. This state is defined as the absolute maximum instantaneous performance level at which the processor may run. The OS may set Maximum performance to any performance value in the range [Lowest Performance, Highest Performance], inclusive.

`DesiredPerformanceState`

On input, the new requested desired performance state. This state is defined as the performance level power manager is requesting from the processor. Desired performance may be set to any performance value in the range [Minimum Performance, Maximum Performance], inclusive. Desired performance may take one of two meanings, depending on whether the desired performance is above or below the guaranteed performance level.

- Below the guaranteed performance level, desired performance expresses the average performance level the platform must provide.
- Above the guaranteed performance level, the platform must provide the guaranteed performance level. The platform should attempt to provide up to the desired performance level, if current operating conditions allow for it, but it is not required to do so.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016

Header	pepfx.h (include Pep_x.h)

Processor power management (PPM) notifications

PEP_PPM_PLATFORM_STATE_RESIDENCIES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_PLATFORM_STATE_RESIDENCIES** structure contains the accumulated residency times and transition counts for the idle states that are supported by the hardware platform.

Syntax

```
typedef struct _PEP_PPM_PLATFORM_STATE_RESIDENCIES {
  ULONG                              Count;
  PPEP_PPM_PLATFORM_STATE_RESIDENCY States;
} PEP_PPM_PLATFORM_STATE_RESIDENCIES, *PPEP_PPM_PLATFORM_STATE_RESIDENCIES;
```

Members

`Count`

[in] The number of elements in the array pointed to by the **States** member. The number of array elements equals the number of platform idle states that the PEP previously provided in response to a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification.

`States`

[in] A pointer to an output buffer to which the PEP writes an array of PEP_PPM_PLATFORM_STATE_RESIDENCY structures. Each structure contains the accumulated residency and transition count information for a particular platform idle state. This buffer is guaranteed to be large enough to contain the number of array elements specified by the **Count** member. Each idle state is identified by its array index. If the array contains N elements, idle state indexes range from 0 to N-1.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_PLATFORM_STATE_RESIDENCIES notification. Both members of the structure contain input values that the Windows power management framework (PoFx) supplies when this notification is sent to the PEP. PoFx allocates the output buffer pointed to by the **States** member, and the PEP writes to this buffer.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES

PEP_NOTIFY_PPM_QUERY_PLATFORM_STATE_RESIDENCIES

PEP_PPM_PLATFORM_STATE_RESIDENCY structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_PLATFORM_STATE_RESIDENCY** structure specifies the accumulated residency time and transition count for a particular platform idle state.

Syntax

```
typedef struct _PEP_PPM_PLATFORM_STATE_RESIDENCY {
  ULONG64 Residency;
  ULONG64 TransitionCount;
} PEP_PPM_PLATFORM_STATE_RESIDENCY, *PPEP_PPM_PLATFORM_STATE_RESIDENCY;
```

Members

`Residency`

The accumulated residency time, in 100-nanosecond units. This is the total amount of time that the hardware platform has spent in this idle state since system startup.

`TransitionCount`

The total number of times that the platform has entered this idle state since system startup.

Remarks

The **States** member of the PEP_PPM_PLATFORM_STATE_RESIDENCIES structure is a pointer to an array of **PEP_PPM_PLATFORM_STATE_RESIDENCY** structures.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_PPM_PLATFORM_STATE_RESIDENCIES

PEP_PPM_QUERY_CAPABILITIES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_CAPABILITIES** structure contains information about the processor power management (PPM) capabilities of the platform extension plug-in (PEP).

Syntax

```
typedef struct _PEP_PPM_QUERY_CAPABILITIES {
  ULONG   FeedbackCounterCount;
  ULONG   IdleStateCount;
  BOOLEAN PerformanceStatesSupported;
  BOOLEAN ParkingSupported;
  UCHAR   DiscretePerformanceStateCount;
} PEP_PPM_QUERY_CAPABILITIES, *PPEP_PPM_QUERY_CAPABILITIES;
```

Members

`FeedbackCounterCount`

[out] The number of processor performance feedback counters supported by the PEP for this processor. On x86/AMD64 platforms, this must be zero.

`IdleStateCount`

[out] The number of processor idle states that the PEP supports. The PEP is not required to support the same number of idle states for all processors. The PEP can set **IdleStateCount** = 0 to indicate that it doesn't support any idle states, in which case the PEP doesn't need to implement any other notifications that deal with processor idle states.

`PerformanceStatesSupported`

[out] Whether the PEP supports performance state controls. Set to TRUE if the PEP supports performance states, or to FALSE if it does not.

`ParkingSupported`

[out] Whether the PEP supports supplying core parking hints. Set to TRUE if the PEP can indicate which cores to park, or to FALSE if it cannot.

`DiscretePerformanceStateCount`

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_CAPABILITIES notification. All four members contain output values that the PEP writes to the structure in response to this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.

Header	pepfx.h (include Pep_x.h)

PEP_PPM_QUERY_COORDINATED_DEPENDENCY structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_COORDINATED_DEPENDENCY** structure describes dependencies for coordinated idle states.

Syntax

```
typedef struct _PEP_PPM_QUERY_COORDINATED_DEPENDENCY {
  ULONG                              StateIndex;
  ULONG                              DependencyIndex;
  ULONG                              DependencySize;
  ULONG                              DependencySizeUsed;
  POHANDLE                           TargetProcessor;
  PEP_COORDINATED_DEPENDENCY_OPTION Options[ANYSIZE_ARRAY];
} PEP_PPM_QUERY_COORDINATED_DEPENDENCY, *PPEP_PPM_QUERY_COORDINATED_DEPENDENCY;
```

Members

`StateIndex`

[in] The index of the coordinated idle state which is having its dependencies queried.

`DependencyIndex`

[in] The index of the dependency being queried.

`DependencySize`

[in] The size of the **Dependencies** array.

`DependencySizeUsed`

[out] The number of elements of the **Dependencies** array filled in by the PEP.

`TargetProcessor`

[out] The **POHANDLE** corresponding to the processor being targeted by this dependency, or **NULL** if this is a coordinated state dependency.

`Options`

[out] A list of PEP_COORDINATED_DEPENDENCY_OPTION structures describing dependency options, one of which must be satisfied for this coordinated state to be entered.

Requirements

Minimum supported client	Supported starting with Windows 10.

Header	pepfx.h (include Pep_x.h)

PEP_PPM_QUERY_CAPABILITIES

Processor power management (PPM) notifications

PEP_PPM_QUERY_DOMAIN_INFO structure

1/30/2019 • 2 minutes to read • Edit Online

Used in the **PEP_NOTIFY_PPM_QUERY_DOMAIN_INFO** notification that queries for information about a performance domain.

Syntax

```
typedef struct _PEP_PPM_QUERY_DOMAIN_INFO {
  ULONG   DomainId;
  UCHAR   CoordinationType;
  BOOLEAN IdleProcessorsDiscounted;
  BOOLEAN SchedulerDirectedTransitionsSupported;
  BOOLEAN AffinitizePerfSet;
  ULONG   WorstCaseTransitionLatency;
  ULONG   WorstCaseTransitionOverhead;
} PEP_PPM_QUERY_DOMAIN_INFO, *PPEP_PPM_QUERY_DOMAIN_INFO;
```

Members

`DomainId`

On input, the domain ID of the domain being queried.

`CoordinationType`

On output, indicates the coordination type of the performance domain. The possible values are:

- PROCESSOR_DOMAIN_COORDIANTION_SW_ALL (0x00)
- PROCESSOR_DOMAIN_COORDIANTION_SW_ANY (0x01)
- PROCESSOR_DOMAIN_COORDIANTION_HW_ALL (0x02)

If this notification is not supported, PROCESSOR_DOMAIN_COORDIANTION_SW_ALL coordination is used.

`IdleProcessorsDiscounted`

On output, and if HW-ALL coordination is used, this value is TRUE if the platform automatically ignores requests from idle processors as it determines the resolved performance level of the domain, FALSE if requests from idle processors continue to be honored.
If PROCESSOR_DOMAIN_COORDIANTION_HW_ALL coordination is not used: this field is ignored.

`SchedulerDirectedTransitionsSupported`

On output, this value is TRUE if the PEP supports the requirements of scheduler directed performance transitions for this domain, FALSE otherwise.

`AffinitizePerfSet`

On output, this value is TRUE if the PEP requires the PEP_NOTIFY_PPM_PERF_SET or PEP_NOTIFY_PPM_PERF_SET_STATE notification to execute on the processor changing frequency, or FALSE if the PEP allows these notifications to execute on any processor. If PROCESSOR_DOMAIN_COORDIANTION_SW_ANY coordination is used: the PEP_NOTIFY_PPM_PERF_SET or PEP_NOTIFY_PPM_PERF_SET_STATE notification will execute on a processor in the domain.

`WorstCaseTransitionLatency`

On output, this value indicates the worst case latency for the processor to transition to a new performance state, measured from the time the OS issues the notification to the PEP to transition to a new performance level, to the time the processor is running at the new performance level, in 100ns units.

`WorstCaseTransitionOverhead`

On output, this value indicates the worst case overhead (PEP code execution time plus time the processor is not executing instructions) measured from the time the OS issues the notification to the PEP to transition to a new performance level, to the time the processor is running at the new performance level, in 100ns units.

Requirements

Minimum supported client	Windows 10, version 1709

Processor power management (PPM) notifications

PEP_PPM_QUERY_FEEDBACK_COUNTERS structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_FEEDBACK_COUNTERS** structure describes all the processor performance counters that the platform extension plug-in (PEP) supports for a particular processor.

Syntax

```
typedef struct _PEP_PPM_QUERY_FEEDBACK_COUNTERS {
  ULONG                          Count;
  PEP_PROCESSOR_FEEDBACK_COUNTER Counters[ANYSIZE_ARRAY];
} PEP_PPM_QUERY_FEEDBACK_COUNTERS, *PPEP_PPM_QUERY_FEEDBACK_COUNTERS;
```

Members

`Count`

[in] The number of processor performance feedback counters supported by the PEP. The PEP previously supplied this count in response to a PEP_NOTIFY_PPM_QUERY_CAPABILITIES notification.

`Counters`

[out] The first element in an array of PEP_PROCESSOR_FEEDBACK_COUNTER structures. If this array contains more than one element, the additional elements immediately follow the end of the **PEP_PPM_QUERY_FEEDBACK_COUNTERS** structure. The **Count** member specifies the number of elements in this array. For more information, see Remarks.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_FEEDBACK_COUNTERS notification. The **Count** member of the structure contains an input value that PoFx supplies when this notification is sent. The **Counters** member contains an output value that the PEP writes in response to the notification. The PEP writes any additional **Counters** array elements to the output buffer area that follows the **PEP_PPM_QUERY_FEEDBACK_COUNTERS** structure. The buffer that PoFx allocated for this structure is guaranteed to be large enough to contain any array elements that follow the structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h, Pep_x.h)

PEP_NOTIFY_PPM_QUERY_FEEDBACK_COUNTERS

PEP_PROCESSOR_FEEDBACK_COUNTER

PEP_PPM_QUERY_IDLE_STATES_V2 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_IDLE_STATES_V2** structure is used during processor initialization to query the platform extension plug-in (PEP) for a list of processor idle states that the processor supports.

Syntax

```
typedef struct _PEP_PPM_QUERY_IDLE_STATES_V2 {
  ULONG                       Count;
  PEP_PROCESSOR_IDLE_STATE_V2 IdleStates[ANYSIZE_ARRAY];
} PEP_PPM_QUERY_IDLE_STATES_V2, *PPEP_PPM_QUERY_IDLE_STATES_V2;
```

Members

`Count`

[in] The number of elements in the **IdleStates** array. The Windows power management framework (PoFx) previously sent the PEP a PEP_NOTIFY_PPM_QUERY_CAPABILITIES notification to determine this number.

`IdleStates`

[out] The first element in an array of PEP_PROCESSOR_IDLE_STATE_V2 structures that describe the processor idle states. If this array contains more than one element, the addition array elements follow the end of the **PEP_PPM_QUERY_IDLE_STATES_V2** structure.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification. The **Count** member of the **PEP_PPM_QUERY_IDLE_STATES_V2** structure contains an input value that is supplied by the Windows power management framework (PoFx). The **IdleStates** array elements contain output values that the PEP writes to the structure in response to this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2

PEP_PROCESSOR_IDLE_STATE_V2

PEP_PPM_QUERY_PERF_CAPABILITIES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_PERF_CAPABILITIES** structure describes the performance capabilities of the processors in the specified processor performance domain.

Syntax

```
typedef struct _PEP_PPM_QUERY_PERF_CAPABILITIES {
  ULONG HighestPerformance;
  ULONG NominalPerformance;
  ULONG LowestNonlinearPerformance;
  ULONG LowestPerformance;
  ULONG DomainId;
  ULONG DomainMembers;
} PEP_PPM_QUERY_PERF_CAPABILITIES, *PPEP_PPM_QUERY_PERF_CAPABILITIES;
```

Members

`HighestPerformance`

[out] The highest performance level in platform-specific units. For more information, see Remarks.

`NominalPerformance`

[out] The nominal performance level in platform-specific units. For more information, see Remarks.

`LowestNonlinearPerformance`

[out] The lowest nonlinear performance level in platform-specific units. For more information, see Remarks.

`LowestPerformance`

[out] The lowest performance level in platform-specific units. For more information, see Remarks.

`DomainId`

[out] The domain ID of the processor performance domain.

`DomainMembers`

[out] The number of processors in this performance domain.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_PERF_CAPABILITIES notification. All six members contain output values that the platform extension plug-in (PEP) writes to the structure in response to this notification.

Processor performance levels are specified in platform-specific units. For example, a hardware platform might use a metric such as the processor clock frequency to provide a rough approximation to the amount of processing work that is being done. For more information, see Platform Performance Thresholds.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_QUERY_PERF_CAPABILITIES

Platform Performance Thresholds

PEP_PPM_PERF_CONSTRAINTS structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_PERF_CONSTRAINTS** structure describes the performance limits to apply to the processor.

Syntax

```
typedef struct _PEP_PPM_QUERY_PERF_CONSTRAINTS {
  ULONG GuaranteedPerformanceLimit;
  ULONG LimitReasons;
} PEP_PPM_PERF_CONSTRAINTS, *PPEP_PPM_PERF_CONSTRAINTS;
```

Members

`GuaranteedPerformanceLimit`

[out] The guaranteed performance threshold in platform-specific units. If nonzero, this value specifies the maximum sustained performance level of the processor, taking into account all known external constraints (power budgeting, thermal constraints, power source, and so on). All processors are expected to be able to simultaneously sustain their guaranteed performance levels. For more information, see Platform Performance Thresholds.

`LimitReasons`

[out] The reasons for which the processor's performance can be limited. Set this member to zero or to the bitwise-OR of one or more of the following values:

LIMIT REASON	MEANING
PERFORMANCE_LIMIT_THERMAL 0x1	The processor performance can be limited due to an out-of-band (that is, non-ACPI Thermal Zone) thermal condition.
PERFORMANCE_LIMIT_POWER 0x2	The processor performance can be limited to keep power consumption of the processor within hardware safety limits.

PER FOR MA NCE _LI MIT _DO MAI N_D EPE NDE NC Y 0x4	The processor performance can be limited because of a voltage or frequency dependency between this processor and another, non-processor device.

Remarks

This structure is used by the PEP_NOTIFY_PPM_PERF_CONSTRAINTS notification. The **GuaranteedPerformanceLimit** and **LimitReasons** members contain output values that the platform extension plug-in (PEP) writes to the structure in response to this notification.

The **GuaranteedPerformanceLimit** member value is specified in platform-specific units. For example, a hardware platform might use a metric such as the processor clock frequency to provide a rough approximation to the amount of processing work that is being done.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_PPM_QUERY_PLATFORM_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_PLATFORM_STATE** structure contains information about a platform idle state.

Syntax

```
typedef struct _PEP_PPM_QUERY_PLATFORM_STATE {
  ULONG                  StateIndex;
  PEP_PLATFORM_IDLE_STATE State;
} PEP_PPM_QUERY_PLATFORM_STATE, *PPEP_PPM_QUERY_PLATFORM_STATE;
```

Members

`StateIndex`

[in] The index of this platform idle state. If the hardware platform supports N platform idle states, the states are numbered 0 to N-1. The Windows power management framework (PoFx) previously sent a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification to the platform extension plug-in (PEP) to determine the number of supported platform idle states.

`State`

[out] A PEP_PLATFORM_IDLE_STATE structure that describes the platform idle state.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_PLATFORM_STATE notification. The **StateIndex** member of the **PEP_PPM_QUERY_PLATFORM_STATE** structure contains an input value that is supplied by the Windows power management framework (PoFx) when this notification is sent to the PEP. The **State** member contains an output value that the PEP writes to the structure in response to the notification.

The buffer that PoFx allocates to hold the **PEP_PPM_QUERY_PLATFORM_STATE** structure is guaranteed to be large enough to contain this structure plus any elements of the **State.DependencyArray** array that follow this structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES

PEP_PLATFORM_IDLE_STATE

PEP_PPM_QUERY_PLATFORM_STATES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_PLATFORM_STATES** structure specifies the number of platform idle states the hardware platform supports.

Syntax

```
typedef struct _PEP_PPM_QUERY_PLATFORM_STATES {
  ULONG PlatformStateCount;
} PEP_PPM_QUERY_PLATFORM_STATES, *PPEP_PPM_QUERY_PLATFORM_STATES;
```

Members

`PlatformStateCount`

The number of platform idle states supported by the platform.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES

PEP_PPM_QUERY_STATE_NAME structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_STATE_NAME** structure contains information about a specific coordinated or platform idle state.

Syntax

```
typedef struct _PEP_PPM_QUERY_STATE_NAME {
  ULONG  StateIndex;
  USHORT NameSize;
  PWSTR  Name;
} PEP_PPM_QUERY_STATE_NAME, *PPEP_PPM_QUERY_STATE_NAME;
```

Members

`StateIndex`

[in] The index of the state that the OS is querying about.

`NameSize`

[in/out] If **Name** is **NULL**, returns the size of the buffer required to hold **Name** (including the trailing **UNICODE_NULL** character), in WCHARs. If **Name** is not **NULL**, supplies the size of the **Name** buffer, in WCHARs.

`Name`

[in] A pointer to a buffer to copy the name of the state to, or **NULL**.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_QUERY_COORDINATED_STATE_NAME notification

PEP_NOTIFY_PPM_QUERY_PROCESSOR_STATE_NAME notification

PEP_PPM_QUERY_VETO_REASON structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_VETO_REASON** structure supplies a wide-character, null-terminated string that contains a descriptive, human-readable name for a veto reason.

Syntax

```
typedef struct _PEP_PPM_QUERY_VETO_REASON {
  ULONG  VetoReason;
  USHORT NameSize;
  PWSTR  Name;
} PEP_PPM_QUERY_VETO_REASON, *PPEP_PPM_QUERY_VETO_REASON;
```

Members

`VetoReason`

[in] The index that identifies this veto reason. If the platform extension plug-in (PEP) supports N veto reasons, valid veto reason indexes range from 1 to N. The PEP previously specified the number of supported veto reasons in response to a PEP_NOTIFY_PPM_QUERY_VETO_REASONS notification.

`NameSize`

[out] The size, in bytes, of the string buffer pointed to by the **Name** member. This string size includes the storage space for the null character that terminates the wide-character string.

`Name`

[in] A pointer to a PoFx-allocated string buffer. If this buffer pointer is non-**NULL**, the PEP writes a wide-character, null-terminated string to the buffer (and writes nothing to the **NameSize** member). Otherwise, the PEP writes nothing to this buffer and instead writes the required string size to the **NameSize** member.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_VETO_REASON notification. The **VetoReason** and **Name** members contain input values that are supplied by the Windows power management framework (PoFx). If the input value of the **Name** member is **NULL**, the PEP writes an output value (the required string buffer size) to the **NameSize** member.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_QUERY_VETO_REASON

PEP_NOTIFY_PPM_QUERY_VETO_REASONS

PEP_PPM_QUERY_VETO_REASONS structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_QUERY_VETO_REASONS** structure specifies the total number of veto reasons that the PEP uses in calls to the ProcessorIdleVeto and PlatformIdleVeto routines.

Syntax

```
typedef struct _PEP_PPM_QUERY_VETO_REASONS {
  ULONG VetoReasonCount;
} PEP_PPM_QUERY_VETO_REASONS, *PPEP_PPM_QUERY_VETO_REASONS;
```

Members

`VetoReasonCount`

[out] The number of veto codes used by the PEP.

Remarks

This structure is used by the PEP_NOTIFY_PPM_QUERY_VETO_REASONS notification. The **VetoReasonCount** member contains an output value that the PEP writes to this member in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_QUERY_VETO_REASONS

PEP_PPM_RESUME_FROM_SYSTEM_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

Used by the **PEP_NOTIFY_PPM_RESUME_FROM_SYSTEM_STATE** notification that notifies the PEP that the system has just resumed from a system power state.

Syntax

```
typedef struct _PEP_PPM_RESUME_FROM_SYSTEM_STATE {
  SYSTEM_POWER_STATE TargetState;
} PEP_PPM_RESUME_FROM_SYSTEM_STATE, *PPEP_PPM_RESUME_FROM_SYSTEM_STATE;
```

Members

`TargetState`

On input, a SYSTEM_POWER_STATE-type value that indicates the power state that the system is entering.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Header	pepfx.h (include Pep_x.h)

Processor power management (PPM) notifications

PEP_PPM_TEST_IDLE_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PPM_TEST_IDLE_STATE** structure contains information about whether the processor can immediately enter a processor idle state.

Syntax

```
typedef struct _PEP_PPM_TEST_IDLE_STATE {
  ULONG ProcessorState;
  ULONG PlatformState;
  ULONG VetoReason;
} PEP_PPM_TEST_IDLE_STATE, *PPEP_PPM_TEST_IDLE_STATE;
```

Members

`ProcessorState`

(input) The index of the processor idle state that is to be entered. The platform extension plug-in (PEP) previously specified the supported processor idle states in response to a PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification. If the PEP specified N processor idle states, valid processor-idle-state indexes range from 0 to N-1.

`PlatformState`

[in] The index of the platform idle state that the hardware platform will enter when the processor enters the processor idle state specified by **ProcessorState**. The PEP previously specified the supported platform idle states in response to a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification. If the PEP specified M platform idle states, valid platform-idle-state indexes range from 0 to M-1. If no change in platform idle state will occur, this member will contain the value **PEP_PLATFORM_IDLE_STATE_NONE** (0xffffffff).

`VetoReason`

[out] The nonzero index value that identifies reason the PEP needs to veto this idle state transition, or **PEP_IDLE_VETO_NONE** (0) if the PEP is prepared to immediately make this transition. If the PEP supports N veto reasons, valid veto reason indexes range from 1 to N. The PEP previously specified the number of supported veto reasons in response to a PEP_NOTIFY_PPM_QUERY_VETO_REASONS notification.

Remarks

This structure is used by the PEP_NOTIFY_PPM_TEST_IDLE_STATE notification. The **ProcessorState** and **PlatformState** members contain input values that are supplied by the Windows power management framework (PoFx). The PEP writes an output value to the **VetoReason** member of this structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_PREPARE_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PREPARE_DEVICE** structure identifies a device that must be started up in preparation for its use by the operating system.

Syntax

```
typedef struct _PEP_PREPARE_DEVICE {
  PCUNICODE_STRING DeviceId;
  BOOLEAN          DeviceAccepted;
} PEP_PREPARE_DEVICE, *PPEP_PREPARE_DEVICE;
```

Members

`DeviceId`

[in] A string that uniquely identifies the device. This member is a pointer to a UNICODE_STRING structure that contains a device identification string.

`DeviceAccepted`

[out] Whether the PEP claims ownership of the device. The PEP sets this member to TRUE to claim ownership of the device, or to FALSE to indicate that it does not own the device. The PEP that claims ownership is responsible for handling device power management (DPM) notifications for the device.

Remarks

This structure is used by the PEP_DPM_PREPARE_DEVICE notification. The **DeviceId** member of the structure contains an input value that is supplied by the Windows power management framework (PoFx). The **DeviceAccepted** member contains an output value that the PEP writes to the structure in response to this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_DPM_PREPARE_DEVICE

UNICODE_STRING

PEP_PROCESSOR_FEEDBACK_COUNTER structure

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_PROCESSOR_FEEDBACK_COUNTER** structure describes a feedback counter to the operating system.

Syntax

```
typedef struct _PEP_PROCESSOR_FEEDBACK_COUNTER {
  struct {
    ULONG Affinitized : 1;
    ULONG Type : 2;
    ULONG Counter : 4;
    ULONG DiscountIdle : 1;
    ULONG Reserved : 24;
  };
  ULONG  NominalRate;
} PEP_PROCESSOR_FEEDBACK_COUNTER, *PPEP_PROCESSOR_FEEDBACK_COUNTER;
```

Members

`Affinitized`

Identifies the counter process affinity. If set to 1, the counter must be read while executing on the target processor, otherwise, it will be set to 0.

`Type`

Specifies the data type of the counter.

The processor feedback counter data types are:

VALUE	MEANING
PR **OCE** **SSO** **R_F** **EED** **BAC** **K_T** **YPE** **_IN** **STA** **NT** **ANE** **OU** **S** 0x0 0	The feedback counter returns the instantaneous value of the property being counted.

PR **OCE** **SSO** **R_F** **EED** **BAC** **K_T** **YPE** **_RE** **LAT** **IVE** 0x0 1	The feedback counter returns two incrementing values: the nominal count, and the actual count. Nominal count increments at a fixed nominal rate. Actual count increments at a variable rate relative to the property being counted. When the property is incrementing at its nominal rate, the two values should increment at the same rate. To compute an average rate over a time period, the OS reads the counter once and the beginning of the period and once at the end and computes:

`Counter`

Specifies the data the counter is providing.

The processor feedback counter types are:

VALUE	MEANING
PR **OCE** **SSO** **R_F** **EED** **BAC** **K_C** **OU** **NTE** **R_F** **REQ** **UEN** **CY** 0x0 0	The feedback counter returns the clock speed of the processor. The nominal rate is the nominal clock speed, in MHz.
PR **OCE** **SSO** **R_F** **EED** **BAC** **K_C** **OU** **NTE** **R_P** **ERF** **OR** **MA** **NCE** 0x0 1	The feedback counter returns the current processor performance. The nominal rate is equivalent to the processor's **NominalPerformance** (see PEP_NOTIFY_PPM_QUERY_PERF_CAPABILITIES notification).

`DiscountIdle`

`Reserved`

This member is reserved and should be set to zero.

`NominalRate`

Specifies the nominal rate of the counter.

Remarks

This structure

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP structures

PEP_NOTIFY_PPM_QUERY_PERF_CAPABILITIES notification

PEP_PROCESSOR_IDLE_DEPENDENCY structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PROCESSOR_IDLE_DEPENDENCY** structure specifies the dependencies of a platform idle state on the specified processor.

Syntax

```
typedef struct _PEP_PROCESSOR_IDLE_DEPENDENCY {
  POHANDLE TargetProcessor;
  UCHAR    ExpectedState;
  BOOLEAN  AllowDeeperStates;
  BOOLEAN  LooseDependency;
} PEP_PROCESSOR_IDLE_DEPENDENCY, *PPEP_PROCESSOR_IDLE_DEPENDENCY;
```

Members

`TargetProcessor`

A **POHANDLE** value that identifies the processor. The platform extension plug-in (PEP) received this handle in a previous PEP_DPM_REGISTER_DEVICE notification.

`ExpectedState`

The index of the processor idle state that this processor must enter to initiate the platform's transition to this platform idle state. If the **IdleStates** array in the PEP_PPM_QUERY_IDLE_STATES_V2 structure contains N elements, the idle states are numbered 0 to N-1 in the order in which they appear in the array.

`AllowDeeperStates`

Whether a secondary (subordinate) processor can be in a deeper processor idle state than **ExpectedState** and still satisfy the constraints of the transition to the platform idle state. Set this member to **TRUE** if a secondary processor in a deeper idle state can still satisfy the constraints, and to **FALSE** if it cannot. A primary processor (identified by the **TargetProcessor** member) can enter the selected idle state only after its secondary processors have entered their corresponding idle states.

`LooseDependency`

Whether the platform idle state has a loose dependency on the idle state of this processor. Set this member to **TRUE** to indicate a loose dependency in which a best effort to synchronize the idle state transitions of the platform and processor is sufficient. Set to **FALSE** to indicate a dependency in which the operating system is required to strictly synchronize these transitions. If **LooseDependency** is **FALSE**, the **WakesSpuriously** bit in the PEP_PROCESSOR_IDLE_STATE_V2 structure for this processor must be **FALSE**.

Remarks

The **DependencyArray** member of the PEP_PPM_IDLE_SELECT structure is a pointer to an array of **PEP_PROCESSOR_IDLE_DEPENDENCY** structures. The **DependencyArray** member of the PEP_PLATFORM_IDLE_STATE structure is the first element in an array of **PEP_PROCESSOR_IDLE_DEPENDENCY** structures.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_PROCESSOR_IDLE_STATE_UPDATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PROCESSOR_IDLE_STATE_UPDATE** structure contains the updated properties of a processor idle state.

Syntax

```
typedef struct _PEP_PROCESSOR_IDLE_STATE_UPDATE {
  ULONG Version;
  ULONG Latency;
  ULONG BreakEvenDuration;
} PEP_PROCESSOR_IDLE_STATE_UPDATE, *PPEP_PROCESSOR_IDLE_STATE_UPDATE;
```

Members

`Version`

The version number of this structure. Set this member to PEP_PROCESSOR_IDLE_STATE_UPDATE_VERSION.

`Latency`

The worst-case latency, in 100-nanosecond units, that the platform requires to wake from this platform idle state in response to a wake event.

`BreakEvenDuration`

The minimum amount of time, specified in 100-nanosecond units, that the platform must spend in this idle state to make a transition to this state worthwhile. PoFx uses this member value as a hint to avoid switching the platform to an idle state unless the platform is likely to remain in this state for at least the amount of time specified by **BreakEvenDuration**.

Remarks

The *Update* parameter to the UpdateProcessorIdleState routine is a pointer to a **PEP_PROCESSOR_IDLE_STATE_UPDATE** structure. This routine updates the properties of the specified idle state for a processor. The PEP must not call this routine until it has responded to a PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification for this processor.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

UpdateProcessorIdleState

PEP_PROCESSOR_IDLE_STATE_V2 structure

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_PROCESSOR_IDLE_STATE_V2** structure describes a processor idle state that the platform extension plug-in (PEP) supports.

Syntax

```
typedef struct _PEP_PROCESSOR_IDLE_STATE_V2 {
  union {
    ULONG Ulong;
    struct {
      ULONG Interruptible : 1;
      ULONG CacheCoherent : 1;
      ULONG ThreadContextRetained : 1;
      ULONG CStateType : 4;
      ULONG WakesSpuriously : 1;
      ULONG PlatformOnly : 1;
      ULONG Autonomous : 1;
      ULONG Reserved : 22;
    };
  };
  ULONG Latency;
  ULONG BreakEvenDuration;
} PEP_PROCESSOR_IDLE_STATE_V2, *PPEP_PROCESSOR_IDLE_STATE_V2;
```

Members

`Ulong`

`Interruptible`

`CacheCoherent`

`ThreadContextRetained`

`CStateType`

`WakesSpuriously`

`PlatformOnly`

`Autonomous`

`Reserved`

`Latency`

The worst-case latency, in 100-nanosecond units, that the processor requires to wake from this idle state in response to a wake event.

`BreakEvenDuration`

The minimum amount of time, specified in 100-nanosecond units, that the processor must spend in this idle state to make a transition to this state worthwhile. The Windows power management framework (PoFx) uses this member value as a hint to avoid switching a processor to an idle state unless the processor is likely to remain in

this state for at least the amount of time specified by **BreakEvenDuration**.

Remarks

This structure is used in conjunction with the PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification. The **IdleStates** member of the PEP_PPM_QUERY_IDLE_STATES_V2 structure is the first element in an array of **PEP_PROCESSOR_IDLE_STATE_V2** structures.

Requirements

PEP_PPM_QUERY_IDLE_STATES_V2

PEP_PROCESSOR_PARK_PREFERENCE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PROCESSOR_PARK_PREFERENCE** structure indicates the preferences of the operating system and platform extension plug-in (PEP) regarding whether the specified processor should be parked to reduce power consumption.

Syntax

```
typedef struct _PEP_PROCESSOR_PARK_PREFERENCE {
  PEPHANDLE Processor;
  UCHAR     PoPreference;
  UCHAR     PepPreference;
} PEP_PROCESSOR_PARK_PREFERENCE, *PPEP_PROCESSOR_PARK_PREFERENCE;
```

Members

`Processor`

A **PEPHANDLE** value that identifies the processor. The PEP supplied this handle in a previous PEP_DPM_REGISTER_DEVICE notification.

`PoPreference`

The operating system's parking preference for this processor. For more information, see Remarks.

`PepPreference`

The PEP's parking preference for this processor. For more information, see Remarks.

Remarks

The **Processors** member of the PEP_PPM_PARK_SELECTION structure is a pointer to an array of **PEP_PROCESSOR_PARK_PREFERENCE** structures.

The **Processor** and **PoPreference** members of the **PEP_PROCESSOR_PARK_PREFERENCE** structure contain input values that are supplied by the Windows power management framework when a PEP_NOTIFY_PPM_PARK_SELECTION notification is sent to the PEP. The **PepPreference** member contains an output value that the PEP writes to the structure in response to this notification.

The following table lists the three values that are defined for the **PoPreference** and **PepPreference** members.

PARKING PREFERENCE	VALUE	MEANING
PROCESSOR_PARK_PREFERENCE_NONE	0x0	No preference. Either parked or unparked is okay.
PROCESSOR_PARK_PREFERENCE_PARKED	0x1	The operating system or PEP specifies that the processor should be parked.

PROCESSOR_PARK_PREFERENCE_UNPARKED	0x2	The operating system or PEP specifies that the processor should not be parked.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_PPM_PARK_SELECTION

PEP_PROCESSOR_PARK_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_PROCESSOR_PARK_STATE** structure describes the parking state for a single processor.

Syntax

```
typedef struct _PEP_PROCESSOR_PARK_STATE {
  PEPHANDLE Processor;
  BOOLEAN   Parked;
  UCHAR     Reserved[3];
} PEP_PROCESSOR_PARK_STATE, *PPEP_PROCESSOR_PARK_STATE;
```

Members

`Processor`

Specifies the **PEPHANDLE** associated with this processor.

`Parked`

Specifies whether or not this processor is parked.

`Reserved`

This member is reserved and should be set to zero.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_PPM_PARK_MASK notification

PEP_PPM_PARK_MASK

PEP_PROCESSOR_PERF_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

Use in the **PEP_NOTIFY_PPM_QUERY_DISCRETE_PERF_STATES** notification. This structure describes the properties of a single performance state.

Syntax

```
typedef struct _PEP_PROCESSOR_PERF_STATE {
  ULONG Performance;
  ULONG Frequency;
  ULONG Reserved[4];
} PEP_PROCESSOR_PERF_STATE, *PPEP_PROCESSOR_PERF_STATE;
```

Members

`Performance`

On output, the performance level (on the scale returned by the PEP_QUERY_COMPONENT_PERF_CAPABILITIES notification) of this performance state.

`Frequency`

On output, the frequency (in MHz) of this performance state.

`Reserved`

Reserved.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Header	pepfx.h (include Pep_x.h)

See Also

Processor power management (PPM) notifications

PEP_QUERY_COMPONENT_PERF_CAPABILITIES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_COMPONENT_PERF_CAPABILITIES** structure specifies the number of performance state (P-state) sets that are defined for a component.

Syntax

```
typedef struct _PEP_QUERY_COMPONENT_PERF_CAPABILITIES {
  PEPHANDLE DeviceHandle;
  ULONG     Component;
  ULONG     SetCount;
} PEP_QUERY_COMPONENT_PERF_CAPABILITIES, *PPEP_QUERY_COMPONENT_PERF_CAPABILITIES;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`SetCount`

[out] The number of P-state sets that are defined for this component.

Remarks

This structure is used by the PEP_DPM_QUERY_COMPONENT_PERF_CAPABILITIES notification. The **DeviceHandle** and **Component** members contain input values that are supplied by the Windows power management framework (PoFx) when this notification is sent. The **SetCount** member contains an output value that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_DPM_REGISTER_DEVICE

PEP_QUERY_COMPONENT_PERF_SET structure

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_COMPONENT_PERF_SET** structure contains query information about a set of performance state values (P-state set) for a component.

Syntax

```
typedef struct _PEP_QUERY_COMPONENT_PERF_SET {
  PEPHANDLE           DeviceHandle;
  ULONG               Component;
  ULONG               Set;
  ULONGLONG           Flags;
  PEP_PERF_STATE_UNIT Unit;
  PEP_PERF_STATE_TYPE Type;
  union {
    struct {
      ULONG Count;
    } Discrete;
    struct {
      ULONGLONG Minimum;
      ULONGLONG Maximum;
    } Range;
  };
} PEP_QUERY_COMPONENT_PERF_SET, *PPEP_QUERY_COMPONENT_PERF_SET;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Set`

[in] The index that identifies this P-state set. If this component has M P-state sets, P-state set indexes range from 0 to M–1. The PEP previously specified the number of P-state sets in response to a PEP_DPM_QUERY_COMPONENT_PERF_CAPABILITIES notification.

`Flags`

[in] A set of input flags. No flag bits are currently defined for this member, which is always zero.

`Unit`

[out] A PEP_PERF_STATE_UNIT enumeration value that indicates whether the values for this P-state set are expressed in hertz (frequency units) or bits per second (bandwidth units).

`Type`

[out] A PEP_PERF_STATE_TYPE enumeration value that indicates whether the performance values for this P-state set are expressed as a list of discrete values or as a continuous range of values.

`Discrete`

`Discrete.Count`

`Range`

`Range.Minimum`

`Range.Maximum`

Remarks

This structure is used by the PEP_DPM_QUERY_COMPONENT_PERF_SET notification. The **DeviceHandle**, **Component**, **Set**, and **Flags** members contain input values that are supplied by the Windows power management framework (PoFx) when this notification is sent. The **Discrete** member or **Range** member contains an output value that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_PERF_STATE_UNIT

PEP_QUERY_COMPONENT_PERF_SET_NAME structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_COMPONENT_PERF_SET_NAME** structure contains query information about a set of performance state values (P-state set) for a component.

Syntax

```
typedef struct _PEP_QUERY_COMPONENT_PERF_SET_NAME {
  PEPHANDLE DeviceHandle;
  ULONG     Component;
  ULONG     Set;
  USHORT    NameSize;
  PWCHAR    Name;
} PEP_QUERY_COMPONENT_PERF_SET_NAME, *PPEP_QUERY_COMPONENT_PERF_SET_NAME;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Set`

[in] The index that identifies this P-state set. If this component has M P-state sets, P-state set indexes range from 0 to M–1. The PEP previously specified the number of P-state sets in response to a PEP_DPM_QUERY_COMPONENT_PERF_CAPABILITIES notification.

`NameSize`

[in, out] On input, the size, in bytes, of the buffer pointed to by the **Name** member. If **Name** is NULL, the PEP overwrites the input value of **NameSize** with the buffer size required for the name string.

`Name`

[in] A pointer to an output buffer. The PEP writes the name of the P-state to this buffer. The name is stored as a wide-character, null-terminated string. The **Name** member is NULL if the Windows power management framework (PoFx) needs to determine how large a buffer to allocate for the name string. If **Name** is non-NULL, the buffer must be large enough to contain the entire string, including the terminating null character.

Remarks

This structure is used by the PEP_DPM_QUERY_COMPONENT_PERF_SET_NAME notification. The

DeviceHandle, **Component**, and **Set** members of the structure contain input values supplied by PoFx when this notification is sent. If the **Name** member is non-NULL, the PEP writes a string to the buffer pointed to by **Name**. If **Name** is NULL, PEP writes the required buffer size to the **NameSize** member.

The string that the PEP writes to the output buffer should contain a descriptive name for the P-state set. This name is intended to make log entries and diagnostic messages easier to understand.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_QUERY_COMPONENT_PERF_STATES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_COMPONENT_PERF_STATES** structure contains a list of discrete performance state (P-state) values for the specified P-state set.

Syntax

```
typedef struct _PEP_QUERY_COMPONENT_PERF_STATES {
  PEPHANDLE       DeviceHandle;
  ULONG           Component;
  ULONG           Set;
  PPEP_PERF_STATE States;
} PEP_QUERY_COMPONENT_PERF_STATES, *PPEP_QUERY_COMPONENT_PERF_STATES;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Set`

[in] The index that identifies this P-state set. If M is the number of P-state sets for this component, P-state set indexes range from 0 to M–1. The PEP previously specified the number of P-state sets in response to a PEP_DPM_QUERY_COMPONENT_PERF_CAPABILITIES notification.

`States`

[in] A pointer to an output buffer. The PEP writes an array of PEP_PERF_STATE structures to this buffer. Each array element describes one P-state in the P-state set specified by the **Set** member. The Windows power management framework (PoFx) allocated this buffer, which is guaranteed to be large enough to contain an array of the length that the PEP previously wrote to the **Discrete.Count** member of the PEP_QUERY_COMPONENT_PERF_SET structure in response to a PEP_DPM_QUERY_COMPONENT_PERF_SET notification.

Remarks

This structure is used by the PEP_DPM_QUERY_COMPONENT_PERF_STATES notification. All four members of this structure contain input values that are supplied by PoFx when this notification is sent.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_QUERY_CURRENT_COMPONENT_PERF_STATE structure

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_CURRENT_COMPONENT_PERF_STATE** structure contains information about the current P-state in the specified P-state set.

Syntax

```
typedef struct _PEP_QUERY_CURRENT_COMPONENT_PERF_STATE {
  PEPHANDLE DeviceHandle;
  ULONG     Component;
  ULONG     Set;
  union {
    ULONG     StateIndex;
    ULONGLONG StateValue;
  };
} PEP_QUERY_CURRENT_COMPONENT_PERF_STATE, *PPEP_QUERY_CURRENT_COMPONENT_PERF_STATE;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Set`

[in] The index that identifies this P-state set. If M is the number of P-state sets for this component, P-state set indexes range from 0 to M–1. The PEP previously specified the number of P-state sets in response to a PEP_DPM_QUERY_COMPONENT_PERF_CAPABILITIES notification.

`StateIndex`

`StateValue`

Remarks

This structure is used by the PEP_DPM_QUERY_CURRENT_COMPONENT_PERF_STATE notification. The **DeviceHandle**, **Component**, and **Set** members contain input values supplied by the Windows power management framework (PoFx) when this notification is sent. The **StateIndex** member or **StateValue** member contains an output value that the PEP writes to the structure in response to the notification.

PEP_QUERY_SOC_SUBSYSTEM structure

1/30/2019 • 3 minutes to read • Edit Online

The **PEP_QUERY_SOC_SUBSYSTEM** structure is used by the PEP_DPM_QUERY_SOC_SUBSYSTEM notification to gather basic information about a particular system on a chip (SoC) subsystem.

Syntax

```
typedef struct _PEP_QUERY_SOC_SUBSYSTEM {
  ULONG          PlatformIdleStateIndex;
  ULONG          SubsystemIndex;
  PVOID          SubsystemHandle;
  UNICODE_STRING ParentName;
  UNICODE_STRING SubsystemName;
  ULONG          MetadataCount;
  ULONG          Flags;
} PEP_QUERY_SOC_SUBSYSTEM, *PPEP_QUERY_SOC_SUBSYSTEM;
```

Members

`PlatformIdleStateIndex`

[in] The platform idle state index that is being queried by the kernel.

`SubsystemIndex`

[in] The subsystem index, which is a unique index assigned by the OS to each subsystem within the context of a given **PlatformIdleStateIndex**.

The kernel initializes this value to zero and increments it for each subsequent subsystem static info notification. A value of 0 means it's the first such notification for the given **PlatformIdleStateIndex**. This field is intended to give the PEP context between instances of this notification. It is the only field whose input value varies across instances of this notification for a given **PlatformIdleStateIndex** and a PEP might use this value to look up a subsystem.

The PEP can ignore this value.

`SubsystemHandle`

[out] A context pointer that the PEP can optionally assign a value to. It will receive the pointer on subsequent notifications for this particular subsystem. In subsequent notifications, a PEP uses **PlatformIdleStateIndex** along with **SubsystemName** and/or **SubsystemHandle** to look up a particular subsystem's accounting data.

By default the value if this member is zero. This value is ignored by the OS and used only in notifications.

The PEP is not required to fill this member.

`ParentName`

[in/out] A buffer for holding the parent name of the corresponding subsystem. Each subsystem has a parent and subsystems with the same value for **ParentName** are considered siblings. Subsystem sibling hierarchies are optional. In the absence of any hierarchy, all subsystems are top level subsystems and specify a common value for **ParentName**. To indicate a hierarchy, top level subsystems specify a common **ParentName** while each non-top-level subsystem specifies its parent subsystem's **SubsystemName** for **ParentName**.

Prior to entry, the kernel will:

- Pre-allocate 64 **WCHARs** for **ParentName.Buffer[]**
- Zero the buffer
- Set **ParentName.MaximumLength** to the size of the buffer in bytes, and
- Set **ParentName.Length** = **0**

Prior to exit, the PEP must copy a null-terminated string into **ParentName.Buffer** and update **ParentName.Length** with a byte count that is **sizeof(WCHAR)** times the number of UNICODE characters copied, not including the terminating **UNICODE_NULL**.

The PEP must use the allocated memory that is pointed to by the address in **ParentName.Buffer** to provide the parent name. Since this memory is pre-allocated, its size cannot be changed. The PEP is responsible for truncating the parent name, if necessary, so that it does not exceed the length specified in **ParentName.MaximumLength** (including the terminating **UNICODE_NULL** character).

`SubsystemName`

[in/out] A buffer for holding this subsystem's name. Every subsystem has a subsystem name and **SubsystemName** must be unique among all subsystems within the context of a given platform idle state. A subsystem's **SubsystemName** cannot be the same as **ParentName**.

Prior to entry, the kernel will:

- Pre-allocate 64 **WCHARs** for **SubsystemName.Buffer[]**
- Zero the buffer
- Set **SubsystemName.MaximumLength** to the size of the buffer in bytes, and
- Set **SubsystemName.Length** = **0**

Prior to exit, the PEP must copy a null-terminated string into **SubsystemName.Buffer** and update **SubsystemName.Length** with a byte count that is **sizeof(WCHAR)** times the number of UNICODE characters copied, not including the terminating **UNICODE_NULL**.

The PEP must use the allocated memory that is pointed to by the address in **SubsystemName.Buffer** to provide the subsystem name. Since this memory is pre-allocated, its size cannot be changed. The PEP is responsible for truncating the subsystem name, if necessary, so that it does not exceed the length specified in **SubsystemName.MaximumLength** (including the terminating **UNICODE_NULL** character).

`MetadataCount`

[out] The number of metadata key/value string pairs tallied by this SoC subsystem.

Metadata is optional. The PEP returns zero if it does not report any metadata for this SoC subsystem.

`Flags`

This member is reserved and should be set to zero.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_DPM_QUERY_SOC_SUBSYSTEM notification

PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME** structure is used by the PEP_DPM_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME notification to collect details about the blocking duration for a particular system on a chip (SoC) subsystem.

Syntax

```
typedef struct _PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME {
  ULONG            PlatformIdleStateIndex;
  PVOID            SubsystemHandle;
  PCUNICODE_STRING SubsystemName;
  ULONG64          BlockingTime;
  ULONG            Flags;
} PEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME, *PPEP_QUERY_SOC_SUBSYSTEM_BLOCKING_TIME;
```

Members

`PlatformIdleStateIndex`

[in] The platform idle state index for the SoC subsystem that the OS is querying.

`SubsystemHandle`

[in] A context pointer that the PEP previously provided on subsystem initialization. The context pointer is optional, so if none was provided then the value will be zero. The PEP is free to ignore this field.

`SubsystemName`

[in] The name of the subsystem whose blocking time is being queried. This name was provided by the PEP on subsystem initialization.

`BlockingTime`

[out] The blocking time tallied for this subsystem in 100 nanosecond units since the previous PEP_DPM_RESET_SOC_SUBSYSTEM_ACCOUNTING notification.

`Flags`

This member is reserved and should be set to zero.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_QUERY_SOC_SUBSYSTEM_COUNT structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_SOC_SUBSYSTEM_COUNT** structure is used to tell the OS whether the PEP supports system on a chip (SoC) subsystem accounting for a given platform idle state.

Syntax

```
typedef struct _PEP_QUERY_SOC_SUBSYSTEM_COUNT {
  ULONG PlatformIdleStateIndex;
  ULONG SubsystemCount;
  ULONG Flags;
} PEP_QUERY_SOC_SUBSYSTEM_COUNT, *PPEP_QUERY_SOC_SUBSYSTEM_COUNT;
```

Members

`PlatformIdleStateIndex`

[in] The platform idle state index for which the kernel is querying about.

`SubsystemCount`

[out] The number of SoC subsystems tallied by the PEP for the specified platform idle state. The PEP cannot return 0 in this parameter; instead the PEP should return **FALSE** to the PEP_DPM_QUERY_SOC_SUBSYSTEM_COUNT notification that provided this structure.

`Flags`

This member is reserved and should be set to zero.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_QUERY_SOC_SUBSYSTEM_METADATA structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_QUERY_SOC_SUBSYSTEM_METADATA** structure is used with the **PEP_DPM_QUERY_SOC_SUBSYSTEM_METADATA** notification to collect optional metadata about the system on a chip (SoC) subsystem whose blocking time has just been queried.

Syntax

```
typedef struct _PEP_QUERY_SOC_SUBSYSTEM_METADATA {
  ULONG                       PlatformIdleStateIndex;
  PVOID                       SubsystemHandle;
  PCUNICODE_STRING            SubsystemName;
  ULONG                       Flags;
  ULONG                       MetadataCount;
  PPEP_SOC_SUBSYSTEM_METADATA Metadata[ANYSIZE_ARRAY];
} PEP_QUERY_SOC_SUBSYSTEM_METADATA, *PPEP_QUERY_SOC_SUBSYSTEM_METADATA;
```

Members

`PlatformIdleStateIndex`

[in] The platform idle state index for for the SoC subsystem that the OS is querying.

`SubsystemHandle`

[in] A context pointer that the PEP previously provided on subsystem initialization. The context pointer is optional, so if none was provided then the value will be zero. The PEP is free to ignore this field.

`SubsystemName`

[in] The name of the subsystem whose metadata is being queried.

`Flags`

This member is reserved and should be set to zero.

`MetadataCount`

[in] The number of entries in the **Metadata** array. The PEP previously provided this value as **PEP_QUERY_SOC_SUBSYSTEM.MetadataCount**.

`Metadata`

[in/out] An array of pointers to PEP_SOC_SUBSYSTEM_METADATA structures. Each entry holds one key/value metadata string-pair.

Requirements

Minimum supported client	Supported starting with Windows 10.

Header	pepfx.h (include Pep_x.h)

PEP_REGISTER_COMPONENT_PERF_STATES structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_REGISTER_COMPONENT_PERF_STATES** structure describes the performance states (P-states) of the specified component.

Syntax

```
typedef struct _PEP_REGISTER_COMPONENT_PERF_STATES {
  PEPHANDLE                DeviceHandle;
  ULONG                    Component;
  ULONGLONG                Flags;
  PPEP_COMPONENT_PERF_INFO PerfStateInfo;
} PEP_REGISTER_COMPONENT_PERF_STATES, *PPEP_REGISTER_COMPONENT_PERF_STATES;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The platform extension plug-in (PEP) supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N−1.

`Flags`

[in] A set of input flags. No flag bits are currently defined for this member, which is always zero.

`PerfStateInfo`

[in] A pointer to a PEP_COMPONENT_PERF_INFO structure that contains the performance information for this component's P-states. If this member is non-NULL, it points to P-state information that was supplied by the device driver.

Remarks

This structure is used by the PEP_DPM_REGISTER_COMPONENT_PERF_STATES notification. The values of all members of the **PEP_REGISTER_COMPONENT_PERF_STATES** structure are supplied by the Windows power management framework (PoFx) when the notification is sent. The PEP must not write to this structure.

If the **PerfStateInfo** member is not NULL, the device driver has provided P-state information and requires the PEP to use it.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_REGISTER_CRASHDUMP_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_REGISTER_CRASHDUMP_DEVICE** structure provides a callback routine to turn on a crash-dump device.

Syntax

```
typedef struct _PEP_REGISTER_CRASHDUMP_DEVICE {
  PPEPCALLBACKPOWERONCRASHDUMPDEVICE PowerOnDumpDeviceCallback;
  PEPHANDLE                          DeviceHandle;
} PEP_REGISTER_CRASHDUMP_DEVICE, *PPEP_REGISTER_CRASHDUMP_DEVICE;
```

Members

`PowerOnDumpDeviceCallback`

[out] A pointer to a PowerOnDumpDeviceCallback callback routine that is implemented by the platform extension plug-in (PEP). This routine handles requests from the Windows kernel to turn on the crash-dump device so that a crash dump can be saved. For more information, see Kernel-Mode Dump Files.

`DeviceHandle`

[in] A PEPHANDLE value that identifies the crash-dump device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

Remarks

This structure is used by the PEP_DPM_REGISTER_CRASHDUMP_DEVICE notification. The **DeviceHandle** member of the structure contains an input value that is supplied by the Windows power management framework (PoFx) when this notification is sent to the PEP. The **PowerOnDumpDeviceCallbackmember** contains an output value that the PEP writes to the structure in response to the notification.

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_REGISTER_DEVICE_V2 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_REGISTER_DEVICE_V2** structure describes a device whose driver stack has just registered with the Windows power management framework (PoFx).

Syntax

```
typedef struct _PEP_REGISTER_DEVICE_V2 {
  PCUNICODE_STRING           DeviceId;
  POHANDLE                   KernelHandle;
  PPEP_DEVICE_REGISTER_V2    Register;
  PEPHANDLE                  DeviceHandle;
  PEP_DEVICE_ACCEPTANCE_TYPE DeviceAccepted;
} PEP_REGISTER_DEVICE_V2, *PPEP_REGISTER_DEVICE_V2;
```

Members

`DeviceId`

[in] A string that uniquely identifies the device. This member is a pointer to a UNICODE_STRING structure that contains a device identification string.

`KernelHandle`

[in] A POHANDLE value that represents the registration of the device with PoFx. The platform extension plug-in (PEP) previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the device's driver stack registered the device with PoFx.

`Register`

[in] A pointer to a PEP_DEVICE_REGISTER_V2 structure that describes the power management attributes of all the components in the device. For more information, see Remarks.

`DeviceHandle`

[out] A PEPHANDLE value that the PEP creates to identify this device. PoFx will use this handle to identify the device in future device power management (DPM) notifications.

`DeviceAccepted`

[out] A PEP_DEVICE_ACCEPTANCE_TYPE enumeration value that indicates whether the PEP claims ownership of the device. The PEP that claims ownership is responsible for handling DPM notifications for the device.

Remarks

This structure is used by the PEP_DPM_REGISTER_DEVICE notification. The first three members of this structure contain input values supplied by PoFx. The last two members contain output values that the PEP writes to the structure in response to this notification.

The **Register** member contains a pointer to an input buffer allocated by PoFx. PoFx writes the PEP_DEVICE_REGISTER_V2 structure and associated data to this structure before sending the PEP_DPM_REGISTER_DEVICE notification to the PEP. The contents of this buffer remain valid only until the PEP

finishes handling the notification and returns from the AcceptDeviceNotification callback.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

UNICODE_STRING

PEP_REQUEST_COMPONENT_PERF_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_REQUEST_COMPONENT_PERF_STATE** structure contains a list of performance state (P-state) changes requested by the Windows power management framework (PoFx), plus status information about the handling of these requests by the platform extension plug-in (PEP).

Syntax

```
typedef struct _PEP_REQUEST_COMPONENT_PERF_STATE {
  PEPHANDLE                          DeviceHandle;
  ULONG                              Component;
  BOOLEAN                            Completed;
  BOOLEAN                            Succeeded;
  ULONG                              PerfRequestsCount;
  PPEP_COMPONENT_PERF_STATE_REQUEST PerfRequests;
} PEP_REQUEST_COMPONENT_PERF_STATE, *PPEP_REQUEST_COMPONENT_PERF_STATE;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Completed`

[out] Whether the PEP has completed the requested P-state changes. Set to TRUE to indicate that the P-state changes completed synchronously. Set to FALSE to indicate that the requested P-state changes are pending and will be completed asynchronously by a PEP worker thread. For more information, see Remarks.

`Succeeded`

[out] Whether the requested P-state changes successfully completed. Set to TRUE if the PEP successfully completed all P-state changes requested in the **PerfRequests** array. Set to FALSE if the PEP was unable to perform all the requested P-state changes, in which case the P-states in the hardware were left unchanged. The **Succeeded** member is used only for *synchronous* P-state changes. If the PEP sets **Completed** to FALSE, PoFx ignores the value in the **Succeeded** member.

`PerfRequestsCount`

[in] The number of P-state changes requested in the array pointed to by the **PerfRequests** member.

`PerfRequests`

[in] A pointer to an array of PEP_COMPONENT_PERF_STATE_REQUEST structures. Each element in the array specifies a new performance level to assign to a P-state set. The number of array elements is specified by the

PerfRequestsCount member.

Remarks

This structure is used by the PEP_DPM_REQUEST_COMPONENT_PERF_STATE notification. The **DeviceHandle**, **Component**, **PerfRequestsCount**, and **PerfRequests** members of the structure contain input values that are supplied by PoFx when this notification is sent. The **Completed** and **Succeeded** members contain output values that the PEP writes to the structure in response to the notification.

The PEP can complete the requested P-state changes either synchronously or asynchronously. The PEP can set the **Completed** member to TRUE to indicate that all the requests in the **PEP_DPM_REQUEST_COMPONENT_PERF_STATE** notification have been completed synchronously—that is, before the return from the PEP's AcceptDeviceNotification callback routine. Or, the PEP can set **Completed** to FALSE to indicate that the requests will be completed asynchronously. To complete the requests asynchronously, the PEP should call the RequestWorker routine to inform PoFx that the PEP has a work request to submit, and PoFx will respond by sending a PEP_DPM_WORK notification to the PEP.

PoFx writes the requested P-state changes to the **PerfRequests** array before the **PEP_DPM_REQUEST_COMPONENT_PERF_STATE** notification is sent. If the PEP handles the requested P-state changes *synchronously*, the contents of the **PerfRequests** array remain valid only until the return from the *AcceptDeviceNotification* callback routine. If the requests are completed *asynchronously*, the array contents remain valid until the PEP calls the CompleteWork routine to notify PoFx that the PEP has completed the pending requests.

PEP_RESET_SOC_SUBSYSTEM_ACCOUNTING structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_RESET_SOC_SUBSYSTEM_ACCOUNTING** structure is provided to the platform extension plug-in (PEP) as part of a PEP_DPM_RESET_SOC_SUBSYSTEM_ACCOUNTING notification.

Syntax

```
typedef struct _PEP_RESET_SOC_SUBSYSTEM_ACCOUNTING {
  ULONG PlatformIdleStateIndex;
  ULONG Flags;
} PEP_RESET_SOC_SUBSYSTEM_ACCOUNTING, *PPEP_RESET_SOC_SUBSYSTEM_ACCOUNTING;
```

Members

`PlatformIdleStateIndex`

[in] The platform idle state index for the subsystem accounting to be reset.

`Flags`

This member is reserved and should be set to zero.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_DPM_RESET_SOC_SUBSYSTEM_ACCOUNTING notification

PEP_SOC_SUBSYSTEM_METADATA structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_SOC_SUBSYSTEM_METADATA** structure contains key-value pairs that contain metadata for a system on a chip (SoC) subsystem. It is used in the context of a PEP_DPM_QUERY_SOC_SUBSYSTEM_METADATA notification sent to a platform extension plug-in (PEP).

Syntax

```
typedef struct _PEP_SOC_SUBSYSTEM_METADATA {
  UNICODE_STRING Key;
  UNICODE_STRING Value;
} PEP_SOC_SUBSYSTEM_METADATA, *PPEP_SOC_SUBSYSTEM_METADATA;
```

Members

`Key`

[in/out] A buffer for the PEP to write the key portion of the metadata string-pair. **Key** must be unique among all **Key** values reported by this subsystem.

Prior to entry into the notification callback routine, the kernel will:

- Pre-allocate 64 **WCHARs** for **Key.Buffer[]**
- Zero the buffer
- Set **Key.MaximumLength** to the size of the buffer in bytes, and
- Set **Key.Length** = **0**

Prior to exit from the callback routine, the PEP must copy a null-terminated string into **Key.Buffer** and update **Key.Length** with a byte count that is **sizeof(WCHAR)** times the number of UNICODE characters copied, not including the terminating **UNICODE_NULL**.

The PEP must use the allocated memory that is pointed to by the address in **Key.Buffer** to provide the key. Since this memory is pre-allocated, its size cannot be changed. The PEP is responsible for truncating the key string, if necessary, so that it does not exceed the length specified in **Key.MaximumLength** (including the terminating **UNICODE_NULL** character).

`Value`

[in/out] A buffer for the PEP to write the value portion of the metadata string-pair.

Prior to entry into the notification callback routine, the kernel will:

- Pre-allocate 64 **WCHARs** for **Value.Buffer[]**
- Zero the buffer
- Set **Value.MaximumLength** to the size of the buffer in bytes, and
- Set **Value.Length** = **0**

Prior to exit from the callback routine, the PEP must copy a null-terminated string into **Value.Buffer** and update **Value.Length** with a byte count that is **sizeof(WCHAR)** times the number of UNICODE characters copied, not including the terminating **UNICODE_NULL**.

The PEP must use the allocated memory that is pointed to by the address in **Value.Buffer** to provide the metadata value. Since this memory is pre-allocated, its size cannot be changed. The PEP is responsible for truncating the value string, if necessary, so that it does not exceed the length specified in **Value.MaximumLength** (including the terminating **UNICODE_NULL** character).

Requirements

Minimum supported client	Supported starting with Windows 10.

PEP_SYSTEM_LATENCY structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_SYSTEM_LATENCY** structure specifies the new value for the system latency tolerance.

Syntax

```
typedef struct _PEP_SYSTEM_LATENCY {
  ULONGLONG Latency;
} PEP_SYSTEM_LATENCY, *PPEP_SYSTEM_LATENCY;
```

Members

`Latency`

[in] The overall system latency tolerance, in 100-nanosecond units. This member specifies the maximum latency that the operating system can tolerate in the time required to move a component from a low-power F*x* state to F0.

Remarks

This structure is used by the PEP_DPM_SYSTEM_LATENCY_UPDATE notification. The **Latency** member of the structure contains an input value that is supplied by the Windows power management framework (PoFx).

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_DPM_SYSTEM_LATENCY_UPDATE

PEP_UNMASKED_INTERRUPT_FLAGS union

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_UNMASKED_INTERRUPT_FLAGS** union indicates whether an unmasked interrupt source is a primary interrupt or a secondary interrupt.

Syntax

```
typedef union _PEP_UNMASKED_INTERRUPT_FLAGS {
  struct {
    USHORT SecondaryInterrupt : 1;
    USHORT Reserved : 15;
  };
  USHORT AsUSHORT;
} PEP_UNMASKED_INTERRUPT_FLAGS, *PPEP_UNMASKED_INTERRUPT_FLAGS;
```

Members

`SecondaryInterrupt`

`Reserved`

`AsUSHORT`

A USHORT value that contains all of the unmasked interrupt flags.

Remarks

The **Flags** member of the PEP_UNMASKED_INTERRUPT_INFORMATION structure is a **PEP_UNMASKED_INTERRUPT_FLAGS** union.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_UNMASKED_INTERRUPT_INFORMATION

PEP_UNMASKED_INTERRUPT_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_UNMASKED_INTERRUPT_INFORMATION** structure contains information about an interrupt source.

Syntax

```
typedef struct _PEP_UNMASKED_INTERRUPT_INFORMATION {
  USHORT                       Version;
  USHORT                       Size;
  PEP_UNMASKED_INTERRUPT_FLAGS Flags;
  KINTERRUPT_MODE              Mode;
  KINTERRUPT_POLARITY          Polarity;
  ULONG                        Gsiv;
  USHORT                       PinNumber;
  PEPHANDLE                    DeviceHandle;
} PEP_UNMASKED_INTERRUPT_INFORMATION, *PPEP_UNMASKED_INTERRUPT_INFORMATION;
```

Members

`Version`

The version of this structure.

`Size`

The size, in bytes, of this structure.

`Flags`

A PEP_UNMASKED_INTERRUPT_FLAGS union that indicates whether the interrupt is a primary or secondary interrupt. For more information, see Primary and Secondary Interrupts.

`Mode`

A KINTERRUPT_MODE enumeration value. This member indicates whether the interrupt is edge-triggered or level-triggered.

`Polarity`

A KINTERRUPT_POLARITY enumeration value. This member indicates which edge or level of the interrupt signal triggers the interrupt.

`Gsiv`

The global system interrupt vector (GSIV) number that identifies this interrupt. The ACPI firmware assigns GSIV numbers to all primary interrupt lines. For secondary (GPIO) interrupt lines, the GSIV number is dynamically assigned by the operating system.

`PinNumber`

For secondary interrupt sources, this member identifies the number of the pin on the general-purpose I/O (GPIO)

controller that is connected to the interrupt signal line from the interrupting device. For primary interrupt sources, this member is undefined.

If a GPIO controller has N GPIO pins, the pins are numbered 0 to N−1. One or more of these GPIO pins might be configured as interrupt inputs.

`DeviceHandle`

For secondary interrupt sources, this member contains the PEP device handle for the GPIO controller that is the source for this interrupt. For primary interrupt sources, this field is undefined.

Remarks

This structure is used by the EnumerateInterruptSource callback routine.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

EnumerateInterruptSource

KINTERRUPT_MODE

KINTERRUPT_POLARITY

PEP_UNREGISTER_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_UNREGISTER_DEVICE** structure identifies a device whose registration is being removed from the Windows power management framework (PoFx).

Syntax

```
typedef struct _PEP_UNREGISTER_DEVICE {
  PEPHANDLE DeviceHandle;
} PEP_UNREGISTER_DEVICE, *PPEP_UNREGISTER_DEVICE;
```

Members

`DeviceHandle`

[in] A PEPHANDLE value that identifies the device. The PEP supplied this handle in response to a previous PEP_DPM_REGISTER_DEVICE notification.

Remarks

This structure is used by the PEP_DPM_UNREGISTER_DEVICE notification. The **DeviceHandle** member contains an input value that is supplied by the Windows power management framework (PoFx).

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_DPM_REGISTER_DEVICE

PEP_DPM_UNREGISTER_DEVICE

PEP_WORK structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK** structure indicates whether the PEP has a work request to submit to the Windows power management framework (PoFx).

Syntax

```
typedef struct _PEP_WORK {
  PPEP_WORK_INFORMATION WorkInformation;
  BOOLEAN               NeedWork;
} PEP_WORK, *PPEP_WORK;
```

Members

`WorkInformation`

[out] A pointer to a PEP-allocated PEP_WORK_INFORMATION structure that describes the work that the PEP is requesting. If **NeedWork** is TRUE, **WorkInformation** must point to a valid **PEP_WORK_INFORMATION** structure. If **NeedWork** is FALSE, **WorkInformation** must be NULL.

`NeedWork`

[out] Whether the PEP has a work request to submit. Set this member to TRUE if the PEP has a work request, or to FALSE if the PEP has no work to request.

Remarks

This structure is used by the PEP_DPM_WORK notification. Both members of the structure contain values that the PEP writes to the structure in response to this notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_DPM_WORK

PEP_WORK_INFORMATION

PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE** structure contains the results of an ACPI control method that was asynchronously evaluated by the platform extension plug-in (PEP).

Syntax

```
typedef struct _PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE {
  POHANDLE              DeviceHandle;
  ULONG                 CompletionFlags;
  NTSTATUS              MethodStatus;
  PVOID                 CompletionContext;
  SIZE_T                OutputArgumentSize;
  PACPI_METHOD_ARGUMENT OutputArguments;
} PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE, *PPEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE;
```

Members

`DeviceHandle`

A POHANDLE value that represents the registration of the device with the Windows power management framework (PoFx). The PEP previously received this handle from PoFx during the PEP_NOTIFY_ACPI_REGISTER_DEVICE notification in which the PEP elected to provide ACPI services for the device.

`CompletionFlags`

A set of completion flags. No flags are currently defined for this member, which is always set to PEP_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE_FLAG_NONE (0x0).

`MethodStatus`

`CompletionContext`

A pointer to a completion context value. This is the same pointer that PoFx passed to the PEP in the PEP_NOTIFY_ACPI_EVALUATE_CONTROL_METHOD notification that initiated the asynchronous evaluation of the ACPI control method.

`OutputArgumentSize`

The size, in bytes, of the buffer pointed to by the **OutputArguments** member.

`OutputArguments`

A pointer to a buffer to which the PEP has written the result of evaluating the ACPI control method. This buffer starts with a ACPI_METHOD_ARGUMENT structure, which might be followed by additional output data. PoFx allocated this buffer and passed the buffer pointer to the PEP in the PEP_NOTIFY_ACPI_EVALUATE_CONTROL_METHOD notification that initiated the asynchronous evaluation of the ACPI control method.

Remarks

The **ControlMethodComplete** member of the PEP_WORK_INFORMATION structure is a **PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE** structure.

A **PEP_WORK_INFORMATION** structure is included in the input parameters to the CompleteWork routine. The PEP writes the control method results to the **ControlMethodComplete** member of this structure before calling the routine. Evaluation of the control method was initiated by a previous PEP_NOTIFY_ACPI_EVALUATE_CONTROL_METHOD notification.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_WORK_ACPI_NOTIFY structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_ACPI_NOTIFY** structure contains the ACPI Notify code for a device that has generated a hardware event.

Syntax

```
typedef struct _PEP_WORK_ACPI_NOTIFY {
  POHANDLE DeviceHandle;
  ULONG    NotifyCode;
} PEP_WORK_ACPI_NOTIFY, *PPEP_WORK_ACPI_NOTIFY;
```

Members

`DeviceHandle`

A POHANDLE value that represents the registration of the device with PoFx. The platform extension plug-in (PEP) previously received this handle from the Windows power management framework (PoFx) during the PEP_NOTIFY_ACPI_REGISTER_DEVICE notification in which the PEP elected to provide ACPI services for the device.

`NotifyCode`

The Notify code. For a list of Notify codes and their meanings, see section 5.6.6, "Device Object Notifications", of the ACPI 5.0 specification.

Remarks

The **AcpiNotify** member of the PEP_WORK_INFORMATION structure is a **PEP_WORK_ACPI_NOTIFY** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

See Also

PEP_NOTIFY_ACPI_REGISTER_DEVICE

PEP_WORK_INFORMATION

PEP_WORK_COMPLETE_IDLE_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_COMPLETE_IDLE_STATE** structure identifies a component that the platform extension plug-in (PEP) has prepared for a transition to a new F*x* power state.

Syntax

```
typedef struct _PEP_WORK_COMPLETE_IDLE_STATE {
  POHANDLE DeviceHandle;
  ULONG    Component;
} PEP_WORK_COMPLETE_IDLE_STATE, *PPEP_WORK_COMPLETE_IDLE_STATE;
```

Members

`DeviceHandle`

A handle that represents the registration of the device with the Windows power management framework (PoFx). A POHANDLE value that represents the registration of the device with PoFx. The PEP previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the device's driver stack registered the device with PoFx.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

Remarks

The **CompleteIdleState** member of the PEP_WORK_INFORMATION structure is a **PEP_WORK_COMPLETE_IDLE_STATE** structure.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_DPM_REGISTER_DEVICE

PEP_WORK_INFORMATION

PEP_WORK_COMPLETE_PERF_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_COMPLETE_PERF_STATE** structure describes the completion status of a previously requested update to the performance values assigned to a list of performance state (P-state) sets.

Syntax

```
typedef struct _PEP_WORK_COMPLETE_PERF_STATE {
  POHANDLE DeviceHandle;
  ULONG    Component;
  BOOLEAN  Succeeded;
} PEP_WORK_COMPLETE_PERF_STATE, *PPEP_WORK_COMPLETE_PERF_STATE;
```

Members

`DeviceHandle`

A handle that represents the registration of the device with the Windows power management framework (PoFx). The PEP received this handle in a previous PEP_DPM_REGISTER_DEVICE notification.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Succeeded`

Whether the requested P-state changes successfully completed. Set to TRUE if the PEP successfully completed all P-state changes requested in a previous PEP_DPM_REQUEST_COMPONENT_PERF_STATE notification. Set to FALSE if the PEP was unable to perform all the requested P-state changes, in which case the P-states in the hardware were left unchanged.

Remarks

The **CompletePerfState** member of the PEP_WORK_INFORMATION structure is a **PEP_WORK_COMPLETE_PERF_STATE** structure. If PoFx sends a PEP_DPM_REQUEST_COMPONENT_PERF_STATE notification to request performance level changes to one or more P-state sets, and the PEP chooses to handle this request asynchronously, the PEP uses a **PEP_WORK_COMPLETE_PERF_STATE** structure to describe the completion status of the request.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_WORK_INFORMATION

PEP_WORK_INFORMATION structure

2/5/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_INFORMATION** structure describes a work item that the PEP is submitting to the Windows power management framework (PoFx).

Syntax

```
typedef struct _PEP_WORK_INFORMATION {
  PEP_WORK_TYPE WorkType;
  union {
    PEP_WORK_POWER_CONTROL                          PowerControl;
    PEP_WORK_COMPLETE_IDLE_STATE                    CompleteIdleState;
    PEP_WORK_COMPLETE_PERF_STATE                    CompletePerfState;
    PEP_WORK_ACPI_NOTIFY                            AcpiNotify;
    PEP_WORK_ACPI_EVALUATE_CONTROL_METHOD_COMPLETE ControlMethodComplete;
  };
} PEP_WORK_INFORMATION, *PPEP_WORK_INFORMATION;
```

Members

`WorkType`

A PEP_WORK_TYPE enumeration value. This member indicates the type of work requested by the PEP, which also determines the type of structure that is contained in the unnamed union in the **PEP_WORK_INFORMATION** structure.

`PowerControl`

`CompleteIdleState`

`CompletePerfState`

`AcpiNotify`

`ControlMethodComplete`

Remarks

The **WorkInformation** member of the PEP_WORK structure is a pointer to a **PEP_WORK_INFORMATION** structure.

Requirements

PEP_WORK_TYPE

PEP_WORK_POWER_CONTROL structure

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_POWER_CONTROL** structure contains the parameters for a power control request that the platform extension plug-in (PEP) sends directly to a processor driver.

Syntax

```
typedef struct _PEP_WORK_POWER_CONTROL {
  POHANDLE DeviceHandle;
  LPCGUID  PowerControlCode;
  PVOID    RequestContext;
  PVOID    InBuffer;
  SIZE_T   InBufferSize;
  PVOID    OutBuffer;
  SIZE_T   OutBufferSize;
} PEP_WORK_POWER_CONTROL, *PPEP_WORK_POWER_CONTROL;
```

Members

`DeviceHandle`

A POHANDLE value that identifies the processor. The PEP received this handle in a previous PEP_DPM_REGISTER_DEVICE notification.

`PowerControlCode`

[in] A pointer to a GUID value that specifies the power control operation to perform.

`RequestContext`

A pointer to a PEP-defined context value. The PEP might use this value to uniquely identify a power control request message (in case the PEP issues multiple requests with the same control code to the same device).

`InBuffer`

[in] A pointer to a driver-allocated input buffer that contains the input parameters for this power control operation.

`InBufferSize`

[in] The size in bytes of the buffer pointed to by **InBuffer**.

`OutBuffer`

[in] A pointer to a driver-allocated output buffer to which the PEP writes the results of this power control operation.

`OutBufferSize`

[in] The size in bytes of the buffer pointed to by **OutBuffer**.

Remarks

The **PowerControl** member of the PEP_WORK_INFORMATION structure is a pointer to a **PEP_WORK_POWER_CONTROL** structure.

The PEP issues a power control request from a worker thread. The Windows power management framework (PoFx) forwards this request by calling the processor driver's PowerControlCallback routine, if the driver implements this routine.

Requirements

Minimum supported client	Supported starting with Windows 10.

PowerControlCallback

PEP_WORK_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PEP_WORK_TYPE** enumeration describes the type of work that the platform extension plug-in (PEP) is requesting.

Syntax

```
typedef enum _PEP_WORK_TYPE {
  PepWorkRequestPowerControl,
  PepWorkCompleteIdleState,
  PepWorkCompletePerfState,
  PepWorkAcpiNotify,
  PepWorkAcpiEvaluateControlMethodComplete,
  PepWorkMax
} PEP_WORK_TYPE, *PPEP_WORK_TYPE;
```

Constants

PepWorkRequestPowerControl	A request for the device driver to perform a custom power-control operation that uses a device-specific context that the PEP provides for the operation. The driver handles this request in its PowerControlCallback routine.
PepWorkCompleteIdleState	A notification to PoFx that the PEP has asynchronously completed the transition of a component to an idle state. PoFx previously initiated this transition by sending a PEP_DPM_NOTIFY_COMPONENT_IDLE_STATE notification to the PEP.
PepWorkCompletePerfState	A notification to PoFx that the PEP has asynchronously completed the transition of a component to a P-state. PoFx previously initiated this transition by sending a PEP_DPM_REQUEST_COMPONENT_PERF_STATE notification to the PEP.
PepWorkAcpiNotify	An ACPI Notify code to describe to PoFx a hardware event that the specified device has generated.
PepWorkAcpiEvaluateControlMethodComplete	A notification to PoFx that the PEP has asynchronously finished evaluating an ACPI control method. PoFx previously initiated the evaluation of this method by sending a PEP_NOTIFY_ACPI_EVALUATE_CONTROL_METHOD notification to the PEP.
PepWorkMax	Reserved for use by operating system.

Remarks

This enumeration is used by the PEP_WORK_INFORMATION structure to describe the type of work item that the PEP is requesting.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PowerControlCallback

PO_FX_CORE_DEVICE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_CORE_DEVICE** structure contains information about the power-state attributes of the components in a core system resource, and provides a software interface for power-managing these components.

Syntax

```
typedef struct _PO_FX_CORE_DEVICE {
  ULONG                                        Version;
  ULONG                                        ComponentCount;
  PPO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK    ComponentActiveConditionCallback;
  PPO_FX_COMPONENT_IDLE_CONDITION_CALLBACK      ComponentIdleConditionCallback;
  PPO_FX_COMPONENT_CRITICAL_TRANSITION_CALLBACK ComponentCriticalTransitionCallback;
  PPO_FX_COMPONENT_IDLE_STATE_CALLBACK          ComponentIdleStateCallback;
  PVOID                                        DeviceContext;
  PO_FX_COMPONENT                              Components[ANYSIZE_ARRAY];
} PO_FX_CORE_DEVICE, *PPO_FX_CORE_DEVICE;
```

Members

`Version`

The version number of this structure.

`ComponentCount`

The number of elements in the **Components** array at the end of this structure. This count includes all elements of the array, and includes both the first element, which is a member of this structure, and any additional elements that follow the end of this structure.

`ComponentActiveConditionCallback`

A pointer to a ComponentActiveConditionCallback callback routine. PoFx calls this routine to notify the driver that the specified component completed a transition from the idle condition to the active condition.

`ComponentIdleConditionCallback`

A pointer to a ComponentIdleConditionCallback callback routine. PoFx calls this routine to notify the driver that the specified component completed a transition from the active condition to the idle condition.

`ComponentCriticalTransitionCallback`

A pointer to a ComponentCriticalTransitionCallback callback routine. PoFx calls this routine to notify the driver that the specified component is about to make a transition between the idle condition and the active condition.

`ComponentIdleStateCallback`

A pointer to a ComponentIdleStateCallback callback routine. PoFx calls this routine to notify the driver of a pending change to the F*x* power state of the specified component.

`DeviceContext`

A pointer to a PEP-defined device context. PoFx supplies this pointer as the first parameter in calls to the *ComponentActiveConditionCallback*, *ComponentIdleConditionCallback*, *ComponentCriticalTransitionCallback*, and

ComponentIdleStateCallback routines. This context is opaque to PoFx.

`Components`

The first element in an array of PO_FX_COMPONENT structures. Each element in the array describes the power attributes of a component in the device. If the array contains more than one element, the additional elements immediately follow the end of the **PO_FX_CORE_DEVICE** structure. The number of elements in the array is specified in the **ComponentCount** member of the **PO_FX_CORE_DEVICE** structure.

Remarks

This structure is used by the PoFxRegisterCoreDevice routine.

A *core system resource* is a hardware device, such as a timer or an interrupt controller, that is managed by the Windows hardware abstraction layer (HAL).

For more information about component transitions between the active condition and the idle condition, see Component-Level Power Management.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_EXTENDED_ADDRESS structure.

Syntax

```
void PEP_ACPI_INITIALIZE_EXTENDED_IO_RESOURCE(
  BOOLEAN            ResourceUsage,
  UCHAR              Decode,
  BOOLEAN            IsMinFixed,
  BOOLEAN            IsMaxFixed,
  UCHAR              ISARanges,
  ULONGLONG          AddressGranularity,
  ULONGLONG          AddressMinimum,
  ULONGLONG          AddressMaximum,
  ULONGLONG          AddressTranslation,
  ULONGLONG          RangeLength,
  ULONGLONG          TypeSpecificAttributes,
  PUNICODE_STRING    DescriptorName,
  BOOLEAN            TranslationTypeNonStatic,
  BOOLEAN            TanslationSparseDensity,
  PPEP_ACPI_RESOURCE Resource
);
```

Parameters

`ResourceUsage`

This parameter is copied into the **GeneralFlags** member of the initialized PEP_ACPI_EXTENDED_ADDRESS structure.

`Decode`

When set, indicates that this bridge subtractively decodes the address. This applies to top level bridges only.

When not set, indicates that this bridge positively decodes this address.

`IsMinFixed`

When set, indicates that the minimum address is fixed.

`IsMaxFixed`

When set, indicates that the maximum address is fixed.

`ISARanges`

This parameter is copied into the **TypeSpecificFlags** member of the initialized PEP_ACPI_EXTENDED_ADDRESS structure.

`AddressGranularity`

A bit mask indicating which bits have been decoded.

`AddressMinimum`

For bridges that translate addresses, this indicates the minimum starting address on the secondary side of the bridge.

`AddressMaximum`

For bridges that translate addresses, this indicates the maximum starting address on the secondary side of the bridge.

`AddressTranslation`

For bridges that translate addresses across the bridge, this is the address on the primary side.

`RangeLength`

The length of the address range.

`TypeSpecificAttributes`

The type-specific attributes for this resource.

`DescriptorName`

The name of the resource descriptor.

`TranslationTypeNonStatic`

When true, indicates that the resource uses type translation. Otherwise, it uses type-static translation.

`TanslationSparseDensity`

When false, indicates that this is a dense translation. Otherwise, it is sparse.

`Resource`

This is cast to *PEP_ACPI_EXTENDED_ADDRESS.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)

See Also

PEP_ACPI_EXTENDED_ADDRESS

PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_EXTENDED_ADDRESS structure.

Syntax

```
void PEP_ACPI_INITIALIZE_EXTENDED_MEMORY_RESOURCE(
  BOOLEAN            ResourceUsage,
  UCHAR              Decode,
  BOOLEAN            IsMinFixed,
  BOOLEAN            IsMaxFixed,
  UCHAR              Cacheable,
  BOOLEAN            ReadWrite,
  ULONGLONG          AddressGranularity,
  ULONGLONG          AddressMinimum,
  ULONGLONG          AddressMaximum,
  ULONGLONG          AddressTranslation,
  ULONGLONG          RangeLength,
  ULONGLONG          TypeSpecificAttributes,
  PUNICODE_STRING    DescriptorName,
  UCHAR              MemoryRangeType,
  BOOLEAN            TranslationTypeNonStatic,
  PPEP_ACPI_RESOURCE Resource
);
```

Parameters

`ResourceUsage`

This parameter is copied into the **GeneralFlags** member of the initialized PEP_ACPI_EXTENDED_ADDRESS structure.

`Decode`

When set, indicates that this bridge subtractively decodes the address. This applies to top level bridges only.

When not set, indicates that this bridge positively decodes this address.

`IsMinFixed`

When set, indicates that the minimum address is fixed.

`IsMaxFixed`

When set, indicates that the maximum address is fixed.

`Cacheable`

The caching flag for the resource.

VALUE	MEANING

0	Indicates the memory is non-cacheable.
1	Indicates the memory is cacheable.
2	Indicates the memory is cacheable and supports write combining.
3	The memory is cacheable and prefetchable.

`ReadWrite`

When true, indicates that the resource is available for read/write access. Otherwise, it's read-only.

`AddressGranularity`

A bit mask indicating which bits have been decoded.

`AddressMinimum`

For bridges that translate addresses, this indicates the minimum starting address on the secondary side of the bridge.

`AddressMaximum`

For bridges that translate addresses, this indicates the maximum starting address on the secondary side of the bridge.

`AddressTranslation`

For bridges that translate addresses across the bridge, this is the address on the primary side.

`RangeLength`

The length of the address range.

`TypeSpecificAttributes`

The type-specific attributes for this resource.

`DescriptorName`

The name of the resource descriptor.

`MemoryRangeType`

This parameter identifies the type of memory range provided by this resource.

VALUE	MEANING
0	Address range memory: This range is available RAM usable by the operating system.
1	Address range reserved: This range of addresses is in use or reserved by the system and is not to be included in the allocatable memory pool of the operating system's memory manager.
2	Address range ACPI: ACPI Reclaim Memory. This range is available RAM usable by the OS after it reads the ACPI tables.

3	Address Range NVS: ACPI NVS Memory. This range of addresses is in use or reserved by the system and must not be used by the operating system. This range is required to be saved and restored across an NVS sleep.

`TranslationTypeNonStatic`

When true, indicates that the resource uses type translation. Otherwise, it uses type-static translation.

`Resource`

This is cast to *PEP_ACPI_EXTENDED_ADDRESS.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_GPIO_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_GPIO_INT_RESOURCE(
  KINTERRUPT_MODE      InterruptType,
  KINTERRUPT_POLARITY  LevelType,
  BOOLEAN              Shareable,
  BOOLEAN              CanWake,
  GPIO_PIN_CONFIG_TYPE PinConfig,
  USHORT               DebounceTimeout,
  UCHAR                ResourceSourceIndex,
  PUNICODE_STRING      ResourceSourceName,
  BOOLEAN              ResourceUsage,
  PUCHAR               VendorData,
  USHORT               VendorDataLength,
  PUSHORT              PinTable,
  UCHAR                PinCount,
  PPEP_ACPI_RESOURCE   Resource
);
```

Parameters

`InterruptType`

A KINTERRUPT_MODE enumeration value that identifies the interrupt type.

`LevelType`

A KINTERRUPT_POLARITY enumeration value that identifies how a device signals an interrupt request on an interrupt line.

`Shareable`

Indicates if the device can be shared.

`CanWake`

Indicates if the device can be woken from a low-power state.

`PinConfig`

A GPIO_PIN_CONFIG_TYPE enumeration value that identifies the GPIO pin configuration type.

`DebounceTimeout`

Specifies the hardware debounce wait time, in hundredths of milliseconds.

`ResourceSourceIndex`

This parameter should always be zero.

`ResourceSourceName`

This parameter should always be "ResourceConsumer."

`ResourceUsage`

Indicates if this device is in use.

`VendorData`

A pointer to a raw data buffer containing vendor-defined byte data to be decoded by the OS driver.

`VendorDataLength`

The size of the buffer in the *VendorData* partameter.

`PinTable`

A list of pin numbers on the resource.

`PinCount`

The number of pins described by the *PinTable* parameter.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_GPIO_RESOURCE.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_GPIO_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_GPIO_IO_RESOURCE(
  BOOLEAN                     Shareable,
  BOOLEAN                     CanWake,
  GPIO_PIN_CONFIG_TYPE        PinConfig,
  USHORT                      DebounceTimeout,
  USHORT                      DriveStrength,
  GPIO_PIN_IORESTRICTION_TYPE IoRestriction,
  UCHAR                       ResourceSourceIndex,
  PUNICODE_STRING             ResourceSourceName,
  BOOLEAN                     ResourceUsage,
  PUCHAR                      VendorData,
  USHORT                      VendorDataLength,
  PUSHORT                     PinTable,
  USHORT                      PinCount,
  PPEP_ACPI_RESOURCE          Resource
);
```

Parameters

`Shareable`

Indicates if the device can be shared.

`CanWake`

Indicates if the device can be woken from a low-power state.

`PinConfig`

A GPIO_PIN_CONFIG_TYPE enumeration value that identifies the GPIO pin configuration type.

`DebounceTimeout`

Specifies the hardware debounce wait time, in hundredths of milliseconds.

`DriveStrength`

`IoRestriction`

`ResourceSourceIndex`

This parameter should always be zero.

`ResourceSourceName`

This parameter should always be "ResourceConsumer."

`ResourceUsage`

Indicates if this device is in use.

`VendorData`

A pointer to a raw data buffer containing vendor-defined byte data to be decoded by the OS driver.

`VendorDataLength`

The size of the buffer in the *VendorData* partameter.

`PinTable`

A list of pin numbers on the resource.

`PinCount`

The number of pins described by the *PinTable* parameter.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_GPIO_RESOURCE.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows

PEP_ACPI_GPIO_RESOURCE

PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_INTERRUPT_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_INTERRUPT_RESOURCE(
  BOOLEAN             ResourceUsage,
  KINTERRUPT_MODE     EdgeLevel,
  KINTERRUPT_POLARITY InterruptLevel,
  BOOLEAN             ShareType,
  BOOLEAN             Wake,
  PULONG              PinTable,
  UCHAR               PinCount,
  PPEP_ACPI_RESOURCE  Resource
);
```

Parameters

`ResourceUsage`

Indicates if this device is in use.

`EdgeLevel`

A KINTERRUPT_MODE enumeration value that identifies the interrupt type.

`InterruptLevel`

A KINTERRUPT_POLARITY enumeration value that identifies how a device signals an interrupt request on an interrupt line.

`ShareType`

Indicates if the device can be shared.

`Wake`

Indicates if the device can be woken from a low-power state.

`PinTable`

A list of pin numbers on the resource.

`PinCount`

The number of pins described by the *PinTable* parameter.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_INTERRUPT_RESOURCE.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_INTERRUPT_RESOURCE

PEP_ACPI_INITIALIZE_IOPORT_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_IOPORT_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_IO_MEMORY_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_IOPORT_RESOURCE(
  UCHAR               Decode,
  USHORT              MinimumAddress,
  USHORT              MaximumAddress,
  UCHAR               Alignment,
  UCHAR               PortLength,
  PPEP_ACPI_RESOURCE Resource
);
```

Parameters

`Decode`

Specifies how to decode the resource address. If bit 0 is a 1, this indicates that the logical device decodes 16-bit addresses. If bit 0 is 0, this indicates that the logical device only decodes the first 10 bits of the address.

Bits 1 to 7 of this parameter are reserved and must be set to zero.

`MinimumAddress`

Specifies the minimum acceptable starting address for the IO range.

`MaximumAddress`

Specifies the maximum acceptable starting address for the IO range.

`Alignment`

Specifies the alignment granularity for the IO address assigned.

`PortLength`

Specifies the number of bytes in the IO range.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_IO_MEMORY_RESOURCE.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_INITIALIZE_MEMORY_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_MEMORY_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_IO_MEMORY_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_MEMORY_RESOURCE(
  UCHAR              ReadWrite,
  ULONG              MinimumAddress,
  ULONG              MaximumAddress,
  ULONG              Alignment,
  ULONG              MemorySize,
  PPEP_ACPI_RESOURCE Resource
);
```

Parameters

`ReadWrite`

If true, indicates that the resource is read/write. Otherwise, it's read-only.

`MinimumAddress`

Specifies the minimum acceptable starting address for the IO range.

`MaximumAddress`

Specifies the maximum acceptable starting address for the IO range.

`Alignment`

Specifies the alignment granularity for the memory address assigned.

`MemorySize`

Specifies the number of bytes in the memory range.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_IO_MEMORY_RESOURCE.

Return Value

This function does not return a value.

Requirements

PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_I2C_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_SPB_I2C_RESOURCE(
  USHORT              SlaveAddress,
  BOOLEAN             DeviceInitiated,
  ULONG               ConnectionSpeed,
  BOOLEAN             AddressingMode,
  PUNICODE_STRING     ResourceSource,
  UCHAR               ResourceSourceIndex,
  BOOLEAN             ResourceUsage,
  BOOLEAN             SharedMode,
  PCHAR               VendorData,
  USHORT              VendorDataLength,
  PPEP_ACPI_RESOURCE Resource
);
```

Parameters

`SlaveAddress`

The I2C bus address for this connection.

`DeviceInitiated`

If true, indicates that communication over this connection is initiated by the device.

`ConnectionSpeed`

The maximum speed, in hertz, supported by this connection.

`AddressingMode`

Indicates that this device is in addressing mode.

`ResourceSource`

The name of the serial bus controller device to which this connection descriptor applies. The name can be a fully qualified path, a relative path, or a simple name segment that utilizes the namespace search rules.

`ResourceSourceIndex`

This parameter should always be set to zero.

`ResourceUsage`

Indicates if the resource is in use.

`SharedMode`

Indicates if the resource is shared.

`VendorData`

A pointer to optional data that is specific to the serial bus connection type.

`VendorDataLength`

The length of the buffer pointed to by the *VendorData* parameter.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_SPB_I2C_RESOURCE.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows

PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_SPI_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_SPB_SPI_RESOURCE(
  USHORT              DeviceSelection,
  UCHAR               DeviceSelectionPolarity,
  UCHAR               WireMode,
  UCHAR               DataBitLength,
  BOOLEAN             SlaveMode,
  ULONG               ConnectionSpeed,
  UCHAR               ClockPolarity,
  UCHAR               ClockPhase,
  PUNICODE_STRING     ResourceSource,
  UCHAR               ResourceSourceIndex,
  BOOLEAN             ResourceUsage,
  BOOLEAN             SharedMode,
  PCHAR               VendorData,
  USHORT              VendorDataLength,
  PPEP_ACPI_RESOURCE Resource
);
```

Parameters

`DeviceSelection`

The device selection value. This value is specific to the device and may refer to a chip-select line, GPIO line, or other line selection mechanism.

`DeviceSelectionPolarity`

The polarity of the clock. If zero, this indicates the clock is low during the first phase. If 1, this indicates the clock is high during the first phase.

`WireMode`

When zero, indicates that this device produces and consumes this resource. Otherwise, this device only consumes this resource.

`DataBitLength`

The size, in bits, of the smallest unit of transfer.

`SlaveMode`

Indicates if the resource is operating in slave mode.

`ConnectionSpeed`

The maximum speed, in hertz, supported by this connection.

`ClockPolarity`

The polarity of the clock. If zero, this indicates the clock is low during the first phase. If 1, this indicates the clock is high during the first phase.

`ClockPhase`

The phase of the clock pulse on which to capture data.

`ResourceSource`

The name of the serial bus controller device to which this connection descriptor applies. The name can be a fully qualified path, a relative path, or a simple name segment that utilizes the namespace search rules.

`ResourceSourceIndex`

This parameter should always be set to zero.

`ResourceUsage`

Indicates if the resource is in use.

`SharedMode`

Indicates if the resource is shared.

`VendorData`

A pointer to optional data that is specific to the serial bus connection type.

`VendorDataLength`

The length of the buffer pointed to by the *VendorData* parameter.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_SPB_SPI_RESOURCE.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE function

1/25/2019 • 2 minutes to read • Edit Online

The **PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE** function initializes a platform extension plug-in's (PEP) PEP_ACPI_SPB_UART_RESOURCE structure.

Syntax

```
void PEP_ACPI_INITIALIZE_SPB_UART_RESOURCE(
  ULONG              BaudRate,
  UCHAR              BitsPerByte,
  UCHAR              StopBits,
  UCHAR              LinesInUse,
  UCHAR              IsBigEndian,
  UCHAR              Parity,
  UCHAR              FlowControl,
  USHORT             RxSize,
  USHORT             TxSize,
  PUNICODE_STRING    ResourceSource,
  UCHAR              ResourceSourceIndex,
  BOOLEAN            ResourceUsage,
  BOOLEAN            SharedMode,
  PCHAR              VendorData,
  USHORT             VendorDataLength,
  PPEP_ACPI_RESOURCE Resource
);
```

Parameters

`BaudRate`

Specifies the baud rate of the connection.

`BitsPerByte`

Specifies the number of bits per byte of data.

`StopBits`

Specifies the stop bits used in the connection.

`LinesInUse`

Flag indicating the serial lines that are enabled. A value of 1 in the bit positions indicates that the line is enabled.

BIT	MEANING
0	This bit is reserved and must be set to zero.
1	This bit is reserved and must be set to zero.

2	Data Carrier Detect (DTD)
3	Ring Indicator (RI)
4	Data Set Ready (DSR)
5	Data Terminal Ready (DTR)
6	Clear to Send (CTS)
7	Request to Send (RTS)

`IsBigEndian`

Indicates if the most significant bits of data are in the lowest address.

`Parity`

Specifies the parity of the connection.

VALUE	MEANING
0x0 0	None
0x0 1	Even
0x0 2	Odd
0x0 3	Mark
0x0 4	Space

`FlowControl`

Specifies the type of flow control used by the connection.

`RxSize`

Specifies the maximum receive buffer size, in bytes, that is supported by this connection.

`TxSize`

Specifies the maximum transmit buffer size, in bytes, that is supported by this connection.

`ResourceSource`

The name of the serial bus controller device to which this connection descriptor applies. The name can be a fully qualified path, a relative path, or a simple name segment that utilizes the namespace search rules.

`ResourceSourceIndex`

This parameter should always be zero.

`ResourceUsage`

Indicates if this resource is in use.

`SharedMode`

Indicates if this resource is shared.

`VendorData`

A pointer to optional data that is specific to the serial bus connection type.

`VendorDataLength`

The length of the buffer pointed to by the *VendorData* parameter.

`Resource`

A pointer to the resource. The structure behind the pointer is of type PEP_ACPI_SPB_UART_RESOURCE.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)

PEP_ACPI_SPB_UART_RESOURCE

PEPCALLBACKNOTIFYACPI callback function

1/25/2019 • 2 minutes to read • Edit Online

An *AcceptAcpiNotification* event callback routine handles ACPI notifications from the Windows power management framework (PoFx).

Syntax

```
PEPCALLBACKNOTIFYACPI Pepcallbacknotifyacpi;

BOOLEAN Pepcallbacknotifyacpi(
  ULONG Notification,
  PVOID Data
)
{...}
```

Parameters

`Notification`

The ACPI notification ID. This parameter specifies the type of ACPI notification that PoFx is sending. For a list of ACPI notification IDs, see ACPI notifications.

`Data`

A pointer to a PoFx-allocated structure that contains the input and/or output data for this notification. The type of this structure depends on the notification ID specified by *Notification*. For a list of the structure types that are defined for the various ACPI notification IDs, see ACPI notifications.

Return Value

The *AcceptAcpiNotification* routine must return TRUE if it handles the notification, or FALSE if it does not.

Remarks

This routine is implemented by the platform extension plug-in (PEP) for a device. The **AcceptAcpiNotification** member of the PEP_INFORMATION structure is a pointer to an *AcceptAcpiNotification* routine. The PEP calls the PoFxRegisterPlugin or PoFxRegisterPluginEx routine to register the PEP's *AcceptAcpiNotification* routine with PoFx.

The IRQL at which the PEP's *AcceptAcpiNotification* routine is called varies according to the type of notification that is being sent. The notification type is specified by the *Notification* parameter. For more information about the IRQL at which each notification type is sent, see the individual reference pages under ACPI notifications.

Requirements

Minimum supported client	Supported starting with Windows 10.

Target Platform	Windows
Header	pepfx.h (include Pep_x.h)
IRQL	"<= HIGH_LEVEL"

See Also

PEP_INFORMATION

PoFxRegisterPlugin

PoFxRegisterPluginEx

PEPCALLBACKNOTIFYDPM callback function

1/25/2019 • 2 minutes to read • Edit Online

An *AcceptDeviceNotification* event callback routine handles device power management (DPM) notifications from the Windows power management framework (PoFx).

Syntax

```
PEPCALLBACKNOTIFYDPM Pepcallbacknotifydpm;

BOOLEAN Pepcallbacknotifydpm(
  ULONG Notification,
  PVOID Data
)
{...}
```

Parameters

`Notification`

The DPM notification ID. This parameter specifies the type of DPM notification that PoFx is sending. For a list of DPM notification IDs, see Device power management (DPM) notifications.

`Data`

A pointer to a PoFx-allocated structure that contains the input and/or output data for this notification. The type of this structure depends on the notification ID specified by *Notification*. For a list of the structure types that are defined for the various DPM notification IDs, see Device power management (DPM) notifications.

Return Value

The *AcceptDeviceNotification* routine must return TRUE if it handles the notification, or FALSE if it does not.

Remarks

This routine is implemented by the platform extension plug-in (PEP) for a device. The **AcceptDeviceNotification** member of the PEP_INFORMATION structure is a pointer to an *AcceptDeviceNotification* routine. The PEP calls the PoFxRegisterPlugin or PoFxRegisterPluginEx routine to register the PEP's *AcceptDeviceNotification* routine with PoFx.

PoFx calls this routine to send a DPM notification to the PEP. In this call, the *Notification* parameter specifies the type of notification, and the *Data* parameter points to a data structure of the type that is associated with this notification. For a list of DPM notification IDs and their associated structure types, see Device power management (DPM) notifications.

DPM notifications inform the PEP about various system, device, or componentÂ–-level events, or pass requests from the device driver to the PEP.

The *AcceptDeviceNotification* routine does not have to accept every request from the device driver—for example, it can ignore idle residency hints. However, the PEP must understand and accept most device power management notifications even if the PEP chooses not to act on them. The PEP must refuse to handle (by returning FALSE) every notification that it does not recognize.

The *AcceptDeviceNotification* routine can be called at IRQL <= DISPATCH_LEVEL. The IRQL at which the PEP's *AcceptAcpiNotification* routine is called varies according to the type of notification that is being sent. The notification type is specified by the *Notification* parameter. For more information, see the individual reference pages under Device power management (DPM) notifications.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)
IRQL	"<= DISPATCH_LEVEL"

PoFxRegisterPlugin

PoFxRegisterPluginEx

PEPCALLBACKNOTIFYPPM callback function

1/25/2019 • 2 minutes to read • Edit Online

An *AcceptProcessorNotification* event callback routine handles processor power management (PPM) notifications from the Windows power management framework (PoFx).

Syntax

```
PEPCALLBACKNOTIFYPPM Pepcallbacknotifyppm;

BOOLEAN Pepcallbacknotifyppm(
  PEPHANDLE Handle,
  ULONG Notification,
  PVOID Data
)
{...}
```

Parameters

`Handle`

The device handle for the PEP for the target processor. If **NULL**, the notification does not target a specific processor.

`Notification`

The PPM notification ID. This parameter specifies the type of PPM notification that PoFx is sending. For a list of PPM notification IDs, see Processor power management (PPM) notifications.

`Data`

A pointer to a PoFx-allocated structure that contains the input and/or output data for this notification. The type of this structure depends on the notification ID specified by *Notification*. For a list of the structure types that are defined for the various PPM notification IDs, see Processor power management (PPM) notifications.

Return Value

The *AcceptProcessorNotification* routine must return TRUE if it handles the notification, or FALSE if it does not.

Remarks

This routine is implemented by the platform extension plug-in (PEP) for a processor. The **AcceptProcessorNotification** member of the PEP_INFORMATION structure is a pointer to an *AcceptProcessorNotification* routine. The PEP calls the PoFxRegisterPlugin or PoFxRegisterPluginEx routine to register the PEP's *AcceptProcessorNotification* routine with PoFx.

The IRQL at which the PEP's *AcceptProcessorNotification* routine is called varies according to the type of notification that is being sent. The context in which this interface is called ranges from PASSIVE_LEVEL to HIGH_LEVEL with interrupts disabled. For more information about the IRQL at which each notification type is sent, see the individual reference pages under Processor power management (PPM) notifications.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)
IRQL	PASSIVE_LEVEL to HIGH_LEVEL

PoFxRegisterPluginEx

PEPCALLBACKPOWERONCRASHDUMPDEVICE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *PowerOnDumpDeviceCallback* callback routine turns on the crash-dump device.

Syntax

```
PEPCALLBACKPOWERONCRASHDUMPDEVICE Pepcallbackpoweroncrashdumpdevice;

BOOLEAN Pepcallbackpoweroncrashdumpdevice(
  PPEP_CRASHDUMP_INFORMATION CrashdumpInformation
)
{...}
```

Parameters

`CrashdumpInformation`

A pointer to a PEP_CRASHDUMP_INFORMATION structure that contains information about the crash-dump device.

Return Value

This routine returns TRUE if it succeeds in turning on power to the crash-dump device. Otherwise, it returns FALSE.

Remarks

This routine is implemented by the platform extension plug-in (PEP). The routine handles requests from the Windows kernel to turn on the crash-dump device so that a crash dump can be saved to disk.

The PEP registers its *PowerOnDumpDeviceCallback* routine in response to a PEP_DPM_REGISTER_CRASHDUMP_DEVICE notification from the Windows power management framework (PoFx).

The *PowerOnDumpDeviceCallback* routine is called at IRQL = HIGH_LEVEL with interrupts disabled. Thus, this routine cannot use timers, events, or any synchronization primitives other than spin locks.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)

IRQL	Called at HIGH_LEVEL.

PEP_DPM_REGISTER_CRASHDUMP_DEVICE

POFXCALLBACKCRITICALRESOURCE callback function

1/25/2019 • 2 minutes to read • Edit Online

The **TransitionCriticalResource** routine changes the active/inactive state of a core system component.

Syntax

```
POFXCALLBACKCRITICALRESOURCE Pofxcallbackcriticalresource;

void Pofxcallbackcriticalresource(
  POHANDLE DeviceHandle,
  ULONG Component,
  BOOLEAN Active
)
{...}
```

Parameters

`DeviceHandle`

A POHANDLE value that represents the registration of the device with PoFx. The PEP previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the device's driver stack registered the device with PoFx.

`Component`

[in] The index that identifies the component. This member is an index into the **Components** array in the PEP_DEVICE_REGISTER_V2 structure that the PEP previously supplied in response to the **PEP_DPM_REGISTER_DEVICE** notification for this device. If the **Components** array contains N elements, component indexes range from 0 to N−1.

`Active`

Whether to transition the device from inactive to active, or vice versa. Set to TRUE to transition the device from inactive to active, or to FALSE to transition the device from active to inactive.

Return Value

None

Remarks

This routine is implemented by the power management framework (PoFx) and is called by the platform extension plug-in (PEP). The **TransitionCriticalResource** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to an **TransitionCriticalResource** routine.

A PEP can call this routine at IRQL <= HIGH_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)
IRQL	"<= HIGH_LEVEL"

PEP_KERNEL_INFORMATION_STRUCT_V3

POFXCALLBACKENUMERATEUNMASKEDINTERRUPTS callback function

1/25/2019 • 2 minutes to read • Edit Online

The **EnumerateUnmaskedInterrupts** routine enumerates interrupt sources whose interrupts are unmasked and enabled.

Syntax

```
POFXCALLBACKENUMERATEUNMASKEDINTERRUPTS Pofxcallbackenumerateunmaskedinterrupts;

NTSTATUS Pofxcallbackenumerateunmaskedinterrupts(
  POHANDLE PluginHandle,
  ULONG EnumerateFlags,
  PPO_ENUMERATE_INTERRUPT_SOURCE_CALLBACK Callback,
  PVOID CallbackContext,
  PPEP_UNMASKED_INTERRUPT_INFORMATION InterruptInformation
)
{...}
```

Parameters

`PluginHandle`

A POHANDLE value. If non-NULL, this parameter is a handle that identifies the platform extension plug-in (PEP), in which case **EnumerateUnmaskedInterrupts** enumerates only interrupts that are managed by this PEP. If this parameter is NULL, **EnumerateUnmaskedInterrupts** enumerates *all* interrupts in the hardware platform that are unmasked and enabled.

`EnumerateFlags`

No flags are currently defined. Set this parameter to PEP_ENUMERATE_UNMASKED_INTERRUPT_FLAGS_NONE (0x0).

`Callback`

A pointer to a caller-implemented EnumerateInterruptSource callback routine. This callback routine is called once for each interrupt source whose interrupt is unmasked. These callbacks occur synchronously before the **EnumerateUnmaskedInterrupts** routine returns.

`CallbackContext`

A pointer to a callback context. This pointer is passed as a parameter to the *EnumerateInterruptSource* callback routine pointed to by the *Callback* parameter. The contents of the callback context are PEP-defined, and are opaque to the power management framework (PoFx).

`InterruptInformation`

A pointer to a caller-allocated buffer whose size is at least **sizeof**(PEP_UNMASKED_INTERRUPT_INFORMATION) bytes. **EnumerateUnmaskedInterrupts** will use this buffer to transfer interrupt information to the PEP during calls to the PEP's *EnumerateInterruptSource* callback routine.

Return Value

EnumerateUnmaskedInterrupts returns STATUS_SUCCESS if the call successfully enumerates the interrupts. Possible error return values include the following status code.

RETURN VALUE	DESCRIPTION
STA TUS _IN VAL ID_P ARA MET ER	The **Size** or **Version** member of the **PEP_UNMASKED_INTERRUPT_INFORMATION** structure contains an invalid value.

Remarks

This routine is implemented by PoFx and is called by the PEP. The **EnumerateUnmaskedInterrupts** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to an **EnumerateUnmaskedInterrupts** routine.

Before the platform enters a system power state in which the interrupt controllers are power-gated, the PEP can call **EnumerateUnmaskedInterrupts** to get the information it needs to properly configure wake-up controllers for interrupts that are to remain unmasked.

The PEP can call this routine at IRQL <= HIGH_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)
IRQL	"<= HIGH_LEVEL"

PEP_KERNEL_INFORMATION_STRUCT_V3

PEP_UNMASKED_INTERRUPT_INFORMATION

POFXCALLBACKPLATFORMIDLEVETO callback function

1/25/2019 • 2 minutes to read • Edit Online

The **PlatformIdleVeto** routine increments or decrements the veto count for a veto code for a platform idle state.

Syntax

```
POFXCALLBACKPLATFORMIDLEVETO Pofxcallbackplatformidleveto;

NTSTATUS Pofxcallbackplatformidleveto(
  POHANDLE ProcessorHandle,
  ULONG PlatformState,
  ULONG VetoReason,
  BOOLEAN Increment
)
{...}
```

Parameters

`ProcessorHandle`

A POHANDLE value that represents the registration of the processor (as a device) with power management framework (PoFx). The platform extension plug-in (PEP) previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the processor had been registered with PoFx.

`PlatformState`

The index of the platform idle state whose veto count is being incremented or decremented. The PEP previously specified the supported platform idle states in response to a PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification. If the PEP specified N platform idle states, valid platform idle state indexes range from 0 to N–1.

`VetoReason`

A PEP-defined veto code that indicates why the platform idle state cannot be entered. The PEP previously specified the number of supported veto reasons in response to a PEP_NOTIFY_PPM_QUERY_VETO_REASONS notification. If the PEP specified M veto reasons, valid veto codes range from 1 to M.

`Increment`

Whether to increment or decrement the veto count. Set to TRUE to increment the veto count for this veto reason, or to FALSE to decrement the count.

Return Value

PlatformIdleVeto returns STATUS_SUCCESS if the call successfully increments or decrements the veto count. Possible error return values include the following status code.

RETURN VALUE	DESCRIPTION

STA TUS _NO T_I MPL EME NTE D	Indicates that the **PlatformIdleVeto** routine is not implemented for this processor.

Remarks

This routine is implemented by the PoFx and is called by the PEP. The **PlatformIdleVeto** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to a **PlatformIdleVeto** routine.

After the PEP handles the PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification, each platform idle state starts with a veto count of zero for all veto codes. The PEP can increment the veto count of a veto code to prevent the operating system from transitioning the platform to this idle state. The PEP decrements the veto count when the veto reason that caused the count to be incremented is no longer in effect. Only after the count for all veto codes has decremented to zero is the operating system allowed to transition the platform to this idle state.

This routine must be called at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)
IRQL	PASSIVE_LEVEL

PEP_NOTIFY_PPM_QUERY_VETO_REASONS

POFXCALLBACKPROCESSORHALT callback function

1/25/2019 • 3 minutes to read • Edit Online

The **ProcessorHalt** routine prepares the processor to be halted.

Syntax

```
POFXCALLBACKPROCESSORHALT Pofxcallbackprocessorhalt;

NTSTATUS Pofxcallbackprocessorhalt(
  ULONG Flags,
  PVOID Context,
  PPROCESSOR_HALT_ROUTINE Halt
)
{...}
```

Parameters

`Flags`

Flags that indicate the properties of the idle state that the processor will enter. The *Flags* parameter is set to zero or to the bitwise-OR of one or more of the following flag bits.

FLAG NAME	VALUE	DESCRIPTION
PROCESSOR_HALT_CACHE_FLUSH_OVERRIDE	0x01	The PEP's *Halt* callback routine is responsible for flushing the processor's caches. If this flag is not set, **ProcessorHalt** will flush the caches on entry to the processor idle state, and will invalidate the caches on exit from this state.
PROCESSOR_HALT_CACHE_COHERENT	0x02	Prepare the processor to enter an idle state in which the processor's caches will remain coherent.
PROCESSOR_HALT_CONTEXT_RETAINED	0x04	Prepare the processor to enter an idle state in which the processor's thread context will be preserved.
PROCESSOR_HALT_RETURN_NOT_SAFE	0x08	The PEP's *Halt* callback routine is guaranteed to not return. Set this flag if the *Halt* callback transitions the processor to a context-losing, power-gated state that cannot be canceled by hardware. When this flag is set, the operating system will treat a return from the *Halt* callback as a fatal error.
PROCESSOR_HALT_VIA_PSCI_CPU_SUSPEND	0x16	

`Context`

A pointer to a PEP-defined processor-halt context. This pointer is passed as a parameter to the *Halt* callback routine. This context is opaque to the Windows power management framework (PoFx).

`Halt`

A pointer to a PEP-implemented *Halt* callback routine. PoFx calls this routine after preparations to halt the processor have been completed. During this callback, the PEP is expected to transition the processor to the *halted* state.

Return Value

ProcessorHalt returns STATUS_SUCCESS if the processor is successfully prepared to be halted. Possible error return values include the following status code.

RETURN VALUE	DESCRIPTION
STA TUS _IN VAL ID_P ARA MET ER	The *Halt* parameter is NULL; or an invalid flag value was specified in *Flags*; or *Flags* contains an illegal combination of flag bits. For more information, see Remarks.
STA TUS _UN SUC CES SFU L	The PEP's *Halt* callback routine unexpectedly returned from an idle state in which the processor's hardware context was not preserved.

Remarks

This routine is implemented by the power management framework (PoFx) and is called by the platform extension plug-in (PEP). The **ProcessorHalt** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to a **ProcessorHalt** routine.

Before halting the processor, the PEP calls the **ProcessorHalt** routine to give PoFx an opportunity to save the processor's hardware context. If necessary, **ProcessorHalt** saves this state internally in PoFx so that the state can later be restored when the processor exits the idle state. After preparing the processor to enter the idle state, **ProcessorHalt** calls the PEP's *Halt* callback routine to halt the processor.

As part of the PEP's handling of a PEP_NOTIFY_PPM_IDLE_EXECUTE notification, the PEP must transition the processor to the idle state that the PEP has selected. The following are the two ways to enter the processor idle state:

- For a processor idle state in which the processor's caches remain coherent so that all system and processor state is maintained, the PEP can enter the idle state directly without first calling **ProcessorHalt**.
- For a processor idle state in which the processor's caches might not remain coherent, or an idle state in which the processor hardware context is not preserved, the PEP must call **ProcessorHalt** before transitioning the processor to the idle state.

The following combinations of flag bits are illegal:

- PROCESSOR_HALT_CONTEXT_RETAINED = 1 and PROCESSOR_HALT_RETURN_NOT_SAFE = 1

  The PEP's *Halt* callback routine must return from any state in which context is retained.

- PROCESSOR_HALT_CACHE_FLUSH_OVERRIDE = 1 and PROCESSOR_HALT_CACHE_COHERENT = 1

  The cache-flush-override flag should be set only if entering an idle state that is not cache coherent.

- PROCESSOR_HALT_CACHE_FLUSH_OVERRIDE = 0 and PROCESSOR_HALT_CACHE_COHERENT = 0

  The cache-flush-override flag must be set for any non-cache coherent halt.

- PROCESSOR_HALT_CONTEXT_RETAINED = 0 and PROCESSOR_HALT_CACHE_COHERENT = 1

  Any idle states that lose processor hardware context (and therefore use the multiprocessor parking protocol to exit the idle state and return control to the operating system) are not cache-coherent states.

If the *Flags* parameter contains an illegal combination of flag bits, **ProcessorHalt** fails and returns STATUS_INVALID_PARAMETER.

The PEP can call this routine at IRQL <= HIGH_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)
IRQL	"<= HIGH_LEVEL"

See Also

POFXCALLBACKPROCESSORIDLEVETO callback function

1/25/2019 • 2 minutes to read • Edit Online

The **ProcessorIdleVeto** routine increments or decrements the veto count for a veto code for a processor idle state.

Syntax

```
POFXCALLBACKPROCESSORIDLEVETO Pofxcallbackprocessoridleveto;

NTSTATUS Pofxcallbackprocessoridleveto(
  POHANDLE ProcessorHandle,
  ULONG ProcessorState,
  ULONG VetoReason,
  BOOLEAN Increment
)
{...}
```

Parameters

`ProcessorHandle`

A POHANDLE value that represents the registration of the processor (as a device) with power management framework (PoFx). The platform extension plug-in (PEP) previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the processor had been registered with PoFx.

`ProcessorState`

The index of the processor idle state whose veto count is being incremented or decremented. The PEP previously specified the supported processor idle states in response to a PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification. If the PEP specified N processor idle states, valid processor idle state indexes range from 0 to N–1.

`VetoReason`

A PEP-defined veto code that indicates why the processor idle state cannot be entered. The PEP previously specified the supported veto reasons in response to a PEP_NOTIFY_PPM_QUERY_VETO_REASONS notification. If the PEP specified M veto reasons, valid veto codes range from 1 to M.

`Increment`

Whether to increment or decrement the veto count. Set to TRUE to increment the veto count for this veto reason, or to FALSE to decrement the count.

Whether to increment or decrement the veto count. Set to TRUE to increment the veto count for this veto reason, or to FALSE to decrement the count.

Return Value

This routine does not return a value.

Remarks

This routine is implemented by the power management framework (PoFx) and is called by the platform extension plug-in (PEP). The **ProcessorIdleVeto** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to an **ProcessorIdleVeto** routine.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)

POFXCALLBACKREQUESTCOMMON callback function

1/25/2019 • 2 minutes to read • Edit Online

The **RequestCommon** routine is a generic request handler.

Syntax

```
POFXCALLBACKREQUESTCOMMON Pofxcallbackrequestcommon;

NTSTATUS Pofxcallbackrequestcommon(
  ULONG RequestId,
  PVOID Data
)
{...}
```

Parameters

`RequestId`

A request ID that specifies the operation being requested.

`Data`

A pointer to a data structure that contains the input data and/or result data for the request specified by the *RequestId* parameter.

Return Value

RequestCommon returns STATUS_SUCCESS if the request is successfully handled. Otherwise, it returns an appropriate error status code.

Remarks

This routine is implemented by the power management framework (PoFx) and is called by the platform extension plug-in (PEP). The **RequestCommon** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to an **RequestCommon** routine.

A PEP can call this routine at IRQL <= HIGH_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)

IRQL	"<= HIGH_LEVEL"

PEP_KERNEL_INFORMATION_STRUCT_V3

POFXCALLBACKREQUESTINTERRUPT callback function

1/25/2019 • 2 minutes to read • Edit Online

The **RequestInterrupt** routine requests that the operating system replay an edge-triggered interrupt that might have been lost while the hardware platform was in a low-power state.

Syntax

```
POFXCALLBACKREQUESTINTERRUPT Pofxcallbackrequestinterrupt;

NTSTATUS Pofxcallbackrequestinterrupt(
  ULONG Gsiv
)
{...}
```

Parameters

`Gsiv`

The global system interrupt vector (GSIV) number that identifies this interrupt. The ACPI firmware assigns GSIV numbers to all primary interrupt lines. For secondary (GPIO) interrupt lines, the GSIV number is dynamically assigned by the operating system.

Return Value

RequestInterrupt returns STATUS_SUCCESS if the specified interrupt is successfully replayed. Possible error return values include the following status code.

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	Not a valid GSIV number.

Remarks

This routine is implemented by the power management framework (PoFx) and is called by the platform extension plug-in (PEP). The **RequestInterrupt** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to an **RequestInterrupt** routine.

Assertion of an edge-triggered interrupt signal is transient in nature and can be lost if the power to a primary interrupt controller is gated off when the interrupt occurs. In contrast, a level-triggered interrupt signal is expected

to remain asserted until it can be serviced.

A PEP can call this routine at IRQL <= HIGH_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)
IRQL	"<= HIGH_LEVEL"

POFXCALLBACKREQUESTWORKER callback function

1/25/2019 • 2 minutes to read • Edit Online

The **RequestWorker** routine is called by a platform extension plug-in (PEP) to inform the Windows power management framework (PoFx) that the platform extension plug-in (PEP) has a work request to submit on behalf of the specified device.

Syntax

```
POFXCALLBACKREQUESTWORKER Pofxcallbackrequestworker;

void Pofxcallbackrequestworker(
  POHANDLE PluginHandle
)
{...}
```

Parameters

`PluginHandle`

A POHANDLE value that represents the registration of the device with PoFx. The PEP previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the device's driver stack registered the device with PoFx.

Return Value

None.

Remarks

This routine is implemented by PoFx and is called by the PEP. The **RequestWorker** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to a **RequestWorker** routine.

Each time the PEP calls this routine, PoFx responds by sending a PEP_DPM_WORK notification to the PEP. This notification might be delayed if a worker thread is not immediately available to process the work request.

A PEP can call this routine at IRQL <= DISPATCH_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)
IRQL	"<= DISPATCH_LEVEL"

POFXCALLBACKUPDATEPLATFORMIDLESTATE callback function

1/25/2019 • 2 minutes to read • Edit Online

The **UpdatePlatformIdleState** routine is called by the platform extension plug-in (PEP) to update the properties of the specified platform idle state.

Syntax

```
POFXCALLBACKUPDATEPLATFORMIDLESTATE Pofxcallbackupdateplatformidlestate;

NTSTATUS Pofxcallbackupdateplatformidlestate(
  POHANDLE ProcessorHandle,
  ULONG PlatformState,
  PPEP_PLATFORM_IDLE_STATE_UPDATE Update
)
{...}
```

Parameters

`ProcessorHandle`

A POHANDLE value that represents the registration of the processor (as a device) with the Windows power management framework (PoFx). The PEP previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the processor had been registered with PoFx.

`PlatformState`

An index that identifies the platform idle state whose properties are to be updated. In response to a previous PEP_NOTIFY_PPM_QUERY_PLATFORM_STATES notification, the PEP specified the number of supported platform idle states. If the PEP specified N platform idle states, valid platform idle state indexes range from 0 to N-1. In response to a previous PEP_NOTIFY_PPM_QUERY_PLATFORM_STATE notification, the PEP specified the properties of this platform idle state.

`Update`

A pointer to a PEP_PLATFORM_IDLE_STATE_UPDATE structure that contains the updated properties of the platform idle state.

Return Value

UpdatePlatformIdleState returns STATUS_SUCCESS if it successfully updates the properties of the platform idle state. Possible error return values include the following status codes.

RETURN VALUE	DESCRIPTION

STA TUS _NO T_S UPP ORT ED	The version number in the **PEP_PLATFORM_IDLE_STATE_UPDATE** structure is not a supported value.
STA TUS _NO T_I MPL EME NTE D	The **UpdatePlatformIdleState** routine is not implemented for this processor.

Remarks

This routine is implemented by PoFx and is called by the PEP. The **UpdatePlatformIdleState** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to an **UpdatePlatformIdleState** routine.

The PEP must wait until after it has completed all PEP_NOTIFY_PPM_QUERY_PLATFORM_STATE notifications to call the **UpdatePlatformIdleState** routine.

The **UpdatePlatformIdleState** routine must be called at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)
IRQL	PASSIVE_LEVEL

See Also

PEP_PLATFORM_IDLE_STATE_UPDATE

POFXCALLBACKUPDATEPROCESSORIDLESTATE callback function

1/25/2019 • 2 minutes to read • Edit Online

The **UpdateProcessorIdleState** routine is called by the platform extension plug-in (PEP) to update the properties of the specified processor idle state.

Syntax

```
POFXCALLBACKUPDATEPROCESSORIDLESTATE Pofxcallbackupdateprocessoridlestate;

NTSTATUS Pofxcallbackupdateprocessoridlestate(
  POHANDLE ProcessorHandle,
  ULONG ProcessorState,
  PPEP_PROCESSOR_IDLE_STATE_UPDATE Update
)
{...}
```

Parameters

`ProcessorHandle`

A POHANDLE value that represents the registration of the processor (as a device) with the Windows power management framework (PoFx). The PEP previously received this handle from PoFx during the PEP_DPM_REGISTER_DEVICE notification that informed the PEP that the processor had been registered with PoFx.

`ProcessorState`

An index that identifies the processor idle state whose properties are to be updated. In response to a previous PEP_NOTIFY_PPM_QUERY_IDLE_STATES_V2 notification, the PEP specified the number of supported processor idle states and the properties of these states. If the PEP specified N processor idle states, valid processor idle state indexes range from 0 to N-1.

`Update`

A pointer to a PEP_PROCESSOR_IDLE_STATE_UPDATE structure that contains the updated properties of the processor idle state.

Return Value

UpdateProcessorIdleState returns STATUS_SUCCESS if it successfully updates the properties of the processor idle state. Possible error return values include the following status codes.

RETURN VALUE	DESCRIPTION

STA TUS _NO T_S UPP ORT ED	The version number in the **PEP_PROCESSOR_IDLE_STATE_UPDATE** structure is not a supported value.
STA TUS _NO T_I MPL EME NTE D	The **UpdateProcessorIdleState** routine is not implemented for this processor.

Remarks

This routine is implemented by PoFx and is called by the PEP. The **UpdateProcessorIdleState** member of the PEP_KERNEL_INFORMATION_STRUCT_V3 structure is a pointer to an **UpdateProcessorIdleState** routine.

The **UpdateProcessorIdleState** routine must be called at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)
IRQL	PASSIVE_LEVEL

PEP_DPM_REGISTER_DEVICE

PEP_KERNEL_INFORMATION_STRUCT_V3

PEP_PROCESSOR_IDLE_STATE_UPDATE

PoFxRegisterCoreDevice function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxRegisterCoreDevice** routine registers a new core system resource with the Windows power management framework (PoFx).

Syntax

```
NTSTATUS PoFxRegisterCoreDevice(
  PCUNICODE_STRING   Id,
  PPO_FX_CORE_DEVICE Device,
  POHANDLE           *Handle
);
```

Parameters

`Id`

A string that uniquely identifies the core system resource. This member is a pointer to a UNICODE_STRING structure that contains a device identification string.

`Device`

A pointer to a PO_FX_CORE_DEVICE structure that describes the power characteristics of the core system resource.

`Handle`

A pointer to a location to which the routine writes a POHANDLE value. This handle represents the registration of the core system resource with PoFx.

Return Value

PoFxRegisterCoreDevice returns STATUS_SUCCESS if the call successfully registers the PEP. Possible error return values include the following status codes.

RETURN VALUE	DESCRIPTION
STA TUS _IN VAL ID_P ARA MET ER	The component count for this device is zero, or the **PO_FX_CORE_DEVICE** structure contains an invalid version number, or the **ComponentCriticalTransitionCallback** member of this structure contains an invalid function pointer.

STA TUS _INS UFFI CIE NT_ RES OU RCE S	Unable to allocate the resources required to complete the requested registration.

Remarks

This routine registers a core system resource so that this resource can be power-managed by PoFx.

Core system resources are hardware devices, such as timers and interrupt controllers, that are managed by the Windows hardware abstraction layer (HAL). These devices provide basic functions that are required by the operating system. Due to the close relationship between core system resources and processors, the power management of these resources needs to be coordinated with processor idle state management.

The **PoFxRegisterCoreDevice** routine should be called at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)
Library	Ntoskrnl.lib
IRQL	PASSIVE_LEVEL

UNICODE_STRING

PoFxRegisterPlugin function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxRegisterPlugin** routine registers a platform extension plug-in (PEP) with the Windows power management framework (PoFx).

Syntax

```
NTSTATUS PoFxRegisterPlugin(
  PPEP_INFORMATION        PepInformation,
  PPEP_KERNEL_INFORMATION KernelInformation
);
```

Parameters

`PepInformation`

A pointer to a PEP_INFORMATION structure.

`KernelInformation`

A pointer to a PEP_KERNEL_INFORMATION_STRUCT_V3 structure.

Return Value

PoFxRegisterPlugin returns STATUS_SUCCESS if the call successfully registers the PEP. Possible error return values include the following status codes.

RETURN VALUE	DESCRIPTION
STATUS_INVALID_PARAMETER	The **Version** or **Size** member of the **PEP_KERNEL_INFORMATION** structure is set to an invalid value; or the **AcceptDeviceNotification** member of this structure is set to NULL.
STATUS_INVALID_PEP_INFO_VERSION	The **Version** member of the **PEP_INFORMATION** structure is set to an invalid value.
STATUS_INSUFFICIENT_RESOURCES	Unable to allocate the resources required to complete the requested registration.

Remarks

A PEP calls this routine to register itself with PoFx.

A PEP cannot unregister, and cannot register twice. If the PEP must be serviced, the operating system must restart.

The PoFxRegisterPluginEx routine is similar to **PoFxRegisterPlugin**, except that it takes an additional parameter, *Flags*.

The PEP must call **PoFxRegisterPlugin** at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)
Library	Ntoskrnl.lib
IRQL	PASSIVE_LEVEL

PEP_KERNEL_INFORMATION_STRUCT_V3

PoFxRegisterPluginEx

PoFxRegisterPluginEx function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxRegisterPluginEx** routine registers a platform extension plug-in (PEP) with the Windows power management framework (PoFx).

Syntax

```
NTSTATUS PoFxRegisterPluginEx(
  PPEP_INFORMATION        PepInformation,
  ULONGLONG               Flags,
  PPEP_KERNEL_INFORMATION KernelInformation
);
```

Parameters

`PepInformation`

A pointer to a PEP_INFORMATION structure that contains pointers to one or more callback routines that are implemented by the PEP. These routines handle notifications that are sent to the PEP by PoFx.

`Flags`

A set of flag bits for configuring the PEP interface. Set this member to zero or to the following value.

FLAG BIT	DESCRIPTION
PEP_FLAG_WORKER_CONCURRENCY	

`KernelInformation`

A pointer to a PEP_KERNEL_INFORMATION structure.

Return Value

PoFxRegisterPluginEx returns STATUS_SUCCESS if the call successfully registers the PEP. Possible error return values include the following status codes.

RETURN VALUE	DESCRIPTION
STA TUS _IN VAL ID_P ARA MET ER	The **Version** or **Size** member of the **PEP_KERNEL_INFORMATION** structure is set to an invalid value; or the **AcceptDeviceNotification** member of this structure is set to NULL.

STA TUS _IN VAL ID_P EP_I NFO _VE RSI ON	The **Version** member of the **PEP_INFORMATION** structure is set to an invalid value.
STA TUS _INS UFFI CIE NT_ RES OU RCE S	Unable to allocate the resources required to complete the requested registration.

Remarks

A PEP calls this routine to register itself with PoFx.

A PEP cannot unregister, and cannot register twice. If the PEP must be serviced, the operating system must restart.

The PoFxRegisterPlugin routine is similar to **PoFxRegisterPluginEx**, except that it does not take a *Flags* parameter.

The PEP must call **PoFxRegisterPluginEx** at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 10.
Target Platform	Windows
Header	pepfx.h (include Pep_x.h)
Library	Ntoskrnl.lib
IRQL	PASSIVE_LEVEL

PEP_KERNEL_INFORMATION

PoFxRegisterPlugin

PPO_ENUMERATE_INTERRUPT_SOURCE_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

An *EnumerateInterruptSource* callback routine supplies a platform extension plug-in (PEP) with information about an interrupt source.

Syntax

```
PPO_ENUMERATE_INTERRUPT_SOURCE_CALLBACK PpoEnumerateInterruptSourceCallback;

BOOLEAN PpoEnumerateInterruptSourceCallback(
  PVOID CallbackContext,
  PPEP_UNMASKED_INTERRUPT_INFORMATION InterruptInformation
)
{...}
```

Parameters

`CallbackContext`

A pointer to a callback context. The PEP specified this pointer value as a parameter in the EnumerateUnmaskedInterrupts call that initiated the enumeration of interrupt sources.

`InterruptInformation`

A pointer to a PEP_UNMASKED_INTERRUPT_INFORMATION structure that contains information about the interrupt source.

Return Value

If the *EnumerateInterruptSource* callback routine returns TRUE, **EnumerateUnmaskedInterrupts** will continue to call the *EnumerateInterruptSource* callback routine while more interrupts are available to be enumerated. If the *EnumerateInterruptSource* callback routine returns FALSE, **EnumerateUnmaskedInterrupts** returns without enumerating any more interrupts.

Remarks

This callback routine is implemented by a PEP, and is called by the Windows power management framework (PoFx). The *Callback* parameter of the EnumerateUnmaskedInterrupts routine is a pointer to an *EnumerateInterruptSource* callback routine.

After a PEP calls **EnumerateUnmaskedInterrupts** to enumerate the unmasked interrupt sources, PoFx calls the PEP's *EnumerateInterruptSource* callback routine once for each unmasked interrupt source. **EnumerateUnmaskedInterrupts** returns only after the last call to the *EnumerateInterruptSource* callback routine completes.

An *EnumerateInterruptSource* callback routine is called at the same IRQL as the PEP's call to **EnumerateUnmaskedInterrupts** that initiates the enumeration callbacks.

Requirements

Target Platform	Windows
Header	pepfx.h (include Pep_x.h)
IRQL	See Remarks.

procgrp.h header

1/8/2019 • 2 minutes to read • Edit Online

This provides the new kernel programming interfaces for device drivers to run on downlevel systems. The library implements wrapper functions for processor-group **Ke*Xxx*** routines.

- Windows kernel procgrp.h contains the following programming interfaces:

Functions

TITLE	DESCRIPTION
WdmlibProcgrpInitialize	The WdmlibProcgrpInitialize function initializes the Processor Group (ProcGrp) compatibility library.

WdmlibProcgrpInitialize function

1/25/2019 • 2 minutes to read • Edit Online

The **WdmlibProcgrpInitialize** function initializes the Processor Group (ProcGrp) compatibility library.

Syntax

```
void WdmlibProcgrpInitialize(

);
```

Parameters

This function has no parameters.

Return Value

None

Remarks

This function initializes the ProcGrp library. Call this function before calling any of the other functions in the ProcGrp library. The library implements wrapper functions that have the same names as the following processor-group **Ke*Xxx*** routines in Windows 7:

KeGetCurrentProcessorNumberEx

KeGetProcessorIndexFromNumber

KeGetProcessorNumberFromIndex

KeQueryActiveGroupCount

KeQueryActiveProcessorCountEx

KeQueryGroupAffinity

KeQueryMaximumProcessorCount

KeQueryMaximumProcessorCountEx

KeQueryMaximumGroupCount

KeSetSystemAffinityThreadEx

KeSetSystemGroupAffinityThread

KeRevertToUserAffinityThreadEx

KeRevertToUserGroupAffinityThread

KeSetTargetProcessorDpcEx

For more information about the ProcGrp library, see Processor Group Compatibility Library.

Requirements

Minimum supported client	Compatible with Windows 7, Windows Server 2008 R2, Windows Server 2008, Windows Vista, Windows Server 2003, Windows XP, and Windows 2000.
Target Platform	Desktop
Header	procgrp.h (include Procgrp.h)
Library	Procgrp.lib
IRQL	PASSIVE_LEVEL

vpci.h header

1/8/2019 • 2 minutes to read • Edit Online

This header contains common types and prototypes for a virtual PCI driver.

- vpci.h contains the following programming interfaces:

IOCTLs

TITLE	DESCRIPTION
IOCTL_VPCI_INVALIDATE_BLOCK	The driver for a PCI Express (PCIe) virtual function (VF) issues the IOCTL_VPCI_INVALIDATE_BLOCK IOCTL request in order to be notified of changes to data in one or more VF configuration blocks.
IOCTL_VPCI_READ_BLOCK	The driver for a PCI Express (PCIe) virtual function (VF) issues an IOCTL_VPCI_READ_BLOCK I/O control code (IOCTL) in order to read data from a VF configuration block. The driver issues this IOCTL to the next-lower driver in the driver stack.
IOCTL_VPCI_WRITE_BLOCK	The driver for a PCI Express (PCIe) virtual function (VF) issues an IOCTL_VPCI_WRITE_BLOCK I/O control code (IOCTL) in order to write data to a VF configuration block. The driver issues this IOCTL to the next-lower driver in the driver stack.

Structures

TITLE	DESCRIPTION
VPCI_INVALIDATE_BLOCK_OUTPUT	The VPCI_INVALIDATE_BLOCK_OUTPUT structure is used in an IOCTL_VPCI_INVALIDATE_BLOCK IOCTL request.
VPCI_READ_BLOCK_INPUT	The VPCI_READ_BLOCK_INPUT structure is used in an IOCTL_VPCI_READ_BLOCK IOCTL request to read data from a specified configuration block of data for a PCI Express (PCIe) virtual function (VF).
VPCI_WRITE_BLOCK_INPUT	The VPCI_WRITE_BLOCK_INPUT structure is used in an IOCTL_VPCI_WRITE_BLOCK IOCTL request to write data to a specified configuration block for a PCI Express (PCIe) virtual function (VF).

wdm.h header

1/8/2019 • 109 minutes to read • Edit Online

This header contains reference material that includes specific details about the routines, structures, and data types that you will need to use to write kernel-mode drivers.

For more information, see:

- Windows kernel wdm.h contains the following programming interfaces:

Functions

TITLE	DESCRIPTION
AppendTailList	The AppendTailList routine appends a doubly linked list of LIST_ENTRY structures to the tail of another doubly linked list of LIST_ENTRY structures.
ARM64_SYSREG_CRM	Returns the CRn field for a given ARM system register.
ARM64_SYSREG_CRN	Returns the CRn field for a given ARM system register.
ARM64_SYSREG_OP1	Returns the op1 field for a given ARM system register.
ARM64_SYSREG_OP2	Returns the op2 field for a given ARM system register.
ASSERTMSG	ASSERTMSG tests an expression. If the expression is false, it breaks into the kernel debugger and sends it the specified message.
ClfsAddLogContainer	The ClfsAddLogContainer routine adds a container to a CLFS log.
ClfsAddLogContainerSet	The ClfsAddLogContainerSet routine atomically adds a set of containers to a CLFS log.
ClfsAdvanceLogBase	The ClfsAdvanceLogBase routine sets the base LSN of a CLFS stream.
ClfsAlignReservedLog	The ClfsAlignReservedLog routine calculates the size of the space that must be reserved for a specified set of records. The size calculation includes the space required for headers and the space required for sector alignment.
ClfsAllocReservedLog	The ClfsAllocReservedLog routine reserves space in a marshalling area for a set of records.
ClfsCloseAndResetLogFile	The ClfsCloseAndResetLogFile routine releases all references to a specified log file object and marks its associated stream for reset.

TITLE	DESCRIPTION
ClfsCloseLogFileObject	The ClfsCloseLogFileObject routine releases all references to a log file object.
ClfsCreateLogFile	The ClfsCreateLogFile routine creates or opens a CLFS stream. If necessary, ClfsCreateLogFile also creates the underlying physical log that holds the stream's records.
ClfsCreateMarshallingArea	The ClfsCreateMarshallingArea routine creates a marshalling area for a CLFS stream and returns a pointer to an opaque context that represents the new marshalling area.
ClfsCreateMarshallingAreaEx	Initalizes a marshalling area for a physical or client log file stream.
ClfsCreateScanContext	The ClfsCreateScanContext routine creates a scan context that can be used to iterate over the containers of a specified CLFS log.
ClfsDeleteLogByPointer	The ClfsDeleteLogByPointer routine marks a CLFS stream for deletion.
ClfsDeleteLogFile	The ClfsDeleteLogFile routine marks a CLFS stream for deletion.
ClfsDeleteMarshallingArea	The ClfsDeleteMarshallingArea routine deletes a marshalling area.
ClfsFlushBuffers	The ClfsFlushBuffers routine forces all log I/O blocks in a specified marshalling area to stable storage.
ClfsFlushToLsn	The ClfsFlushToLsn routine forces, to stable storage, all records that have an LSN less than or equal to a specified LSN.
ClfsGetContainerName	The ClfsGetContainerName routine returns the path name of a specified container.
ClfsGetIoStatistics	The ClfsGetIoStatistics routine returns I/O statistics for a specified CLFS log.
ClfsLsnBlockOffset	The ClfsLsnBlockOffset routine returns the sector-aligned block offset contained in a specified LSN.
ClfsLsnContainer	The ClfsLsnContainer routine returns the logical container identifier contained in a specified LSN.
ClfsLsnCreate	The ClfsLsnCreate routine creates a log sequence number (LSN), given a container identifier, a block offset, and a record sequence number.
ClfsLsnEqual	The ClfsLsnEqual routine determines whether two LSNs from the same stream are equal.

TITLE	DESCRIPTION
ClfsLsnGreater	The ClfsLsnGreater routine determines whether one LSN is greater than another LSN. The two LSNs must be from the same stream.
ClfsLsnLess	The ClfsLsnLess routine determines whether one LSN is less than another LSN. The two LSNs must be from the same stream.
ClfsLsnNull	The ClfsLsnNull routine determines whether a specified LSN is equal to the smallest possible LSN, CLFS_LSN_NULL.
ClfsLsnRecordSequence	The ClfsLsnRecordSequence routine returns the record sequence number contained in a specified LSN.
ClfsMgmtDeregisterManagedClient	The ClfsMgmtDeregisterManagedClient routine removes the connection between a client and a log, so that the client no longer manages the log.
ClfsMgmtHandleLogFileFull	The ClfsMgmtHandleLogFileFull routine attempts to make more space available in a log. It might make more space available by adding containers to the log, or it might ask clients to move their log tails.
ClfsMgmtInstallPolicy	The ClfsMgmtInstallPolicy routine adds a CLFS_MGMT_POLICY structure to a physical log.
ClfsMgmtQueryPolicy	The ClfsMgmtQueryPolicy routine retrieves a specific CLFS_MGMT_POLICY structure for a log.
ClfsMgmtRegisterManagedClient	The ClfsMgmtRegisterManagedClient routine creates a client that will manage a CLFS log.
ClfsMgmtRemovePolicy	The ClfsMgmtRemovePolicy routine resets a log's CLFS_MGMT_POLICY structure to its default value.
ClfsMgmtSetLogFileSize	The ClfsMgmtSetLogFileSize routine adds containers to a log or deletes containers from a log.
ClfsMgmtSetLogFileSizeAsClient	The ClfsMgmtSetLogFileSizeAsClient routine sets the log file size by adding containers to a client log or deleting containers from a client log.
ClfsMgmtTailAdvanceFailure	The ClfsMgmtTailAdvanceFailure routine notifies CLFS management that the client could not advance the log's tail.
ClfsQueryLogFileInformation	The ClfsQueryLogFileInformation routine returns metadata and state information for a specified CLFS stream or its underlying physical log or both.
ClfsReadLogRecord	The ClfsReadLogRecord routine reads a target record in a CLFS stream and returns a read context that the caller can use to read the records preceding or following it in the stream.
ClfsReadNextLogRecord	The ClfsReadNextLogRecord routine reads the next record in a sequence, relative to the current record in a read context.

TITLE	DESCRIPTION
ClfsReadPreviousRestartArea	The ClfsReadPreviousRestartArea routine reads the previous restart record relative to the current record in a read context.
ClfsReadRestartArea	The ClfsReadRestartArea routine reads the restart record that was most recently written to a specified CLFS stream.
ClfsRemoveLogContainer	The ClfsRemoveLogContainer routine removes a container from a CLFS log.
ClfsRemoveLogContainerSet	The ClfsRemoveLogContainerSet routine atomically removes a set of containers from a CLFS log.
ClfsReserveAndAppendLog	The ClfsReserveAndAppendLog routine reserves space in a marshalling area or appends a record to a marshalling area or does both atomically.
ClfsReserveAndAppendLogAligned	The ClfsReserveAndAppendLogAligned routine reserves space in a marshalling area or appends a record to a marshalling area or does both atomically. The record's data is aligned on specified boundaries.
ClfsScanLogContainers	The ClfsScanLogContainers routine retrieves descriptive information for a sequence of containers that belong to a particular CLFS log.
ClfsSetArchiveTail	The ClfsSetArchiveTail routine sets the archive tail of a CLFS log to a specified LSN.
ClfsSetEndOfLog	The ClfsSetEndOfLog routine truncates a CLFS stream.
ClfsSetLogFileInformation	The ClfsSetLogFileInformation routine sets metadata and state information for a specified stream and its underlying physical log.
ClfsTerminateReadLog	The ClfsTerminateReadLog routine invalidates a specified read context after freeing resources associated with the context.
ClfsWriteRestartArea	The ClfsWriteRestartArea routine atomically appends a new restart record to a CLFS stream, flushes the restart record to stable storage, and optionally updates the base LSN of the stream.
CmCallbackGetKeyObjectID	The CmCallbackGetKeyObjectID routine retrieves the unique identifier and object name that are associated with a specified registry key object.
CmCallbackGetKeyObjectIDEx	The CmCallbackGetKeyObjectIDEx routine retrieves the unique identifier and object name that are associated with a specified registry key object.

TITLE	DESCRIPTION
CmCallbackReleaseKeyObjectIDEx	The CmCallbackReleaseKeyObjectIDEx routine frees an object name string obtained from the CmCallbackGetKeyObjectIDEx routine.
CmGetBoundTransaction	The CmGetBoundTransaction routine returns a pointer to the transaction object that represents the transaction, if any, that is associated with a specified registry key object.
CmGetCallbackVersion	The CmGetCallbackVersion routine retrieves the major and minor version numbers for the current version of the configuration manager's registry callback feature.
CmRegisterCallback	The CmRegisterCallback routine is obsolete for Windows Vista and later operating system versions. Use CmRegisterCallbackEx instead.The CmRegisterCallback routine registers a RegistryCallback routine.
CmRegisterCallbackEx	The CmRegisterCallbackEx routine registers a RegistryCallback routine.
CmSetCallbackObjectContext	The CmSetCallbackObjectContext routine associates specified context information with a specified registry object.
CmUnRegisterCallback	The CmUnRegisterCallback routine unregisters a RegistryCallback routine that a CmRegisterCallback or CmRegisterCallbackEx routine previously registered.
DbgBreakPoint	The DbgBreakPoint routine breaks into the kernel debugger.
DbgBreakPointWithStatus	The DbgBreakPointWithStatus routine breaks into the kernel debugger and sends the value of Status to the debugger.
DbgPrint	The DbgPrint routine sends a message to the kernel debugger.
DbgPrintEx	The DbgPrintEx routine sends a string to the kernel debugger if the conditions you specify are met.
EtwActivityIdControl	The EtwActivityIdControl function creates, queries, and sets the current activity identifier.
EtwEventEnabled	The EtwEventEnabled function verifies whether an event is enabled.
EtwProviderEnabled	The EtwProviderEnabled function verifies that a provider is enabled for event logging at a specified level and keyword.
EtwRegister	The EtwRegister function registers the event provider and must be called before a provider can start tracing.
EtwUnregister	The EtwUnregister function unregisters the event provider and must be called before the provider exits.
EtwWrite	The EtwWrite function is a tracing function for publishing events in your kernel-mode driver code.

TITLE	DESCRIPTION
EtwWriteEx	The EtwWriteEx function is a tracing function for publishing events that support filtering in your kernel-mode driver code.
EtwWriteString	The EventWriteString function is a tracing function that you can use when no sophisticated data is required. This function is similar to a debug print statement.
EtwWriteTransfer	The EtwWriteTransfer function marks an event that links two activities together; this type of event is referred to as a transfer event.
ExAcquirePushLockExclusive	Acquires the given push lock for exclusive access by the calling thread.
ExAcquirePushLockShared	Acquires the given push lock for shared access by the calling thread.
ExAcquireResourceExclusiveLite	The ExAcquireResourceExclusiveLite routine acquires the given resource for exclusive access by the calling thread.
ExAcquireResourceSharedLite	The ExAcquireResourceSharedLite routine acquires the given resource for shared access by the calling thread.
ExAcquireRundownProtection	The ExAcquireRundownProtection routine tries to acquire run-down protection on a shared object so the caller can safely access the object.
ExAcquireRundownProtectionEx	The ExAcquireRundownProtectionEx routine tries to acquire run-down protection on a shared object so the caller can safely access the object.
ExAcquireSharedStarveExclusive	The ExAcquireSharedStarveExclusive routine acquires a given resource for shared access without waiting for any pending attempts to acquire exclusive access to the same resource.
ExAcquireSharedWaitForExclusive	The ExAcquireSharedWaitForExclusive routine acquires the given resource for shared access if shared access can be granted and there are no exclusive waiters.
ExAllocateFromLookasideListEx	The ExAllocateFromLookasideListEx routine removes the first entry from the specified lookaside list, or, if the list is empty, dynamically allocates the storage for a new entry.
ExAllocateFromNPagedLookasideList	The ExAllocateFromNPagedLookasideList routine returns a pointer to a nonpaged entry from the given lookaside list, or it returns a pointer to a newly allocated nonpaged entry.
ExAllocateFromPagedLookasideList	The ExAllocateFromPagedLookasideList routine returns a pointer to a paged entry from the given lookaside list, or it returns a pointer to a newly allocated paged entry.
ExAllocatePool	The ExAllocatePool routine is obsolete, and is exported only for existing binaries. Use ExAllocatePoolWithTag instead.ExAllocatePool allocates pool memory of the specified type and returns a pointer to the allocated block.

TITLE	DESCRIPTION
ExAllocatePoolWithQuota	The ExAllocatePoolWithQuota routine is obsolete, and is exported only for existing driver binaries. Use ExAllocatePoolWithQuotaTag instead.ExAllocatePoolWithQuota allocates pool memory, charging quota against the current process.
ExAllocatePoolWithQuotaTag	The ExAllocatePoolWithQuotaTag routine allocates pool memory, charging the quota against the current process.
ExAllocatePoolWithTag	The ExAllocatePoolWithTag routine allocates pool memory of the specified type and returns a pointer to the allocated block.
ExAllocatePoolWithTagPriority	The ExAllocatePoolWithTagPriority routine allocates pool memory of the specified type.
ExAllocateTimer	The ExAllocateTimer routine allocates and initializes a timer object.
ExCancelTimer	The ExCancelTimer routine cancels a timer that was set by a previous call to the ExSetTimer routine.
ExConvertExclusiveToSharedLite	The ExConvertExclusiveToSharedLite routine converts a given resource from acquired for exclusive access to acquired for shared access.
ExCreateCallback	The ExCreateCallback routine either creates a new callback object or opens an existing callback object on behalf of the caller.
ExDeleteLookasideListEx	The ExDeleteLookasideListEx routine deletes a lookaside list.
ExDeleteNPagedLookasideList	The ExDeleteNPagedLookasideList routine destroys a nonpaged lookaside list.
ExDeletePagedLookasideList	The ExDeletePagedLookasideList routine destroys a paged lookaside list.
ExDeleteResourceLite	The ExDeleteResourceLite routine deletes a given resource from the system's resource list.
ExDeleteTimer	The ExDeleteTimer routine deletes a timer object that was previously allocated by the ExAllocateTimer routine.
ExFlushLookasideListEx	The ExFlushLookasideListEx routine flushes all entries from the specified lookaside list and frees the allocated storage for each entry.
ExFreePool	The ExFreePool routine deallocates a block of pool memory.
ExFreePoolWithTag	The ExFreePoolWithTag routine deallocates a block of pool memory allocated with the specified tag.

TITLE	DESCRIPTION
ExFreeToLookasideListEx	The ExFreeToLookasideListEx routine inserts an entry into a lookaside list, or, if the list is full, frees the allocated storage for the entry.
ExFreeToNPagedLookasideList	The ExFreeToNPagedLookasideList routine returns a nonpaged entry to the given lookaside list or to nonpaged pool.
ExFreeToPagedLookasideList	The ExFreeToPagedLookasideList routine returns a pageable entry to the given lookaside list or to paged pool.
ExGetExclusiveWaiterCount	The ExGetExclusiveWaiterCount routine returns the number of waiters on exclusive access to a given resource.
ExGetFirmwareEnvironmentVariable	The ExGetFirmwareEnvironmentVariable routine gets the value of the specified system firmware environment variable.
ExGetFirmwareType	Returns the system firmware type.
ExGetPreviousMode	The ExGetPreviousMode routine returns the previous processor mode for the current thread.
ExGetSharedWaiterCount	The ExGetSharedWaiterCount routine returns the number of waiters on shared access to a given resource.
ExInitializeDeleteTimerParameters	The ExInitializeDeleteTimerParameters routine initializes an EXT_DELETE_PARAMETERS structure.
ExInitializeFastMutex	The ExInitializeFastMutex routine initializes a fast mutex variable, used to synchronize mutually exclusive access by a set of threads to a shared resource.
ExInitializeLookasideListEx	The ExInitializeLookasideListEx routine initializes a lookaside list.
ExInitializeNPagedLookasideList	The ExInitializeNPagedLookasideList routine initializes a lookaside list for nonpaged entries of the specified size.
ExInitializePagedLookasideList	The ExInitializePagedLookasideList routine initializes a lookaside list for pageable entries of the specified size.
ExInitializePushLock	Initializes a push lock variable.
ExInitializeResourceLite	The ExInitializeResourceLite routine initializes a resource variable.
ExInitializeRundownProtection	The ExInitializeRundownProtection routine initializes run-down protection on a shared object.
ExInitializeSetTimerParameters	The ExInitializeSetTimerParameters routine initializes an EXT_SET_PARAMETERS structure.
ExInitializeWorkItem	ExInitializeWorkItem initializes a work-queue item with a caller-supplied context and callback routine to be queued for execution when a system worker thread is given control.

TITLE	DESCRIPTION
ExInterlockedAddLargeInteger	The ExInterlockedAddLargeInteger routine adds a large integer value to the specified variable as an atomic operation.
ExInterlockedAddLargeStatistic	The ExInterlockedAddLargeStatistic routine performs an interlocked addition of a ULONG increment value to a LARGE_INTEGER variable.
ExInterlockedAddUlong	The ExInterlockedAddUlong routine adds an unsigned long value to a given unsigned integer as an atomic operation.
ExInterlockedCompareExchange64	The ExInterlockedCompareExchange64 routine compares one integer variable to another and, if they are equal, sets the first variable to a caller-supplied value.
ExInterlockedFlushSList	The ExInterlockedFlushSList routine atomically removes all entries from a sequenced singly linked list.
ExInterlockedInsertHeadList	The ExInterlockedInsertHeadList routine atomically inserts an entry at the beginning of a doubly linked list of LIST_ENTRY structures.
ExInterlockedInsertTailList	The ExInterlockedInsertTailList routine atomically inserts an entry at the end of a doubly linked list of LIST_ENTRY structures.
ExInterlockedPopEntryList	The ExInterlockedPopEntryList routine atomically removes an entry from the beginning of a singly linked list of SINGLE_LIST_ENTRY structures.
ExInterlockedPopEntrySList	The ExInterlockedPopEntrySList routine atomically removes the first entry from a sequenced singly linked list.
ExInterlockedPushEntryList	The ExInterlockedPushEntryList routine atomically inserts an entry at the beginning of a singly linked list of SINGLE_LIST_ENTRY structures.
ExInterlockedPushEntrySList	The ExInterlockedPushEntrySList routine atomically inserts an entry at the beginning of a sequenced singly linked list.
ExInterlockedRemoveHeadList	The ExInterlockedRemoveHeadList routine removes an entry from the beginning of a doubly linked list of LIST_ENTRY structures.
ExIsProcessorFeaturePresent	The ExIsProcessorFeaturePresent routine queries for the existence of a specified processor feature.
ExIsResourceAcquiredExclusiveLite	The ExIsResourceAcquiredExclusiveLite routine returns whether the current thread has exclusive access to a given resource.
ExIsResourceAcquiredSharedLite	The ExIsResourceAcquiredSharedLite routine returns whether the current thread has access (either shared or exclusive) to a given resource.

TITLE	DESCRIPTION
ExIsSoftBoot	Determines whether the system has gone through a soft restart.
ExLocalTimeToSystemTime	The ExLocalTimeToSystemTime routine converts a system time value for the current time zone to an unbiased, GreenGMT value.
ExNotifyCallback	The ExNotifyCallback routine causes all callback routines registered for the given object to be called.
ExQueryDepthSList	The ExQueryDepthSList routine returns the number of entries currently in a given sequenced singly linked list.
ExQueryTimerResolution	The ExQueryTimerResolution routine reports the range of timer resolutions that are supported by the system clock.
ExQueueWorkItem	ExQueueWorkItem inserts a given work item into a queue from which a system worker thread removes the item and gives control to the routine that the caller supplied to ExInitializeWorkItem.
ExRaiseStatus	The ExRaiseStatus routine is called by drivers that supply structured exception handlers to handle particular errors that occur while they are processing I/O requests.
ExRegisterCallback	The ExRegisterCallback routine registers a given callback routine with a given callback object.
ExReinitializeResourceLite	The ExReinitializeResourceLite routine reinitializes an existing resource variable.
ExReInitializeRundownProtection	The ExReInitializeRundownProtection routine reinitializes an EX_RUNDOWN_REF structure after the associated object is run down.
ExReleasePushLockExclusive	Releases a specified push lock for exclusive access owned by the current thread.
ExReleasePushLockShared	Releases a specified push lock for shared access owned by the current thread.
ExReleaseResourceForThreadLite	The ExReleaseResourceForThreadLite routine releases the input resource of the indicated thread.
ExReleaseResourceLite	The ExReleaseResourceLite routine releases a specified executive resource owned by the current thread.
ExReleaseRundownProtection	The ExReleaseRundownProtection routine releases run-down protection that the caller previously acquired by calling the ExAcquireRundownProtection routine.
ExReleaseRundownProtectionEx	The ExReleaseRundownProtectionEx routine releases run-down protection that the caller previously acquired by calling the ExAcquireRundownProtectionEx routine.

TITLE	DESCRIPTION
ExReleaseSpinLockExclusive	The ExReleaseSpinLockExclusive routine releases a spin lock that the caller previously acquired for exclusive access, and restores the IRQL to its original value.
ExReleaseSpinLockShared	The ExReleaseSpinLockShared routine releases ownership of a spin lock that the caller previously acquired for shared access, and restores the IRQL to its original value.
ExRundownCompleted	The ExRundownCompleted routine updates the run-down status of a shared object to indicate that the run down of the object has completed.
ExSetFirmwareEnvironmentVariable	The ExSetFirmwareEnvironmentVariable routine sets the value of the specified system firmware environment variable.
ExSetResourceOwnerPointer	The ExSetResourceOwnerPointer routine sets the owner thread pointer for an executive resource.
ExSetResourceOwnerPointerEx	The ExSetResourceOwnerPointerEx routine transfers the ownership of an executive resource from the calling thread to an owner pointer, which is a system address that identifies the resource owner.
ExSetTimer	The ExSetTimer routine starts a timer operation and sets the timer to expire at the specified due time.
ExSetTimerResolution	The ExSetTimerResolution routine modifies the frequency at which the system clock interrupts. Use this routine with extreme caution (see the following Remarks section).
ExSystemTimeToLocalTime	The ExSystemTimeToLocalTime routine converts a GMT system time value to the local system time for the current time zone.
ExTryConvertSharedSpinLockExclusive	The ExTryConvertSharedSpinLockExclusive routine attempts to convert the access state of a spin lock from acquired for shared access to exclusive access.
ExUnregisterCallback	The ExUnregisterCallback routine removes a callback routine previously registered with a callback object from the list of routines to be called during the notification process.
ExWaitForRundownProtectionRelease	The ExWaitForRundownProtectionRelease routine waits until all drivers that have already been granted run-down protection complete their accesses of the shared object.
FIELD_OFFSET	The FIELD_OFFSET macro returns the byte offset of a named field in a known structure type.
FirstEntrySList	The FirstEntrySList routine returns the first entry in a sequenced singly linked list.
IMAGE_POLICY_OVERRIDE	Reserved.

TITLE	DESCRIPTION
InitializeListHead	The InitializeListHead routine initializes a LIST_ENTRY structure that represents the head of a doubly linked list.
InitializeSListHead	The InitializeSListHead routine (or ExInitializeSListHead) initializes an SLIST_HEADER structure that represents the head of a sequenced singly linked list.
InsertHeadList	The InsertHeadList routine inserts an entry at the head of a doubly linked list of LIST_ENTRY structures.
InsertTailList	The InsertTailList routine inserts an entry at the tail of a doubly linked list of LIST_ENTRY structures.
InterlockedAnd	The InterlockedAnd macro atomically computes a bitwise AND operation.
InterlockedCompareExchange	The InterlockedCompareExchange routine performs an atomic operation that compares the input value pointed to by Destination with the value of Comperand.
InterlockedCompareExchangePointer	The InterlockedCompareExchangePointer routine performs an atomic operation that compares the input pointer value pointed to by Destination with the pointer value Comperand.
InterlockedDecrement	The InterlockedDecrement routine decrements a caller-supplied variable of type LONG as an atomic operation.
InterlockedExchange	The InterlockedExchange routine sets an integer variable to a given value as an atomic operation.
InterlockedExchangeAdd	The InterlockedExchangeAdd routine adds a value to a given integer as an atomic operation and returns the original value of the given integer.
InterlockedExchangePointer	The InterlockedExchangePointer routine performs an atomic operation that sets a pointer to a new value.
InterlockedIncrement	The InterlockedIncrement routine increments a caller-supplied variable as an atomic operation.
InterlockedOr	The InterlockedOr routine atomically computes a bitwise OR operation.
InterlockedXor	The InterlockedOr routine atomically computes a bitwise exclusive OR operation.
IoAcquireRemoveLock	The IoAcquireRemoveLock routine increments the count for a remove lock, indicating that the associated device object should not be detached from the device stack or deleted.
IoAdjustPagingPathCount	The IoAdjustPagingPathCount routine increments or decrements a caller-supplied page-file counter as an atomic operation.

TITLE	DESCRIPTION
IoAllocateDriverObjectExtension	The IoAllocateDriverObjectExtension routine allocates a per-driver context area, called a driver object extension, and assigns a unique identifier to it.
IoAllocateErrorLogEntry	The IoAllocateErrorLogEntry routine allocates an error log entry, and returns a pointer to the packet that the caller uses to supply information about an I/O error.
IoAllocateIrp	The IoAllocateIrp routine allocates an IRP, given the number of I/O stack locations for each driver layered under the caller, and, optionally, for the caller.
IoAllocateMdl	The IoAllocateMdl routine allocates a memory descriptor list (MDL) large enough to map a buffer, given the buffer's starting address and length. Optionally, this routine associates the MDL with an IRP.
IoAllocateWorkItem	The IoAllocateWorkItem routine allocates a work item.
IoAttachDevice	The IoAttachDevice routine attaches the caller's device object to a named target device object, so that I/O requests bound for the target device are routed first to the caller.
IoAttachDeviceToDeviceStack	The IoAttachDeviceToDeviceStack routine attaches the caller's device object to the highest device object in the chain and returns a pointer to the previously highest device object.
IoBuildAsynchronousFsdRequest	The IoBuildAsynchronousFsdRequest routine allocates and sets up an IRP to be sent to lower-level drivers.
IoBuildDeviceIoControlRequest	The IoBuildDeviceIoControlRequest routine allocates and sets up an IRP for a synchronously processed device control request.
IoBuildPartialMdl	The IoBuildPartialMdl routine builds a new memory descriptor list (MDL) that represents part of a buffer that is described by an existing MDL.
IoBuildSynchronousFsdRequest	The IoBuildSynchronousFsdRequest routine allocates and sets up an IRP for a synchronously processed I/O request.
IoCallDriver	The IoCallDriver routine sends an IRP to the driver associated with a specified device object.
IoCancelIrp	The IoCancelIrp routine sets the cancel bit in a given IRP and calls the cancel routine for the IRP if there is one.
IoCheckLinkShareAccess	The IoCheckLinkShareAccess routine is called by file system drivers (FSDs) or other highest-level drivers to check whether link shared access to a file object is permitted.
IoCheckShareAccess	The IoCheckShareAccess routine is called by file system drivers (FSDs) or other highest-level drivers to check whether shared access to a file object is permitted.

TITLE	DESCRIPTION
IoCheckShareAccessEx	The IoCheckShareAccessEx routine is called by file system drivers (FSDs) or other highest-level drivers to check whether shared access to a file object is permitted.
IoCompleteRequest	The IoCompleteRequest routine indicates that the caller has completed all processing for a given I/O request and is returning the given IRP to the I/O manager.
IoConnectInterrupt	The IoConnectInterrupt routine registers a device driver's InterruptService routine (ISR), so that it will be called when a device interrupts on any of a specified set of processors.
IoConnectInterruptEx	For more information, see the WdmlibIoConnectInterruptEx function.#define IoConnectInterruptEx WdmlibIoConnectInterruptEx
IoCopyCurrentIrpStackLocationToNext	The IoCopyCurrentIrpStackLocationToNext routine copies the IRP stack parameters from the current I/O stack location to the stack location of the next-lower driver.
IoCreateDevice	The IoCreateDevice routine creates a device object for use by a driver.
IoCreateFile	The IoCreateFile routine either causes a new file or directory to be created, or it opens an existing file, device, directory, or volume, giving the caller a handle for the file object.
IoCreateNotificationEvent	The IoCreateNotificationEvent routine creates or opens a named notification event used to notify one or more threads of execution that an event has occurred.
IoCreateSymbolicLink	The IoCreateSymbolicLink routine sets up a symbolic link between a device object name and a user-visible name for the device.
IoCreateSynchronizationEvent	The IoCreateSynchronizationEvent routine creates or opens a named synchronization event for use in serialization of access to hardware between two otherwise unrelated drivers.
IoCreateSystemThread	The IoCreateSystemThread routine creates a system thread that executes in kernel mode, and supplies a handle for the thread.
IoCreateUnprotectedSymbolicLink	The IoCreateUnprotectedSymbolicLink routine sets up an unprotected symbolic link between a device object name and a corresponding Win32-visible name.
IoCsqInitialize	The IoCsqInitialize routine initializes the driver's cancel-safe IRP queue dispatch table.
IoCsqInitializeEx	The IoCsqInitializeEx routine initializes the dispatch table for a cancel-safe IRP queue.
IoCsqInsertIrp	The IoCsqInsertIrp routine inserts an IRP in the driver's cancel-safe IRP queue.

TITLE	DESCRIPTION
IoCsqInsertIrpEx	The IoCsqInsertIrpEx routine inserts an IRP into the driver's cancel-safe IRP queue.
IoCsqRemoveIrp	The IoCsqRemoveIrp routine removes a particular IRP from the queue.
IoCsqRemoveNextIrp	The IoCsqRemoveNextIrp routine removes the next matching IRP in the queue.
IoDeleteDevice	The IoDeleteDevice routine removes a device object from the system, for example, when the underlying device is removed from the system.
IoDeleteSymbolicLink	The IoDeleteSymbolicLink routine removes a symbolic link from the system.
IoDetachDevice	The IoDetachDevice routine releases an attachment between the caller's device object and a lower driver's device object.
IoDisconnectInterrupt	The IoDisconnectInterrupt routine releases a device driver's set of interrupt object(s) when the device is paused or removed, or when the driver is being unloaded.
IoDisconnectInterruptEx	For more information, see the WdmlibIoDisconnectInterruptEx function.#define IoDisconnectInterruptEx WdmlibIoDisconnectInterruptEx
IofCallDriver	Call **IoCallDriver** instead. Sends an IRP to the driver associated with a specified device object.
IoForwardIrpSynchronously	The IoForwardIrpSynchronously routine sends an IRP to a specified driver and waits for that driver to complete the IRP.
IoFreeErrorLogEntry	The IoFreeErrorLogEntry routine frees an unused error log entry.
IoFreeIrp	The IoFreeIrp routine releases a caller-allocated IRP from the caller's IoCompletion routine.
IoFreeMdl	The IoFreeMdl routine releases a caller-allocated memory descriptor list (MDL).
IoFreeWorkItem	The IoFreeWorkItem routine frees a work item that was allocated by IoAllocateWorkItem.
IoGetAffinityInterrupt	For more information, see the WdmlibIoGetAffinityInterrupt function.#define IoGetAffinityInterrupt WdmlibIoGetAffinityInterrupt
IoGetAttachedDeviceReference	The IoGetAttachedDeviceReference routine returns a pointer to the highest level device object in a driver stack and increments the reference count on that object.

TITLE	DESCRIPTION
IoGetBootDiskInformation	The IoGetBootDiskInformation routine returns information describing the boot and system disks.
IoGetContainerInformation	The IoGetContainerInformation routine provides information about the current state of a user session.
IoGetCurrentIrpStackLocation	The IoGetCurrentIrpStackLocation routine returns a pointer to the caller's I/O stack location in the specified IRP.
IoGetCurrentProcess	The IoGetCurrentProcess routine returns a pointer to the current process.
IoGetDeviceDirectory	Returns a handle to a directory on disk specific to the specified driver object where the driver can read and write files.
IoGetDeviceInterfaceAlias	The IoGetDeviceInterfaceAlias routine returns the alias device interface of the specified device interface instance, if the alias exists.
IoGetDeviceInterfacePropertyData	The IoGetDeviceInterfacePropertyData routine retrieves the current value of a device interface property.
IoGetDeviceInterfaces	The IoGetDeviceInterfaces routine returns a list of device interface instances of a particular device interface class (such as all devices on the system that support a HID interface).
IoGetDeviceNumaNode	The IoGetDeviceNumaNode routine gets the node number of a device.
IoGetDeviceObjectPointer	The IoGetDeviceObjectPointer routine returns a pointer to the top object in the named device object's stack and a pointer to the corresponding file object, if the requested access to the objects can be granted.
IoGetDeviceProperty	The IoGetDeviceProperty routine retrieves information about a device such as configuration information and the name of its PDO.
IoGetDevicePropertyData	The IoGetDevicePropertyData routine retrieves the current setting for a device property.
IoGetDmaAdapter	The IoGetDmaAdapter routine returns a pointer to the DMA adapter structure for a physical device object.
IoGetDriverDirectory	Returns a handle to a directory on disk from which the driver can read and write files. The files in that directory apply to a specific driver object.
IoGetDriverObjectExtension	The IoGetDriverObjectExtension routine retrieves a previously allocated per-driver context area.
IoGetFunctionCodeFromCtlCode	The IoGetFunctionCodeFromCtlCode macro returns the value of the function code contained in an I/O control code.

TITLE	DESCRIPTION
IoGetInitialStack	The IoGetInitialStack routine returns the base address of the current thread's stack.
IoGetIommuInterface	Retrieves a pointer to the interface that contains pointers to IOMMU routines.
IoGetIoPriorityHint	The IoGetIoPriorityHint routine gets the priority hint value from an IRP.
IoGetNextIrpStackLocation	The IoGetNextIrpStackLocation routine gives a higher level driver access to the next-lower driver's I/O stack location in an IRP so the caller can set it up for the lower driver.
IoGetRelatedDeviceObject	Given a file object, the IoGetRelatedDeviceObject routine returns a pointer to the corresponding device object.
IoGetRemainingStackSize	The IoGetRemainingStackSize routine returns the current amount of available kernel-mode stack space.
IoGetStackLimits	The IoGetStackLimits routine returns the boundaries of the current thread's stack frame.
IoGetTopLevelIrp	The IoGetTopLevelIrp routine returns the value of the TopLevelIrp field of the current thread.
IoInitializeDpcRequest	The IoInitializeDpcRequest routine registers a driver-supplied DpcForIsr routine.
IoInitializeIrp	The IoInitializeIrp routine initializes a given IRP that was allocated by the caller.
IoInitializeRemoveLock	The IoInitializeRemoveLock routine initializes a remove lock for a device object.
IoInitializeTimer	The IoInitializeTimer routine sets up a driver-supplied IoTimer routine associated with a given device object.
IoInitializeWorkItem	The IoInitializeWorkItem routine initializes a work item that the caller has already allocated.
IoInvalidateDeviceRelations	The IoInvalidateDeviceRelations routine notifies the PnP manager that the relations for a device (such as bus relations, ejection relations, removal relations, and the target device relation) have changed.
IoInvalidateDeviceState	The IoInvalidateDeviceState routine notifies the PnP manager that some aspect of the PnP state of a device has changed.
IoIs32bitProcess	The IoIs32bitProcess routine checks whether the originator of the current I/O request is a 32-bit user-mode application.
IoIsErrorUserInduced	The IoIsErrorUserInduced routine determines whether an I/O error encountered while processing a request to a removable-media device was caused by the user.

TITLE	DESCRIPTION
IoIsWdmVersionAvailable	The IoIsWdmVersionAvailable routine checks whether a given WDM version is supported by the operating system.
IoMarkIrpPending	The IoMarkIrpPending routine marks the specified IRP, indicating that a driver's dispatch routine subsequently returned STATUS_PENDING because further processing is required by other driver routines.
IoOpenDeviceInterfaceRegistryKey	The IoOpenDeviceInterfaceRegistryKey routine returns a handle to a registry key for storing information about a particular device interface instance.
IoOpenDeviceRegistryKey	The IoOpenDeviceRegistryKey routine returns a handle to a device-specific or a driver-specific registry key for a particular device instance.
IoOpenDriverRegistryKey	Reserved.
IoQueueWorkItem	The IoQueueWorkItem routine associates a WorkItem routine with a work item, and it inserts the work item into a queue for later processing by a system worker thread.
IoQueueWorkItemEx	The IoQueueWorkItemEx routine associates a WorkItemEx routine with a work item, and it inserts the work item into a queue for later processing by a system worker thread.
IoRegisterContainerNotification	The IoRegisterContainerNotification routine registers a kernel-mode driver to receive notifications about a specified class of events.
IoRegisterDeviceInterface	The IoRegisterDeviceInterface routine registers a device interface class, if it has not been previously registered, and creates a new instance of the interface class, which a driver can subsequently enable for use by applications or other system components.
IoRegisterLastChanceShutdownNotification	The IoRegisterLastChanceShutdownNotification routine registers a driver to receive an IRP_MJ_SHUTDOWN IRP when the system is shut down, after all file systems have been flushed.
IoRegisterPlugPlayNotification	The IoRegisterPlugPlayNotification routine registers a Plug and Play (PnP) notification callback routine to be called when a PnP event of the specified category occurs.
IoRegisterShutdownNotification	The IoRegisterShutdownNotification routine registers the driver to receive an IRP_MJ_SHUTDOWN IRP when the system is shut down.
IoReleaseRemoveLock	The IoReleaseRemoveLock routine releases a remove lock acquired with a previous call to IoAcquireRemoveLock.

TITLE	DESCRIPTION
IoReleaseRemoveLockAndWait	The IoReleaseRemoveLockAndWait routine releases a remove lock that the driver acquired in a previous call to IoAcquireRemoveLock, and waits until all acquisitions of the lock have been released.
IoRemoveLinkShareAccess	The IoRemoveLinkShareAccess routine removes the access and link share-access information for a given open instance of a file object.
IoRemoveShareAccess	The IoRemoveShareAccess routine removes the access and share-access information for a given open instance of a file object.
IoReportInterruptActive	The IoReportInterruptActive routine informs the operating system that a registered interrupt service routine (ISR) is active and ready to handle interrupt requests.
IoReportInterruptInactive	The IoReportInterruptInactive routine informs the operating system that a registered interrupt service routine (ISR) is inactive and is not expecting interrupt requests.
IoReportTargetDeviceChange	The IoReportTargetDeviceChange routine notifies the PnP manager that a custom event has occurred on a device.
IoReportTargetDeviceChangeAsynchronous	The IoReportTargetDeviceChangeAsynchronous routine notifies the PnP manager that a custom event has occurred on a device.
IoRequestDeviceEject	The IoRequestDeviceEject routine notifies the PnP manager that the device eject button was pressed.
IoRequestDpc	The IoRequestDpc routine queues a driver-supplied DpcForIsr routine to complete interrupt-driven I/O processing at a lower IRQL.
IoReuseIrp	The IoReuseIrp routine reinitializes an IRP so that it can be reused.
IoSetCancelRoutine	The IoSetCancelRoutine routine sets up a driver-supplied Cancel routine to be called if a given IRP is canceled.
IoSetCompletionRoutine	The IoSetCompletionRoutine routine registers an IoCompletion routine, which will be called when the next-lower-level driver has completed the requested operation for the given IRP.
IoSetCompletionRoutineEx	The IoSetCompletionRoutineEx routine registers an IoCompletion routine, which is called when the next-lower-level driver has completed the requested operation for the given IRP.
IoSetDeviceInterfacePropertyData	The IoSetDeviceInterfacePropertyData routine modifies the current value of a device interface property.

TITLE	DESCRIPTION
IoSetDeviceInterfaceState	The IoSetDeviceInterfaceState routine enables or disables an instance of a previously registered device interface class.
IoSetDevicePropertyData	The IoSetDevicePropertyData routine modifies the current setting for a device property.
IoSetIoPriorityHint	The IoSetIoPriorityHint routine sets the priority hint value for an IRP.
IoSetLinkShareAccess	The IoSetLinkShareAccess routine sets the access rights for link sharing the specified file object.
IoSetNextIrpStackLocation	The IoSetNextIrpStackLocation routine sets the IRP stack location in a driver-allocated IRP to that of the caller.
IoSetShareAccess	The IoSetShareAccess routine sets the access rights for sharing the given file object.
IoSetShareAccessEx	The IoSetShareAccessEx routine sets the access rights for sharing the specified file object.
IoSetStartIoAttributes	The IoSetStartIoAttributes routine sets attributes for the driver's StartIo routine.
IoSetTopLevelIrp	The IoSetTopLevelIrp routine sets the value of the TopLevelIrp field of the current thread.
IoSizeOfIrp	The IoSizeOfIrp routine determines the size in bytes for an IRP, given the number of stack locations in the IRP.
IoSizeofWorkItem	The IoSizeofWorkItem routine returns the size, in bytes, of an IO_WORKITEM structure.
IoStartNextPacket	The IoStartNextPacket routine dequeues the next IRP, if any, from the given device object's associated device queue and calls the driver's StartIo routine.
IoStartNextPacketByKey	The IoStartNextPacketByKey routine dequeues the next I/O request packet from the specified device object's associated device queue according to a specified sort-key value and calls the driver's StartIo routine with that IRP.
IoStartPacket	The IoStartPacket routine calls the driver's StartIo routine with the given IRP or inserts the IRP into the device queue associated with the given device object if the device is already busy.
IoStartTimer	The IoStartTimer routine enables the timer associated with a given device object so the driver-supplied IoTimer routine is called once per second.
IoStopTimer	The IoStopTimer routine disables the timer for a specified device object so the driver-supplied IoTimer routine is not called.

TITLE	DESCRIPTION
IoUninitializeWorkItem	The IoUninitializeWorkItem routine uninitializes a work item that was initialized by IoInitializeWorkItem.
IoUnregisterContainerNotification	The IoUnregisterContainerNotification routine cancels a container notification registration that was previously created by the IoRegisterContainerNotification routine.
IoUnregisterPlugPlayNotification	This routine is obsolete in Windows 7 and later versions of Windows. For more information, see the following Remarks section.The IoUnregisterPlugPlayNotification routine removes the registration of a driver's callback routine for a PnP event.
IoUnregisterPlugPlayNotificationEx	The IoUnregisterPlugPlayNotificationEx routine cancels the registration of a driver's callback routine for notifications of Plug and Play (PnP) events.
IoUnregisterShutdownNotification	The IoUnregisterShutdownNotification routine removes a registered driver from the shutdown notification queue.
IoUpdateLinkShareAccess	The IoUpdateLinkShareAccess routine updates the share access for the given file object, usually when the file is being opened.
IoUpdateShareAccess	The IoUpdateShareAccess routine updates the share access for the given file object, usually when the file is being opened.
IoValidateDeviceIoControlAccess	For more information, see the WdmlibIoValidateDeviceIoControlAccess function.
IoWithinStackLimits	The IoWithinStackLimits routine determines whether a region of memory is within the stack limit of the current thread.
IoWMIAllocateInstanceIds	The IoWMIAllocateInstanceIds routine allocates one or more instance IDs that are unique to the GUID.
IoWMIDeviceObjectToInstanceName	The IoWMIDeviceObjectToInstanceName routine determines the instance name for the WMI class instance implemented by the driver that is specified by a device object.
IoWMIDeviceObjectToProviderId	The IoWMIDeviceObjectToProviderId routine translates the specified device object into the corresponding WMI Provider ID.
IoWMIExecuteMethod	The IoWMIExecuteMethod routine runs a WMI class method on the specified WMI data block instance.
IoWMIHandleToInstanceName	The IoWMIHandleToInstanceName routine determines the instance name for the WMI class instance implemented by the driver that is specified by a file handle.
IoWMIOpenBlock	The IoWMIOpenBlock routine opens the WMI data block object for the specified WMI class.
IoWMIQueryAllData	The IoWMIQueryAllData routine returns all WMI data blocks that implement a given WMI class.

TITLE	DESCRIPTION
IoWMIQueryAllDataMultiple	The IoWMIQueryAllDataMultiple routine returns all WMI data blocks that implement one of a set of WMI classes.
IoWMIQuerySingleInstance	The IoWMIQuerySingleInstance routine returns the specified instance of a WMI data block.
IoWMIQuerySingleInstanceMultiple	The IoWMIQuerySingleInstanceMultiple routine returns all WMI data block instances that implement the specified WMI classes with the specified instance names.
IoWMIRegistrationControl	The IoWMIRegistrationControl routine registers or unregisters the caller as a WMI data provider for a specified device object.
IoWMISetNotificationCallback	The IoWMISetNotificationCallback routine registers a notification callback for a WMI event.
IoWMISetSingleInstance	The IoWMISetSingleInstance routine sets the values for properties within the data block instance that matches the specified WMI class and instance name.
IoWMISetSingleItem	The IoWMISetSingleItem routine sets a single property in the data block instance that matches the specified WMI class and instance name.
IoWMISuggestInstanceName	The IoWMISuggestInstanceName routine is used to request that WMI suggest a base name which a driver can use to build WMI instance names for the device.
IoWMIWriteEvent	The IoWMIWriteEvent routine delivers a given event to the user-mode WMI components for notification.
IoWriteErrorLogEntry	The IoWriteErrorLogEntry routine queues a given error log packet to the system error logging thread.
IsListEmpty	The IsListEmpty routine indicates whether a doubly linked list of LIST_ENTRY structures is empty.
KdBreakPointWithStatus	The KdBreakPointWithStatus macro breaks into the kernel debugger and sends the value of Status to the debugger.
KdChangeOption	The KdChangeOption routine accesses and changes state in the kernel that is related to kernel debugging.
KdDisableDebugger	The KdDisableDebugger routine disables the kernel debugger.
KdEnableDebugger	The KdEnableDebugger routine re-enables the kernel debugger after a call to the KdDisableDebugger routine disables the kernel debugger.
KdPrint	The KdPrint macro sends a message to the kernel debugger.

TITLE	DESCRIPTION
KdPrintEx	The KdPrintEx macro sends a string to the kernel debugger if the conditions you specify are met.A call to KdPrintEx requires double parentheses.
KdRefreshDebuggerNotPresent	The KdRefreshDebuggerNotPresent macro refreshes the value of the KD_DEBUGGER_NOT_PRESENT global kernel variable.
KeAcquireSpinLock	The KeAcquireSpinLock routine acquires a spin lock so the caller can synchronize access to shared data in a multiprocessor-safe way by raising IRQL.
KeAcquireSpinLockAtDpcLevel	The KeAcquireSpinLockAtDpcLevel routine acquires a spin lock when the caller is already running at IRQL >= DISPATCH_LEVEL.
KeAddTriageDumpDataBlock	Adds a triage dump data block to a triage dump data block array.
KeAreAllApcsDisabled	The KeAreAllApcsDisabled routine indicates whether the calling thread is inside a guarded region or running at IRQL >= APC_LEVEL, which disables all APC delivery.
KeAreApcsDisabled	The KeAreApcsDisabled routine returns whether the calling thread is within a critical region or a guarded region, which disables normal kernel APC delivery.
KeBugCheckEx	The KeBugCheckEx routine brings down the system in a controlled manner when the caller discovers an unrecoverable inconsistency that would corrupt the system if the caller continued to run.
KeCancelTimer	The KeCancelTimer routine dequeues a timer object before the timer interval, if any was set, expires.
KeClearEvent	The KeClearEvent routine sets an event to a not-signaled state.
KeConvertAuxiliaryCounterToPerformanceCounter	The KeConvertAuxiliaryCounterToPerformanceCounter routine converts the specified auxiliary counter value into a performance counter value.
KeConvertPerformanceCounterToAuxiliaryCounter	The KeConvertPerformanceCounterToAuxiliaryCounter routine converts the specified performance counter value into an auxiliary counter value.
KeDelayExecutionThread	The KeDelayExecutionThread routine puts the current thread into an alertable or nonalertable wait state for a specified interval.
KeDeregisterBoundCallback	The KeDeregisterBoundCallback routine deregisters a user-mode bound exception callback registered by KeRegisterBoundCallback.
KeDeregisterBugCheckCallback	The KeDeregisterBugCheckCallback routine removes a callback routine that was registered by KeRegisterBugCheckCallback.

TITLE	DESCRIPTION
KeDeregisterBugCheckReasonCallback	The KeDeregisterBugCheckReasonCallback routine removes a callback routine that was registered by KeRegisterBugCheckReasonCallback.
KeDeregisterNmiCallback	The KeDeregisterNmiCallback routine deregisters a nonmaskable interrupt (NMI) callback registered by KeRegisterNmiCallback.
KeDeregisterProcessorChangeCallback	The KeDeregisterProcessorChangeCallback routine unregisters a callback function that was previously registered with the operating system by calling the KeRegisterProcessorChangeCallback routine.
KeEnterCriticalRegion	The KeEnterCriticalRegion routine temporarily disables the execution of normal kernel APCs, but does not prevent special kernel APCs from running.
KeEnterGuardedRegion	The KeEnterGuardedRegion routine enters a guarded region, which disables all kernel-mode APC delivery to the current thread.
KeFlushIoBuffers	The KeFlushIoBuffers routine flushes the memory region described by an MDL from caches of all processors.
KeFlushQueuedDpcs	The KeFlushQueuedDpcs routine returns after all queued DPCs on all processors have executed.
KefReleaseSpinLockFromDpcLevel	The KeReleaseSpinLockFromDpcLevel routine releases an executive spin lock without changing the IRQL.
KeGetCurrentIrql	The KeGetCurrentIrql routine returns the current IRQL.
KeGetCurrentNodeNumber	The KeGetCurrentNodeNumber routine gets the NUMA node number for the logical processor that the caller is running on.
KeGetCurrentProcessorNumberEx	The KeGetCurrentProcessorNumberEx routine gets the processor number of the logical processor that the caller is running on.
KeGetCurrentThread	The KeGetCurrentThread routine identifies the current thread.
KeGetProcessorIndexFromNumber	The KeGetProcessorIndexFromNumber routine converts a group number and a group-relative processor number to a systemwide processor index.
KeGetProcessorNumberFromIndex	The KeGetProcessorNumberFromIndex routine converts a systemwide processor index to a group number and a group-relative processor number.
KeGetRecommendedSharedDataAlignment	The KeGetRecommendedSharedDataAlignment routine returns the preferred alignment for memory structures that can be accessed by more than one processor.
KeInitializeCrashDumpHeader	The KeInitializeCrashDumpHeader routine supplies the header information the system requires for a crash dump file.

TITLE	DESCRIPTION
KeInitializeDeviceQueue	The KeInitializeDeviceQueue routine initializes a device queue object to a not-busy state.
KeInitializeDpc	The KeInitializeDpc routine initializes a DPC object, and registers a CustomDpc routine for that object.
KeInitializeEvent	The KeInitializeEvent routine initializes an event object as a synchronization (single waiter) or notification type event and sets it to a signaled or not-signaled state.
KeInitializeGuardedMutex	The KeInitializeGuardedMutex routine initializes a guarded mutex.
KeInitializeMutex	The KeInitializeMutex routine initializes a mutex object, setting it to a signaled state.
KeInitializeSemaphore	The KeInitializeSemaphore routine initializes a semaphore object with a specified count and specifies an upper limit that the count can attain.
KeInitializeSpinLock	The KeInitializeSpinLock routine initializes a variable of type KSPIN_LOCK.
KeInitializeThreadedDpc	The KeInitializeThreadedDpc routine initializes a threaded DPC object, and registers a CustomThreadedDpc routine for that object.
KeInitializeTimer	The KeInitializeTimer routine initializes a timer object.
KeInitializeTimerEx	The KeInitializeTimerEx routine initializes an extended kernel timer object.
KeInsertByKeyDeviceQueue	The KeInsertByKeyDeviceQueue routine acquires the spin lock for the specified DeviceQueue and queues an entry according to the specified sort-key value if the device queue is set to a busy state.
KeInsertDeviceQueue	The KeInsertDeviceQueue routine acquires the spin lock for the specified device queue object and, if the device queue is set to a busy state, queues the specified entry.
KeInsertQueueDpc	The KeInsertQueueDpc routine queues a DPC for execution.
KeIpiGenericCall	The KeIpiGenericCall routine causes the specified routine to run on all processors simultaneously.
KeIsExecutingDpc	Checks whether a DPC is being executed on current processor.
KeLeaveCriticalRegion	The KeLeaveCriticalRegion routine reenables the delivery of normal kernel-mode APCs that were disabled by a preceding call to KeEnterCriticalRegion.

TITLE	DESCRIPTION
KeLeaveGuardedRegion	The KeLeaveGuardedRegion routine exits a guarded region entered by KeEnterGuardedRegion.
KeLowerIrql	The KeLowerIrql routine restores the IRQL on the current processor to its original value.
KeMemoryBarrier	The KeMemoryBarrier routine creates a barrier at its position in the code—across which the compiler and the processor cannot move any operations.
KeQueryActiveGroupCount	The KeQueryActiveGroupCount routine returns the number of active processor groups in a multiprocessor system.
KeQueryActiveProcessorCount	The KeQueryActiveProcessorCount routine returns the number of currently active processors.
KeQueryActiveProcessorCountEx	The KeQueryActiveProcessorCountEx routine returns the number of active logical processors in a specified group in a multiprocessor system or in the entire system.
KeQueryActiveProcessors	The KeQueryActiveProcessors routine returns a bitmask of the currently active processors.
KeQueryAuxiliaryCounterFrequency	The KeQueryAuxiliaryCounterFrequency routine returns frequency of the auxiliary counter in units of Hz.
KeQueryDpcWatchdogInformation	The KeQueryDpcWatchdogInformation routine returns the deferred procedure call (DPC) watchdog timer values for the current processor.
KeQueryGroupAffinity	The KeQueryGroupAffinity routine returns an affinity mask that identifies the active logical processors in a specified group in a multiprocessor system.
KeQueryHighestNodeNumber	The KeQueryHighestNodeNumber routine returns the highest node number in a multiprocessor system that has a non-uniform memory access (NUMA) architecture.
KeQueryInterruptTime	The KeQueryInterruptTime routine returns the current value of the system interrupt time count, with accuracy to within system clock tick.
KeQueryInterruptTimePrecise	The KeQueryInterruptTimePrecise routine returns the current value of the system interrupt time count, with accuracy to within a microsecond.
KeQueryLogicalProcessorRelationship	The KeQueryLogicalProcessorRelationship routine gets information about the relationships of one or more processors to the other processors in a multiprocessor system.
KeQueryMaximumGroupCount	The KeQueryMaximumGroupCount routine returns the maximum number of groups in a multiprocessor system.
KeQueryMaximumProcessorCount	The KeQueryMaximumProcessorCount routine returns the maximum number of processors.

TITLE	DESCRIPTION
KeQueryMaximumProcessorCountEx	The KeQueryMaximumProcessorCountEx routine returns the maximum number of logical processors in a specified group in a multiprocessor system.
KeQueryNodeActiveAffinity	The KeQueryNodeActiveAffinity routine gets the current processor affinity of a specified node in a multiprocessor system that has a non-uniform memory access (NUMA) architecture.
KeQueryNodeMaximumProcessorCount	The KeQueryNodeMaximumProcessorCount routine returns the maximum number of logical processors that a specified node in a non-uniform memory access (NUMA) multiprocessor system can contain.
KeQueryPerformanceCounter	The KeQueryPerformanceCounter routine retrieves the current value and frequency of the performance counter.Use KeQueryPerformanceCounter to acquire high resolution (<1us) time stamps for time interval measurements.
KeQueryPriorityThread	The KeQueryPriorityThread routine returns the current priority of a particular thread.
KeQueryRuntimeThread	The KeQueryRuntimeThread routine reports the accumulated kernel-mode and user-mode run time of a thread, in clock ticks.
KeQuerySystemTime	The KeQuerySystemTime routine obtains the current system time.
KeQuerySystemTimePrecise	The KeQuerySystemTimePrecise routine retrieves the current system time, and is more precise than the KeQuerySystemTime routine.
KeQueryTickCount	The KeQueryTickCount routine maintains a count of the interval timer interrupts that have occurred since the system was booted.
KeQueryTimeIncrement	The KeQueryTimeIncrement routine returns the number of 100-nanosecond units that are added to the system time each time the interval clock interrupts.
KeQueryTotalCycleTimeThread	The KeQueryTotalCycleTimeThread routine returns the accumulated cycle time for the specified thread.
KeQueryUnbiasedInterruptTime	The KeQueryUnbiasedInterruptTime routine returns the current value of the system interrupt time count.
KeRaiseIrql	The KeRaiseIrql routine raises the hardware priority to the specified IRQL value, thereby masking off interrupts of equivalent or lower IRQL on the current processor.

TITLE	DESCRIPTION
KeRaiseIrqlToDpcLevel	The KeRaiseIrqlToDpcLevel routine raises the hardware priority to IRQL = DISPATCH_LEVEL, thereby masking off interrupts of equivalent or lower IRQL on the current processor.
KeReadStateEvent	The KeReadStateEvent routine returns the current state, signaled or not-signaled, of an event object.
KeReadStateMutex	The KeReadStateMutex routine returns the current state, signaled or not-signaled, of the specified mutex object.
KeReadStateSemaphore	The KeReadStateSemaphore routine returns the current state, signaled or not-signaled, of the specified semaphore object.
KeReadStateTimer	The KeReadStateTimer routine reads the current state of a timer object.
KeRegisterBoundCallback	The KeRegisterBoundCallback routine registers a routine to be called whenever a user-mode bound exception occurs.
KeRegisterBugCheckCallback	The KeRegisterBugCheckCallback routine registers a BugCheckCallback routine, which executes when the operating system issues a bug check.
KeRegisterBugCheckReasonCallback	The KeRegisterBugCheckReasonCallback routine registers a BugCheckDumpIoCallback, BugCheckSecondaryDumpDataCallback, or BugCheckAddPagesCallback routine, which executes when the operating system issues a bug check.
KeRegisterNmiCallback	The KeRegisterNmiCallback routine registers a routine to be called whenever a nonmaskable interrupt (NMI) occurs.
KeRegisterProcessorChangeCallback	The KeRegisterProcessorChangeCallback routine registers a callback function with the operating system so that the operating system will notify the driver when a new processor is added to the hardware partition.
KeReleaseGuardedMutex	The KeReleaseGuardedMutex routine releases a guarded mutex acquired with KeAcquireGuardedMutex or KeTryToAcquireGuardedMutex.
KeReleaseGuardedMutexUnsafe	The KeReleaseGuardedMutexUnsafe routine releases a guarded mutex acquired by KeAcquireGuardedMutexUnsafe.
KeReleaseInStackQueuedSpinLock	The KeReleaseInStackQueuedSpinLock routine releases a queued spin lock acquired by KeAcquireInStackQueuedSpinLock.
KeReleaseInStackQueuedSpinLockForDpc	The KeReleaseInStackQueuedSpinLockForDpc routine releases a queued spin lock that was acquired by calling KeAcquireInStackQueuedSpinLockForDpc.
KeReleaseInStackQueuedSpinLockFromDpcLevel	The KeReleaseInStackQueuedSpinLockFromDpcLevel routine releases a queued spin lock acquired by KeAcquireInStackQueuedSpinLockAtDpcLevel.

TITLE	DESCRIPTION
KeReleaseInterruptSpinLock	The KeReleaseInterruptSpinLock routine releases an interrupt spin lock acquired by KeAcquireInterruptSpinLock.
KeReleaseMutex	The KeReleaseMutex routine releases a mutex object, and specifies whether the caller is to call one of the KeWaitXxx routines as soon as KeReleaseMutex returns control.
KeReleaseSemaphore	The KeReleaseSemaphore routine releases the specified semaphore object.
KeReleaseSpinLock	The KeReleaseSpinLock routine releases a spin lock and restores the original IRQL at which the caller was running.
KeReleaseSpinLockForDpc	The KeReleaseSpinLockForDpc routine releases a spin lock that was acquired by calling KeAcquireSpinLockForDpc.
KeReleaseSpinLockFromDpcLevel	The KeReleaseSpinLockFromDpcLevel routine releases an executive spin lock without changing the IRQL.
KeRemoveByKeyDeviceQueue	The KeRemoveByKeyDeviceQueue routine removes an entry, selected according to a sort key value, from the specified device queue.
KeRemoveDeviceQueue	The KeRemoveDeviceQueue routine removes an entry from the head of a specified device queue.
KeRemoveEntryDeviceQueue	The KeRemoveEntryDeviceQueue routine returns whether the specified entry is in the device queue and removes it, if it was queued, from the device queue.
KeRemoveQueueDpc	The KeRemoveQueueDpc routine removes the specified DPC object from the system DPC queue.
KeResetEvent	The KeResetEvent routine resets a specified event object to a not-signaled state and returns the previous state of that event object.
KeRestoreExtendedProcessorState	The KeRestoreExtendedProcessorState routine restores extended processor state information that was previously saved.
KeRestoreFloatingPointState	The KeRestoreFloatingPointState routine restores the nonvolatile floating-point context saved by the preceding call to KeSaveFloatingPointState.
KeRevertToUserAffinityThreadEx	The KeRevertToUserAffinityThreadEx routine restores the previous affinity of the current thread.
KeRevertToUserGroupAffinityThread	The KeRevertToUserGroupAffinityThread routine restores the group affinity of the calling thread to its original value at the time that the thread was created.
KeSaveExtendedProcessorState	The KeSaveExtendedProcessorState routine saves extended processor state information.

TITLE	DESCRIPTION
KeSaveFloatingPointState	The KeSaveFloatingPointState routine saves the nonvolatile floating-point context so the caller can carry out floating-point operations.
KeSetCoalescableTimer	The KeSetCoalescableTimer routine sets the initial expiration time and period of a timer object and specifies how much delay can be tolerated in the expiration times.
KeSetEvent	The KeSetEvent routine sets an event object to a signaled state if the event was not already signaled, and returns the previous state of the event object.
KeSetImportanceDpc	The KeSetImportanceDpc routine specifies how soon the DPC routine is run.
KeSetPriorityThread	The KeSetPriorityThread routine sets the run-time priority of a driver-created thread.
KeSetSystemAffinityThread	The KeSetSystemAffinityThread routine sets the system affinity of the current thread.
KeSetSystemAffinityThreadEx	The KeSetSystemAffinityThreadEx routine sets the system affinity of the current thread.
KeSetSystemGroupAffinityThread	The KeSetSystemGroupAffinityThread routine changes the group number and affinity mask of the calling thread.
KeSetTargetProcessorDpc	The KeSetTargetProcessorDpc routine specifies the processor that a DPC routine will be run on.
KeSetTargetProcessorDpcEx	The KeSetTargetProcessorDpcEx routine specifies the processor that a DPC routine will run on.
KeSetTimer	The KeSetTimer routine sets the absolute or relative interval at which a timer object is to be set to a signaled state and, optionally, supplies a CustomTimerDpc routine to be executed when that interval expires.
KeSetTimerEx	The KeSetTimerEx routine sets the absolute or relative interval at which a timer object is to be set to a signaled state, optionally supplies a CustomTimerDpc routine to be executed when that interval expires, and optionally supplies a recurring interval for the timer.
KeStallExecutionProcessor	The KeStallExecutionProcessor routine stalls the caller on the current processor for a specified time interval.
KeSynchronizeExecution	The KeSynchronizeExecution routine synchronizes the execution of the specified routine with the interrupt service routine (ISR) that is assigned to a set of one or more interrupt objects.
KeTestSpinLock	The KeTestSpinLock routine tests for the availability of a spin lock.

TITLE	DESCRIPTION
KeTryToAcquireSpinLockAtDpcLevel	The KeTryToAcquireSpinLockAtDpcLevel routine attempts to acquire a spin lock at DISPATCH_LEVEL.
KeWaitForMultipleObjects	The KeWaitForMultipleObjects routine puts the current thread into an alertable or nonalertable wait state until any or all of a number of dispatcher objects are set to a signaled state or (optionally) until the wait times out.
KeWaitForSingleObject	The KeWaitForSingleObject routine puts the current thread into a wait state until the given dispatcher object is set to a signaled state or (optionally) until the wait times out.
KzLowerIrql	Restores the IRQL on the current processor to its original value.
KzRaiseIrql	Raises the hardware priority to the specified IRQL value, thereby masking off interrupts of equivalent or lower IRQL on the current processor.
MmAdvanceMdl	The MmAdvanceMdl routine advances the beginning of an MDL's virtual memory range by the specified number of bytes.
MmAllocateContiguousMemory	The MmAllocateContiguousMemory routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateContiguousMemorySpecifyCache	The MmAllocateContiguousMemorySpecifyCache routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateContiguousMemorySpecifyCacheNode	The MmAllocateContiguousMemorySpecifyCacheNode routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateContiguousNodeMemory	The MmAllocateContiguousNodeMemory routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.
MmAllocateMappingAddress	The MmAllocateMappingAddress routine reserves a range of system virtual address space of the specified size.
MmAllocateMdlForIoSpace	The MmAllocateMdlForIoSpace routine allocates an MDL and initializes this MDL to describe a set of physical address ranges in I/O address space.
MmAllocateNodePagesForMdlEx	The MmAllocateNodePagesForMdlEx routine allocates nonpaged physical memory from an ideal node, and allocates an MDL structure to describe this memory.
MmAllocatePagesForMdl	The MmAllocatePagesForMdl routine allocates zero-filled, nonpaged, physical memory pages to an MDL.
MmAllocatePagesForMdlEx	The MmAllocatePagesForMdlEx routine allocates nonpaged, physical memory pages to an MDL.

TITLE	DESCRIPTION
MmBuildMdlForNonPagedPool	The MmBuildMdlForNonPagedPool routine receives an MDL that specifies a nonpaged virtual memory buffer, and updates it to describe the underlying physical pages.
MmFreeContiguousMemory	The MmFreeContiguousMemory routine releases a range of physically contiguous memory that was allocated by an MmAllocateContiguousMemoryXxx routine.
MmFreeContiguousMemorySpecifyCache	The MmFreeContiguousMemorySpecifyCache routine frees a buffer that was allocated by an MmAllocateContiguousMemorySpecifyCacheXxx routine.
MmFreeMappingAddress	The MmFreeMappingAddress routine frees a range of virtual memory reserved by the MmAllocateMappingAddress routine.
MmFreePagesFromMdl	The MmFreePagesFromMdl routine frees all the physical pages that are described by an MDL that was created by the MmAllocatePagesForMdl routine.
MmGetMdlByteCount	The MmGetMdlByteCount macro returns the length, in bytes, of the buffer described by the specified MDL.
MmGetSystemAddressForMdl	The MmGetSystemAddressForMdl routine is obsolete for Windows 2000 and later versions of Windows, and for Windows Me.
MmGetSystemRoutineAddress	The MmGetSystemRoutineAddress routine returns a pointer to a function specified by SystemRoutineName.
MmIsDriverSuspectForVerifier	The MmIsDriverSuspectForVerifier routine indicates whether the driver represented by the specified driver object is in the list of drivers that are selected to be verified by Driver Verifier.
MmIsDriverVerifying	The MmIsDriverVerifying routine indicates whether the kernel-mode driver that is identified by the specified driver object is being verified or calls a driver that is being verified by Driver Verifier.
MmIsDriverVerifyingByAddress	The MmIsDriverVerifyingByAddress routine checks whether the kernel-mode driver that is identified by the specified image address is being verified or calls a driver that is being verified by Driver Verifier.
MmLockPagableCodeSection	The MmLockPagableCodeSection routine locks a section of driver code, containing a set of driver routines marked with a special compiler directive, into system space.
MmLockPagableDataSection	The MmLockPagableDataSection routine locks an entire section of driver data into system space.
MmMapIoSpace	The MmMapIoSpace routine maps the given physical address range to nonpaged system space.

TITLE	DESCRIPTION
MmMapIoSpaceEx	The MmMapIoSpaceEx routine maps the given physical address range to non-paged system space using the specified page protection.
MmMapLockedPages	The MmMapLockedPages routine is obsolete for Windows 2000 and later versions of Windows, and for Windows Me.
MmMapLockedPagesSpecifyCache	The MmMapLockedPagesSpecifyCache routine maps the physical pages that are described by an MDL to a virtual address, and enables the caller to specify the cache attribute that is used to create the mapping.
MmMapLockedPagesWithReservedMapping	The MmMapLockedPagesWithReservedMapping routine maps all or part of an address range that was previously reserved by the MmAllocateMappingAddress routine.
MmMapMdl	This function maps physical pages described by a memory descriptor list (MDL) into the system virtual address space.
MmPageEntireDriver	The MmPageEntireDriver routine causes all of a driver's code and data to be made pageable, overriding the attributes of the various sections that make up the driver's image.
MmProbeAndLockPages	The MmProbeAndLockPages routine probes the specified virtual memory pages, makes them resident, and locks them in memory.
MmProbeAndLockSelectedPages	The MmProbeAndLockSelectedPages routine probes the selected virtual memory pages, makes them resident, and locks them in memory.
MmProtectMdlSystemAddress	The MmProtectMdlSystemAddress routine sets the protection type for a memory address range.
MmQuerySystemSize	The MmQuerySystemSize routine returns an estimate of the amount of memory in the system.
MmResetDriverPaging	The MmResetDriverPaging routine resets the pageable status of a driver's sections to that specified when the driver was compiled.
MmSizeOfMdl	The MmSizeOfMdl routine returns the number of bytes to allocate for an MDL describing a given address range.
MmUnlockPagableImageSection	The MmUnlockPagableImageSection routine releases a section of driver code or driver data, previously locked into system space with MmLockPagableCodeSection, MmLockPagableDataSection or MmLockPagableSectionByHandle, so the section can be paged out again.
MmUnlockPages	The MmUnlockPages routine unlocks the physical pages that are described by the specified memory descriptor list (MDL).

TITLE	DESCRIPTION
MmUnmapIoSpace	The MmUnmapIoSpace routine unmaps a specified range of physical addresses previously mapped by MmMapIoSpace.
MmUnmapLockedPages	The MmUnmapLockedPages routine releases a mapping that was set up by a preceding call to the MmMapLockedPages or MmMapLockedPagesSpecifyCache routine.
MmUnmapReservedMapping	The MmUnmapReservedMapping routine unmaps a memory buffer that was mapped by the MmMapLockedPagesWithReservedMapping routine.
NtCommitComplete	The ZwCommitComplete routine notifies KTM that the calling resource manager has finished committing a transaction's data.
NtCommitEnlistment	The ZwCommitEnlistment routine initiates the commit operation for a specified enlistment's transaction.
NtCommitTransaction	The ZwCommitTransaction routine initiates a commit operation for a specified transaction.
NtCreateEnlistment	The ZwCreateEnlistment routine creates a new enlistment object for a transaction.
NtCreateResourceManager	The ZwCreateResourceManager routine creates a resource manager object.
NtCreateTransaction	The ZwCreateTransaction routine creates a transaction object.
NtCreateTransactionManager	The ZwCreateTransactionManager routine creates a new transaction manager object.
NtEnumerateTransactionObject	The ZwEnumerateTransactionObject routine enumerates the KTM objects on a computer.
NtGetNotificationResourceManager	The ZwGetNotificationResourceManager routine retrieves the next transaction notification from a specified resource manager's notification queue.
NtOpenEnlistment	The ZwOpenEnlistment routine obtains a handle to an existing enlistment object.
NtOpenResourceManager	The ZwOpenResourceManager routine returns a handle to an existing resource manager object.
NtOpenTransaction	The ZwOpenTransaction routine obtains a handle to an existing transaction object.
NtOpenTransactionManager	The ZwOpenTransactionManager routine obtains a handle to an existing transaction manager object.
NtPowerInformation	The ZwPowerInformation routine sets or retrieves system power information.

TITLE	DESCRIPTION
NtPrepareComplete	The ZwPrepareComplete routine notifies KTM that the calling resource manager has finished preparing a transaction's data.
NtPrepareEnlistment	The ZwPrepareEnlistment routine initiates the prepare operation for a specified enlistment's transaction.
NtPrePrepareComplete	The ZwPrePrepareComplete routine notifies KTM that the calling resource manager has finished preliminary preparation of a transaction's data.
NtPrePrepareEnlistment	The ZwPrePrepareEnlistment routine initiates the pre-prepare operation for a specified enlistment's transaction.
NtQueryInformationEnlistment	The ZwQueryInformationEnlistment routine retrieves information about a specified enlistment object.
NtQueryInformationResourceManager	The ZwQueryInformationResourceManager routine retrieves information about a specified resource manager object.
NtQueryInformationTransaction	The ZwQueryInformationTransaction routine retrieves information about a specified transaction.
NtQueryInformationTransactionManager	The ZwQueryInformationTransactionManager routine retrieves information about a specified transaction manager object.
NtReadOnlyEnlistment	The ZwReadOnlyEnlistment routine sets a specified enlistment to be read-only.
NtRecoverEnlistment	The ZwRecoverEnlistment routine initiates a recovery operation for the transaction that is associated with a specified enlistment.
NtRecoverResourceManager	The ZwRecoverResourceManager routine tries to recover the transaction that is associated with each enlistment of a specified resource manager object.
NtRecoverTransactionManager	The ZwRecoverTransactionManager routine reconstructs the state of the transaction manager object (including all transactions, enlistments, and resource managers) from the recovery information that is in the log stream.
NtRenameTransactionManager	The NtRenameTransactionManager routine changes the identity of the transaction manager object that is stored in the CLFS log file stream contained in the log file name.
NtRollbackComplete	The ZwRollbackComplete routine notifies KTM that the calling resource manager has finished rolling back a transaction's data.
NtRollbackEnlistment	The ZwRollbackEnlistment routine rolls back the transaction that is associated with a specified enlistment.
NtRollbackTransaction	The ZwRollbackTransaction routine initiates a rollback operation for a specified transaction.

TITLE	DESCRIPTION
NtRollforwardTransactionManager	The ZwRollforwardTransactionManager routine initiates recovery operations for all of the in-progress transactions that are assigned to a specified transaction manager.
NtSetInformationEnlistment	The ZwSetInformationEnlistment routine sets information for a specified enlistment object.
NtSetInformationResourceManager	The ZwSetInformationResourceManager routine is not used.
NtSetInformationTransaction	The ZwSetInformationTransaction routine sets information for a specified transaction.
NtSetInformationTransactionManager	Do not call this routine from kernel-mode code.
NtSinglePhaseReject	The ZwSinglePhaseReject routine informs KTM that the calling resource manager will not support single-phase commit operations for a specified enlistment.
ObCloseHandle	The ObCloseHandle routine closes an object handle.
ObDereferenceObject	The ObDereferenceObject routine decrements the given object's reference count and performs retention checks.
ObDereferenceObjectDeferDelete	The ObDereferenceObjectDeferDelete routine decrements the reference count for the given object, checks for object retention, and avoids deadlocks.
ObDereferenceObjectDeferDeleteWithTag	The ObDereferenceObjectDeferDeleteWithTag routine decrements the reference count for the specified object, defers deletion of the object to avoid deadlocks, and writes a four-byte tag value to the object to support object reference tracing.
ObDereferenceObjectWithTag	The ObDereferenceObjectWithTag routine decrements the reference count of the specified object, and writes a four-byte tag value to the object to support object reference tracing.
ObfReferenceObject	The ObReferenceObject routine increments the reference count to the given object.
ObGetObjectSecurity	The ObGetObjectSecurity routine gets the security descriptor for a given object.
ObReferenceObject	The ObReferenceObject routine increments the reference count to the given object.
ObReferenceObjectByHandle	The ObReferenceObjectByHandle routine provides access validation on the object handle, and, if access can be granted, returns the corresponding pointer to the object's body.
ObReferenceObjectByHandleWithTag	The ObReferenceObjectByHandleWithTag routine increments the reference count of the object that is identified by the specified handle, and writes a four-byte tag value to the object to support object reference tracing.

TITLE	DESCRIPTION
ObReferenceObjectByPointer	The ObReferenceObjectByPointer routine increments the pointer reference count for a given object.
ObReferenceObjectByPointerWithTag	The ObReferenceObjectByPointerWithTag routine increments the reference count of the specified object, and writes a four-byte tag value to the object to support object reference tracing.
ObReferenceObjectSafe	The ObReferenceObjectSafe function increments the reference count for an object and determines if it is safe to use the object. It returns FALSE if the object is being deleted or TRUE if it's safe to use the object further.
ObReferenceObjectWithTag	The ObReferenceObjectWithTag routine increments the reference count of the specified object, and writes a four-byte tag value to the object to support object reference tracing.
ObRegisterCallbacks	The ObRegisterCallbacks routine registers a list of callback routines for thread, process, and desktop handle operations.
ObReleaseObjectSecurity	The ObReleaseObjectSecurity routine is the reciprocal to ObGetObjectSecurity.
ObUnRegisterCallbacks	The ObUnRegisterCallbacks routine unregisters a set of callback routines that were registered with the ObRegisterCallbacks routine.
PcwAddInstance	The PcwAddInstance function adds the specified instance of the counter set to the consumer buffer.
PcwCloseInstance	The PcwCloseInstance function closes the specified instance of the counter set.
PcwCreateInstance	The PcwCreateInstance function creates a new instance for the specified registered counter set.
PcwRegister	The PcwRegister function registers the caller as a provider of the specified counter set.
PcwUnregister	The PcwUnregister function unregisters the provider of the specified counter set.
PoCallDriver	The PoCallDriver routine passes a power IRP to the next-lower driver in the device stack. (Windows Server 2003, Windows XP, and Windows 2000 only.).
PoClearPowerRequest	The PoClearPowerRequest routine decrements the count for the specified power request type.
PoCreatePowerRequest	The PoCreatePowerRequest routine creates a power request object.
PoDeletePowerRequest	The PoDeletePowerRequest routine deletes a power request object.

TITLE	DESCRIPTION
PoEndDeviceBusy	The PoEndDeviceBusy routine marks the end of a period of time in which the device is busy.
PoFxActivateComponent	The PoFxActivateComponent routine increments the activation reference count on the specified component.
PoFxCompleteDevicePowerNotRequired	The PoFxCompleteDevicePowerNotRequired routine notifies the power management framework (PoFx) that the calling driver has completed its response to a call to the driver's DevicePowerNotRequiredCallback callback routine.
PoFxCompleteIdleCondition	The PoFxCompleteIdleCondition routine informs the power management framework (PoFx) that the specified component has completed a pending change to the idle condition.
PoFxCompleteIdleState	The PoFxCompleteIdleState routine informs the power management framework (PoFx) that the specified component has completed a pending change to an Fx state.
PoFxIdleComponent	The PoFxIdleComponent routine decrements the activation reference count on the specified component.
PoFxIssueComponentPerfStateChange	The PoFxIssueComponentPerfStateChange routine submits a request to place a device component in a particular performance state.
PoFxIssueComponentPerfStateChangeMultiple	The PoFxIssueComponentPerfStateChangeMultiple routine submits a request to change the performance states in multiple performance state sets simultaneously for a device component.
PoFxNotifySurprisePowerOn	The PoFxNotifySurprisePowerOn routine notifies the power management framework (PoFx) that a device was turned on as a side effect of supplying power to some other device.
PoFxPowerControl	The PoFxPowerControl routine sends a power control request to the power management framework (PoFx).
PoFxPowerOnCrashdumpDevice	The PoFxPowerOnCrashdumpDevice routine requests that a crash-dump device be turned on.
PoFxQueryCurrentComponentPerfState	The PoFxQueryCurrentComponentPerfState routine retrieves the active performance state in a component's performance state set.
PoFxRegisterComponentPerfStates	The PoFxRegisterComponentPerfStates routine registers a device component for performance state management by the power management framework (PoFx).
PoFxRegisterCrashdumpDevice	The PoFxRegisterCrashdumpDevice routine registers a crash-dump device.
PoFxRegisterDevice	The PoFxRegisterDevice routine registers a device with the power management framework (PoFx).

TITLE	DESCRIPTION
PoFxReportDevicePoweredOn	The PoFxReportDevicePoweredOn routine notifies the power management framework (PoFx) that the device completed the requested transition to the D0 (fully on) power state.
PoFxSetComponentLatency	The PoFxSetComponentLatency routine specifies the maximum latency that can be tolerated in the transition from the idle condition to the active condition in the specified component.
PoFxSetComponentResidency	The PoFxSetComponentResidency routine sets the estimated time for how long a component is likely to remain idle after the component enters the idle condition.
PoFxSetComponentWake	The PoFxSetComponentWake routine indicates whether the driver arms the specified component to wake whenever the component enters the idle condition.
PoFxSetDeviceIdleTimeout	The PoFxSetDeviceIdleTimeout routine specifies the minimum time interval from when the last component of the device enters the idle condition to when the power management framework (PoFx) calls the driver's DevicePowerNotRequiredCallback routine.
PoFxSetTargetDripsDevicePowerState	This routine is called to notify the power manager of the device's target device power state for DRIPS. The driver can override the DRIPS constraint provided by the PEP.
PoFxStartDevicePowerManagement	The PoFxStartDevicePowerManagement routine completes the registration of a device with the power management framework (PoFx) and starts device power management.
PoFxUnregisterDevice	The PoFxUnregisterDevice routine removes the registration of a device from the power management framework (PoFx).
PoGetSystemWake	The PoGetSystemWake routine determines whether a specified IRP has been marked as waking the system from a sleeping state.
PopEntryList	The PopEntryList routine removes the first entry from a singly linked list of SINGLE_LIST_ENTRY structures.
PoQueryWatchdogTime	The PoQueryWatchdogTime routine indicates whether the power manager has enabled a watchdog time-out counter for any power IRP that is currently assigned to the device stack.
PoRegisterDeviceForIdleDetection	The PoRegisterDeviceForIdleDetection routine enables or cancels idle detection and sets idle time-out values for a device.
PoRegisterPowerSettingCallback	The PoRegisterPowerSettingCallback routine registers a power-setting callback routine to receive notifications of changes in the specified power setting.
PoRegisterSystemState	The PoRegisterSystemState routine registers the system as busy due to certain activity.

TITLE	DESCRIPTION
PoRequestPowerIrp	The PoRequestPowerIrp routine allocates a power IRP and sends it to the top driver in the device stack for the specified device.
PoSetDeviceBusyEx	The PoSetDeviceBusyEx routine notifies the power manager that the device associated with the specified idle counter is busy.
PoSetPowerRequest	The PoSetPowerRequest routine increments the count for the specified power request type.
PoSetPowerState	The PoSetPowerState routine notifies the system of a change in the device power state for a device.
PoSetSystemState	Drivers call the PoSetSystemState routine to indicate that the system is active.
PoSetSystemWake	The PoSetSystemWake routine marks the specified IRP as one that contributed to waking the system from a sleep state.
PoStartDeviceBusy	The PoStartDeviceBusy routine marks the start of a period of time in which the device is busy.
PoStartNextPowerIrp	The PoStartNextPowerIrp routine signals the power manager that the driver is ready to handle the next power IRP. (Windows Server 2003, Windows XP, and Windows 2000 only.).
PoUnregisterPowerSettingCallback	The PoUnregisterPowerSettingCallback routine unregisters a power-setting callback routine that a driver previously registered by calling the PoRegisterPowerSettingCallback routine.
PoUnregisterSystemState	The PoUnregisterSystemState routine cancels a system state registration created by PoRegisterSystemState.
ProbeForRead	The ProbeForRead routine checks that a user-mode buffer actually resides in the user portion of the address space, and is correctly aligned.
ProbeForWrite	The ProbeForWrite routine checks that a user-mode buffer actually resides in the user-mode portion of the address space, is writable, and is correctly aligned.
PsCreateSystemThread	The PsCreateSystemThread routine creates a system thread that executes in kernel mode and returns a handle for the thread.
PsGetCurrentThread	The PsGetCurrentThread routine identifies the current thread.
PsGetVersion	This function is obsolete in Windows XP and later versions of the Windows operating system. Use RtlGetVersion instead.PsGetVersion returns caller-selected information about the current version of the NT-based operating system.

TITLE	DESCRIPTION
PsQueryTotalCycleTimeProcess	The PsQueryTotalCycleTimeProcess routine returns the accumulated cycle time for the specified process.
PsTerminateSystemThread	The PsTerminateSystemThread routine terminates the current system thread.
PushEntryList	The PushEntryList routine inserts an entry at the beginning of a singly linked list of SINGLE_LIST_ENTRY structures.
READ_PORT_BUFFER_UCHAR	The READ_PORT_BUFFER_UCHAR routine reads a number of bytes from the specified port address into a buffer.
READ_PORT_BUFFER_ULONG	The READ_PORT_BUFFER_ULONG routine reads a number of ULONG values from the specified port address into a buffer.
READ_PORT_BUFFER_USHORT	The READ_PORT_BUFFER_USHORT routine reads a number of USHORT values from the specified port address into a buffer.
READ_PORT_UCHAR	The READ_PORT_UCHAR routine reads a byte from the specified port address.
READ_PORT_ULONG	The READ_PORT_ULONG routine reads a ULONG value from the specified port address.
READ_PORT_USHORT	The READ_PORT_USHORT routine reads a USHORT value from the specified port address.
READ_REGISTER_BUFFER_UCHAR	The READ_REGISTER_BUFFER_UCHAR routine reads a number of bytes from the specified register address into a buffer.
READ_REGISTER_BUFFER_ULONG	The READ_REGISTER_BUFFER_ULONG routine reads a number of ULONG values from the specified register address into a buffer.
READ_REGISTER_BUFFER_ULONG64	The READ_REGISTER_BUFFER_ULONG64 function reads a number of ULONG64 values from the specified register address into a buffer.
READ_REGISTER_BUFFER_USHORT	The READ_REGISTER_BUFFER_USHORT routine reads a number of USHORT values from the specified register address into a buffer.
READ_REGISTER_UCHAR	The READ_REGISTER_UCHAR routine reads a byte from the specified register address.
READ_REGISTER_ULONG	The READ_REGISTER_ULONG routine reads a ULONG value from the specified register address.
READ_REGISTER_ULONG64	The READ_REGISTER_ULONG64 function reads a ULONG64 value from the specified register address.
READ_REGISTER_USHORT	The READ_REGISTER_USHORT routine reads a USHORT value from the specified register address.

TITLE	DESCRIPTION
RemoveEntryList	The RemoveEntryList routine removes an entry from a doubly linked list of LIST_ENTRY structures.
RemoveHeadList	The RemoveHeadList routine removes an entry from the beginning of a doubly linked list of LIST_ENTRY structures.
RemoveTailList	The RemoveTailList routine removes an entry from the end of a doubly linked list of LIST_ENTRY structures.
RtlAnsiStringToUnicodeSize	The RtlAnsiStringToUnicodeSize routine returns the number of bytes required to hold an ANSI string converted into a Unicode string.
RtlAnsiStringToUnicodeString	RtlAnsiStringToUnicodeString converts the given ANSI source string into a Unicode string.
RtlAppendUnicodeStringToString	The RtlAppendUnicodeStringToString routine concatenates two Unicode strings.
RtlAppendUnicodeToString	The RtlAppendUnicodeToString routine concatenates the supplied Unicode string to a buffered Unicode string.
RtlAreBitsClear	The RtlAreBitsClear routine determines whether a given range of bits within a bitmap variable is clear.
RtlAreBitsSet	The RtlAreBitsSet routine determines whether a given range of bits within a bitmap variable is set.
RtlCheckBit	The RtlCheckBit routine determines whether a particular bit in a given bitmap variable is clear or set.
RtlCheckRegistryKey	The RtlCheckRegistryKey routine checks for the existence of a given named key in the registry.
RtlClearAllBits	The RtlClearAllBits routine sets all bits in a given bitmap variable to zero.
RtlClearBit	The RtlClearBit routine sets the specified bit in a bitmap to zero.
RtlClearBits	The RtlClearBits routine sets all bits in the specified range of bits in the bitmap to zero.
RtlCmDecodeMemIoResource	The RtlCmDecodeMemIoResource routine provides the starting address and length of a CM_PARTIAL_RESOURCE_DESCRIPTOR structure that describes a range of memory or I/O port addresses.
RtlCmEncodeMemIoResource	The RtlCmEncodeMemIoResource routine updates a CM_PARTIAL_RESOURCE_DESCRIPTOR structure to describe a range of memory or I/O port addresses.
RtlCompareMemory	The RtlCompareMemory routine compares two blocks of memory and returns the number of bytes that match.

TITLE	DESCRIPTION
RtlCompareUnicodeString	The RtlCompareUnicodeString routine compares two Unicode strings.
RtlConvertLongToLargeInteger	The RtlConvertLongToLargeInteger routine converts the input signed integer to a signed large integer.
RtlConvertUlongToLargeInteger	The RtlConvertUlongToLargeInteger routine converts the input unsigned integer to a signed large integer. For Windows XP and later versions of Windows, do not use this routine; use the native support for __int64.
RtlCopyMemory	The RtlCopyMemory routine copies the contents of a source memory block to a destination memory block.
RtlCopyMemoryNonTemporal	This function copies from one buffer to another using non-temporal moves that do not pollute the cache. The buffers shouldn't overlap.
RtlCopyUnicodeString	The RtlCopyUnicodeString routine copies a source string to a destination string.
RtlCreateRegistryKey	The RtlCreateRegistryKey routine adds a key object in the registry along a given relative path.
RtlCreateSecurityDescriptor	The RtlCreateSecurityDescriptor routine initializes a new absolute-format security descriptor. On return, the security descriptor is initialized with no system ACL, no discretionary ACL, no owner, no primary group, and all control flags set to zero.
RtlDeleteRegistryValue	The RtlDeleteRegistryValue routine removes the specified entry name and the associated values from the registry along the given relative path.
RtlDowncaseUnicodeChar	The RtlDowncaseUnicodeChar routine converts the specified Unicode character to lowercase.
RtlEqualMemory	The RtlEqualMemory routine compares two blocks of memory to determine whether the specified number of bytes are identical.
RtlEqualUnicodeString	The RtlEqualUnicodeString routine compares two Unicode strings to determine whether they are equal.
RtlFillMemory	The RtlFillMemory routine fills a block of memory with the specified fill value.
RtlFindClearBits	The RtlFindClearBits routine searches for a range of clear bits of a requested size within a bitmap.
RtlFindClearBitsAndSet	The RtlFindClearBitsAndSet routine searches for a range of clear bits of a requested size within a bitmap and sets all bits in the range when it has been located.

TITLE	DESCRIPTION
RtlFindClearRuns	The RtlFindClearRuns routine finds the specified number of runs of clear bits within a given bitmap.
RtlFindFirstRunClear	The RtlFindFirstRunClear routine searches for the initial contiguous range of clear bits within a given bitmap.
RtlFindLastBackwardRunClear	The RtlFindLastBackwardRunClear routine searches a given bitmap for the preceding clear run of bits, starting from the specified index position.
RtlFindLeastSignificantBit	The RtlFindLeastSignificantBit routine returns the zero-based position of the least significant nonzero bit in its parameter.
RtlFindLongestRunClear	The RtlFindLongestRunClear routine searches for the largest contiguous range of clear bits within a given bitmap.
RtlFindMostSignificantBit	The RtlFindMostSignificantBit routine returns the zero-based position of the most significant nonzero bit in its parameter.
RtlFindNextForwardRunClear	The RtlFindNextForwardRunClear routine searches a given bitmap variable for the next clear run of bits, starting from the specified index position.
RtlFindSetBits	The RtlFindSetBits routine searches for a range of set bits of a requested size within a bitmap.
RtlFindSetBitsAndClear	The RtlFindSetBitsAndClear routine searches for a range of set bits of a requested size within a bitmap and clears all bits in the range when it has been located.
RtlFreeAnsiString	The RtlFreeAnsiString routine releases storage that was allocated by RtlUnicodeStringToAnsiString.
RtlFreeUnicodeString	The RtlFreeUnicodeString routine releases storage that was allocated by RtlAnsiStringToUnicodeString or RtlUpcaseUnicodeString.
RtlGetVersion	The RtlGetVersion routine returns version information about the currently running operating system.
RtlGUIDFromString	The RtlGUIDFromString routine converts the given Unicode string to a GUID in binary format.
RtlHashUnicodeString	The RtlHashUnicodeString routine creates a hash value from a given Unicode string and hash algorithm.
RtlInitAnsiString	The RtlInitAnsiString routine initializes a counted string of ANSI characters.
RtlInitializeBitMap	The RtlInitializeBitMap routine initializes the header of a bitmap variable.
RtlInitString	The RtlInitString routine initializes a counted string of 8-bit characters.

TITLE	DESCRIPTION
RtlInitStringEx	The RtlInitStringEx routine initializes a counted string of 8-bit characters.
RtlInitUnicodeString	For more information, see the WdmlibRtlInitUnicodeStringEx function.
RtlInt64ToUnicodeString	The RtlInt64ToUnicodeString routine converts a specified unsigned 64-bit integer value to a Unicode string that represents the value in a specified base.
RtlIntegerToUnicodeString	The RtlIntegerToUnicodeString routine converts an unsigned integer value to a null-terminated string of one or more Unicode characters in the specified base.
RtlIntPtrToUnicodeString	The RtlIntPtrToUnicodeString routine converts a specified ULONG_PTR value to a Unicode string that represents the value in a specified base.
RtlIoDecodeMemIoResource	The RtlIoDecodeMemIoResource routine provides the address information that is contained in an IO_RESOURCE_DESCRIPTOR structure that describes a range of memory or I/O port addresses.
RtlIoEncodeMemIoResource	The RtlIoEncodeMemIoResource routine updates an IO_RESOURCE_DESCRIPTOR structure to describe a range of memory or I/O port addresses.
RtlIsNtDdiVersionAvailable	The RtlIsNtDdiVersionAvailable routine determines if a specified version of the Microsoft Windows device driver interface (DDI) is available.
RtlIsServicePackVersionInstalled	The RtlIsServicePackVersionInstalled routine determines if a specified service pack version of the Microsoft Windows device driver interface (DDI) is installed.
RtlLengthSecurityDescriptor	The RtlLengthSecurityDescriptor routine returns the size of a given security descriptor.
RtlMoveMemory	The RtlMoveMemory routine copies the contents of a source memory block to a destination memory block, and supports overlapping source and destination memory blocks.
RtlNumberOfClearBits	The RtlNumberOfClearBits routine returns a count of the clear bits in a given bitmap variable.
RtlNumberOfSetBits	The RtlNumberOfSetBits routine returns a count of the set bits in a given bitmap variable.
RtlNumberOfSetBitsUlongPtr	The RtlNumberOfSetBitsUlongPtr routine returns the number of bits in the specified ULONG_PTR integer value that are set to one.
RtlPrefetchMemoryNonTemporal	The RtlPrefetchMemoryNonTemporal routine provides a hint to the processor that a buffer should be temporarily moved into the processor cache.

TITLE	DESCRIPTION
RtlQueryRegistryValues	The RtlQueryRegistryValues routine allows the caller to query several values from the registry subtree with a single call.
RtlSanitizeUnicodeStringPadding	Sanitizes the padding for a Unicode string.
RtlSecureZeroMemory	The RtlSecureZeroMemory routine fills a block of memory with zeros in a way that is guaranteed to be secure.
RtlSetAllBits	The RtlSetAllBits routine sets all bits in a given bitmap variable.
RtlSetBit	The RtlSetBit routine sets the specified bit in a bitmap to one.
RtlSetBits	The RtlSetBits routine sets all bits in a given range of a given bitmap variable.
RtlSetDaclSecurityDescriptor	The RtlSetDaclSecurityDescriptor routine sets the DACL information of an absolute-format security descriptor, or if there is already a DACL present in the security descriptor, it is superseded.
RtlStringFromGUID	The RtlStringFromGUID routine converts a given GUID from binary format into a Unicode string.
RtlTestBit	The RtlTestBit routine returns the value of a bit in a bitmap.
RtlTimeFieldsToTime	The RtlTimeFieldsToTime routine converts TIME_FIELDS information to a system time value.
RtlTimeToTimeFields	The RtlTimeToTimeFields routine converts system time into a TIME_FIELDS structure.
RtlUlongByteSwap	The RtlUlongByteSwap routine reverses the ordering of the four bytes in a 32-bit unsigned integer value.
RtlUlonglongByteSwap	The RtlUlonglongByteSwap routine reverses the ordering of the eight bytes in a 64-bit unsigned integer value.
RtlUnicodeStringToAnsiSize	The RtlUnicodeStringToAnsiSize routine returns the number of bytes required for a null-terminated ANSI string that is equivalent to a specified Unicode string.
RtlUnicodeStringToAnsiString	The RtlUnicodeStringToAnsiString routine converts a given Unicode string into an ANSI string.
RtlUnicodeStringToInteger	The RtlUnicodeStringToInteger routine converts a Unicode string representation of a number to the equivalent integer value.
RtlUnicodeToUTF8N	The RtlUnicodeToUTF8N routine converts a Unicode string to a UTF-8 string.
RtlUpcaseUnicodeChar	The RtlUpcaseUnicodeChar routine converts the specified Unicode character to uppercase.

TITLE	DESCRIPTION
RtlUshortByteSwap	The RtlUshortByteSwap routine reverses the ordering of the two bytes in a 16-bit unsigned integer value.
RtlUTF8ToUnicodeN	The RtlUTF8ToUnicodeN routine converts a UTF-8 string to a Unicode string.
RtlValidRelativeSecurityDescriptor	The RtlValidRelativeSecurityDescriptor routine checks the validity of a self-relative security descriptor.
RtlValidSecurityDescriptor	The RtlValidSecurityDescriptor routine checks a given security descriptor's validity.
RtlVerifyVersionInfo	The RtlVerifyVersionInfo routine compares a specified set of operating system version requirements to the corresponding attributes of the currently running version of the operating system.
RtlWriteRegistryValue	The RtlWriteRegistryValue routine writes caller-supplied data into the registry along the specified relative path at the given value name.
RtlxAnsiStringToUnicodeSize	The RtlxAnsiStringToUnicodeSize routine returns the number of bytes that are required for a null-terminated Unicode string that is equivalent to a specified ANSI string.
RtlxUnicodeStringToAnsiSize	The RtlxUnicodeStringToAnsiSize routine returns the number of bytes required for a null-terminated ANSI string that is equivalent to a specified Unicode string.
RtlZeroMemory	The RtlZeroMemory routine fills a block of memory with zeros, given a pointer to the block and the length, in bytes, to be filled.
SeAccessCheck	The SeAccessCheck routine determines whether the requested access rights can be granted to an object protected by a security descriptor and an object owner.
SeAssignSecurity	The SeAssignSecurity routine builds a self-relative security descriptor for a new object, given the security descriptor of its parent directory and any originally requested security for the object.
SeAssignSecurityEx	The SeAssignSecurityEx routine builds a self-relative security descriptor for a new object given the following optional parameters:_a security descriptor of the object's parent directory, an explicit security descriptor for the object, and the object type.
SeCaptureSubjectContext	The SeCaptureSubjectContext routine captures the security context of the calling thread for access validation and auditing.
SeDeassignSecurity	The SeDeassignSecurity routine deallocates the memory associated with a security descriptor that was assigned using SeAssignSecurity.

TITLE	DESCRIPTION
SeEtwWriteKMCveEvent	The SeEtwWriteKMCveEvent function is a tracing function for publishing events when an attempted security vulnerability exploit is detected in your kernel-mode drivers.
SeLockSubjectContext	The SeLockSubjectContext routine locks the primary and impersonation tokens of a captured subject context.
SeReleaseSubjectContext	The SeReleaseSubjectContext routine releases a subject security context captured by an earlier call to SeCaptureSubjectContext.
SeUnlockSubjectContext	The SeUnlockSubjectContext routine unlocks the tokens of a captured subject context that were locked by a call to SeLockSubjectContext.
SeValidSecurityDescriptor	The SeValidSecurityDescriptor routine returns whether a given security descriptor is structurally valid.
TmCommitComplete	The TmCommitComplete routine notifies KTM that the calling resource manager has finished committing a transaction.
TmCommitEnlistment	The TmCommitEnlistment routine initiates the commit operation for a specified enlistment's transaction.
TmCommitTransaction	The TmCommitTransaction routine initiates a commit operation for a specified transaction.
TmCreateEnlistment	The TmCreateEnlistment routine creates a new enlistment object for a transaction.
TmDereferenceEnlistmentKey	The TmDereferenceEnlistmentKey routine decrements the reference count for the key of a specified enlistment object.
TmEnableCallbacks	The TmEnableCallbacks routine enables a callback routine that receives transaction notifications.
TmGetTransactionId	The TmGetTransactionId routine retrieves a transaction object's unit of work (UOW) identifier.
TmInitializeTransactionManager	The TmInitializeTransactionManager routine initializes a transaction manager object.
TmIsTransactionActive	The TmIsTransactionActive routine indicates whether a specified transaction is in its active state.
TmPrepareComplete	The TmPrepareComplete routine notifies KTM that the calling resource manager has finished preparing a transaction's data.
TmPrepareEnlistment	The TmPrepareEnlistment routine initiates the prepare operation for a specified enlistment's transaction.
TmPrePrepareComplete	The TmPrePrepareComplete routine notifies KTM that the calling resource manager has finished preliminary preparation of a transaction's data.

TITLE	DESCRIPTION
TmPrePrepareEnlistment	The TmPrePrepareEnlistment routine initiates the pre-prepare operation for a specified enlistment's transaction.
TmReadOnlyEnlistment	The TmReadOnlyEnlistment routine sets a specified enlistment to be read-only.
TmRecoverEnlistment	The TmRecoverEnlistment routine initiates a recovery operation for the transaction that is associated with a specified enlistment.
TmRecoverResourceManager	The TmRecoverResourceManager routine tries to recover the transaction that is associated with each enlistment of a specified resource manager object.
TmRecoverTransactionManager	The TmRecoverTransactionManager routine reconstructs the state of the transaction manager object (including all transactions, enlistments, and resource managers) from the recovery information that is in the log stream.
TmReferenceEnlistmentKey	The TmReferenceEnlistmentKey routine increments the reference count for the key of a specified enlistment object and retrieves the key.
TmRenameTransactionManager	The TmRenameTransactionManager routine changes the identity of the transaction manager object that is stored in the CLFS log file stream contained in the log file name.
TmRequestOutcomeEnlistment	The TmRequestOutcomeEnlistment routine asks KTM to try to provide an immediate outcome (commit or rollback) for the transaction that is associated with a specified enlistment.
TmRollbackComplete	The TmRollbackComplete routine notifies KTM that the calling resource manager has finished rolling back a transaction's data.
TmRollbackEnlistment	The TmRollbackEnlistment routine rolls back a specified enlistment.
TmRollbackTransaction	The TmRollbackTransaction routine initiates a rollback operation for a specified transaction.
TmSinglePhaseReject	The TmSinglePhaseReject routine informs KTM that the calling resource manager will not support a single-phase commit operation for a specified enlistment.
vDbgPrintEx	The vDbgPrintEx routine sends a string to the kernel debugger if certain conditions are met.
vDbgPrintExWithPrefix	The vDbgPrintExWithPrefix routine sends a string to the kernel debugger if certain conditions that you specify are met. This routine can append a prefix to debugger output to help organize debugging results.

TITLE	DESCRIPTION
VslCreateSecureSection	This material is not yet available. This placeholder topic is provided as an example of documentation that may be included in a later release.
VslDeleteSecureSection	This material is not yet available. This placeholder topic is provided as an example of documentation that may be included in a later release.
WmiQueryTraceInformation	The WmiQueryTraceInformation routine returns information about a WMI event trace.
WmiTraceMessage	The WmiTraceMessage routine adds a message to the output log of a WPP software tracing session.
WmiTraceMessageVa	The WmiTraceMessageVa routine adds a message to the output log of a WPP software tracing session.
WRITE_PORT_BUFFER_UCHAR	The WRITE_PORT_BUFFER_UCHAR routine writes a number of bytes from a buffer to the specified port.
WRITE_PORT_BUFFER_ULONG	The WRITE_PORT_BUFFER_ULONG routine writes a number of ULONG values from a buffer to the specified port address.
WRITE_PORT_BUFFER_USHORT	The WRITE_PORT_BUFFER_USHORT routine writes a number of USHORT values from a buffer to the specified port address.
WRITE_PORT_UCHAR	The WRITE_PORT_UCHAR routine writes a byte to the specified port address.
WRITE_PORT_ULONG	The WRITE_PORT_ULONG routine writes a ULONG value to the specified port address.
WRITE_PORT_USHORT	The WRITE_PORT_USHORT routine writes a USHORT value to the specified port address.
WRITE_REGISTER_BUFFER_UCHAR	The WRITE_REGISTER_BUFFER_UCHAR routine writes a number of bytes from a buffer to the specified register.
WRITE_REGISTER_BUFFER_ULONG	The WRITE_REGISTER_BUFFER_ULONG routine writes a number of ULONG values from a buffer to the specified register.
WRITE_REGISTER_BUFFER_ULONG64	The WRITE_REGISTER_BUFFER_ULONG64 function writes a number of ULONG64 values from a buffer to the specified register.
WRITE_REGISTER_BUFFER_USHORT	The WRITE_REGISTER_BUFFER_USHORT routine writes a number of USHORT values from a buffer to the specified register.
WRITE_REGISTER_UCHAR	The WRITE_REGISTER_UCHAR routine writes a byte to the specified address.

TITLE	DESCRIPTION
WRITE_REGISTER_ULONG	The WRITE_REGISTER_ULONG routine writes a ULONG value to the specified address.
WRITE_REGISTER_ULONG64	The WRITE_REGISTER_ULONG64 function writes a ULONG64 value to the specified address.
WRITE_REGISTER_USHORT	The WRITE_REGISTER_USHORT routine writes a USHORT value to the specified address.
ZwClose	The ZwClose routine closes an object handle.
ZwCommitComplete	The ZwCommitComplete routine notifies KTM that the calling resource manager has finished committing a transaction's data.
ZwCommitEnlistment	The ZwCommitEnlistment routine initiates the commit operation for a specified enlistment's transaction.
ZwCommitTransaction	The ZwCommitTransaction routine initiates a commit operation for a specified transaction.
ZwCreateDirectoryObject	The ZwCreateDirectoryObject routine creates or opens an object-directory object.
ZwCreateEnlistment	The ZwCreateEnlistment routine creates a new enlistment object for a transaction.
ZwCreateFile	The ZwCreateFile routine creates a new file or opens an existing file.
ZwCreateKey	The ZwCreateKey routine creates a new registry key or opens an existing one.
ZwCreateKeyTransacted	The ZwCreateKeyTransacted routine creates a new registry key or opens an existing one, and it associates the key with a transaction.
ZwCreateResourceManager	The ZwCreateResourceManager routine creates a resource manager object.
ZwCreateSection	The ZwCreateSection routine creates a section object.
ZwCreateTransaction	The ZwCreateTransaction routine creates a transaction object.
ZwCreateTransactionManager	The ZwCreateTransactionManager routine creates a new transaction manager object.
ZwDeleteKey	The ZwDeleteKey routine deletes an open key from the registry.
ZwDeleteValueKey	The ZwDeleteValueKey routine deletes a value entry matching a name from an open key in the registry. If no such entry exists, an error is returned.

TITLE	DESCRIPTION
ZwEnumerateKey	The ZwEnumerateKey routine returns information about a subkey of an open registry key.
ZwEnumerateTransactionObject	The ZwEnumerateTransactionObject routine enumerates the KTM objects on a computer.
ZwEnumerateValueKey	The ZwEnumerateValueKey routine gets information about the value entries of an open key.
ZwFlushKey	The ZwFlushKey routine forces a registry key to be committed to disk.
ZwGetNotificationResourceManager	The ZwGetNotificationResourceManager routine retrieves the next transaction notification from a specified resource manager's notification queue.
ZwLoadDriver	The ZwLoadDriver routine loads a driver into the system.
ZwMakeTemporaryObject	The ZwMakeTemporaryObject routine changes the attributes of an object to make it temporary.
ZwMapViewOfSection	The ZwMapViewOfSection routine maps a view of a section into the virtual address space of a subject process.
ZwOpenEnlistment	The ZwOpenEnlistment routine obtains a handle to an existing enlistment object.
ZwOpenEvent	The ZwOpenEvent routine opens a handle to an existing named event object with the specified desired access.
ZwOpenFile	The ZwOpenFile routine opens an existing file, directory, device, or volume.
ZwOpenKey	The ZwOpenKey routine opens an existing registry key.
ZwOpenKeyEx	The ZwOpenKeyEx routine opens an existing registry key.
ZwOpenKeyTransacted	The ZwOpenKeyTransacted routine opens an existing registry key and associates the key with a transaction.
ZwOpenKeyTransactedEx	The ZwOpenKeyTransactedEx routine opens an existing registry key and associates the key with a transaction.
ZwOpenResourceManager	The ZwOpenResourceManager routine returns a handle to an existing resource manager object.
ZwOpenSection	The ZwOpenSection routine opens a handle for an existing section object.
ZwOpenSymbolicLinkObject	The ZwOpenSymbolicLinkObject routine opens an existing symbolic link.

TITLE	DESCRIPTION
ZwOpenTransaction	The ZwOpenTransaction routine obtains a handle to an existing transaction object.
ZwOpenTransactionManager	The ZwOpenTransactionManager routine obtains a handle to an existing transaction manager object.
ZwPrepareComplete	The ZwPrepareComplete routine notifies KTM that the calling resource manager has finished preparing a transaction's data.
ZwPrepareEnlistment	The ZwPrepareEnlistment routine initiates the prepare operation for a specified enlistment's transaction.
ZwPrePrepareComplete	The ZwPrePrepareComplete routine notifies KTM that the calling resource manager has finished preliminary preparation of a transaction's data.
ZwPrePrepareEnlistment	The ZwPrePrepareEnlistment routine initiates the pre-prepare operation for a specified enlistment's transaction.
ZwQueryFullAttributesFile	The ZwQueryFullAttributesFile routine supplies network open information for the specified file.
ZwQueryInformationEnlistment	The ZwQueryInformationEnlistment routine retrieves information about a specified enlistment object.
ZwQueryInformationFile	The ZwQueryInformationFile routine returns various kinds of information about a file object.
ZwQueryInformationResourceManager	The ZwQueryInformationResourceManager routine retrieves information about a specified resource manager object.
ZwQueryInformationTransaction	The ZwQueryInformationTransaction routine retrieves information about a specified transaction.
ZwQueryInformationTransactionManager	The ZwQueryInformationTransactionManager routine retrieves information about a specified transaction manager object.
ZwQueryKey	The ZwQueryKey routine provides information about the class of a registry key, and the number and sizes of its subkeys.
ZwQuerySymbolicLinkObject	The ZwQuerySymbolicLinkObject routine returns a Unicode string that contains the target of a symbolic link.
ZwQueryValueKey	The ZwQueryValueKey routine returns a value entry for a registry key.
ZwReadFile	The ZwReadFile routine reads data from an open file.
ZwReadOnlyEnlistment	The ZwReadOnlyEnlistment routine sets a specified enlistment to be read-only.
ZwRecoverEnlistment	The ZwRecoverEnlistment routine initiates a recovery operation for the transaction that is associated with a specified enlistment.

TITLE	DESCRIPTION
ZwRecoverResourceManager	The ZwRecoverResourceManager routine tries to recover the transaction that is associated with each enlistment of a specified resource manager object.
ZwRecoverTransactionManager	The ZwRecoverTransactionManager routine reconstructs the state of the transaction manager object (including all transactions, enlistments, and resource managers) from the recovery information that is in the log stream.
ZwRollbackComplete	The ZwRollbackComplete routine notifies KTM that the calling resource manager has finished rolling back a transaction's data.
ZwRollbackEnlistment	The ZwRollbackEnlistment routine rolls back the transaction that is associated with a specified enlistment.
ZwRollbackTransaction	The ZwRollbackTransaction routine initiates a rollback operation for a specified transaction.
ZwRollforwardTransactionManager	The ZwRollforwardTransactionManager routine initiates recovery operations for all of the in-progress transactions that are assigned to a specified transaction manager.
ZwSetInformationEnlistment	The ZwSetInformationEnlistment routine sets information for a specified enlistment object.
ZwSetInformationFile	The ZwSetInformationFile routine changes various kinds of information about a file object.
ZwSetInformationResourceManager	The ZwSetInformationResourceManager routine is not used.
ZwSetInformationTransaction	The ZwSetInformationTransaction routine sets information for a specified transaction.
ZwSetValueKey	The ZwSetValueKey routine creates or replaces a registry key's value entry.
ZwSinglePhaseReject	The ZwSinglePhaseReject routine informs KTM that the calling resource manager will not support single-phase commit operations for a specified enlistment.
ZwUnloadDriver	The ZwUnloadDriver routine unloads a driver from the system.
ZwUnmapViewOfSection	The ZwUnmapViewOfSection routine unmaps a view of a section from the virtual address space of a subject process.
ZwWriteFile	The ZwWriteFile routine writes data to an open file.

Callback functions

TITLE	DESCRIPTION

TITLE	DESCRIPTION
ALLOCATE_FUNCTION_EX	The LookasideListAllocateEx routine allocates the storage for a new lookaside-list entry when a client requests an entry from a lookaside list that is empty.
BOUND_CALLBACK	The BoundCallback routine is executed whenever the system issues a bounds exception for a user-mode thread.
D3COLD_REQUEST_AUX_POWER	Enables the function device object (FDO) to convey its auxiliary power requirement.
D3COLD_REQUEST_CORE_POWER_RAIL	Enables the function device object (FDO) to indicate whether the core power rail is needed.
D3COLD_REQUEST_PERST_DELAY	Enables the function device object (FDO) to convey its requirement for a fixed delay time.
DMA_COMPLETION_ROUTINE	The DmaCompletionRoutine callback routine notifies the driver that previously requested a system DMA transfer that this transfer is complete.
DRIVER_ADD_DEVICE	The AddDevice routine is responsible for creating functional device objects (FDO) or filter device objects (filter DO) for devices enumerated by the Plug and Play (PnP) manager.
DRIVER_CANCEL	The Cancel routine cancels an I/O operation.
DRIVER_CONTROL	This routine starts a DMA data-transfer or a data transfer operation.
DRIVER_DISPATCH	The callback routine services various IRPs. For a list of function codes, see Remarks.
DRIVER_INITIALIZE	DriverEntry is the first routine called after a driver is loaded, and is responsible for initializing the driver.
DRIVER_LIST_CONTROL	The AdapterListControl routine starts a direct memory access (DMA) scatter/gather operation.
DRIVER_STARTIO	The StartIo routine starts the I/O operation described by an IRP.
DRIVER_UNLOAD	The Unload routine performs any operations that are necessary before the system unloads the driver.
ENABLE_VIRTUALIZATION	The EnableVirtualization routine enables or disables virtualization for a PCI Express (PCIe) device that supports the single root I/O virtualization (SR-IOV) interface.
ETWENABLECALLBACK	The EtwEnableCallback function is an optional driver-supplied callback function that is used to receive enable or disable notifications.
EX_CALLBACK_FUNCTION	A filter driver's RegistryCallback routine can monitor, block, or modify a registry operation.

TITLE	DESCRIPTION
EXT_CALLBACK	An ExTimerCallback callback routine runs after an EX_TIMER timer object's time interval expires.
EXT_DELETE_CALLBACK	An ExTimerDeleteCallback callback routine runs when the operating system deletes an EX_TIMER timer object.
FPGA_BUS_SCAN	Reserved for future use. Triggers a bus scan at the parent of the FPGA device.
FPGA_CONTROL_CONFIG_SPACE	Reserved for future use. Enables or disables the access to the configuration space of the FPGA device.
FPGA_CONTROL_ERROR_REPORTING	Reserved for future use. Toggles the error reporting for the FPGA device and its parent bridge.
FPGA_CONTROL_LINK	Reserved for future use.
FREE_FUNCTION_EX	The LookasideListFreeEx routine frees the storage for a lookaside-list entry when a client tries to insert the entry into a lookaside list that is full.
GET_D3COLD_CAPABILITY	The GetBusDriverD3ColdSupport routine enables the driver for a device to query whether the enumerating bus driver supports the D3cold device power state.
GET_D3COLD_LAST_TRANSITION_STATUS	The GetLastTransitionStatus routine enables the driver for a device to query whether the most recent transition to the D3hot substate was followed by a transition to the D3cold substate.
GET_DMA_ADAPTER	The GetDmaAdapter routine returns a DMA_ADAPTER structure for the target device.
GET_IDLE_WAKE_INFO	The GetIdleWakeInfo routine enables the driver for a device to discover the device power states from which the device can signal a wake event.
GET_SDEV_IDENTIFIER	This material is not yet available. This placeholder topic is provided as an example of documentation that may be included in a later release.
GET_SET_DEVICE_DATA	The GetBusData routine reads data from the device's configuration space.
GET_UPDATED_BUS_RESOURCE	Reports the latest resource lists.
GET_VIRTUAL_DEVICE_DATA	The GetVirtualFunctionData routine reads data from the PCI Express (PCIe) configuration space of a virtual function (VF) on a device that supports the single root I/O virtualization (SR-IOV) interface.
GET_VIRTUAL_DEVICE_LOCATION	The GetLocation routine returns the device location of a PCI Express (PCIe) virtual function (VF) on a PCI bus. A device that supports the single root I/O virtualization (SR-IOV) interface can expose one or more VFs on the PCI bus.

TITLE	DESCRIPTION
GET_VIRTUAL_DEVICE_RESOURCES	The GetResources routine returns the resources that the PCI Express (PCIe) physical function (PF) requires in order to enable virtualization on a device that supports the single root I/O virtualization (SR-IOV) interface.
GET_VIRTUAL_FUNCTION_PROBED_BARS	The GetVirtualFunctionProbedBars routine returns the values of the PCI Express (PCIe) Base Address Registers (BARs) of a device that supports the single root I/O virtualization (SR-IOV) interface.
IO_COMPLETION_ROUTINE	The IoCompletion routine completes the processing of I/O operations.
IO_CSQ_ACQUIRE_LOCK	The CsqAcquireLock routine is used by the system to acquire the lock for a driver-implemented, cancel-safe IRP queue.
IO_CSQ_COMPLETE_CANCELED_IRP	The CsqCompleteCanceledIrp routine is used by the system to signal to the driver that it can complete a canceled IRP.
IO_CSQ_INSERT_IRP	The CsqInsertIrp routine is used by the system to insert an IRP into a driver-implemented, cancel-safe IRP queue.
IO_CSQ_INSERT_IRP_EX	The CsqInsertIrpEx routine is used by the system to insert an IRP into a driver-implemented, cancel-safe IRP queue.
IO_CSQ_PEEK_NEXT_IRP	The CsqPeekNextIrp routine is used by the system to find the next matching IRP in a driver-implemented, cancel-safe IRP queue.
IO_CSQ_RELEASE_LOCK	The CsqReleaseLock routine is used by the system to release the lock that was acquired using CsqAcquireLock.
IO_CSQ_REMOVE_IRP	The CsqRemoveIrp routine is used by the system to remove the specified IRP from a driver-implemented, cancel-safe IRP queue.
IO_DPC_ROUTINE	The DpcForIsr routine finishes the servicing of an I/O operation, after an InterruptService routine returns.
IO_SESSION_NOTIFICATION_FUNCTION	The IO_SESSION_NOTIFICATION_FUNCTION function type defines a callback routine through which a driver receives notifications of changes in the state of user sessions that the driver is interested in.
IO_TIMER_ROUTINE	The IoTimer routine is a DPC that, if registered, is called once per second.
IO_WORKITEM_ROUTINE	A WorkItem routine performs the processing for a work item that was queued by the IoQueueWorkItem routine.

TITLE	DESCRIPTION
IO_WORKITEM_ROUTINE_EX	A WorkItemEx routine performs the processing for a work item that was queued by the IoQueueWorkItemEx or IoTryQueueWorkItem routine.
IOMMU_DEVICE_FAULT_HANDLER	Reports fault from a specific device and domain.
IOMMU_DOMAIN_ATTACH_DEVICE	Attaches a device to an existing domain.
IOMMU_DOMAIN_CONFIGURE	Configures a domain for use.
IOMMU_DOMAIN_CREATE	Creates a new DMA remapping device domain (a container for a set of page tables).
IOMMU_DOMAIN_DELETE	Deletes an existing domain.
IOMMU_DOMAIN_DETACH_DEVICE	Detaches a device from an existing domain.
IOMMU_FLUSH_DOMAIN	Flushes the TLB for all entries which match this domain.
IOMMU_FLUSH_DOMAIN_VA_LIST	Flushes the TLB for all entries that match the specified domain's ASID and one of the addresses in the provided list.
IOMMU_MAP_IDENTITY_RANGE	Creates an identity mapping for the provided MDL in the provided domain.
IOMMU_MAP_LOGICAL_RANGE	Maps a range of pages into the address space of a domain.
IOMMU_QUERY_INPUT_MAPPINGS	Attempts to find input mapping IDs which are valid for the given device and populate the provied buffer with those IDs.
IOMMU_SET_DEVICE_FAULT_REPORTING	This routine sets the device fault reporting state to a device already attached to a domain.
IOMMU_UNMAP_IDENTITY_RANGE	Deletes an identity mapping for the specified MDL.
IOMMU_UNMAP_LOGICAL_RANGE	Unmaps a linear range from a domain.
KBUGCHECK_CALLBACK_ROUTINE	The BugCheckCallback routine is executed whenever the system issues a bug check.
KBUGCHECK_REASON_CALLBACK_ROUTINE	Driver-implemented callback functions that the system executes when it issues a bug check.
KDEFERRED_ROUTINE	The callback routine performs actions, after an InterruptService returns, of a threaded DPC, The CustomDpc routine finishes the servicing of an I/O operation, after an InterruptService routine returns.The CustomThreadedDpc routine performs the action of a threaded DPC. The system executes this routine when the threaded DPC runs.The CustomTimerDpc routine executes after a timer object's time interval expires.
KIPI_BROADCAST_WORKER	The IpiGenericCall routine runs simultaneously on all processors.

TITLE	DESCRIPTION
KMESSAGE_SERVICE_ROUTINE	An InterruptMessageService routine services a message-signaled interrupt.
KSERVICE_ROUTINE	The InterruptService routine (ISR) quickly services a device interrupt and schedules post-interrupt processing of received data, if necessary.
KSTART_ROUTINE	The ThreadStart routine provides an entry point for a driver-created system thread.
KSYNCHRONIZE_ROUTINE	The SynchCritSection routine is used to access hardware resources or driver data that are shared with a driver's InterruptService routine.
MM_MDL_ROUTINE	A driver-supplied callback routine that is invoked after a memory descriptor list (MDL) is mapped by calling the MmMapMdl function.
PALLOCATE_ADAPTER_CHANNEL	The AllocateAdapterChannel routine prepares the system for a DMA operation on behalf of the target device object, and then calls the driver-supplied AdapterControl routine to carry out the DMA operation.
PALLOCATE_ADAPTER_CHANNEL_EX	The AllocateAdapterChannelEx routine allocates the resources that are needed to perform a DMA transfer, and then calls the driver-supplied AdapterControl routine to initiate the DMA transfer.
PALLOCATE_COMMON_BUFFER	The AllocateCommonBuffer routine allocates memory and maps it so that it is simultaneously accessible from both the processor and a device for DMA operations.
PALLOCATE_COMMON_BUFFER_EX	The AllocateCommonBufferEx routine allocates memory for a common buffer and maps this memory so that it can be accessed both by the processor and by a device that performs DMA operations.
PALLOCATE_COMMON_BUFFER_WITH_BOUNDS	
PALLOCATE_DOMAIN_COMMON_BUFFER	
PBUILD_MDL_FROM_SCATTER_GATHER_LIST	The BuildMdlFromScatterGatherList routine builds an MDL from a scatter/gather list allocated by the system.Note This routine is reserved for system use.
PBUILD_SCATTER_GATHER_LIST	The BuildScatterGatherList routine prepares the system for a DMA operation, using a driver-supplied buffer to build the scatter/gather list.
PBUILD_SCATTER_GATHER_LIST_EX	The BuildScatterGatherListEx routine allocates the resources that are required for a DMA transfer, builds a scatter/gather list, and calls the driver-supplied AdapterListControl routine to initiate the DMA transfer.

TITLE	DESCRIPTION
PCALCULATE_SCATTER_GATHER_LIST_SIZE	The CalculateScatterGatherList routine calculates the size, in bytes, of scatter/gather list necessary to hold a given buffer.
PCANCEL_ADAPTER_CHANNEL	The CancelAdapterChannel routine tries to cancel a pending request to allocate a DMA channel.
PCANCEL_MAPPED_TRANSFER	The CancelMappedTransfer routine cancels a system DMA transfer that is currently mapped to an adapter.
PCI_MSIX_MASKUNMASK_ENTRY	The MaskTableEntry routine masks an interrupt in the MSI-X hardware interrupt table.
PCI_MSIX_SET_ENTRY	The SetTableEntry routine sets the message ID for a table entry in the MSI-X hardware interrupt table.
PCLFS_CLIENT_ADVANCE_TAIL_CALLBACK	The ClfsAdvanceTailCallback function advances the base log sequence number (LSN) of the client's log.
PCLFS_CLIENT_LFF_HANDLER_COMPLETE_CALLBACK	The ClfsLogGrowthCompleteCallback function implements the actions that the client will take when space is freed in a log that had previously been full.
PCLFS_CLIENT_LOG_UNPINNED_CALLBACK	The ClfsLogUnpinnedCallback function implements any actions that the client will take when a log that had previously been pinned becomes unpinned.
PCONFIGURE_ADAPTER_CHANNEL	The ConfigureAdapterChannel routine invokes a custom function that is implemented by the DMA controller represented by an adapter object.
PCW_CALLBACK	Providers can implement a PCW_CALLBACK function to receive notification when consumers perform certain actions, such as adding or removing counters from a query.
PDEVICE_RESET_HANDLER	The DeviceReset routine is used to reset and recover a malfunctioning device.
PFLUSH_ADAPTER_BUFFERS	The FlushAdapterBuffers routine flushes any data remaining in the system DMA controller's internal cache or in a bus-master adapter's internal cache at the end of a DMA transfer operation.
PFLUSH_ADAPTER_BUFFERS_EX	The FlushAdapterBuffersEx routine flushes any data that remains in the data cache at the end of a DMA transfer operation performed by a system DMA controller or bus-master device.
PFLUSH_DMA_BUFFER	
PFREE_ADAPTER_CHANNEL	The FreeAdapterChannel routine releases the system DMA controller when a driver has completed all DMA operations necessary to satisfy the current IRP.
PFREE_ADAPTER_OBJECT	The FreeAdapterObject routine releases the specified adapter object after a driver has completed all DMA operations.

TITLE	DESCRIPTION
PFREE_COMMON_BUFFER	The FreeCommonBuffer routine frees a common buffer allocated by AllocateCommonBuffer, along with all resources the buffer uses.
PFREE_MAP_REGISTERS	The FreeMapRegisters routine releases a set of map registers that were saved from a call to AllocateAdapterChannel.
PGET_DMA_ADAPTER_INFO	The GetDmaAdapterInfo routine retrieves information about the hardware capabilities of a system DMA channel.
PGET_DMA_ALIGNMENT	The GetDmaAlignment routine returns the alignment requirements of the DMA system.
PGET_DMA_DOMAIN	
PGET_DMA_TRANSFER_INFO	The GetDmaTransferInfo routine calculates the allocation requirements for a scatter/gather DMA transfer.
PGET_SCATTER_GATHER_LIST	The GetScatterGatherList routine prepares the system for a DMA scatter/gather operation on behalf of the target device object, through either the system DMA controller or a bus-master adapter.
PGET_SCATTER_GATHER_LIST_EX	The GetScatterGatherListEx routine allocates the resources that are required for a DMA transfer, builds a scatter/gather list, and calls the driver-supplied AdapterListControl routine to initiate the DMA transfer.
PINITIALIZE_DMA_TRANSFER_CONTEXT	The InitializeDmaTransferContext routine initializes an opaque DMA transfer context that is used to track pending allocations of DMA resources.
PINTERFACE_DEREFERENCE	The InterfaceDereference routine decrements the reference count on a driver-defined interface.
PINTERFACE_REFERENCE	The InterfaceReference routine increments the reference count on a driver-defined interface.
PJOIN_DMA_DOMAIN	
PLEAVE_DMA_DOMAIN	
PMAP_TRANSFER	The MapTransfer routine sets up map registers for an adapter object to map a DMA transfer from a locked-down buffer.
PMAP_TRANSFER_EX	The MapTransferEx routine sets up map registers to map the physical addresses in a scatter/gather list to the logical addresses that are required to do a DMA transfer.

TITLE	DESCRIPTION
PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK	The ComponentActiveConditionCallback callback routine notifies the driver that the specified component completed a transition from the idle condition to the active condition.
PO_FX_COMPONENT_CRITICAL_TRANSITION_CALLBACK	The ComponentCriticalTransitionCallback callback routine handles a transition of the specified component between the F0 (fully on) and low-power Fx component power states.
PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK	The ComponentIdleConditionCallback callback routine notifies the driver that the specified component completed a transition from the active condition to the idle condition.
PO_FX_COMPONENT_IDLE_STATE_CALLBACK	The ComponentIdleStateCallback callback routine notifies the driver of a pending change to the Fx power state of the specified component.
PO_FX_COMPONENT_PERF_STATE_CALLBACK	The ComponentPerfStateCallback callback routine notifies the driver that its request to change the performance state of a component is complete.
PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK	The DevicePowerNotRequiredCallback callback routine notifies the device driver that the device is not required to stay in the D0 power state.
PO_FX_DEVICE_POWER_REQUIRED_CALLBACK	The DevicePowerRequiredCallback callback routine notifies the device driver that the device must enter and remain in the D0 power state.
PO_FX_POWER_CONTROL_CALLBACK	The PowerControlCallback callback routine performs a power control operation that is requested by the power management framework (PoFx).
POB_POST_OPERATION_CALLBACK	The ObjectPostCallback routine is called by the operating system after a process or thread handle operation occurs.
POB_PRE_OPERATION_CALLBACK	The ObjectPreCallback routine is called by the operating system when a process or thread handle operation occurs.
PPUT_DMA_ADAPTER	The PutDmaAdapter routine frees a DMA_ADAPTER structure previously allocated by IoGetDmaAdapter.
PPUT_SCATTER_GATHER_LIST	The PutScatterGatherList routine frees the previously allocated map registers and scatter/gather list used in scatter/gather DMA.
PREAD_DMA_COUNTER	The ReadDmaCounter routine returns the number of bytes remaining to be transferred during the current subordinate DMA operation.
PREENUMERATE_SELF	A ReenumerateSelf routine requests that a bus driver reenumerate a child device.
PROCESSOR_HALT_ROUTINE	A Halt callback routine transitions the processor to an idle state.

TITLE	DESCRIPTION
PTM_RM_NOTIFICATION	A resource manager's ResourceManagerNotification callback routine receives and handles transaction notifications.
REQUEST_POWER_COMPLETE	The PowerCompletion callback routine completes the processing of a power IRP.
RTL_QUERY_REGISTRY_ROUTINE	The QueryRoutine routine provides information about a registry value that was requested in a preceding call to the RtlQueryRegistryValues routine.
SET_D3COLD_SUPPORT	The SetD3ColdSupport routine enables or disables transitions to the D3cold device power state.
SET_VIRTUAL_DEVICE_DATA	The SetVirtualFunctionData routine writes data to the PCI Express (PCIe) configuration space of a virtual function (VF) on a device that supports the single root I/O virtualization (SR-IOV) interface.
TRANSLATE_BUS_ADDRESS	The TranslateBusAddress routine translates addresses on the parent bus to logical addresses.

Structures

TITLE	DESCRIPTION
DMA_ADAPTER	The DMA_ADAPTER structure describes a system-defined interface to a DMA controller for a given device. A driver calls IoGetDmaAdapter to obtain this structure.
DMA_OPERATIONS	The DMA_OPERATIONS structure provides a table of pointers to functions that control the operation of a DMA controller.
ACCESS_STATE	The ACCESS_STATE structure describes the state of an access in progress.
ACL	The ACL structure is the header of an access-control list (ACL). A complete ACL consists of an ACL structure followed by an ordered list of zero or more access-control entries (ACE).
BATTERY_REPORTING_SCALE	Battery miniclass drivers fill in this structure in response to certain BatteryMiniQueryInformation requests.
BOOTDISK_INFORMATION	The BOOTDISK_INFORMATION structure contains basic information describing the boot and system disks.
BOOTDISK_INFORMATION_EX	The BOOTDISK_INFORMATION_EX structure contains extended information describing the boot and system disks.
BUS_INTERFACE_STANDARD	The BUS_INTERFACE_STANDARD interface structure enables device drivers to make direct calls to parent bus driver routines. This structure defines the GUID_BUS_INTERFACE_STANDARD interface.

TITLE	DESCRIPTION
BUS_RESOURCE_UPDATE_INTERFACE	Enables device drivers to make direct calls to parent bus driver routines. This structure defines the GUID_BUS_RESOURCE_UPDATE_INTERFACE interface.
CLFS_LOG_NAME_INFORMATION	The CLFS_LOG_NAME_INFORMATION structure holds the name of a Common Log File System (CLFS) stream or log.
CLFS_MGMT_CLIENT_REGISTRATION	The CLFS_MGMT_CLIENT_REGISTRATION structure is given to CLFS management by clients who manage their own logs.
CLFS_MGMT_POLICY	The CLFS_MGMT_POLICY structure holds a description of a policy for managing a CLFS log.
CLFS_STREAM_ID_INFORMATION	The CLFS_STREAM_ID_INFORMATION structure holds a value that identifies a stream in a Common Log File System (CLFS) log.
CLS_CONTAINER_INFORMATION	The CLFS_CONTAINER_INFORMATION structure holds descriptive information for an individual container in a Common Log File System (CLFS) log.
CLS_INFORMATION	The CLFS_INFORMATION structure holds metadata and state information for a Common Log File System (CLFS) stream and/or its underlying physical log.
CLS_IO_STATISTICS	The CLFS_IO_STATISTICS structure holds I/O statistics data for a Common Log File System (CLFS) log.
CLS_IO_STATISTICS_HEADER	The CLFS_IO_STATISTICS_HEADER structure holds the header portion of a CLFS_IO_STATISTICS structure.
CLS_LSN	The CLFS_LSN structure identifies an individual record in a Common Log File System (CLFS) stream.
CLS_SCAN_CONTEXT	The CLFS_SCAN_CONTEXT structure holds context information to support a scan of the containers in a Common Log File System (CLFS) log.
CLS_WRITE_ENTRY	The CLFS_WRITE_ENTRY structure holds the address and size of a buffer that contains one unit of data to be written to a Common Log File System (CLFS) stream.
CM_EISA_FUNCTION_INFORMATION	The CM_EISA_FUNCTION_INFORMATION structure defines detailed EISA configuration information returned by HalGetBusData for the input BusDataType EisaConfiguration, or by HalGetBusDataByOffset for the input BusDataType EisaConfiguration and the Offset zero, assuming the caller-allocated Buffer is of sufficient Length.
CM_EISA_SLOT_INFORMATION	The CM_EISA_SLOT_INFORMATION structure defines EISA configuration header information returned by HalGetBusData for the input BusDataType = EisaConfiguration, or by HalGetBusDataByOffset for the inputs BusDataType = EisaConfiguration and Offset = 0, assuming the caller-allocated Buffer is of sufficient Length.

TITLE	DESCRIPTION
CM_FLOPPY_DEVICE_DATA	The CM_FLOPPY_DEVICE_DATA structure defines a device-type-specific data record that is stored in the \Registry\Machine\Hardware\Description tree for a floppy controller if the system can collect this information during the boot process.
CM_FULL_RESOURCE_DESCRIPTOR	The CM_FULL_RESOURCE_DESCRIPTOR structure specifies a set of system hardware resources of various types, assigned to a device that is connected to a specific bus. This structure is contained within a CM_RESOURCE_LIST structure.
CM_INT13_DRIVE_PARAMETER	The CM_INT13_DRIVE_PARAMETER structure defines a device-type-specific data record that is stored in the \Registry\Machine\Hardware\Description tree for a disk controller if the system can collect this information during the boot process.
CM_KEYBOARD_DEVICE_DATA	The CM_KEYBOARD_DEVICE_DATA structure defines a device-type-specific data record that is stored in the \Registry\Machine\Hardware\Description tree for a keyboard peripheral if the system can collect this information during the boot process.
CM_MCA_POS_DATA	The CM_MCA_POS_DATA structure is obsolete. It defines IBM-compatible MCA POS configuration information for a slot.
CM_PARTIAL_RESOURCE_DESCRIPTOR	The CM_PARTIAL_RESOURCE_DESCRIPTOR structure specifies one or more system hardware resources, of a single type, assigned to a device.
CM_PARTIAL_RESOURCE_LIST	The CM_PARTIAL_RESOURCE_LIST structure specifies a set of system hardware resources, of various types, assigned to a device. This structure is contained within a CM_FULL_RESOURCE_DESCRIPTOR structure.
CM_POWER_DATA	The CM_POWER_DATA structure contains information about a device's power management state and capabilities.
CM_RESOURCE_LIST	The CM_RESOURCE_LIST structure specifies all of the system hardware resources assigned to a device.
CM_SCSI_DEVICE_DATA	The CM_SCSI_DEVICE_DATA structure defines a device-type-specific data record that is stored in the \Registry\Machine\Hardware\Description tree for a SCSI HBA if the system can collect this information during the boot process.
CM_SERIAL_DEVICE_DATA	The CM_SERIAL_DEVICE_DATA structure defines a device-type-specific data record that is stored in the \Registry\Machine\Hardware\Description tree for a serial controller if the system can collect this information during the boot process.
COUNTED_REASON_CONTEXT	The COUNTED_REASON_CONTEXT structure contains one or more strings that give reasons for a power request.

TITLE	DESCRIPTION
D3COLD_AUX_POWER_AND_TIMING_INTERFACE	Allows device drivers to negotiate a higher auxiliary power for their PCI devices while in D3Cold state.
D3COLD_SUPPORT_INTERFACE	The D3COLD_SUPPORT_INTERFACE interface structure contains pointers to the routines in the GUID_D3COLD_SUPPORT_INTERFACE driver interface.
DEVICE_CAPABILITIES	A DEVICE_CAPABILITIES structure describes PnP and power capabilities of a device. This structure is returned in response to an IRP_MN_QUERY_CAPABILITIES IRP.
DEVICE_DESCRIPTION	The DEVICE_DESCRIPTION structure describes the attributes of the physical device for which a driver is requesting a DMA adapter.
DEVICE_FAULT_CONFIGURATION	This structure is used in seting the device fault reporting state
DEVICE_INTERFACE_CHANGE_NOTIFICATION	The DEVICE_INTERFACE_CHANGE_NOTIFICATION structure describes a device interface that has been enabled (arrived) or disabled (removed).
DEVICE_OBJECT	A device object represents a logical, virtual, or physical device for which a driver handles I/O requests.
DEVICE_RESET_INTERFACE_STANDARD	The DEVICE_RESET_INTERFACE_STANDARD structure enables function drivers to reset and recover malfunctioning devices. This structure describes the GUID_DEVICE_RESET_INTERFACE_STANDARD interface.
DMA_ADAPTER_INFO	The DMA_ADAPTER_INFO structure is a container for a DMA_ADAPTER_INFO_XXX structure that describes the capabilities of a system DMA controller.
DMA_ADAPTER_INFO_V1	The DMA_ADAPTER_INFO_V1 structure describes the capabilities of the system DMA controller that is represented by an adapter object.
DMA_IOMMU_INTERFACE	
DMA_TRANSFER_INFO	The DMA_TRANSFER_INFO structure is a container for a DMA_TRANSFER_INFO_XXX structure that describes the allocation requirements for a scatter/gather list.
DMA_TRANSFER_INFO_V1	The DMA_TRANSFER_INFO_V1 structure contains the allocation requirements for a scatter/gather list that describes the I/O data buffer for a DMA transfer.
DMA_TRANSFER_INFO_V2	Contains the allocation requirements for a scatter/gather list that describes the I/O data buffer for a DMA transfer.
DOMAIN_CONFIGURATION	Contains information required to configure a domain.
DOMAIN_CONFIGURATION_ARM64	Contains information required to configure a domain for an ARM64 system.

TITLE	DESCRIPTION
DRIVER_OBJECT	Each driver object represents the image of a loaded kernel-mode driver.
ENLISTMENT_BASIC_INFORMATION	The ENLISTMENT_BASIC_INFORMATION structure contains information about an enlistment object.
EXT_DELETE_PARAMETERS	The EXT_DELETE_PARAMETERS structure contains an extended set of parameters for the ExDeleteTimer routine.
EXT_SET_PARAMETERS	The EXT_SET_PARAMETERS structure contains an extended set of parameters for the ExSetTimer routine.
FAST_IO_DISPATCH	Contains a set of callback routines that a file system driver or file system filter driver (legacy) provides for fast I/O processing.
FAULT_INFORMATION	Contains information to set the fault report on a device.
FAULT_INFORMATION_ARM64	Contains fault information for an ARM64 system.
FAULT_INFORMATION_ARM64_FLAGS	Defines fault information.
FILE_BASIC_INFORMATION	The FILE_BASIC_INFORMATION structure is used as an argument to routines that query or set file information.
FILE_FS_DEVICE_INFORMATION	The FILE_FS_DEVICE_INFORMATION structure provides file system device information about the type of device object associated with a file object.
FILE_FULL_EA_INFORMATION	The FILE_FULL_EA_INFORMATION structure provides extended attribute (EA) information. This structure is used primarily by network drivers.
FILE_IO_PRIORITY_HINT_INFORMATION	The FILE_IO_PRIORITY_HINT_INFORMATION structure is used by the ZwQueryInformationFile and ZwSetInformationFile routines to query and set the default IRP priority hint for requests on the specified file handle.
FILE_IS_REMOTE_DEVICE_INFORMATION	The FILE_IS_REMOTE_DEVICE_INFORMATION structure is used as an argument to the ZwQueryInformationFile routine.
FILE_MEMORY_PARTITION_INFORMATION	Stores information about memory partition. This structure is used by the ZwSetInformationFile function.
FILE_NETWORK_OPEN_INFORMATION	The FILE_NETWORK_OPEN_INFORMATION structure is used as an argument to ZwQueryInformationFile.
FILE_OBJECT	The FILE_OBJECT structure is used by the system to represent a file object.
FILE_POSITION_INFORMATION	The FILE_POSITION_INFORMATION structure is used as an argument to routines that query or set file information.

TITLE	DESCRIPTION
FILE_STANDARD_INFORMATION	The FILE_STANDARD_INFORMATION structure is used as an argument to routines that query or set file information.
FILE_STANDARD_INFORMATION_EX	The FILE_STANDARD_INFORMATION_EX structure is used as an argument to routines that query or set file information.
FPGA_CONTROL_INTERFACE	Reserved for future use.
FUNCTION_LEVEL_DEVICE_RESET_PARAMETERS	The FUNCTION_LEVEL_DEVICE_RESET_PARAMETER structure is used as an argument to the DeviceReset routine of the GUID_DEVICE_RESET_INTERFACE_STANDARD interface.
GENERIC_MAPPING	The GENERIC_MAPPING structure describes the ACCESS_MASK value of specific access rights associated with each type of generic access right.
HWPROFILE_CHANGE_NOTIFICATION	The HWPROFILE_CHANGE_NOTIFICATION structure describes an event related to a hardware profile configuration change.
IMAGE_POLICY_ENTRY	This structure is not supported.
IMAGE_POLICY_METADATA	This structure is not supported.
INPUT_MAPPING_ELEMENT	Contains the input mapping IDs for a device.
INTERFACE	The INTERFACE structure describes an interface that is exported by a driver for use by other drivers.
IO_CONNECT_INTERRUPT_PARAMETERS	The IO_CONNECT_INTERRUPT_PARAMETERS structure contains the parameters that a driver supplies to the IoConnectInterruptEx routine to register an interrupt service routine (ISR).
IO_DISCONNECT_INTERRUPT_PARAMETERS	The IO_DISCONNECT_INTERRUPT_PARAMETERS structure describes the parameters when unregistering an interrupt-handling routine with IoDisconnectInterruptEx.
IO_ERROR_LOG_PACKET	The IO_ERROR_LOG_PACKET structure serves as the header for an error log entry.
IO_INTERRUPT_MESSAGE_INFO	The IO_INTERRUPT_MESSAGE_INFO structure describes the driver's message-signaled interrupts.
IO_INTERRUPT_MESSAGE_INFO_ENTRY	The IO_INTERRUPT_MESSAGE_INFO_ENTRY structure describes the properties of a single message-signaled interrupt.
IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS	The IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS structure contains the connection context for a registered interrupt service routine (ISR) that was connected to an interrupt or interrupts by a previous call to the IoConnectInterruptEx routine.

TITLE	DESCRIPTION
IO_RESOURCE_DESCRIPTOR	The IO_RESOURCE_DESCRIPTOR structure describes a range of raw hardware resources, of one type, that can be used by a device. An array of IO_RESOURCE_DESCRIPTOR structures is contained within each IO_RESOURCE_LIST structure.
IO_RESOURCE_LIST	The IO_RESOURCE_LIST structure describes a range of raw hardware resources, of various types, that can be used by a device.
IO_RESOURCE_REQUIREMENTS_LIST	The IO_RESOURCE_REQUIREMENTS_LIST structure describes sets of resource configurations that can be used by a device. Each configuration represents a range of raw resources, of various types, that can be used by a device.
IO_SECURITY_CONTEXT	The IO_SECURITY_CONTEXT structure represents the security context of an IRP_MJ_CREATE request.
IO_SESSION_CONNECT_INFO	The IO_SESSION_CONNECT_INFO structure provides information about a user session.
IO_SESSION_STATE_INFORMATION	The IO_SESSION_STATE_INFORMATION structure contains information about the state of a user session.
IO_SESSION_STATE_NOTIFICATION	The IO_SESSION_STATE_NOTIFICATION structure contains information that a kernel-mode driver supplies to the IoRegisterContainerNotification routine when the driver registers to receive notifications of session events.
IO_STACK_LOCATION	The IO_STACK_LOCATION structure defines an I/O stack location, which is an entry in the I/O stack that is associated with each IRP.
IO_STATUS_BLOCK	A driver sets an IRP's I/O status block to indicate the final status of an I/O request, before calling IoCompleteRequest for the IRP.
IRP	The IRP structure is a partially opaque structure that represents an I/O request packet. Drivers can use the following members of the IRP structure.
KBUGCHECK_ADD_PAGES	The KBUGCHECK_ADD_PAGES structure describes one or more pages of driver-supplied data to be written by a BugCheckAddPagesCallback callback routine to the crash dump file.
KBUGCHECK_DUMP_IO	The KBUGCHECK_DUMP_IO structure describes an I/O operation on the crash dump file.
KBUGCHECK_SECONDARY_DUMP_DATA	The KBUGCHECK_SECONDARY_DUMP_DATA structure describes a section of driver-supplied data to be written by BugCheckSecondaryDumpDataCallback to the crash dump file.
KDPC_WATCHDOG_INFORMATION	The KDPC_WATCHDOG_INFORMATION structure holds time-out information about the current deferred procedure call (DPC).

TITLE	DESCRIPTION
KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT	The KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT structure describes the notification context that is passed to a registered callback function when a new processor is dynamically added to a hardware partition.
KEY_BASIC_INFORMATION	The KEY_BASIC_INFORMATION structure defines a subset of the full information that is available for a registry key.
KEY_FULL_INFORMATION	The KEY_FULL_INFORMATION structure defines the information available for a registry key, including information about its subkeys and the maximum length for their names and value entries.
KEY_NODE_INFORMATION	The KEY_NODE_INFORMATION structure defines the basic information available for a registry (sub)key.
KEY_VALUE_BASIC_INFORMATION	The KEY_VALUE_BASIC_INFORMATION structure defines a subset of the full information available for a value entry of a registry key.
KEY_VALUE_ENTRY	The KEY_VALUE_ENTRY structure is used by the REG_QUERY_MULTIPLE_VALUE_KEY_INFORMATION structure to describe a single value entry for a registry key.
KEY_VALUE_FULL_INFORMATION	The KEY_VALUE_FULL_INFORMATION structure defines information available for a value entry of a registry key.
KEY_VALUE_PARTIAL_INFORMATION	The KEY_VALUE_PARTIAL_INFORMATION structure defines a subset of the value information available for a value entry of a registry key.
KEY_WRITE_TIME_INFORMATION	The KEY_WRITE_TIME_INFORMATION structure is used by the system to set the last write time for a registry key.
KTMOBJECT_CURSOR	The KTMOBJECT_CURSOR structure receives enumeration information about KTM objects when a component calls ZwEnumerateTransactionObject.
KTRIAGE_DUMP_DATA_ARRAY	
LINK_SHARE_ACCESS	The share access structure used by file systems for only link files.
LUID_AND_ATTRIBUTES	LUID_AND_ATTRIBUTES represents a locally unique identifier (LUID) and its attributes.
MDL	An MDL structure is a partially opaque structure that represents a memory descriptor list (MDL).
MEM_EXTENDED_PARAMETER	
MM_PHYSICAL_ADDRESS_LIST	The MM_PHYSICAL_ADDRESS_LIST structure specifies a range of physical addresses.

TITLE	DESCRIPTION
OB_CALLBACK_REGISTRATION	The OB_CALLBACK_REGISTRATION structure specifies the parameters when the ObRegisterCallbacks routine registers ObjectPreCallback and ObjectPostCallback callback routines.
OB_OPERATION_REGISTRATION	The OB_OPERATION_REGISTRATION structure specifies ObjectPreCallback and ObjectPostCallback callback routines and the types of operations that the routines are called for.
OB_POST_CREATE_HANDLE_INFORMATION	The OB_POST_CREATE_HANDLE_INFORMATION structure provides information to a ObjectPostCallback routine about a thread or process handle that has been opened.
OB_POST_DUPLICATE_HANDLE_INFORMATION	The OB_POST_DUPLICATE_HANDLE_INFORMATION structure provides information to an ObjectPostCallback routine about a thread or process handle that has been duplicated.
OB_POST_OPERATION_INFORMATION	The OB_POST_OPERATION_INFORMATION structure provides information about a process or thread handle operation to an ObjectPostCallback routine.
OB_POST_OPERATION_PARAMETERS	The OB_POST_OPERATION_PARAMETERS union describes the operation-specific parameters for an ObjectPostCallback routine.
OB_PRE_CREATE_HANDLE_INFORMATION	The OB_PRE_CREATE_HANDLE_INFORMATION structure provides information to an ObjectPreCallback routine about a thread or process handle that is being opened.
OB_PRE_DUPLICATE_HANDLE_INFORMATION	The OB_PRE_DUPLICATE_HANDLE_INFORMATION structure provides information to an ObjectPreCallback routine about a thread or process handle that is being duplicated.
OB_PRE_OPERATION_INFORMATION	The OB_PRE_OPERATION_INFORMATION structure provides information about a process or thread handle operation to an ObjectPreCallback routine.
OB_PRE_OPERATION_PARAMETERS	The OB_PRE_OPERATION_PARAMETERS union describes the operation-specific parameters for an ObjectPreCallback routine.
OSVERSIONINFOEXW	The RTL_OSVERSIONINFOEXW structure contains operating system version information.
OSVERSIONINFOW	The RTL_OSVERSIONINFOW structure contains operating system version information.
PCI_CAPABILITIES_HEADER	The PCI_CAPABILITIES_HEADER structure defines a header that is present in every PCI capability structure.
PCI_COMMON_CONFIG	The PCI_COMMON_CONFIG structure is obsolete.
PCI_DEVICE_PRESENT_INTERFACE	The PCI_DEVICE_PRESENT_INTERFACE structure is reserved for system use.

TITLE	DESCRIPTION
PCI_EXPRESS_AER_CAPABILITIES	The PCI_EXPRESS_AER_CAPABILITIES structure describes a PCI Express (PCIe) advanced error capabilities and control register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_AER_CAPABILITY	The PCI_EXPRESS_AER_CAPABILITY structure describes a PCI Express (PCIe) advanced error reporting capability structure.
PCI_EXPRESS_BRIDGE_AER_CAPABILITY	The PCI_EXPRESS_BRIDGE_AER_CAPABILITY structure describes a PCI Express (PCIe) advanced error reporting capability structure for a PCIe bridge device.
PCI_EXPRESS_CORRECTABLE_ERROR_MASK	The PCI_EXPRESS_CORRECTABLE_ERROR_MASK structure describes a PCI Express (PCIe) correctable error mask register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_CORRECTABLE_ERROR_STATUS	The PCI_EXPRESS_CORRECTABLE_ERROR_STATUS structure describes a PCI Express (PCIe) correctable error status register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_ENHANCED_CAPABILITY_HEADER	The PCI_EXPRESS_ENHANCED_CAPABILITY_HEADER structure describes the header for a PCI Express (PCIe) extended capability structure.
PCI_EXPRESS_ERROR_SOURCE_ID	The PCI_EXPRESS_ERROR_SOURCE_ID structure describes the identifiers of the first correctable error and the first uncorrectable error that are reported in the PCI Express (PCIe) root error status register.
PCI_EXPRESS_LINK_QUIESCENT_INTERFACE	The PCI_EXPRESS_LINK_QUIESCENT_INTERFACE structure is reserved for system use.
PCI_EXPRESS_PTM_CAPABILITY	Reserved. Do not use.
PCI_EXPRESS_PTM_CAPABILITY_REGISTER	Reserved. Do not use.
PCI_EXPRESS_PTM_CONTROL_REGISTER	Reserved. Do not use.
PCI_EXPRESS_ROOT_ERROR_COMMAND	The PCI_EXPRESS_ROOT_ERROR_COMMAND structure describes a PCI Express (PCIe) root error command register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_ROOT_ERROR_STATUS	The PCI_EXPRESS_ROOT_ERROR_STATUS structure describes a PCI Express (PCIe) root error status register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_ROOT_PORT_INTERFACE	The PCI_EXPRESS_ROOT_PORT_INTERFACE structure is reserved for system use.
PCI_EXPRESS_ROOTPORT_AER_CAPABILITY	The PCI_EXPRESS_ROOTPORT_AER_CAPABILITY structure describes a PCI Express (PCIe) advanced error reporting capability structure for a root port or a root complex event collector.

TITLE	DESCRIPTION
PCI_EXPRESS_SEC_AER_CAPABILITIES	The PCI_EXPRESS_SEC_AER_CAPABILITIES structure describes a PCI Express (PCIe) secondary error capabilities and control register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_SEC_UNCORRECTABLE_ERROR_MASK	The PCI_EXPRESS_SEC_UNCORRECTABLE_ERROR_MASK structure describes a PCI Express (PCIe) secondary uncorrectable error mask register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_SEC_UNCORRECTABLE_ERROR_SEVERITY	The PCI_EXPRESS_SEC_UNCORRECTABLE_ERROR_SEVERITY structure describes a PCI Express (PCIe) secondary uncorrectable error severity register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_SEC_UNCORRECTABLE_ERROR_STATUS	The PCI_EXPRESS_SEC_UNCORRECTABLE_ERROR_STATUS structure describes a PCI Express (PCIe) secondary uncorrectable error status register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_SERIAL_NUMBER_CAPABILITY	The PCI_EXPRESS_SERIAL_NUMBER_CAPABILITY structure describes a serial number for a PCI Express (PCIe) device.
PCI_EXPRESS_UNCORRECTABLE_ERROR_MASK	The PCI_EXPRESS_UNCORRECTABLE_ERROR_MASK structure describes a PCI Express (PCIe) uncorrectable error mask register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_UNCORRECTABLE_ERROR_SEVERITY	The PCI_EXPRESS_UNCORRECTABLE_ERROR_SEVERITY structure describes a PCI Express (PCIe) uncorrectable error severity register of a PCIe advanced error reporting capability structure.
PCI_EXPRESS_UNCORRECTABLE_ERROR_STATUS	The PCI_EXPRESS_UNCORRECTABLE_ERROR_STATUS structure describes a PCI Express (PCIe) uncorrectable error status register of a PCIe advanced error reporting capability structure.
PCI_MSIX_TABLE_CONFIG_INTERFACE	The PCI_MSIX_TABLE_CONFIG_INTERFACE structure enables device drivers to modify their MSI-X interrupt settings. This structure describes the GUID_MSIX_TABLE_CONFIG_INTERFACE interface.
PCI_PM_CAPABILITY	The PCI_PM_CAPABILITY structure reports the power management capabilities of the device.
PCI_PMC	The PCI_PMC structure is used to report the contents of the power management capabilities register.
PCI_PMCSR	The PCI_PMCSR structure is used to report the contents of the device's power management control status register.
PCI_PMCSR_BSE	The PCI_PMCSR_BSE structure is used to report the contents of the power management control status register for PCI bridge support extensions.

TITLE	DESCRIPTION
PCI_SLOT_NUMBER	The PCI_SLOT_NUMBER structure is obsolete.
PCI_X_CAPABILITY	The PCI_X_CAPABILITY structure reports the contents of the command and status registers of a device that is compliant with the PCI-X Addendum to the PCI Local Bus Specification.
PCW_CALLBACK_INFORMATION	The PCW_CALLBACK_INFORMATION union supplies details about the notification to send. A provider passes a pointer to this union as a parameter to the PcwCallback function.
PCW_COUNTER_DESCRIPTOR	The PCW_COUNTER_DESCRIPTOR structure supplies details about the notification to send.
PCW_COUNTER_INFORMATION	The PCW_COUNTER_INFORMATION structure describes attributes that identify a specific instance of a counter set.
PCW_DATA	The PCW_DATA structure describes the array of data blocks that are associated with an instance.
PCW_MASK_INFORMATION	The PCW_MASK_INFORMATION structure supplies details about the notification to send to the provider. This information is passed as part of the Info parameter to the PcwCallback function. This mask information is included in PCW_CALLBACK_INFORMATION.
PCW_REGISTRATION_INFORMATION	The PCW_REGISTRATION_INFORMATION structure supplies details about the provider and the counter set.
PLUGPLAY_NOTIFICATION_HEADER	A PLUGPLAY_NOTIFICATION_HEADER structure is included at the beginning of each PnP notification structure, such as a DEVICE_INTERFACE_CHANGE_NOTIFICATION structure.
PNP_BUS_INFORMATION	The PNP_BUS_INFORMATION structure describes a bus.
PO_FX_COMPONENT_IDLE_STATE	The PO_FX_COMPONENT_IDLE_STATE structure specifies the attributes of an Fx power state of a component in a device.
PO_FX_COMPONENT_PERF_INFO	The PO_FX_COMPONENT_PERF_INFO structure describes all the sets of performance states for a single component within a device.
PO_FX_COMPONENT_PERF_SET	The PO_FX_COMPONENT_PERF_SET structure represents a set of performance states for a single component within a device.
PO_FX_COMPONENT_V1	The PO_FX_COMPONENT structure describes the power state attributes of a component in a device.
PO_FX_COMPONENT_V2	The PO_FX_COMPONENT structure describes the power state attributes of a component in a device.
PO_FX_DEVICE_V1	The PO_FX_DEVICE structure describes the power attributes of a device to the power management framework (PoFx).

TITLE	DESCRIPTION
PO_FX_DEVICE_V2	The PO_FX_DEVICE structure describes the power attributes of a device to the power management framework (PoFx).
PO_FX_PERF_STATE	The PO_FX_PERF_STATE structure represents a performance state for a single component within a device.
PO_FX_PERF_STATE_CHANGE	The PO_FX_PERF_STATE_CHANGE structure contains information about a change to a performance state that is being requested by calling the PoFxIssueComponentPerfStateChange or PoFxIssueComponentPerfStateChangeMultiple routine.
POWER_PLATFORM_INFORMATION	The POWER_PLATFORM_INFORMATION structure contains information about the power capabilities of the system.
POWER_STATE	The POWER_STATE union specifies a system power state value or a device power state value.
PRIVILEGE_SET	The PRIVILEGE_SET structure specifies a set of security privileges. For more information, see the reference page for PRIVILEGE_SET in the Microsoft Windows SDK documentation.
PTM_CONTROL_INTERFACE	Resereved. Do not use.
REENUMERATE_SELF_INTERFACE_STANDARD	The REENUMERATE_SELF_INTERFACE_STANDARD interface structure enables a driver to request that its parent bus driver reenumerate the driver's device. This structure defines the GUID_REENUMERATE_SELF_INTERFACE_STANDARD interface.
REG_CALLBACK_CONTEXT_CLEANUP_INFORMATION	The REG_CALLBACK_CONTEXT_CLEANUP_INFORMATION structure contains information that a driver's RegistryCallback routine can use to free resources that the driver previously allocated for the context that is associated with a registry object.
REG_CREATE_KEY_INFORMATION	The REG_CREATE_KEY_INFORMATION structure contains information that a driver's RegistryCallback routine can use when a registry key that is being created.
REG_CREATE_KEY_INFORMATION_V1	The REG_CREATE_KEY_INFORMATION_V1 structure contains information that a filter driver's RegistryCallback routine can use when a registry key is being created.
REG_DELETE_KEY_INFORMATION	The REG_DELETE_KEY_INFORMATION structure contains information that a driver's RegistryCallback routine can use when a registry key is being deleted.
REG_DELETE_VALUE_KEY_INFORMATION	The REG_DELETE_VALUE_KEY_INFORMATION structure contains information that a driver's RegistryCallback routine can use when a registry key's value is being deleted.
REG_ENUMERATE_KEY_INFORMATION	The REG_ENUMERATE_KEY_INFORMATION structure describes one subkey of a key whose subkeys are being enumerated.

TITLE	DESCRIPTION
REG_ENUMERATE_VALUE_KEY_INFORMATION	The REG_ENUMERATE_VALUE_KEY_INFORMATION structure describes one value entry of a key whose value entries are being enumerated.
REG_KEY_HANDLE_CLOSE_INFORMATION	The REG_KEY_HANDLE_CLOSE_INFORMATION structure contains information about a registry key whose handle is about to be closed.
REG_LOAD_KEY_INFORMATION	The REG_LOAD_KEY_INFORMATION structure contains information about a registry hive that is being loaded.
REG_POST_CREATE_KEY_INFORMATION	The REG_POST_CREATE_KEY_INFORMATION structure contains the result of an attempt to create a registry key.
REG_POST_OPERATION_INFORMATION	The REG_POST_OPERATION_INFORMATION structure contains information about a completed registry operation that a RegistryCallback routine can use.
REG_PRE_CREATE_KEY_INFORMATION	The REG_PRE_OPEN_KEY_INFORMATION structure contains the name of a registry key that is about to be opened.
REG_QUERY_KEY_INFORMATION	The REG_QUERY_KEY_INFORMATION structure describes the metadata that is about to be queried for a key.
REG_QUERY_KEY_NAME	The REG_QUERY_KEY_NAME structure describes the full registry key name of an object being queried.
REG_QUERY_KEY_SECURITY_INFORMATION	The REG_QUERY_KEY_SECURITY_INFORMATION structure receives security information for a registry key object.
REG_QUERY_MULTIPLE_VALUE_KEY_INFORMATION	The REG_QUERY_MULTIPLE_VALUE_KEY_INFORMATION structure describes the multiple value entries that are being retrieved for a key.
REG_QUERY_VALUE_KEY_INFORMATION	The REG_QUERY_VALUE_KEY_INFORMATION structure contains information about a registry key's value entry that is being queried.
REG_RENAME_KEY_INFORMATION	The REG_RENAME_KEY_INFORMATION structure contains the new name for a registry key whose name is about to be changed.
REG_REPLACE_KEY_INFORMATION	The REG_REPLACE_KEY_INFORMATION structure describes the metadata that is about to be replaced for a key.
REG_RESTORE_KEY_INFORMATION	The REG_RESTORE_KEY_INFORMATION structure contains the information for a registry key that is about to be restored.
REG_SAVE_KEY_INFORMATION	The REG_SAVE_KEY_INFORMATION structure contains the information for a registry key that is about to be saved.
REG_SET_INFORMATION_KEY_INFORMATION	The REG_SET_INFORMATION_KEY_INFORMATION structure describes a new setting for a key's metadata.

TITLE	DESCRIPTION
REG_SET_KEY_SECURITY_INFORMATION	The REG_SET_KEY_SECURITY_INFORMATION structure specifies security information for a registry key object.
REG_SET_VALUE_KEY_INFORMATION	The REG_SET_VALUE_INFORMATION structure describes a new setting for a registry key's value entry.
REG_UNLOAD_KEY_INFORMATION	The REG_UNLOAD_KEY_INFORMATION structure contains information that a driver's RegistryCallback routine can use when a registry hive is unloaded.
RESOURCEMANAGER_BASIC_INFORMATION	The RESOURCEMANAGER_BASIC INFORMATION structure contains information about a resource manager object.
RESOURCEMANAGER_COMPLETION_INFORMATION	The RESOURCEMANAGER_COMPLETION_INFORMATION structure is not used.
SCATTER_GATHER_LIST	The SCATTER_GATHER_LIST structure describes the scatter/gather list for a DMA operation.
SDEV_IDENTIFIER_INTERFACE	This material is not yet available. This placeholder topic is provided as an example of documentation that may be included in a later release.
SECTION_OBJECT_POINTERS	The SECTION_OBJECT_POINTERS structure, allocated by a file system or a redirector driver, is used by the memory manager and cache manager to store file-mapping and cache-related information for a file stream.
SECURITY_SUBJECT_CONTEXT	The SECURITY_SUBJECT_CONTEXT structure is used to capture subject security context for access validation and auditing.
SLIST_ENTRY	An SLIST_ENTRY structure describes an entry in a sequenced singly linked list.
SYSTEM_POWER_STATE_CONTEXT	The SYSTEM_POWER_STATE_CONTEXT structure is a partially opaque system structure that contains information about the previous system power states of a computer.
TARGET_DEVICE_CUSTOM_NOTIFICATION	The TARGET_DEVICE_CUSTOM_NOTIFICATION structure describes a custom device event.
TARGET_DEVICE_REMOVAL_NOTIFICATION	The TARGET_DEVICE_REMOVAL_NOTIFICATION structure describes a device-removal event. The PnP manager sends this structure to a driver that registered a callback routine for notification of EventCategoryTargetDeviceChange events.
TRANSACTION_BASIC_INFORMATION	The TRANSACTION_BASIC_INFORMATION structure contains information about a transaction object.
TRANSACTION_ENLISTMENT_PAIR	The TRANSACTION_ENLISTMENT_PAIR structure contains information about an enlistment that is associated with a transaction object.

TITLE	DESCRIPTION
TRANSACTION_ENLISTMENTS_INFORMATION	The TRANSACTION_ENLISTMENTS_INFORMATION structure contains information about the enlistments that are associated with a transaction object.
TRANSACTION_PROPERTIES_INFORMATION	The TRANSACTION_PROPERTIES_INFORMATION structure contains a transaction object's properties.
TRANSACTIONMANAGER_BASIC_INFORMATION	The TRANSACTIONMANAGER_BASIC_INFORMATION structure contains information about a transaction manager object.
TRANSACTIONMANAGER_LOG_INFORMATION	The TRANSACTIONMANAGER_LOG_INFORMATION structure contains information about a transaction manager object.
TRANSACTIONMANAGER_LOGPATH_INFORMATION	The TRANSACTIONMANAGER_LOGPATH_INFORMATION structure contains information about a transaction manager object.
TRANSACTIONMANAGER_RECOVERY_INFORMATION	The TRANSACTIONMANAGER_RECOVERY_INFORMATION structure contains information about a transaction manager object.
VPB	The volume parameter block (VPB) structure is used to map a device object that represents a mounted file system volume to a device object that represents a physical or virtual disk device.
WAIT_CONTEXT_BLOCK	Reserved. Do not use.
WORK_QUEUE_ITEM	The WORK_QUEUE_ITEM structure is used to post a work items to a system work queue.
XSAVE_CET_U_FORMAT	Format for CET_U XSTATE component.

Enumerations

TITLE	DESCRIPTION
BOUND_CALLBACK_STATUS	The BOUND_CALLBACK_STATUS enumeration indicates how a user-mode bounds exception was processed by the BoundCallback function.
CLFS_CONTEXT_MODE	The CLFS_CONTEXT_MODE enumeration indicates the type of sequence that the Common Log File System (CLFS) driver follows when it reads a set of records from a stream.
CLFS_MGMT_POLICY_TYPE	The CLFS_MGMT_POLICY_TYPE enumeration type identifies the type of a CLFS management policy.
CLS_LOG_INFORMATION_CLASS	The CLFS_LOG_INFORMATION_CLASS enumeration indicates the type of information that is requested by a call to ClfsQueryLogFileInformation.

TITLE	DESCRIPTION
D3COLD_LAST_TRANSITION_STATUS	The D3COLD_LAST_TRANSITION_STATUS enumeration indicates whether the most recent transition to the D3hot device power state was followed by a transition to the D3cold device power state.
DEVICE_DIRECTORY_TYPE	The directory from which the driver is loaded.
DEVICE_INSTALL_STATE	The DEVICE_INSTALL_STATE enumeration describes a device's installation state.
DEVICE_POWER_STATE	The DEVICE_POWER_STATE enumeration type indicates a device power state.
DEVICE_REGISTRY_PROPERTY	The DEVICE_REGISTRY_PROPERTY enumeration identifies device properties that are stored in the registry.
DEVICE_REMOVAL_POLICY	The DEVICE_REMOVAL_POLICY enumeration describes a device's removal policy.
DEVICE_RESET_TYPE	The DEVICE_RESET_TYPE enumeration specifies the type of device reset that is being requested by a call to the DeviceReset routine of the GUID_DEVICE_RESET_INTERFACE_STANDARD interface.
DEVICE_WAKE_DEPTH	The DEVICE_WAKE_DEPTH enumeration specifies the deepest device power state from which a device can trigger a wake signal.
DIRECTORY_NOTIFY_INFORMATION_CLASS	A value that specifies which structure to use to query or set information for a files in a directory.
DMA_COMPLETION_STATUS	The DMA_COMPLETION_STATUS enumeration describes the completion status of a DMA transfer.
DOMAIN_CONFIGURATION_ARCH	Defines values for type of system architecture specified.
DRIVER_DIRECTORY_TYPE	
ENLISTMENT_INFORMATION_CLASS	The ENLISTMENT_INFORMATION_CLASS enumeration identifies the type of information that the ZwSetInformationEnlistment routine can set and that the ZwQueryInformationEnlistment routine can retrieve for an enlistment object.
FAULT_INFORMATION_ARCH	Defines values for type of system architecture.
FAULT_INFORMATION_ARM64_TYPE	Defines values for the type of fault.
FILE_INFORMATION_CLASS	A value that specifies which structure to use to query or set information for a file object.
FS_INFORMATION_CLASS	The FS_INFORMATION_CLASS enumeration contains the information class constants that specify what type of information structure is present for a set or a query operation.

TITLE	DESCRIPTION
IMAGE_POLICY_ENTRY_TYPE	This enumeration is not supported.
IMAGE_POLICY_ID	This enumeration is not supported.
INTERFACE_TYPE	The INTERFACE_TYPE enumeration indicates the bus type.
IO_ACCESS_MODE	Defines the types of access mode for Scheduled File I/O (SFIO).
IO_ACCESS_TYPE	Defines the access rights for Scheduled File I/O (SFIO).
IO_ALLOCATION_ACTION	The IO_ALLOCATION_ACTION enumerated type is used to specify return values for AdapterControl and ControllerControl routines.
IO_CONTAINER_INFORMATION_CLASS	The IO_CONTAINER_INFORMATION_CLASS enumeration contains constants that indicate the classes of system information that a kernel-mode driver can request.
IO_CONTAINER_NOTIFICATION_CLASS	The IO_CONTAINER_NOTIFICATION_CLASS enumeration contains constants that indicate the classes of events for which a kernel-mode driver can register to receive notifications.
IO_PAGING_PRIORITY	The IO_PAGING_PRIORITY enumeration describes the priority value for a paging I/O IRP.
IO_PRIORITY_HINT	The IO_PRIORITY_HINT enumeration type specifies the priority hint for an IRP.
IO_SESSION_EVENT	The IO_SESSION_EVENT enumeration indicates the type of session event for which a driver is receiving notification.
IO_SESSION_STATE	The IO_SESSION_STATE enumeration contains constants that indicate the current state of a user session.
IRQ_DEVICE_POLICY	The IRQ_DEVICE_POLICY enumeration type indicates the policy the operating system can use to assign the interrupts from a device to different processors.
IRQ_PRIORITY	The IRQ_PRIORITY enumeration type indicates the priority the system should give to servicing a device's interrupts.
KBUGCHECK_CALLBACK_REASON	The KBUGCHECK_CALLBACK_REASON enumeration type specifies the situations in which a bug-check callback executes.
KBUGCHECK_DUMP_IO_TYPE	The KBUGCHECK_DUMP_IO_TYPE enumeration type identifies the type of a section of data within a crash dump file.
KEY_INFORMATION_CLASS	The KEY_INFORMATION_CLASS enumeration type represents the type of information to supply about a registry key.
KEY_SET_INFORMATION_CLASS	The KEY_SET_INFORMATION_CLASS enumeration type represents the type of information to set for a registry key.

TITLE	DESCRIPTION
KEY_VALUE_INFORMATION_CLASS	The KEY_VALUE_INFORMATION_CLASS enumeration type specifies the type of information to supply about the value of a registry key.
KINTERRUPT_MODE	The KINTERRUPT_MODE enumeration type indicates whether an interrupt is level-triggered or edge-triggered.
KINTERRUPT_POLARITY	The KINTERRUPT_POLARITY enumeration indicates how a device signals an interrupt request on an interrupt line.
KTMOBJECT_TYPE	The KTMOBJECT_TYPE enumeration identifies the types of objects that KTM supports.
LOCK_OPERATION	The LOCK_OPERATION enumeration specifies the type of access that is appropriate for a type of I/O operation.
MEM_EXTENDED_PARAMETER_TYPE	Defines values for extended parameters are used for file mapping into an address space.
MEM_SECTION_EXTENDED_PARAMETER_TYPE	
MEMORY_CACHING_TYPE	The MEMORY_CACHING_TYPE enumeration type specifies the permitted caching behavior when allocating or mapping memory.
MONITOR_DISPLAY_STATE	Indicates the power state of the monitor being displayed on.
PCW_CALLBACK_TYPE	The PCW_CALLBACK_TYPE enumeration defines the notification type to send to the registered provider of the counter set. A provider passes a pointer to this enumeration as a parameter to the PcwCallback function.
PO_FX_PERF_STATE_TYPE	The PO_FX_PERF_STATE_TYPE enumeration contains values that describe the type of performance states in a PO_FX_COMPONENT_PERF_SET.
PO_FX_PERF_STATE_UNIT	The PO_FX_PERF_STATE_UNIT enumeration contains values that describe the type of unit that is controlled by the performance states in a PO_FX_COMPONENT_PERF_SET.
POOL_TYPE	The POOL_TYPE enumeration type specifies the type of system memory to allocate.
POWER_ACTION	The POWER_ACTION enumeration identifies the system power actions that can occur on a computer.
POWER_INFORMATION_LEVEL	Indicates power level information.
POWER_REQUEST_TYPE	The POWER_REQUEST_TYPE enumeration indicates the power request type.
POWER_STATE_TYPE	The POWER_STATE_TYPE enumeration type indicates that a power state value is a system power state or a device power state.

TITLE	DESCRIPTION
REG_NOTIFY_CLASS	The REG_NOTIFY_CLASS enumeration type specifies the type of registry operation that the configuration manager is passing to a RegistryCallback routine.
RESOURCEMANAGER_INFORMATION_CLASS	The RESOURCEMANAGER_INFORMATION_CLASS enumeration identifies the type of information that the ZwQueryInformationResourceManager routine can retrieve for a resource manager object.
SE_IMAGE_TYPE	
SECURITY_IMPERSONATION_LEVEL	The SECURITY_IMPERSONATION_LEVEL enumeration type contains values that specify security impersonation levels. Security impersonation levels govern the degree to which a server process can act on behalf of a client process.
SYSTEM_POWER_STATE	The SYSTEM_POWER_STATE enumeration type is used to indicate a system power state.
TRACE_INFORMATION_CLASS	The TRACE_INFORMATION_CLASS enumeration type is used to indicate types of information associated with a WMI event tracing session.
TRANSACTION_INFORMATION_CLASS	The TRANSACTION_INFORMATION_CLASS enumeration specifies the type of information that ZwSetInformationTransaction can set and ZwQueryInformationTransaction can retrieve for a transaction manager object.
TRANSACTION_OUTCOME	The TRANSACTION_OUTCOME enumeration defines the outcomes (results) that KTM can assign to a transaction.
TRANSACTION_STATE	The TRANSACTION_STATE enumeration defines the states that KTM can assign to a transaction.
TRANSACTIONMANAGER_INFORMATION_CLASS	The TRANSACTIONMANAGER_INFORMATION_CLASS enumeration specifies the type of information that the ZwQueryInformationTransactionManager routine can retrieve for a transaction manager object.
WORK_QUEUE_TYPE	The WORK_QUEUE_TYPE enumeration type indicates the type of system worker thread that handles a work item.

DMA_COMPLETION_STATUS Enumeration

1/25/2019 • 2 minutes to read • Edit Online

The **DMA_COMPLETION_STATUS** enumeration describes the completion status of a DMA transfer.

Syntax

```
typedef enum  {
  DmaComplete,
  DmaAborted,
  DmaError,
  DmaCancelled
} DMA_COMPLETION_STATUS;
```

Constants

DmaComplete	The DMA transfer completed successfully.
DmaAborted	Not used.
DmaError	The DMA transfer did not complete successfully because an error occurred.
DmaCancelled	The DMA transfer did not complete successfully because the client canceled the transfer.

Remarks

The *Status* parameter of the DmaCompletionRoutine routine is a **DMA_COMPLETION_STATUS** enumeration value.

Requirements

Minimum supported client	Supported starting with Windows 8.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

POWER_INFORMATION_LEVEL Enumeration

1/25/2019 • 3 minutes to read • Edit Online

Indicates power level information.

Syntax

```
typedef enum  {
  SystemPowerPolicyAc,
  SystemPowerPolicyDc,
  VerifySystemPolicyAc,
  VerifySystemPolicyDc,
  SystemPowerCapabilities,
  SystemBatteryState,
  SystemPowerStateHandler,
  ProcessorStateHandler,
  SystemPowerPolicyCurrent,
  AdministratorPowerPolicy,
  SystemReserveHiberFile,
  ProcessorInformation,
  SystemPowerInformation,
  ProcessorStateHandler2,
  LastWakeTime,
  LastSleepTime,
  SystemExecutionState,
  SystemPowerStateNotifyHandler,
  ProcessorPowerPolicyAc,
  ProcessorPowerPolicyDc,
  VerifyProcessorPowerPolicyAc,
  VerifyProcessorPowerPolicyDc,
  ProcessorPowerPolicyCurrent,
  SystemPowerStateLogging,
  SystemPowerLoggingEntry,
  SetPowerSettingValue,
  NotifyUserPowerSetting,
  PowerInformationLevelUnused0,
  SystemMonitorHiberBootPowerOff,
  SystemVideoState,
  TraceApplicationPowerMessage,
  TraceApplicationPowerMessageEnd,
  ProcessorPerfStates,
  ProcessorIdleStates,
  ProcessorCap,
  SystemWakeSource,
  SystemHiberFileInformation,
  TraceServicePowerMessage,
  ProcessorLoad,
  PowerShutdownNotification,
  MonitorCapabilities,
  SessionPowerInit,
  SessionDisplayState,
  PowerRequestCreate,
  PowerRequestAction,
  GetPowerRequestList,
  ProcessorInformationEx,
  NotifyUserModeLegacyPowerEvent,
  GroupPark,
  ProcessorIdleDomains,
  WakeTimerList,
  SystemHiberFileSize,
  ProcessorIdleStatesHv,
```

```
    ProcessorPerfStatesHv,
    ProcessorPerfCapHv,
    ProcessorSetIdle,
    LogicalProcessorIdling,

    PhysicalPowerButtonPress,
    QueryPotentialDripsConstraint,
    EnergyTrackerCreate,
    EnergyTrackerQuery,
    UpdateBlackBoxRecorder,
    PowerInformationLevelMaximum
} POWER_INFORMATION_LEVEL;
```

Constants

SystemPowerPolicyAc	Indicates SystemPowerPolicyAc.
SystemPowerPolicyDc	Indicates SystemPowerPolicyDc.
VerifySystemPolicyAc	Indicates VerifySystemPolicyAc.
VerifySystemPolicyDc	Indicates VerifySystemPolicyDc.
SystemPowerCapabilities	Indicates the power capabilities of the system.
SystemBatteryState	Indicates the system's battery state.
SystemPowerStateHandler	Indicates the system's power state handler.

ProcessorStateHandler	Indicates the processor state handler.
SystemPowerPolicyCurrent	Indicates the system's current power policy.
AdministratorPowerPolicy	Indicates the administrator's power policy.
SystemReserveHiberFile	Indicates the SystemReserveHiberFile.
ProcessorInformation	Indicates the processor information.
SystemPowerInformation	Indicates the system power information.
ProcessorStateHandler2	Indicates the processor state handler.
LastWakeTime	Indicates the last wake time.
LastSleepTime	Indicates the last sleep time.
SystemExecutionState	Indicates the system execution state.
SystemPowerStateNotifyHandler	Indicates the system power state notify handler.
ProcessorPowerPolicyAc	Indicates ProcessorPowerPolicyAc.
ProcessorPowerPolicyDc	Indicates ProcessorPowerPolicyDc.
VerifyProcessorPowerPolicyAc	Indicates VerifyProcessorPowerPolicyAc.
VerifyProcessorPowerPolicyDc	Indicates VerifyProcessorPowerPolicyDc.
ProcessorPowerPolicyCurrent	Indicates the current processor power policy.
SystemPowerStateLogging	Indicates SystemPowerStateLogging.
SystemPowerLoggingEntry	Indicates SystemPowerLoggingEntry.
SetPowerSettingValue	Indicates that the power setting value is set.
NotifyUserPowerSetting	Indicates that the user should be notified of the power setting.
PowerInformationLevelUnused0	Indicates that the power information level is unused.
SystemMonitorHiberBootPowerOff	Indicates that the system monitor boot power is off.
SystemVideoState	Indicates the system video state.
TraceApplicationPowerMessage	Indicates the trace application power message.
TraceApplicationPowerMessageEnd	Indicates the end of the trace application power message.
ProcessorPerfStates	Indicates the processor performance states.

ProcessorIdleStates	Indicates the processor idle states.
ProcessorCap	Indicates the processor cap.
SystemWakeSource	Indicates the system wake source.
SystemHiberFileInformation	Indicates the system's hibernation file information.
TraceServicePowerMessage	Indicates the trace service power message.
ProcessorLoad	Indicates the processor load.
PowerShutdownNotification	Indicates the power shutdown notification.
MonitorCapabilities	Indicates the monitor's capabilities.
SessionPowerInit	Indicates the session power has been initialized.
SessionDisplayState	Indicates the session display state.
PowerRequestCreate	Indicates that a power request has been created.
PowerRequestAction	Indicates the action of the power request.
GetPowerRequestList	Indicates that the power request list should be queued.
ProcessorInformationEx	Indicates ProcessorInformationEx.
NotifyUserModeLegacyPowerEvent	Indicates that a notification should be created for the user mode legacy power event.
GroupPark	Indicates the group park.
ProcessorIdleDomains	Indicates the processor's idle domains.
WakeTimerList	Indicates the wake timer list.
SystemHiberFileSize	Indicates the system's hibernation file size.
ProcessorIdleStatesHv	Indicates the processor's idle states.
ProcessorPerfStatesHv	Indicates the processor's performance states.
ProcessorPerfCapHv	Indicates the processor's performance capabilities.
ProcessorSetIdle	Indicates that the processor has been set to idle.
LogicalProcessorIdling	Indicates that the processor is idling.
UserPresence	Indicates the user presence.
PowerSettingNotificationName	Indicates the power setting notification name.

GetPowerSettingValue	Indicates that the power setting value should be queued.
IdleResiliency	Indicates the idle resiliency.
SessionRITState	Indicates the session's RIT state.
SessionConnectNotification	Indicates the session's connect notification.
SessionPowerCleanup	Indicates the session's power cleanup.
SessionLockState	Indicates the session's lock state.
SystemHiberbootState	Indicates the system's hibernation boot state.
PlatformInformation	Indicates the platform information.
PdcInvocation	Indicates the pdc invocation.
MonitorInvocation	Indicates the monitor invocation.
FirmwareTableInformationRegistered	Indicates the registered firmware table information.
SetShutdownSelectedTime	Indicates that the shutdown time should be set.
SuspendResumeInvocation	Indicates SuspendResumeInvocation.
PlmPowerRequestCreate	Indicates that the power request has been created.
ScreenOff	Indicates that the screen is off.
CsDeviceNotification	Indicates the device notification.
PlatformRole	Indicates the platform role.
LastResumePerformance	Indicates the last time performance was resumed.
DisplayBurst	Indicates display burst.
ExitLatencySamplingPercentage	Indicates the latency sampling percentage.
RegisterSpmPowerSettings	Indicates that the power settings are registered.
PlatformIdleStates	Indicates the platform's idle states.
ProcessorIdleVeto	Indicates the processor's idle veto.
PlatformIdleVeto	Indicates the platform's idle veto.
SystemBatteryStatePrecise	Indicates the system's battery state.
ThermalEvent	Indicates the thermal event.

PowerRequestActionInternal	Indicates the internal power request action.
BatteryDeviceState	Indicates the battery's device state.
PowerInformationInternal	Indicates the internal power information.
ThermalStandby	Indicates thermal standby.
SystemHiberFileType	Indicates the system's hibernation file type.
PhysicalPowerButtonPress	Indicates a physical power button press.
QueryPotentialDripsConstraint	Indicates the potential drips constraint.
EnergyTrackerCreate	Indicates that the energy tracker is created.
EnergyTrackerQuery	Indicates that the energy tracker is queried.
UpdateBlackBoxRecorder	Indicates that the black box recorder is updated.
PowerInformationLevelMaximum	Indicates the maximum power level.

DEVICE_REGISTRY_PROPERTY Enumeration

1/25/2019 • 2 minutes to read • Edit Online

The **DEVICE_REGISTRY_PROPERTY** enumeration identifies device properties that are stored in the registry.

Syntax

```
typedef enum  {
  DevicePropertyDeviceDescription,
  DevicePropertyHardwareID,
  DevicePropertyCompatibleIDs,
  DevicePropertyBootConfiguration,
  DevicePropertyBootConfigurationTranslated,
  DevicePropertyClassName,
  DevicePropertyClassGuid,
  DevicePropertyDriverKeyName,
  DevicePropertyManufacturer,
  DevicePropertyFriendlyName,
  DevicePropertyLocationInformation,
  DevicePropertyPhysicalDeviceObjectName,
  DevicePropertyBusTypeGuid,
  DevicePropertyLegacyBusType,
  DevicePropertyBusNumber,
  DevicePropertyEnumeratorName,
  DevicePropertyAddress,
  DevicePropertyUINumber,
  DevicePropertyInstallState,
  DevicePropertyRemovalPolicy,
  DevicePropertyResourceRequirements,
  DevicePropertyAllocatedResources,
  DevicePropertyContainerID
} DEVICE_REGISTRY_PROPERTY;
```

Constants

DevicePropertyDeviceDescription	
DevicePropertyHardwareID	
DevicePropertyCompatibleIDs	
DevicePropertyBootConfiguration	
DevicePropertyBootConfigurationTranslated	
DevicePropertyClassName	
DevicePropertyClassGuid	
DevicePropertyDriverKeyName	
DevicePropertyManufacturer	

DevicePropertyFriendlyName	
DevicePropertyLocationInformation	
DevicePropertyPhysicalDeviceObjectName	
DevicePropertyBusTypeGuid	
DevicePropertyLegacyBusType	
DevicePropertyBusNumber	
DevicePropertyEnumeratorName	
DevicePropertyAddress	
DevicePropertyUINumber	
DevicePropertyInstallState	
DevicePropertyRemovalPolicy	
DevicePropertyResourceRequirements	
DevicePropertyAllocatedResources	
DevicePropertyContainerID

BOOTDISK_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **BOOTDISK_INFORMATION** structure contains basic information describing the boot and system disks.

Syntax

```
typedef struct _BOOTDISK_INFORMATION {
  LONGLONG BootPartitionOffset;
  LONGLONG SystemPartitionOffset;
  ULONG    BootDeviceSignature;
  ULONG    SystemDeviceSignature;
} BOOTDISK_INFORMATION, *PBOOTDISK_INFORMATION;
```

Members

`BootPartitionOffset`

Specifies the offset, in bytes, on the boot disk where the boot partition begins.

`SystemPartitionOffset`

Specifies the offset, in bytes, on the system disk where the system partition begins.

`BootDeviceSignature`

If the boot disk is formatted with an MBR partition table, this specifies the signature for the disk's MBR partition table. Otherwise, this member is unused.

`SystemDeviceSignature`

If the system disk is formatted with an MBR partition table, this specifies the signature for the disk's MBR partition table. Otherwise, this member is unused.

Remarks

IoGetBootDiskInformation returns this structure to describe the boot and system disks.

Requirements

Minimum supported client	Drivers on Microsoft Windows XP and later versions of the Windows operating system should use the BOOTDISK_INFORMATION_EX structure instead.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

BOOTDISK_INFORMATION_EX

IoGetBootDiskInformation

BOOTDISK_INFORMATION_EX structure

1/30/2019 • 2 minutes to read • Edit Online

The **BOOTDISK_INFORMATION_EX** structure contains extended information describing the boot and system disks.

Syntax

```
typedef struct _BOOTDISK_INFORMATION_EX {
  LONGLONG BootPartitionOffset;
  LONGLONG SystemPartitionOffset;
  ULONG    BootDeviceSignature;
  ULONG    SystemDeviceSignature;
  GUID     BootDeviceGuid;
  GUID     SystemDeviceGuid;
  BOOLEAN  BootDeviceIsGpt;
  BOOLEAN  SystemDeviceIsGpt;
} BOOTDISK_INFORMATION_EX, *PBOOTDISK_INFORMATION_EX;
```

Members

`BootPartitionOffset`

Specifies the offset, in bytes, on the boot disk where the boot partition begins.

`SystemPartitionOffset`

Specifies the offset, in bytes, on the system disk where the system partition begins.

`BootDeviceSignature`

If the **BootDeviceIsGpt** member is **FALSE**, this specifies the signature for the disk's MBR partition table. Otherwise, this member is unused.

`SystemDeviceSignature`

If the **SystemDeviceIsGpt** member is **FALSE**, this specifies the signature for the disk's MBR partition table. Otherwise, this member is unused.

`BootDeviceGuid`

If the **BootDeviceIsGpt** member is **TRUE**, this specifies the GUID for the boot disk. Otherwise, this member is unused.

`SystemDeviceGuid`

If the **SystemDeviceIsGpt** member is **TRUE**, this specifies the GUID for the boot disk. Otherwise, this member is unused.

`BootDeviceIsGpt`

TRUE if the boot disk is formatted with the GPT partition table type.

`SystemDeviceIsGpt`

TRUE if the system disk is formatted with the GPT partition table type.

Remarks

On Windows XP and later, IoGetBootDiskInformation returns this structure to describe the boot and system disks.

Requirements

BOUND_CALLBACK_STATUS Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **BOUND_CALLBACK_STATUS** enumeration indicates how a user-mode bounds exception was processed by the BoundCallback function.

Syntax

```
typedef enum _BOUND_CALLBACK_STATUS {
  BoundExceptionContinueSearch,
  BoundExceptionHandled,
  BoundExceptionError,
  BoundExceptionMaximum
} BOUND_CALLBACK_STATUS, *PBOUND_CALLBACK_STATUS;
```

Constants

BoundExceptionContinueSearch	The bounds exception was not handled by the callback, and the exception should continue to propagate.
BoundExceptionHandled	The exception was handled by the callback, and the exception should not propagate any further.
BoundExceptionError	The user mode process should be terminated by the system.
BoundExceptionMaximum	This value is not currently used.

Remarks

The return value of the BoundCallback routine is a **BOUND_CALLBACK_STATUS** value.

Requirements

Minimum supported client	Available starting with Windows 10.
Header	wdm.h

BoundCallback

BUS_INTERFACE_STANDARD structure

1/30/2019 • 2 minutes to read • Edit Online

The **BUS_INTERFACE_STANDARD** interface structure enables device drivers to make direct calls to parent bus driver routines. This structure defines the GUID_BUS_INTERFACE_STANDARD interface.

Syntax

```
typedef struct _BUS_INTERFACE_STANDARD {
  USHORT                 Size;
  USHORT                 Version;
  PVOID                  Context;
  PINTERFACE_REFERENCE   InterfaceReference;
  PINTERFACE_DEREFERENCE InterfaceDereference;
  PTRANSLATE_BUS_ADDRESS TranslateBusAddress;
  PGET_DMA_ADAPTER       GetDmaAdapter;
  PGET_SET_DEVICE_DATA   SetBusData;
  PGET_SET_DEVICE_DATA   GetBusData;
} BUS_INTERFACE_STANDARD, *PBUS_INTERFACE_STANDARD;
```

Members

`Size`

The size, in bytes, of this structure.

`Version`

The driver-defined interface version.

`Context`

A pointer to interface-specific context information.

`InterfaceReference`

A pointer to an InterfaceReference routine that increments the interface's reference count.

`InterfaceDereference`

A pointer to an InterfaceDereference routine that decrements the interface's reference count.

`TranslateBusAddress`

A pointer to a TranslateBusAddress routine that translates addresses on the parent bus to logical addresses.

`GetDmaAdapter`

A pointer to a GetDmaAdapter routine that returns a DMA adapter structure (DMA_ADAPTER) for the target device.

`SetBusData`

A pointer to a SetBusData routine that writes data to the device's configuration space.

`GetBusData`

A pointer to a GetBusData routine that reads data from the device's configuration space.

Remarks

The **BUS_INTERFACE_STANDARD** structure is an extension of the INTERFACE structure.

Some operations on a device are reserved for the device's parent bus driver. These operations might include accessing the device-specific configuration space of a bus or programming a DMA controller.

To read from or write to a device's configuration space, a device driver must rely on the agency of the bus driver in either of two ways:

- By sending the I/O request packets (IRPs) IRP_MN_READ_CONFIG and IRP_MN_WRITE_CONFIG to the bus driver.
- By obtaining an interface from the bus driver. The device driver can then access its device's configuration space by making direct calls to the bus driver routines provided by the **BUS_INTERFACE_STANDARD** interface structure. Its member routines, GetBusData and SetBusData, can be used to read from and write to a device's configuration space, respectively.

For more information about the ways to access configuration space, see Accessing Device Configuration Space.

Some types of devices, such as a bus-mastering storage device, have on-board DMA controllers. However, the device drivers for these devices cannot program these DMA controllers directly. Instead they must rely on routines provided by the parent bus driver. For a device driver to program the DMA controller for its device, it must first request an adapter object from the parent bus driver. The adapter object contains the routines supplied by the bus driver that can be used to program the device's DMA controller. Device drivers must rely on the **BUS_INTERFACE_STANDARD**, either directly or indirectly, to obtain the adapter object.

If the driver is executing at IRQL = PASSIVE_LEVEL, it should obtain a device's DMA adapter object by calling IoGetDmaAdapter. **IoGetDmaAdapter** detects whether the bus driver supports the **BUS_INTERFACE_STANDARD** interface. If it does, **IoGetDmaAdapter** calls the routine pointed to by the GetDmaAdapter member of this interface to obtain the adapter object. Otherwise, **IoGetDmaAdapter** calls an equivalent legacy routine.

However, if a driver must obtain an adapter object while running at IRQL >= DISPATCH_LEVEL, it cannot do so with IoGetDmaAdapter. In this case, the driver must query for the **BUS_INTERFACE_STANDARD** interface while still at IRQL = PASSIVE_LEVEL by using IRP_MN_QUERY_INTERFACE.

CLFS_CONTEXT_MODE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **CLFS_CONTEXT_MODE** enumeration indicates the type of sequence that the Common Log File System (CLFS) driver follows when it reads a set of records from a stream.

Syntax

```
typedef enum _CLFS_CONTEXT_MODE {
  ClfsContextNone,
  ClfsContextUndoNext,
  ClfsContextPrevious,
  ClfsContextForward
} CLFS_CONTEXT_MODE, *PCLFS_CONTEXT_MODE, PPCLFS_CONTEXT_MODE;
```

Constants

ClfsContextNone	Indicates that a variable of type **CLFS_CONTEXT_MODE** has not yet been assigned a meaningful value.
ClfsContextUndoNext	Indicates that the next record in the sequence is pointed to by the undo-next LSN of the current record.
ClfsContextPrevious	Indicates that the next record in the sequence is pointed to by the previous LSN of the current record.
ClfsContextForward	Indicates that the next record in the sequence is the record in the stream that immediately follows the current record.

CLFS_LOG_NAME_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **CLFS_LOG_NAME_INFORMATION** structure holds the name of a Common Log File System (CLFS) stream or log.

Syntax

```
typedef struct _CLFS_LOG_NAME_INFORMATION {
  USHORT NameLengthInBytes;
  WCHAR  Name[1];
} CLFS_LOG_NAME_INFORMATION, *PCLFS_LOG_NAME_INFORMATION, PPCLFS_LOG_NAME_INFORMATION;
```

Members

`NameLengthInBytes`

The size, in bytes, of the log name.

`Name`

An array of wide characters that holds the log name.

Requirements

Header	wdm.h (include Wdm.h)

ClfsSetLogFileInformation

CLFS_MGMT_CLIENT_REGISTRATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **CLFS_MGMT_CLIENT_REGISTRATION** structure is given to CLFS management by clients who manage their own logs.

Syntax

```
typedef struct _CLFS_MGMT_CLIENT_REGISTRATION {
  ULONG                                    Version;
  PCLFS_CLIENT_ADVANCE_TAIL_CALLBACK       AdvanceTailCallback;
  PVOID                                    AdvanceTailCallbackData;
  PCLFS_CLIENT_LFF_HANDLER_COMPLETE_CALLBACK LogGrowthCompleteCallback;
  PVOID                                    LogGrowthCompleteCallbackData;
  PCLFS_CLIENT_LOG_UNPINNED_CALLBACK       LogUnpinnedCallback;
  PVOID                                    LogUnpinnedCallbackData;
} CLFS_MGMT_CLIENT_REGISTRATION, *PCLFS_MGMT_CLIENT_REGISTRATION;
```

Members

`Version`

The version of the **CLFS_MGMT_CLIENT_REGISTRATION** structure. Set this to **CLFS_MGMT_CLIENT_REGISTRATION_VERSION**.

`AdvanceTailCallback`

A pointer to the log's ClfsAdvanceTailCallback function.

`AdvanceTailCallbackData`

A pointer to user-defined data that will be supplied to the *ClfsAdvanceTailCallback* function when the function is invoked.

`LogGrowthCompleteCallback`

A pointer to the log's ClfsLogGrowthCompleteCallback function.

`LogGrowthCompleteCallbackData`

A pointer to user-defined data that will be supplied to the *ClfsLogGrowthCompleteCallback* function when the function is invoked.

`LogUnpinnedCallback`

A pointer to the log's ClfsLogUnpinnedCallback function.

`LogUnpinnedCallbackData`

A pointer to user-defined data that will be supplied to the *ClfsLogUnpinnedCallback* function when the function is invoked.

Requirements

Header	wdm.h (include Wdm.h)

CLFS_MGMT_POLICY structure

1/30/2019 • 3 minutes to read • Edit Online

The **CLFS_MGMT_POLICY** structure holds a description of a policy for managing a CLFS log.

Syntax

```
typedef struct _CLFS_MGMT_POLICY {
  ULONG                 Version;
  ULONG                 LengthInBytes;
  ULONG                 PolicyFlags;
  CLFS_MGMT_POLICY_TYPE PolicyType;
  union {
    struct {
      ULONG Containers;
    } MaximumSize;
    struct {
      ULONG Containers;
    } MinimumSize;
    struct {
      ULONG SizeInBytes;
    } NewContainerSize;
    struct {
      ULONG AbsoluteGrowthInContainers;
      ULONG RelativeGrowthPercentage;
    } GrowthRate;
    struct {
      ULONG MinimumAvailablePercentage;
      ULONG MinimumAvailableContainers;
    } LogTail;
    struct {
      ULONG Percentage;
    } AutoShrink;
    struct {
      ULONG Enabled;
    } AutoGrow;
    struct {
      USHORT PrefixLengthInBytes;
      WCHAR  PrefixString[1];
    } NewContainerPrefix;
    struct {
      ULONGLONG NextContainerSuffix;
    } NewContainerSuffix;
    struct {
      USHORT ExtensionLengthInBytes;
      WCHAR  ExtensionString[1];
    } NewContainerExtension;
  } PolicyParameters;
} CLFS_MGMT_POLICY, *PCLFS_MGMT_POLICY;
```

Members

`Version`

The version of the **CLFS_MGMT_POLICY** structure. Set this to **CLFS_MGMT_POLICY_VERSION**.

`LengthInBytes`

The length of the **CLFS_MGMT_POLICY** structure.

`PolicyFlags`

The flags that apply to this instance of the **CLFS_MGMT_POLICY** structure. The only flag that has been implemented for this release is **LOG_POLICY_OVERWRITE**, which indicates that when the policy is installed, it will replace the policy of the same type, if such a policy already exists.

`PolicyType`

A value of the CLFS_MGMT_POLICY_TYPE enumeration that supplies the type of this instance of the **CLFS_MGMT_POLICY** structure.

`PolicyParameters`

The union that provides the detailed information about this instance of the **CLFS_MGMT_POLICY** structure.

`PolicyParameters.MaximumSize`

`PolicyParameters.MaximumSize.Containers`

The maximum number of containers that the log will use.

`PolicyParameters.MinimumSize`

`PolicyParameters.MinimumSize.Containers`

The minimum number of containers that the log will use.

`PolicyParameters.NewContainerSize`

`PolicyParameters.NewContainerSize.SizeInBytes`

The size of each of the log's containers.

`PolicyParameters.GrowthRate`

`PolicyParameters.GrowthRate.AbsoluteGrowthInContainers`

The number of containers that should be added when the size of the log is increased. If the **RelativeGrowthPercentage** member is nonzero, then **AbsoluteGrowthInContainers** must be zero.

`PolicyParameters.GrowthRate.RelativeGrowthPercentage`

The percentage by which the log's size should increase when the log grows, expressed as a number between zero and 100. For example, if the log consisted of 32 containers and **RelativeGrowthPercentage** was ten, then, when the log needed to grow, it would grow by three (32 * 10 percent, rounded down to the nearest integer) containers. If the **AbsoluteGrowthInContainers** member is nonzero, then **RelativeGrowthPercentage** must be zero.

`PolicyParameters.LogTail`

`PolicyParameters.LogTail.MinimumAvailablePercentage`

When CLFS management notifies the client to move its log tail, it will specify that the tail be moved to an LSN that leaves at least **MinimumAvailablePercentage** percent of the log free. If the **MinimumAvailableContainers** member is nonzero, then **MinimumAvailablePercentage** must be zero.

`PolicyParameters.LogTail.MinimumAvailableContainers`

When CLFS management notifies the client to move its log tail, it will specify that the tail be moved to an LSN that leaves at least **MinimumAvailableContainers** containers free. If the **MinimumAvailablePercentage** member is nonzero, then **MinimumAvailableContainers** must be zero.

`PolicyParameters.AutoShrink`

`PolicyParameters.AutoShrink.Percentage`

When the percentage of free space in the log reaches **Percentage**, the log will shrink. Percentage is expressed as a number between 0 and 100, so a value of 25 would mean 25 percent.

`PolicyParameters.AutoGrow`

`PolicyParameters.AutoGrow.Enabled`

A numeric value that determines whether automatic log growth is enabled. Any nonzero value enables automatic growth.

`PolicyParameters.NewContainerPrefix`

`PolicyParameters.NewContainerPrefix.PrefixLengthInBytes`

The length, in bytes, of the **PrefixString** member.

`PolicyParameters.NewContainerPrefix.PrefixString`

A wide-character string that contains the full path to the directory where the log's containers reside, as well as a prefix that will be used as part of the file name for each container in the log.

`PolicyParameters.NewContainerSuffix`

`PolicyParameters.NewContainerSuffix.NextContainerSuffix`

The number to use as the suffix of the file name for the next container in the log. To form the file name, the number is converted to a string of decimal digits and appended to the prefix string. The number is incremented for the file name of each subsequent container.

`PolicyParameters.NewContainerExtension`

`PolicyParameters.NewContainerExtension.ExtensionLengthInBytes`

The length, in bytes, of the **ExtensionString** member.

`PolicyParameters.NewContainerExtension.ExtensionString`

A wide-character string that contains the extension to the file name for each container in the log. Container file names are built using the format [prefix][suffix][.extension]. An extension is optional. The default extension is the empty string.

Remarks

The way a **CLFS_MGMT_POLICY** structure is interpreted depends on the type of policy that the structure holds.

You can provide *policies* that specify how the log will be managed. Each policy is an instance of the **CLFS_MGMT_POLICY** structure, but the structure is interpreted differently depending on the policy type. CLFS uses the information that you provided in the policies to tailor how it manages the log.

When you create a **CLFS_MGMT_POLICY** structure whose **PolicyType** is **ClfsMgmtPolicyNewContainerPrefix**, be sure to allocate enough space to hold the **PolicyParameters.NewContainerPrefix.PrefixString** string.

You can only install a policy whose policy type specified in the **PolicyType** value is **ClfsMgmtPolicyNewContainerSize** before there are any containers in the log. You can change other policies after the log exists.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

CLFS_MGMT_POLICY_TYPE

ClfsMgmtInstallPolicy

ClfsMgmtQueryPolicy

ClfsMgmtRemovePolicy

CLFS_MGMT_POLICY_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **CLFS_MGMT_POLICY_TYPE** enumeration type identifies the type of a CLFS management policy.

Syntax

```
typedef enum _CLFS_MGMT_POLICY_TYPE {
  ClfsMgmtPolicyMaximumSize,
  ClfsMgmtPolicyMinimumSize,
  ClfsMgmtPolicyNewContainerSize,
  ClfsMgmtPolicyGrowthRate,
  ClfsMgmtPolicyLogTail,
  ClfsMgmtPolicyAutoShrink,
  ClfsMgmtPolicyAutoGrow,
  ClfsMgmtPolicyNewContainerPrefix,
  ClfsMgmtPolicyNewContainerSuffix,
  ClfsMgmtPolicyNewContainerExtension,
  ClfsMgmtPolicyInvalid
} CLFS_MGMT_POLICY_TYPE, *PCLFS_MGMT_POLICY_TYPE;
```

Constants

ClfsMgmtPolicyMaximumSize	Indicates a policy that specifies the maximum size of a log.
ClfsMgmtPolicyMinimumSize	Indicates a policy that specifies the minimum size of a log.
ClfsMgmtPolicyNewContainerSize	Indicates a policy that specifies the size of new containers that are created.
ClfsMgmtPolicyGrowthRate	Indicates a policy that specifies how many new containers will be added to the log each time the log grows.
ClfsMgmtPolicyLogTail	Indicates a policy that specifies how much free space will be requested when a client is notified to move its log tail.
ClfsMgmtPolicyAutoShrink	Indicates a policy that specifies when the log will shrink based on the percentage of the log that is free.
ClfsMgmtPolicyAutoGrow	Indicates a policy that specifies whether the log should grow when fewer than two containers are free.
ClfsMgmtPolicyNewContainerPrefix	Indicates a policy that specifies a prefix for the file name of each container, as well as the full path to the directory where the containers will be placed.
ClfsMgmtPolicyNewContainerSuffix	Indicates a policy that specifies a number to use as the starting suffix for container file names.
ClfsMgmtPolicyNewContainerExtension	Indicates a policy that specifies an extension for the file name of each container.

ClfsMgmtPolicyInvalid	Reserved for internal use.

Remarks

Each type of CLFS management policy corresponds to a specific interpretation of the CLFS_MGMT_POLICY structure. The **PolicyType** member of the **CLFS_MGMT_POLICY** structure is a valid value of the **CLFS_MGMT_POLICY_TYPE** enumeration.

Requirements

Header	wdm.h (include Wdm.h)

CLFS_MGMT_POLICY

CLFS_STREAM_ID_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **CLFS_STREAM_ID_INFORMATION** structure holds a value that identifies a stream in a Common Log File System (CLFS) log.

Syntax

```
typedef struct _CLFS_STREAM_ID_INFORMATION {
  UCHAR StreamIdentifier;
} CLFS_STREAM_ID_INFORMATION, *PCLFS_STREAM_ID_INFORMATION, PPCLFS_STREAM_ID_INFORMATION;
```

Members

`StreamIdentifier`

An 8-bit value that identifies a stream.

Remarks

A stream identifier is unique within a given CLFS log.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ClfsQueryLogFileInformation

CLS_CONTAINER_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **CLFS_CONTAINER_INFORMATION** structure holds descriptive information for an individual container in a Common Log File System (CLFS) log.

Syntax

```
typedef struct _CLS_CONTAINER_INFORMATION {
  ULONG                FileAttributes;
  ULONGLONG            CreationTime;
  ULONGLONG            LastAccessTime;
  ULONGLONG            LastWriteTime;
  LONGLONG             ContainerSize;
  ULONG                FileNameActualLength;
  ULONG                FileNameLength;
  WCHAR                FileName[CLFS_MAX_CONTAINER_INFO];
  CLFS_CONTAINER_STATE State;
  CLFS_CONTAINER_ID    PhysicalContainerId;
  CLFS_CONTAINER_ID    LogicalContainerId;
} CLS_CONTAINER_INFORMATION, *PCLS_CONTAINER_INFORMATION, PPCLS_CONTAINER_INFORMATION;
```

Members

`FileAttributes`

A set of flags that specifies attributes of the container. See the *fFlagsAndAttributes* parameter of the ClfsCreateLogFile function.

`CreationTime`

The time that the container was created.

`LastAccessTime`

The time that the container was last accessed.

`LastWriteTime`

The time of the last write to the container.

`ContainerSize`

The size, in bytes, of the container.

`FileNameActualLength`

The size, in characters, of the actual file name of the container.

`FileNameLength`

The size of the file name in the **FileName** buffer.

`FileName`

An array of wide characters that holds the file name of the container.

`State`

An integer that specifies the state of the container. This member must be one of the following values.

VALUE	MEANING
ClfsContainerInitializing	The container has not yet been initialized.
ClfsContainerInactive	The container has been initialized but does not hold any records that are in the active portion of the log.
ClfsContainerActive	The container is being used to hold records that belong to the active portion of the log.
ClfsContainerActivePendingDelete	The container is marked for deletion, but still holds records that belong to the active portion of the log.
ClfsContainerPendingArchive	The container is pending archival.
ClfsContainerPendingArchiveAndDelete	The container is marked for deletion, but still contains records that are pending archival.

`PhysicalContainerId`

A 32-bit identifier that remains the same over the life of the log.

`LogicalContainerId`

A 32-bit identifier that changes every time the container is recycled.

Remarks

The ClfsScanLogContainers function writes descriptive information into an array of **CLFS_CONTAINER_INFORMATION** structures.

Time values **CreationTime**, **LastAccessTime**, and **LastWriteTime** are expressed in absolute system time format. Absolute system time is the number of 100-nanosecond intervals since the start of the year 1601 in the Gregorian calendar.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

CLFS_SCAN_CONTEXT

ClfsCreateLogFile

ClfsCreateScanContext

ClfsScanLogContainers

CLS_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **CLFS_INFORMATION** structure holds metadata and state information for a Common Log File System (CLFS) stream and/or its underlying physical log.

Syntax

```
typedef struct _CLS_INFORMATION {
  LONGLONG  TotalAvailable;
  LONGLONG  CurrentAvailable;
  LONGLONG  TotalReservation;
  ULONGLONG BaseFileSize;
  ULONGLONG ContainerSize;
  ULONG     TotalContainers;
  ULONG     FreeContainers;
  ULONG     TotalClients;
  ULONG     Attributes;
  ULONG     FlushThreshold;
  ULONG     SectorSize;
  CLS_LSN   MinArchiveTailLsn;
  CLS_LSN   BaseLsn;
  CLS_LSN   LastFlushedLsn;
  CLS_LSN   LastLsn;
  CLS_LSN   RestartLsn;
  GUID      Identity;
} CLS_INFORMATION, *PCLS_INFORMATION, *PPCLS_INFORMATION;
```

Members

`TotalAvailable`

The total available space allocated to the log. This is calculated as the sum of the sizes of all containers in the log.

`CurrentAvailable`

The amount of space available in the log for new records and reservation allocations. This space is the total available space minus the undo commitment space and space used for storing owner pages in a multiplexed log.

`TotalReservation`

The amount of space reserved in the stream (or physical log) for undo operations.

`BaseFileSize`

The size, in bytes, of the base log file.

`ContainerSize`

The size, in bytes, of an individual container in the log. Note that all containers in the log are the same size.

`TotalContainers`

The number of containers in the log.

`FreeContainers`

The number of containers in the log that are not active.

`TotalClients`

The number of streams that share the log.

`Attributes`

A set of flags that specify stream (or physical log) attributes. See the *fFlagsAndAttributes* parameter of the ClfsCreateLogFile function.

`FlushThreshold`

The number of bytes of data (including headers) that are allowed to remain pending on the internal flush queue before CLFS automatically schedules a thread to write the flush queue to stable storage.

`SectorSize`

The sector size, in bytes, of the underlying disk geometry. The sector size is assumed to be a multiple of 512 and consistent across containers.

`MinArchiveTailLsn`

The LSN of the oldest record in the log for which archiving has not taken place. The minimum of this and the base LSN determines the last container that can be reused when containers are recycled.

`BaseLsn`

The LSN of the oldest record in the stream (or physical log) that is still needed by the stream (or log) clients.

`LastFlushedLsn`

The LSN of the last record that was flushed to stable storage.

`LastLsn`

The LSN of the youngest record in the stream (or physical log) that is still needed by the stream (or log) clients.

`RestartLsn`

The LSN of the last restart record written to the stream (or physical log). If there are no restart records, this member is equal to CLFS_LSN_INVALID.

`Identity`

A GUID that serves as a unique identifier for the log.

Remarks

The ClfsQueryLogFileInformation function returns information about a CLFS stream and/or its underlying physical log. The type of information returned depends on the *eInformationClass* parameter.

If the *eInformationClass* parameter is equal to **ClfsLogBasicInformationPhysical**, **ClfsQueryLogFileInformation** returns information in a **CLFS_INFORMATION** structure, and every structure member holds a piece of information about a physical CLFS log. Even if the log is multiplexed (that is, it has several streams), all structure members hold information about the underlying physical log rather than information about one of the streams.

If *eInformationClass* parameter is equal to **ClfsLogBasicInformation**, **ClfsQueryLogFileInformation** returns information in a **CLFS_INFORMATION** structure. Most of the structure members hold information about a CLFS physical log, but if the log is multiplexed, certain members hold information that is specific to a particular stream.

The following structure members hold information that is specific to a stream rather than the underlying physical log:

- **TotalUndoCommitment**
- **Attributes**
- **BaseLsn**
- **LastLsn**
- **RestartLsn**

CLS_IO_STATISTICS structure

1/30/2019 • 2 minutes to read • Edit Online

The **CLFS_IO_STATISTICS** structure holds I/O statistics data for a Common Log File System (CLFS) log.

Syntax

```
typedef struct _CLS_IO_STATISTICS {
  CLS_IO_STATISTICS_HEADER hdrIoStats;
  ULONGLONG                cFlush;
  ULONGLONG                cbFlush;
  ULONGLONG                cMetaFlush;
  ULONGLONG                cbMetaFlush;
} CLS_IO_STATISTICS, *PCLS_IO_STATISTICS, PPCLS_IO_STATISTICS;
```

Members

`hdrIoStats`

A CLFS_IO_STATISTICS_HEADER structure that holds header information for the set of statistics.

`cFlush`

The number of data flushes.

`cbFlush`

The number of bytes of data flushed.

`cMetaFlush`

The number of metadata flushes.

`cbMetaFlush`

The number of bytes of metadata flushed.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntddk.h)

CLFS_IO_STATISTICS_HEADER

ClfsGetIoStatistics

CLS_IO_STATISTICS_HEADER structure

1/30/2019 • 2 minutes to read • Edit Online

The **CLFS_IO_STATISTICS_HEADER** structure holds the header portion of a CLFS_IO_STATISTICS structure.

Syntax

```
typedef struct _CLS_IO_STATISTICS_HEADER {
  UCHAR              ubMajorVersion;
  UCHAR              ubMinorVersion;
  CLFS_IOSTATS_CLASS eStatsClass;
  USHORT             cbLength;
  ULONG              coffData;
} CLS_IO_STATISTICS_HEADER, *PCLS_IO_STATISTICS_HEADER, PPCLS_IO_STATISTICS_HEADER;
```

Members

`ubMajorVersion`

The major version of the CLFS_IO_STATISTICS structure.

`ubMinorVersion`

The minor version of the **CLFS_IO_STATISTICS** structure.

`eStatsClass`

Reserved for future use. This member is ignored.

`cbLength`

The size, in bytes, of the **CLFS_IO_STATISTICS** structure, including the header.

`coffData`

The offset, in bytes, from the beginning of the **CLFS_IO_STATISTICS** structure to the beginning of the statistics data. This member allows for transparent modifications to the header.

Requirements

CLS_LOG_INFORMATION_CLASS Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **CLFS_LOG_INFORMATION_CLASS** enumeration indicates the type of information that is requested by a call to ClfsQueryLogFileInformation.

Syntax

```
typedef enum _CLS_LOG_INFORMATION_CLASS {
  ClfsLogBasicInformation,
  ClfsLogBasicInformationPhysical,
  ClfsLogPhysicalNameInformation,
  ClfsLogStreamIdentifierInformation,
  ClfsLogSystemMarkingInformation,
  ClfsLogPhysicalLsnInformation
} CLS_LOG_INFORMATION_CLASS, *PCLS_LOG_INFORMATION_CLASS, PPCLS_LOG_INFORMATION_CLASS;
```

Constants

ClfsLogBasicInformation	Indicates that the request is for basic information about a CLFS stream and its underlying physical log. The information is returned in a CLFS_INFORMATION structure. Most of the structure members contain information about the underlying physical log, but some members contain information that is specific to the stream.
ClfsLogBasicInformationPhysical	Indicates that the request is for basic information about the physical log that underlies a CLFS stream. The information is returned in a **CLFS_INFORMATION** structure. All of the structure members contain information about the underlying physical log.
ClfsLogPhysicalNameInformation	Indicates that the request is for information about the name of a physical CLFS log. The information is returned in a **CLFS_LOG_NAME_INFORMATION** structure.
ClfsLogStreamIdentifierInformation	Indicates that the request is for a CLFS stream identifier. The information is returned in a CLFS_STREAM_ID_INFORMATION structure.
ClfsLogSystemMarkingInformation	Count of system marking references. This enumeration constant is supported only in Windows Vista and later versions of Windows.
ClfsLogPhysicalLsnInformation	Maps virtual LSNs to physical LSNs; only valid for physical logs. This enumeration constant is supported only in Windows Vista and later versions of Windows.

Remarks

The *eInformationClass* parameter of the ClfsQueryLogFileInformation function is a value from the **CLFS_LOG_INFORMATION_CLASS** enumeration.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ClfsQueryLogFileInformation

CLS_LSN structure

1/30/2019 • 2 minutes to read • Edit Online

The **CLFS_LSN** structure identifies an individual record in a Common Log File System (CLFS) stream.

Syntax

```
typedef struct _CLS_LSN {
  ULONGLONG Internal;
} CLS_LSN, *PCLS_LSN, PPCLS_LSN;
```

Members

`Internal`

A 64-bit value that holds three pieces of information about a log record: container identifier, block offset, and record sequence number.

Remarks

A container is a contiguous physical disk extent that serves as part of a CLFS log. A given CLFS log has several containers. Each container has several sector-aligned blocks, each of which holds a numbered sequence of records. A record can be identified by the triple (logical container identifier, block offset, record sequence number).

To obtain the container identifier, block offset, and record sequence number from a **CLFS_LSN** structure, call ClfsLsnContainer, ClfsLsnBlockOffset, and ClfsLsnRecordSequence.

Requirements

Header	wdm.h (include Wdm.h)

CLS_SCAN_CONTEXT structure

1/30/2019 • 2 minutes to read • Edit Online

The **CLFS_SCAN_CONTEXT** structure holds context information to support a scan of the containers in a Common Log File System (CLFS) log. The client allocates this structure by calling ClfsCreateScanContext. Then, the client passes the structure repeatedly to ClfsScanLogContainers.

Syntax

```
typedef struct _CLS_SCAN_CONTEXT {
  CLFS_NODE_ID               cidNode;
  PLOG_FILE_OBJECT           plfoLog;
  ULONG                      cIndex;
  ULONG                      cContainers;
  ULONG                      cContainersReturned;
  CLFS_SCAN_MODE             eScanMode;
  PCLS_CONTAINER_INFORMATION pinfoContainer;
} CLS_SCAN_CONTEXT, *PCLS_SCAN_CONTEXT, PPCLS_SCAN_CONTEXT;
```

Members

`cidNode`

A CLFS_NODE_ID structure that contains the scan context's node identity and type.

`plfoLog`

A pointer to a LOG_FILE_OBJECT structure that represents a CLFS log.

`cIndex`

The index of the current container.

`cContainers`

The number of containers to scan in each call to **ClfsScanLogContainers**. This is the number of elements in the array pointed to by *pinfoContainer*.

`cContainersReturned`

The number of containers actually scanned in a call to **ClfsScanLogContainers**.

`eScanMode`

This member can be one of the following values.

VALUE	MEANING
CLFS_SCAN_INIT	The scan is reinitialized and begins at the first container in the container list.
CLFS_SCAN_FORWARD	The next set of containers is scanned.
CLFS_SCAN_BACKWARD	The previous set of containers is scanned.

CLFS_SCAN_CLOSE	The scan is closed. No containers are scanned.

`pinfoContainer`

A pointer to an array of CLFS_CONTAINER_INFORMATION structures. The *cContainers* parameter specifies the number of elements in this array.

Requirements

Header	wdm.h (include Wdm.h)

CLS_WRITE_ENTRY structure

1/30/2019 • 2 minutes to read • Edit Online

The **CLFS_WRITE_ENTRY** structure holds the address and size of a buffer that contains one unit of data to be written to a Common Log File System (CLFS) stream.

Syntax

```
typedef struct _CLS_WRITE_ENTRY {
  PVOID Buffer;
  ULONG ByteLength;
} CLS_WRITE_ENTRY, *PCLS_WRITE_ENTRY, PPCLS_WRITE_ENTRY;
```

Members

`Buffer`

A pointer to the buffer that holds the data.

`ByteLength`

The size, in bytes, of the buffer pointed to by **Buffer**.

Remarks

CLFS collects the buffers pointed to by several **CLFS_WRITE_ENTRY** structures into a single log record. The log record is then placed in a log I/O block along with other log records. Eventually the log I/O block is flushed to disk.

Requirements

Header	wdm.h (include Wdm.h)

CM_EISA_FUNCTION_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **CM_EISA_FUNCTION_INFORMATION** structure defines detailed EISA configuration information returned by HalGetBusData for the input *BusDataType***EisaConfiguration**, or by **HalGetBusDataByOffset** for the input *BusDataType***EisaConfiguration** and the *Offset* zero, assuming the caller-allocated *Buffer* is of sufficient *Length*.

Syntax

```
typedef struct _CM_EISA_FUNCTION_INFORMATION {
  ULONG                     CompressedId;
  UCHAR                     IdSlotFlags1;
  UCHAR                     IdSlotFlags2;
  UCHAR                     MinorRevision;
  UCHAR                     MajorRevision;
  UCHAR                     Selections[26];
  UCHAR                     FunctionFlags;
  UCHAR                     TypeString[80];
  EISA_MEMORY_CONFIGURATION EisaMemory[9];
  EISA_IRQ_CONFIGURATION    EisaIrq[7];
  EISA_DMA_CONFIGURATION    EisaDma[4];
  EISA_PORT_CONFIGURATION   EisaPort[20];
  UCHAR                     InitializationData[60];
} CM_EISA_FUNCTION_INFORMATION, *PCM_EISA_FUNCTION_INFORMATION;
```

Members

`CompressedId`

The EISA compressed identification of the device at this slot. The value is identical to the **CompressedId** member of the CM_EISA_SLOT_INFORMATION structure.

`IdSlotFlags1`

The EISA slot identification flags.

`IdSlotFlags2`

The EISA slot identification flags.

`MinorRevision`

Information supplied by the manufacturer.

`MajorRevision`

Information supplied by the manufacturer.

`Selections`

The EISA selections for the device.

`FunctionFlags`

Indicates which of the members has available information. Callers can use the following system-defined masks to determine whether a particular type of configuration information can be or has been returned by **HalGetBusData**

or HalGetBusDataByOffset:

EISA_FUNCTION_ENABLED

EISA_FREE_FORM_DATA

EISA_HAS_PORT_INIT_ENTRY

EISA_HAS_PORT_RANGE

EISA_HAS_DMA_ENTRY

EISA_HAS_IRQ_ENTRY

EISA_HAS_MEMORY_ENTRY

EISA_HAS_TYPE_ENTRY

EISA_HAS_INFORMATION

The EISA_HAS_INFORMATION mask is a combination of the following:

EISA_HAS_PORT_RANGE

EISA_HAS_DMA_ENTRY

EISA_HAS_IRQ_ENTRY

EISA_HAS_MEMORY_ENTRY

EISA_HAS_TYPE_ENTRY

`TypeString`

Specifies the type of device.

`EisaMemory`

Describes the EISA device memory configuration information, defined as follows:

```
typedef struct _EISA_MEMORY_CONFIGURATION {
    EISA_MEMORY_TYPE ConfigurationByte;
    UCHAR DataSize;
    USHORT AddressLowWord;
    UCHAR AddressHighByte;
    USHORT MemorySize;
} EISA_MEMORY_CONFIGURATION, *PEISA_MEMORY_CONFIGURATION;
```

`EisaIrq`

Describes the EISA interrupt configuration information, defined as follows:

```
typedef struct _EISA_IRQ_CONFIGURATION {
    EISA_IRQ_DESCRIPTOR ConfigurationByte;
    UCHAR Reserved;
} EISA_IRQ_CONFIGURATION, *PEISA_IRQ_CONFIGURATION;
```

`EisaDma`

Describes the EISA DMA configuration information, defined as follows:

```
typedef struct _EISA_DMA_CONFIGURATION {
    DMA_CONFIGURATION_BYTE0 ConfigurationByte0;
    DMA_CONFIGURATION_BYTE1 ConfigurationByte1;
} EISA_DMA_CONFIGURATION, *PEISA_DMA_CONFIGURATION;
```

`EisaPort`

Describes the EISA device port configuration information, defined as follows:

```
typedef struct _EISA_PORT_CONFIGURATION {
    EISA_PORT_DESCRIPTOR Configuration;
    USHORT PortAddress;
} EISA_PORT_CONFIGURATION, *PEISA_PORT_CONFIGURATION;
```

`InitializationData`

Vendor-supplied, device-specific initialization data, if any.

Remarks

The information returned by **HalGetBusData** or **HalGetBusDataByOffset** in **CM_EISA_FUNCTION_INFORMATION** and/or in the CM_EISA_SLOT_INFORMATION header immediately preceding it is read-only.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

See Also

CM_EISA_SLOT_INFORMATION

HalGetBusData

HalGetBusDataByOffset

CM_EISA_SLOT_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **CM_EISA_SLOT_INFORMATION** structure defines EISA configuration header information returned by HalGetBusData for the input *BusDataType* = **EisaConfiguration**, or by HalGetBusDataByOffset for the inputs *BusDataType* = **EisaConfiguration** and *Offset* = 0, assuming the caller-allocated *Buffer* is of sufficient *Length*.

Syntax

```
typedef struct _CM_EISA_SLOT_INFORMATION {
  UCHAR  ReturnCode;
  UCHAR  ReturnFlags;
  UCHAR  MajorRevision;
  UCHAR  MinorRevision;
  USHORT Checksum;
  UCHAR  NumberFunctions;
  UCHAR  FunctionInformation;
  ULONG  CompressedId;
} CM_EISA_SLOT_INFORMATION, *PCM_EISA_SLOT_INFORMATION;
```

Members

`ReturnCode`

Contains a status code if an error occurs when the EISA BIOS is queried. Possible status codes include the following:

- EISA_INVALID_SLOT
- EISA_INVALID_FUNCTION
- EISA_INVALID_CONFIGURATION
- EISA_EMPTY_SLOT
- EISA_INVALID_BIOS_CALL

`ReturnFlags`

The return flags.

`MajorRevision`

Information supplied by the manufacturer.

`MinorRevision`

Information supplied by the manufacturer.

`Checksum`

The checksum value, allowing validation of the configuration data.

`NumberFunctions`

The number at this slot.

`FunctionInformation`

Whether there is available CM_EISA_FUNCTION_INFORMATION for this slot.

`CompressedId`

The EISA compressed identification of the device at this slot. This value is identical to the **CompressedId** member of the **CM_EISA_FUNCTION_INFORMATION** structure. This member can be read to determine whether the caller should call **HalGetBusData** or **HalGetBusDataByOffset** again with sufficient buffer space to get more detailed **CM_EISA_FUNCTION_INFORMATION** for a device it supports.

Remarks

The information returned by **HalGetBusData** or **HalGetBusDataByOffset** in **CM_EISA_SLOT_INFORMATION** and in **CM_EISA_FUNCTION_INFORMATION** immediately following it is read-only.

The driver of an EISA device might call **HalGetBusData** or **HalGetBusDataByOffset** for each slot on each EISA bus in the system, requesting only **CM_EISA_SLOT_INFORMATION** in order to find the device(s) it supports by examining the returned **CompressedId** values. Then, such a driver could allocate sufficient buffer space to call **HalGetBusData(ByOffset)** again for **CM_EISA_SLOT_INFORMATION** and **CM_EISA_FUNCTION_INFORMATION** at slots where its device(s) can be found.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

CM_FLOPPY_DEVICE_DATA structure

1/30/2019 • 2 minutes to read • Edit Online

The **CM_FLOPPY_DEVICE_DATA** structure defines a device-type-specific data record that is stored in the \Registry\Machine\Hardware\Description tree for a floppy controller if the system can collect this information during the boot process.

Syntax

```
typedef struct _CM_FLOPPY_DEVICE_DATA {
  USHORT Version;
  USHORT Revision;
  CHAR   Size[8];
  ULONG  MaxDensity;
  ULONG  MountDensity;
  UCHAR  StepRateHeadUnloadTime;
  UCHAR  HeadLoadTime;
  UCHAR  MotorOffTime;
  UCHAR  SectorLengthCode;
  UCHAR  SectorPerTrack;
  UCHAR  ReadWriteGapLength;
  UCHAR  DataTransferLength;
  UCHAR  FormatGapLength;
  UCHAR  FormatFillCharacter;
  UCHAR  HeadSettleTime;
  UCHAR  MotorSettleTime;
  UCHAR  MaximumTrackValue;
  UCHAR  DataTransferRate;
} CM_FLOPPY_DEVICE_DATA, *PCM_FLOPPY_DEVICE_DATA;
```

Members

`Version`

The version number of this structure.

`Revision`

The revision of this structure.

`Size`

The floppy disk density size.

`MaxDensity`

The maximum density.

`MountDensity`

The mount density.

`StepRateHeadUnloadTime`

The step rate head unload time in milliseconds.

`HeadLoadTime`

The head load time in milliseconds.

`MotorOffTime`

The motor off time in seconds.

`SectorLengthCode`

Indicates the sector size as an exponent in the formula ((2**_code_) * 128).

`SectorPerTrack`

The number of sectors per track.

`ReadWriteGapLength`

The read/write gap length, in bytes.

`DataTransferLength`

The data transfer length, in bytes, not including the synchronization field.

`FormatGapLength`

The format gap length, in bytes.

`FormatFillCharacter`

The format fill character.

`HeadSettleTime`

The head settle time in milliseconds.

`MotorSettleTime`

The motor settle time in milliseconds.

`MaximumTrackValue`

The maximum track number on the media. Track numbers are zero-based values.

`DataTransferRate`

The value written to the Datarate register before accessing the media.

CM_FULL_RESOURCE_DESCRIPTOR structure

1/30/2019 • 2 minutes to read • Edit Online

The **CM_FULL_RESOURCE_DESCRIPTOR** structure specifies a set of system hardware resources of various types, assigned to a device that is connected to a specific bus. This structure is contained within a CM_RESOURCE_LIST structure.

Syntax

```
typedef struct _CM_FULL_RESOURCE_DESCRIPTOR {
  INTERFACE_TYPE           InterfaceType;
  ULONG                    BusNumber;
  CM_PARTIAL_RESOURCE_LIST PartialResourceList;
} CM_FULL_RESOURCE_DESCRIPTOR, *PCM_FULL_RESOURCE_DESCRIPTOR;
```

Members

`InterfaceType`

Specifies the type of bus to which the device is connected. This must be one of the types defined by INTERFACE_TYPE, in Wdm.h or Ntddk.h. (Not used by WDM drivers.)

`BusNumber`

The system-assigned, driver-supplied, zero-based number of the bus to which the device is connected. (Not used by WDM drivers.)

`PartialResourceList`

A CM_PARTIAL_RESOURCE_LIST structure.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)

CM_INT13_DRIVE_PARAMETER structure

1/30/2019 • 2 minutes to read • Edit Online

The **CM_INT13_DRIVE_PARAMETER** structure defines a device-type-specific data record that is stored in the \Registry\Machine\Hardware\Description tree for a disk controller if the system can collect this information during the boot process.

Syntax

```
typedef struct _CM_INT13_DRIVE_PARAMETER {
  USHORT DriveSelect;
  ULONG  MaxCylinders;
  USHORT SectorsPerTrack;
  USHORT MaxHeads;
  USHORT NumberDrives;
} CM_INT13_DRIVE_PARAMETER, *PCM_INT13_DRIVE_PARAMETER;
```

Members

`DriveSelect`

The drive selected value.

`MaxCylinders`

The maximum number of cylinders.

`SectorsPerTrack`

The number of sectors per track.

`MaxHeads`

The maximum number of heads.

`NumberDrives`

The number of drives.

CM_KEYBOARD_DEVICE_DATA structure

1/30/2019 • 2 minutes to read • Edit Online

The **CM_KEYBOARD_DEVICE_DATA** structure defines a device-type-specific data record that is stored in the \Registry\Machine\Hardware\Description tree for a keyboard peripheral if the system can collect this information during the boot process.

Syntax

```
typedef struct _CM_KEYBOARD_DEVICE_DATA {
  USHORT Version;
  USHORT Revision;
  UCHAR  Type;
  UCHAR  Subtype;
  USHORT KeyboardFlags;
} CM_KEYBOARD_DEVICE_DATA, *PCM_KEYBOARD_DEVICE_DATA;
```

Members

`Version`

The version number of this structure.

`Revision`

The revision of this structure.

`Type`

The type of the keyboard.

`Subtype`

The subtype of the keyboard.

`KeyboardFlags`

Defined by x86 BIOS INT 16h, function 02 as:

BIT	DEFINED AS
7	Insert on.
6	Caps Lock on.
5	Num Lock on.
4	Scroll Lock on.
3	Alt Key is down.
2	Ctrl Key is down.

1	Left shift key is down.

CM_PARTIAL_RESOURCE_DESCRIPTOR structure

1/30/2019 • 9 minutes to read • Edit Online

The **CM_PARTIAL_RESOURCE_DESCRIPTOR** structure specifies one or more system hardware resources, of a single type, assigned to a device. This structure is used to create an array within a CM_PARTIAL_RESOURCE_LIST structure.

Syntax

```
typedef struct _CM_PARTIAL_RESOURCE_DESCRIPTOR {
  UCHAR  Type;
  UCHAR  ShareDisposition;
  USHORT Flags;
  union {
    struct {
      PHYSICAL_ADDRESS Start;
      ULONG            Length;
    } Generic;
    struct {
      PHYSICAL_ADDRESS Start;
      ULONG            Length;
    } Port;
    struct {
#if ...
      USHORT    Level;
      USHORT    Group;
#else
      ULONG     Level;
#endif
      ULONG     Vector;
      KAFFINITY Affinity;
    } Interrupt;
    struct {
      union {
        struct {
          USHORT    Group;
          USHORT    Reserved;
          USHORT    MessageCount;
          ULONG     Vector;
          KAFFINITY Affinity;
        } Raw;
        struct {
#if ...
          USHORT    Level;
          USHORT    Group;
#else
          ULONG     Level;
#endif
          ULONG     Vector;
          KAFFINITY Affinity;
        } Translated;
      } DUMMYUNIONNAME;
    } MessageInterrupt;

      PHYSICAL_ADDRESS Start;
      ULONG            Length;
    } Memory;
    struct {
      ULONG Channel;
      ULONG Port;
      ULONG Reserved1;
```

```
      ULONG Reserved1;
    } Dma;
    struct {
      ULONG Channel;
      ULONG RequestLine;
      UCHAR TransferWidth;
      UCHAR Reserved1;
      UCHAR Reserved2;
      UCHAR Reserved3;
    } DmaV3;
    struct {
      ULONG Data[3];
    } DevicePrivate;
    struct {
      ULONG Start;
      ULONG Length;
      ULONG Reserved;
    } BusNumber;
    struct {
      ULONG DataSize;
      ULONG Reserved1;
      ULONG Reserved2;
    } DeviceSpecificData;
    struct {
      PHYSICAL_ADDRESS Start;
      ULONG            Length40;
    } Memory40;
    struct {
      PHYSICAL_ADDRESS Start;
      ULONG            Length48;
    } Memory48;
    struct {
      PHYSICAL_ADDRESS Start;
      ULONG            Length64;
    } Memory64;
    struct {
      UCHAR Class;
      UCHAR Type;
      UCHAR Reserved1;
      UCHAR Reserved2;
      ULONG IdLowPart;
      ULONG IdHighPart;
    } Connection;
  } u;
} CM_PARTIAL_RESOURCE_DESCRIPTOR, *PCM_PARTIAL_RESOURCE_DESCRIPTOR;
```

Members

`Type`

Identifies the resource type. The constant value specified for **Type** indicates which structure within the **u** union is valid, as indicated in the following table. (These flags are used within both **CM_PARTIAL_RESOURCE_DESCRIPTOR** and IO_RESOURCE_DESCRIPTOR structures, except where noted.)

TYPE VALUE	U MEMBER SUBSTRUCTURE
CmResourceTypePort	**u.Port**
CmResourceTypeInterrupt	**u.Interrupt** or **u.MessageInterrupt**.If the CM_RESOURCE_INTERRUPT_MESSAGE flag of **Flags** is set, use **u.MessageInterrupt**; otherwise, use **u.Interrupt**.
CmResourceTypeMemory	**u.Memory**

CmResourceTypeMemoryLarge	One of **u.Memory40**, **u.Memory48**, or **u.Memory64**.The CM_RESOURCE_MEMORY_LARGE_*XXX* flags set in the **Flags** member determines which structure is used.
CmResourceTypeDma	**u.Dma** (if CM_RESOURCE_DMA_V3 is not set) or **u.DmaV3** (if CM_RESOURCE_DMA_V3 flag is set)
CmResourceTypeDevicePrivate	**u.DevicePrivate**
CmResourceTypeBusNumber	**u.BusNumber**
CmResourceTypeDeviceSpecific	**u.DeviceSpecificData**(Not used within **IO_RESOURCE_DESCRIPTOR**.)
CmResourceTypePcCardConfig	**u.DevicePrivate**
CmResourceTypeMfCardConfig	**u.DevicePrivate**
CmResourceTypeConnection	**u.Connection**
CmResourceTypeConfigData	*Reserved for system use.*
CmResourceTypeNonArbitrated	*Not used.*

`ShareDisposition`

Indicates whether the described resource can be shared. Valid constant values are listed in the following table.

VALUE	MEANING
CmResourceShareDeviceExclusive	The device requires exclusive use of the resource.
CmResourceShareDriverExclusive	The driver requires exclusive use of the resource. (Not supported for WDM drivers.)

CmResourceShareShared	The resource can be shared without restriction.

`Flags`

Contains flag bits that are specific to the resource type, as indicated in the following table. Flags can be bitwise-ORed together as appropriate.

RESOURCE TYPE	FLAG	DEFINITION
CmResourceTypePort		
	CM_RESOURCE_PORT_MEMORY	The device is accessed in memory address space.
	CM_RESOURCE_PORT_IO	The device is accessed in I/O address space.
	CM_RESOURCE_PORT_10_BIT_DECODE	The device decodes 10 bits of the port address.
	CM_RESOURCE_PORT_12_BIT_DECODE	The device decodes 12 bits of the port address.
	CM_RESOURCE_PORT_16_BIT_DECODE	The device decodes 16 bits of the port address.
	CM_RESOURCE_PORT_POSITIVE_DECODE	The device uses "positive decode" instead of "subtractive decode". (In general, PCI devices use positive decode and ISA buses use subtractive decode.)
	CM_RESOURCE_PORT_PASSIVE_DECODE	The device decodes the port but the driver does not use it.
	CM_RESOURCE_PORT_WINDOW_DECODE	Reserved for system use.
CmResourceTypeInterrupt		
	CM_RESOURCE_INTERRUPT_LEVEL_SENSITIVE	The IRQ line is level-triggered. (These IRQs are usually sharable.)
	CM_RESOURCE_INTERRUPT_LATCHED	The IRQ line is edge-triggered.

	CM_RESOURCE_INTERRUPT_MESSAGE	If this flag is set, the interrupt is a message-signaled interrupt. Otherwise, the interrupt is a line-based interrupt. This flag can be set starting with Windows Vista.
	CM_RESOURCE_INTERRUPT_POLICY_INCLUDED	Not used with the **CM_PARTIAL_RESOURCE_DESCRIPTOR** structure. For more information about this flag, see IO_RESOURCE_DESCRIPTOR.
	CM_RESOURCE_INTERRUPT_SECONDARY_INTERRUPT	The interrupt is a secondary interrupt. This flag can be set starting with Windows 8. For more information about secondary interrupts, see GPIO Interrupts.
	CM_RESOURCE_INTERRUPT_WAKE_HINT	The interrupt is capable of waking the operating system from a low-power idle state or a system sleep state. This flag can be set starting with Windows 8. For more information about wake capabilities, see Enabling Device Wake-Up.
CmResourceTypeMemory		
	CM_RESOURCE_MEMORY_READ_WRITE	The memory range is readable and writable.
	CM_RESOURCE_MEMORY_READ_ONLY	The memory range is read-only.
	CM_RESOURCE_MEMORY_WRITE_ONLY	The memory range is write-only.
	CM_RESOURCE_MEMORY_PREFETCHABLE	The memory range is prefetchable.
	CM_RESOURCE_MEMORY_COMBINEDWRITE	Combined-write caching is allowed.
	CM_RESOURCE_MEMORY_24	The device uses 24-bit addressing.
	CM_RESOURCE_MEMORY_CACHEABLE	The memory range is cacheable.
CmResourceTypeMemoryLarge		

	CM_RESOURCE_MEMORY_LARGE_40	The memory descriptor uses the **u.Memory40** member.
	CM_RESOURCE_MEMORY_LARGE_48	The memory descriptor uses the **u.Memory48** member.
	CM_RESOURCE_MEMORY_LARGE_64	The memory descriptor uses the **u.Memory64** member.
CmResourceTypeDma		
	CM_RESOURCE_DMA_8	8-bit DMA channel
	CM_RESOURCE_DMA_16	16-bit DMA channel
	CM_RESOURCE_DMA_32	32-bit DMA channel
	CM_RESOURCE_DMA_8_AND_16	8-bit and 16-bit DMA channel
	CM_RESOURCE_DMA_BUS_MASTER	The device supports bus master DMA transfers.
	CM_RESOURCE_DMA_TYPE_A	Type A DMA
	CM_RESOURCE_DMA_TYPE_B	Type B DMA
	CM_RESOURCE_DMA_TYPE_F	Type F DMA
	CM_RESOURCE_DMA_V3	Use the **DmaV3** member instead of the **Dma** member. The **DmaV3** member is available starting with Windows 8.

`u`

`u.Generic`

`u.Generic.Start`

`u.Generic.Length`

`u.Port`

`u.Port.Start`

For raw resources: Specifies the bus-relative physical address of the lowest of a range of contiguous I/O port addresses allocated to the device.

For translated resources: Specifies the system physical address of the lowest of a range of contiguous I/O port addresses allocated to the device.

For more information about raw and translated resources, see Remarks.

`u.Port.Length`

The length, in bytes, of the range of allocated I/O port addresses.

`u.Interrupt`

`u.Interrupt.Level.#1877845754`

`u.Interrupt.Group`

Specifies the processor group number. This member exists only if the NT_PROCESSOR_GROUPS constant is defined at compile time. This member can be nonzero only on Windows 7 and later versions of Windows. The **Group** and **Affinity** members together specify a group affinity that indicates which processors the device can interrupt. To specify an affinity for any group, set **Group** to ALL_PROCESSOR_GROUPS.

`u.Interrupt.Level.#3336307498`

`u.Interrupt.Vector`

For raw resources: Specifies the device's bus-specific interrupt vector (if appropriate for the platform and bus).

For translated resources: Specifies the global system interrupt vector assigned to the device.

For more information about raw and translated resources, see Remarks.

`u.Interrupt.Affinity`

Contains a **KAFFINITY**-typed bitmask value indicating the set of processors the device can interrupt. To indicate that the device can interrupt any processor, this member is set to -1.

`u.MessageInterrupt`

`u.MessageInterrupt.DUMMYUNIONNAME`

`u.MessageInterrupt.DUMMYUNIONNAME.Raw`

`u.MessageInterrupt.DUMMYUNIONNAME.Raw.Group`

Specifies a processor group number. This member exists only if NT_PROCESSOR_GROUPS is defined at compile time. This member can be nonzero only on Windows 7 and later versions of Windows. The **Group** and **Affinity** members together specify a group affinity that indicates which processors can receive the device's interrupts. To specify an affinity for any group, set **Group** to ALL_PROCESSOR_GROUPS.

`u.MessageInterrupt.DUMMYUNIONNAME.Raw.Reserved`

Not used.

`u.MessageInterrupt.DUMMYUNIONNAME.Raw.MessageCount`

Specifies the number of message-signaled interrupts generated for this driver.

`u.MessageInterrupt.DUMMYUNIONNAME.Raw.Vector`

Specifies the device's interrupt vector.

`u.MessageInterrupt.DUMMYUNIONNAME.Raw.Affinity`

Specifies a KAFFINITY value that indicates the processors that receive the device's interrupts.

`u.MessageInterrupt.DUMMYUNIONNAME.Translated`

`u.MessageInterrupt.DUMMYUNIONNAME.Translated.Level.#1877845754`

`u.MessageInterrupt.DUMMYUNIONNAME.Translated.Group`

Specifies a processor group number. This member exists only if NT_PROCESSOR_GROUPS is defined at compile time. This member can be nonzero only on Windows 7 and later versions of Windows. The **Translated.Group** and

Translated.Affinity members together specify a group affinity that indicates which processors can receive the device's interrupts. To specify an affinity for any group, set **Translated.Group** to ALL_PROCESSOR_GROUPS.

`u.MessageInterrupt.DUMMYUNIONNAME.Translated.Level.#3336307498`

`u.MessageInterrupt.DUMMYUNIONNAME.Translated.Vector`

Specifies the device's interrupt vector.

`u.MessageInterrupt.DUMMYUNIONNAME.Translated.Affinity`

Specifies a KAFFINITY value that identifies the processors that receive the device's interrupts.

`u.Memory`

`u.Memory.Start`

For raw resources: Specifies the bus-relative physical address of the lowest of a range of contiguous memory addresses allocated to the device.

For translated resources: Specifies the system physical address of the lowest of a range of contiguous memory addresses allocated to the device.

For more information about raw and translated resources, see Remarks.

`u.Memory.Length`

Specifies the length, in bytes, of the range of allocated memory addresses.

`u.Dma`

`u.Dma.Channel`

Specifies the number of the DMA channel on a system DMA controller that the device can use.

`u.Dma.Port`

Specifies the number of the DMA port that an MCA-type device can use.

`u.Dma.Reserved1`

Not used.

`u.DmaV3`

`u.DmaV3.Channel`

Specifies the number of the DMA channel on the system DMA controller that is allocated to the device.

`u.DmaV3.RequestLine`

Specifies the number of the request line on the system DMA controller that is allocated to the device.

`u.DmaV3.TransferWidth`

Specifies the width, in bits, of the data bus that the system DMA controller that is allocated to the device uses to transfer data to or from the device.

`u.DmaV3.Reserved1`

Not used.

`u.DmaV3.Reserved2`

Not used.

`u.DmaV3.Reserved3`

Not used.

`u.DevicePrivate`

`u.DevicePrivate.Data`

`u.BusNumber`

`u.BusNumber.Start`

Specifies the lowest-numbered of a range of contiguous buses allocated to the device.

`u.BusNumber.Length`

Specifies the number of buses allocated to the device.

`u.BusNumber.Reserved`

Not used.

`u.DeviceSpecificData`

`u.DeviceSpecificData.DataSize`

Specifies the number of bytes appended to the end of the **CM_PARTIAL_RESOURCE_DESCRIPTOR** structure.

`u.DeviceSpecificData.Reserved1`

Not used.

`u.DeviceSpecificData.Reserved2`

Not used.

`u.Memory40`

`u.Memory40.Start`

For raw resources: Specifies the bus-relative physical address of the lowest of a range of contiguous memory addresses that are allocated to the device.

For translated resources: Specifies the system physical address of the lowest of a range of contiguous memory addresses that are allocated to the device.

For more information about raw and translated resources, see Remarks.

`u.Memory40.Length40`

Contains the high 32 bits of the 40-bit length, in bytes, of the range of allocated memory addresses. The lowest 8 bits are treated as zero.

`u.Memory48`

`u.Memory48.Start`

For raw resources: Specifies the bus-relative physical address of the lowest of a range of contiguous memory addresses that are allocated to the device.

For translated resources: Specifies the system physical address of the lowest of a range of contiguous memory addresses that are allocated to the device.

For more information about raw and translated resources, see Remarks.

`u.Memory48.Length48`

Contains the high 32 bits of the 48-bit length, in bytes, of the range of allocated memory addresses. The lowest 16 bits are treated as zero.

`u.Memory64`

`u.Memory64.Start`

For raw resources: Specifies the bus-relative physical address of the lowest of a range of contiguous memory addresses that are allocated to the device.

For translated resources: Specifies the system physical address of the lowest of a range of contiguous memory addresses that are allocated to the device.

For more information about raw and translated resources, see Remarks.

`u.Memory64.Length64`

Contains the high 32 bits of the 64-bit length, in bytes, of the range of allocated memory addresses. The lowest 32 bits are treated as zero.

`u.Connection`

`u.Connection.Class`

Specifies the connection class. This member is set to one of the following values.

VALUE	MEANING
CM_RESOURCE_CONNECTION_CLASS_GPIO	Access the device through one or more pins on a GPIO controller.
CM_RESOURCE_CONNECTION_CLASS_SERIAL	Access the device through a serial bus or serial port.

`u.Connection.Type`

Specifies the connection type.

If **Class** = CM_RESOURCE_CONNECTION_CLASS_GPIO, **Type** is set to the following value.

VALUE	MEANING
CM_RESOURCE_CONNECTION_TYPE_GPIO_IO	Access the device through GPIO pins that are configured for I/O.

Note A GPIO pin that is configured as an interrupt request input is accessed as an ordinary interrupt resource (**CmResourceTypeInterrupt**).

If **Class** = CM_RESOURCE_CONNECTION_CLASS_SERIAL, **Type** is set to one of the following values.

VALUE	MEANING
CM_RESOURCE_CONNECTION_TYPE_SERIAL_I2C	The device is connected to an I^2C bus.
CM_RESOURCE_CONNECTION_TYPE_SERIAL_SPI	The device is connected to an SPI bus.

CM_RESOURCE_CONNECTION_TYPE_SERIAL_UART	The device is connected to a serial port.

`u.Connection.Reserved1`

Not used.

`u.Connection.Reserved2`

Not used.

`u.Connection.IdLowPart`

Contains the lower 32 bits of the 64-bit connection ID.

`u.Connection.IdHighPart`

Contains the upper 32 bits of the 64-bit connection ID.

Remarks

A **CM_PARTIAL_RESOURCE_DESCRIPTOR** structure can describe either a raw (bus-relative) resource or a translated (system physical) resource, depending on the routine or IRP with which it is being used. For more information, see Raw and Translated Resources and IRP_MN_START_DEVICE.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)

CM_PARTIAL_RESOURCE_LIST structure

1/30/2019 • 2 minutes to read • Edit Online

The **CM_PARTIAL_RESOURCE_LIST** structure specifies a set of system hardware resources, of various types, assigned to a device. This structure is contained within a CM_FULL_RESOURCE_DESCRIPTOR structure.

Syntax

```
typedef struct _CM_PARTIAL_RESOURCE_LIST {
  USHORT                          Version;
  USHORT                          Revision;
  ULONG                           Count;
  CM_PARTIAL_RESOURCE_DESCRIPTOR PartialDescriptors[1];
} CM_PARTIAL_RESOURCE_LIST, *PCM_PARTIAL_RESOURCE_LIST;
```

Members

`Version`

The version number of this structure. This value should be 1.

`Revision`

The revision of this structure. This value should be 1.

`Count`

The number of elements contained in the **PartialDescriptors** array.

`PartialDescriptors`

The first element in an array of one or more CM_PARTIAL_RESOURCE_DESCRIPTOR structures.

Remarks

This structure is the header for an array of **CM_PARTIAL_RESOURCE_DESCRIPTOR** structures. The **PartialDescriptors** member contains the first element in this array, and the **Count** member specifies the total number of array elements. If the array contains more than one element, the remaining elements in the array immediately follow the **CM_PARTIAL_RESOURCE_LIST** structure in memory. The total number of bytes occupied by the **CM_PARTIAL_RESOURCE_LIST** structure and any array elements that follow this structure is **sizeof**(**CM_PARTIAL_RESOURCE_LIST**) + (**Count** - 1) * **sizeof**(**CM_PARTIAL_RESOURCE_DESCRIPTOR**).

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)

See Also

CM_FULL_RESOURCE_DESCRIPTOR

CM_RESOURCE_LIST structure

1/30/2019 • 3 minutes to read • Edit Online

The **CM_RESOURCE_LIST** structure specifies all of the system hardware resources assigned to a device.

Syntax

```
typedef struct _CM_RESOURCE_LIST {
  ULONG                    Count;
  CM_FULL_RESOURCE_DESCRIPTOR List[1];
} CM_RESOURCE_LIST, *PCM_RESOURCE_LIST;
```

Members

`Count`

The number of full resource descriptors that are specified by this **CM_RESOURCE_LIST** structure. The **List** member is the header for the first full resource descriptor. For WDM drivers, **Count** is always 1.

`List`

The CM_FULL_RESOURCE_DESCRIPTOR structure that serves as the header for the first full resource descriptor. If the **CM_RESOURCE_LIST** structure contains more than one full resource descriptor, the second full resource descriptor immediately follows the first in memory, and so on. The size of each full resource descriptor depends on the length of the CM_PARTIAL_RESOURCE_DESCRIPTOR array that it contains. For more information, see the following Remarks section.

Remarks

This structure describes the assignment of hardware resources to a device. An IRP_MN_START_DEVICE IRP uses this structure to specify the resources that the Plug and Play manager assigns to a device. Drivers for legacy devices use this structure to pass their resource requirements to the IoReportResourceForDetection routine. For more information about hardware resource allocation, see Hardware Resources.

The **CM_RESOURCE_LIST** structure is a header for a larger data structure, of variable size, that contains one or more full resource descriptors. All of the data in this larger structure occupies a contiguous block of memory. Each full resource descriptor occupies a subblock within the larger block.

A full resource descriptor begins with a CM_FULL_RESOURCE_DESCRIPTOR structure, which serves as a header for an array of CM_PARTIAL_RESOURCE_DESCRIPTOR structures. The length of this array determines the size of the full resource descriptor. The last member in the **CM_FULL_RESOURCE_DESCRIPTOR** structure is a CM_PARTIAL_RESOURCE_LIST structure that contains, as its last member, the first element in this array. If the array contains more than one element, the remaining elements immediately follow, in memory, the end of the **CM_PARTIAL_RESOURCE_LIST** structure, which is also the end of the **CM_FULL_RESOURCE_DESCRIPTOR** structure.

Driver code can use pointer arithmetic to step from one full resource descriptor to the next. For example, if a parameter named *list* is a pointer to the **CM_FULL_RESOURCE_DESCRIPTOR** structure at the start of one full resource descriptor, *list* can be updated to point to the start of the next full resource descriptor as follows:

```
    list = (PCM_FULL_RESOURCE_DESCRIPTOR)(list->PartialResourceList.PartialDescriptors +
                                          list->PartialResourceList.Count);
```

In this example, `list->PartialResourceList.PartialDescriptors` is a pointer to the start of the **CM_PARTIAL_RESOURCE_DESCRIPTOR** array, and `list->PartialResourceList.Count` is the number of elements in the array. For more information about the **PartialDescriptors** and **Count** members, see CM_PARTIAL_RESOURCE_LIST. #### Examples All PnP drivers must handle IRP_MN_START_DEVICE IRPs. Typically, a driver's handler for this IRP walks the lists of assigned resources that are pointed to by the **Parameters.StartDevice.AllocatedResources** and **Parameters.StartDevice.AllocatedResourcesTranslated** members of the IO_STACK_LOCATION structure in the IRP. The following code example contains a function—named GetAssignedResources—that is called in the handler to walk each list. This function verifies that the required resources are specified in the list, and configures the device to use the resources. The GetAssignedResources function returns **TRUE** if it succeeds. Otherwise, it returns **FALSE** (probably from the **switch** statement, although the details are omitted to simplify the code example).

```
/* Process the assigned hardware resources. */

BOOLEAN GetAssignedResources(PCM_RESOURCE_LIST reslist)
{
    PCM_FULL_RESOURCE_DESCRIPTOR list;

    list = reslist->List;

    for (int ix = 0; ix < reslist->Count; ++ix)
    {
        /* Process resources in CM_FULL_RESOURCE_DESCRIPTOR block number ix. */

        for (int jx = 0; jx < list->PartialResourceList.Count; ++jx)
        {
            PCM_PARTIAL_RESOURCE_DESCRIPTOR desc;

            desc = list->PartialResourceList.PartialDescriptors + jx;

            switch (desc->Type)
            {
                /* Process element jx in PartialDescriptors array. */

                ...

            }
        }

        /* Advance to next CM_FULL_RESOURCE_DESCRIPTOR block in memory. */

        list = (PCM_FULL_RESOURCE_DESCRIPTOR)(list->PartialResourceList.PartialDescriptors +
                                              list->PartialResourceList.Count);
    }

    return TRUE;
}
```

CM_SCSI_DEVICE_DATA structure

1/30/2019 • 2 minutes to read • Edit Online

The **CM_SCSI_DEVICE_DATA** structure defines a device-type-specific data record that is stored in the \Registry\Machine\Hardware\Description tree for a SCSI HBA if the system can collect this information during the boot process.

Syntax

```
typedef struct _CM_SCSI_DEVICE_DATA {
  USHORT Version;
  USHORT Revision;
  UCHAR  HostIdentifier;
} CM_SCSI_DEVICE_DATA, *PCM_SCSI_DEVICE_DATA;
```

Members

`Version`

The version number of this structure.

`Revision`

The revision for this structure.

`HostIdentifier`

The SCSI bus identifier used by the ARC firmware.

Requirements

CM_SERIAL_DEVICE_DATA structure

1/30/2019 • 2 minutes to read • Edit Online

The **CM_SERIAL_DEVICE_DATA** structure defines a device-type-specific data record that is stored in the \Registry\Machine\Hardware\Description tree for a serial controller if the system can collect this information during the boot process.

Syntax

```
typedef struct _CM_SERIAL_DEVICE_DATA {
  USHORT Version;
  USHORT Revision;
  ULONG  BaudClock;
} CM_SERIAL_DEVICE_DATA, *PCM_SERIAL_DEVICE_DATA;
```

Members

`Version`

The version number of this structure.

`Revision`

The revision of this structure.

`BaudClock`

The clock baud rate, in megahertz, at which data is transferred.

COUNTED_REASON_CONTEXT structure

1/30/2019 • 2 minutes to read • Edit Online

The **COUNTED_REASON_CONTEXT** structure contains one or more strings that give reasons for a power request.

Syntax

```
typedef struct _COUNTED_REASON_CONTEXT {
  ULONG Version;
  ULONG Flags;
  union {
    struct {
      UNICODE_STRING  ResourceFileName;
      USHORT          ResourceReasonId;
      ULONG           StringCount;
      PUNICODE_STRING ReasonStrings;
    } DUMMYSTRUCTNAME;
    UNICODE_STRING SimpleString;
  } DUMMYUNIONNAME;
} COUNTED_REASON_CONTEXT, *PCOUNTED_REASON_CONTEXT;
```

Members

`Version`

The version number of the structure. Set this member to DIAGNOSTIC_REASON_VERSION.

`Flags`

Indicates whether the structure contains a simple reason string or a detailed set of reason strings. Set this member to one of the following constants:

- DIAGNOSTIC_REASON_SIMPLE_STRING
- DIAGNOSTIC_REASON_DETAILED_STRING

If **Flags** = DIAGNOSTIC_REASON_SIMPLE_STRING, the **SimpleString** member of the union is valid. If **Flags** = DIAGNOSTIC_REASON_DETAILED_STRING, the **ResourceFileName**, **ResourceReasonId**, **StringCount**, and **ReasonStrings** members are valid (and the **SimpleString** member is not valid).

`DUMMYUNIONNAME`

`DUMMYUNIONNAME.DUMMYSTRUCTNAME`

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.ResourceFileName`

A pointer to a wide-character, null-terminated string that contains the pathname of a resource file. This resource file contains one or more localized strings that give reasons for a power request. This member is optional and can be specified as **NULL** or as an empty string if no resource file is required. This member is valid only if **Flags** = DIAGNOSTIC_REASON_DETAILED_STRING.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.ResourceReasonId`

The resource ID assigned to the first reason string in the resource file that is specified by **ResourceFileName**. This

member is valid only if **Flags** = DIAGNOSTIC_REASON_DETAILED_STRING.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.StringCount`

The number of reason strings in the **ReasonStrings** array or in the resource file that is specified by **ResourceFileName**. This member is valid only if **Flags** = DIAGNOSTIC_REASON_DETAILED_STRING.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.ReasonStrings`

A pointer to an array of string pointers. Each array element is a pointer to a wide-character, null-terminated string. The number of array elements is specified by **StringCount**. This member is valid only if **Flags** = DIAGNOSTIC_REASON_DETAILED_STRING.

`DUMMYUNIONNAME.SimpleString`

A pointer to a wide-character, null-terminated string that explains the reason for a power request. This member is valid only if **Flags** = DIAGNOSTIC_REASON_SIMPLE_STRING.

Remarks

This structure is used by the PoCreatePowerRequest routine.

The power manager uses the reason string or strings contained in this structure as a diagnostic aid during functional and performance testing.

The **COUNTED_REASON_CONTEXT** structure can contain either a simple reason string or a set of detailed reason strings. If **Flags** = DIAGNOSTIC_REASON_SIMPLE_STRING, the **SimpleString** member points to a string that explains the reason for the power request. If **Flags** = DIAGNOSTIC_REASON_DETAILED_STRING, the **ResourceFileName**, **ResourceReasonId**, **StringCount**, and **ReasonStrings** members can give a detailed set of reasons for the power request.

The DIAGNOSTIC_REASON_DETAILED_STRING flag supports localization. If the localized resource file specified by **ResourceFileName** exists, the power manager retrieves a set of resource strings from the file and uses these strings in place of the strings contained in the **ReasonStrings** array. **ResourceId** specifies the resource index of the first string in the file to use as a reason string, and **StringCount** specifies the number of resource strings to use as reason strings. The resource strings must have consecutive resource indexes.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Ntpoapi.h)

D3COLD_LAST_TRANSITION_STATUS Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **D3COLD_LAST_TRANSITION_STATUS** enumeration indicates whether the most recent transition to the D3hot device power state was followed by a transition to the D3cold device power state.

Syntax

```
typedef enum _D3COLD_LAST_TRANSITION_STATUS {
  LastDStateTransitionStatusUnknown,
  LastDStateTransitionD3hot,
  LastDStateTransitionD3cold
} D3COLD_LAST_TRANSITION_STATUS, *PD3COLD_LAST_TRANSITION_STATUS;
```

Constants

LastDStateTransitionStatusUnknown	Information is not available from the bus driver or platform firmware about whether the most recent transition to D3hot was followed by a transition to D3cold.
LastDStateTransitionD3hot	The most recent transition to the D3hot device power state was not followed by a transition to the D3cold device power state.
LastDStateTransitionD3cold	The most recent transition to the D3hot device power state was followed by a transition to the D3cold device power state.

Remarks

The *LastTransitionStatus* parameter of the GetLastTransitionStatus routine is a pointer to a variable of type **D3COLD_LAST_TRANSITION_STATUS**.

Requirements

Header	wdm.h (include Wdm.h)

D3COLD_SUPPORT_INTERFACE structure

1/30/2019 • 2 minutes to read • Edit Online

The **D3COLD_SUPPORT_INTERFACE** interface structure contains pointers to the routines in the GUID_D3COLD_SUPPORT_INTERFACE driver interface.

Syntax

```
typedef struct _D3COLD_SUPPORT_INTERFACE {
  USHORT                              Size;
  USHORT                              Version;
  PVOID                               Context;
  PINTERFACE_REFERENCE                InterfaceReference;
  PINTERFACE_DEREFERENCE              InterfaceDereference;
  PSET_D3COLD_SUPPORT                 SetD3ColdSupport;
  PGET_IDLE_WAKE_INFO                 GetIdleWakeInfo;
  PGET_D3COLD_CAPABILITY              GetD3ColdCapability;
  PGET_D3COLD_CAPABILITY              GetBusDriverD3ColdSupport;
  PGET_D3COLD_LAST_TRANSITION_STATUS GetLastTransitionStatus;
} D3COLD_SUPPORT_INTERFACE, *PD3COLD_SUPPORT_INTERFACE;
```

Members

`Size`

The size, in bytes, of this structure.

`Version`

The driver-defined interface version. The current version of this interface is D3COLD_SUPPORT_INTERFACE_VERSION.

`Context`

A pointer to interface-specific context information.

`InterfaceReference`

A pointer to an InterfaceReference routine that increments the interface's reference count.

`InterfaceDereference`

A pointer to an InterfaceDereference routine that decrements the interface's reference count.

`SetD3ColdSupport`

A pointer to a SetD3ColdSupport routine that enables or disables transitions to the D3cold device power state.

`GetIdleWakeInfo`

A pointer to a GetIdleWakeInfo routine that the device driver calls to discover the device power states from which this device can signal wake events to the processor.

`GetD3ColdCapability`

A pointer to a GetD3ColdCapability routine that reports whether this device is capable of entering the D3cold

device power state.

`GetBusDriverD3ColdSupport`

A pointer to a GetBusDriverD3ColdSupport routine that reports whether the underlying bus driver and ACPI system firmware support D3cold for this device.

`GetLastTransitionStatus`

A pointer to a GetLastTransitionStatus routine that reports whether this device's most recent transition to D3hot was followed by a transition to D3cold.

Remarks

A device driver that successfully queries for the GUID_D3COLD_SUPPORT_INTERFACE interface receives a pointer to a **D3COLD_SUPPORT_INTERFACE** structure in which the pointers to the routines in the interface are all non-NULL and valid.

The **D3COLD_SUPPORT_INTERFACE** structure is an extended version of the INTERFACE structure.

Requirements

Minimum supported client	Supported starting with Windows 8.

DEVICE_CAPABILITIES structure

1/30/2019 • 8 minutes to read • Edit Online

A **DEVICE_CAPABILITIES** structure describes PnP and power capabilities of a device. This structure is returned in response to an IRP_MN_QUERY_CAPABILITIES IRP.

Syntax

```
typedef struct _DEVICE_CAPABILITIES {
  USHORT             Size;
  USHORT             Version;
  ULONG              DeviceD1 : 1;
  ULONG              DeviceD2 : 1;
  ULONG              LockSupported : 1;
  ULONG              EjectSupported : 1;
  ULONG              Removable : 1;
  ULONG              DockDevice : 1;
  ULONG              UniqueID : 1;

```

Members

`Size`

Specifies the size of the structure, in bytes. This field is set by the component that sends the **IRP_MN_QUERY_CAPABILITIES** request.

`Version`

Specifies the version of the structure, currently version 1. This field is set by the component that sends the **IRP_MN_QUERY_CAPABILITIES** request.

`DeviceD1`

Specifies whether the device hardware supports the D1 power state. Drivers should not change this value.

`DeviceD2`

Specifies whether the device hardware supports the D2 power state. Drivers should not change this value.

`LockSupported`

Specifies whether the device supports physical-device locking that prevents device ejection. This member pertains to ejecting the device from its slot, rather than ejecting a piece of removable media from the device.

`EjectSupported`

Specifies whether the device supports software-controlled device ejection while the system is in the **PowerSystemWorking** state. This member pertains to ejecting the device from its slot, rather than ejecting a piece of removable media from the device.

`Removable`

Specifies whether the device can be dynamically removed from its immediate parent. If **Removable** is set to **TRUE**, the device does not belong to the same physical object as its parent.

For example, if **Removable** is set to **TRUE** for a USB composite device inside a multifunction printer, the composite device does not belong to the physical object of its immediate parent, such as a USB hub inside a notebook PC.

In most cases the bus driver, not the function driver, should determine the value of the**Removable** parameter of the device. For USB devices, the USB hub driver sets the **Removable** parameter. It should not be modified by the function driver.

If **Removable** is set to **TRUE**, the device is displayed in the **Unplug or Eject Hardware** program, unless **SurpriseRemovalOK** is also set to **TRUE**.

`DockDevice`

Specifies whether the device is a docking peripheral.

`UniqueID`

Specifies whether the device's instance ID is unique system-wide. This bit is clear if the instance ID is unique only within the scope of the bus. For more information, see Device Identification Strings.

`SilentInstall`

Specifies whether Device Manager should suppress all installation dialog boxes; except required dialog boxes such as "no compatible drivers found."

`RawDeviceOK`

Specifies whether the driver for the underlying bus can drive the device if there is no function driver (for example, SCSI devices in pass-through mode). This mode of operation is called raw mode.

`SurpriseRemovalOK`

Specifies whether the function driver for the device can handle the case where the device is removed before Windows can send **IRP_MN_QUERY_REMOVE_DEVICE** to it. If **SurpriseRemovalOK** is set to **TRUE**, the device can be safely removed from its immediate parent regardless of the state that its driver is in.

For example, a standard USB mouse does not maintain any state in its hardware and thus can be safely removed at any time. However, an external hard disk whose driver caches writes in memory cannot be safely removed without

first letting the driver flush its cache to the hardware.

> **Note** Drivers for USB devices that support surprise removal must set this to **TRUE** only when the IRP is being passed back up the driver stack.

`WakeFromD0`

Specifies whether the device can respond to an external wake signal while in the D0 state. Drivers should not change this value.

`WakeFromD1`

Specifies whether the device can respond to an external wake signal while in the D1 state. Drivers should not change this value.

`WakeFromD2`

Specifies whether the device can respond to an external wake signal while in the D2 state. Drivers should not change this value.

`WakeFromD3`

Specifies whether the device can respond to an external wake signal while in the D3 state. Drivers should not change this value.

`HardwareDisabled`

When set, this flag specifies that the device's hardware is disabled.

A device's parent bus driver or a bus filter driver sets this flag when such a driver determines that the device hardware is disabled.

The PnP manager sends one **IRP_MN_QUERY_CAPABILITIES** IRP right after a device is enumerated and sends another after the device has been started. The PnP manager only checks this bit right after the device is enumerated. Once the device is started, this bit is ignored.

`NonDynamic`

Reserved for future use.

`WarmEjectSupported`

Reserved for future use.

`NoDisplayInUI`

Do not display the device in the user interface. If this bit is set, the device is never displayed in the user interface, even if the device is present but fails to start. Only bus drivers and associated bus filter drivers should set this bit. (Also see the **PNP_DEVICE_DONT_DISPLAY_IN_UI** flag in the PNP_DEVICE_STATE structure.)

`Reserved1`

Reserved for system use.

`WakeFromInterrupt`

Indicates whether the driver or ACPI is responsible for handling the wake event. If set, the driver is responsible for handling the wake event. ACPI arms the device when it receives an IRP_MN_WAIT_WAKE IRP, but does not connect the interrupt, complete the IRP to notify the device stack of a wake event.

`SecureDevice`

Indicates whether the device is a secure device.

`ChildOfVgaEnabledBridge`

For a VGA device, indicates whether the parent bridge has the VGA decoding bit set.

`DecodeIoOnBoot`

Indictates whether the device has IO decode enabled on boot.

`Reserved`

Reserved for system use.

`Address`

Specifies an address indicating where the device is located on its underlying bus.

The interpretation of this number is bus-specific. If the address is unknown or the bus driver does not support an address, the bus driver leaves this member at its default value of 0xFFFFFFFF.

The following list describes the information certain bus drivers store in the **Address** field for their child devices:

1394
Does not supply an address because the addresses are volatile. Defaults to 0xFFFFFFFF.

EISA
Slot Number (0-F).

IDE
For an IDE device, the address contains the target ID and LUN. For an IDE channel, the address is zero or one (0 = primary channel and 1 = secondary channel).

ISApnp
Does not supply an address. Defaults to 0xFFFFFFFF.

PC Card (PCMCIA)
The socket number (typically 0x00 or 0x40).

PCI
The device number in the high word and the function number in the low word.

SCSI
The target ID.

USB
The port number.

`UINumber`

Specifies a number associated with the device that can be displayed in the user interface.

This number is typically a user-perceived slot number, such as a number printed next to the slot on the board, or some other number that makes locating the physical device easier for the user. For buses with no such convention, or when the **UINumber** is unknown, the bus driver leaves this member at its default value of 0xFFFFFFFF.

`DeviceState`

An array of values indicating the most-powered device power state that the device can maintain for each system power state. The **DeviceState[PowerSystemWorking]** element of the array corresponds to the S0 system state. The entry for **PowerSystemUnspecified** is reserved for system use.

The entries in this array are based on the capabilities of the parent devnode. As a general rule, a driver should not

change these values. However, if necessary, a driver can lower the value, for example, from **PowerDeviceD1** to **PowerDeviceD2**.

If the bus driver is unable to determine the appropriate device power state for a root-enumerated device, it sets **DeviceState[PowerSystemWorking]** to **PowerDeviceD0** and all other entries to **PowerDeviceD3**.

`SystemWake`

Specifies the least-powered system power state from which the device can signal a wake event. A value of **PowerSystemUnspecified** indicates that the device cannot wake the system.

A bus driver can get this information from its parent devnode.

In general, a driver should not change this value. If necessary, however, a driver can raise the power state, for example, from **PowerSystemHibernate** to **PowerSystemS1**, to indicate that its device cannot wake the system from a hibernation state but can from a higher-powered sleep state.

`DeviceWake`

Specifies the least-powered device power state from which the device can signal a wake event. A value of **PowerDeviceUnspecified** indicates that the device cannot signal a wake event.

`D1Latency`

Specifies the device's approximate worst-case latency, in 100-microsecond units, for returning the device to the **PowerDeviceD0** state from the **PowerDeviceD1** state. Set to zero if the device does not support the D1 state.

`D2Latency`

Specifies the device's approximate worst-case latency, in 100-microsecond units, for returning the device to the **PowerDeviceD0** state from the **PowerDeviceD2** state. Set to zero if the device does not support the D2 state.

`D3Latency`

Specifies the device's approximate worst-case latency, in 100-microsecond units, for returning the device to the **PowerDeviceD0** state from the **PowerDeviceD3** state. Set to zero if the device does not support the D3 state.

Remarks

Bus drivers set the appropriate values in this structure in response to an **IRP_MN_QUERY_CAPABILITIES** IRP. Bus filter drivers, function drivers, and filter drivers might alter the capabilities set by the bus driver.

Drivers that send an **IRP_MN_QUERY_CAPABILITIES** request must initialize the **Size**, **Version**, **Address**, and **UINumber** members of this structure before sending the IRP.

For more information about using the **DEVICE_CAPABILITIES** structure to describe a device's power capabilities, see Reporting Device Power Capabilities.

DEVICE_DESCRIPTION structure

1/30/2019 • 7 minutes to read • Edit Online

The **DEVICE_DESCRIPTION** structure describes the attributes of the physical device for which a driver is requesting a DMA adapter.

Syntax

```
typedef struct _DEVICE_DESCRIPTION {
  ULONG            Version;
  BOOLEAN          Master;
  BOOLEAN          ScatterGather;
  BOOLEAN          DemandMode;
  BOOLEAN          AutoInitialize;
  BOOLEAN          Dma32BitAddresses;
  BOOLEAN          IgnoreCount;
  BOOLEAN          Reserved1;
  BOOLEAN          Dma64BitAddresses;
  ULONG            BusNumber;
  ULONG            DmaChannel;
  INTERFACE_TYPE   InterfaceType;
  DMA_WIDTH        DmaWidth;
  DMA_SPEED        DmaSpeed;
  ULONG            MaximumLength;
  ULONG            DmaPort;
  ULONG            DmaAddressWidth;
  ULONG            DmaControllerInstance;
  ULONG            DmaRequestLine;
  PHYSICAL_ADDRESS DeviceAddress;
} DEVICE_DESCRIPTION, *PDEVICE_DESCRIPTION;
```

Members

`Version`

The version of this structure. The **Version** member of the **DEVICE_DESCRIPTION** structure that is passed to the IoGetDmaAdapter routine determines which version of the DMA_ADAPTER structure is returned by this routine. The following is a list of the possible values of the **Version** member and the corresponding **DMA_ADAPTER** versions:

DEVICE_DESCRIPTION_VERSION

If **Version** = **DEVICE_DESCRIPTION_VERSION**, **IoGetDmaAdapter** ignores the **IgnoreCount** member, and returns version 1 of the **DMA_ADAPTER** structure.

DEVICE_DESCRIPTION_VERSION1

If **Version** = **DEVICE_DESCRIPTION_VERSION1**, **IoGetDmaAdapter** uses the **IgnoreCount** member, and returns version 1 of the **DMA_ADAPTER** structure.

DEVICE_DESCRIPTION_VERSION2

If **Version** = **DEVICE_DESCRIPTION_VERSION2**, **IoGetDmaAdapter** uses the **IgnoreCount** member, and returns version 2 of the **DMA_ADAPTER** structure. Version 2 is available starting with Windows XP.

DEVICE_DESCRIPTION_VERSION3

If **Version** = **DEVICE_DESCRIPTION_VERSION3**, **IoGetDmaAdapter** uses the **IgnoreCount** member, and returns version 3 of the **DMA_ADAPTER** structure. Version 3 is available starting with Windows 8.

`Master`

Whether the device is a bus-master DMA device. Set to **TRUE** if the device is a bus-master DMA device. Set to **FALSE** if it is a subordinate DMA device.

`ScatterGather`

For a bus-master DMA device, this member indicates whether the device supports scatter/gather DMA. Set to **TRUE** if the device can do scatter/gather DMA. Otherwise, set this member to **FALSE**.

For a subordinate DMA device, the **ScatterGather** value is not used. Instead, **IoGetDmaAdapter** assumes that the scatter/gather capability of a subordinate DMA device is the same as that of the underlying system DMA controller to which the device is connected.

`DemandMode`

This member is used only if **Version** is DEVICE_DESCRIPTION_VERSION2.

For a subordinate DMA device, this member indicates whether to use the system DMA controller's demand mode. Set to **TRUE** to use demand mode. Otherwise, set this member to **FALSE**.

For a bus-master DMA device, the **DemandMode** value is not used.

If **Version** is DEVICE_DESCRIPTION_VERSION, DEVICE_DESCRIPTION_VERSION1, or DEVICE_DESCRIPTION_VERSION3, the **DemandMode** value is not used.

`AutoInitialize`

For a subordinate DMA device, this member indicates whether to use the system DMA controller's autoinitialize mode. Set to **TRUE** to use autoinitialize mode. Otherwise, set this member to **FALSE**.

For a bus-master DMA device, the **AutoInitialize** value is not used.

`Dma32BitAddresses`

This member is used only if **Version** is DEVICE_DESCRIPTION_VERSION, DEVICE_DESCRIPTION_VERSION1, or DEVICE_DESCRIPTION_VERSION2.

Dma32BitAddresses specifies whether the device can use full 32-bit addresses for DMA operations. Set to **TRUE** if the device supports 32-bit addresses. Otherwise, set this member to **FALSE**.

If **Version** = DEVICE_DESCRIPTION_VERSION3, the **Dma32BitAddresses** value is not used.

`IgnoreCount`

Whether to ignore the DMA controller's transfer counter. Set to**TRUE** if the DMA controller in this platform does not maintain an accurate transfer counter, and therefore requires a workaround. Otherwise, set this member to **FALSE**.

If **Version** = DEVICE_DESCRIPTION_VERSION, the **IgnoreCount** value is not used.

For more information, see the Remarks section.

`Reserved1`

Reserved for system use. Must be **FALSE**.

`Dma64BitAddresses`

This member is used only if **Version** is DEVICE_DESCRIPTION_VERSION, DEVICE_DESCRIPTION_VERSION1, or DEVICE_DESCRIPTION_VERSION2.

Dma64BitAddresses specifies whether the device can use full 64-bit addresses for DMA operations. Set to **TRUE**

if the device supports 64-bit addresses. Otherwise, set this member to **FALSE**.

If **Version** = DEVICE_DESCRIPTION_VERSION3, the **Dma64BitAddresses** value is not used.

`BusNumber`

The system-assigned bus number for the I/O bus. This member is not used by WDM drivers.

`DmaChannel`

The number of the DMA channel to which a subordinate device is assigned. The device driver obtains this channel number from the resource list that it receives in the IRP_MN_START_DEVICE request that starts the device. For more information about this number, see the description of the **Dma.Channel** member in CM_PARTIAL_RESOURCE_DESCRIPTOR.

`InterfaceType`

The interface type of the I/O bus to use for DMA. Set this member to the INTERFACE_TYPE enumeration value that indicates the interface type. For more information, see the Remarks section.

`DmaWidth`

For a subordinate DMA device, this member specifies the DMA data width for transfers by the system DMA controller. Possible values are **Width8Bits**, **Width16Bits**, **Width32Bits**, and **Width64Bits**.

For a bus-master DMA device, the **DmaWidth** value is not used.

`DmaSpeed`

This member is used only if **Version** is DEVICE_DESCRIPTION_VERSION, DEVICE_DESCRIPTION_VERSION1, or DEVICE_DESCRIPTION_VERSION2.

For a subordinate DMA device, this member specifies one of the following speeds for system DMA: **Compatible**, **TypeA**, **TypeB**, **TypeC**, or **TypeF**.

For a bus-master DMA device, the **DmaSpeed** value is not used.

If **Version** = DEVICE_DESCRIPTION_VERSION3, the **DmaSpeed** value is not used.

`MaximumLength`

The maximum number of bytes the device can transfer in a DMA operation that uses the allocated adapter object.

`DmaPort`

The Microchannel-type bus port number. This parameter is obsolete, but is retained in the structure for compatibility with legacy drivers.

`DmaAddressWidth`

This member is used only if **Version** = DEVICE_DESCRIPTION_VERSION3.

For a bus-master DMA device, **DmaAddressWidth** specifies the width, in bits, of a DMA address. The **DmaAddressWidth** value must be nonzero and must not exceed 64. If the memory address width is greater than the DMA address width, map registers are required to access a region of memory that is beyond the address reach of the DMA controller.

For a subordinate DMA device, the **DmaAddressWidth** value is not used. Instead, **IoGetDmaAdapter** assumes that the address width of a subordinate DMA device is the same as that of the underlying system DMA controller to which the device is connected.

`DmaControllerInstance`

Not used.

`DmaRequestLine`

This member is used only if **Version** = DEVICE_DESCRIPTION_VERSION3.

For a subordinate DMA device, **DmaRequestLine** specifies the request line on the DMA controller to which the device is connected. The device driver obtains the number of this request line from the resource list it receives in the **IRP_MN_START_DEVICE** request that starts the device. For more information about the request line number, see the description of the **u.DmaV3.RequestLine** member in CM_PARTIAL_RESOURCE_DESCRIPTOR.

For a bus-master DMA device, the **DmaRequestLine** value is not used.

`DeviceAddress`

This member is used only if **Version** = DEVICE_DESCRIPTION_VERSION3.

For a subordinate DMA device, **DeviceAddress** is the memory-mapped address of the data register on the device that is used as the source or destination for a DMA transfer. This data register is located at a known, device-specific offset from the device start address. The width of this register is specified by the **DmaWidth** member. The device driver obtains the device start address from the resource list it receives in the **IRP_MN_START_DEVICE** request that starts the device. For more information about this address, see the description of the **u.Memory.Start** member in CM_PARTIAL_RESOURCE_DESCRIPTOR.

For a bus-master DMA device, the **DeviceAddress** member is not used.

Remarks

The driver of a device that uses DMA to transfer data uses the **DEVICE_DESCRIPTION** structure to pass information about the device to the IoGetDmaAdapter routine. The driver calls this routine to request an adapter object for a physical device object (PDO). This PDO represents the device's physical connection to the I/O bus to use for DMA. For more information, see Getting an Adapter Object.

To allocate resources for a DMA controller, the I/O manager needs information about the controller but can obtain some of this information only from a driver. For example, the driver for a bus-master device knows whether the device supports scatter/gather DMA or uses full 32-bit addresses. Or, the driver for a subordinate device can determine the DMA channel number from the resource list that the driver receives in the IRP_MN_START_DEVICE request that starts the device. The driver uses the **DEVICE_DESCRIPTION** structure to pass this information to the I/O manager.

Before calling **IoGetDmaAdapter**, the driver should first zero-initialize the entire **DEVICE_DESCRIPTION** structure, then fill in selected members to describe the device.

The **InterfaceType** member specifies the type of bus interface that will be used for DMA. If you set **InterfaceType** to **InterfaceTypeUndefined**, **IoGetDmaAdapter** queries the PDO to determine the correct interface type for your device. Or, you can specify an explicit interface type, such as **Internal**, **Isa**, **Eisa**, or **PCIBus**. For more information, see the list of supported interface types in INTERFACE_TYPE.

If the **ScatterGather** member is set to **TRUE** and the **InterfaceType** member is set to **PCIBus**, the **Dma32BitAddresses** member is ignored and **IoGetDmaAdapter** assumes that the device supports 32-bit DMA addresses.

If the **Dma64BitAddresses** member is set to **TRUE**, the **Dma32BitAddresses** member is ignored and **IoGetDmaAdapter** assumes that the device supports 64-bit DMA addresses.

To indicate that the DMA controller hardware cannot reliably maintain an accurate transfer count, set **IgnoreCount** to **TRUE**, and set **Version** to a value other than DEVICE_DESCRIPTION_VERSION. In a platform that has such a DMA controller, the operating system ignores the DMA transfer counter but must take special

precautions to maintain data integrity during DMA operations. Typically, the use of a workaround to compensate for a deficient DMA controller degrades the speed of DMA transfers.

A driver should specify **TypeF** as the **DmaSpeed** value only if the computer's ACPI firmware supports it.

Requirements

Minimum supported client	Supported starting with Windows 2000.

DEVICE_INSTALL_STATE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **DEVICE_INSTALL_STATE** enumeration describes a device's installation state.

Syntax

```
typedef enum _DEVICE_INSTALL_STATE {
  InstallStateInstalled,
  InstallStateNeedsReinstall,
  InstallStateFailedInstall,
  InstallStateFinishInstall
} DEVICE_INSTALL_STATE, *PDEVICE_INSTALL_STATE;
```

Constants

InstallStateInstalled	The device is installed.
InstallStateNeedsReinstall	The system will try to reinstall the device on a later enumeration.
InstallStateFailedInstall	The device did not install properly.
InstallStateFinishInstall	The installation of this device is not yet complete.

Remarks

The IoGetDeviceProperty routine supplies a **DEVICE_INSTALL_STATE** enumeration value when a driver requests **DevicePropertyInstallState**. The operating system uses the value as a hint about the install state of the device.

Requirements

Minimum supported client	Available in Microsoft Windows XP and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h)

DEVICE_INTERFACE_CHANGE_NOTIFICATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **DEVICE_INTERFACE_CHANGE_NOTIFICATION** structure describes a device interface that has been enabled (arrived) or disabled (removed). The PnP manager sends this structure to a driver that registered a callback routine for notification of **EventCategoryDeviceInterfaceChange** events.

Syntax

```
typedef struct _DEVICE_INTERFACE_CHANGE_NOTIFICATION {
  USHORT          Version;
  USHORT          Size;
  GUID            Event;
  GUID            InterfaceClassGuid;
  PUNICODE_STRING SymbolicLinkName;
} DEVICE_INTERFACE_CHANGE_NOTIFICATION, *PDEVICE_INTERFACE_CHANGE_NOTIFICATION;
```

Members

`Version`

Specifies the version of the data structure, currently 1.

`Size`

Specifies the size of the structure, in bytes, including the size of the standard first three members plus the event-specific data.

`Event`

Specifies a GUID identifying the event: GUID_DEVICE_INTERFACE_ARRIVAL or GUID_DEVICE_INTERFACE_REMOVAL. The GUIDs are defined in Wdmguid.h.

`InterfaceClassGuid`

Specifies the class of the device interface that has just been enabled or disabled.

`SymbolicLinkName`

Pointer to a Unicode string that contains the name of the symbolic link for the device interface.

Remarks

This structure is allocated from paged memory.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

DEVICE_OBJECT structure

1/30/2019 • 11 minutes to read • Edit Online

The **DEVICE_OBJECT** structure is used by the operating system to represent a device object. A device object represents a logical, virtual, or physical device for which a driver handles I/O requests.

Syntax

```
typedef struct _DEVICE_OBJECT {
  CSHORT                    Type;
  USHORT                    Size;
  LONG                      ReferenceCount;
  struct _DRIVER_OBJECT     *DriverObject;
  struct _DEVICE_OBJECT     *NextDevice;
  struct _DEVICE_OBJECT     *AttachedDevice;
  struct _IRP               *CurrentIrp;
  PIO_TIMER                 Timer;
  ULONG                     Flags;
  ULONG                     Characteristics;
  __volatile PVPB           Vpb;
  PVOID                     DeviceExtension;
  DEVICE_TYPE               DeviceType;
  CCHAR                     StackSize;
  union {
    LIST_ENTRY         ListEntry;
    WAIT_CONTEXT_BLOCK Wcb;
  } Queue;
  ULONG                     AlignmentRequirement;
  KDEVICE_QUEUE             DeviceQueue;
  KDPC                      Dpc;
  ULONG                     ActiveThreadCount;
  PSECURITY_DESCRIPTOR      SecurityDescriptor;
  KEVENT                    DeviceLock;
  USHORT                    SectorSize;
  USHORT                    Spare1;
  struct _DEVOBJ_EXTENSION *DeviceObjectExtension;
  PVOID                     Reserved;
} DEVICE_OBJECT, *PDEVICE_OBJECT;
```

Members

`Type`

Used by the operating system to indicate that an object is a device object. For device objects, the value of this member is 3. This is a read-only member.

`Size`

Specifies the size, in bytes, of the device object. This size includes the driver-specified device extension pointed to by the **DeviceExtension** member, but does not include the opaque device object extension pointed to by the **DeviceObjectExtension** member. **Size** is a read-only member.

`ReferenceCount`

Used by the I/O manager to track the number of open handles for the device that are associated with the device object. This allows the I/O manager to avoid unloading a driver when there are outstanding handles for the driver's

device(s). This is a read-only member.

`DriverObject`

A pointer to the driver object (DRIVER_OBJECT), that represents the loaded image of the driver that was input to the DriverEntry and AddDevice routines. This member is set by the I/O manager upon a successful call to IoCreateDevice or IoCreateDeviceSecure. This is a read-only member.

`NextDevice`

A pointer to the next device object, if any, that was created by the same driver. The I/O manager updates this list at each successful call to IoCreateDevice or IoCreateDeviceSecure.

A non- Plug and Play (PnP) driver that is being unloaded must traverse ("walk") the list of its device objects and delete them. A PnP driver does not have to walk this list of device objects. Instead, PnP drivers perform their cleanup during the device removal PnP operation (IRP_MN_REMOVE_DEVICE).

A driver that recreates its device objects dynamically also uses this member. This is a read/write member.

`AttachedDevice`

A pointer to the attached device object. If there is no attached device object, this member is **NULL**. The device object that is pointed to by the **AttachedDevice** member typically is the device object of a filter driver, which intercepts I/O requests originally targeted to the device represent by the device object. For more information, see the IoAttachDevice and IoAttachDeviceByPointer topics. This is an opaque member.

`CurrentIrp`

A pointer to the current IRP if the driver has a StartIo routine whose entry point was set in the driver object and if the driver is currently processing IRP(s). Otherwise, this member is **NULL**. For more information, see the IoStartPacket and IoStartNextPacket topics. This is a read-only member.

`Timer`

A pointer to a timer object. This allows the I/O manager to call a driver-supplied timer routine every second. For more information, see IoInitializeTimer. This is a read/write member.

`Flags`

Device drivers perform a bitwise **OR** operation with this member in their newly created device objects by using one or more of the following system-defined values:

DO_BUFFERED_IO or DO_DIRECT_IO

Specifies the type of buffering that is used by the I/O manager for I/O requests that are sent to the device stack. Higher-level drivers OR this member with the same value as the next-lower driver in the stack, except possibly for highest-level drivers.

DO_BUS_ENUMERATED_DEVICE

The operating system sets this flag in each physical device object (PDO). Drivers must not modify this flag.

DO_DEVICE_INITIALIZING

The I/O manager sets this flag when it creates the device object. A device function driver or filter driver clears the flag in its AddDevice routine, after it does the following:

- Attaches the device object to the device stack.
- Establishes the device power state.
- Performs a bitwise OR operation on the member with one of the power flags (if it is necessary).

The Plug and Play (PnP) manager checks that the flag is clear after the AddDevice routine returns.

DO_EXCLUSIVE

Indicates that the driver services an exclusive device, such as a video, serial, parallel, or sound device. WDM drivers must not set this flag. For more information, see the Specifying Exclusive Access to Device Objects topic.

DO_MAP_IO_BUFFER

This flag is no longer used. Drivers should not set this flag.

DO_POWER_INRUSH

Drivers of devices that require inrush current when the device is turned on must set this flag. A driver cannot set both this flag and DO_POWER_PAGABLE.

DO_POWER_PAGABLE

Pageable drivers that are compatible with Microsoft Windows 2000 and later versions of Windows, are not part of the paging path, and do not require inrush current must set this flag. The system calls such drivers at IRQL = PASSIVE_LEVEL. Drivers cannot set both this flag and DO_POWER_INRUSH. All drivers for WDM, Microsoft Windows 98, and Windows Millennium Edition must set DO_POWER_PAGABLE.

DO_SHUTDOWN_REGISTERED

Used by the I/O manager to indicate that a driver has registered the device object for shutdown notifications. This flag should not be used by drivers.

DO_VERIFY_VOLUME

Removable-media drivers set this flag while they process transfer requests. Such drivers should also check for this flag in the target for a transfer request before they transfer any data. For more information, see the Supporting Removable Media topic.

For more information about how to set the **Flags** member, see Initializing a Device Object.

`Characteristics`

Specifies one or more system-defined constants, combined with a bitwise OR operation, that provide additional information about the driver's device. These constants include the following:

FILE_AUTOGENERATED_DEVICE_NAME

Directs the I/O manager to generate a name for the device, instead of the caller specifying a *DeviceName* when it calls this routine. The I/O manager makes sure that the name is unique. This characteristic is typically specified by a PnP bus driver to generate a name for a physical device object (PDO) for a child device on the same bus. This characteristic is new starting with Microsoft Windows 2000 and Microsoft Windows 98.

FILE_CHARACTERISTIC_PNP_DEVICE

Indicates that the device object is part of a Plug and Play (PnP) stack. This characteristic is required if a bus driver (or bus filter driver) registers WMI support for a device object that has not yet received the IRP_MN_START_DEVICE request. FILE_CHARACTERISTIC_PNP_DEVICE is also required if a function or filter driver registers for WMI before attaching to its device stack.

FILE_CHARACTERISTIC_TS_DEVICE

Indicates that the device object is part of a Terminal Services device stack. Drivers should not set this characteristic.

FILE_CHARACTERISTIC_WEBDAV_DEVICE

Indicates that a Web-based Distributed Authoring and Versioning (WebDAV) file system is mounted on the device. Drivers should not set this characteristic.

FILE_DEVICE_IS_MOUNTED

Indicates that a file system is mounted on the device. Drivers should not set this characteristic.

FILE_DEVICE_SECURE_OPEN

Directs the I/O manager to apply the security descriptor of the device object to relative opens and trailing file name opens for the device. For more information, see the Controlling Device Namespace Access topic.

FILE_FLOPPY_DISKETTE

Indicates that the device is a floppy disk device.

FILE_READ_ONLY_DEVICE

Indicates that the device cannot be written to.

FILE_REMOTE_DEVICE

Indicates that the device is remote.

FILE_REMOVABLE_MEDIA

Indicates that the storage device supports removable media. Notice that this characteristic indicates removable *media*, not a removable *device*. For example, drivers for JAZ drive devices should specify this characteristic, but drivers for PCMCIA flash disks should not.

FILE_VIRTUAL_VOLUME

Indicates that the volume is virtual. Drivers should not set this characteristic.

FILE_WRITE_ONCE_MEDIA

Indicates that the device supports write-once media. Drivers do not set this member directly. For more information about how to set device characteristics, see the Specifying Device Characteristics topic.

FILE_CHARACTERISTIC_CSV

Indicates that the device is a Cluster Shared Volume (CSV).

FILE_DEVICE_ALLOW_APPCONTAINER_TRAVERSAL

The IO Manager normally performs a full security check for traverse access on every file open when the client is an app container. Setting of this flag bypasses this enforced traverse access check if the client token already has traverse privileges.

FILE_PORTABLE_DEVICE

Indicates that the underlying stack considers the device portable. This is used by the storage stack and means that the device is not in the local machine container and is not on a fixed bus type.

`Vpb`

A pointer to the volume parameter block (VPB) that is associated with the device object. For file system drivers, the VPB can provide a connection to any unnamed logical device object that represents an instance of a mounted volume. This is an opaque member.

`DeviceExtension`

A pointer to the device extension. The structure and contents of the device extension are driver-defined. The size is driver-determined, specified in the driver's call to IoCreateDevice or IoCreateDeviceSecure. For more information about device extensions, see Device Extensions. This is a read-only member. However, the object that the member points to can be modified by the driver.

`DeviceType`

Set by IoCreateDevice and IoCreateDeviceSecure by using the value that is specified for that routine's *DeviceType* parameter. For more information, see the Specifying Device Types topic.

`StackSize`

Specifies the minimum number of stack locations in IRPs to be sent to this driver. IoCreateDevice and IoCreateDeviceSecure set this member to 1 in newly created device objects; lowest-level drivers can therefore ignore this member. The I/O manager automatically sets the **StackSize** member in a higher-level driver's device object to the appropriate value if the driver calls IoAttachDevice or IoAttachDeviceToDeviceStack. Only a higher-level driver that chains itself over another driver with **IoGetDeviceObjectPointer** must explicitly set the value of **StackSize** in its own device object(s) to 1 + the **StackSize** value of the next-lower driver's device object.

`Queue`

Used internally by the I/O manager to queue the device object when it is required. This is an opaque member.

`Queue.ListEntry`

A LIST_ENTRY structure that contains forward and backward pointers for a doubly linked list.

`Queue.Wcb`

Device context information used by I/O manager.

`AlignmentRequirement`

Specifies the device's address alignment requirement for data transfers. The value must be one of the FILE_*XXX*_ALIGNMENT values that are defined in Wdm.h. For more information, see the Initializing a Device Object, GetDmaAlignment, and ZwQueryInformationFile topics.

`DeviceQueue`

The device queue object for the device object. The device queue object contains any IRPs that are waiting to be processed by the driver that is associated with the device object. For more information, see the Driver-Managed IRP Queues topic. This is an opaque member.

`Dpc`

The deferred procedure call (DPC) object for the device object. For more information, see the Introduction to DPC Objects topic. This is an opaque member.

`ActiveThreadCount`

Reserved for future use. This is an opaque member.

`SecurityDescriptor`

Specifies a security descriptor (SECURITY_DESCRIPTOR) for the device object when the device object is created. If this member is **NULL**, the device object receives default security settings. This is a read-only member, although the member can be modified through the ZwSetSecurityObjectfunction.

`DeviceLock`

A synchronization event object that is allocated by the I/O manager. The I/O manager obtains his event object before it dispatches a mount or mount-verify request to a file-system driver. This is an opaque member.

`SectorSize`

If the device object does not represent a volume, this member is set to zero. If the device object represents a volume, this member specifies the volume's sector size, in bytes. The I/O manager uses this member to make sure that all read operations, write operations, and set file position operations that are issued are aligned correctly when intermediate buffering is disabled. A default system bytes-per-sector value is used when the device object is created, however, file system drivers; and more rarely, legacy and minifilter drivers, can update this value that is based on the geometry of the underlying volume hardware when a mount occurs. Other drivers should not modify this member.

`Spare1`

Reserved for system use. This is an opaque member.

`DeviceObjectExtension`

A pointer to a device object extension that is used by the I/O manager and PnP manager to store information about the state of the device. This is an opaque member.

`Reserved`

Reserved for system use. This is an opaque member.

Remarks

The operating system represents devices by device objects. For more information, see the Device Objects and Device Stacks topic.

Drivers create device objects by using the IoCreateDevice and IoCreateDeviceSecure routines. For more information about how to create device objects, see Creating a Device Object.

A device object is partially opaque. Drivers do not set members of the device object directly, unless otherwise documented. For more information about the members that drivers can modify directly, see Initializing a Device Object. For information about other device object properties, see Properties of Device Objects.

Opaque members within a device object must be considered inaccessible. Drivers that have dependencies on object member locations or access to opaque members might not remain portable and interoperable with other drivers over time.

The system-supplied video port driver sets up the fields of the device objects that it creates on behalf of video miniport drivers.

The system-supplied SCSI port driver sets up the fields of the device objects that it creates on behalf of SCSI miniport drivers.

The system-supplied NDIS library sets up the fields of the device objects that it creates on behalf of NDIS miniport drivers.

DEVICE_POWER_STATE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **DEVICE_POWER_STATE** enumeration type indicates a device power state.

Syntax

```
typedef enum _DEVICE_POWER_STATE {
  PowerDeviceUnspecified,
  PowerDeviceD0,
  PowerDeviceD1,
  PowerDeviceD2,
  PowerDeviceD3,
  PowerDeviceMaximum
} DEVICE_POWER_STATE, *PDEVICE_POWER_STATE;
```

Constants

PowerDeviceUnspecified	Indicates an unspecified device power state.
PowerDeviceD0	Indicates a maximum device power state, which corresponds to device working state D0.
PowerDeviceD1	Indicates a device sleeping state less than **PowerDeviceD0** and greater than **PowerDeviceD2**, which corresponds to device power state D1.
PowerDeviceD2	Indicates a device sleeping state less than **PowerDeviceD1** and greater than **PowerDeviceD3**, which corresponds to device power state D2.
PowerDeviceD3	Indicates the lowest-powered device sleeping state, which corresponds to device power state D3.
PowerDeviceMaximum	The number of device power state values for this enumeration type that represent actual power states. The value of the other device power states is less than this value.

Remarks

A power state indicates the level of power consumption—and thus the extent of computing activity—by the system or by a single device. The power manager sets the power state of the system as a whole, where the system power state is indicated by one of the values of the SYSTEM_POWER_STATE enumeration type. Device drivers set the power state of their individual devices, where the device power state is indicated by one of the values of the **DEVICE_POWER_STATE** enumeration type.

For more information about system power states, see Handling System Power State Requests. For more information about device power states, see Managing Power for Individual Devices. For more information about power management in general, see Introduction to Power Management.

Requirements

Header	wdm.h (include Wdm.h, Ntpoapi.h)

SYSTEM_POWER_STATE

DEVICE_REMOVAL_POLICY Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **DEVICE_REMOVAL_POLICY** enumeration describes a device's removal policy.

Syntax

```
typedef enum _DEVICE_REMOVAL_POLICY {
  RemovalPolicyExpectNoRemoval,
  RemovalPolicyExpectOrderlyRemoval,
  RemovalPolicyExpectSurpriseRemoval
} DEVICE_REMOVAL_POLICY, *PDEVICE_REMOVAL_POLICY;
```

Constants

RemovalPolicyExpectNoRemoval	The device is not typically removed.
RemovalPolicyExpectOrderlyRemoval	The device is typically removed in an orderly fashion. (Before the device is removed, the Plug and Play [PnP] manager sends an IRP_MN_QUERY_REMOVE_DEVICE request to the device's driver.)
RemovalPolicyExpectSurpriseRemoval	The device can be removed suddenly. (The driver receives no advance warning that the device will be removed. The Plug and Play [PnP] manager sends an IRP_MN_SURPRISE_REMOVAL request when the device is removed.)

Remarks

The IoGetDeviceProperty routine supplies a **DEVICE_REMOVAL_POLICY** enumeration value when a driver requests **DevicePropertyRemovalPolicy**. The operating system uses the value as a hint as to how the device is typically removed from the computer.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h)

DEVICE_RESET_INTERFACE_STANDARD structure

1/30/2019 • 2 minutes to read • Edit Online

The **DEVICE_RESET_INTERFACE_STANDARD** structure enables function drivers to reset and recover malfunctioning devices. This structure describes the GUID_DEVICE_RESET_INTERFACE_STANDARD interface. For more information see Working with the GUID_DEVICE_RESET_INTERFACE_STANDARD.

Syntax

```
typedef struct _DEVICE_RESET_INTERFACE_STANDARD {
  USHORT                 Size;
  USHORT                 Version;
  PVOID                  Context;
  PINTERFACE_REFERENCE   InterfaceReference;
  PINTERFACE_DEREFERENCE InterfaceDereference;
  PDEVICE_RESET_HANDLER  DeviceReset;
  ULONG                  SupportedResetTypes;
  PVOID                  Reserved;
} DEVICE_RESET_INTERFACE_STANDARD, *PDEVICE_RESET_INTERFACE_STANDARD;
```

Members

`Size`

The size, in bytes, of this structure.

`Version`

The driver-defined interface version.

`Context`

A pointer to interface-specific context information

`InterfaceReference`

A pointer to an InterfaceReference routine that increments the interface's reference count.

`InterfaceDereference`

A pointer to an InterfaceDereference routine that decrements the interface's reference count.

`DeviceReset`

A pointer to the interface's DeviceReset routine. This routine can be used by function drivers to attempt to reset and recover a malfunctioning device.

`SupportedResetTypes`

`Reserved`

This member is reserved for future use.

Remarks

The **DEVICE_RESET_INTERFACE_STANDARD** structure is an extension of the INTERFACE structure. A driver

obtains a pointer to the **DEVICE_RESET_INTERFACE_STANDARD** structure by sending an IRP_MN_QUERY_INTERFACE IRP to its bus driver with **InterfaceType** set to GUID_DEVICE_RESET_INTERFACE_STANDARD.

For more information about the purpose of this interface, see Working with the GUID_DEVICE_RESET_INTERFACE_STANDARD.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	wdm.h

DEVICE_RESET_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **DEVICE_RESET_TYPE** enumeration specifies the type of device reset that is being requested by a call to the DeviceReset routine of the GUID_DEVICE_RESET_INTERFACE_STANDARD interface. For more information see Working with the GUID_DEVICE_RESET_INTERFACE_STANDARD.

Syntax

```
typedef enum _DEVICE_RESET_TYPE {
  FunctionLevelDeviceReset,
  PlatformLevelDeviceReset
} DEVICE_RESET_TYPE;
```

Constants

FunctionLevelDeviceReset	A function-level device reset, which is restricted to a specific device.
PlatformLevelDeviceReset	A platform-level device reset, which affects a specific device and all other devices that are connected to it via the same power rail or reset line.

Requirements

Header	wdm.h

See Also

DEVICE_RESET_INTERFACE_STANDARD

DeviceReset

DEVICE_WAKE_DEPTH Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **DEVICE_WAKE_DEPTH** enumeration specifies the deepest device power state from which a device can trigger a wake signal.

Syntax

```
typedef enum _DEVICE_WAKE_DEPTH {
  DeviceWakeDepthNotWakeable,
  DeviceWakeDepthD0,
  DeviceWakeDepthD1,
  DeviceWakeDepthD2,
  DeviceWakeDepthD3hot,
  DeviceWakeDepthD3cold,
  DeviceWakeDepthMaximum
} DEVICE_WAKE_DEPTH, *PDEVICE_WAKE_DEPTH;
```

Constants

DeviceWakeDepthNotWakeable	There is no device power state that can trigger a wake signal.
DeviceWakeDepthD0	D0 is the deepest device power state from which the device can trigger a wake signal. For more information, see Remarks.
DeviceWakeDepthD1	D1 is the deepest low-power device power state from which the device can trigger a wake signal.
DeviceWakeDepthD2	D2 is the deepest low-power device power state from which the device can trigger a wake signal.
DeviceWakeDepthD3hot	D3hot is the deepest low-power device power state from which the device can trigger a wake signal.
DeviceWakeDepthD3cold	D3cold is the deepest low-power device power state from which the device can trigger a wake signal.
DeviceWakeDepthMaximum	Reserved for use by the operating system.

Remarks

The *DeepestWakeableDstate* parameter of the GetIdleWakeInfo routine is a pointer to a variable of type **DEVICE_WAKE_DEPTH**.

The drivers for most devices have no reason to arm a wake signal when the device is in D0. These drivers can treat the **DeviceWakeDepthD0** output value as equivalent to a call to the *GetIdleWakeInfo* routine that fails and returns an error status.

Requirements

Header	wdm.h (include Wdm.h)

See Also

GetIdleWakeInfo

DMA_ADAPTER structure

1/30/2019 • 2 minutes to read • Edit Online

The **DMA_ADAPTER** structure describes a system-defined interface to a DMA controller for a given device. A driver calls IoGetDmaAdapter to obtain this structure.

Syntax

```
typedef struct _DMA_ADAPTER {
  USHORT          Version;
  USHORT          Size;
  PDMA_OPERATIONS DmaOperations;
} *PADAPTER_OBJECT, DMA_ADAPTER, *PDMA_ADAPTER;
```

Members

`Version`

Specifies the version of this structure. Version 3 of the **DMA_ADAPTER** structure is available starting with Windows 8. For versions 1 and 2 of this structure, this member is set to the value 1. For more information, see the following Remarks section.

`Size`

Specifies the size, in bytes, of this structure.

`DmaOperations`

Pointer to a DMA_OPERATIONS structure that contains pointers to DMA adapter functions. The version of the **DMA_OPERATIONS** structure that this member points to is determined by the version of the **DMA_ADAPTER** structure. Thus, for version 1 of the **DMA_ADAPTER** structure, *DmaOperations* points to version 1 of the **DMA_OPERATIONS** structure, and so on. For more information about structure versions, see the following Remarks section.

Remarks

Drivers for devices that use DMA to transfer data use this structure to obtain the addresses of functions that enable use of a DMA controller. Usually, drivers obtain this structure by calling the IoGetDmaAdapter routine. Drivers can also obtain this structure by querying for the BUS_INTERFACE_STANDARD interface.

> **Note** When the **IoGetDmaAdapter** routine returns a pointer to version 1 or version 2 of the **DMA_ADAPTER** structure, this routine always sets the **Version** member of this structure to 1. Thus, the caller cannot use the **Version** member to distinguish between versions 1 and 2 of the **DMA_ADAPTER** structure. For more information about how to determine the version of a **DMA_ADAPTER** structure that is returned by this routine, see IoGetDmaAdapter.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

BUS_INTERFACE_STANDARD

DMA_OPERATIONS

IoGetDmaAdapter

DMA_ADAPTER_INFO structure

2/5/2019 • 2 minutes to read • Edit Online

The **DMA_ADAPTER_INFO** structure is a container for a **DMA_ADAPTER_INFO**_*XXX* structure that describes the capabilities of a system DMA controller.

Syntax

```
typedef struct _DMA_ADAPTER_INFO {
  ULONG Version;
  union {
    DMA_ADAPTER_INFO_V1 V1;
  };
} DMA_ADAPTER_INFO, *PDMA_ADAPTER_INFO;
```

Members

`Version`

The version number of the **DMA_ADAPTER_INFO**_*XXX* structure that follows this member. For a DMA_ADAPTER_INFO_V1 structure, set this member to DMA_ADAPTER_INFO_VERSION1 before calling the GetDmaAdapterInfo routine.

`V1`

The capabilities of the bus-master DMA device or the system DMA controller. For more information, see DMA_ADAPTER_INFO_V1.

Remarks

A device driver calls the GetDmaAdapterInfo routine to obtain a **DMA_ADAPTER_INFO** structure that describes the capabilities of a DMA controller.

The unnamed union in this structure contains a **DMA_ADAPTER_INFO**_*XXX* structure. The **Version** member indicates which version of the **DMA_ADAPTER_INFO**_*XXX* structure is contained in the union. Currently, only version 1 is supported.

Requirements

Minimum supported client	Supported starting with Windows 8.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

DMA_ADAPTER_INFO_V1

GetDmaAdapterInfo

DMA_ADAPTER_INFO_V1 structure

1/30/2019 • 2 minutes to read • Edit Online

The **DMA_ADAPTER_INFO_V1** structure describes the capabilities of the system DMA controller that is represented by an adapter object.

Syntax

```
typedef struct _DMA_ADAPTER_INFO_V1 {
  ULONG ReadDmaCounterAvailable;
  ULONG ScatterGatherLimit;
  ULONG DmaAddressWidth;
  ULONG Flags;
  ULONG MinimumTransferUnit;
} DMA_ADAPTER_INFO_V1, *PDMA_ADAPTER_INFO_V1;
```

Members

`ReadDmaCounterAvailable`

Whether the counter value in each DMA channel can be read. This member is **TRUE** if the counter can be read, and is **FALSE** if it cannot be read.

`ScatterGatherLimit`

The maximum number of elements in a scatter/gather list that the DMA controller can process in a single scatter/gather DMA transfer.

`DmaAddressWidth`

The memory address width, in bits, of the DMA controller. The width is expressed as the number of bits in a DMA address. If the DMA address width is less than the memory address width, the platform hardware drives the remaining, high-order memory address bits to zero during a DMA transfer.

`Flags`

A set of flags that describe the capabilities of the DMA adapter. No flags are currently defined for this member.

`MinimumTransferUnit`

The size, in bytes, of the minimum transfer unit. The number of bytes specified by an element in a scatter/gather list must be an integer multiple of the minimum transfer unit.

Remarks

The **V1** member of the DMA_ADAPTER_INFO structure is a structure of type **DMA_ADAPTER_INFO_V1**.

A driver calls GetDmaAdapterInfo to obtain information about the hardware capabilities of a system DMA channel. **GetDmaAdapterInfo** writes this information into the **V1** member of a caller-supplied **DMA_ADAPTER_INFO** structure.

Requirements

Minimum supported client	Supported starting with Windows 8.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

  PFREE_ADAPTER_OBJECT                  FreeAdapterObject;
  PCANCEL_MAPPED_TRANSFER               CancelMappedTransfer;
  PALLOCATE_DOMAIN_COMMON_BUFFER        AllocateDomainCommonBuffer;
  PFLUSH_DMA_BUFFER                     FlushDmaBuffer;
  PJOIN_DMA_DOMAIN                      JoinDmaDomain;
  PLEAVE_DMA_DOMAIN                     LeaveDmaDomain;
  PGET_DMA_DOMAIN                       GetDmaDomain;
  PALLOCATE_COMMON_BUFFER_WITH_BOUNDS AllocateCommonBufferWithBounds;
} *PDMA_OPERATIONS, DMA_OPERATIONS;
```

Members

`Size`

The size, in bytes, of this **DMA_OPERATIONS** structure.

`PutDmaAdapter`

A pointer to a system-defined routine to free a DMA_ADAPTER structure. For more information, see PutDmaAdapter.

`AllocateCommonBuffer`

A pointer to a system-defined routine to allocate a physically contiguous DMA buffer. For more information, see AllocateCommonBuffer.

`FreeCommonBuffer`

A pointer to a system-defined routine to free a physically contiguous DMA buffer previously allocated by **AllocateCommonBuffer**. For more information, see FreeCommonBuffer.

`AllocateAdapterChannel`

A pointer to a system-defined routine to allocate a channel for DMA operations. For more information, see AllocateAdapterChannel.

`FlushAdapterBuffers`

A pointer to a system-defined routine to flush data from the system or bus-master adapter's internal cache after a DMA operation. For more information, see FlushAdapterBuffers.

`FreeAdapterChannel`

A pointer to a system-defined routine to free a channel previously allocated for DMA operations by **AllocateAdapterChannel**. For more information, see FreeAdapterChannel.

`FreeMapRegisters`

A pointer to a system-defined routine to free map registers allocated for DMA operations. For more information, see FreeMapRegisters.

`MapTransfer`

A pointer to a system-defined routine to begin a DMA operation. For more information, see MapTransfer.

`GetDmaAlignment`

A pointer to a system-defined routine to obtain the DMA alignment requirements of the controller. For more information, see GetDmaAlignment.

`ReadDmaCounter`

A pointer to a system-defined routine to obtain the current transfer count for a DMA operation. For more information, see ReadDmaCounter.

`GetScatterGatherList`

A pointer to a system-defined routine that allocates map registers and creates a scatter/gather list for DMA. For more information, see GetScatterGatherList.

`PutScatterGatherList`

A pointer to a system-defined routine that frees map registers and a scatter/gather list after a DMA operation is complete. For more information, see PutScatterGatherList.

`CalculateScatterGatherList`

A pointer to a system-defined routine that determines the buffer size needed to hold the scatter/gather list that describes an I/O data buffer. This member is available only in versions 2 and later of **DMA_OPERATIONS**. For more information, see CalculateScatterGatherList.

`BuildScatterGatherList`

A pointer to a system-defined routine that allocates map registers and creates a scatter/gather list for DMA in a driver-supplied buffer. This member is available only in versions 2 and later of **DMA_OPERATIONS**. For more

information, see BuildScatterGatherList.

`BuildMdlFromScatterGatherList`

A pointer to a system-defined routine that builds an MDL corresponding to a scatter/gather list. This member is available only in versions 2 and later of **DMA_OPERATIONS**. For more information, see BuildMdlFromScatterGatherList.

`GetDmaAdapterInfo`

A pointer to a system-defined routine that describes the capabilities of a bus-master DMA device or a system DMA controller. **GetDmaAdapterInfo** is available only in version 3 of **DMA_OPERATIONS**. For more information, see GetDmaAdapterInfo.

`GetDmaTransferInfo`

A pointer to a system-defined routine that describes the allocation requirements for a scatter/gather list. This routine replaces CalculateScatterGatherList. **GetDmaTransferInfo** is available only in version 3 of **DMA_OPERATIONS**. For more information, see GetDmaTransferInfo.

`InitializeDmaTransferContext`

A pointer to a system-defined routine that initializes an opaque DMA transfer context. The operating system stores the internal status of a DMA transfer in this context. **InitializeDmaTransferContext** is available only in version 3 of **DMA_OPERATIONS**. For more information, see InitializeDmaTransferContext.

`AllocateCommonBufferEx`

A pointer to a system-defined routine that allocates memory for a common buffer and maps this memory so that it can accessed both by the processor and by a DMA device. **AllocateCommonBufferEx** is available only in version 3 of **DMA_OPERATIONS**. For more information, see AllocateCommonBufferEx.

`AllocateAdapterChannelEx`

A pointer to a system-defined routine that allocates the resources required for a DMA transfer and then calls the driver-supplied *AdapterControl* routine to initiate the DMA transfer. **AllocateAdapterChannelEx** is available only in version 3 of **DMA_OPERATIONS**. For more information, see AllocateAdapterChannelEx.

`ConfigureAdapterChannel`

A pointer to a system-defined routine enables a custom function that is implemented by the DMA controller. **ConfigureAdapterChannel** is available only in version 3 of **DMA_OPERATIONS**. For more information, see ConfigureAdapterChannel.

`CancelAdapterChannel`

A pointer to a system-defined routine that tries to cancel a pending request to allocate a DMA channel. **CancelAdapterChannel** is available only in version 3 of **DMA_OPERATIONS**. For more information, see CancelAdapterChannel.

`MapTransferEx`

A pointer to a system-defined routine that sets up map registers to map the physical addresses in a scatter/gather list to the logical addresses that are required to do a DMA transfer. **MapTransferEx** is available only in version 3 of **DMA_OPERATIONS**. For more information, see MapTransferEx.

`GetScatterGatherListEx`

A pointer to a system-defined routine that allocates resources required for a DMA transfer, builds a scatter/gather list, and then calls the driver-supplied AdapterListControl routine to initiate the DMA transfer.

GetScatterGatherListEx is available only in version 3 of **DMA_OPERATIONS**. For more information, see GetScatterGatherListEx. This routine is a wrapper of **AllocateAdapterChannelEx** and **MapTransferEx**.

`BuildScatterGatherListEx`

A pointer to a system-defined routine that builds a scatter/gather list in a caller-allocated buffer, and then calls the driver-supplied *AdapterListControl* routine to initiate the DMA transfer. **BuildScatterGatherListEx** is available only in version 3 of **DMA_OPERATIONS**. For more information, see BuildScatterGatherListEx.

`FlushAdapterBuffersEx`

A pointer to a system-defined routine that flushes any data that remains in the system DMA controller's internal cache or in a bus-master adapter's internal cache at the end of a DMA transfer. For a device that uses a system DMA controller, this routine cancels the current DMA transfer on the controller if the transfer is not complete. **FlushAdapterBuffersEx** is available only in version 3 of **DMA_OPERATIONS**. For more information, see FlushAdapterBuffersEx.

`FreeAdapterObject`

A pointer to a system-defined routine that releases the specified adapter object after a driver has completed all DMA operations. **FreeAdapterObject** is available only in version 3 of **DMA_OPERATIONS**. For more information, see FreeAdapterObject.

`CancelMappedTransfer`

A pointer to a system-defined routine that cancels a mapped transfer. **CancelMappedTransfer** is available only in version 3 of **DMA_OPERATIONS**. For more information, see CancelMappedTransfer.

`AllocateDomainCommonBuffer`

A pointer to a *PALLOCATE_DOMAIN_COMMON_BUFFER* callback routine to allocate a domain common buffer. This option is available in Windows 10 and later versions.

`FlushDmaBuffer`

A pointer to a *PFLUSH_DMA_BUFFER* callback function that flushes any data remaining in the cache. This option is available in Windows 10 and later versions.

`JoinDmaDomain`

A pointer to a *PJOIN_DMA_DOMAIN* callback function that joins the specified DMA domain. This option is available in Windows 10 and later versions.

`LeaveDmaDomain`

A pointer to a *PLEAVE_DMA_DOMAIN* callback function that leaves the specified DMA domain. This option is available in Windows 10 and later versions.

`GetDmaDomain`

A pointer to the *PGET_DMA_DOMAIN* callback function that gets a handle to the DMA domain. This option is available in Windows 10 and later versions.

`AllocateCommonBufferWithBounds`

A pointer to a *PALLOCATE_COMMON_BUFFER_WITH_BOUNDS* callback function that allocates the memory for a common buffer and maps it so that it can be accessed by a master device and the CPU. The common buffer can be bound by an optional minimum and maximum logical address. This option is available starting in Windows 10, version 1803.

Remarks

All members of this structure, with the exception of **Size**, are pointers to functions that drivers use to perform DMA operations for their devices. Drivers obtain these pointers by calling the IoGetDmaAdapter routine. The version of the **DMA_OPERATIONS** structure that this routine returns depends on the **Version** member of the DEVICE_DESCRIPTION structure that is passed to **IoGetDmaAdapter** as an input parameter. If **Version** is DEVICE_DESCRIPTION_VERSION or DEVICE_DESCRIPTION_VERSION1, version 1 of this structure is returned. If **Version** is DEVICE_DESCRIPTION_VERSION2, version 2 of this structure is returned. Version 2 of **DMA_OPERATIONS** is available starting with Windows XP. If **Version** is DEVICE_DESCRIPTION_VERSION3, version 3 of this structure is returned. Version 3 of **DMA_OPERATIONS** is available starting with Windows 8.

Requirements

Minimum supported client	Supported starting with Windows 2000.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

DMA_TRANSFER_INFO structure

2/5/2019 • 2 minutes to read • Edit Online

The **DMA_TRANSFER_INFO** structure is a container for a **DMA_TRANSFER_INFO_*XXX*** structure that describes the allocation requirements for a scatter/gather list.

Syntax

```
typedef struct _DMA_TRANSFER_INFO {
  ULONG Version;
  union {
    DMA_TRANSFER_INFO_V1 V1;
    DMA_TRANSFER_INFO_V2 V2;
  };
} DMA_TRANSFER_INFO, *PDMA_TRANSFER_INFO;
```

Members

`Version`

The version number of the **DMA_TRANSFER_INFO_*XXX*** structure that follows this member. For a DMA_TRANSFER_INFO_V1 structure, set this member to DMA_TRANSFER_INFO_VERSION1 before calling the GetDmaTransferInfo routine.

`V1`

The allocation requirements for a scatter/gather list. For more information, see DMA_TRANSFER_INFO_V1.

`V2`

The allocation requirements for a scatter/gather list. For more information, see **DMA_TRANSFER_INFO_V2**.

Remarks

A device driver calls the GetDmaTransferInfo routine to obtain a **DMA_TRANSFER_INFO** structure that describes the allocation requirements for the scatter/gather list to use in a DMA transfer.

The unnamed union in this structure contains a **DMA_TRANSFER_INFO_*XXX*** structure. The **Version** member indicates which version of the **DMA_TRANSFER_INFO_*XXX*** structure is contained in the union.

Requirements

Minimum supported client	Supported starting with Windows 8.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

DMA_TRANSFER_INFO_V1

DMA_TRANSFER_INFO_V1 structure

1/30/2019 • 2 minutes to read • Edit Online

The **DMA_TRANSFER_INFO_V1** structure contains the allocation requirements for a scatter/gather list that describes the I/O data buffer for a DMA transfer.

Syntax

```
typedef struct _DMA_TRANSFER_INFO_V1 {
  ULONG MapRegisterCount;
  ULONG ScatterGatherElementCount;
  ULONG ScatterGatherListSize;
} DMA_TRANSFER_INFO_V1, *PDMA_TRANSFER_INFO_V1;
```

Members

`MapRegisterCount`

The number of map registers required to translate all the physical addresses in the scatter/gather list to logical addresses.

`ScatterGatherElementCount`

The number of scatter/gather elements in the scatter/gather list. Each element is a structure of type **SCATTER_GATHER_ELEMENT**.

`ScatterGatherListSize`

The required size, in bytes, of the scatter/gather buffer. This buffer contains the scatter/gather list that describes the memory that is used to buffer I/O data during the DMA transfer. The scatter/gather buffer must be large enough to contain a SCATTER_GATHER_LIST structure and an array of **SCATTER_GATHER_ELEMENT** structures, plus additional data that is used internally by the operating system.

Remarks

The **V1** member of the DMA_TRANSFER_INFO structure is a structure of type **DMA_TRANSFER_INFO_V1**.

The *Mdl*, *Offset*, and *Length* parameters to the GetDmaTransferInfo routine together describe the I/O data buffer for a DMA transfer. For the purpose of programming a DMA controller, this buffer can more conveniently be described by a scatter/gather list. (A scatter/gather list describes the memory in an I/O data buffer but does not contain this memory.) A driver calls **GetDmaTransferInfo** to obtain the allocation requirements for this scatter/gather list. **GetDmaTransferInfo** writes the allocation requirements into the **V1** member of a caller-supplied **DMA_TRANSFER_INFO** structure.

Requirements

Minimum supported client	Supported starting with Windows 8.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

GetDmaTransferInfo

SCATTER_GATHER_LIST

DRIVER_OBJECT structure

1/30/2019 • 4 minutes to read • Edit Online

Each driver object represents the image of a loaded kernel-mode driver. A pointer to the driver object is an input parameter to a driver's DriverEntry, AddDevice, and optional Reinitialize routines and to its Unload routine, if any.

A driver object is partially opaque. Driver writers must know about certain members of a driver object to initialize a driver and to unload it if the driver is unloadable. The following members of the driver object are accessible to drivers.

Syntax

```
typedef struct _DRIVER_OBJECT {
  CSHORT             Type;
  CSHORT             Size;
  PDEVICE_OBJECT     DeviceObject;
  ULONG              Flags;
  PVOID              DriverStart;
  ULONG              DriverSize;
  PVOID              DriverSection;
  PDRIVER_EXTENSION  DriverExtension;
  UNICODE_STRING     DriverName;
  PUNICODE_STRING    HardwareDatabase;
  PFAST_IO_DISPATCH  FastIoDispatch;
  PDRIVER_INITIALIZE DriverInit;
  PDRIVER_STARTIO    DriverStartIo;
  PDRIVER_UNLOAD     DriverUnload;
  PDRIVER_DISPATCH   MajorFunction[IRP_MJ_MAXIMUM_FUNCTION + 1];
} DRIVER_OBJECT, *PDRIVER_OBJECT;
```

Members

`Type`

`Size`

`DeviceObject`

Pointer to the device objects created by the driver. This member is automatically updated when the driver calls IoCreateDevice successfully. A driver can use this member and the **NextDevice** member of DEVICE_OBJECT to step through a list of all the device objects that the driver created.

`Flags`

`DriverStart`

`DriverSize`

`DriverSection`

`DriverExtension`

Pointer to the driver extension. The only accessible member of the driver extension is **DriverExtension->AddDevice**, into which a driver's **DriverEntry** routine stores the driver's AddDevice routine.

`DriverName`

`HardwareDatabase`

Pointer to the **\Registry\Machine\Hardware** path to the hardware configuration information in the registry.

`FastIoDispatch`

Pointer to a structure defining the driver's fast I/O entry points. This member is used only by FSDs and network transport drivers.

`DriverInit`

The entry point for the DriverEntry routine, which is set up by the I/O manager.

`DriverStartIo`

The entry point for the driver's StartIo routine, if any, which is set by the **DriverEntry** routine when the driver initializes. If a driver has no *StartIo* routine, this member is **NULL**.

`DriverUnload`

The entry point for the driver's Unload routine, if any, which is set by the **DriverEntry** routine when the driver initializes. If a driver has no *Unload* routine, this member is **NULL**.

`MajorFunction`

A dispatch table consisting of an array of entry points for the driver's *DispatchXxx* routines. The array's index values are the **IRP_MJ_*XXX*** values representing each IRP major function code. Each driver must set entry points in this array for the **IRP_MJ_*XXX*** requests that the driver handles. For more information, see Writing Dispatch Routines.

To help Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools, each *DispatchXxx* routine is declared using the DRIVER_DISPATCH type, as shown in this code example:

```
DRIVER_DISPATCH DispatchXxx;
```

Then, the callback routine is implemented as follows:

```
_Use_decl_annotations_
NTSTATUS
  DispatchXxx(
    struct _DEVICE_OBJECT  *DeviceObject,
    struct _IRP  *Irp
    )
  {
      // Function body
  }
```

The DRIVER_DISPATCH function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the DRIVER_DISPATCH function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Remarks

Each kernel-mode driver's initialization routine should be named DriverEntry so the system will load the driver automatically. If this routine's name is something else, the driver writer must define the name of the initialization routine for the linker; otherwise, the system loader or I/O manager cannot find the driver's transfer address. The names of other standard driver routines can be chosen at the discretion of the driver writer.

A driver must set its *DispatchXxx* entry points in the driver object that is passed in to the **DriverEntry** routine when the driver is loaded. A device driver must set one or more *DispatchXxx* entry points for the **IRP_MJ_*XXX*** that any driver of the same type of device is required to handle. A higher-level driver must set one or more *DispatchXxx* entry points for all the **IRP_MJ_*XXX*** that it must pass on to the underlying device driver. Otherwise, a driver is not sent IRPs for any **IRP_MJ_*XXX*** for which it does not set up a *DispatchXxx* routine in the driver object. For more information about the set of **IRP_MJ_*XXX*** that drivers for different types of underlying devices are required to handle, see IRP Major Function Codes.

The **DriverEntry** routine also sets the driver's *AddDevice*, *StartIo* and/or Unload entry points, if any, in the driver object.

The **HardwareDatabase** string can be used by device drivers to get hardware configuration information from the registry when the driver is loaded. A driver is given read-only access to this string.

The *RegistryPath* input to the **DriverEntry** routine points to the **\Registry\Machine\System\CurrentControlSet\Services<i>DriverName** key, where the value entry of *DriverName* identifies the driver. As for the **HardwareDatabase** in the input driver object, a driver is given read-only access to this string.

Undocumented members within a driver object should be considered inaccessible. Drivers with dependencies on object member locations or on access to undocumented members might not remain portable and interoperable with other drivers over time.

Requirements

Unload

ENLISTMENT_BASIC_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **ENLISTMENT_BASIC_INFORMATION** structure contains information about an enlistment object.

Syntax

```
typedef struct _ENLISTMENT_BASIC_INFORMATION {
  GUID EnlistmentId;
  GUID TransactionId;
  GUID ResourceManagerId;
} ENLISTMENT_BASIC_INFORMATION, *PENLISTMENT_BASIC_INFORMATION;
```

Members

`EnlistmentId`

A GUID that KTM has assigned to the enlistment object.

`TransactionId`

A GUID that KTM has assigned to the transaction object that is associated with the enlistment object that the **EnlistmentId** member identifies.

`ResourceManagerId`

A GUID that KTM has assigned to the resource manager that created the enlistment.

Remarks

The **ENLISTMENT_BASIC INFORMATION** structure is used with the ZwQueryInformationEnlistment routine.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

ENLISTMENT_INFORMATION_CLASS

ZwQueryInformationEnlistment

ENLISTMENT_INFORMATION_CLASS Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **ENLISTMENT_INFORMATION_CLASS** enumeration identifies the type of information that the ZwSetInformationEnlistment routine can set and that the ZwQueryInformationEnlistment routine can retrieve for an enlistment object.

Syntax

```
typedef enum _ENLISTMENT_INFORMATION_CLASS {
  EnlistmentBasicInformation,
  EnlistmentRecoveryInformation,
  EnlistmentCrmInformation
} ENLISTMENT_INFORMATION_CLASS;
```

Constants

EnlistmentBasicInformation	Information about an enlistment object is stored in an ENLISTMENT_BASIC_INFORMATION structure.
EnlistmentRecoveryInformation	A resource manager is setting or obtaining customized recovery information for an enlistment. To learn more about recovery information, see ZwSetInformationEnlistment.
EnlistmentCrmInformation	Information about an enlistment object is stored in an **ENLISTMENT_CRM_INFORMATION** structure.

Requirements

Minimum supported client	Available starting with Windows Vista.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

ENLISTMENT_BASIC_INFORMATION

ZwQueryInformationEnlistment

ZwSetInformationEnlistment

EXT_DELETE_PARAMETERS structure

1/30/2019 • 2 minutes to read • Edit Online

The **EXT_DELETE_PARAMETERS** structure contains an extended set of parameters for the ExDeleteTimer routine.

Syntax

```
typedef struct _EXT_DELETE_PARAMETERS {
  ULONG                Version;
  ULONG                Reserved;
  PEXT_DELETE_CALLBACK DeleteCallback;
  PVOID                DeleteContext;
} EXT_DELETE_PARAMETERS, *PEXT_DELETE_PARAMETERS;
```

Members

`Version`

The version number of this **EXT_DELETE_PARAMETERS** structure. The ExInitializeDeleteTimerParameters routine sets this member to the correct version number.

`Reserved`

Set to zero. The **ExInitializeDeleteTimerParameters** routine sets this member to zero.

`DeleteCallback`

A pointer to a driver-implemented ExTimerDeleteCallback callback routine. The operating system calls this routine when the timer is deleted. This parameter is optional and can be **NULL** if no timer-deletion callback routine is needed.

The **ExInitializeDeleteTimerParameters** routine sets this member to **NULL**. For more information, see Remarks.

`DeleteContext`

A context value for the timer-deletion callback routine. The operating system passes this value as a parameter to the timer-deletion callback routine, if one is specified. This parameter is typically a pointer to a caller-defined structure that contains context information used by the callback routine. This parameter is optional and can be set to **NULL** if no context information is needed.

The **ExInitializeDeleteTimerParameters** routine sets this member to **NULL**.

Remarks

The *Parameters* parameter of the ExDeleteTimer routine is a pointer to an **EXT_DELETE_PARAMETERS** structure. Before passing an **EXT_DELETE_PARAMETERS** structure to this routine, call the ExInitializeDeleteTimerParameters routine to initialize the structure.

Your driver can use an ExTimerDeleteCallback callback routine to free any storage or other system resources that the driver might have previously allocated to use with the timer object that is being deleted. For example, the driver's context value might point to a caller-allocated structure that needs to be freed if the timer object is to be

deleted. The operating system calls the *ExTimerDeleteCallback* routine only after the timer object has been disabled to prevent further timer operations and any pending timer operation on the timer object is canceled or completed.

Requirements

Minimum supported client	Supported starting with Windows 8.1.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

ExDeleteTimer

ExInitializeDeleteTimerParameters

ExTimerDeleteCallback

EXT_SET_PARAMETERS structure

1/30/2019 • 2 minutes to read • Edit Online

The **EXT_SET_PARAMETERS** structure contains an extended set of parameters for the ExSetTimer routine.

Syntax

```
typedef struct _EXT_SET_PARAMETERS_V0 {
  ULONG    Version;
  ULONG    Reserved;
  LONGLONG NoWakeTolerance;
} EXT_SET_PARAMETERS, *PEXT_SET_PARAMETERS;
```

Members

`Version`

The version number of this **EXT_SET_PARAMETERS** structure. The ExInitializeSetTimerParameters routine sets this member to the correct version number.

`Reserved`

Set to zero. The **ExInitializeSetTimerParameters** routine sets this member to zero.

`NoWakeTolerance`

The maximum time, in system time units (100-nanosecond intervals), that the timer can wait to wake the processor after the timer reaches its expiration time. Only after the processor wakes can the timer expire. If a timer is set to expire when the processor is in a low-power state, the timer will not wake the processor to expire until the expiration time plus the **NoWakeTolerance** delay is exceeded. As an option, a driver can set this member to EX_TIMER_UNLIMITED_TOLERANCE, which indicates that the timer never wakes the processor and, thus, cannot expire until the processor wakes for some other reason.

Do not set this member to a negative value (other than EX_TIMER_UNLIMITED_TOLERANCE). Otherwise, the routine bug checks.

Remarks

The *Parameters* parameter of the ExSetTimer routine is a pointer to an **EXT_SET_PARAMETERS** structure. Before passing an **EXT_SET_PARAMETERS** structure to this routine, call the ExInitializeSetTimerParameters routine to initialize the structure.

The **ExInitializeSetTimerParameters** routine sets the **NoWakeTolerance** member to zero, which means that the timer immediately wakes the processor if the timer reaches its expiration time when the processor is in a low-power state. To reduce power consumption, a driver can set this member to a nonzero value to extend the time that the processor spends in a low-power state.

Requirements

Minimum supported client	Supported starting with Windows 8.1.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ExInitializeSetTimerParameters

ExSetTimer

FILE_BASIC_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_BASIC_INFORMATION** structure is used as an argument to routines that query or set file information.

Syntax

```
typedef struct _FILE_BASIC_INFORMATION {
  LARGE_INTEGER CreationTime;
  LARGE_INTEGER LastAccessTime;
  LARGE_INTEGER LastWriteTime;
  LARGE_INTEGER ChangeTime;
  ULONG         FileAttributes;
} FILE_BASIC_INFORMATION, *PFILE_BASIC_INFORMATION;
```

Members

`CreationTime`

Specifies the time that the file was created.

`LastAccessTime`

Specifies the time that the file was last accessed.

`LastWriteTime`

Specifies the time that the file was last written to.

`ChangeTime`

Specifies the last time the file was changed.

`FileAttributes`

Specifies one or more FILE_ATTRIBUTE_*XXX* flags. For descriptions of these flags, see the documentation for the **GetFileAttributes** function in the Microsoft Windows SDK.

Remarks

The FILE_ATTRIBUTE_NORMAL flag cannot be set or returned in combination with any other attributes. All other **FileAttributes** values override this attribute.

Time values **CreationTime**, **LastAccessTime**, **LastWriteTime**, and **ChangeTime** are expressed in absolute system time format. Absolute system time is the number of 100-nanosecond intervals since the start of the year 1601 in the Gregorian calendar.

If you specify a value of zero for any of the *Xxx***Time** members of the **FILE_BASIC_INFORMATION** structure, the ZwSetInformationFile function keeps a file's current setting for that time.

The file system updates the values of the **LastAccessTime**, **LastWriteTime**, and **ChangeTime** members as appropriate after an I/O operation is performed on a file. However, a driver or application can request that the file system not update one or more of these members for I/O operations that are performed on the caller's file handle by setting the appropriate members to -1. The caller can set one, all, or any other combination of these three

members to -1. Only the members that are set to -1 will be unaffected by I/O operations on the file handle; the other members will be updated as appropriate.

To set the members of this structure, the caller must have FILE_WRITE_ATTRIBUTES access to the file.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

FILE_FS_DEVICE_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_FS_DEVICE_INFORMATION** structure provides file system device information about the type of device object associated with a file object.

Syntax

```
typedef struct _FILE_FS_DEVICE_INFORMATION {
  DEVICE_TYPE DeviceType;
  ULONG       Characteristics;
} FILE_FS_DEVICE_INFORMATION, *PFILE_FS_DEVICE_INFORMATION;
```

Members

`DeviceType`

Set when a driver calls **IoCreateDevice** as appropriate for the type of underlying device. For more information, see Specifying Device Types.

`Characteristics`

The device characteristics. For a description of relevant values, see DEVICE_OBJECT.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

DEVICE_OBJECT

FILE_FULL_EA_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_FULL_EA_INFORMATION** structure provides extended attribute (EA) information. This structure is used primarily by network drivers.

Syntax

```
typedef struct _FILE_FULL_EA_INFORMATION {
  ULONG  NextEntryOffset;
  UCHAR  Flags;
  UCHAR  EaNameLength;
  USHORT EaValueLength;
  CHAR   EaName[1];
} FILE_FULL_EA_INFORMATION, *PFILE_FULL_EA_INFORMATION;
```

Members

`NextEntryOffset`

The offset of the next **FILE_FULL_EA_INFORMATION**-type entry. This member is zero if no other entries follow this one.

`Flags`

Can be zero or can be set with FILE_NEED_EA, indicating that the file to which the EA belongs cannot be interpreted without understanding the associated extended attributes.

`EaNameLength`

The length in bytes of the **EaName** array. This value does not include a null-terminator to **EaName**.

`EaValueLength`

The length in bytes of each EA value in the array.

`EaName`

An array of characters naming the EA for this entry.

Remarks

This structure is longword-aligned. If a set of **FILE_FULL_EA_INFORMATION** entries is buffered, **NextEntryOffset** value in each entry, except the last, falls on a longword boundary.

The value(s) associated with each entry follows the **EaName** array. That is, an EA's values are located at **EaName** + (**EaNameLength** + 1).

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

FILE_IO_PRIORITY_HINT_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_IO_PRIORITY_HINT_INFORMATION** structure is used by the ZwQueryInformationFile and ZwSetInformationFile routines to query and set the default IRP priority hint for requests on the specified file handle.

Syntax

```
typedef struct _FILE_IO_PRIORITY_HINT_INFORMATION {
  IO_PRIORITY_HINT PriorityHint;
} FILE_IO_PRIORITY_HINT_INFORMATION, *PFILE_IO_PRIORITY_HINT_INFORMATION;
```

Members

`PriorityHint`

Specifies the IO_PRIORITY_HINT value that indicates the priority hint for a file handle.

Remarks

For more information about priority hints, see Using IRP Priority Hints.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

FILE_IS_REMOTE_DEVICE_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_IS_REMOTE_DEVICE_INFORMATION** structure is used as an argument to the ZwQueryInformationFile routine.

Syntax

```
typedef struct _FILE_IS_REMOTE_DEVICE_INFORMATION {
  BOOLEAN IsRemote;
} FILE_IS_REMOTE_DEVICE_INFORMATION, *PFILE_IS_REMOTE_DEVICE_INFORMATION;
```

Members

`IsRemote`

A value that indicates whether the file system that contains the file is a remote file system.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

ZwQueryInformationFile

FILE_NETWORK_OPEN_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_NETWORK_OPEN_INFORMATION** structure is used as an argument to ZwQueryInformationFile.

Syntax

```
typedef struct _FILE_NETWORK_OPEN_INFORMATION {
  LARGE_INTEGER CreationTime;
  LARGE_INTEGER LastAccessTime;
  LARGE_INTEGER LastWriteTime;
  LARGE_INTEGER ChangeTime;
  LARGE_INTEGER AllocationSize;
  LARGE_INTEGER EndOfFile;
  ULONG         FileAttributes;
} FILE_NETWORK_OPEN_INFORMATION, *PFILE_NETWORK_OPEN_INFORMATION;
```

Members

`CreationTime`

Specifies the time that the file was created.

`LastAccessTime`

Specifies the time that the file was last accessed.

`LastWriteTime`

Specifies he time that the file was last written to.

`ChangeTime`

Specifies the time that the file was last changed.

`AllocationSize`

Specifies the file allocation size, in bytes. Usually, this value is a multiple of the sector or cluster size of the underlying physical device.

`EndOfFile`

Specifies the absolute end-of-file position as a byte offset from the start of the file. **EndOfFile** specifies the byte offset to the end of the file. Because this value is zero-based, it actually refers to the first free byte in the file. In other words, **EndOfFile** is the offset to the byte immediately following the last valid byte in the file.

`FileAttributes`

Specifies one or more FILE_ATTRIBUTE_*XXX* flags. For descriptions of these flags, see the documentation of the **GetFileAttributes** function in the Microsoft Windows SDK.

Remarks

FILE_READ_ATTRIBUTES access to the file is required to query this information.

Time values **CreationTime**, **LastAccessTime**, **LastWriteTime**, and **ChangeTime** are expressed in absolute system time format. Absolute system time is the number of 100-nanosecond intervals since the start of the year 1601 in the Gregorian calendar.

This structure must be aligned on a LONGLONG (8-byte) boundary.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

FILE_OBJECT structure

1/30/2019 • 10 minutes to read • Edit Online

The **FILE_OBJECT** structure is used by the system to represent a file object. To user-mode protected subsystems, a file object represents an open instance of a file, device, directory, or volume. To device and intermediate drivers, a file object usually represents a device object. To drivers in the file system stack, a file object usually represents a directory or file.

A file object is partially opaque. Certain types of drivers, such as file system drivers and network transport drivers, use some of the fields of file objects.

Syntax

```
typedef struct _FILE_OBJECT {
  CSHORT                          Type;
  CSHORT                          Size;
  PDEVICE_OBJECT                  DeviceObject;
  PVPB                            Vpb;
  PVOID                           FsContext;
  PVOID                           FsContext2;
  PSECTION_OBJECT_POINTERS        SectionObjectPointer;
  PVOID                           PrivateCacheMap;
  NTSTATUS                        FinalStatus;
  struct _FILE_OBJECT             *RelatedFileObject;
  BOOLEAN                         LockOperation;
  BOOLEAN                         DeletePending;
  BOOLEAN                         ReadAccess;
  BOOLEAN                         WriteAccess;
  BOOLEAN                         DeleteAccess;
  BOOLEAN                         SharedRead;
  BOOLEAN                         SharedWrite;
  BOOLEAN                         SharedDelete;
  ULONG                           Flags;
  UNICODE_STRING                  FileName;
  LARGE_INTEGER                   CurrentByteOffset;
  __volatile ULONG                Waiters;
  __volatile ULONG                Busy;
  PVOID                           LastLock;
  KEVENT                          Lock;
  KEVENT                          Event;
  __volatile PIO_COMPLETION_CONTEXT CompletionContext;
  KSPIN_LOCK                      IrpListLock;
  LIST_ENTRY                      IrpList;
  __volatile PVOID                FileObjectExtension;
} FILE_OBJECT, *PFILE_OBJECT;
```

Members

`Type`

A read-only member used by the system to indicate that the object is a file object. If the object is a file object, the value of this member is 5.

`Size`

A read-only member that specifies the size, in bytes, of the file object. This size does not include the file object extension, if one is present.

`DeviceObject`

A pointer to the device object on which the file is opened.

`Vpb`

A pointer to the volume parameter block associated with the file object.

Note that if the **Vpb** member is non-**NULL**, the file resides on a mounted volume.

`FsContext`

A pointer to whatever optional state a driver maintains about the file object; otherwise, **NULL**. For file system drivers, this member must point to a FSRTL_ADVANCED_FCB_HEADER header structure that is contained within a file-system-specific structure; otherwise system instability can result. Usually, this header structure is embedded in a file control block (FCB). However, on some file systems that support multiple data streams, such as NTFS, this header structure is a stream control block (SCB).

> **Note** In a WDM device stack, only the functional device object (FDO) can use the two context pointers. File system drivers share this member across multiple opens to the same data stream.

`FsContext2`

A pointer to whatever additional state a driver maintains about the file object; otherwise, **NULL**.

> **Note** This member is opaque for drivers in the file system stack because the underlying file system utilizes this member.

`SectionObjectPointer`

A pointer to the file object's read-only section object. This member is set only by file systems and used for Cache Manager interaction.

`PrivateCacheMap`

An opaque member, set only by file systems, that points to handle-specific information and that is used for Cache Manager interaction.

`FinalStatus`

A read-only member that is used, in certain synchronous cases, to indicate the final status of the file object's I/O request.

`RelatedFileObject`

A pointer to a **FILE_OBJECT** structure used to indicate that the current file object has been opened relative to an already open file object. The file object pointed to by this member is usually a directory (meaning the current file has been opened relative to this directory). However, a file can be reopened relative to itself, and alternate data streams for a file can be opened relative to an already open primary data stream for that same file. The **RelatedFileObject** member is only valid during the processing of the IRP_MJ_CREATE requests.

`LockOperation`

A read-only member. If **FALSE**, a lock operation (**NtLockFile**) has never been performed on the file object. If **TRUE**, at least one lock operation has been performed on the file object. Once set to **TRUE**, this member always remains **TRUE** (for example, releasing file locks on the file object does not reset this member to **FALSE**).

`DeletePending`

A read-only member. If **TRUE**, a delete operation for the file associated with the file object exists. If **FALSE**, there currently is no pending delete operation for the file object.

`ReadAccess`

A read-only member. If **TRUE**, the file associated with the file object has been opened for read access. If **FALSE**, the file has been opened without read access. This information is used when checking and/or setting the share access of the file.

`WriteAccess`

A read-only member. If **TRUE**, the file associated with the file object has been opened for write access. If **FALSE**, the file has been opened without write access. This information is used when checking and/or setting the share access of the file.

`DeleteAccess`

A read-only member. If **TRUE**, the file associated with the file object has been opened for delete access. If **FALSE**, the file has been opened without delete access. This information is used when checking and/or setting the share access of the file.

`SharedRead`

A read-only member. If **TRUE**, the file associated with the file object has been opened for read sharing access. If **FALSE**, the file has been opened without read sharing access. This information is used when checking and/or setting the share access of the file.

`SharedWrite`

A read-only member. If **TRUE**, the file associated with the file object has been opened for write sharing access. If **FALSE**, the file has been opened without write sharing access. This information is used when checking and/or setting the share access of the file.

`SharedDelete`

A read-only member. If **TRUE**, the file associated with the file object has been opened for delete sharing access. If **FALSE**, the file has been opened without delete sharing access. This information is used when checking and/or setting the share access of the file.

`Flags`

A read-only member used by the system to hold one or more (a bitwise inclusive OR combination) of the following private flag values.

FLAG	MEANING
FO_FILE_OPEN	Deprecated.
FO_SYNCHRONOUS_IO	The file object is opened for synchronous I/O.
FO_ALERTABLE_IO	Any wait in the I/O manager, as a result of a request made to this file object, is alertable.
FO_NO_INTERMEDIATE_BUFFERING	The file associated with the file object cannot be cached or buffered in a driver's internal buffers.
FO_WRITE_THROUGH	System services, file system drivers, and drivers that write data to the file must transfer the data into the file before any requested write operation is considered complete.

FO_SEQUENTIAL_ONLY	The file associated with the file object was opened for sequential I/O operations only.
FO_CACHE_SUPPORTED	The file associated with the file object is cacheable. This flag should be set only by a file system driver, and only if the **FsContext** member points to a valid FSRTL_ADVANCED_FCB_HEADER structure.
FO_NAMED_PIPE	The file object represents a named pipe.
FO_STREAM_FILE	The file object represents a file stream.
FO_MAILSLOT	The file object represents a mailslot.
FO_GENERATE_AUDIT_ON_CLOSE	Deprecated.
FO_QUEUE_IRP_TO_THREAD	IRPs will not be queued to this file object.
FO_DIRECT_DEVICE_OPEN	The device targeted by this file object was opened directly.
FO_FILE_MODIFIED	The file associated with the file object has been modified.
FO_FILE_SIZE_CHANGED	The file associated with the file object has changed in size.
FO_CLEANUP_COMPLETE	The file system has completed its cleanup for this file object.
FO_TEMPORARY_FILE	The file associated with the file object is a temporary file.
FO_DELETE_ON_CLOSE	The file associated with the file object will be deleted by the file system upon close.
FO_OPENED_CASE_SENSITIVE	The file name case of the file associated with the file object is respected.
FO_HANDLE_CREATED	A file handle was created for file object.
FO_FILE_FAST_IO_READ	A fast I/O read was performed on this file object.
FO_RANDOM_ACCESS	The file associated with the file object was opened for random access.
FO_FILE_OPEN_CANCELLED	The create request for this file object was canceled before completing.
FO_VOLUME_OPEN	The file object represents a volume open request.
FO_REMOTE_ORIGIN	The create request for the file associated with the file object originated on a remote machine.
FO_SKIP_COMPLETION_PORT	For a file object associated with a port, determines if the system should skip queuing to the completion port when the IRP is completed synchronously with a non-error status return value.

FO_SKIP_SET_EVENT	Skip setting the event for the file object upon IRP completion.
FO_SKIP_SET_FAST_IO	Skip setting an event supplied to a system service when the fast I/O path is successful.

`FileName`

A UNICODE_STRING structure whose **Buffer** member points to a read-only Unicode string that holds the name of the file opened on the volume. If the volume is being opened, the **Length** member of the **UNICODE_STRING** structure will be zero. Note that the file name in this string is valid only during the initial processing of an IRP_MJ_CREATE request. This file name should not be considered valid after the file system starts to process the **IRP_MJ_CREATE** request. The storage for the string pointed to by the **Buffer** member of the **UNICODE_STRING** structure is allocated in paged system memory. For more information about obtaining a file name, see FltGetFileNameInformation.

`CurrentByteOffset`

A read-only member that specifies the file offset, in bytes, associated with the file object.

`Waiters`

A read-only member used by the system to count the number of outstanding waiters on a file object opened for synchronous access.

`Busy`

A read-only member used by the system to indicate whether a file object opened for synchronous access is currently busy.

`LastLock`

An opaque pointer to the last lock applied to the file object.

`Lock`

An opaque member used by the system to hold a file object event lock. The event lock is used to control synchronous access to the file object. Applicable only to file objects that are opened for synchronous access.

`Event`

An opaque member used by the system to hold an event object for the file object. The event object is used to signal the completion of an I/O request on the file object if no user event was supplied or a synchronous API was called.

`CompletionContext`

An opaque pointer to completion port information (port pointer and key) associated with the file object, if any.

`IrpListLock`

An opaque pointer to a KSPIN_LOCK structure that serves as the spin lock used to synchronize access to the file object's IRP list.

`IrpList`

An opaque pointer to the head of the IRP list associated with the file object.

`FileObjectExtension`

An opaque pointer to the file object's file object extension (FOBX) structure. The **FOBX** structure contains various opaque contexts used internally as well as the per-file object contexts available through **FsRtl*Xxx*** routines.

Remarks

Drivers can use the **FsContext** and **FsContext2** members to maintain driver-determined state about an open file object. A driver cannot use these members unless the file object is accessible in the driver's I/O stack location of an IRP.

All remaining members in a file object are either opaque or read-only:

- Opaque members within a file object should be considered inaccessible. Drivers with dependencies on object field locations or access to opaque members might not remain portable and interoperable with other drivers over time.
- Drivers can use read-only members to acquire relevant information but must not modify read-only members and, if a pointer, the object that the member points to.

During the processing of an IRP_MJ_CREATE request, a file system driver calls the IoSetShareAccess routine (if the client is the first to open the file) or the IoCheckShareAccess routine (for subsequent clients that want to share the file). **IoSetShareAccess** and **IoCheckShareAccess** update the **ReadAccess**, **WriteAccess**, and **DeleteAccess** members to indicate the access rights that are granted to the client if the client has exclusive access to the file. Additionally, **IoCheckShareAccess** updates the **SharedRead**, **SharedWrite**, and **SharedDelete** members to indicate the access rights that are simultaneously granted to two or more clients that share the file. If the driver for a device other than a file system has to monitor the access rights of clients, this driver typically stores access rights information in context buffers that are pointed to by the **FsContext** and **FsContext2** members.

> **Note** The type of object (for example, a file, directory, or volume) that a given file object represents cannot be determined by only examining the contents of the file object structure. For information about how to determine the type of object that a file object represents, see ZwQueryInformationFile.

The Common Log File System (CLFS) uses the **LOG_FILE_OBJECT** structure to represent logs. The ClfsCreateLogFile function returns a pointer to a **LOG_FILE_OBJECT** structure, which clients then pass to other CLFS functions. CLFS clients do not directly access the members of a **LOG_FILE_OBJECT** structure.

C++

```
typedef FILE_OBJECT LOG_FILE_OBJECT, *PLOG_FILE_OBJECT, **PPLOG_FILE_OBJECT;
```

ZwQueryInformationFile

FILE_POSITION_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_POSITION_INFORMATION** structure is used as an argument to routines that query or set file information.

Syntax

```
typedef struct _FILE_POSITION_INFORMATION {
  LARGE_INTEGER CurrentByteOffset;
} FILE_POSITION_INFORMATION, *PFILE_POSITION_INFORMATION;
```

Members

`CurrentByteOffset`

The byte offset of the current file pointer.

Remarks

FILE_READ_DATA or FILE_WRITE_DATA access to the file is required to change this information about the file, and the file must be opened for synchronous I/O.

If the file was opened or created with the FILE_NO_INTERMEDIATE_BUFFERING option, the value of **CurrentByteOffset** must be an integral multiple of the sector size of the underlying device.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

FILE_STANDARD_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **FILE_STANDARD_INFORMATION** structure is used as an argument to routines that query or set file information.

Syntax

```
typedef struct _FILE_STANDARD_INFORMATION {
  LARGE_INTEGER AllocationSize;
  LARGE_INTEGER EndOfFile;
  ULONG        NumberOfLinks;
  BOOLEAN      DeletePending;
  BOOLEAN      Directory;
} FILE_STANDARD_INFORMATION, *PFILE_STANDARD_INFORMATION;
```

Members

`AllocationSize`

The file allocation size in bytes. Usually, this value is a multiple of the sector or cluster size of the underlying physical device.

`EndOfFile`

The end of file location as a byte offset.

`NumberOfLinks`

The number of hard links to the file.

`DeletePending`

The delete pending status. **TRUE** indicates that a file deletion has been requested.

`Directory`

The file directory status. **TRUE** indicates the file object represents a directory.

Remarks

EndOfFile specifies the byte offset to the end of the file. Because this value is zero-based, it actually refers to the first free byte in the file; that is, it is the offset to the byte immediately following the last valid byte in the file.

Requirements

The **FILE_STANDARD_INFORMATION_EX** structure is used as an argument to routines that query or set file information.

Syntax

```
typedef struct _FILE_STANDARD_INFORMATION_EX {
  LARGE_INTEGER AllocationSize;
  LARGE_INTEGER EndOfFile;
  ULONG         NumberOfLinks;
  BOOLEAN       DeletePending;
  BOOLEAN       Directory;
  BOOLEAN       AlternateStream;
  BOOLEAN       MetadataAttribute;
} FILE_STANDARD_INFORMATION_EX, *PFILE_STANDARD_INFORMATION_EX;
```

Members

`AllocationSize`

The file allocation size in bytes. Usually, this value is a multiple of the sector or cluster size of the underlying physical device.

`EndOfFile`

The end of file location as a byte offset.

`NumberOfLinks`

The number of hard links to the file.

`DeletePending`

The delete pending status. **TRUE** indicates that a file deletion has been requested.

`Directory`

The file directory status. **TRUE** indicates the file object represents a directory.

`AlternateStream`

The alternate data stream status. **TRUE** indicates the file object represents an alternate data stream.

`MetadataAttribute`

The metadata attribute status. **TRUE** indicates the file object represents a metadata attribute.

Remarks

EndOfFile specifies the byte offset to the end of the file. Because this value is zero-based, it actually refers to the first free byte in the file; that is, it is the offset to the byte immediately following the last valid byte in the file.

FUNCTION_LEVEL_DEVICE_RESET_PARAMETERS structure

1/30/2019 • 2 minutes to read • Edit Online

The **FUNCTION_LEVEL_DEVICE_RESET_PARAMETER** structure is used as an argument to the DeviceReset routine of the GUID_DEVICE_RESET_INTERFACE_STANDARD interface. This structure specifies a callback routine that is called when a function-level device reset is completed, and a context structure that is passed to the callback routine. For more information, see Working with the GUID_DEVICE_RESET_INTERFACE_STANDARD

Syntax

```
typedef struct _FUNCTION_LEVEL_DEVICE_RESET_PARAMETERS {
  ULONG                    Size;
  PDEVICE_RESET_COMPLETION DeviceResetCompletion;
  PVOID                    CompletionContext;
} FUNCTION_LEVEL_DEVICE_RESET_PARAMETERS, *PFUNCTION_LEVEL_DEVICE_RESET_PARAMETERS;
```

Members

`Size`

The size, in bytes, of this structure.

`DeviceResetCompletion`

Pointer to a completion callback routine to be called when a function-level device reset is completed. The function prototype for this callback routine is defined as follows:

```
typedef
VOID
(*PDEVICE_RESET_COMPLETION)(
    _In_ NTSTATUS Status,
    _Inout_opt_ PVOID Context
    );
```

`CompletionContext`

Points to a caller-supplied context structure to be passed to the *DeviceResetCompletion* callback.

Requirements

Header	wdm.h

GENERIC_MAPPING structure

1/30/2019 • 2 minutes to read • Edit Online

The **GENERIC_MAPPING** structure describes the ACCESS_MASK value of specific access rights associated with each type of generic access right.

Syntax

```
typedef struct _GENERIC_MAPPING {
  ACCESS_MASK GenericRead;
  ACCESS_MASK GenericWrite;
  ACCESS_MASK GenericExecute;
  ACCESS_MASK GenericAll;
} GENERIC_MAPPING;
```

Members

`GenericRead`

Describes the specific access rights corresponding to the GENERIC_READ access right.

`GenericWrite`

Describes the specific access rights corresponding to the GENERIC_WRITE access right.

`GenericExecute`

Describes the specific access rights corresponding to the GENERIC_EXECUTE access right.

`GenericAll`

Describes the specific access rights corresponding to the GENERIC_ALL access right.

Remarks

Use the IoGetFileObjectGenericMapping routine to get the specific access rights corresponding to generic access rights for file objects. Use RtlMapGenericMask to subtract off the access rights within an ACCESS_MASK that do not derive from generic access rights.

For more information about generic access rights, see the reference page for **GENERIC_MAPPING** in the Microsoft Windows SDK documentation.

Requirements

HWPROFILE_CHANGE_NOTIFICATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **HWPROFILE_CHANGE_NOTIFICATION** structure describes an event related to a hardware profile configuration change. The PnP manager sends this structure to a driver that registered a callback routine for notification of **EventCategoryHardwareProfileChange** events.

Syntax

```
typedef struct _HWPROFILE_CHANGE_NOTIFICATION {
  USHORT Version;
  USHORT Size;
  GUID   Event;
} HWPROFILE_CHANGE_NOTIFICATION, *PHWPROFILE_CHANGE_NOTIFICATION;
```

Members

`Version`

Specifies the version of the data structure, currently 1.

`Size`

Specifies the size of the structure, in bytes including the size of the standard first three members plus the event-specific data.

`Event`

Specifies a GUID identifying the event: GUID_HWPROFILE_QUERY_CHANGE, GUID_HWPROFILE_CHANGE_COMPLETE, or GUID_HWPROFILE_CHANGE_CANCELLED. The GUIDs are defined in Wdmguid.h.

Remarks

There is no event-specific data for a hardware-profile-change event.

Requirements

INTERFACE structure

1/30/2019 • 2 minutes to read • Edit Online

The **INTERFACE** structure describes an interface that is exported by a driver for use by other drivers.

Syntax

```
typedef struct _INTERFACE {
  USHORT                 Size;
  USHORT                 Version;
  PVOID                  Context;
  PINTERFACE_REFERENCE   InterfaceReference;
  PINTERFACE_DEREFERENCE InterfaceDereference;
} INTERFACE, *PINTERFACE;
```

Members

`Size`

Size, in bytes, of a structure defining a driver interface, including this structure and interface-specific members.

`Version`

Driver-defined interface version.

`Context`

Pointer to interface-specific context information.

`InterfaceReference`

Pointer to a driver-supplied InterfaceReference routine that increments the interface's reference count.

`InterfaceDereference`

Pointer to a driver-supplied InterfaceDereference routine that decrements the interface's reference count.

Remarks

The **INTERFACE** structure must be included as the first member of all structures that describe interfaces returned by drivers in response to an IRP_MN_QUERY_INTERFACE request.

The *InterfaceReference* routine must be called by the driver that exports the interface, each time the driver supplies that interface in response to **IRP_MN_QUERY_INTERFACE**. Likewise, if the driver that requests the interface subsequently passes it to another driver, the driver that passes the interface must call *InterfaceReference* on behalf of the driver that receives it.

Each driver that imports the interface (whether by sending **IRP_MN_QUERY_INTERFACE** or by receiving the interface from another driver) must call the *InterfaceDereference* routine after it has finished using the interface. After calling the *InterfaceDereference* routine, a driver cannot use the interface again without first reobtaining it.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

InterfaceReference

INTERFACE_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **INTERFACE_TYPE** enumeration indicates the bus type.

Syntax

```
typedef enum _INTERFACE_TYPE {
  InterfaceTypeUndefined,
  Internal,
  Isa,
  Eisa,
  MicroChannel,
  TurboChannel,
  PCIBus,
  VMEBus,
  NuBus,
  PCMCIABus,
  CBus,
  MPIBus,
  MPSABus,
  ProcessorInternal,
  InternalPowerBus,
  PNPISABus,
  PNPBus,
  Vmcs,
  ACPIBus,
  MaximumInterfaceType
} INTERFACE_TYPE, *PINTERFACE_TYPE;
```

Constants

InterfaceTypeUndefined	Indicates that the interface type is undefined.
Internal	For internal use only.
Isa	Indicates that the interface is published by the ISA bus driver.
Eisa	Indicates that the interface is published by the EISA bus driver.
MicroChannel	Indicates that the interface is published by the MicroChannel bus driver.
TurboChannel	Indicates that the interface is published by the TurboChannel bus driver.
PCIBus	Indicates that the interface is published by the PCI bus driver.
VMEBus	Indicates that the interface is published by the VME bus driver.
NuBus	Indicates that the interface is published by the NuBus driver.

PCMCIABus	Indicates that the interface is published by the PCMCIA bus driver.
CBus	Indicates that the interface is published by the Cbus driver.
MPIBus	Indicates that the interface is published by the MPI bus driver.
MPSABus	Indicates that the interface is published by the MPSA bus driver.
ProcessorInternal	Indicates that the interface is published by the ISA bus driver.
InternalPowerBus	Indicates that the interface is published for an internal power bus. Some devices have power control ports that allow them to share power control with other devices. The Windows architecture represents these devices as slots on a virtual bus called an "internal power bus."
PNPISABus	Indicates that the interface is published by the PNPISA bus driver.
PNPBus	Indicates that the interface is published by the PNP bus driver.
Vmcs	Reserved for use by the operating system.
ACPIBus	Indicates that the interface is published by the ACPI bus driver. The ACPI bus driver enumerates devices that are described in the ACPI firmware of the hardware platform. These devices might physically reside on buses that are controlled by other bus drivers, but the ACPI bus driver must enumerate these devices because the other bus drivers cannot detect them. This interface type is defined starting with Windows 8.
MaximumInterfaceType	Marks the upper limit of the possible bus types.

Requirements

Header	wdm.h (include Wdm.h, Miniport.h, Wudfwdm.h)

IO_ACCESS_MODE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

Defines the types of access mode for Scheduled File I/O (SFIO).

Syntax

```
typedef enum _IO_ACCESS_MODE {
  SequentialAccess,
  RandomAccess
} IO_ACCESS_MODE;
```

Constants

SequentialAccess	Indicates that the input/output will be sent down in a sequential order.
RandomAccess	Indicates that the input/output might not be in a predictable order.

Requirements

Header	wdm.h (include Wdm.h, Ntddsfio.h)

IO_ACCESS_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

Defines the access rights for Scheduled File I/O (SFIO).

Syntax

```
typedef enum _IO_ACCESS_TYPE {
  ReadAccess,
  WriteAccess,
  ModifyAccess
} IO_ACCESS_TYPE;
```

Constants

ReadAccess	Indicates that the input/output will be comprised solely of reads.
WriteAccess	Indicates that the input/output will be comprised solely of writes.
ModifyAccess	Indicates that the input/output will be comprised of reads and writes.

Requirements

Header	wdm.h (include Ntddsfio.h)

IO_ALLOCATION_ACTION Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **IO_ALLOCATION_ACTION** enumerated type is used to specify return values for AdapterControl and ControllerControl routines.

Syntax

```
typedef enum _IO_ALLOCATION_ACTION {
  KeepObject,
  DeallocateObject,
  DeallocateObjectKeepRegisters
} IO_ALLOCATION_ACTION, *PIO_ALLOCATION_ACTION;
```

Constants

KeepObject	Indicates that you want the driver to retain ownership of the adapter or controller object.
DeallocateObject	Indicates that you do not want the driver to retain ownership of the adapter or controller object.
DeallocateObjectKeepRegisters	For adapter objects only. Indicates that you do not want the driver to retain ownership of the adapter object, but you do want the driver to retain ownership of the allocated map registers.

Remarks

If an *AdapterControl* or *ControllerControl* routine completes an IRP, or if it can set up an operation (such as a disk seek) for a target device object that could be overlapped with an operation for another device object, it should return **DeallocateObject**.

If a driver uses packet-based bus-master DMA, its *AdapterControl* routine should return **DeallocateObjectKeepRegisters**.

Otherwise, the driver should return **KeepObject**.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h)

IO_CONNECT_INTERRUPT_PARAMETERS structure

2/5/2019 • 7 minutes to read • Edit Online

The **IO_CONNECT_INTERRUPT_PARAMETERS** structure contains the parameters that a driver supplies to the IoConnectInterruptEx routine to register an interrupt service routine (ISR).

Syntax

```
typedef struct _IO_CONNECT_INTERRUPT_PARAMETERS {
  ULONG Version;
  union {
    IO_CONNECT_INTERRUPT_FULLY_SPECIFIED_PARAMETERS FullySpecified;
    IO_CONNECT_INTERRUPT_LINE_BASED_PARAMETERS      LineBased;
    IO_CONNECT_INTERRUPT_MESSAGE_BASED_PARAMETERS   MessageBased;
  };
} IO_CONNECT_INTERRUPT_PARAMETERS, *PIO_CONNECT_INTERRUPT_PARAMETERS;
```

Members

`Version`

On input, specifies the particular operation to be performed by **IoConnectInterruptEx**, as follows.

VERSION VALUE	IOCONNECTINTERRUPTEX OPERATION
CONNECT_FULLY_SPECIFIED	Connects to a specific interrupt using information provided by the Plug and Play (PnP) manager. Use the **FullySpecified** member to provide the additional parameters of the operation.
CONNECT_LINE_BASED	Registers an InterruptService routine for the device's line-based interrupts. Use the **LineBased** member to provide the additional parameters of the operation.
CONNECT_MESSAGE_BASED	Registers an InterruptMessageService routine for the device's message-signaled interrupts. The caller can also specify a fallback *InterruptService* routine if the device only has line-based interrupts. Use the **MessageBased** member to provide the additional parameters of the operation.

On return, the routine provides information about the operation, as follows.

VERSION VALUE	DESCRIPTION
CONNECT_FULLY_SPECIFIED	The caller specified CONNECT_LINE_BASED or CONNECT_MESSAGE_BASED for **Version** on a platform that does not support it. Retry the operation using CONNECT_FULLY_SPECIFIED.
CONNECT_LINE_BASED	The caller specified CONNECT_MESSAGE_BASED and the caller's fallback *InterruptService* routine was registered.

CONNECT_MESSAGE_BASED	The caller specified CONNECT_MESSAGE_BASED and the caller's *InterruptMessageService* routine was registered.

`FullySpecified`

Specifies the additional parameters of the operation to be performed by IoConnectInterruptEx when **Version** has a value of CONNECT_FULLY_SPECIFIED (or CONNECT_FULLY_SPECIFIED_GROUP if the **Group** member is used). For more information, see Using the CONNECT_FULLY_SPECIFIED Version of IoConnectInterruptEx.

PhysicalDeviceObject

A pointer to the PDO for the device.

InterruptObject

A pointer to a location that receives a pointer to the set of interrupt objects for the device.

ServiceRoutine

A pointer to the InterruptService routine to register as the ISR for the device's interrupts.

ServiceContext

Specifies the value to be passed as the *ServiceContext* parameter of the InterruptService routine.

SpinLock

Either a pointer to a spin lock to serve as the interrupt spin lock for the set of interrupts, or **NULL**. If **NULL**, the system allocates a spin lock to serve as the interrupt spin lock. If non-**NULL**, you should have initialized the spin lock with KeInitializeSpinLock.

SynchronizeIrql

Specifies the DIRQL at which the ISR will run. If the ISR handles more than one interrupt vector or the driver has more than one ISR, this value must be the maximum IRQL of the set of interrupts. The IRQL for an interrupt is passed in the **CmResourceTypeInterrupt** resource at the **u.Interrupt.Level** member of CM_PARTIAL_RESOURCE_DESCRIPTOR. Otherwise, the **Irql** and **SynchronizeIrql** values are identical.

FloatingSave

Specifies if the system saves the processor's floating-point state when the interrupt occurs. If **TRUE**, the system saves the floating-point state.

ShareVector

Specifies whether the interrupt vector is sharable. Line-based PCI interrupts must be sharable. For message-signaled PCI interrupts, driver writers can choose whether their interrupts are sharable, but should choose to make them sharable by default.

Vector

Specifies the interrupt vector passed in the **CmResourceTypeInterrupt** resource at the **u.Interrupt.Vector** member of **CM_PARTIAL_RESOURCE_DESCRIPTOR**.

Irql

Specifies the DIRQL passed in the **CmResourceTypeInterrupt** resource at the **u.Interrupt.Level** member of CM_PARTIAL_RESOURCE_DESCRIPTOR. Starting with Windows 8, a driver can register an ISR that runs at passive level by setting **Irql** and **SynchronizeIrql** to PASSIVE_LEVEL, and setting **SpinLock** to **NULL**. For more information, see Using Passive-Level Interrupt Service Routines.

InterruptMode

Specifies a KINTERRUPT_MODE that determines whether the interrupt is level-triggered (**InterruptMode** = **LevelSensitive**) or edge-triggered (**InterruptMode** = **Latched**). For shared interrupt lines from a PCI bus, specify **LevelSensitive**. For PCI message-signaled interrupts, specify **Latched**.

ProcessorEnableMask

Specifies the **KAFFINITY** mask that represents the set of processors on which the device's interrupts can occur. This value is passed in the **CmResourceTypeInterrupt** resource at the **u.Interrupt.Affinity** member of

CM_PARTIAL_RESOURCE_DESCRIPTOR.

Group

Specifies a group number that identifies the processor group to which the interrupt is to be delivered. Typically, a driver receives its group number as part of the translated resources that are included in an IRP_MN_START_DEVICE request. Starting with Windows 7, the **Group** member is used if the **Version** member of the **IO_CONNECT_INTERRUPT_PARAMETERS** structure is set to CONNECT_FULLY_SPECIFIED_GROUP. The **Group** member is ignored if **Version** is set to CONNECT_FULLY_SPECIFIED, in which case the group number for delivery of the interrupt is always 0.

`LineBased`

Specifies the additional parameters of the operation to be performed by IoConnectInterruptEx when **Version** has a value of CONNECT_LINE_BASED. For more information, see Using the CONNECT_LINE_BASED Version of IoConnectInterruptEx.

PhysicalDeviceObject

A pointer to the physical device object (PDO) of the device.

InterruptObject

A pointer to a location that receives a pointer to the set of interrupt objects for the device.

ServiceRoutine

A pointer to the InterruptService routine to register as the ISR for the device's interrupts.

ServiceContext

Specifies the value to be passed as the *ServiceContext* parameter of the *InterruptService* routine.

SpinLock

Either a pointer to a spin lock to serve as the interrupt spin lock for the set of interrupts, or **NULL**. If **NULL**, the system allocates a spin lock to serve as the interrupt spin lock. If non-**NULL**, you should have initialized the spin lock with KeInitializeSpinLock.

SynchronizeIrql

Specifies the minimum device IRQL (DIRQL) at which the ISR runs. The system uses this value only if it is greater than the maximum IRQL of the set of interrupts; otherwise, the system uses the maximum IRQL. Drivers almost always specify PASSIVE_LEVEL for **SynchronizeIrql**. (A driver should specify a value other than PASSIVE_LEVEL only if the ISR must run above a certain IRQL.) Starting with Windows 8, a set of line-based interrupt resources that are assigned to a device can share an ISR that runs at IRQL = PASSIVE_LEVEL. If **SynchronizeIrql** = PASSIVE_LEVEL, and the maximum IRQL of this set of interrupts is PASSIVE_LEVEL, the *InterruptService* routine is called at PASSIVE_LEVEL. For more information, see Using Passive-Level Interrupt Service Routines.

FloatingSave

Specifies if the system saves the processor's floating-point state when the interrupt occurs. If **TRUE**, the system saves floating-point state. For x86-based and Itanium-based platforms, this value must be set to **FALSE**. For more information about saving floating-point and MMX state, see Using Floating Point or MMX in a WDM Driver.

`MessageBased`

Specifies the additional parameters of the operation to be performed by IoConnectInterruptEx when **Version** has a value of CONNECT_MESSAGE_BASED. For more information, see Using the CONNECT_MESSAGE_BASED Version of IoConnectInterruptEx.

PhysicalDeviceObject

A pointer to the PDO of the device.

ConnectionContext

A pointer to a location that receives a pointer to the connection context. If on return **Version** has a value of CONNECT_LINE_BASED, the routine provides a pointer to a KINTERRUPT structure. If on return **Version** has a

value of CONNECT_MESSAGE_BASED, the routine provides a pointer to an IO_INTERRUPT_MESSAGE_INFO structure.

To minimize casting, **ConnectionContext** is defined as a union. Use **ConnectionContext.Generic** to treat the location as a PVOID. Use **ConnectionContext.InterruptObject** and **ConnectionContext.InterruptMessageTable** to treat the location as a PKINTERRUPT or PIO_INTERRUPT_MESSAGE_INFO variable respectively.

`Generic`

A pointer to a PVOID variable into which the **IoConnectInterruptEx** routine writes a pointer to the connection context.

`InterruptMessageTable`

A pointer to a PIO_INTERRUPT_MESSAGE_INFO variable into which the **IoConnectInterruptEx** routine writes a pointer to the connection context.

`InterruptObject`

A pointer to a PKINTERRUPT variable into which the **IoConnectInterruptEx** routine writes a pointer to the connection context.

MessageServiceRoutine

A pointer to the InterruptMessageService routine to register as the ISR for the device's interrupts.

ServiceContext

Specifies the value to be passed as the *ServiceContext* parameter of the InterruptMessageService or InterruptService routine for the interrupt.

SpinLock

Either a pointer to a spin lock to serve as the interrupt spin lock for the set of interrupts, or **NULL**. If **NULL**, the system allocates a spin lock to serve as the interrupt spin lock. If non-**NULL**, you should have initialized the spin lock with KeInitializeSpinLock.

SynchronizeIrql

Specifies the minimum device IRQL (DIRQL) at which the ISR runs. The system only uses this value if it is greater than the maximum IRQL of the set of interrupts; otherwise, the system uses the maximum IRQL. Drivers almost always specify PASSIVE_LEVEL for **SynchronizeIrql**.

FloatingSave

Specifies if the system saves the processor's floating-point state when the interrupt occurs. If **TRUE**, the system saves floating-point state.

FallBackServiceRoutine

A pointer to an InterruptService routine to use as the ISR for line-based interrupts. If the device has no message-signaled interrupts, but has line-based interrupts, the system registers this routine to handle the line-based interrupts.

Remarks

The IoConnectInterruptEx routine takes a single *Parameters* parameter, which points to an **IO_CONNECT_INTERRUPT_PARAMETERS** structure that contains all of the parameters of the operation.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IO_CONTAINER_INFORMATION_CLASS Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **IO_CONTAINER_INFORMATION_CLASS** enumeration contains constants that indicate the classes of system information that a kernel-mode driver can request.

Syntax

```
typedef enum _IO_CONTAINER_INFORMATION_CLASS {
  IoSessionStateInformation,
  IoMaxContainerInformationClass
} IO_CONTAINER_INFORMATION_CLASS;
```

Constants

IoSessionStateInformation	Session state information. A driver uses this enumeration constant to request information about a user session.
IoMaxContainerInformationClass	Specifies the maximum value in this enumeration type.

Remarks

To request system information, a driver calls the IoGetContainerInformation routine and sets this routine's *InformationClass* parameter to an **IO_CONTAINER_NOTIFICATION_CLASS** constant (other than **IoMaxContainerInformationClass**). Currently, **IoGetContainerInformation** supports only *InformationClass* = **IoSessionStateInformation**.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Fltkernel.h)

See Also

IoGetContainerInformation

IO_CONTAINER_NOTIFICATION_CLASS Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **IO_CONTAINER_NOTIFICATION_CLASS** enumeration contains constants that indicate the classes of events for which a kernel-mode driver can register to receive notifications.

Syntax

```
typedef enum _IO_CONTAINER_NOTIFICATION_CLASS {
  IoSessionStateNotification,
  IoMaxContainerNotificationClass
} IO_CONTAINER_NOTIFICATION_CLASS;
```

Constants

IoSessionStateNotification	Session state notifications. The driver uses this enumeration constant to request notifications about changes in the state of user sessions that the driver is interested in.
IoMaxContainerNotificationClass	Specifies the maximum value in this enumeration type.

Remarks

To register for notifications, a driver calls the IoRegisterContainerNotification routine and sets this routine's *NotificationClass* parameter to an **IO_CONTAINER_NOTIFICATION_CLASS** constant (other than **IoMaxContainerNotificationClass**). Currently, **IoRegisterContainerNotification** supports only *NotificationClass* = **IoSessionStateNotification**.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Fltkernel.h)

IoRegisterContainerNotification

IO_DISCONNECT_INTERRUPT_PARAMETERS structure

1/30/2019 • 2 minutes to read • Edit Online

The **IO_DISCONNECT_INTERRUPT_PARAMETERS** structure describes the parameters when unregistering an interrupt-handling routine with IoDisconnectInterruptEx.

Syntax

```
typedef struct _IO_DISCONNECT_INTERRUPT_PARAMETERS {
  ULONG Version;
  union {
    PVOID                      Generic;
    PKINTERRUPT                InterruptObject;
    PIO_INTERRUPT_MESSAGE_INFO InterruptMessageTable;
  } ConnectionContext;
} IO_DISCONNECT_INTERRUPT_PARAMETERS, *PIO_DISCONNECT_INTERRUPT_PARAMETERS;
```

Members

`Version`

Specifies the particular operation to be performed by **IoDisconnectInterruptEx**. The value for **Version** depends on the value specified for *Parameters*->**Version** when IoConnectInterruptEx registered the interrupt handing routine, as shown in the following table.

IO_CONNECT_INTERRUPT_PARAMETERS VERSION VALUE	IO_DISCONNECT_INTERRUPT_PARAMETERS VERSION VALUE
CONNECT_LINE_BASED	CONNECT_LINE_BASED
CONNECT_MESSAGE_BASED	The value of **Version** output by **IoConnectInterruptEx**.
CONNECT_FULLY_SPECIFIED	CONNECT_FULLY_SPECIFIED

`ConnectionContext`

A pointer to the KINTERRUPT or IO_INTERRUPT_MESSAGE_INFO structure that was provided by IoConnectInterruptEx when the interrupt was connected. The value for **ConnectionContext** depends on the value specified for *Parameters*->**Version** when **IoConnectInterruptEx** registered the interrupt handling routine, as shown in the following table.

IOCONNECTINTERRUPTEX VERSION VALUE	IODISCONNECTINTERRUPTEX CONNECTIONCONTEXT VALUE
CONNECT_LINE_BASED	The value stored in **LineBased.InterruptObject**.
CONNECT_MESSAGE_BASED	The value stored in **MessageBased.ConnectionContext**.
CONNECT_FULLY_SPECIFIED	The value stored in **FullySpecified.InterruptObject**.

To minimize casting, **ConnectionContext** is defined as a union. Use **ConnectionContext.Generic** to specify the

value as a PVOID. Use **ConnectionContext.InterruptObject** and **ConnectionContext.InterruptMessageTable** to specify the value as a pointer to a KINTERRUPT or IO_INTERRUPT_MESSAGE_INFO structure.

`ConnectionContext.Generic`

A pointer to a data structure of unspecified type.

`ConnectionContext.InterruptObject`

A pointer to a KINTERRUPT structure.

`ConnectionContext.InterruptMessageTable`

A pointer to an IO_INTERRUPT_MESSAGE_INFO structure.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

IO_INTERRUPT_MESSAGE_INFO

IoDisconnectInterruptEx

KINTERRUPT

IO_ERROR_LOG_PACKET structure

1/30/2019 • 3 minutes to read • Edit Online

The **IO_ERROR_LOG_PACKET** structure serves as the header for an error log entry.

Syntax

```
typedef struct _IO_ERROR_LOG_PACKET {
  UCHAR         MajorFunctionCode;
  UCHAR         RetryCount;
  USHORT        DumpDataSize;
  USHORT        NumberOfStrings;
  USHORT        StringOffset;
  USHORT        EventCategory;
  NTSTATUS      ErrorCode;
  ULONG         UniqueErrorValue;
  NTSTATUS      FinalStatus;
  ULONG         SequenceNumber;
  ULONG         IoControlCode;
  LARGE_INTEGER DeviceOffset;
  ULONG         DumpData[1];
} IO_ERROR_LOG_PACKET, *PIO_ERROR_LOG_PACKET;
```

Members

`MajorFunctionCode`

Indicates the **IRP_MJ_*XXX*** major function code of the IRP the driver was handling when the error occurred. Setting this value is optional.

`RetryCount`

Indicates the number of times the driver has retried the operation and encountered this error. Use zero to indicate the driver attempted the operation once, or add one for each retry beyond the initial attempt.

`DumpDataSize`

Indicates the size, in bytes, of the variable-length **DumpData** member of this structure. The specified value must be a multiple of **sizeof**(ULONG).

`NumberOfStrings`

Indicates the number of insertion strings the driver will supply with this error log entry. Drivers set this value to zero for errors that need no insertion strings. The Event Viewer uses these strings to fill in the "%2" through "%*n*" entries in the string template for this error code.

The null-terminated Unicode strings themselves follow the **IO_ERROR_LOG_PACKET** structure in memory.

`StringOffset`

Indicates the offset, in bytes, from the beginning of the structure, at which any driver-supplied insertion string data begins. Normally this will be **sizeof**(**IO_ERROR_LOG_PACKET**) plus the value of the **DumpDataSize** member. If there are no driver-supplied insertion strings, **StringOffset** can be zero.

`EventCategory`

Specifies the event category for the error. A driver specifies the event categories it supports and corresponding descriptive strings in its message catalog. The Event Viewer displays the descriptive string as the **Category** value for the error.

`ErrorCode`

Specifies the type of error. The Event Viewer uses the error code to determine which string to display as the Description value for the error. The Event Viewer takes the string template for the error supplied in the driver's message catalog, replaces "%1" in the template with the name of the driver's device object, and replaces "%2" through "%*n*" with the insertion strings supplied with the error log entry.

ErrorCode is a system-defined or driver-defined constant; see Logging Errors for more information.

`UniqueErrorValue`

A driver-specific value that indicates where the error was detected in the driver. Setting this value is optional.

`FinalStatus`

Specifies the NTSTATUS value to be returned for the operation that triggered the error. Setting this value is optional.

`SequenceNumber`

Specifies a driver-assigned sequence number for the current IRP, which should be constant for the life of a given request. Setting this value is optional.

`IoControlCode`

For an IRP_MJ_DEVICE_CONTROL or IRP_MJ_INTERNAL_DEVICE_CONTROL IRP, this member specifies the I/O control code for the request that trigged the error. Otherwise, this value is zero. Setting this value is optional.

`DeviceOffset`

Specifies the driver-specified offset into the device where the error occurred. Setting this value is optional.

`DumpData`

A variable-size array that can be used to store driver-specific binary data, such as register values or any other information useful in identifying the cause of the error. Drivers must specify the size, in bytes, of the array in the **DumpDataSize** member of this structure.

Remarks

Drivers use the IoAllocateErrorLogEntry routine to allocate an error log entry. The **IO_ERROR_LOG_PACKET** structure serves as the header for the returned buffer. It is followed in memory by any insertion strings for the log entry.

Note that the I/O manager itself inserts some information into the system error log, such as the name of the device and driver. The I/O manager reserves 80 bytes to hold this information. If the size of this information exceeds 80 bytes, then the I/O manager truncates the driver's insertion strings as necessary.

For more information about how to use this structure, see Logging Errors.

IO_INTERRUPT_MESSAGE_INFO structure

1/30/2019 • 2 minutes to read • Edit Online

The **IO_INTERRUPT_MESSAGE_INFO** structure describes the driver's message-signaled interrupts.

Syntax

```
typedef struct _IO_INTERRUPT_MESSAGE_INFO {
  KIRQL                           UnifiedIrql;
  ULONG                           MessageCount;
  IO_INTERRUPT_MESSAGE_INFO_ENTRY MessageInfo[1];
} IO_INTERRUPT_MESSAGE_INFO, *PIO_INTERRUPT_MESSAGE_INFO;
```

Members

`UnifiedIrql`

Specifies the IRQL at which the driver's InterruptMessageService routine runs. If the driver specified an interrupt spin lock for its interrupts, **UnifiedIrql** also specifies the IRQL at which the interrupt spin lock is acquired.

`MessageCount`

Specifies the number of message-signaled interrupts allocated for the driver.

`MessageInfo`

Variable-length array that specifies an IO_INTERRUPT_MESSAGE_INFO_ENTRY structure for each message-signaled interrupt allocated for the driver. The **MessageCount** member specifies the number of entries in this array.

Remarks

When a driver calls IoConnectInterruptEx to register an InterruptMessageService routine, **IoConnectInterruptEx** provides a pointer to **IO_INTERRUPT_MESSAGE_INFO** in *Parameters*->**MessageBased.ConnectionContext**. For more information, see IO_CONNECT_INTERRUPT_PARAMETERS.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IoConnectInterruptEx

IO_INTERRUPT_MESSAGE_INFO_ENTRY structure

1/30/2019 • 2 minutes to read • Edit Online

The **IO_INTERRUPT_MESSAGE_INFO_ENTRY** structure describes the properties of a single message-signaled interrupt.

Syntax

```
typedef struct _IO_INTERRUPT_MESSAGE_INFO_ENTRY {
  PHYSICAL_ADDRESS    MessageAddress;
  KAFFINITY           TargetProcessorSet;
  PKINTERRUPT         InterruptObject;
  ULONG               MessageData;
  ULONG               Vector;
  KIRQL               Irql;
  KINTERRUPT_MODE     Mode;
  KINTERRUPT_POLARITY Polarity;
} IO_INTERRUPT_MESSAGE_INFO_ENTRY, *PIO_INTERRUPT_MESSAGE_INFO_ENTRY;
```

Members

`MessageAddress`

Specifies the physical address that triggers the interrupt message.

`TargetProcessorSet`

Specifies a **KAFFINITY** value that determines the set of processors that can receive the interrupt.

`InterruptObject`

Pointer to the interrupt object that represents the interrupt.

`MessageData`

Specifies the value to be written to the address specified by **MessageAddress** to trigger the interrupt.

`Vector`

Specifies the interrupt vector for the interrupt.

`Irql`

Specifies the device IRQL (DIRQL) for the interrupt.

`Mode`

Specifies a KINTERRUPT_MODE value that determines whether the interrupt is level-sensitive or latched.

`Polarity`

Specifies a KINTERRUPT_POLARITY value that determines whether the interrupt is active-high or active-low.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IO_INTERRUPT_MESSAGE_INFO

IO_PAGING_PRIORITY Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **IO_PAGING_PRIORITY** enumeration describes the priority value for a paging I/O IRP.

Syntax

```
typedef enum _IO_PAGING_PRIORITY {
  IoPagingPriorityInvalid,
  IoPagingPriorityNormal,
  IoPagingPriorityHigh,
  IoPagingPriorityReserved1,
  IoPagingPriorityReserved2
} IO_PAGING_PRIORITY;
```

Constants

IoPagingPriorityInvalid	The IRP is not a paging I/O IRP.
IoPagingPriorityNormal	The associated IRP has a normal priority level for paging I/O.
IoPagingPriorityHigh	The associated IRP has a high priority level for paging I/O.
IoPagingPriorityReserved1	Reserved for system use.
IoPagingPriorityReserved2	Reserved for system use.

Remarks

The IoGetPagingIoPriority routine returns an **IO_PAGING_PRIORITY** value to indicate the priority value of a paging I/O IRP.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

IoGetPagingIoPriority

IO_PRIORITY_HINT Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **IO_PRIORITY_HINT** enumeration type specifies the priority hint for an IRP.

Syntax

```
typedef enum _IO_PRIORITY_HINT {
  IoPriorityVeryLow,
  IoPriorityLow,
  IoPriorityNormal,
  IoPriorityHigh,
  IoPriorityCritical,
  MaxIoPriorityTypes
} IO_PRIORITY_HINT;
```

Constants

IoPriorityVeryLow	Specifies the lowest possible priority hint level. The system uses this value for background I/O operations.
IoPriorityLow	Specifies a low-priority hint level.
IoPriorityNormal	Specifies a normal-priority hint level. This value is the default setting for an IRP.
IoPriorityHigh	Specifies a high-priority hint level. This value is reserved for use by the system.
IoPriorityCritical	Specifies the highest-priority hint level. This value is reserved for use by the system.
MaxIoPriorityTypes	Marks the limit for priority hints. Any priority hint value must be less than **MaxIoPriorityTypes**.

Remarks

For more information about priority hints, see Using IRP Priority Hints.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS structure

1/30/2019 • 2 minutes to read • Edit Online

The **IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS** structure contains the connection context for a registered interrupt service routine (ISR) that was connected to an interrupt or interrupts by a previous call to the IoConnectInterruptEx routine.

Syntax

```
typedef struct _IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS {
  ULONG Version;
  union {
    PVOID                      Generic;
    PKINTERRUPT                InterruptObject;
    PIO_INTERRUPT_MESSAGE_INFO InterruptMessageTable;
  } ConnectionContext;
} IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS, *PIO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS;
```

Members

`Version`

The interrupt connection type described by this structure. This member must match the connection type the caller obtained from the **IoConnectInterruptEx** call that connected the interrupt. The following are valid values for this member:

- CONNECT_FULLY_SPECIFIED
- CONNECT_LINE_BASED
- CONNECT_MESSAGE_BASED
- CONNECT_FULLY_SPECIFIED_GROUP

For more information, see Remarks.

`ConnectionContext`

A union that contains the connection context associated with the interrupt. Each union member is a pointer to a connection context of a particular type. If **Version** = CONNECT_MESSAGE_BASED, the **InterruptMessageTable** member of this union contains a pointer to an IO_INTERRUPT_MESSAGE_INFO structure. For all other **Version** values, the **InterruptObject** member of this union contains a pointer to a KINTERRUPT structure. Use the **Generic** member of this union to treat the connection context pointer as a PVOID value (and avoid casting).

For more information, see Remarks.

`ConnectionContext.Generic`

A PVOID pointer to a connection context.

`ConnectionContext.InterruptObject`

A pointer to a connection context of type KINTERRUPT.

`ConnectionContext.InterruptMessageTable`

A pointer to a connection context of type IO_INTERRUPT_MESSAGE_INFO.

Remarks

This structure is supplied as a parameter to the IoReportInterruptActive and IoReportInterruptInactive routines.

The **Version** member indicates the type of the connection context specified in the **ConnectionContext** member. Set this member to the *Parameters*->**Version** value obtained from the IoConnectInterruptEx call that connected the interrupt.

If the *Parameters*->**Version** value obtained from **IoConnectInterruptEx** is CONNECT_FULLY_SPECIFIED or CONNECT_FULLY_SPECIFIED_GROUP, set the **ConnectionContext.InterruptObject** member of the **IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS** structure to the *(*Parameters*->**FullySpecified.InterruptObject**) pointer value obtained from **IoConnectInterruptEx**.

If the *Parameters*->**Version** value obtained from **IoConnectInterruptEx** is CONNECT_MESSAGE_BASED, set the **ConnectionContext.InterruptMessageTable** member of the **IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS** structure to the *(*Parameters*->**MessageBased.ConnectionContext.InterruptMessageTable**) pointer value obtained from **IoConnectInterruptEx**.

If the *Parameters*->**Version** value obtained from **IoConnectInterruptEx** is CONNECT_LINE_BASED, but the caller initially set *Parameters*->**Version** to CONNECT_MESSAGE_BASED, set the **ConnectionContext.InterruptObject** member of the **IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS** structure to the *(*Parameters*->**MessageBased.ConnectionContext.InterruptObject**) pointer value obtained from **IoConnectInterruptEx**.

If the *Parameters*->**Version** value obtained from **IoConnectInterruptEx** is CONNECT_LINE_BASED, and the caller initially set *Parameters*->**Version** to CONNECT_LINE_BASED, set the **ConnectionContext.InterruptObject** member of the **IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS** structure to the *(*Parameters*->**LineBased.InterruptObject**) pointer value obtained from **IoConnectInterruptEx**.

Requirements

Header	wdm.h (include Wdm.h)

IO_RESOURCE_DESCRIPTOR structure

1/30/2019 • 7 minutes to read • Edit Online

The **IO_RESOURCE_DESCRIPTOR** structure describes a range of raw hardware resources, of one type, that can be used by a device. An array of **IO_RESOURCE_DESCRIPTOR** structures is contained within each IO_RESOURCE_LIST structure.

Syntax

```
typedef struct _IO_RESOURCE_DESCRIPTOR {
  UCHAR  Option;
  UCHAR  Type;
  UCHAR  ShareDisposition;
  UCHAR  Spare1;
  USHORT Flags;
  USHORT Spare2;
  union {
    struct {
      ULONG            Length;
      ULONG            Alignment;
      PHYSICAL_ADDRESS MinimumAddress;
      PHYSICAL_ADDRESS MaximumAddress;
    } Port;
    struct {
      ULONG            Length;
      ULONG            Alignment;
      PHYSICAL_ADDRESS MinimumAddress;
      PHYSICAL_ADDRESS MaximumAddress;
    } Memory;
    struct {
      ULONG             MinimumVector;
      ULONG             MaximumVector;
      IRQ_DEVICE_POLICY AffinityPolicy;
      USHORT            Group;
      IRQ_PRIORITY      PriorityPolicy;
      KAFFINITY         TargetedProcessors;
    } Interrupt;
    struct {
      ULONG MinimumChannel;
      ULONG MaximumChannel;
    } Dma;
    struct {
      ULONG RequestLine;
      ULONG Reserved;
      ULONG Channel;
      ULONG TransferWidth;
    } DmaV3;
    struct {
      ULONG            Length;
      ULONG            Alignment;
      PHYSICAL_ADDRESS MinimumAddress;
      PHYSICAL_ADDRESS MaximumAddress;
    } Generic;
    struct {
      ULONG Data[3];
    } DevicePrivate;
    struct {
      ULONG Length;
      ULONG MinBusNumber;
      ULONG MaxBusNumber;
      ULONG Reserved;
```

```
      ULONG Reserved;
    } BusNumber;
    struct {
      ULONG Priority;
      ULONG Reserved1;
      ULONG Reserved2;
    } ConfigData;
    struct {
      ULONG            Length40;
      ULONG            Alignment40;
      PHYSICAL_ADDRESS MinimumAddress;
      PHYSICAL_ADDRESS MaximumAddress;
    } Memory40;
    struct {
      ULONG            Length48;
      ULONG            Alignment48;
      PHYSICAL_ADDRESS MinimumAddress;
      PHYSICAL_ADDRESS MaximumAddress;
    } Memory48;
    struct {
      ULONG            Length64;
      ULONG            Alignment64;
      PHYSICAL_ADDRESS MinimumAddress;
      PHYSICAL_ADDRESS MaximumAddress;
    } Memory64;
    struct {
      UCHAR Class;
      UCHAR Type;
      UCHAR Reserved1;
      UCHAR Reserved2;
      ULONG IdLowPart;
      ULONG IdHighPart;
    } Connection;
  } u;
} IO_RESOURCE_DESCRIPTOR, *PIO_RESOURCE_DESCRIPTOR;
```

Members

`Option`

Specifies whether this resource description is required, preferred, or alternative. One of the following values must be used:

VALUE	MEANING
0	The specified resource range is required, unless alternative ranges are also specified.
IO_RESOURCE_PREFERRED	The specified resource range is preferred to any alternative ranges.

IO_RESOURCE_ALTERNATIVE	The specified resource range is an alternative to the range preceding it. For example, if one **IO_RESOURCE_DESCRIPTOR** structure specifies IRQ 5, with IO_RESOURCE_PREFERRED set, and the next structure specifies IRQ 3, with IO_RESOURCE_ALTERNATIVE set, the PnP manager assigns IRQ 3 to the device only if IRQ 5 is unavailable. (Multiple alternatives can be specified for each resource. Both IO_RESOURCE_ALTERNATIVE and IO_RESOURCE_PREFERRED can be set, indicating a preferred alternative.)
IO_RESOURCE_DEFAULT	Not used.

`Type`

Identifies the resource type. For a list of valid values, see the **Type** member of the CM_PARTIAL_RESOURCE_DESCRIPTOR structure.

`ShareDisposition`

Indicates whether the described resource can be shared. For a list of valid values, see the **ShareDisposition** member of the CM_PARTIAL_RESOURCE_DESCRIPTOR structure.

`Spare1`

`Flags`

Contains bit flags that are specific to the resource type. The following table shows the flags that are valid if **Type** = **CmResourceTypeInterrupt.**

VALUE	MEANING
CM_RESOURCE_INTERRUPT_LEVEL_SENSITIVE	The IRQ line is level-triggered. (These IRQs are usually sharable.)

CM_RESOURCE_INTERRUPT_LATCHED	The IRQ line is edge-triggered.
CM_RESOURCE_INTERRUPT_MESSAGE	If this flag is set, the interrupt is a message-signaled interrupt. Otherwise, the interrupt is a line-based interrupt. This flag can be set starting with Windows Vista.
CM_RESOURCE_INTERRUPT_POLICY_INCLUDED	If this flag is set, the u.Interrupt member includes data that describes the device's interrupt policy. This flag can be set starting with Windows Vista.
CM_RESOURCE_INTERRUPT_SECONDARY_INTERRUPT	The interrupt is a secondary interrupt. This flag can be set starting with Windows 8. For more information about secondary interrupts, see GPIO Interrupts.

CM_ RES OU RCE _IN TER RUP T_W AKE _HI NT	The interrupt is capable of waking the operating system from a low-power idle state or a system sleep state. This flag can be set starting with Windows 8. For more information about wake capabilities, see Enabling Device Wake-Up.

For a list of valid flags for other resource types, see the description of the **Flags** member of the CM_PARTIAL_RESOURCE_DESCRIPTOR structure.

`Spare2`

`u`

port

Specifies a range of I/O port addresses, using the following members.

Drivers for Windows Vista and later versions of the Windows operating system must use RtlIoDecodeMemIoResource and RtlIoEncodeMemIoResource to read and update this member, rather than updating it directly.

Length

The length, in bytes, of the range of assignable I/O port addresses.

Alignment

The alignment, in bytes, that the assigned starting address must adhere to. The assigned starting address must be an integer multiple of *Alignment*.

MinimumAddress

The minimum bus-relative I/O port address that can be assigned to the device.

MaximumAddress

The maximum bus-relative I/O port address that can be assigned to the device.

`u.Port`

`u.Port.Length`

`u.Port.Alignment`

`u.Port.MinimumAddress`

`u.Port.MaximumAddress`

`u.Memory`

`u.Memory.Length`

The length, in bytes, of the range of assignable memory addresses.

`u.Memory.Alignment`

The alignment, in bytes, that the assigned starting address must adhere to. The assigned starting address must be an integer multiple of *Alignment*.

`u.Memory.MinimumAddress`

The minimum bus-relative memory address that can be assigned to the device.

`u.Memory.MaximumAddress`

The maximum bus-relative memory address that can be assigned to the device.

`u.Interrupt`

`u.Interrupt.MinimumVector`

The minimum bus-relative vector that can be assigned to the device.

`u.Interrupt.MaximumVector`

The maximum bus-relative vector that can be assigned to the device.

If the **CM_RESOURCE_INTERRUPT_MESSAGE** flag bit is set, the values of the **MinimumVector** and **MaximumVector** members have special meanings. For more information, see Using Interrupt Resource Descriptors.

The system supplies the following additional members on Windows Vista and later versions of the Windows operating system:

`u.Interrupt.AffinityPolicy`

Specifies an IRQ_DEVICE_POLICY value that indicates how the system should distribute a device's interrupts between processors.

Specifies an IRQ_DEVICE_POLICY value that indicates how the system should distribute a device's interrupts between processors.

`u.Interrupt.Group`

Specifies a processor group number. **Group** is a valid (but optional) member of **u.Interrupt** only in Windows 7 and later versions of Windows. This member exists only if NT_PROCESSOR_GROUPS is defined at compile time. If the **Group** member exists, the **Group** and **TargetedProcessors** members together specify a group affinity that identifies the set of processors that should handle the device's interrupts. To specify an affinity for a particular group, set **AffinityPolicy** to **IrqPolicySpecifiedProcessors** and set **Group** to the appropriate group number. In addition, **TargetedProcessors** must specify the target processors in the group. If you set **AffinityPolicy** to a value other than **IrqPolicySpecifiedProcessors**, set **Group** to ALL_PROCESSOR_GROUPS to indicate that the driver is group-aware (that is, designed to handle information about processor groups). A driver cannot specify target processors if **Group** equals ALL_PROCESSOR_GROUPS; such target specifications are ignored.

`u.Interrupt.PriorityPolicy`

Specifies an IRQ_PRIORITY value that indicates the priority with which the system should dispatch the device's interrupts.

`u.Interrupt.TargetedProcessors`

Specifies a **KAFFINITY** value that indicates which processors should handle the device's interrupts. This value is used only if **AffinityPolicy** is **IrqPolicySpecifiedProcessors.**

`u.Dma`

`u.Dma.MinimumChannel`

The minimum bus-relative DMA channel that can be assigned to the device.

`u.Dma.MaximumChannel`

The maximum bus-relative DMA channel that can be assigned to the device.

`u.DmaV3`

`u.DmaV3.RequestLine`

The number of the request line on the system DMA controller that is allocated to the device.

`u.DmaV3.Reserved`

Not used.

`u.DmaV3.Channel`

The number of the DMA channel on the system DMA controller that is allocated to the device.

`u.DmaV3.TransferWidth`

Specifies the width, in bits, of the data bus that the system DMA controller that is allocated to the device uses to transfer data to or from the device.

`u.Generic`

`u.Generic.Length`

`u.Generic.Alignment`

`u.Generic.MinimumAddress`

`u.Generic.MaximumAddress`

`u.DevicePrivate`

`u.DevicePrivate.Data`

`u.BusNumber`

`u.BusNumber.Length`

The number of bus numbers required.

`u.BusNumber.MinBusNumber`

The minimum bus-relative bus number that can be assigned to the device.

`u.BusNumber.MaxBusNumber`

The maximum bus-relative bus number that can be assigned to the device.

`u.BusNumber.Reserved`

Not used.

`u.ConfigData`

`u.ConfigData.Priority`

`u.ConfigData.Reserved1`

`u.ConfigData.Reserved2`

`u.Memory40`

`u.Memory40.Length40`

The high 32 bits of the 40-bit length, in bytes, of the range of assignable memory addresses. The lower 8 bits are treated as zero.

`u.Memory40.Alignment40`

The high 32 bits of the 40-bit alignment, in bytes, that the assigned starting address must adhere to. The lower 8 bits are treated as zero. The assigned starting address will be a multiple of the alignment.

`u.Memory40.MinimumAddress`

The minimum bus-relative memory address that can be assigned to the device.

`u.Memory40.MaximumAddress`

The maximum bus-relative memory address that can be assigned to the device.

`u.Memory48`

`u.Memory48.Length48`

The high 32 bits of the 48-bit length, in bytes, of the range of assignable memory addresses. The lower 16 bits are treated as zero.

`u.Memory48.Alignment48`

The high 32 bits of the 48-bit alignment, in bytes, that the assigned starting address must adhere to. The lower 16 bits are treated as zero. The assigned starting address will be a multiple of the alignment.

`u.Memory48.MinimumAddress`

The minimum bus-relative memory address that can be assigned to the device.

`u.Memory48.MaximumAddress`

The maximum bus-relative memory address that can be assigned to the device.

`u.Memory64`

`u.Memory64.Length64`

The high 32 bits of the 64-bit length, in bytes, of the range of assignable memory addresses. The lower 32 bits are treated as zero.

`u.Memory64.Alignment64`

The high 32 bits of the 64-bit alignment, in bytes, that the assigned starting address must adhere to. The lower 32 bits are treated as zero. The assigned starting address will be a multiple of the alignment.

`u.Memory64.MinimumAddress`

The minimum bus-relative memory address that can be assigned to the device.

`u.Memory64.MaximumAddress`

The maximum bus-relative memory address that can be assigned to the device.

`u.Connection`

`u.Connection.Class`

The connection class. This member is set to one of the following values.

VALUE	MEANING

CM_RESOURCE_CONNECTION_CLASS_GPIO	Access the device through one or more pins on a GPIO controller.
CM_RESOURCE_CONNECTION_CLASS_SERIAL	Access the device through a serial bus or serial port.

`u.Connection.Type`

The connection type. If *Class* = CM_RESOURCE_CONNECTION_CLASS_GPIO, *Type* is set to the following value:

VALUE	MEANING
CM_RESOURCE_CONNECTION_TYPE_GPIO_IO	Access the device through GPIO pins that are configured for I/O.

Note A GPIO pin that is configured as an interrupt request input is accessed as an ordinary interrupt resource (**CmResourceTypeInterrupt**).

If **Class** = CM_RESOURCE_CONNECTION_CLASS_SERIAL, **Type** is set to one of the following values:

VALUE	MEANING

CM_RESOURCE_CONNECTION_TYPE_I2C	The device is connected to an I²C bus.
CM_RESOURCE_CONNECTION_TYPE_SPI	The device is connected to an SPI bus.
CM_RESOURCE_CONNECTION_TYPE_SERIAL_UART	The device is connected to a serial port.

`u.Connection.Reserved1`

Not used.

`u.Connection.Reserved2`

Not used.

`u.Connection.IdLowPart`

The lower 32 bits of the 64-bit connection ID.

`u.Connection.IdHighPart`

The upper 32 bits of the 64-bit connection ID.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

CM_PARTIAL_RESOURCE_DESCRIPTOR

IO_RESOURCE_LIST

IO_RESOURCE_REQUIREMENTS_LIST

IoConnectInterrupt

IO_RESOURCE_LIST structure

1/30/2019 • 2 minutes to read • Edit Online

The **IO_RESOURCE_LIST** structure describes a range of raw hardware resources, of various types, that can be used by a device. The resources specified represent a single, acceptable resource configuration for a device. An array of **IO_RESOURCE_LIST** structures is contained within each IO_RESOURCE_REQUIREMENTS_LIST structure.

Syntax

```
typedef struct _IO_RESOURCE_LIST {
  USHORT                  Version;
  USHORT                  Revision;
  ULONG                   Count;
  IO_RESOURCE_DESCRIPTOR Descriptors[1];
} IO_RESOURCE_LIST, *PIO_RESOURCE_LIST;
```

Members

`Version`

The version number of this structure. This value should be 1.

`Revision`

The revision of this structure. This value should be 1.

`Count`

The number of elements in the **Descriptors** array.

`Descriptors`

The first element in an array of one or more IO_RESOURCE_DESCRIPTOR structures.

Remarks

This structure is the header for an array of **IO_RESOURCE_DESCRIPTOR** structures. The **Descriptors** member contains the first element in this array, and the **Count** member specifies the total number of array elements. If the array contains more than one element, the remaining elements in the array immediately follow the **IO_RESOURCE_LIST** structure in memory. The total number of bytes occupied by the **IO_RESOURCE_LIST** structure and any array elements that follow this structure is **sizeof**(**IO_RESOURCE_LIST**) + (**Count** - 1) * **sizeof**(**IO_RESOURCE_DESCRIPTOR**).

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

See Also

IO_RESOURCE_DESCRIPTOR

IO_RESOURCE_REQUIREMENTS_LIST

IO_RESOURCE_REQUIREMENTS_LIST structure

1/30/2019 • 3 minutes to read • Edit Online

The **IO_RESOURCE_REQUIREMENTS_LIST** structure describes sets of resource configurations that can be used by a device. Each configuration represents a range of raw resources, of various types, that can be used by a device.

Syntax

```
typedef struct _IO_RESOURCE_REQUIREMENTS_LIST {
  ULONG            ListSize;
  INTERFACE_TYPE   InterfaceType;
  ULONG            BusNumber;
  ULONG            SlotNumber;
  ULONG            Reserved[3];
  ULONG            AlternativeLists;
  IO_RESOURCE_LIST List[1];
} IO_RESOURCE_REQUIREMENTS_LIST, *PIO_RESOURCE_REQUIREMENTS_LIST;
```

Members

`ListSize`

The total number of bytes that constitute the **IO_RESOURCE_REQUIREMENTS_LIST** structure, its IO_RESOURCE_LIST array, and the latter's IO_RESOURCE_DESCRIPTOR array.

`InterfaceType`

Specifies an interface type. This must be one of the types defined by INTERFACE_TYPE, in Wdm.h or Ntddk.h. (Not used by WDM drivers.)

`BusNumber`

A system-assigned, zero-based bus number. (Not used by WDM drivers.)

`SlotNumber`

A system slot number. (Not used by WDM drivers.)

`Reserved`

Not used.

`AlternativeLists`

The number of alternative lists (or configurations) of hardware resources that are described by this **IO_RESOURCE_REQUIREMENTS_LIST** structure. The **List** member is the header for the first alternative list.

`List`

The IO_RESOURCE_LIST structure that serves as the header for the first alternative list of hardware resources. If the **IO_RESOURCE_REQUIREMENTS_LIST** structure describes more than one alternative list, the second alternative list immediately follows the first alternative list in memory, and so on. The size of each alternative list depends on the length of the IO_RESOURCE_DESCRIPTOR array that it contains. For more information, see the following Remarks section.

Remarks

This structure is used by the IRP_MN_FILTER_RESOURCE_REQUIREMENTS and IRP_MN_QUERY_RESOURCE_REQUIREMENTS IRPs to describe one or more alternative configurations of hardware resources.

The **IO_RESOURCE_REQUIREMENTS_LIST** structure is a header for a larger data structure, of variable size, that specifies one or more alternative lists of resources. All of the data in this larger structure occupies a contiguous block of memory, whose size is specified by the **ListSize** member. Each alternative list occupies a subblock within the larger block.

Each alternative list begins with an **IO_RESOURCE_LIST** structure, which serves as a header for an array of **IO_RESOURCE_DESCRIPTOR** structures. The length of this array determines the size of the list, which can vary from one alternative list to the next. Driver code can use pointer arithmetic to step from one alternative list to the next. For example, if a parameter named *list* is a pointer to the **IO_RESOURCE_LIST** structure at the start of one alternative list, *list* can be updated to point to the start of the next list as follows:

```
list = (PIO_RESOURCE_LIST)(list->Descriptors + list->Count);
```

In this example, `list->Descriptors` is a pointer to the start of the **IO_RESOURCE_DESCRIPTOR** array, and `list->Count` is the number of elements in the array. For more information about the **Descriptors** and **Count** members, see IO_RESOURCE_LIST. #### Examples If a driver contains a handler for an **IRP_MN_FILTER_RESOURCE_REQUIREMENTS** IRP, the handler typically walks the resource list that is pointed to by the **IoStatus.Information** field in the IRP. The following code example contains a function—named FilterResources—that is called in the handler to walk the list. This function either verifies that a particular resource is specified in the list, or changes the resource requirements in the list without changing the size of the list. (A function that changes the size of the list would need to allocate a buffer for the updated list, write the list to this buffer, update the **IoStatus.Information** field in the IRP to point to the updated list, and free the buffer that contains the original list.) The FilterResources function returns **TRUE** (probably from the **switch** statement, although the details are omitted to simplify the code example) if it finds the resource that it is looking for in the list, or if it makes a change to the list that does not change the size of the list. Otherwise, it returns **FALSE**.

```
/* Modify the resource list in place (without changing its size). */

BOOLEAN FilterResources(PIO_RESOURCE_REQUIREMENTS_LIST reqlist)
{
    PIO_RESOURCE_LIST list;

    list = reqlist->List;

    for (int ix = 0; ix < reqlist->AlternativeLists; ++ix)
    {
        /* Process resources in IO_RESOURCE_LIST block number ix. */

        for (int jx = 0; jx < list->Count; ++jx)
        {
            PIO_RESOURCE_DESCRIPTOR desc;

            desc = list->Descriptors + jx;

            switch (desc->Type)
            {
               /* Process element jx in Descriptors array. */

               ...

            }
        }

        /* Advance to next IO_RESOURCE_LIST block in memory. */

        list = (PIO_RESOURCE_LIST)(list->Descriptors + list->Count);
    }

    return FALSE;
}
```

Requirements

IO_SECURITY_CONTEXT structure

1/30/2019 • 2 minutes to read • Edit Online

The **IO_SECURITY_CONTEXT** structure represents the security context of an IRP_MJ_CREATE request.

Syntax

```
typedef struct _IO_SECURITY_CONTEXT {
  PSECURITY_QUALITY_OF_SERVICE SecurityQos;
  PACCESS_STATE                AccessState;
  ACCESS_MASK                  DesiredAccess;
  ULONG                        FullCreateOptions;
} IO_SECURITY_CONTEXT, *PIO_SECURITY_CONTEXT;
```

Members

`SecurityQos`

Reserved for system use.

`AccessState`

Reserved for use by file systems and file system filter drivers. This member is a pointer to an ACCESS_STATE structure that contains the object's subject context, granted access types, and remaining desired access types.

`DesiredAccess`

An ACCESS_MASK value that expresses the access rights that are requested in the IRP_MJ_CREATE request.

`FullCreateOptions`

Reserved for system use.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ACCESS_STATE

IRP_MJ_CREATE

IO_SESSION_CONNECT_INFO structure

1/30/2019 • 2 minutes to read • Edit Online

The **IO_SESSION_CONNECT_INFO** structure provides information about a user session.

Syntax

```
typedef struct _IO_SESSION_CONNECT_INFO {
  ULONG   SessionId;
  BOOLEAN LocalSession;
} IO_SESSION_CONNECT_INFO, *PIO_SESSION_CONNECT_INFO;
```

Members

`SessionId`

Session ID. This member contains the Terminal Services session identifier of the user session for which the driver is receiving this notification.

`LocalSession`

Indicates whether the user session is a local session or a remote session. If **TRUE**, the user is logged on locally. If **FALSE**, the user is logged on remotely.

Remarks

If a driver is registered to receive notifications of events in a user session, and if this session enters the *connected* state, the I/O manager calls the driver's IO_SESSION_NOTIFICATION_FUNCTION function. For this call, the I/O manager sets the function's *Event* parameter to **IoSessionEventConnected**. Additionally, the I/O manager sets the function's *NotificationPayload* parameter to point to an **IO_SESSION_CONNECT_INFO** structure that contains information about the user session. For more information about **IoSessionEventConnected**, see IO_SESSION_EVENT.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Fltkernel.h)

IO_SESSION_NOTIFICATION_FUNCTION

IO_SESSION_EVENT Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **IO_SESSION_EVENT** enumeration indicates the type of session event for which a driver is receiving notification.

Syntax

```
typedef enum _IO_SESSION_EVENT {
  IoSessionEventIgnore,
  IoSessionEventCreated,
  IoSessionEventTerminated,
  IoSessionEventConnected,
  IoSessionEventDisconnected,
  IoSessionEventLogon,
  IoSessionEventLogoff,
  IoSessionEventMax
} IO_SESSION_EVENT, *PIO_SESSION_EVENT;
```

Constants

IoSessionEventIgnore	
IoSessionEventCreated	The user session was created.
IoSessionEventTerminated	The user session terminated.
IoSessionEventConnected	The user session was connected.
IoSessionEventDisconnected	The user session was disconnected.
IoSessionEventLogon	The user logged on to the session.
IoSessionEventLogoff	The user logged off of the session.
IoSessionEventMax	Specifies the maximum value in this enumeration type.

Remarks

When the I/O manager calls the driver's IO_SESSION_NOTIFICATION_FUNCTION function, it sets the *Event* parameter of this function to an **IO_SESSION_EVENT** enumeration constant (other than **IoSessionEventMax**).

A session event causes a transition from one session state to another. For more information about session state transitions, see IO_SESSION_STATE.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Fltkernel.h)

IO_SESSION_NOTIFICATION_FUNCTION

IO_SESSION_STATE

IO_SESSION_STATE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **IO_SESSION_STATE** enumeration contains constants that indicate the current state of a user session.

Syntax

```
typedef enum _IO_SESSION_STATE {
  IoSessionStateCreated,
  IoSessionStateInitialized,
  IoSessionStateConnected,
  IoSessionStateDisconnected,
  IoSessionStateDisconnectedLoggedOn,
  IoSessionStateLoggedOn,
  IoSessionStateLoggedOff,
  IoSessionStateTerminated,
  IoSessionStateMax
} IO_SESSION_STATE, *PIO_SESSION_STATE;
```

Constants

IoSessionStateCreated	The session has been created.
IoSessionStateInitialized	The session has been initialized but has not yet been created.
IoSessionStateConnected	The session is connected but the user has not yet logged on.
IoSessionStateDisconnected	The session has been disconnected.
IoSessionStateDisconnectedLoggedOn	The session was disconnected while the user was logged on.
IoSessionStateLoggedOn	The user is logged on to the session.
IoSessionStateLoggedOff	The user has logged off of the session.
IoSessionStateTerminated	The session has been terminated.
IoSessionStateMax	Specifies the maximum value in this enumeration type.

Remarks

When a driver calls the IoGetContainerInformation routine to obtain information about a user session (*InformationClass* = **IoSessionStateInformation**), the I/O manager writes an IO_SESSION_STATE_INFORMATION structure to the buffer pointed to by the routine's *Buffer* parameter. The I/O manager sets the **SessionState** member of this structure to an **IO_SESSION_STATE** enumeration constant (other than **IoSessionStateMax**).

The following table shows the session state transitions. For each state transition, the table shows the following:

- The *from* state (a column label in a gray box)

- The *to* state (a row label in a gray box)
- The event that causes the transition (a table entry in a white box)

A blank white box indicates that no transition can occur directly from the associated *from* state to the corresponding *to* state.

		From state						
		Initialized	Created	Connected	Disconnected	Disconnected + LoggedOn	LoggedOn	LoggedOff
To state	Created	*Created*						
	Connected		*Connected*		*Connected*			
	Disconnected		*Disconnected*	*Disconnected*		*Logoff*		*Disconnected*
	Disconnected + LoggedOn				*Logon*		*Disconnected*	
	LoggedOn			*Logon*				
	LoggedOff						*Logoff*	
	Terminated		*Terminated*	*Terminated*	*Terminated*	*Terminated*	*Terminated*	*Terminated*

In the preceding table, the *from* and *to* states are represented by **IO_SESSION_STATE** enumeration constants, and the events are represented by IO_SESSION_EVENT enumeration constants. For example, if the session state is **IoSessionStateConnected** (abbreviated as "Connected" in the table), an **IoSessionEventLogon** event (abbreviated as "Logon") causes a transition to the **IoSessionStateLoggedOn** state (abbreviated as "LoggedOn"). The starting state for a new session is **IoSessionStateInitialized** (abbreviated as "Initialized").

Requirements

Minimum supported client	Supported in Windows 7 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Fltkernel.h)

IO_SESSION_EVENT

IO_SESSION_STATE_INFORMATION

IoGetContainerInformation

IO_SESSION_STATE_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **IO_SESSION_STATE_INFORMATION** structure contains information about the state of a user session.

Syntax

```
typedef struct _IO_SESSION_STATE_INFORMATION {
  ULONG            SessionId;
  IO_SESSION_STATE SessionState;
  BOOLEAN          LocalSession;
} IO_SESSION_STATE_INFORMATION, *PIO_SESSION_STATE_INFORMATION;
```

Members

`SessionId`

The session ID. This member contains the Terminal Services session identifier of a user session. The IoGetContainerInformation routine sets this member to the session ID of the session that is represented by the session object that the *ContainerObject* parameter of **IoGetContainerInformation** points to.

`SessionState`

The current state of the user session that is identified by *SessionId*. This member is set to one of the following IO_SESSION_STATE enumeration constants:

- **IoSessionStateCreated**
- **IoSessionStateInitialized**
- **IoSessionStateConnected**
- **IoSessionStateDisconnected**
- **IoSessionStateDisconnectedLoggedOn**
- **IoSessionStateLoggedOn**
- **IoSessionStateLoggedOff**
- **IoSessionStateTerminated**

`LocalSession`

Indicates whether the user session identified by *SessionId* is a local session. If **TRUE**, the user is logged on locally. If **FALSE**, the user is logged on remotely. This member is valid only if the session is connected. The following **IO_SESSION_STATE** enumeration constants represent session states in which the session is connected:

- **IoSessionStateConnected**
- **IoSessionStateLoggedOn**
- **IoSessionStateLoggedOff**

Remarks

To obtain information about a user session, a driver calls the **IoGetContainerInformation** routine. This routine's *Buffer* parameter points to an **IO_SESSION_STATE_INFORMATION** structure that contains information about the session state.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Fltkernel.h)

IO_SESSION_STATE

IoGetContainerInformation

IO_SESSION_STATE_NOTIFICATION structure

1/30/2019 • 3 minutes to read • Edit Online

The **IO_SESSION_STATE_NOTIFICATION** structure contains information that a kernel-mode driver supplies to the IoRegisterContainerNotification routine when the driver registers to receive notifications of session events.

Syntax

```
typedef struct _IO_SESSION_STATE_NOTIFICATION {
  ULONG Size;
  ULONG Flags;
  PVOID IoObject;
  ULONG EventMask;
  PVOID Context;
} IO_SESSION_STATE_NOTIFICATION, *PIO_SESSION_STATE_NOTIFICATION;
```

Members

`Size`

The size, in bytes, of the **IO_SESSION_STATE_NOTIFICATION** structure.

`Flags`

No flags are currently defined for this member. Set to zero.

`IoObject`

A pointer to an I/O object owned by the driver. This member can point to a DEVICE_OBJECT, DRIVER_OBJECT, or FILE_OBJECT structure. The I/O object must remain valid for the lifetime of the registration. Before you delete a registered device object, unload a registered driver, or close a registered file object, call the IoUnregisterContainerNotification routine to cancel the registration. A driver can maintain simultaneous registrations for more than one I/O object, but it cannot create more than one active registration for the same I/O object.

`EventMask`

Mask bits for session events. These mask bits indicate the events for which the driver requests notifications.

To register to receive notifications of session events, a kernel-mode driver calls the IoRegisterContainerNotification routine. To specify the session events for which the driver wants to receive notifications, the driver sets this structure's **EventMask** member to the bitwise OR of one or more **IO_SESSION_STATE_*XXX*** constants.

Set this member to the bitwise OR of one or more of the following **IO_SESSION_STATE_*XXX*** constants:

VALUE	MEANING

IO_SESSION_STATE_ALL_EVENTS 0xffffffff	Send notifications of all session events.
IO_SESSION_STATE_CREATION_EVENT 0x00000001	Send a notification when the user session is created.
IO_SESSION_STATE_TERMINATION_EVENT 0x00000002	Send a notification when the user session ends.

IO_SESSION_STATE_CONNECT_EVENT 0x00000004	Send a notification when the user session is connected.
IO_SESSION_STATE_DISCONNECT_EVENT 0x00000008	Send a notification when the user session is disconnected.
IO_SESSION_STATE_LOGON_EVENT 0x00000010	Send a notification when the user logs on to the session.

IO_SESSION_LOGOFF_EVENT 0x00000020	Send a notification when the user logs off of the session.
IO_SESSION_EVENT_ALL_EVENT_MASK 0x0000003f	Send a notification when any type of session event occurs.

`Context`

A pointer to a context buffer in which the driver can store its private data for a particular session notification registration. The I/O manager passes this pointer to the driver's notification callback routine (specified by the **IoRegisterContainerNotification** routine's *CallbackFunction* parameter). The I/O manager does not try to validate the *Context* pointer or to access the buffer that it points to. This member can be **NULL** if the driver does not require a context buffer.

Remarks

This structure is used by the **IoRegisterContainerNotification** routine. A driver that calls **IoRegisterContainerNotification** uses this structure to specify the session event notifications that it is registering for.

A per-session device object represents a device that can be accessed only by a particular user session. If a driver sets the **IoObject** member to point to a device object that is a per-session device object, **IoRegisterContainerNotification** registers the driver to receive only notifications of events that occur in the session that is represented by the device object. If **IoObject** points to a device object that is not a per-session device object, or if **IoObject** points to an object that is not a device object, **IoRegisterContainerNotification** registers the driver to receive notifications of events that occur in all sessions on the computer.

To determine whether a device object is a per-session device object, a driver can call the IoGetDevicePropertyData routine to query the DEVPKEY_Device_SessionId property key in the property store of the device object. If the **DEVPKEY_Device_SessionId** property exists and the value of the property is set to a nonzero Terminal Services session identifier, the device object is a per-session device object. For more information, see DEVPKEY_Device_SessionId.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Fltkernel.h)

IO_STACK_LOCATION structure

2/5/2019 • 8 minutes to read • Edit Online

The **IO_STACK_LOCATION** structure defines an I/O stack location, which is an entry in the I/O stack that is associated with each IRP. Each I/O stack location in an IRP has some common members and some request-type-specific members.

Syntax

```
typedef struct _IO_STACK_LOCATION {
  UCHAR                 MajorFunction;
  UCHAR                 MinorFunction;
  UCHAR                 Flags;
  UCHAR                 Control;
  union {
    struct {
      PIO_SECURITY_CONTEXT     SecurityContext;
      ULONG                    Options;
      USHORT POINTER_ALIGNMENT FileAttributes;
      USHORT                   ShareAccess;
      ULONG POINTER_ALIGNMENT  EaLength;
    } Create;
    struct {
      PIO_SECURITY_CONTEXT          SecurityContext;
      ULONG                         Options;
      USHORT POINTER_ALIGNMENT      Reserved;
      USHORT                        ShareAccess;
      PNAMED_PIPE_CREATE_PARAMETERS Parameters;
    } CreatePipe;
    struct {
      PIO_SECURITY_CONTEXT        SecurityContext;
      ULONG                       Options;
      USHORT POINTER_ALIGNMENT    Reserved;
      USHORT                      ShareAccess;
      PMAILSLOT_CREATE_PARAMETERS Parameters;
    } CreateMailslot;
    struct {
      ULONG                   Length;
      ULONG POINTER_ALIGNMENT Key;

Members

`MajorFunction`

The IRP major function code indicating the type of I/O operation to be performed.

`MinorFunction`

A subfunction code for **MajorFunction**. The PnP manager, the power manager, file system drivers, and SCSI class drivers set this member for some requests.

`Flags`

Request-type-specific values used almost exclusively by file system drivers. Removable-media device drivers check whether this member is set with SL_OVERRIDE_VERIFY_VOLUME for read requests to determine whether to continue the read operation even if the device object's **Flags** is set with DO_VERIFY_VOLUME. Intermediate drivers layered over a removable-media device driver must copy this member into the I/O stack location of the next-lower driver in all incoming IRP_MJ_READ requests.

Possible flag values include:

FLAG	VALUE	DESCRIPTION
SL_KEY_SPECIFIED	`0x01`	Indicates that the `IO_STACK_LOCATION.Parameters.Read(OrWrite).K` contains which copy of a given sector should be read when redundancy is enabled. Today this flag is use only with IRP_MJ_READ operations.
SL_OVERRIDE_VERIFY_VOLUME	`0x02`	This flag is used to determine whether to continue the read operation even if the device object's **Flags** is set with DO_VERIFY_VOLUME.
SL_WRITE_THROUGH	`0x04`	This flag informs the storage driver to set appropriate flags so that the disk bypasses the write cache in order to force the disk to write through to its persistent storage media. **This flag is device-specific; not all disk drives support bypassing disk-cache.**
SL_FT_SEQUENTIAL_WRITE	`0x08`	Reserved for system use.

SL_FORCE_DIRECT_WRITE	`0x10`	This flag lets kernel-mode drivers write to volume areas that they normally cannot write to because of blocking direct write in the file system and storage driver stack. **This flag was introduced in Windows Vista.** **Note** Direct write blocking, introduced in Windows Vista helps improve security. This flag is checked both at the file system layer and storage stack layer. For more information about direct write blocking, see Blocking Direct Write Operations to Volumes and Disks.
SL_REALTIME_STREAM	`0x20`	This flag hints that the IO is for real-time streaming requests to a CD-ROM class driver. This hints the driver to perform READ/WRITE operations at a guaranteed speed for real-time streaming. **This flag is valid only with optical media.**
SL_PERSISTENT_MEMORY_FIXED_MAPPING	`0x20`	The persistent memory mapping of the bytes in the write request cannot change while handling this write request. **This flag is valid only with a persistent memory device and IRP_MJ_WRITE.**

Note (For persistent memory devices) One of the reasons for remapping (modifying the physical address of a given LBA) on persistent memory devices is to provide efficient sector level atomicity. If the flag is not set, remapping is allowed especially if it results in the driver providing sector atomicity. File systems (or the requester) prefer that a persistent memory device driver provides sector atomicity. If the flag is set, a persistent memory driver shall not remap the physical addresses corresponding to the LBAs. If that means sector atomicity can't be provided, so be it. However, the driver is more than welcome to provide sector atomicity as long as there is no remapping.

`Control`

Drivers can check this member to determine whether it is set with SL_PENDING_RETURNED. Drivers have read-only access to this member.

`Parameters`

A union that depends on the major and minor IRP function code values contained in **MajorFunction** and **MinorFunction**. The following table shows which IRPs use the individual members of the **Parameters** union.

MEMBER NAME	IRPS THAT USE THIS MEMBER
Create	IRP_MJ_CREATE
Read	IRP_MJ_READ
Write	IRP_MJ_WRITE
QueryFile	IRP_MJ_QUERY_INFORMATION
SetFile	IRP_MJ_SET_INFORMATION

QueryVolume	IRP_MJ_QUERY_VOLUME_INFORMATION
DeviceIoControl	IRP_MJ_DEVICE_CONTROL and IRP_MJ_INTERNAL_DEVICE_CONTROL
MountVolume	**IRP_MN_MOUNT_VOLUME**

`DeviceObject`

A pointer to the driver-created DEVICE_OBJECT structure representing the target physical, logical, or virtual device for which this driver is to handle the IRP.

`FileObject`

A pointer to a FILE_OBJECT structure that represents the file object, if any, that is associated with **DeviceObject** pointer.

`CompletionRoutine`

The completion routines that is invoked depending on the flags in the preceding flags field.

`Context`

Driver-defined context that is used to store the address of the context parameter that is passed to the CompletionRoutine.

Remarks

For each IRP, there is one **IO_STACK_LOCATION** structure for each driver in a driver stack. Each IRP's set of I/O stack locations is appended to the IRP, following the IRP structure.

Every higher-level driver is responsible for setting up the I/O stack location for the next-lower driver in each IRP. A driver must call IoGetCurrentIrpStackLocation to get a pointer to its own stack location for each IRP. Higher-level drivers can call IoGetNextIrpStackLocation to get a pointer to the next-lower driver's stack location.

The higher-level driver must set up the stack location contents before calling IoCallDriver to pass an IRP to the lower-level driver. If the driver will pass the input IRP on to the next lower-level driver, the dispatch routine should call IoSkipCurrentIrpStackLocation or IoCopyCurrentIrpStackLocationToNext to set up the I/O stack location of the next-lower driver.

A higher-level driver's call to **IoCallDriver** sets the **DeviceObject** member to the next-lower-level driver's target device object, in the I/O stack location of the lower driver. The I/O manager passes each higher-level driver's IoCompletion routine a pointer to its own device object when the *IoCompletion* routine is called on completion of the

IRP.

If a higher-level driver allocates IRPs to make requests of its own, its *IoCompletion* routine is passed a **NULL** **DeviceObject** pointer if that driver neither allocates a stack location for itself nor sets up the **DeviceObject** pointer in its own stack location of the newly allocated IRP.

In some cases, a higher-level driver layered over a mass-storage device driver is responsible for splitting up large transfer requests for the underlying device driver. In particular, SCSI class drivers must check the **Parameters.Read.Length** and **Parameters.Write.Length**, determine whether the size of the requested transfer exceeds the underlying HBA's transfer capabilities, and, if so, split the **Length** of the original request into a sequence of partial transfers to satisfy the original IRP.

IO_STATUS_BLOCK structure

1/30/2019 • 2 minutes to read • Edit Online

A driver sets an IRP's I/O status block to indicate the final status of an I/O request, before calling IoCompleteRequest for the IRP.

Syntax

```
typedef struct _IO_STATUS_BLOCK {
  union {
    NTSTATUS Status;
    PVOID    Pointer;
  } DUMMYUNIONNAME;
  ULONG_PTR Information;
} IO_STATUS_BLOCK, *PIO_STATUS_BLOCK;
```

Members

`DUMMYUNIONNAME`

`DUMMYUNIONNAME.Status`

This is the completion status, either STATUS_SUCCESS if the requested operation was completed successfully or an informational, warning, or error STATUS_*XXX* value. For more information, see Using NTSTATUS values.

`DUMMYUNIONNAME.Pointer`

Reserved. For internal use only.

`Information`

This is set to a request-dependent value. For example, on successful completion of a transfer request, this is set to the number of bytes transferred. If a transfer request is completed with another STATUS_*XXX*, this member is set to zero.

Remarks

Unless a driver's dispatch routine completes an IRP with an error status value, the lowest-level driver in the chain frequently sets the IRP's I/O status block to the values that will be returned to the original requester of the I/O operation.

The IoCompletion routines of higher-level drivers usually check the I/O status block in IRPs completed by lower drivers. By design, the I/O status block in an IRP is the only information passed back from the underlying device driver to all higher-level drivers' *IoCompletion* routines.

The operating system implements support routines that write **IO_STATUS_BLOCK** values to caller-supplied output buffers. For example, see ZwOpenFile or NtOpenFile. These routines return status codes that might not match the status codes in the **IO_STATUS_BLOCK** structures. If one of these routines returns STATUS_PENDING, the caller should wait for the I/O operation to complete, and then check the status code in the **IO_STATUS_BLOCK** structure to determine the final status of the operation. If the routine returns a status code other than STATUS_PENDING, the caller should rely on this status code instead of the status code in the **IO_STATUS_BLOCK** structure.

For more information, see I/O Status Blocks.

IoCompleteRequest

IoSetCompletionRoutine

IRP structure

2/5/2019 • 6 minutes to read • Edit Online

The **IRP** structure is a partially opaque structure that represents an *I/O request packet*. Drivers can use the following members of the IRP structure.

Syntax

```
typedef struct _IRP {
  CSHORT                    Type;
  USHORT                    Size;
  PMDL                      MdlAddress;
  ULONG                     Flags;
  union {
    struct _IRP     *MasterIrp;
    __volatile LONG IrpCount;
    PVOID           SystemBuffer;
  } AssociatedIrp;
  LIST_ENTRY                ThreadListEntry;
  IO_STATUS_BLOCK           IoStatus;
  KPROCESSOR_MODE           RequestorMode;
  BOOLEAN                   PendingReturned;
  CHAR                      StackCount;
  CHAR                      CurrentLocation;
  BOOLEAN                   Cancel;
  KIRQL                     CancelIrql;
  CCHAR                     ApcEnvironment;
  UCHAR                     AllocationFlags;
  PIO_STATUS_BLOCK          UserIosb;
  PKEVENT                   UserEvent;
  union {
    struct {
      union {
        PIO_APC_ROUTINE UserApcRoutine;
        PVOID           IssuingProcess;
      };
      PVOID UserApcContext;
    } AsynchronousParameters;
    LARGE_INTEGER AllocationSize;
  } Overlay;
  __volatile PDRIVER_CANCEL CancelRoutine;
  PVOID                     UserBuffer;
  union {
    struct {
      union {
        KDEVICE_QUEUE_ENTRY DeviceQueueEntry;
        struct {
          PVOID DriverContext[4];
        };
      };
      PETHREAD     Thread;
      PCHAR        AuxiliaryBuffer;
      struct {
        LIST_ENTRY ListEntry;
        union {
          struct _IO_STACK_LOCATION *CurrentStackLocation;
          ULONG                     PacketType;
        };
      };
      PFILE_OBJECT OriginalFileObject;
    } Overlay;
    KAPC  Apc;
    PVOID CompletionKey;
  } Tail;
} IRP;
```

Members

`Type`

`Size`

`MdlAddress`

Pointer to an MDL describing a user buffer, if the driver is using direct I/O, and the IRP major function code is one of the following:

IRP_MJ_READ

The MDL describes an empty buffer that the device or driver fills in.

IRP_MJ_WRITE

The MDL describes a buffer that contains data for the device or driver.

IRP_MJ_DEVICE_CONTROL or IRP_MJ_INTERNAL_DEVICE_CONTROL

If the IOCTL code specifies the METHOD_IN_DIRECT transfer type, the MDL describes a buffer that contains data for the device or driver.

If the IOCTL code specifies the METHOD_OUT_DIRECT transfer type, the MDL describes an empty buffer that the device or driver fills in.

For more information about the buffers that are associated with METHOD_IN_DIRECT and METHOD_OUT_DIRECT transfer types in IOCTL codes, see Buffer Descriptions for I/O Control Codes.

If the driver is not using direct I/O, this pointer is **NULL**.

`Flags`

File system drivers use this field, which is read-only for all drivers. Network and, possibly, highest-level device drivers also might read this field. This field is set either to zero or to the bitwise-OR of one or more of the following system-defined flag bits:

IRP_NOCACHE

IRP_PAGING_IO

IRP_MOUNT_COMPLETION

IRP_SYNCHRONOUS_API

IRP_ASSOCIATED_IRP

IRP_BUFFERED_IO

IRP_DEALLOCATE_BUFFER

IRP_INPUT_OPERATION

IRP_SYNCHRONOUS_PAGING_IO

IRP_CREATE_OPERATION

IRP_READ_OPERATION

IRP_WRITE_OPERATION

IRP_CLOSE_OPERATION

IRP_DEFER_IO_COMPLETION

IRP_OB_QUERY_NAME

IRP_HOLD_DEVICE_QUEUE

IRP_UM_DRIVER_INITIATED_IO

`AssociatedIrp`

`AssociatedIrp.MasterIrp`

Pointer to the master IRP in an IRP that was created by a highest-level driver's call to IoMakeAssociatedIrp.

`AssociatedIrp.IrpCount`

`AssociatedIrp.SystemBuffer`

Pointer to a system-space buffer.

If the driver is using buffered I/O, the buffer's purpose is determined by the IRP major function code, as follows:

SystemBuffer.IRP_MJ_READ

The buffer receives data from the device or driver. The buffer's length is specified by **Parameters.Read.Length** in the driver's IO_STACK_LOCATION structure.

NULL.

SystemBuffer.IRP_MJ_WRITE

The buffer supplies data for the device or driver. The buffer's length is specified by **Parameters.Write.Length** in the driver's **IO_STACK_LOCATION** structure.

NULL.

SystemBuffer.IRP_MJ_DEVICE_CONTROL or IRP_MJ_INTERNAL_DEVICE_CONTROL

The buffer represents both the input and output buffers that are supplied to **DeviceIoControl** and **IoBuildDeviceIoControlRequest**. Output data overwrites input data.

For input, the buffer's length is specified by **Parameters.DeviceIoControl.InputBufferLength** in the driver's **IO_STACK_LOCATION** structure.

For output, the buffer's length is specified by **Parameters.DeviceIoControl.OutputBufferLength** in the driver's **IO_STACK_LOCATION** structure.

For more information, see Buffer Descriptions for I/O Control Codes.

The buffer represents the input buffer that is supplied to **DeviceIoControl** and **IoBuildDeviceIoControlRequest**.

The buffer's length is specified by **Parameters.DeviceIoControl.InputBufferLength** in the driver's **IO_STACK_LOCATION** structure.

For more information, see Buffer Descriptions for I/O Control Codes.

If the driver is using direct I/O, the buffer's purpose is determined by the IRP major function code, as follows:

`ThreadListEntry`

`IoStatus`

Contains the IO_STATUS_BLOCK structure in which a driver stores status and information before calling IoCompleteRequest.

`RequestorMode`

Indicates the execution mode of the original requester of the operation, one of **UserMode** or **KernelMode**.

`PendingReturned`

If set to **TRUE**, a driver has marked the IRP pending. Each IoCompletion routine should check the value of this flag. If the flag is **TRUE**, and if the IoCompletion routine will not return STATUS_MORE_PROCESSING_REQUIRED, the routine should call IoMarkIrpPending to propagate the pending status to drivers above it in the device stack.

`StackCount`

`CurrentLocation`

`Cancel`

If set to **TRUE**, the IRP either is or should be canceled.

`CancelIrql`

Contains the IRQL at which a driver is running when IoAcquireCancelSpinLock is called.

`ApcEnvironment`

`AllocationFlags`

`UserIosb`

`UserEvent`

`Overlay`

`Overlay.AsynchronousParameters`

`Overlay.AsynchronousParameters`

`Overlay.AsynchronousParameters.UserApcRoutine`

`Overlay.AsynchronousParameters.IssuingProcess`

`Overlay.AsynchronousParameters.UserApcContext`

`Overlay.AllocationSize`

`CancelRoutine`

Contains the entry point for a driver-supplied Cancel routine to be called if the IRP is canceled. **NULL** indicates that the IRP is not currently cancelable.

`UserBuffer`

Contains the address of an output buffer if both of the following conditions apply:

- The major function code in the I/O stack location is IRP_MJ_DEVICE_CONTROL or IRP_MJ_INTERNAL_DEVICE_CONTROL.
- The I/O control code was defined with METHOD_NEITHER or METHOD_BUFFERED.

For METHOD_BUFFERED, the driver should use the buffer pointed to by **Irp->AssociatedIrp.SystemBuffer** as the output buffer. When the driver completes the request, the I/O manager copies the contents of this buffer to the output buffer that is pointed to by **Irp->UserBuffer**. The driver should not write directly to the buffer pointed to by **Irp->UserBuffer**. For more information, see Buffer Descriptions for I/O Control Codes.

`Tail`

`Tail.Overlay`

`Tail.Overlay`

`Tail.Overlay.DeviceQueueEntry`

If IRPs are queued in the device queue associated with the driver's device object, this field links IRPs in the device queue. These links can be used only while the driver is processing the IRP.

`Tail.Overlay`

`Tail.Overlay.DriverContext`

If IRPs are not queued in the device queue associated with the driver's device object, this field can be used by the driver to store up to four pointers. This field can be used only while the driver owns the IRP.

`Tail.Overlay.Thread`

A pointer to the caller's thread control block (TCB). For requests that originate in user-mode, the I/O manager always sets this field to point to the TCB of the thread that issued the request.

`Tail.Overlay.AuxiliaryBuffer`

`Tail.Overlay`

`Tail.Overlay.ListEntry`

If a driver manages its own internal queues of IRPs, it uses this field to link one IRP to the next. These links can be used only while the driver is holding the IRP in its queue or is processing the IRP.

`Tail.Overlay`

`Tail.Overlay.CurrentStackLocation`

`Tail.Overlay.PacketType`

`Tail.Overlay.OriginalFileObject`

`Tail.Apc`

`Tail.CompletionKey`

Remarks

Undocumented members of the IRP structure are reserved, used only by the I/O manager or, in some cases, by FSDs.

An IRP is the basic I/O manager structure used to communicate with drivers and to allow drivers to communicate with each other. A packet consists of two different parts:

- *Header*, or *fixed part of the packet*— This is used by the I/O manager to store information about the original request, such as the caller's device-independent parameters, the address of the device object upon which a file is open, and so on. It is also used by drivers to store information such as the final status of the request.
- *I/O stack locations*— Following the header is a set of I/O stack locations, one per driver in the chain of layered drivers for which the request is bound. Each stack location contains the parameters, function codes, and context used by the corresponding driver to determine what it is supposed to be doing. For more information, see the IO_STACK_LOCATION structure.

While a higher-level driver might check the value of the **Cancel** Boolean in an IRP, that driver cannot assume the IRP will be completed with STATUS_CANCELLED by a lower-level driver even if the value is **TRUE**.

IRQ_DEVICE_POLICY Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **IRQ_DEVICE_POLICY** enumeration type indicates the policy the operating system can use to assign the interrupts from a device to different processors.

Syntax

```
typedef enum _IRQ_DEVICE_POLICY {
  IrqPolicyMachineDefault,
  IrqPolicyAllCloseProcessors,
  IrqPolicyOneCloseProcessor,
  IrqPolicyAllProcessorsInMachine,
  IrqPolicySpecifiedProcessors,
  IrqPolicySpreadMessagesAcrossAllProcessors,
  IrqPolicyAllProcessorsInMachineWhenSteered
} IRQ_DEVICE_POLICY, *PIRQ_DEVICE_POLICY;
```

Constants

IrqPolicyMachineDefault	The device does not require any particular assignment of interrupts to processors.
IrqPolicyAllCloseProcessors	The operating system should assign interrupts from the device to processors that are close to the device. On non-NUMA computers, the effect of this value is identical to that of **IrqPolicyAllProcessorsInMachine**.
IrqPolicyOneCloseProcessor	The operating system should assign a single interrupt for the device to one processor that is close to the device. On non-NUMA computers, the operating system can assign the interrupt to any processor.
IrqPolicyAllProcessorsInMachine	The operating system should assign interrupts from the device to all processors.
IrqPolicySpecifiedProcessors	The operating system should assign interrupts from the device to a specific set of processors.
IrqPolicySpreadMessagesAcrossAllProcessors	The operating system should assign different message-signaled interrupts to different processors, if possible.
IrqPolicyAllProcessorsInMachineWhenSteered	

Remarks

The **Interrupt.AffinityPolicy** member of the IO_RESOURCE_DESCRIPTOR structure is an **IRQ_DEVICE_POLICY** enumeration value.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

See Also

IO_RESOURCE_DESCRIPTOR

IRQ_PRIORITY Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **IRQ_PRIORITY** enumeration type indicates the priority the system should give to servicing a device's interrupts.

Syntax

```
typedef enum _IRQ_PRIORITY {
  IrqPriorityUndefined,
  IrqPriorityLow,
  IrqPriorityNormal,
  IrqPriorityHigh
} IRQ_PRIORITY, *PIRQ_PRIORITY;
```

Constants

IrqPriorityUndefined	Specifies that the device does not require any particular priority for its interrupts.
IrqPriorityLow	Specifies that the device's interrupts are of low priority. This setting is appropiate for devices that can tolerate higher-than-normal latency.
IrqPriorityNormal	Specifies that the device's interrupts are of normal priority.
IrqPriorityHigh	Specifies that the device's interrupts are of high priority. This setting is appropriate for devices that require low latency.

Remarks

The system uses **IRQ_PRIORITY** to assign IRQLs for devices. For example, it might assign a higher IRQL to a device that has an **IRQ_PRIORITY** of **IrqPriorityHigh** than it does to a device that has an **IRQ_PRIORITY** of **IrqPriorityLow**.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

IO_RESOURCE_DESCRIPTOR

KBUGCHECK_ADD_PAGES structure

1/30/2019 • 2 minutes to read • Edit Online

The **KBUGCHECK_ADD_PAGES** structure describes one or more pages of driver-supplied data to be written by a BugCheckAddPagesCallback callback routine to the crash dump file.

Syntax

```
typedef struct _KBUGCHECK_ADD_PAGES {
  PVOID     Context;
  ULONG     Flags;
  ULONG     BugCheckCode;
  ULONG_PTR Address;
  ULONG_PTR Count;
} KBUGCHECK_ADD_PAGES, *PKBUGCHECK_ADD_PAGES;
```

Members

`Context`

Contains private context data for the exclusive use of the callback routine. The callback routine can set this member to any value. Typically, if the callback routine needs to be called more than one time, the routine sets this member to point to a driver-supplied buffer during the initial call. During subsequent calls, the callback routine can read the previous contents of this buffer and update its contents. Before the initial call to the callback routine, **Context** is **NULL**.

`Flags`

Contains flags that describe the add-page request. The callback routine must set the value of this member. Set this member to the bitwise OR of one or more of the following flag bits:

KB_ADD_PAGES_FLAG_VIRTUAL_ADDRESS

Indicates that the **Address** member contains a virtual address.

KB_ADD_PAGES_FLAG_PHYSICAL_ADDRESS

Indicates that the **Address** member contains a physical address.

KB_ADD_PAGES_FLAG_ADDITIONAL_RANGES_EXIST

Indicates that the callback routine requests that it be called again so that it can add more pages.

The callback routine must set either the KB_ADD_PAGES_FLAG_VIRTUAL_ADDRESS flag or the KB_ADD_PAGES_FLAG_PHYSICAL_ADDRESS flag, but not both. On entry to the callback routine, **Flags** is initialized to zero.

`BugCheckCode`

Contains a bug check code, which specifies the reason for the bug check. The callback routine can use this information to decide whether to add any pages to the crash dump file. For a full list of bug check codes, see the Bugcodes.h header file.

`Address`

Specifies the physical or virtual address of the page or pages that the callback routine requests be added to the crash dump file.

`Count`

Specifies the number of contiguous pages to add to the crash dump file, starting from the virtual or physical address that is specified by the **Address** member. If **Count** > 1 and **Address** is a virtual address, the pages are contiguous in virtual memory space. If **Count** > 1 and **Address** is a physical address, the pages are contiguous in physical memory space. The callback routine can set this member to zero to indicate that it does not need to add any pages to the crash dump file.

Remarks

In a call to the *BugCheckAddPagesCallback* callback routine, the operating system sets the *Reason* parameter to **KbCallbackAddPages**, and sets the *ReasonSpecificData* parameter to point to a **KBUGCHECK_ADD_PAGES** structure.

For more information about how this structure is used, see BugCheckAddPagesCallback.

Requirements

Minimum supported client	Supported in Windows Server 2008 and later versions of Windows.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

BugCheckAddPagesCallback

KBUGCHECK_CALLBACK_REASON Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **KBUGCHECK_CALLBACK_REASON** enumeration type specifies the situations in which a bug-check callback executes.

Syntax

```
typedef enum _KBUGCHECK_CALLBACK_REASON {
  KbCallbackInvalid,
  KbCallbackReserved1,
  KbCallbackSecondaryDumpData,
  KbCallbackDumpIo,
  KbCallbackAddPages,
  KbCallbackSecondaryMultiPartDumpData,
  KbCallbackRemovePages,
  KbCallbackTriageDumpData
} KBUGCHECK_CALLBACK_REASON;
```

Constants

KbCallbackInvalid	Reserved for system use. Do not use.
KbCallbackReserved1	Reserved for system use. Do not use.
KbCallbackSecondaryDumpData	Specifies that the callback is executed to provide data that the system appends to the secondary section of the crash dump file. For more information about this type of callback, see BugCheckSecondaryDumpDataCallback.
KbCallbackDumpIo	Specifies that the callback is executed each time a section of the dump file is written. For more information about this type of callback, see BugCheckDumpIoCallback.
KbCallbackAddPages	Specifies that the callback is executed to provide one or more pages of data that the system adds to the primary section of the crash dump file. For more information about this type of callback, see BugCheckAddPagesCallback. This enumeration value is supported in Windows Server 2008 and later versions of Windows.
KbCallbackSecondaryMultiPartDumpData	Specifies that the callback is executed to get the amount of data the driver wants to store in the dump file. For more information about this type of callback, see BugCheckAddPagesCallback. This enumeration value is supported in Windows Server 2008 and later versions of Windows.
KbCallbackRemovePages	
KbCallbackTriageDumpData	

Requirements

Minimum supported client	Supported on Windows XP with Service Pack 1 (SP1), Windows Server 2003, and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KBUGCHECK_DUMP_IO structure

1/30/2019 • 2 minutes to read • Edit Online

The **KBUGCHECK_DUMP_IO** structure describes an I/O operation on the crash dump file.

Syntax

```
typedef struct _KBUGCHECK_DUMP_IO {
  IN ULONG64                Offset;
  IN PVOID                  Buffer;
  IN ULONG                  BufferLength;
  IN KBUGCHECK_DUMP_IO_TYPE Type;
} KBUGCHECK_DUMP_IO, *PKBUGCHECK_DUMP_IO;
```

Members

`Offset`

Specifies the current offset in the crash dump file, or -1 if the crash dump file is being written sequentially.

`Buffer`

Pointer to a buffer that contains the current data to be written to the dump file.

`BufferLength`

Specifies the length of the buffer, in bytes, that is specified by the **Buffer** member.

`Type`

Specifies the KBUGCHECK_DUMP_IO_TYPE value that signifies the type of data to be written to the dump file.

Remarks

For information about how this structure is used, see BugCheckDumpIoCallback.

Requirements

Minimum supported client	Available on Microsoft Windows XP with Service Pack 1 (SP1), Windows Server 2003, and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

BugCheckDumpIoCallback

KBUGCHECK_DUMP_IO_TYPE

KBUGCHECK_DUMP_IO_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **KBUGCHECK_DUMP_IO_TYPE** enumeration type identifies the type of a section of data within a crash dump file.

Syntax

```
typedef enum _KBUGCHECK_DUMP_IO_TYPE {
  KbDumpIoInvalid,
  KbDumpIoHeader,
  KbDumpIoBody,
  KbDumpIoSecondaryData,
  KbDumpIoComplete
} KBUGCHECK_DUMP_IO_TYPE;
```

Constants

KbDumpIoInvalid	Reserved for system use. Do not use.
KbDumpIoHeader	Specifies that crash dump data is header information.
KbDumpIoBody	Specifies that the crash dump data is part of the main body of the crash dump, such as the memory state at the time of the bug check.
KbDumpIoSecondaryData	Specifies that the crash dump data is data returned by a BugCheckSecondaryDumpDataCallback routine.
KbDumpIoComplete	Specifies that the crash dump data has been completely written.

Remarks

KBUGCHECK_DUMP_IO_TYPE values are used in the **Type** member of KBUGCHECK_DUMP_IO to specify the type of data in an I/O operation on the crash dump file.

For more information about how this enumeration type is used, see BugCheckDumpIoCallback.

Requirements

Minimum supported client	Available on Microsoft Windows XP with Service Pack 1 (SP1), Windows Server 2003, and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

BugCheckDumpIoCallback

BugCheckSecondaryDumpDataCallback

KBUGCHECK_DUMP_IO

KBUGCHECK_SECONDARY_DUMP_DATA structure

1/30/2019 • 2 minutes to read • Edit Online

The **KBUGCHECK_SECONDARY_DUMP_DATA** structure describes a section of driver-supplied data to be written by BugCheckSecondaryDumpDataCallback to the crash dump file.

Syntax

```
typedef struct _KBUGCHECK_SECONDARY_DUMP_DATA {
  IN PVOID  InBuffer;
  IN ULONG  InBufferLength;
  IN ULONG  MaximumAllowed;
  OUT GUID  Guid;
  OUT PVOID OutBuffer;
  OUT ULONG OutBufferLength;
} KBUGCHECK_SECONDARY_DUMP_DATA, *PKBUGCHECK_SECONDARY_DUMP_DATA;
```

Members

`InBuffer`

Pointer to a buffer that is allocated by the system.

`InBufferLength`

Specifies the size of the buffer, in bytes, specified by the **InBuffer** member.

`MaximumAllowed`

Specifies the maximum amount of data that the *BugCheckSecondaryDumpDataCallback* routine can write to the crash dump file.

`Guid`

Specifies a GUID that identifies the driver's crash dump data. (Drivers must use unique GUIDs to mark their crash dump data. Use the GuidGen.exe tool to generate GUIDs for your driver. This tool is included in the Microsoft Windows SDK.)

`OutBuffer`

Pointer to the buffer where the driver writes its crash dump data, or **NULL**.

`OutBufferLength`

Specifies the size of the buffer, in bytes, that was specified by the **OutBuffer** member.

Remarks

For more information about how this structure is used, see BugCheckSecondaryDumpDataCallback.

Requirements

Minimum supported client	Available on Microsoft Windows XP with Service Pack 1 (SP1), Windows Server 2003, and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

BugCheckSecondaryDumpDataCallback

KDPC_WATCHDOG_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **KDPC_WATCHDOG_INFORMATION** structure holds time-out information about the current deferred procedure call (DPC).

Syntax

```
typedef struct _KDPC_WATCHDOG_INFORMATION {
  ULONG DpcTimeLimit;
  ULONG DpcTimeCount;
  ULONG DpcWatchdogLimit;
  ULONG DpcWatchdogCount;
  ULONG Reserved;
} KDPC_WATCHDOG_INFORMATION, *PKDPC_WATCHDOG_INFORMATION;
```

Members

`DpcTimeLimit`

Time limit for a single, current deferred procedure call. If DPC time-out has been disabled, this value is set to 0.

`DpcTimeCount`

Time remaining for the current deferred procedure call, if DPC time-out has been enabled.

`DpcWatchdogLimit`

Total time limit permitted for a sequence of deferred procedure calls. If DPC watchdog has been disabled, this value is set to zero.

`DpcWatchdogCount`

Time value remaining for the current sequence of deferred procedure calls, if enabled.

`Reserved`

Reserved for system use.

Remarks

Time figures stored in each member are dimensionless.

Requirements

Minimum supported client	Available starting with Windows Vista.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

KeQueryDpcWatchdogInformation

KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT structure

1/30/2019 • 2 minutes to read • Edit Online

The **KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT** structure describes the notification context that is passed to a registered callback function when a new processor is dynamically added to a hardware partition.

Syntax

```
typedef struct _KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT {
  KE_PROCESSOR_CHANGE_NOTIFY_STATE State;
  ULONG                            NtNumber;
  NTSTATUS                         Status;
  PROCESSOR_NUMBER                 ProcNumber;
} KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT, *PKE_PROCESSOR_CHANGE_NOTIFY_CONTEXT;
```

Members

`State`

The state of the processor add operation. Possible values are as follows:

KeProcessorAddStartNotify

The operating system is about to add the processor. At this state, a device driver that receives this notification can allocate any per-processor data structures and perform any other required tasks to prepare the driver for execution on the new processor.

KeProcessorAddCompleteNotify

The operating system has successfully added the processor. At this state, a device driver that receives this notification can start scheduling threads on the new processor.

KeProcessorAddFailureNotify

The operating system failed to add the processor. If a device driver receives this notification, it should free any per-processor data structures that it allocated for the new processor when it received the **KeProcessorAddStartNotify** notification.

`NtNumber`

The processor index of the new processor. For information about the relationship between a processor index and a processor number, see KeGetProcessorNumberFromIndex.

`Status`

If the **State** member contains **KeProcessorAddFailureNotify**, this member contains the error status that indicates why the processor add operation failed.

`ProcNumber`

The processor number of the new processor. This member is a PROCESSOR_NUMBER structure that specifies a group number and a group-relative processor number.

Remarks

The **KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT** structure is available starting with Windows Server 2008.

A device driver registers to receive notification when a new processor is dynamically added to the hardware partition by calling the KeRegisterProcessorChangeCallback function. For more information about registering for this notification, see Registering for Synchronous Driver Notification.

When a new processor is dynamically added to the hardware partition, the operating system calls each registered callback function two times. The operating system calls each registered callback function the first time with the **KeProcessorAddStartNotify** state, and the second time with either the **KeProcessorAddCompleteNotify** state or the **KeProcessorAddFailureNotify** state.

A device driver's callback function that receives these notifications must not modify the contents of the **KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT** structure.

Requirements

Minimum supported client	Supported starting with Windows Server 2008.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

PROCESSOR_NUMBER

KEY_BASIC_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **KEY_BASIC_INFORMATION** structure defines a subset of the full information that is available for a registry key.

Syntax

```
typedef struct _KEY_BASIC_INFORMATION {
  LARGE_INTEGER LastWriteTime;
  ULONG         TitleIndex;
  ULONG         NameLength;
  WCHAR         Name[1];
} KEY_BASIC_INFORMATION, *PKEY_BASIC_INFORMATION;
```

Members

`LastWriteTime`

The last time this key or any of its values changed. This time value is expressed in absolute system time format. Absolute system time is the number of 100-nanosecond intervals since the start of the year 1601 in the Gregorian calendar.

`TitleIndex`

Device and intermediate drivers should ignore this member.

`NameLength`

The size, in bytes, of the key name string in the **Name** array.

`Name`

An array of wide characters that contains the name of the registry key. This character string is not null-terminated. Only the first element in this array is included in the **KEY_BASIC_INFORMATION** structure definition. The storage for the remaining elements in the array immediately follows this element.

Remarks

The ZwEnumerateKey and ZwQueryKey routines use the **KEY_BASIC_INFORMATION** structure to contain the basic information for a registry key. When the *KeyInformationClass* parameter of either routine is **KeyBasicInformation**, the *KeyInformation* buffer is treated as a **KEY_BASIC_INFORMATION** structure. For more information about the **KeyBasicInformation** enumeration value, see KEY_INFORMATION_CLASS.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KEY_FULL_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **KEY_FULL_INFORMATION** structure defines the information available for a registry key, including information about its subkeys and the maximum length for their names and value entries. This information can be used to size buffers to get the names of subkeys and their value entries.

Syntax

```
typedef struct _KEY_FULL_INFORMATION {
  LARGE_INTEGER LastWriteTime;
  ULONG         TitleIndex;
  ULONG         ClassOffset;
  ULONG         ClassLength;
  ULONG         SubKeys;
  ULONG         MaxNameLen;
  ULONG         MaxClassLen;
  ULONG         Values;
  ULONG         MaxValueNameLen;
  ULONG         MaxValueDataLen;
  WCHAR         Class[1];
} KEY_FULL_INFORMATION, *PKEY_FULL_INFORMATION;
```

Members

`LastWriteTime`

The last time this key or any of its values changed. This time value is expressed in absolute system time format. Absolute system time is the number of 100-nanosecond intervals since the start of the year 1601 in the Gregorian calendar.

`TitleIndex`

Device and intermediate drivers should ignore this member.

`ClassOffset`

The byte offset from the start of this structure to the **Class** member.

`ClassLength`

The size, in bytes, of the key class name string in the **Class** array.

`SubKeys`

The number of subkeys for this key.

`MaxNameLen`

The maximum size, in bytes, of any name for a subkey.

`MaxClassLen`

The maximum size, in bytes, of a class name.

`Values`

The number of value entries for this key.

`MaxValueNameLen`

The maximum size, in bytes, of a value entry name.

`MaxValueDataLen`

The maximum size, in bytes, of a value entry data field.

`Class`

An array of wide characters that contains the name of the class of the key. This character string is not null-terminated. Only the first element in this array is included in the **KEY_FULL_INFORMATION** structure definition. The storage for the remaining elements in the array immediately follows this element.

Remarks

The ZwEnumerateKey and ZwQueryKey routines use the **KEY_FULL_INFORMATION** structure to contain the full information for a registry key. When the *KeyInformationClass* parameter of either routine is **KeyFullInformation**, the *KeyInformation* buffer is treated as a **KEY_FULL_INFORMATION** structure. For more information about the **KeyFullInformation** enumeration value, see KEY_INFORMATION_CLASS.

Requirements

KEY_INFORMATION_CLASS Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **KEY_INFORMATION_CLASS** enumeration type represents the type of information to supply about a registry key.

Syntax

```
typedef enum _KEY_INFORMATION_CLASS {
  KeyBasicInformation,
  KeyNodeInformation,
  KeyFullInformation,
  KeyNameInformation,
  KeyCachedInformation,
  KeyFlagsInformation,
  KeyVirtualizationInformation,
  KeyHandleTagsInformation,
  KeyTrustInformation,
  KeyLayerInformation,
  MaxKeyInfoClass
} KEY_INFORMATION_CLASS;
```

Constants

KeyBasicInformation	A KEY_BASIC_INFORMATION structure is supplied.
KeyNodeInformation	A KEY_NODE_INFORMATION structure is supplied.
KeyFullInformation	A KEY_FULL_INFORMATION structure is supplied.
KeyNameInformation	A KEY_NAME_INFORMATION structure is supplied.
KeyCachedInformation	A KEY_CACHED_INFORMATION structure is supplied.
KeyFlagsInformation	Reserved for system use.
KeyVirtualizationInformation	A KEY_VIRTUALIZATION_INFORMATION structure is supplied.
KeyHandleTagsInformation	Reserved for system use.
KeyTrustInformation	
KeyLayerInformation	
MaxKeyInfoClass	The maximum value in this enumeration type.

Remarks

Use the **KEY_INFORMATION_CLASS** values to specify the type of data to be supplied by the ZwEnumerateKey and ZwQueryKey routines.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KEY_NODE_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **KEY_NODE_INFORMATION** structure defines the basic information available for a registry (sub)key.

Syntax

```
typedef struct _KEY_NODE_INFORMATION {
  LARGE_INTEGER LastWriteTime;
  ULONG         TitleIndex;
  ULONG         ClassOffset;
  ULONG         ClassLength;
  ULONG         NameLength;
  WCHAR         Name[1];
} KEY_NODE_INFORMATION, *PKEY_NODE_INFORMATION;
```

Members

`LastWriteTime`

The last time this key or any of its values changed. This time value is expressed in absolute system time format. Absolute system time is the number of 100-nanosecond intervals since the start of the year 1601 in the Gregorian calendar.

`TitleIndex`

Device and intermediate drivers should ignore this member.

`ClassOffset`

The byte offset from the start of this structure to the class name string, which is located in the **Name** array immediately following the key name string. Like the key name string, the class name string is not null-terminated.

`ClassLength`

The size, in bytes, in the class name string.

`NameLength`

The size, in bytes, of the key name string contained in the **Name** array.

`Name`

An array of wide characters that contains the name of the registry key. This character string is not null-terminated. Only the first element in this array is included in the **KEY_NODE_INFORMATION** structure definition. The storage for the remaining elements in the array immediately follows this element.

Remarks

The ZwEnumerateKey and ZwQueryKey routines use the **KEY_NODE_INFORMATION** structure to contain the registry key name and key class name. When the *KeyInformationClass* parameter of either routine is **KeyNodeInformation**, the *KeyInformation* buffer is treated as a **KEY_NODE_INFORMATION** structure. For more information about the **KeyNodeInformation** enumeration value, see KEY_INFORMATION_CLASS.

KEY_SET_INFORMATION_CLASS Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **KEY_SET_INFORMATION_CLASS** enumeration type represents the type of information to set for a registry key.

Syntax

```
typedef enum _KEY_SET_INFORMATION_CLASS {
  KeyWriteTimeInformation,
  KeyWow64FlagsInformation,
  KeyControlFlagsInformation,
  KeySetVirtualizationInformation,
  KeySetDebugInformation,
  KeySetHandleTagsInformation,
  KeySetLayerInformation,
  MaxKeySetInfoClass
} KEY_SET_INFORMATION_CLASS;
```

Constants

KeyWriteTimeInformation	Indicates that a KEY_WRITE_TIME_INFORMATION structure is supplied.
KeyWow64FlagsInformation	Reserved for system use.
KeyControlFlagsInformation	Reserved for system use.
KeySetVirtualizationInformation	Reserved for system use.
KeySetDebugInformation	Reserved for system use.
KeySetHandleTagsInformation	Reserved for system use.
KeySetLayerInformation	
MaxKeySetInfoClass	This member constant is always the maximum value in the enumeration.

Remarks

A RegistryCallback routine can receive a pointer to a **KEY_SET_INFORMATION_CLASS** structure as an input parameter.

Requirements

Minimum supported client	Available starting with Windows XP.

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KEY_WRITE_TIME_INFORMATION

RegistryCallback

KEY_VALUE_BASIC_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **KEY_VALUE_BASIC_INFORMATION** structure defines a subset of the full information available for a value entry of a registry key.

Syntax

```
typedef struct _KEY_VALUE_BASIC_INFORMATION {
  ULONG TitleIndex;
  ULONG Type;
  ULONG NameLength;
  WCHAR Name[1];
} KEY_VALUE_BASIC_INFORMATION, *PKEY_VALUE_BASIC_INFORMATION;
```

Members

`TitleIndex`

Device and intermediate drivers should ignore this member.

`Type`

Specifies the system-defined type for the value entry in the registry key, which is one of the following:

REG_*XXX* TYPE	**VALUE**
REG_BINARY	Binary data in any form
REG_DWORD	A 4-byte numerical value
REG_DWORD_LITTLE_ENDIAN	A 4-byte numerical value whose least significant byte is at the lowest address
REG_DWORD_BIG_ENDIAN	A 4-byte numerical value whose least significant byte is at the highest address
REG_EXPAND_SZ	A null-terminated Unicode string, containing unexpanded references to environment variables, such as "%PATH%"
REG_LINK	A Unicode string naming a symbolic link. This type is irrelevant to device and intermediate drivers
REG_MULTI_SZ	An array of null-terminated strings, terminated by another zero
REG_NONE	Data with no particular type
REG_SZ	A null-terminated Unicode string

REG_RESOURCE_LIST	A device driver's list of hardware resources, used by the driver or one of the physical devices it controls, in the **\ResourceMap** tree
REG_RESOURCE_REQUIREMENTS_LIST	A device driver's list of possible hardware resources it or one of the physical devices it controls can use, from which the system writes a subset into the **\ResourceMap** tree
REG_FULL_RESOURCE_DESCRIPTOR	A list of hardware resources that a physical device is using, detected and written into the **\HardwareDescription** tree by the system

`NameLength`

Specifies the size in bytes of the following value entry name.

`Name`

A string of Unicode characters naming a value entry of the key.

Remarks

A kernel-mode driver can obtain a **KEY_VALUE_BASIC_INFORMATION** that describes a registry key by calling the ZwQueryValueKey or ZwEnumerateValueKey routine.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KEY_VALUE_ENTRY structure

1/30/2019 • 2 minutes to read • Edit Online

The **KEY_VALUE_ENTRY** structure is used by the REG_QUERY_MULTIPLE_VALUE_KEY_INFORMATION structure to describe a single value entry for a registry key.

Syntax

```
typedef struct _KEY_VALUE_ENTRY {
  PUNICODE_STRING ValueName;
  ULONG           DataLength;
  ULONG           DataOffset;
  ULONG           Type;
} KEY_VALUE_ENTRY, *PKEY_VALUE_ENTRY;
```

Members

`ValueName`

Pointer to a UNICODE_STRING structure that contains the name of the value entry.

`DataLength`

Specifies the size, in bytes, of the data for the value entry.

`DataOffset`

Specifies the offset, in bytes, of the value entry's data within the buffer that is pointed to by the **ValueBuffer** member of REG_QUERY_MULTIPLE_VALUE_KEY_INFORMATION.

`Type`

Specifies the type of the value entry's data. For a description of the possible values for **Type**, see the *Type* parameter of ZwSetValueKey.

Remarks

The **ValueEntries** member of REG_QUERY_MULTIPLE_VALUE_KEY_INFORMATION points to an array of KEY_VALUE_ENTRY structures.

Requirements

Minimum supported client	Available on Microsoft Windows XP and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KEY_VALUE_FULL_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **KEY_VALUE_FULL_INFORMATION** structure defines information available for a value entry of a registry key.

Syntax

```
typedef struct _KEY_VALUE_FULL_INFORMATION {
  ULONG TitleIndex;
  ULONG Type;
  ULONG DataOffset;
  ULONG DataLength;
  ULONG NameLength;
  WCHAR Name[1];
} KEY_VALUE_FULL_INFORMATION, *PKEY_VALUE_FULL_INFORMATION;
```

Members

`TitleIndex`

Device and intermediate drivers should ignore this member.

`Type`

Specifies the system-defined type for the registry value(s) following the **Name** member. For a summary of these types, see KEY_VALUE_BASIC_INFORMATION.

`DataOffset`

Specifies the offset from the start of this structure to the data immediately following the **Name** string.

`DataLength`

Specifies the number of bytes of registry information for the value entry identified by **Name**.

`NameLength`

Specifies the size in bytes of the following value entry name.

`Name`

A string of Unicode characters naming a value entry of the key.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KEY_VALUE_INFORMATION_CLASS Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **KEY_VALUE_INFORMATION_CLASS** enumeration type specifies the type of information to supply about the value of a registry key.

Syntax

```
typedef enum _KEY_VALUE_INFORMATION_CLASS {
  KeyValueBasicInformation,
  KeyValueFullInformation,
  KeyValuePartialInformation,
  KeyValueFullInformationAlign64,
  KeyValuePartialInformationAlign64,
  KeyValueLayerInformation,
  MaxKeyValueInfoClass
} KEY_VALUE_INFORMATION_CLASS;
```

Constants

KeyValueBasicInformation	The information is stored as a KEY_VALUE_BASIC_INFORMATION structure.
KeyValueFullInformation	The information is stored as a KEY_VALUE_FULL_INFORMATION structure.
KeyValuePartialInformation	The information is stored as a KEY_VALUE_PARTIAL_INFORMATION structure.
KeyValueFullInformationAlign64	The information is stored as a **KEY_VALUE_FULL_INFORMATION** structure that is aligned to a 64-bit (that is, 8-byte) boundary in memory. If the caller-supplied buffer does not start on a 64-bit boundary, the information is stored starting at the first 64-bit boundary in the buffer.
KeyValuePartialInformationAlign64	The information is stored as a **KEY_VALUE_PARTIAL_INFORMATION** structure that is aligned to a 64-bit (that is, 8-byte) boundary in memory. If the caller-supplied buffer does not start on a 64-bit boundary, the information is stored starting at the first 64-bit boundary in the buffer.
KeyValueLayerInformation	
MaxKeyValueInfoClass	The maximum value in this enumeration type.

Remarks

Use the **KEY_VALUE_INFORMATION_CLASS** values to specify the type of data to be supplied by the ZwEnumerateValueKey and ZwQueryValueKey routines.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KEY_WRITE_TIME_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **KEY_WRITE_TIME_INFORMATION** structure is used by the system to set the last write time for a registry key.

Syntax

```
typedef struct _KEY_WRITE_TIME_INFORMATION {
  LARGE_INTEGER LastWriteTime;
} KEY_WRITE_TIME_INFORMATION, *PKEY_WRITE_TIME_INFORMATION;
```

Members

`LastWriteTime`

Specifies the last time that the key was changed. This time value is expressed in absolute system time format. Absolute system time is the number of 100-nanosecond intervals since the start of the year 1601 in the Gregorian calendar.

Requirements

Minimum supported client	Available on Microsoft Windows XP and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KEY_SET_INFORMATION_CLASS

KINTERRUPT_MODE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **KINTERRUPT_MODE** enumeration type indicates whether an interrupt is level-triggered or edge-triggered.

Syntax

```
typedef enum _KINTERRUPT_MODE {
  LevelSensitive,
  Latched
} KINTERRUPT_MODE;
```

Constants

LevelSensitive	The interrupt is level-triggered. This is the mode for traditional PCI line-based interrupts.
Latched	The interrupt is edge-triggered. This is the mode for PCI message-signaled interrupts.

Remarks

The interrupt mode is an electrical characteristic of the interrupt. A device signals a level-triggered interrupt by changing the voltage on the interrupt pin, and holding it there until the processor signals that the interrupt is received. In contrast, to signal an edge-triggered interrupt, the device changes the voltage state for a fixed period of time, before reverting to the original voltage state.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)

IoConnectInterrupt

IoConnectInterruptEx

KINTERRUPT_POLARITY

KINTERRUPT_POLARITY Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **KINTERRUPT_POLARITY** enumeration indicates how a device signals an interrupt request on an interrupt line.

Syntax

```
typedef enum _KINTERRUPT_POLARITY {
  InterruptPolarityUnknown,
  InterruptActiveHigh,
  InterruptRisingEdge,
  InterruptActiveLow,
  InterruptFallingEdge,
  InterruptActiveBoth,
  InterruptActiveBothTriggerLow,
  InterruptActiveBothTriggerHigh
} KINTERRUPT_POLARITY, *PKINTERRUPT_POLARITY;
```

Constants

InterruptPolarityUnknown	The interrupt polarity is unknown.
InterruptActiveHigh	Active-high interrupt. The interrupt input type is level-triggered, and an interrupt request is indicated by a high signal level on the interrupt line. The request remains active as long as the line remains high.
InterruptRisingEdge	Rising-edge-triggered interrupt. The interrupt input type is edge-triggered, and an interrupt request is indicated by a low-to-high transition on the interrupt line.
InterruptActiveLow	Active-low interrupt. The interrupt input type is level-triggered, and an interrupt request is indicated by a low signal level on the interrupt line. The request remains active as long as the line remains low.
InterruptFallingEdge	Falling-edge-triggered interrupt. The interrupt input type is edge-triggered, and an interrupt request is indicated by a high-to-low transition on the interrupt line.
InterruptActiveBoth	Active-both interrupt. The interrupt input type is edge-triggered, and an interrupt request is indicated by a low-to-high or a high-to-low transition on the interrupt line. After a low-to-high transition signals an interrupt request, the interrupt line remains high until a high-to-low transition signals the next interrupt request. Similarly, after a high-to-low transition signals an interrupt request, the interrupt line remains low until a low-to-high transition signals the next interrupt request.
InterruptActiveBothTriggerLow	Reserved for use by the operating system.

InterruptActiveBothTriggerHigh	Reserved for use by the operating system.

Remarks

A **KINTERRUPT_POLARITY** enumeration constant is frequently used in conjunction with a KINTERRUPT_MODE enumeration constant to describe an interrupt signal. A **KINTERRUPT_MODE** enumeration constant indicates whether the interrupt signal from a device is level-triggered or edge-triggered.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

See Also

KINTERRUPT_MODE

KTMOBJECT_CURSOR structure

1/30/2019 • 2 minutes to read • Edit Online

The **KTMOBJECT_CURSOR** structure receives enumeration information about KTM objects when a component calls ZwEnumerateTransactionObject.

Syntax

```
typedef struct _KTMOBJECT_CURSOR {
  GUID  LastQuery;
  ULONG ObjectIdCount;
  GUID  ObjectIds[1];
} KTMOBJECT_CURSOR, *PKTMOBJECT_CURSOR;
```

Members

`LastQuery`

After **ZwEnumerateTransactionObject** returns, this member contains the GUID of the last object that **ZwEnumerateTransactionObject** enumerated. Before it calls **ZwEnumerateTransactionObject** the first time, the caller must set this value to zero.

`ObjectIdCount`

After **ZwEnumerateTransactionObject** returns, this member contains the number of GUIDs that the **ObjectIds** array contains.

`ObjectIds`

A caller-allocated array of GUID-typed elements. After **ZwEnumerateTransactionObject** returns, this array contains GUIDs that identify enumerated objects.

Remarks

The **KTMOBJECT_CURSOR** structure is used at the beginning of buffers that callers pass to the **ZwEnumerateTransactionObject** routine.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

ZwEnumerateTransactionObject

KTMOBJECT_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **KTMOBJECT_TYPE** enumeration identifies the types of objects that KTM supports.

Syntax

```
typedef enum _KTMOBJECT_TYPE {
  KTMOBJECT_TRANSACTION,
  KTMOBJECT_TRANSACTION_MANAGER,
  KTMOBJECT_RESOURCE_MANAGER,
  KTMOBJECT_ENLISTMENT,
  KTMOBJECT_INVALID
} KTMOBJECT_TYPE, *PKTMOBJECT_TYPE;
```

Constants

KTMOBJECT_TRANSACTION	KTM transaction objects.
KTMOBJECT_TRANSACTION_MANAGER	KTM transaction manager objects.
KTMOBJECT_RESOURCE_MANAGER	KTM resource manager objects.
KTMOBJECT_ENLISTMENT	KTM enlistment objects.
KTMOBJECT_INVALID	Invalid object type.

Remarks

The **KTMOBJECT_TYPE** enumeration is used with the ZwEnumerateTransactionObject routine.

For more information about KTM objects, see KTM Objects.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

ZwEnumerateTransactionObject

LINK_SHARE_ACCESS structure

1/30/2019 • 2 minutes to read • Edit Online

The share access structure used by file systems for only link files.

Syntax

```
typedef struct _LINK_SHARE_ACCESS {
  ULONG OpenCount;
  ULONG Deleters;
  ULONG SharedDelete;
} LINK_SHARE_ACCESS, *PLINK_SHARE_ACCESS;
```

Members

`OpenCount`

The number of open requests to the file.

`Deleters`

File associated with the file object has been opened for delete access.

`SharedDelete`

File associated with the file object has been opened for delete sharing access.

Requirements

Header	wdm.h

See Also

IoCheckLinkShareAccess

IoSetLinkShareAccess

MDL structure

1/30/2019 • 2 minutes to read • Edit Online

An **MDL** structure is a partially opaque structure that represents a memory descriptor list (MDL).

Syntax

```
typedef struct _MDL {
  struct _MDL      *Next;
  CSHORT           Size;
  CSHORT           MdlFlags;
  struct _EPROCESS *Process;
  PVOID            MappedSystemVa;
  PVOID            StartVa;
  ULONG            ByteCount;
  ULONG            ByteOffset;
} MDL, *PMDL;
```

Members

`Next`

Pointer to the next MDL in an MDL chain. For more information about MDL chains, see Using MDLs.

`Size`

`MdlFlags`

`Process`

`MappedSystemVa`

`StartVa`

`ByteCount`

`ByteOffset`

Remarks

An MDL describes the layout of a virtual memory buffer in physical memory. For more information, see Using MDLs.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

MEMORY_CACHING_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **MEMORY_CACHING_TYPE** enumeration type specifies the permitted caching behavior when allocating or mapping memory.

Syntax

```
typedef enum _MEMORY_CACHING_TYPE {
  MmNonCached,
  MmCached,
  MmWriteCombined,
  MmHardwareCoherentCached,
  MmNonCachedUnordered,
  MmUSWCCached,
  MmMaximumCacheType,
  MmNotMapped
} MEMORY_CACHING_TYPE;
```

Constants

MmNonCached	The requested memory should not be cached by the processor.
MmCached	The processor should cache the requested memory.
MmWriteCombined	The requested memory should not be cached by the processor, but writes to the memory can be combined by the processor.
MmHardwareCoherentCached	Reserved for system use.
MmNonCachedUnordered	Reserved for system use.
MmUSWCCached	Reserved for system use.
MmMaximumCacheType	Reserved for system use.
MmNotMapped	

Remarks

Processor translation buffers cache virtual to physical address translations. These translation buffers allow many virtual addresses to map a single physical address. However, only one caching behavior is allowed for any given physical address translation. Therefore, if a driver maps two different virtual address ranges to the same physical address, it must ensure that it specifies the same caching behavior for both. Otherwise, the processor behavior is undefined with unpredictable system results.

Requirements

Minimum supported client	Supported in Windows 2000 and later versions of Windows.
Header	wdm.h (include Ntddk.h, Wdm.h, Miniport.h, Wudfwdm.h)

See Also

MM_PHYSICAL_ADDRESS_LIST structure

1/30/2019 • 2 minutes to read • Edit Online

The **MM_PHYSICAL_ADDRESS_LIST** structure specifies a range of physical addresses.

Syntax

```
typedef struct _MM_PHYSICAL_ADDRESS_LIST {
  PHYSICAL_ADDRESS PhysicalAddress;
  SIZE_T           NumberOfBytes;
} MM_PHYSICAL_ADDRESS_LIST, *PMM_PHYSICAL_ADDRESS_LIST;
```

Members

`PhysicalAddress`

The starting physical address of the range. This address must be aligned to a page boundary in physical memory.

`NumberOfBytes`

The number of bytes in the range. This member must be nonzero and an integer multiple of the memory page size.

Remarks

The first parameter to the MmAllocateMdlForIoSpace routine is a pointer to an array of **MM_PHYSICAL_ADDRESS_LIST** structures.

Requirements

Header	wdm.h (include Wdm.h)

See Also

MmAllocateMdlForIoSpace

MONITOR_DISPLAY_STATE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

Indicates the power state of the monitor being displayed on.

Syntax

```
typedef enum _MONITOR_DISPLAY_STATE {
  PowerMonitorOff,
  PowerMonitorOn,
  PowerMonitorDim
} MONITOR_DISPLAY_STATE, *PMONITOR_DISPLAY_STATE;
```

Constants

PowerMonitorOff	This indicates that the monitor is off.
PowerMonitorOn	This indicates that the monitor is on.
PowerMonitorDim	This indicates that the monitor is dim.

Requirements

Header	wdm.h (include Ntpoapi.h)

OB_CALLBACK_REGISTRATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **OB_CALLBACK_REGISTRATION** structure specifies the parameters when the ObRegisterCallbacks routine registers ObjectPreCallback and ObjectPostCallback callback routines.

Syntax

```
typedef struct _OB_CALLBACK_REGISTRATION {
  USHORT                    Version;
  USHORT                    OperationRegistrationCount;
  UNICODE_STRING            Altitude;
  PVOID                     RegistrationContext;
  OB_OPERATION_REGISTRATION *OperationRegistration;
} OB_CALLBACK_REGISTRATION, *POB_CALLBACK_REGISTRATION;
```

Members

`Version`

The version of object callback registration that is requested. Drivers should specify OB_FLT_REGISTRATION_VERSION.

`OperationRegistrationCount`

The number of entries in the **OperationRegistration** array.

`Altitude`

A Unicode string that specifies the altitude of the driver. For more information about altitude, see Load Order Groups and Altitudes for Minifilter Drivers.

`RegistrationContext`

The system passes the **RegistrationContext** value to the callback routine when the callback routine is run. The meaning of this value is driver-defined.

`OperationRegistration`

A pointer to an array of OB_OPERATION_REGISTRATION structures. Each structure specifies ObjectPreCallback and ObjectPostCallback callback routines and the types of operations that the routines are called for.

Remarks

This structure is used by the ObRegisterCallbacks routine. The *CallBackRegistration* parameter to this routine is a pointer to a buffer that contains an **OB_CALLBACK_REGISTRATION** structure that is followed by an array of one or more OB_OPERATION_REGISTRATION structures.

Requirements

Minimum supported client	Available starting with Windows Server 2008.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

OB_OPERATION_REGISTRATION

ObRegisterCallbacks

ObjectPostCallback

ObjectPreCallback

OB_OPERATION_REGISTRATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **OB_OPERATION_REGISTRATION** structure specifies ObjectPreCallback and ObjectPostCallback callback routines and the types of operations that the routines are called for.

Syntax

```
typedef struct _OB_OPERATION_REGISTRATION {
  POBJECT_TYPE                *ObjectType;
  OB_OPERATION                Operations;
  POB_PRE_OPERATION_CALLBACK  PreOperation;
  POB_POST_OPERATION_CALLBACK PostOperation;
} OB_OPERATION_REGISTRATION, *POB_OPERATION_REGISTRATION;
```

Members

`ObjectType`

A pointer to the object type that triggers the callback routine. Specify one of the following values:

- **PsProcessType** for process handle operations
- **PsThreadType** for thread handle operations
- **ExDesktopObjectType** for desktop handle operations. This value is supported in Windows 10 and not in the earlier versions of the operating system.

`Operations`

Specify one or more of the following flags:

OB_OPERATION_HANDLE_CREATE

A new process, thread, or desktop handle was or will be opened.

OB_OPERATION_HANDLE_DUPLICATE

A process, thread, or desktop handle was or will be duplicated.

`PreOperation`

A pointer to an ObjectPreCallback routine. The system calls this routine before the requested operation occurs.

`PostOperation`

A pointer to an ObjectPostCallback routine. The system calls this routine after the requested operation occurs.

Remarks

This structure is used by the ObRegisterCallbacks routine. The *CallBackRegistration* parameter to this routine is a pointer to a buffer that contains an OB_CALLBACK_REGISTRATION structure that is followed by an array of one or more **OB_OPERATION_REGISTRATION** structures.

In each **OB_OPERATION_REGISTRATION** structure passed to **ObRegisterCallback**, the caller must supply one or both callback routines. If the **PreOperation** and **PostOperation** members of this structure are both **NULL**, the callback registration operation fails.

Requirements

Minimum supported client	Available starting with Windows Server 2008.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

OB_POST_CREATE_HANDLE_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **OB_POST_CREATE_HANDLE_INFORMATION** structure provides information to a ObjectPostCallback routine about a thread or process handle that has been opened.

Syntax

```
typedef struct _OB_POST_CREATE_HANDLE_INFORMATION {
  ACCESS_MASK GrantedAccess;
} OB_POST_CREATE_HANDLE_INFORMATION, *POB_POST_CREATE_HANDLE_INFORMATION;
```

Members

`GrantedAccess`

An ACCESS_MASK value that specifies the access that is granted for the handle.

Requirements

Minimum supported client	Available in Windows Server 2008 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ACCESS_MASK

ObjectPostCallback

OB_POST_OPERATION_INFORMATION structure

2/5/2019 • 2 minutes to read • Edit Online

The **OB_POST_OPERATION_INFORMATION** structure provides information about a process or thread handle operation to an ObjectPostCallback routine.

Syntax

```
typedef struct _OB_POST_OPERATION_INFORMATION {
  OB_OPERATION                  Operation;
  union {
    ULONG Flags;
    struct {
      ULONG KernelHandle : 1;
      ULONG Reserved : 31;
    };
  };
  PVOID                         Object;
  POBJECT_TYPE                  ObjectType;
  PVOID                         CallContext;
  NTSTATUS                      ReturnStatus;
  POB_POST_OPERATION_PARAMETERS Parameters;
} OB_POST_OPERATION_INFORMATION, *POB_POST_OPERATION_INFORMATION;
```

Members

`Operation`

The type of handle operation. This member might be one of the following values:

OB_OPERATION_HANDLE_CREATE

A new handle to a process or thread was created. Use **Parameters->CreateHandleInformation** for create-specific information.

OB_OPERATION_HANDLE_DUPLICATE

A process or thread handle was duplicated. Use **Parameters->DuplicateHandleInformation** for duplicate-specific information.

`Flags`

Reserved. Use the **KernelHandle** member instead.

`KernelHandle`

A ULONG value that specifies whether the handle is a kernel handle. If this value is **TRUE**, the handle is a kernel handle. Otherwise, the handle is not a kernel handle.

`Reserved`

Reserved for system use.

`Object`

A pointer to the process or thread object that is the target of the handle operation.

`ObjectType`

A pointer to the object type of the object. This type can be **PsProcessType** for a process or **PsThreadType** for a thread.

`CallContext`

A pointer to driver-specific context information for the operation. This value is the value that the *OperationInformation*->**CallContext** member specifies to the ObjectPreCallback routine.

`ReturnStatus`

The NTSTATUS value for the handle operation.

`Parameters`

A pointer to an OB_POST_OPERATION_PARAMETERS union that contains operation-specific information. The **Operation** member determines which member of the union is valid. The pointer is valid only when **ReturnStatus** is a success code.

Remarks

Unlike the OB_PRE_OPERATION_INFORMATION structure, the members of the **OB_POST_OPERATION_INFORMATION** structure are purely informational; you cannot modify them.

Requirements

Minimum supported client	Available in Windows Server 2008 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

OB_PRE_OPERATION_INFORMATION

ObjectPostCallback

ObjectPreCallback

OB_POST_OPERATION_PARAMETERS union

1/30/2019 • 2 minutes to read • Edit Online

The **OB_POST_OPERATION_PARAMETERS** union describes the operation-specific parameters for an ObjectPostCallback routine.

Syntax

```
typedef union _OB_POST_OPERATION_PARAMETERS {
  OB_POST_CREATE_HANDLE_INFORMATION    CreateHandleInformation;
  OB_POST_DUPLICATE_HANDLE_INFORMATION DuplicateHandleInformation;
} OB_POST_OPERATION_PARAMETERS, *POB_POST_OPERATION_PARAMETERS;
```

Members

`CreateHandleInformation`

An OB_POST_CREATE_HANDLE_INFORMATION structure that contains information that is specific to a handle that is being opened.

`DuplicateHandleInformation`

An OB_POST_DUPLICATE_HANDLE_INFORMATION structure that contains information that is specific to a handle that is being duplicated.

Requirements

Minimum supported client	Available in Windows Server 2008 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

OB_POST_CREATE_HANDLE_INFORMATION

OB_POST_DUPLICATE_HANDLE_INFORMATION

ObjectPostCallback

OB_PRE_CREATE_HANDLE_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **OB_PRE_CREATE_HANDLE_INFORMATION** structure provides information to an ObjectPreCallback routine about a thread or process handle that is being opened.

Syntax

```
typedef struct _OB_PRE_CREATE_HANDLE_INFORMATION {
  ACCESS_MASK DesiredAccess;
  ACCESS_MASK OriginalDesiredAccess;
} OB_PRE_CREATE_HANDLE_INFORMATION, *POB_PRE_CREATE_HANDLE_INFORMATION;
```

Members

`DesiredAccess`

An ACCESS_MASK value that specifies the access rights to grant for the handle. By default, this member equals *OriginalDesiredAccess*, but the *ObjectPreCallback* routine can modify this value to restrict the access that is granted.

Drivers can use the following flags for handles to processes:

FLAG	ALLOWED OPERATIONS
PROCESS_CREATE_PROCESS	Create a new child process of the process.
PROCESS_CREATE_THREAD	Create a new thread in the context of the process.
PROCESS_DUP_HANDLE	Duplicate handles to or from the context of the process, such as by calling the user-mode **DuplicateHandle** routine.
PROCESS_SET_QUOTA	Set the working set size for the process, such as by calling the user-mode **SetProcessWorkingSetSize** routine.
PROCESS_SET_INFORMATION	Modify process settings, such as by calling the user-mode **SetPriorityClass** routine.
PROCESS_SUSPEND_RESUME	Suspend or resume the process.
PROCESS_TERMINATE	Terminate the process, such as by calling the user-mode **TerminateProcess** routine..
PROCESS_VM_OPERATION	Modify the address space of the process, such as by calling the user-mode **WriteProcessMemory** and **VirtualProtectEx** routines.
PROCESS_VM_WRITE	Write to the address space of the process, such as by calling the user-mode **WriteProcessMemory** routine.

Drivers can use the following flags for handles to threads:

FLAG	ALLOWED OPERATIONS
THREAD_DIRECT_IMPERSONATION	Enable a server thread to impersonate one of its clients.
THREAD_IMPERSONATE	Impersonate the operating system's anonymous logon token, such as by calling the user-mode **ImpersonateAnonymousToken** routine.
THREAD_SET_CONTEXT	Modify the thread's execution context, such as by calling the user-mode **SetThreadContext** routine.
THREAD_SET_INFORMATION	Modify thread settings, such as by calling the user-mode **SetThreadIdealProcessor** routine. The operations that are permitted by this access right are a superset of those that are permitted by the THREAD_SET_LIMITED_INFORMATION access right.
THREAD_SET_LIMITED_INFORMATION	Modify a limited set of thread settings, such as by calling the user-mode **SetThreadAffinityMask** and **SetThreadPriorityBoost** routines.
THREAD_SET_THREAD_TOKEN	Modify properties of the thread's impersonation token, such as by calling the user-mode **SetTokenInformation** routine.
THREAD_SUSPEND_RESUME	Suspend or resume the thread, such as by calling the user-mode **SuspendThread** and **ResumeThread** routines.
THREAD_TERMINATE	Terminate the thread, such as by calling the user-mode **TerminateThread** routine.

`OriginalDesiredAccess`

An ACCESS_MASK value that specifies the original access that was requested for the handle.

Remarks

You can never add access rights beyond what is specified in the **DesiredAccess** member. If the access right is listed as a modifiable flag, the access right can be removed.

Requirements

Minimum supported client	Available in Windows Server 2008 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

ObjectPreCallback

OB_PRE_DUPLICATE_HANDLE_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **OB_PRE_DUPLICATE_HANDLE_INFORMATION** structure provides information to an ObjectPreCallback routine about a thread or process handle that is being duplicated.

Syntax

```
typedef struct _OB_PRE_DUPLICATE_HANDLE_INFORMATION {
  ACCESS_MASK DesiredAccess;
  ACCESS_MASK OriginalDesiredAccess;
  PVOID       SourceProcess;
  PVOID       TargetProcess;
} OB_PRE_DUPLICATE_HANDLE_INFORMATION, *POB_PRE_DUPLICATE_HANDLE_INFORMATION;
```

Members

`DesiredAccess`

An ACCESS_MASK value that specifies the access rights to grant for the handle. By default, this member equals *OriginalDesiredAccess*, but the *ObjectPreCallback* routine can modify this value to restrict the access that is granted. For a description of the access rights that drivers can use, see OB_PRE_CREATE_HANDLE_INFORMATION.

`OriginalDesiredAccess`

An ACCESS_MASK value that specifies the original access that was requested for the handle.

`SourceProcess`

A pointer to the process object for the process that is the source of the handle.

`TargetProcess`

A pointer to the process object for the process that receives the duplicated handle.

Remarks

You can never add access rights beyond what is specified in the **DesiredAccess** member. If the access right is listed as a modifiable flag, the access right can be removed.

Requirements

Minimum supported client	Available in Windows Server 2008 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ObjectPreCallback

OB_PRE_OPERATION_INFORMATION structure

2/5/2019 • 2 minutes to read • Edit Online

The **OB_PRE_OPERATION_INFORMATION** structure provides information about a process or thread handle operation to an ObjectPreCallback routine.

Syntax

```
typedef struct _OB_PRE_OPERATION_INFORMATION {
  OB_OPERATION                  Operation;
  union {
    ULONG Flags;
    struct {
      ULONG KernelHandle : 1;
      ULONG Reserved : 31;
    };
  };
  PVOID                         Object;
  POBJECT_TYPE                  ObjectType;
  PVOID                         CallContext;
  POB_PRE_OPERATION_PARAMETERS Parameters;
} OB_PRE_OPERATION_INFORMATION, *POB_PRE_OPERATION_INFORMATION;
```

Members

`Operation`

The type of handle operation. This member might be one of the following values:

OB_OPERATION_HANDLE_CREATE

A new handle to a process or thread will be opened. Use **Parameters->CreateHandleInformation** for create-specific information.

OB_OPERATION_HANDLE_DUPLICATE

A process or thread handle will be duplicated. Use **Parameters->DuplicateHandleInformation** for duplicate-specific information.

`Flags`

Reserved. Use the **KernelHandle** member instead.

`KernelHandle`

A bit that specifies whether the handle is a kernel handle. If this member is **TRUE**, the handle is a kernel handle. Otherwise, this handle is not a kernel handle.

`Reserved`

Reserved for system use.

`Object`

A pointer to the process or thread object that is the target of the handle operation.

`ObjectType`

A pointer to the object type of the object. This member is **PsProcessType** for a process or **PsThreadType** for a thread.

`CallContext`

A pointer to driver-specific context information for the operation. By default, the Filter Manager sets this member to **NULL**, but the ObjectPreCallback routine can reset the **CallContext** member in a driver-specific manner. The Filter Manager passes this value to the matching ObjectPostCallback routine.

`Parameters`

A pointer to an OB_PRE_OPERATION_PARAMETERS union that contains operation-specific information. The **Operation** member determines which member of the union is valid.

Requirements

Minimum supported client	Available in Windows Server 2008 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

OSVERSIONINFOEXW structure

1/30/2019 • 4 minutes to read • Edit Online

The **RTL_OSVERSIONINFOEXW** structure contains operating system version information.

Syntax

```
typedef struct _OSVERSIONINFOEXW {
  ULONG  dwOSVersionInfoSize;
  ULONG  dwMajorVersion;
  ULONG  dwMinorVersion;
  ULONG  dwBuildNumber;
  ULONG  dwPlatformId;
  WCHAR  szCSDVersion[128];
  USHORT wServicePackMajor;
  USHORT wServicePackMinor;
  USHORT wSuiteMask;
  UCHAR  wProductType;
  UCHAR  wReserved;
} OSVERSIONINFOEXW, *POSVERSIONINFOEXW, *LPOSVERSIONINFOEXW, RTL_OSVERSIONINFOEXW, *PRTL_OSVERSIONINFOEXW;
```

Members

`dwOSVersionInfoSize`

The size, in bytes, of an **RTL_OSVERSIONINFOEXW** structure. This member must be set before the structure is used with RtlGetVersion.

`dwMajorVersion`

The major version number of the operating system. For example, for Windows 2000, the major version number is five. For more information, see the table in Remarks.

`dwMinorVersion`

The minor version number of the operating system. For example, for Windows 2000, the minor version number is zero. For more information, see the table in Remarks.

`dwBuildNumber`

The build number of the operating system.

`dwPlatformId`

The operating system platform. For Win32 on NT-based operating systems, **RtlGetVersion** returns the value VER_PLATFORM_WIN32_NT.

`szCSDVersion`

The service-pack version string. This member contains a null-terminated string, such as "Service Pack 3", which indicates the latest service pack installed on the system. If no service pack is installed, **RtlGetVersion** might not initialize this string. Initialize *szCSDVersion* to zero (empty string) before the call to **RtlGetVersion**.

`wServicePackMajor`

The major version number of the latest service pack installed on the system. For example, for Service Pack 3, the

major version number is three. If no service pack has been installed, the value is zero.

`wServicePackMinor`

The minor version number of the latest service pack installed on the system. For example, for Service Pack 3, the minor version number is zero.

`wSuiteMask`

The product suites available on the system. This member is set to zero or to the bitwise OR of one or more of the following values.

VALUE	MEANING
VER_SUITE_BACKOFFICE	Microsoft BackOffice components are installed.
VER_SUITE_BLADE	Windows Server 2003, Web Edition is installed.
VER_SUITE_COMPUTE_SERVER	Windows Server 2003, Compute Cluster Edition is installed.
VER_SUITE_DATACENTER	Windows Server 2008 Datacenter, Windows Server 2003, Datacenter Edition, or Windows 2000 Datacenter Server is installed.
VER_SUITE_ENTERPRISE	Windows Server 2008 Enterprise, Windows Server 2003, Enterprise Edition, or Windows 2000 Advanced Server is installed.
VER_SUITE_EMBEDDEDNT	Windows XP Embedded is installed.
VER_SUITE_PERSONAL	Windows Vista Home Premium, Windows Vista Home Basic, or Windows XP Home Edition is installed.
VER_SUITE_SINGLEUSERTS	Remote Desktop is supported, but only one interactive session is supported. This value is set unless the system is running in application server mode.
VER_SUITE_SMALLBUSINESS (see note)	Microsoft Small Business Server was once installed on the system, but may have been upgraded to another version of Windows. For more information about this flag bit, see the following Remarks section.
VER_SUITE_SMALLBUSINESS_RESTRICTED	Microsoft Small Business Server is installed with the restrictive client license in force. For more information about this flag bit, see the following Remarks section.
VER_SUITE_STORAGE_SERVER	Windows Storage Server 2003 R2 or Windows Storage Server 2003 is installed.
VER_SUITE_TERMINAL	Terminal Services is installed. This value is always set. If VER_SUITE_TERMINAL is set but VER_SUITE_SINGLEUSERTS is not set, the operating system is running in application server mode.
VER_SUITE_WH_SERVER	Windows Home Server is installed.

Note You should not rely solely on the VER_SUITE_SMALLBUSINESS flag to determine whether Small Business Server is currently installed. Both this flag and the VER_SUITE_SMALLBUSINESS_RESTRICTED flag are set when this product suite is installed. If you upgrade this installation to Windows Server, Standard Edition, the VER_SUITE_SMALLBUSINESS_RESTRICTED flag is cleared, but the VER_SUITE_SMALLBUSINESS flag remains set, which, in this case, indicates that Small Business Server was previously installed on this system. If this installation is further upgraded to Windows Server, Enterprise Edition, the VER_SUITE_SMALLBUSINESS flag remains set.

`wProductType`

The product type. This member contains additional information about the system. This member can be one of the following values:

VALUE	MEANING
VER_NT_WORKSTATION	Windows 2000 or later professional version
VER_NT_DOMAIN_CONTROLLER	Windows 2000 or later domain controller
VER_NT_SERVER	Windows 2000 or later server

`wReserved`

Reserved for future use.

Remarks

The information in this structure includes the major and minor version numbers, the build number, the platform identifier, the installed product suites, and the latest service pack that is installed on the system. This structure is used with the RtlGetVersion and RtlVerifyVersionInfo routines.

Relying on version information is not always the best way to test whether a feature is available. For guidance, refer to the documentation for the feature you are interested in.

If possible, design the version detection code in your driver to enable the driver to run on future versions of Windows. If your driver requires a particular operating system version, be sure to treat this version as the minimum supported version, and not as the only version on which the driver can run.

The following table summarizes the version information that is returned by supported versions of Windows. Use the information in the "Other" column to distinguish between operating systems with identical version numbers.

OPERATING SYSTEM	VERSION NUMBER	DWMAJORVERSION	DWMINORVERSION	OTHER
Windows 10	10.0	10	0	**wProductType** == VER_NT_WORKSTATION
Windows 8.1	6.3	6	3	**wProductType** == VER_NT_WORKSTATION
Windows 8	6.2	6	2	**wProductType** == VER_NT_WORKSTATION

Windows Server 2012	6.2	6	2	**wProductType** != VER_NT_WORKSTATION
Windows 7	6.1	6	1	**wProductType** == VER_NT_WORKSTATION
Windows Server 2008 R2	6.1	6	1	**wProductType** != VER_NT_WORKSTATION
Windows Server 2008	6.0	6	0	**wProductType** != VER_NT_WORKSTATION
Windows Vista	6.0	6	0	**wProductType** == VER_NT_WORKSTATION
Windows Home Server	5.2	5	2	**wSuiteMask** == VER_SUITE_WH_SERVER
Windows Server 2003	5.2	5	2	Not applicable
Windows XP Professional x64 Edition (see note)	5.2	5	2	**wProductType** == VER_NT_WORKSTATION
Windows XP	5.1	5	1	Not applicable
Windows 2000	5.0	5	0	Not applicable

Note Only a 64-bit kernel-mode driver can run on Windows XP Professional x64 Edition. Therefore, a 32-bit kernel-mode driver can safely omit checking for this version of Windows.

RTL_OSVERSIONINFOW

RtlGetVersion

RtlVerifyVersionInfo

OSVERSIONINFOW structure

1/30/2019 • 2 minutes to read • Edit Online

The **RTL_OSVERSIONINFOW** structure contains operating system version information. The information includes major and minor version numbers, a build number, a platform identifier, and descriptive text about the operating system. The **RTL_OSVERSIONINFOW** structure is used with RtlGetVersion.

Syntax

```
typedef struct _OSVERSIONINFOW {
  ULONG dwOSVersionInfoSize;
  ULONG dwMajorVersion;
  ULONG dwMinorVersion;
  ULONG dwBuildNumber;
  ULONG dwPlatformId;
  WCHAR szCSDVersion[128];
} OSVERSIONINFOW, *POSVERSIONINFOW, *LPOSVERSIONINFOW, RTL_OSVERSIONINFOW, *PRTL_OSVERSIONINFOW;
```

Members

`dwOSVersionInfoSize`

The size in bytes of an **RTL_OSVERSIONINFOW** structure. This member must be set before the structure is used with RtlGetVersion.

`dwMajorVersion`

The major version number of the operating system. For example, for Windows 2000, the major version number is five. For more information, see RTL_OSVERSIONINFOEXW.

`dwMinorVersion`

The minor version number of the operating system. For example, for Windows 2000 the minor version number is zero. For more information, see RTL_OSVERSIONINFOEXW.

`dwBuildNumber`

The build number of the operating system.

`dwPlatformId`

The operating system platform. For Microsoft Win32 on NT-based operating systems, **RtlGetVersion** returns the value VER_PLATFORM_WIN32_NT.

`szCSDVersion`

The service-pack version string. This member contains a null-terminated string, such as "Service Pack 3", which indicates the latest service pack installed on the system. If no service pack is installed, **RtlGetVersion** might not initialize this string. Initialize *szCSDVersion* to zero (empty string) before the call to **RtlGetVersion**.

Remarks

For a list of the major and minor version numbers for the various versions of Windows, see RTL_OSVERSIONINFOEXW.

PCI_COMMON_CONFIG structure

1/30/2019 • 2 minutes to read • Edit Online

The **PCI_COMMON_CONFIG** structure is obsolete. It defines standard PCI configuration information returned by the obsolete HalGetBusData or HalGetBusDataByOffset routine for the input *BusDataType* PCIConfiguration, assuming the caller-allocated *Buffer* is of sufficient *Length*.

Syntax

```
typedef struct _PCI_COMMON_CONFIG {
  UCHAR      DeviceSpecific[192];
  base_class PCI_COMMON_HEADER;
} PCI_COMMON_CONFIG, *PPCI_COMMON_CONFIG;
```

Members

`DeviceSpecific`

Contains any device-specific initialization information that is available.

`PCI_COMMON_HEADER`

Remarks

Certain members of this structure have read-only values, so attempts to reset them are ignored. These members include the following: **VendorID**, **DeviceID**, **RevisionID**, **ProgIf**, **SubClass**, **BaseClass**, **HeaderType**, **InterruptPin**, **MinimumGrant**, and **MaximumLatency.**

Other members are provisionally read-only: that is, the system initializes them to their correct values, so drivers can safely treat them as read-only. However, they can be reset if a bus-master driver finds it necessary. These members include the following: **CacheLineSize** and **LatencyTimer**.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

PCI_MSIX_TABLE_CONFIG_INTERFACE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PCI_MSIX_TABLE_CONFIG_INTERFACE** structure enables device drivers to modify their MSI-X interrupt settings. This structure describes the GUID_MSIX_TABLE_CONFIG_INTERFACE interface.

Syntax

```
typedef struct _PCI_MSIX_TABLE_CONFIG_INTERFACE {
  USHORT                      Size;
  USHORT                      Version;
  PVOID                       Context;
  PINTERFACE_REFERENCE        InterfaceReference;
  PINTERFACE_DEREFERENCE      InterfaceDereference;
  PPCI_MSIX_SET_ENTRY         SetTableEntry;
  PPCI_MSIX_MASKUNMASK_ENTRY MaskTableEntry;
  PPCI_MSIX_MASKUNMASK_ENTRY UnmaskTableEntry;
  PPCI_MSIX_GET_ENTRY         GetTableEntry;
  PPCI_MSIX_GET_TABLE_SIZE    GetTableSize;
} PCI_MSIX_TABLE_CONFIG_INTERFACE, *PPCI_MSIX_TABLE_CONFIG_INTERFACE;
```

Members

`Size`

The size, in bytes, of this structure.

`Version`

The driver-defined interface version.

`Context`

A pointer to interface-specific context information.

`InterfaceReference`

A pointer to an InterfaceReference routine that increments the interface's reference count.

`InterfaceDereference`

A pointer to an InterfaceDereference routine that decrements the interface's reference count.

`SetTableEntry`

A pointer to the interface's SetTableEntry routine.

`MaskTableEntry`

A pointer to the interface's MaskTableEntry routine.

`UnmaskTableEntry`

A pointer to the interface's UnmaskTableEntry routine.

`GetTableEntry`

Reserved for future use.

`GetTableSize`

Reserved for future use.

Remarks

A driver obtains a pointer to the **PCI_MSIX_TABLE_CONFIG_INTERFACE** structure by sending an IRP_MN_QUERY_INTERFACE IRP to its bus driver with **InterfaceType** set to GUID_MSIX_TABLE_CONFIG_INTERFACE.

Requirements

Minimum supported client	Available in Windows Vista with Service Pack 1 (SP1), Windows Server 2008, and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

PCI_SLOT_NUMBER structure

1/30/2019 • 2 minutes to read • Edit Online

The **PCI_SLOT_NUMBER** structure is obsolete. It defines the format of the *Slot* parameter to the obsolete **Hal*Xxx* BusData** routines when they are called with the *BusDataType* value **PCIConfiguration**.

Syntax

```
typedef struct _PCI_SLOT_NUMBER {
  union {
    struct {
      ULONG DeviceNumber : 5;
      ULONG FunctionNumber : 3;
      ULONG Reserved : 24;
    } bits;
    ULONG AsULONG;
  } u;
} PCI_SLOT_NUMBER, *PPCI_SLOT_NUMBER;
```

Members

`u`

`u.bits`

`u.bits.DeviceNumber`

`u.bits.FunctionNumber`

`u.bits.Reserved`

`u.AsULONG`

Specifies the logical slot number of the device being configured.

Remarks

Drivers of PCI devices can call HalGetBusData or HalGetBusDataByOffset more than once for the same slot number to get the configuration information for their device(s).

For example, a driver might search for devices it supports on all PCI buses in the machine first, and then call `HalGetBusData(ByOffset)` again to request more configuration information about devices of interest. Such a driver could code a loop that calls `HalGetBusData(ByOffset)` with an input `Buffer` of sufficient `Length` only to contain enough of the PCI_COMMON_CONFIG to determine the `VendorID` and `DeviceID` of each PCI device. After finding the `Slot` numbers for any promising PCI devices, the driver would call HalGetBusData or HalGetBusDataByOffset one or more times with additional buffer space to get the information needed to configure its devices.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

PLUGPLAY_NOTIFICATION_HEADER structure

1/30/2019 • 2 minutes to read • Edit Online

A **PLUGPLAY_NOTIFICATION_HEADER** structure is included at the beginning of each PnP notification structure, such as a DEVICE_INTERFACE_CHANGE_NOTIFICATION structure.

Syntax

```
typedef struct _PLUGPLAY_NOTIFICATION_HEADER {
  USHORT Version;
  USHORT Size;
  GUID   Event;
} PLUGPLAY_NOTIFICATION_HEADER, *PPLUGPLAY_NOTIFICATION_HEADER;
```

Members

`Version`

Specifies the version of the data structure, currently set to 1.

`Size`

Specifies the size of the structure, in bytes.

`Event`

Specifies a GUID identifying the event.

Remarks

Drivers can cast a PnP notification structure to this type to access the **Event** field and identify the exact type of the structure.

Requirements

IRP_MN_QUERY_BUS_INFORMATION

PO_FX_COMPONENT_IDLE_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_COMPONENT_IDLE_STATE** structure specifies the attributes of an Fx power state of a component in a device.

Syntax

```
typedef struct _PO_FX_COMPONENT_IDLE_STATE {
  ULONGLONG TransitionLatency;
  ULONGLONG ResidencyRequirement;
  ULONG     NominalPower;
} PO_FX_COMPONENT_IDLE_STATE, *PPO_FX_COMPONENT_IDLE_STATE;
```

Members

`TransitionLatency`

The transition latency. This latency is the amount of time, in 100-nanosecond units, that the component requires to return from this Fx state to the F0 state. For a **PO_FX_COMPONENT_IDLE_STATE** structure that specifies the attributes of the F0 state, set this member to zero.

`ResidencyRequirement`

The residency requirement. The residency requirement is the minimum amount of time, in 100-nanosecond units, that the component must spend in this Fx state to make a transition to this Fx state worthwhile. PoFx uses this member value as a hint to avoid switching a component to an Fx state unless the component is likely to remain in this state for at least the amount of time specified by **ResidencyRequirement**. For a **PO_FX_COMPONENT_IDLE_STATE** structure that describes the attributes of the F0 state, set this member to zero.

`NominalPower`

The power, in microwatts, that the component consumes in this Fx state. Set this member to **PO_FX_UNKNOWN_POWER** to indicate that PoFx should ignore (treat as negligible) the component's internal power consumption in this Fx state when PoFx evaluates which power state to switch to when the component is idle.

Remarks

The PO_FX_COMPONENT structure contains a pointer to an array of **PO_FX_COMPONENT_IDLE_STATE** structures. Each array element specifies the attributes of an Fx state. Element 0 describes F0, element 1 describes F1, and so on.

When the driver registers a device with PoFx, the driver supplies an array of **PO_FX_COMPONENT** structures. Each array element describes the power attributes of a component in the device.

Do not set **TransitionLatency** and **ResidencyRequirement** to **PO_FX_UNKNOWN_TIME** because it may prevent the power management framework (PoFx) from selecting the idle state.

Requirements

Minimum supported client	Supported starting with Windows 8.
Header	wdm.h (include Wudfwdm.h)

See Also

PO_FX_COMPONENT

PO_FX_COMPONENT_PERF_INFO structure

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_COMPONENT_PERF_INFO** structure describes all the sets of performance states for a single component within a device.

Syntax

```
typedef struct _PO_FX_COMPONENT_PERF_INFO {
  ULONG                    PerfStateSetsCount;
  PO_FX_COMPONENT_PERF_SET PerfStateSets[ANYSIZE_ARRAY];
} PO_FX_COMPONENT_PERF_INFO, *PPO_FX_COMPONENT_PERF_INFO;
```

Members

`PerfStateSetsCount`

The number of elements in the array **PerfStateSets** array.

`PerfStateSets`

This member is the first element in an array of one or more PO_FX_COMPONENT_PERF_SET elements. Each **PO_FX_COMPONENT_PERF_SET** represents one set of supported performance states for a component. If the array contains more than one element, the additional elements immediately follow the first element.

Remarks

When a device driver calls the PoFxRegisterComponentPerfStates routine to register a component for performance state support with the power management framework (PoFx), the driver can supply a **PO_FX_COMPONENT_PERF_INFO** structure that describes the sets of the performance states supported by the component. The **PerfStateSets** member of the **PO_FX_COMPONENT_PERF_INFO** structure contains an array of PO_FX_COMPONENT_PERF_SET structures that represent the supported performance states.

Most drivers are expected to define a single set of performance states per component. For example, a driver might define one set of performance states to control the clock frequency for a component. However, some drivers may need to define more than one performance state set to control multiple dimensions of performance states for a component. For example, a driver might define two sets of performance states to control the clock frequency and bus bandwidth.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	wdm.h (include Wudfwdm.h)

See Also

Component-Level Performance State Management

PO_FX_COMPONENT_PERF_SET

PoFxRegisterComponentPerfStates

PO_FX_COMPONENT_PERF_SET structure

2/5/2019 • 2 minutes to read • Edit Online

The **PO_FX_COMPONENT_PERF_SET** structure represents a set of performance states for a single component within a device.

Syntax

```
typedef struct _PO_FX_COMPONENT_PERF_SET {
  UNICODE_STRING        Name;
  ULONGLONG             Flags;
  PO_FX_PERF_STATE_UNIT Unit;
  PO_FX_PERF_STATE_TYPE Type;
  union {
    struct {
      ULONG             Count;
      PPO_FX_PERF_STATE States;
    } Discrete;
    struct {
      ULONGLONG Minimum;
      ULONGLONG Maximum;
    } Range;
  };
} PO_FX_COMPONENT_PERF_SET, *PPO_FX_COMPONENT_PERF_SET;
```

Members

`Name`

An optional character string used to describe the component property controlled by the performance state set. For example, "Clock frequency" or "Memory bandwidth".

`Flags`

Set to 0. Currently, no flags are defined for this member.

`Unit`

A PO_FX_PERF_STATE_UNIT value that specifies the type of unit that is controlled by the performance state set.

`Type`

A PO_FX_PERF_STATE_TYPE value that specifies the type of performance states in the set (a discrete number of states or a continuous distribution of states between a minimum and maximum value).

`Discrete`

`Discrete.Count`

The number of performance states in the set.

`Discrete.States`

A pointer to a PO_FX_PERF_STATE array. The length of this array is specified by the **Count** member. Each array element describes one power state in the set.

`Range`

`Range.Minimum`

The minimum performance state value.

`Range.Maximum`

The maximum performance state value.

Remarks

When a device driver calls the PoFxRegisterComponentPerfStates routine to register a component for performance state support with the power management framework (PoFx), the driver can supply a PO_FX_COMPONENT_PERF_INFO structure that describes the sets of the performance states supported by the component. The **PerfStateSets** member of the **PO_FX_COMPONENT_PERF_INFO** structure contains an array of **PO_FX_COMPONENT_PERF_SET** structures that represent the supported performance states.

Most drivers are expected to define a single set of performance states per component. For example, a driver might define one set of performance states to control the clock frequency for a component. However, some drivers may need to define more than one performance state set to control multiple dimensions of performance states for a component. For example, a driver might define two sets of performance states to control the clock frequency and bus bandwidth.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	wdm.h (include Wudfwdm.h)

Device Performance State Management

PO_FX_COMPONENT_PERF_INFO

PoFxRegisterComponentPerfStates

PO_FX_COMPONENT_V1 structure

1/30/2019 • 3 minutes to read • Edit Online

The **PO_FX_COMPONENT** structure describes the power state attributes of a component in a device.

Syntax

```
typedef struct _PO_FX_COMPONENT_V1 {
  GUID                          Id;
  ULONG                         IdleStateCount;
  ULONG                         DeepestWakeableIdleState;
  PPO_FX_COMPONENT_IDLE_STATE IdleStates;
} PO_FX_COMPONENT_V1, *PPO_FX_COMPONENT_V1;
```

Members

`Id`

A component ID that uniquely identifies this component with respect to the other components in the device. The driver should specify a nonzero value for this member if the power management framework (PoFx) requires a component ID to distinguish this component from other, similar components in the same device. This member is optional. If this member is not used, it must be set to all zeros.

`IdleStateCount`

The number of elements in the array that is pointed to by the **IdleStates** member. Additionally, this member specifies the number of Fx power states that the component supports. A component must support at least one Fx state (F0).

`DeepestWakeableIdleState`

The index of the deepest Fx state from which the component can wake. Specify 0 for F0, 1 for F1, and so on. This index must be less than **IdleStateCount**.

`IdleStates`

A pointer to a PO_FX_COMPONENT_IDLE_STATE array. The length of this array is specified by the **IdleStateCount** member. Each array element specifies the attributes of an Fx power state that is supported by the component. Element 0 describes F0, element 1 describes F1, and so on.

Remarks

When a device driver registers a device with PoFx, the driver supplies a PO_FX_DEVICE structure that holds the registration information. This structure contains an array of **PO_FX_COMPONENT** structures. The elements in this array describe the power attributes of the individual components in the device. PoFx uses the information in this array to manage the power settings of these components.

The **Id** member contains a component ID that PoFx can use to uniquely identify a component. Do not confuse the component ID with the component index, which a routine such as PoFxActivateComponent uses to identify a component in a registered device. A component index is an index into the **Components** array in the **PO_FX_DEVICE** structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes are integer values in the range 0 to N–1. In contrast, a component ID is a

GUID value.

The **Flags** member may be set to the **PO_FX_COMPONENT_FLAG_F0_ON_DX** value if the driver specified support for **PO_FX_VERSION_V2** during registration with PoFx (that is, during the call to the PoFxRegisterDevice routine, the driver specified the value **PO_FX_VERSION_V2** for the **Version** member of the PO_FX_DEVICE structure that was passed to the *Device* parameter). If the **PO_FX_COMPONENT_FLAG_F0_ON_DX** flag is specified, PoFx will place the component into the F0 power state during Dx transitions and for wait/wake IRPs. Before dispatching a Dx IRP or wait/wake IRP to the device stack (whichever event happens first), the power manager will transition the component into the F0 state. The component will be kept in F0 until the wake/wait IRP is canceled or completed, or the Dx IRP is completed and driver has called the PoFxReportDevicePoweredOn routine (whichever event happens last).

Component dependencies

PoFx supports logical component dependencies within a device (but not across different devices). During device registration for each component, the driver can supply a number (the *ProviderCount* member) and an array of component indexes (the *Providers* member) this component depends on; these are known as *providers*. PoFx guarantees that the component will not become active until all of its providers are active.

Component dependencies form a directed graph where an edge points from a dependent component to a provider and represents a dependency. During device registration, PoFx validates the dependency graph: cycles and repeated edges are not allowed and the depth of the graph for the depth-first search traversal cannot exceed four. PoFx also sets the components' active reference count according to the dependency graph; that is, each provider's active reference count is incremented once for each component that depends on it.

During the component activation, PoFx asynchronously activates all providers first. After a component is active, PoFx checks every dependent component and continues their activation if necessary.

When the component transitions to the idle state, PoFx first makes the dependent components idle. After the driver completes the ComponentIdleConditionCallback and the platform extension plug-in (PEP) is notified that the component is idle, PoFx recursively traverses the dependency graph in breadth-first traversal and asynchronously idles each provider.

Requirements

Minimum supported client	Supported starting with Windows 8.
Header	wdm.h (include Wudfwdm.h)

Component-Level Power Management

PO_FX_COMPONENT_IDLE_STATE

PO_FX_DEVICE

PO_FX_COMPONENT_V2 structure

1/30/2019 • 4 minutes to read • Edit Online

The **PO_FX_COMPONENT** structure describes the power state attributes of a component in a device.

Syntax

```
typedef struct _PO_FX_COMPONENT_V2 {
  GUID                          Id;
  ULONGLONG                     Flags;
  ULONG                         DeepestWakeableIdleState;
  ULONG                         IdleStateCount;
  PPO_FX_COMPONENT_IDLE_STATE IdleStates;
  ULONG                         ProviderCount;
  PULONG                        Providers;
} PO_FX_COMPONENT_V2, *PPO_FX_COMPONENT_V2;
```

Members

`Id`

A component ID that uniquely identifies this component with respect to the other components in the device. The driver should specify a nonzero value for this member if the power management framework (PoFx) requires a component ID to distinguish this component from other, similar components in the same device. This member is optional. If this member is not used, it must be set to all zeros.

`Flags`

This member can be set to the following flag bit: **PO_FX_COMPONENT_FLAG_F0_ON_DX**. For more information, see Remarks.

`DeepestWakeableIdleState`

The index of the deepest Fx state from which the component can wake. Specify 0 for F0, 1 for F1, and so on. This index must be less than **IdleStateCount**.

`IdleStateCount`

The number of elements in the array that is pointed to by the **IdleStates** member. Additionally, this member specifies the number of Fx power states that the component supports. A component must support at least one Fx state (F0).

`IdleStates`

A pointer to a PO_FX_COMPONENT_IDLE_STATE array. The length of this array is specified by the **IdleStateCount** member. Each array element specifies the attributes of an Fx power state that is supported by the component. Element 0 describes F0, element 1 describes F1, and so on.

`ProviderCount`

A value that specifies the number of components this component depends on. For more information, see *Component dependencies* under Remarks.

`Providers`

A pointer to an array of component indexes this component depends on. For more information, see *Component dependencies* under Remarks.

Remarks

When a device driver registers a device with PoFx, the driver supplies a PO_FX_DEVICE structure that holds the registration information. This structure contains an array of **PO_FX_COMPONENT** structures. The elements in this array describe the power attributes of the individual components in the device. PoFx uses the information in this array to manage the power settings of these components.

The **Id** member contains a component ID that PoFx can use to uniquely identify a component. Do not confuse the component ID with the component index, which a routine such as PoFxActivateComponent uses to identify a component in a registered device. A component index is an index into the **Components** array in the **PO_FX_DEVICE** structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes are integer values in the range 0 to N–1. In contrast, a component ID is a GUID value.

The **Flags** member may be set to the **PO_FX_COMPONENT_FLAG_F0_ON_DX** value if the driver specified support for **PO_FX_VERSION_V2** during registration with PoFx (that is, during the call to the PoFxRegisterDevice routine, the driver specified the value **PO_FX_VERSION_V2** for the **Version** member of the PO_FX_DEVICE structure that was passed to the *Device* parameter). If the **PO_FX_COMPONENT_FLAG_F0_ON_DX** flag is specified, PoFx will place the component into the F0 power state during Dx transitions and for wait/wake IRPs. Before dispatching a Dx IRP or wait/wake IRP to the device stack (whichever event happens first), the power manager will transition the component into the F0 state. The component will be kept in F0 until the wake/wait IRP is canceled or completed, or the Dx IRP is completed and driver has called the PoFxReportDevicePoweredOn routine (whichever event happens last).

Component dependencies

PoFx supports logical component dependencies within a device (but not across different devices). During device registration for each component, the driver can supply a number (the *ProviderCount* member) and an array of component indexes (the *Providers* member) this component depends on; these are known as *providers*. PoFx guarantees that the component will not become active until all of its providers are active.

Component dependencies form a directed graph where an edge points from a dependent component to a provider and represents a dependency. During device registration, PoFx validates the dependency graph: cycles and repeated edges are not allowed and the depth of the graph for the depth-first search traversal cannot exceed four. PoFx also sets the components' active reference count according to the dependency graph; that is, each provider's active reference count is incremented once for each component that depends on it.

During the component activation, PoFx asynchronously activates all providers first. After a component is active, PoFx checks every dependent component and continues their activation if necessary.

When the component transitions to the idle state, PoFx first makes the dependent components idle. After the driver completes the ComponentIdleConditionCallback and the platform extension plug-in (PEP) is notified that the component is idle, PoFx recursively traverses the dependency graph in breadth-first traversal and asynchronously idles each provider.

PO_FX_COMPONENT_IDLE_STATE

PO_FX_DEVICE

PO_FX_DEVICE_V1 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_DEVICE** structure describes the power attributes of a device to the power management framework (PoFx).

Syntax

```
typedef struct _PO_FX_DEVICE_V1 {
  ULONG                                    Version;
  ULONG                                    ComponentCount;
  PPO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK ComponentActiveConditionCallback;
  PPO_FX_COMPONENT_IDLE_CONDITION_CALLBACK   ComponentIdleConditionCallback;
  PPO_FX_COMPONENT_IDLE_STATE_CALLBACK       ComponentIdleStateCallback;
  PPO_FX_DEVICE_POWER_REQUIRED_CALLBACK      DevicePowerRequiredCallback;
  PPO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK  DevicePowerNotRequiredCallback;
  PPO_FX_POWER_CONTROL_CALLBACK              PowerControlCallback;
  PVOID                                    DeviceContext;
  PO_FX_COMPONENT_V1                       Components[ANYSIZE_ARRAY];
} PO_FX_DEVICE_V1, *PPO_FX_DEVICE_V1;
```

Members

`Version`

The version number of this structure. If the driver will register for performance state support with PoFx, set this member to **PO_FX_VERSION_V2**. Otherwise, set this member to **PO_FX_VERSION_V1**.

`ComponentCount`

The number of elements in the **Components** array. Additionally, this member specifies the number of components in the device.

`ComponentActiveConditionCallback`

A pointer to the ComponentActiveConditionCallback callback routine that is implemented by the device driver.

`ComponentIdleConditionCallback`

A pointer to the ComponentIdleConditionCallback callback routine that is implemented by the device driver.

`ComponentIdleStateCallback`

A pointer to the ComponentIdleStateCallback callback routine that is implemented by the device driver.

`DevicePowerRequiredCallback`

A pointer to the DevicePowerRequiredCallback callback routine that is implemented by the device driver.

`DevicePowerNotRequiredCallback`

A pointer to the DevicePowerNotRequiredCallback callback routine that is implemented by the device driver.

`PowerControlCallback`

A pointer to the PowerControlCallback callback routine that is implemented by the device driver.

`DeviceContext`

A pointer to a caller-allocated device context. This pointer is passed as a parameter to each driver-implemented callback function that is pointed to by this structure. The device driver uses this context to store information about the current power state of the device. This context is opaque to PoFx.

`Components`

This member is the first element in an array of one or more PO_FX_COMPONENT elements. If the array contains more than one element, the additional elements immediately follow the **PO_FX_DEVICE** structure. The array contains one element for each component in the device. The Fx power state of each component can be controlled independently of the Fx power states of the other components in the device. The **ANYSIZE_ARRAY** constant is defined to be 1 in the Ntdef.h header file.

Remarks

To register a device with PoFx, a driver calls the PoFxRegisterDevice routine and supplies, as a parameter, a pointer to a **PO_FX_DEVICE** structure that describes the device.

Each element in the **Components** array describes the power state attributes of one component in the device. Each component in the device is identified by its **Components** array index. Routines such as PoFxActivateComponent and PoFxCompleteIdleCondition use the array index of a component to identify the component.

A device driver is not required to implement all six callback routines. The driver can set a function pointer in the **PO_FX_DEVICE** structure to NULL if the driver does not implement the corresponding callback routine. However, certain callback routines must be implemented. Specifically, if one or more components in a device has more than one Fx state, the driver must implement ComponentIdleStateCallback, ComponentActiveConditionCallback, and ComponentIdleConditionCallback routines. Otherwise, device registration fails and PoFxRegisterDevice returns **STATUS_INVALID_PARAMETER**.

Requirements

PO_FX_DEVICE_V2 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_DEVICE** structure describes the power attributes of a device to the power management framework (PoFx).

Syntax

```
typedef struct _PO_FX_DEVICE_V2 {
  ULONG                                    Version;
  ULONGLONG                                Flags;
  PPO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK ComponentActiveConditionCallback;
  PPO_FX_COMPONENT_IDLE_CONDITION_CALLBACK   ComponentIdleConditionCallback;
  PPO_FX_COMPONENT_IDLE_STATE_CALLBACK       ComponentIdleStateCallback;
  PPO_FX_DEVICE_POWER_REQUIRED_CALLBACK      DevicePowerRequiredCallback;
  PPO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK  DevicePowerNotRequiredCallback;
  PPO_FX_POWER_CONTROL_CALLBACK              PowerControlCallback;
  PVOID                                    DeviceContext;
  ULONG                                    ComponentCount;
  PO_FX_COMPONENT_V2                       Components[ANYSIZE_ARRAY];
} PO_FX_DEVICE_V2, *PPO_FX_DEVICE_V2;
```

Members

`Version`

The version number of this structure. If the driver will register for performance state support with PoFx, set this member to **PO_FX_VERSION_V2**. Otherwise, set this member to **PO_FX_VERSION_V1**.

`Flags`

Set to 0. Currently, no flags are defined for this member.

`ComponentActiveConditionCallback`

A pointer to the ComponentActiveConditionCallback callback routine that is implemented by the device driver.

`ComponentIdleConditionCallback`

A pointer to the ComponentIdleConditionCallback callback routine that is implemented by the device driver.

`ComponentIdleStateCallback`

A pointer to the ComponentIdleStateCallback callback routine that is implemented by the device driver.

`DevicePowerRequiredCallback`

A pointer to the DevicePowerRequiredCallback callback routine that is implemented by the device driver.

`DevicePowerNotRequiredCallback`

A pointer to the DevicePowerNotRequiredCallback callback routine that is implemented by the device driver.

`PowerControlCallback`

A pointer to the PowerControlCallback callback routine that is implemented by the device driver.

`DeviceContext`

A pointer to a caller-allocated device context. This pointer is passed as a parameter to each driver-implemented callback function that is pointed to by this structure. The device driver uses this context to store information about the current power state of the device. This context is opaque to PoFx.

`ComponentCount`

The number of elements in the **Components** array. Additionally, this member specifies the number of components in the device.

`Components`

This member is the first element in an array of one or more PO_FX_COMPONENT elements. If the array contains more than one element, the additional elements immediately follow the **PO_FX_DEVICE** structure. The array contains one element for each component in the device. The Fx power state of each component can be controlled independently of the Fx power states of the other components in the device. The **ANYSIZE_ARRAY** constant is defined to be 1 in the Ntdef.h header file.

Remarks

To register a device with PoFx, a driver calls the PoFxRegisterDevice routine and supplies, as a parameter, a pointer to a **PO_FX_DEVICE** structure that describes the device.

Each element in the **Components** array describes the power state attributes of one component in the device. Each component in the device is identified by its **Components** array index. Routines such as PoFxActivateComponent and PoFxCompleteIdleCondition use the array index of a component to identify the component.

A device driver is not required to implement all six callback routines. The driver can set a function pointer in the **PO_FX_DEVICE** structure to NULL if the driver does not implement the corresponding callback routine. However, certain callback routines must be implemented. Specifically, if one or more components in a device has more than one Fx state, the driver must implement ComponentIdleStateCallback, ComponentActiveConditionCallback, and ComponentIdleConditionCallback routines. Otherwise, device registration fails and PoFxRegisterDevice returns **STATUS_INVALID_PARAMETER**.

PO_FX_PERF_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_PERF_STATE** structure represents a performance state for a single component within a device.

Syntax

```
typedef struct _PO_FX_PERF_STATE {
  ULONGLONG Value;
  PVOID     Context;
} PO_FX_PERF_STATE, *PPO_FX_PERF_STATE;
```

Members

`Value`

The value of this performance state. The units are specified by the **Unit** member of the PO_FX_COMPONENT_PERF_SET that contains this performance state. For example, if **Value** is 100000000 and the **Unit** member of the **PO_FX_COMPONENT_PERF_SET** is **PoFxPerfStateUnitFrequency**, this performance state represents 100 MHz.

`Context`

A pointer to additional context for the performance state that cannot be presented by the **Value** member. This data can be shared between the driver and the platform extension plug-in (PEP).

> **Note** Using the **Context** member can hinder the visualization of performance states in Windows Performance Analyzer.

Remarks

The **States** member of the PO_FX_COMPONENT_PERF_SET structure contains an array of **PO_FX_PERF_STATE** elements.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	wdm.h (include Wudfwdm.h)

PO_FX_PERF_STATE_CHANGE structure

2/5/2019 • 2 minutes to read • Edit Online

The **PO_FX_PERF_STATE_CHANGE** structure contains information about a change to a performance state that is being requested by calling the PoFxIssueComponentPerfStateChange or PoFxIssueComponentPerfStateChangeMultiple routine.

Syntax

```
typedef struct _PO_FX_PERF_STATE_CHANGE {
  ULONG Set;
  union {
    ULONG     StateIndex;
    ULONGLONG StateValue;
  };
} PO_FX_PERF_STATE_CHANGE, *PPO_FX_PERF_STATE_CHANGE;
```

Members

`Set`

The index of the performance state set that is being changed within the collection of performance state sets for the component.

`StateIndex`

For sets that represent a discrete number of performance states (that is, where the **Type** member of the PO_FX_COMPONENT_PERF_SET is **PoFxPerfStateTypeDiscrete**), this member is the index of the performance state to use for the new performance level.

`StateValue`

For sets that represent a continuous distribution of performance states (that is, where the **Type** member of the PO_FX_COMPONENT_PERF_SET is **PoFxPerfStateTypeRange**), this member is the value of the performance state to use for the new performance level.

Remarks

The **PO_FX_PERF_STATE_CHANGE** structure is used for the *PerfChange* parameter of the PoFxIssueComponentPerfStateChange routine and the *PerfChanges* parameter of the PoFxIssueComponentPerfStateChangeMultiple routine.

Requirements

Minimum supported client	Supported starting with Windows 10.

PO_FX_PERF_STATE_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_PERF_STATE_TYPE** enumeration contains values that describe the type of performance states in a PO_FX_COMPONENT_PERF_SET.

Syntax

```
typedef enum _PO_FX_PERF_STATE_TYPE {
  PoFxPerfStateTypeDiscrete,
  PoFxPerfStateTypeRange,
  PoFxPerfStateTypeMaximum
} PO_FX_PERF_STATE_TYPE, *PPO_FX_PERF_STATE_TYPE;
```

Constants

PoFxPerfStateTypeDiscrete	Indicates that the performance state set contains a discrete number of states.
PoFxPerfStateTypeRange	Indicates that the performance state set contains a continuous distribution of states between a minimum and maximum value.
PoFxPerfStateTypeMaximum	This value is reserved for system use.

Remarks

The **Type** member of the PO_FX_COMPONENT_PERF_SET structure is a value from the **PO_FX_PERF_STATE_TYPE** enumeration.

Requirements

Minimum supported client	Supported starting with Windows 10.

PO_FX_PERF_STATE_UNIT Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_PERF_STATE_UNIT** enumeration contains values that describe the type of unit that is controlled by the performance states in a PO_FX_COMPONENT_PERF_SET.

Syntax

```
typedef enum _PO_FX_PERF_STATE_UNIT {
  PoFxPerfStateUnitOther,
  PoFxPerfStateUnitFrequency,
  PoFxPerfStateUnitBandwidth,
  PoFxPerfStateUnitMaximum
} PO_FX_PERF_STATE_UNIT, *PPO_FX_PERF_STATE_UNIT;
```

Constants

PoFxPerfStateUnitOther	Indicates that the performance states control a unit other than frequency or bandwidth.
PoFxPerfStateUnitFrequency	Indicates that the performance states control frequency, measured in Hz.
PoFxPerfStateUnitBandwidth	Indicates that the performance states control bandwidth, measured in bits per second.
PoFxPerfStateUnitMaximum	This value is reserved for system use.

Remarks

The **Unit** member of the PO_FX_COMPONENT_PERF_SET structure is a value from the **PO_FX_PERF_STATE_UNIT** enumeration.

Requirements

Minimum supported client	Supported starting with Windows 10.

POOL_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **POOL_TYPE** enumeration type specifies the type of system memory to allocate.

Syntax

```
typedef enum _POOL_TYPE {
  NonPagedPool,
  NonPagedPoolExecute,
  PagedPool,
  NonPagedPoolMustSucceed,
  DontUseThisType,
  NonPagedPoolCacheAligned,
  PagedPoolCacheAligned,
  NonPagedPoolCacheAlignedMustS,
  MaxPoolType,
  NonPagedPoolBase,
  NonPagedPoolBaseMustSucceed,
  NonPagedPoolBaseCacheAligned,
  NonPagedPoolBaseCacheAlignedMustS,
  NonPagedPoolSession,
  PagedPoolSession,
  NonPagedPoolMustSucceedSession,
  DontUseThisTypeSession,
  NonPagedPoolCacheAlignedSession,
  PagedPoolCacheAlignedSession,
  NonPagedPoolCacheAlignedMustSSession,
  NonPagedPoolNx,
  NonPagedPoolNxCacheAligned,
  NonPagedPoolSessionNx
} POOL_TYPE;
```

Constants

NonPagedPool	*Nonpaged pool*, which is nonpageable system memory. Nonpaged pool can be accessed from any IRQL, but it is a scarce resource and drivers should allocate it only when necessary. System memory allocated with the **NonPagedPool** pool type is executable. For more information, see the description of the **NonPagedPoolExecute** pool type. Starting with Windows 8, drivers should allocate most or all of their nonpaged memory from the no-execute (NX) nonpaged pool instead of the executable nonpaged pool. For more information, see the description of the **NonPagedPoolNx** pool type.

NonPagedPoolExecute	Starting with Windows 8, **NonPagedPoolExecute** is an alternate name for the **NonPagedPool** value. This value indicates that the allocated memory is to be nonpaged and executable—that is, instruction execution is enabled in this memory. To port a driver from an earlier version of Windows, you should typically replace all or most instances of the **NonPagedPool** name in the driver source code with **NonPagedPoolNx**. Avoid replacing instances of the **NonPagedPool** name with **NonPagedPoolExecute** except in cases in which executable memory is explicitly required. For more information, see No-Execute (NX) Nonpaged Pool.
PagedPool	*Paged pool*, which is pageable system memory. Paged pool can only be allocated and accessed at IRQL < DISPATCH_LEVEL.
NonPagedPoolMustSucceed	This value is for internal use only, and is allowed only during system startup. Drivers must not specify this value at times other than system startup, because a "must succeed" request crashes the system if the requested memory size is unavailable.
DontUseThisType	Reserved for system use.
NonPagedPoolCacheAligned	Nonpaged pool, aligned on processor cache boundaries. This value is for internal use only.
PagedPoolCacheAligned	Paged pool, aligned on processor cache boundaries. This value is for internal use only.
NonPagedPoolCacheAlignedMustS	This value is for internal use only, and is allowed only during system startup. It is the cache-aligned equivalent of **NonPagedPoolMustSucceed**.
MaxPoolType	Reserved for system use.
NonPagedPoolBase	Reserved for system use.
NonPagedPoolBaseMustSucceed	Reserved for system use.
NonPagedPoolBaseCacheAligned	Reserved for system use.
NonPagedPoolBaseCacheAlignedMustS	Reserved for system use.
NonPagedPoolSession	Deprecated. Do not use.
PagedPoolSession	Deprecated. Do not use.
NonPagedPoolMustSucceedSession	Deprecated. Do not use.
DontUseThisTypeSession	Deprecated. Do not use.
NonPagedPoolCacheAlignedSession	Deprecated. Do not use.
PagedPoolCacheAlignedSession	Deprecated. Do not use.

NonPagedPoolCacheAlignedMustSSession	Deprecated. Do not use.
NonPagedPoolNx	*No-execute* (NX) nonpaged pool. This pool type is available starting with Windows 8. In contrast to the nonpaged pool designated by **NonPagedPool**, which allocates executable memory, the NX nonpaged pool allocates memory in which instruction execution is disabled. For more information, see No-Execute (NX) Nonpaged Pool. Nonpaged pool can be accessed from any IRQL, but it is a scarce resource and drivers should allocate it only when necessary.
NonPagedPoolNxCacheAligned	NX nonpaged pool, aligned on processor cache boundaries. This value is reserved for exclusive use by the operating system.
NonPagedPoolSessionNx	Reserved for exclusive use by the operating system.

POWER_PLATFORM_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **POWER_PLATFORM_INFORMATION** structure contains information about the power capabilities of the system.

Syntax

```
typedef struct _POWER_PLATFORM_INFORMATION {
  BOOLEAN AoAc;
} POWER_PLATFORM_INFORMATION, *PPOWER_PLATFORM_INFORMATION;
```

Members

`AoAc`

Indicates whether the system supports the connected standby power model.

Requirements

Minimum supported client	Windows 8
Minimum supported server	Windows Server 2012
Header	wdm.h (include Ntpoapi.h)

POWER_REQUEST_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **POWER_REQUEST_TYPE** enumeration indicates the power request type.

Syntax

```
typedef enum _POWER_REQUEST_TYPE {
  PowerRequestDisplayRequired,
  PowerRequestSystemRequired,
  PowerRequestAwayModeRequired,
  PowerRequestExecutionRequired
} POWER_REQUEST_TYPE, *PPOWER_REQUEST_TYPE;
```

Constants

PowerRequestDisplayRequired	Not used by drivers. For more information, see Remarks.
PowerRequestSystemRequired	Prevents the computer from automatically entering sleep mode after a period of user inactivity.
PowerRequestAwayModeRequired	Not used by drivers. For more information, see Remarks.
PowerRequestExecutionRequired	Not used by drivers. For more information, see Remarks.

Remarks

This enumeration is used by the kernel-mode PoClearPowerRequest and PoSetPowerRequest routines. Drivers that call these routines must specify the **PowerRequestSystemRequired** enumeration value.

The other three enumeration values—**PowerRequestDisplayRequired**, **PowerRequestAwayModeRequired**, and **PowerRequestExecutionRequired**—are not used by drivers. Applications specify these power request types in calls to the PowerSetRequest and PowerClearRequest functions.

A **PowerRequestDisplayRequired** power request has the following effects:

- After a period of user inactivity, the session display stays on and will not automatically turn off. If the display is already turned off, the power request turns the display on.
- A screensaver will not automatically start after a period of user inactivity. If a screensaver is already running, the power request stops the screensaver.
- The session will not be automatically locked after a period of user inactivity. If the session is already locked when the driver sends the power request, the session remains locked.

While a **PowerRequestAwayModeRequired** power request is in effect, if the user tries to put the computer into sleep mode (for example, by clicking **Start** and then clicking **Sleep**), the power manager turns off audio and video so that the computer appears to be in sleep mode, but the computer continues to run.

While a **PowerRequestExecutionRequired** power request is in effect, the calling process continues to run instead of being suspended or terminated by process lifetime management (PLM) mechanisms. When and how long the

process is allowed to run depends on the operating system and power policy settings. This type of power request is supported starting with Windows 8.

Requirements

Minimum supported client	Supported starting with Windows 7.

POWER_STATE union

1/30/2019 • 2 minutes to read • Edit Online

The **POWER_STATE** union specifies a system power state value or a device power state value.

Syntax

```
typedef union _POWER_STATE {
  SYSTEM_POWER_STATE SystemState;
  DEVICE_POWER_STATE DeviceState;
} POWER_STATE, *PPOWER_STATE;
```

Members

`SystemState`

A system power state value of type SYSTEM_POWER_STATE.

`DeviceState`

A device power state value of type DEVICE_POWER_STATE.

Remarks

The **POWER_STATE** union is used in conjunction with the POWER_STATE_TYPE enumeration type to specify a system power state value or a device power state value. This union is also used in cases where the power state type is implicitly determined by the context in which it is used. For example, see PoRequestPowerIrp and PoSetPowerState.

For more information about power management, see Introduction to Power Management.

REENUMERATE_SELF_INTERFACE_STANDARD structure

1/30/2019 • 2 minutes to read • Edit Online

The **REENUMERATE_SELF_INTERFACE_STANDARD** interface structure enables a driver to request that its parent bus driver reenumerate the driver's device. This structure defines the GUID_REENUMERATE_SELF_INTERFACE_STANDARD interface.

Syntax

```
typedef struct _REENUMERATE_SELF_INTERFACE_STANDARD {
  USHORT                 Size;
  USHORT                 Version;
  PVOID                  Context;
  PINTERFACE_REFERENCE   InterfaceReference;
  PINTERFACE_DEREFERENCE InterfaceDereference;
  PREENUMERATE_SELF      SurpriseRemoveAndReenumerateSelf;
} REENUMERATE_SELF_INTERFACE_STANDARD, *PREENUMERATE_SELF_INTERFACE_STANDARD;
```

Members

`Size`

The size, in bytes, of this structure.

`Version`

The driver-defined interface version.

`Context`

A pointer to interface-specific context information.

`InterfaceReference`

A pointer to an InterfaceReference routine that increments the interface's reference count.

`InterfaceDereference`

A pointer to an InterfaceDereference routine that decrements the interface's reference count.

`SurpriseRemoveAndReenumerateSelf`

A pointer to a ReenumerateSelf routine that requests device reenumeration.

Remarks

A driver obtains a pointer to the **REENUMERATE_SELF_INTERFACE_STANDARD** structure by sending an IRP_MN_QUERY_INTERFACE IRP to its bus driver with **InterfaceType** set to GUID_REENUMERATE_SELF_INTERFACE_STANDARD.

The **REENUMERATE_SELF_INTERFACE_STANDARD** structure is an extension of the INTERFACE structure.

Requirements

Minimum supported client	Available starting with Windows Vista.
Header	wdm.h (include Wdm.h, Ntddk.h)

REG_CALLBACK_CONTEXT_CLEANUP_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_CALLBACK_CONTEXT_CLEANUP_INFORMATION** structure contains information that a driver's RegistryCallback routine can use to free resources that the driver previously allocated for the context that is associated with a registry object.

Syntax

```
typedef struct _REG_CALLBACK_CONTEXT_CLEANUP_INFORMATION {
  PVOID Object;
  PVOID ObjectContext;
  PVOID Reserved;
} REG_CALLBACK_CONTEXT_CLEANUP_INFORMATION, *PREG_CALLBACK_CONTEXT_CLEANUP_INFORMATION;
```

Members

`Object`

A pointer to the registry key object for the key to be deleted.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext.

`Reserved`

This member is reserved for future use.

Remarks

This structure is used by the RegistryCallback routine. When the *Argument1* parameter to the *RegistryCallback* routine is **RegNtCallbackObjectContextCleanup**, the *Argument2* parameter is a pointer to a **REG_CALLBACK_CONTEXT_CLEANUP_INFORMATION** structure.

The driver's *RegistryCallback* routine will receive a **RegNtCallbackObjectContextCleanup** notification after the key object's handle has been closed. In response to this notification, the routine should release any resources that it allocated for the object's context. The **RegNtCallbackObjectContextCleanup** notification occurs when the driver has called CmUnRegisterCallback or the driver's *RegistryCallback* routine has just finished processing a **RegNtPreKeyHandleClose** notification.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available starting with Windows Vista.

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

RegistryCallback

REG_CREATE_KEY_INFORMATION structure

1/30/2019 • 3 minutes to read • Edit Online

The **REG_CREATE_KEY_INFORMATION** structure contains information that a driver's RegistryCallback routine can use when a registry key that is being created.

> **Note** Starting with Windows 7, the V1 version of this structure, REG_CREATE_KEY_INFORMATION_V1, is used instead.

Syntax

```
typedef struct _REG_CREATE_KEY_INFORMATION {
  PUNICODE_STRING CompleteName;
  PVOID           RootObject;
  PVOID           ObjectType;
  ULONG           CreateOptions;
  PUNICODE_STRING Class;
  PVOID           SecurityDescriptor;
  PVOID           SecurityQualityOfService;
  ACCESS_MASK     DesiredAccess;
  ACCESS_MASK     GrantedAccess;
  PULONG          Disposition;
  PVOID           *ResultObject;
  PVOID           CallContext;
  PVOID           RootObjectContext;
  PVOID           Transaction;
  PVOID           Reserved;
} REG_CREATE_KEY_INFORMATION, REG_OPEN_KEY_INFORMATION, *PREG_CREATE_KEY_INFORMATION,
*PREG_OPEN_KEY_INFORMATION;
```

Members

`CompleteName`

A pointer to a UNICODE_STRING structure that contains the path of the new registry key. The path can be absolute or relative. If the path is absolute, this structure contains a fully qualified path that starts with the "\" character. For an absolute path, the **RootObject** member specifies the **\REGISTRY** key, which is the root directory of the registry tree. If the path is relative, the path starts with a character other than "\", and is relative to the key that is specified by the *RootObject* member.

`RootObject`

Pointer to the registry key object that serves as the root for the path specified by the *CompleteName* member.

`ObjectType`

The **ObjectType** member is reserved for internal use. Drivers must not access this member. This member is defined starting with Windows Vista.

`CreateOptions`

A bitwise OR of flags. For more information about these flags, see the *CreateOptions* parameter of the ZwCreateKey routine. This member is defined starting with Windows Vista.

`Class`

A pointer to a UNICODE_STRING structure that identifies the key's object class. For more information about this member, see the *Class* parameter of the ZwCreateKey routine. This member is defined starting with Windows Vista.

`SecurityDescriptor`

A pointer to a SECURITY_DESCRIPTOR structure that contains security information for the key object. This member is defined starting with Windows Vista.

`SecurityQualityOfService`

A pointer to a **SECURITY_QUALITY_OF_SERVICE** structure, which is defined in Winnt.h. This member is defined starting with Windows Vista.

`DesiredAccess`

The access mask that was specified by the thread that is attempting to create the registry key. This member is defined starting with Windows Vista.

`GrantedAccess`

An access mask that indicates the access rights that have been granted to the thread that is attempting to create the registry key. For more information about this member, see Remarks. This member is defined starting with Windows Vista.

`Disposition`

A value that indicates whether the registry key was created. For more information about this member, see the *Disposition* parameter of the ZwCreateKey routine and the following Remarks section. This member is defined starting with Windows Vista.

`ResultObject`

A pointer to a location that receives the address of the key object that represents the created registry key. For more information about this member, see Remarks. This member is defined starting with Windows Vista.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined starting with Windows Vista.

`RootObjectContext`

A pointer to a driver-defined context information that the driver has associated with the root of the path for the registry object by calling CmSetCallbackObjectContext. This member is defined starting with Windows Vista.

`Transaction`

A pointer to a transaction object that the operation is attempted on. If this member is **NULL**, the operation is being performed in non-transactional context. This member is defined starting with Windows Vista.

`Reserved`

Starting with Windows Vista, if this member is 1, then it is safe to cast this structure to type REG_CREATE_KEY_INFORMATION_V1, which contains additional parameters.

In versions of Windows before Windows Vista, this member is always 0.

Remarks

The configuration manager passes this structure to the RegistryCallback routine every time a thread attempts to create a key—for example, when a user-mode thread calls **RegCreateKey** or **RegCreateKeyEx** or when a driver

calls ZwCreateKey.

If the driver's *RegistryCallback* routine returns STATUS_CALLBACK_BYPASS for a **RegNtPreCreateKeyEx** notification, the driver must supply the **GrantedAccess**, **Disposition**, and **ResultObject** values.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available starting with Windows Server 2003, but some structure members are available only in Windows Vista and later versions.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

REG_CREATE_KEY_INFORMATION_V1 structure

1/30/2019 • 5 minutes to read • Edit Online

The **REG_CREATE_KEY_INFORMATION_V1** structure contains information that a filter driver's RegistryCallback routine can use when a registry key is being created.

Syntax

```
typedef struct _REG_CREATE_KEY_INFORMATION_V1 {
  PUNICODE_STRING CompleteName;
  PVOID           RootObject;
  PVOID           ObjectType;
  ULONG           Options;
  PUNICODE_STRING Class;
  PVOID           SecurityDescriptor;
  PVOID           SecurityQualityOfService;
  ACCESS_MASK     DesiredAccess;
  ACCESS_MASK     GrantedAccess;
  PULONG          Disposition;
  PVOID           *ResultObject;
  PVOID           CallContext;
  PVOID           RootObjectContext;
  PVOID           Transaction;
  ULONG_PTR       Version;
  PUNICODE_STRING RemainingName;
  ULONG           Wow64Flags;
  ULONG           Attributes;
  KPROCESSOR_MODE CheckAccessMode;
} REG_CREATE_KEY_INFORMATION_V1, REG_OPEN_KEY_INFORMATION_V1, *PREG_CREATE_KEY_INFORMATION_V1,
*PREG_OPEN_KEY_INFORMATION_V1;
```

Members

`CompleteName`

A pointer to a UNICODE_STRING structure that contains the path of the new registry key. The path can be absolute or relative. If the path is absolute, this structure contains a fully qualified path that starts with the "\" character. For an absolute path, the **RootObject** member specifies the **\REGISTRY** key, which is the root directory of the registry tree. If the path is relative, the path starts with a character other than "\", and is relative to the key that is specified by the **RootObject** member.

`RootObject`

A pointer to a registry key object that represents the root registry key for the path that is specified by the **CompleteName** member.

`ObjectType`

This member is reserved for use by the operating system. Drivers must not access this member.

`Options`

Specifies the options for the key-create routine to use to create or open the new key. For more information, see the description of the *CreateOptions* parameter of the ZwCreateKey routine and the description of the *OpenOptions* parameter of the ZwOpenKeyEx routine.

`Class`

A pointer to a **UNICODE_STRING** structure that identifies the object class of the new key. For more information about this member, see the *Class* parameter of the **ZwCreateKey** routine. This pointer value can be **NULL**.

`SecurityDescriptor`

A pointer to a SECURITY_DESCRIPTOR structure that contains security information for the key object. This pointer was obtained from the **SecurityDescriptor** member of the OBJECT_ATTRIBUTES structure that was passed as an input parameter in the call to create the new registry key.

`SecurityQualityOfService`

A pointer to a SECURITY_QUALITY_OF_SERVICE structure. This structure indicates whether a server can impersonate the client that is trying to create the registry key, and, if impersonation is permitted, the extent to which it is permitted.

`DesiredAccess`

The access mask that was specified by the thread that is trying to create the registry key. For more information about this access mask, see the description of the *DesiredAccess* parameter of the **ZwCreateKey** routine.

`GrantedAccess`

An access mask that indicates the access rights that were granted to the thread that is trying to create the registry key. For more information about this member, see the following Remarks section.

`Disposition`

A value that indicates whether the requested registry operation will create a new key or open an existing one. For more information about this member, see the description of the *Disposition* parameter of the **ZwCreateKey** routine and the following Remarks section.

`ResultObject`

A pointer to a location that receives the address of the key object that represents the created registry key.

`CallContext`

Optional driver-defined context information that the driver's *RegistryCallback* routine can supply.

`RootObjectContext`

A pointer to driver-defined context information that the driver has associated with the root of the path of the registry object by calling the CmSetCallbackObjectContext routine.

`Transaction`

A pointer to a transaction object for the registry operation. You can supply this pointer to the ObOpenObjectByPointer routine to obtain the corresponding transaction handle. If this member is **NULL**, the operation is being performed in non-transactional context.

`Version`

The structure version number. This member distinguishes the REG_CREATE_KEY_INFORMATION structure in Windows Vista from the **REG_CREATE_KEY_INFORMATION_V1** structure in Windows 7 and later versions of Windows. The following version numbers are currently defined.

VERSION NUMBER	VERSION OF STRUCTURE
0	**REG_CREATE_KEY_INFORMATION**

1	**REG_CREATE_KEY_INFORMATION_V1**

Future versions of this structure might add new members but will not change the members that are already defined in existing versions of the structure. This member is defined in the **REG_CREATE_KEY_INFORMATION_V1** structure that is supported in Windows 7 and later versions of the Windows operating systems. In the **REG_CREATE_KEY_INFORMATION** structure that Windows Vista supports, this member is named **Reserved** and is set to zero. Filter drivers should rely on the version number and not the operating system version to determine which version of the structure they are using.

`RemainingName`

A pointer to a **UNICODE_STRING** structure that contains the relative path of the new registry key. This member always expresses the path of the new key relative to the path of the key that is specified by the **RootObject** member. In contrast, the **CompleteName** member can contain an absolute path if the **RootObject** member specifies the **\REGISTRY** key.

`Wow64Flags`

Contains the Wow64 flags from the access mask that was passed as an input parameter in the call to create the new registry key. This member indicates whether a 32-bit client program that is running on a 64-bit version of Windows is trying to create a registry key. This member is set to zero or to one of the following flag bits:

- KEY_WOW64_32KEY
- KEY_WOW64_64KEY

These flag bits are defined in the Wdm.h and Winnt.h header files. For more information about these flags, see Registry Key Security and Access Rights.

`Attributes`

Contains the object-attribute flags from the **Attributes** member of the **OBJECT_ATTRIBUTES** structure that was passed as an input parameter in the call to create the new registry key. This member might contain one or more of the following flag bits:

- OBJ_KERNEL_HANDLE
- OBJ_FORCE_ACCESS_CHECK
- OBJ_OPENLINK

For more information about these flags, see OBJECT_ATTRIBUTES.

`CheckAccessMode`

Indicates how the configuration manager performs the security access check for the call to create the new key. This member contains one of the following MODE enumeration values from the Wdm.h header file:

- **KernelMode**
- **UserMode**

This security check is similar to that performed by the SeAccessCheck routine, which has an *AccessMode* parameter that can be set to either **UserMode** or **KernelMode**. If **CheckAccessMode** is set to **UserMode**, the configuration manager performs a full security access check regardless of whether the call originated in user mode or kernel mode. For more information about how to force user-mode security access checks on a call that originates in kernel mode, see the description of the OBJ_FORCE_ACCESS_CHECK flag in the **Attributes** member of the **OBJECT_ATTRIBUTES** structure.

Remarks

The configuration manager passes this structure to the *RegistryCallback* routine every time that a thread tries to create a key—for example, when a user-mode thread calls RegCreateKey or RegCreateKeyEx, or when a kernel-mode driver calls ZwCreateKey.

This structure is an extended version of the REG_CREATE_KEY_INFORMATION structure that Windows Vista supports. The first 14 members, **CompleteName** through **Transaction**, are identical in the two structures. The last five members of the **REG_CREATE_KEY_INFORMATION_V1** structure, **Version** through **CheckAccessMode**, are not part of the **REG_CREATE_KEY_INFORMATION** structure.

If the driver's *RegistryCallback* routine returns STATUS_CALLBACK_BYPASS for a **RegNtPreCreateKeyEx** notification, the driver must supply the values for the **GrantedAccess**, **Disposition**, and **ResultObject** members.

The **REG_CREATE_KEY_INFORMATION_V1** structure is one of a number of structures that a filter driver can receive through its *RegistryCallback* routine. For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available on Windows 7 and later versions of the Windows operating systems.

REG_DELETE_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_DELETE_KEY_INFORMATION** structure contains information that a driver's RegistryCallback routine can use when a registry key is being deleted.

Syntax

```
typedef struct _REG_DELETE_KEY_INFORMATION {
  PVOID Object;
  PVOID CallContext;
  PVOID ObjectContext;
  PVOID Reserved;
} REG_DELETE_KEY_INFORMATION, *PREG_DELETE_KEY_INFORMATION, REG_FLUSH_KEY_INFORMATION,
*PREG_FLUSH_KEY_INFORMATION;
```

Members

`Object`

A pointer to the registry key object for the key to be deleted.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined for Windows Vista and later versions of the Windows operating system.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined for Windows Vista and later versions of the Windows operating system.

`Reserved`

This member is reserved for future use. This member is defined for Windows Vista and later versions of the Windows operating system.

Remarks

The system passes this structure to the RegistryCallback routine every time a thread attempts to delete a key—for example, when a user-mode thread calls **RegDeleteKey** or **RegDeleteKeyEx** or when a driver calls ZwDeleteKey.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available for Microsoft Windows XP and later versions of the Windows operating system, but some structure members are available only for Windows Vista and later versions.

REG_DELETE_VALUE_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_DELETE_VALUE_KEY_INFORMATION** structure contains information that a driver's RegistryCallback routine can use when a registry key's value is being deleted.

Syntax

```
typedef struct _REG_DELETE_VALUE_KEY_INFORMATION {
  PVOID           Object;
  PUNICODE_STRING ValueName;
  PVOID           CallContext;
  PVOID           ObjectContext;
  PVOID           Reserved;
} REG_DELETE_VALUE_KEY_INFORMATION, *PREG_DELETE_VALUE_KEY_INFORMATION;
```

Members

`Object`

A pointer to the registry key object for the key whose value entry is about to be deleted.

`ValueName`

A pointer to a UNICODE_STRING structure that contains the name of the value entry that is about to be deleted.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined for Windows Vista and later versions of the Windows operating system.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined for Windows Vista and later versions of the Windows operating system.

`Reserved`

This member is reserved for future use. This member is defined for Windows Vista and later versions of the Windows operating system.

Remarks

The system passes this structure to the RegistryCallback routine every time a thread attempts to delete a value entry—for example, when a user-mode thread calls **RegDeleteValue** or when a driver calls ZwDeleteValueKey.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available on Microsoft Windows XP and later versions of the Windows operating system.

REG_ENUMERATE_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_ENUMERATE_KEY_INFORMATION** structure describes one subkey of a key whose subkeys are being enumerated.

Syntax

```
typedef struct _REG_ENUMERATE_KEY_INFORMATION {
  PVOID                 Object;
  ULONG                 Index;
  KEY_INFORMATION_CLASS KeyInformationClass;
  PVOID                 KeyInformation;
  ULONG                 Length;
  PULONG                ResultLength;
  PVOID                 CallContext;
  PVOID                 ObjectContext;
  PVOID                 Reserved;
} REG_ENUMERATE_KEY_INFORMATION, *PREG_ENUMERATE_KEY_INFORMATION;
```

Members

`Object`

A pointer to the registry key object for the key whose subkeys are being enumerated.

`Index`

The zero-based index of the subkey within the key.

`KeyInformationClass`

The KEY_INFORMATION_CLASS value that indicates the type of information to be returned by the system in the **KeyInformation** buffer.

`KeyInformation`

A pointer to a buffer that contains the information to be returned by the system. The format of the buffer depends on the value of **KeyInformationClass**. For more information, see KEY_INFORMATION_CLASS.

`Length`

The size, in bytes, of the **KeyInformation** buffer.

`ResultLength`

A pointer to a ULONG that receives (from the system) the amount of valid data, in bytes, in the **KeyInformation** buffer.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined for Windows Vista and later versions of the Windows operating system.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined for Windows Vista and later versions of the Windows operating system.

`Reserved`

This member is reserved for future use. This member is defined for Windows Vista and later versions of the Windows operating system.

Remarks

The system passes this structure to a RegistryCallback routine every time a thread attempts to enumerate the subkeys of a key—for example, when a user-mode thread calls **RegEnumKey** or **RegEnumKeyEx** or when a driver calls ZwEnumerateKey.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available on Microsoft Windows XP and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

REG_ENUMERATE_VALUE_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_ENUMERATE_VALUE_KEY_INFORMATION** structure describes one value entry of a key whose value entries are being enumerated.

Syntax

```
typedef struct _REG_ENUMERATE_VALUE_KEY_INFORMATION {
  PVOID                       Object;
  ULONG                       Index;
  KEY_VALUE_INFORMATION_CLASS KeyValueInformationClass;
  PVOID                       KeyValueInformation;
  ULONG                       Length;
  PULONG                      ResultLength;
  PVOID                       CallContext;
  PVOID                       ObjectContext;
  PVOID                       Reserved;
} REG_ENUMERATE_VALUE_KEY_INFORMATION, *PREG_ENUMERATE_VALUE_KEY_INFORMATION;
```

Members

`Object`

A pointer to the registry key object for the key whose value entries are being enumerated.

`Index`

The zero-based index of the subkey within the key.

`KeyValueInformationClass`

The KEY_VALUE_INFORMATION_CLASS value that indicates the type of information to be returned by the system in the **KeyValueInformation** buffer.

`KeyValueInformation`

A pointer to a buffer that contains the information to be returned by the system. The format of the buffer depends on the value of **KeyValueInformationClass**. For more information see KEY_VALUE_INFORMATION_CLASS.

`Length`

The size, in bytes, of the **KeyValueInformation** buffer.

`ResultLength`

A pointer to a variable that receives (from the system) the amount of valid data, in bytes, in the **KeyValueInformation** buffer.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined for Windows Vista and later versions of the Windows operating system.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined for Windows Vista and later versions of the Windows operating system.

`Reserved`

This member is reserved for future use. This member is defined for Windows Vista and later versions of the Windows operating system.

Remarks

The system passes this structure to a RegistryCallback routine every time a thread attempts to enumerate a value entry of a key—for example, when a user-mode thread calls **RegEnumValue** or when a driver calls ZwEnumerateValueKey.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available on Microsoft Windows XP and later versions of the Windows operating system.

REG_LOAD_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_LOAD_KEY_INFORMATION** structure contains information about a registry hive that is being loaded.

Syntax

```
typedef struct _REG_LOAD_KEY_INFORMATION {
  PVOID           Object;
  PUNICODE_STRING KeyName;
  PUNICODE_STRING SourceFile;
  ULONG           Flags;
  PVOID           TrustClassObject;
  PVOID           UserEvent;
  ACCESS_MASK     DesiredAccess;
  PHANDLE         RootHandle;
  PVOID           CallContext;
  PVOID           ObjectContext;
  PVOID           Reserved;
} REG_LOAD_KEY_INFORMATION, *PREG_LOAD_KEY_INFORMATION;
```

Members

`Object`

A pointer to the registry key object for the root key of the hive that is about to be loaded.

`KeyName`

A pointer to a UNICODE_STRING structure that contains the name of the root key.

`SourceFile`

A pointer to a **UNICODE_STRING** structure that contains the path name of a file that contains the registry hive information that is being loaded.

`Flags`

Reserved for system use.

`TrustClassObject`

Reserved for system use.

`UserEvent`

A pointer to an event object that is signaled when the hive is unloaded.

`DesiredAccess`

The access mask that was specified by the thread that is trying to load the registry key. For more information about this access mask, see the description of the *DesiredAccess* parameter of the ZwCreateKey routine.

`RootHandle`

An optional pointer to a location that receives the handle to the root of the hive that is being loaded. This member can be non-**NULL** if an application hive is being loaded. In all other cases, this member should be **NULL**.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling the CmSetCallbackObjectContext routine.

`Reserved`

Reserved for system use.

Remarks

The operating system passes the **REG_LOAD_KEY_INFORMATION** structure to a RegistryCallback routine every time a user-mode thread calls RegLoadKey to load a registry hive.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available starting with Windows Vista.

Constants

RegNtDeleteKey	Specifies that a thread is attempting to delete a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value only on Windows XP.
RegNtPreDeleteKey	Specifies that a thread is attempting to delete a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtSetValueKey	Specifies that a thread is attempting to set a value entry for a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value only on Windows XP.
RegNtPreSetValueKey	Specifies that a thread is attempting to set a value entry for a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtDeleteValueKey	Specifies that a thread is attempting to delete a value entry for a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value only on Windows XP.
RegNtPreDeleteValueKey	Specifies that a thread is attempting to delete a value entry for a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtSetInformationKey	Specifies that a thread is attempting to set the metadata for a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value only on Windows XP.
RegNtPreSetInformationKey	Specifies that a thread is attempting to set the metadata for a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtRenameKey	Specifies that a thread is attempting to rename a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value only on Windows XP.
RegNtPreRenameKey	Specifies that a thread is attempting to rename a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtEnumerateKey	Specifies that a thread is attempting to enumerate a subkey of a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value only on Windows XP.
RegNtPreEnumerateKey	Specifies that a thread is attempting to enumerate a subkey of a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtEnumerateValueKey	Specifies that a thread is attempting to enumerate a value entry for a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value only on Windows XP.

RegNtPreEnumerateValueKey	Specifies that a thread is attempting to enumerate a value entry for a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtQueryKey	Specifies that a thread is attempting to read the metadata for a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value only on Windows XP.
RegNtPreQueryKey	Specifies that a thread is attempting to read the metadata for a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtQueryValueKey	Specifies that a thread is attempting to read a value entry for a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value only on Windows XP.
RegNtPreQueryValueKey	Specifies that a thread is attempting to read a value entry for a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtQueryMultipleValueKey	Specifies that a thread is attempting to query multiple value entries for a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value on only Windows XP.
RegNtPreQueryMultipleValueKey	Specifies that a thread is attempting to query multiple value entries for a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtPreCreateKey	Specifies that a thread is attempting to create a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows XP and later versions of the Windows operating system.
RegNtPostCreateKey	Specifies that a thread has successfully created a key. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows XP and later versions of the Windows operating system.
RegNtPreOpenKey	Specifies that a thread is attempting to open an existing key. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows XP and later versions of the Windows operating system.
RegNtPostOpenKey	Specifies that a thread has successfully opened an existing key. This value indicates a post-notification call to *RegistryCallback* . Use this value on Windows XP and later versions of the Windows operating system.
RegNtKeyHandleClose	Specifies that a thread is attempting to close a key handle. This value indicates a pre-notification call to *RegistryCallback*. Use this value only on Windows XP.

RegNtPreKeyHandleClose	Specifies that a thread is attempting to close a key handle. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system. Drivers can monitor this registry operation but they cannot block or modify it.
RegNtPostDeleteKey	Specifies that the system has attempted to delete the key. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtPostSetValueKey	Specifies that the system has attempted to set a value entry for a key. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtPostDeleteValueKey	Specifies that the system has attempted to delete a value entry for a key. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtPostSetInformationKey	Specifies that the system has attempted to set the key's metadata. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtPostRenameKey	Specifies that the system has attempted to rename the key. This value indicates a post-notification call to *RegistryCallback* . Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtPostEnumerateKey	Specifies that the system has attempted to enumerate the subkey of a key. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtPostEnumerateValueKey	Specifies that the system has attempted to enumerate the value entry of a key. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtPostQueryKey	Specifies that the system has attempted to query the metadata for a key. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtPostQueryValueKey	Specifies that the system has attempted to query a value entry for the key. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtPostQueryMultipleValueKey	Specifies that the system has attempted to query multiple value entries for the key. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.

RegNtPostKeyHandleClose	Specifies that the system has attempted to close a key handle. This value indicates a post-notification call to *RegistryCallback* . Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtPreCreateKeyEx	Specifies that a thread is attempting to create a key. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtPostCreateKeyEx	Specifies that the system has attempted to create a key. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtPreOpenKeyEx	Specifies that a thread is attempting to open an existing key. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtPostOpenKeyEx	Specifies that the system has attempted to open an existing key. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Server 2003 and later versions of the Windows operating system.
RegNtPreFlushKey	Specifies that a thread is attempting to write a key to disk. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Vista and later versions of the Windows operating system.
RegNtPostFlushKey	Specifies that the system has attempted to write a key to disk. This value indicates a post-notification call to *RegistryCallback* . Use this value on Windows Vista and later versions of the Windows operating system.
RegNtPreLoadKey	Specifies that a thread is attempting to load a registry hive from a file. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Vista and later versions of the Windows operating system.
RegNtPostLoadKey	Specifies that the system has attempted to load a registry hive from a file. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Vista and later versions of the Windows operating system.
RegNtPreUnLoadKey	Specifies that a thread is attempting to unload a registry hive. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Vista and later versions of the Windows operating system.
RegNtPostUnLoadKey	Specifies that the system has attempted to unload a registry hive. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Vista and later versions of the Windows operating system.
RegNtPreQueryKeySecurity	Specifies that a thread is attempting to obtain a registry key's security information. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Vista and later versions of the Windows operating system.

RegNtPostQueryKeySecurity	Specifies that a thread has attempted to obtain a registry key's security information. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Vista and later versions of the Windows operating system.
RegNtPreSetKeySecurity	Specifies that a thread is attempting to set a registry key's security information. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Vista and later versions of the Windows operating system.
RegNtPostSetKeySecurity	Specifies that a thread has attempted to set a registry key's security information. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Vista and later versions of the Windows operating system.
RegNtCallbackObjectContextCleanup	Specifies that the driver has called CmUnRegisterCallback or the driver's RegistryCallback routine has just finished processing a **RegNtPreKeyHandleClose** class value. Use this value on Windows Vista and later versions of the Windows operating system.
RegNtPreRestoreKey	Specifies that a thread is attempting to restore a registry key's information. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Vista SP2 and later versions of the Windows operating system.
RegNtPostRestoreKey	Specifies that a thread has attempted to restore a registry key's information. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Vista SP2 and later versions of the Windows operating system.
RegNtPreSaveKey	Specifies that a thread is attempting to save a registry key's information. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Vista SP2 and later versions of the Windows operating system.
RegNtPostSaveKey	Specifies that a thread has attempted to save a registry key's information. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Vista SP2 and later versions of the Windows operating system.
RegNtPreReplaceKey	Specifies that a thread is attempting to replace a registry key's information. This value indicates a pre-notification call to *RegistryCallback*. Use this value on Windows Vista SP2 and later versions of the Windows operating system.
RegNtPostReplaceKey	Specifies that a thread has attempted to replace a registry key's information. This value indicates a post-notification call to *RegistryCallback*. Use this value on Windows Vista SP2 and later versions of the Windows operating system.
RegNtPreQueryKeyName	Specifies that a thread is attempting to obtain the full path of a registry key. Use this value on Windows 10 and later versions of the Windows operating system.

RegNtPostQueryKeyName	Specifies that a thread has attempted to obtain the full path of a registry key. Use this value on Windows 10 and later versions of the Windows operating system.
MaxRegNtNotifyClass	Specifies the maximum value in this enumeration type.

Remarks

When the configuration manager calls a driver's *RegistryCallback* routine, it passes a **REG_NOTIFY_CLASS** enumeration value to the routine. The configuration manager also passes a notification-specific structure that contains information about the notification. For a list of these structures, see RegistryCallback.

Requirements

Minimum supported client	Available for Windows XP and later versions of the Windows operating system, but some enumeration values are available only for specified later versions of the Windows operating system.

RegistryCallback

REG_POST_CREATE_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_POST_CREATE_KEY_INFORMATION** structure contains the result of an attempt to create a registry key.

Syntax

```
typedef struct _REG_POST_CREATE_KEY_INFORMATION {
  PUNICODE_STRING CompleteName;
  PVOID           Object;
  NTSTATUS        Status;
} REG_POST_CREATE_KEY_INFORMATION, REG_POST_OPEN_KEY_INFORMATION, *PREG_POST_CREATE_KEY_INFORMATION,
*PREG_POST_OPEN_KEY_INFORMATION;
```

Members

`CompleteName`

A pointer to a UNICODE_STRING structure that specifies the complete path of the registry key.

`Object`

A pointer to the registry key object that was created.

`Status`

The NTSTATUS value that the system will return for the registry operation.

Remarks

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available only on Microsoft Windows XP.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

RegistryCallback

UNICODE_STRING

ZwCreateKey

REG_POST_OPERATION_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_POST_OPERATION_INFORMATION** structure contains information about a completed registry operation that a RegistryCallback routine can use.

Syntax

```
typedef struct _REG_POST_OPERATION_INFORMATION {
  PVOID    Object;
  NTSTATUS Status;
  PVOID    PreInformation;
  NTSTATUS ReturnStatus;
  PVOID    CallContext;
  PVOID    ObjectContext;
  PVOID    Reserved;
} REG_POST_OPERATION_INFORMATION, *PREG_POST_OPERATION_INFORMATION;
```

Members

`Object`

A pointer to the registry key object for which the operation has completed. This member is valid only if the Status member of the structure is set to STATUS_SUCCESS. For more information, see Invalid Key Object Pointers in Registry Notifications.

`Status`

The NTSTATUS-typed value that the system will return for the registry operation.

`PreInformation`

A pointer to the structure that contains preprocessing information for the registry operation that has completed. For example, if the RegistryCallback routine is processing a **RegNtPostQueryValueKey** operation, the **PreInformation** member points to a REG_QUERY_VALUE_KEY_INFORMATION structure. This member is defined for Windows Vista and later versions of the Windows operating system.

`ReturnStatus`

A driver-supplied NTSTATUS-typed value. If the driver's *RegistryCallback* routine returns STATUS_CALLBACK_BYPASS, the operating system uses the **ReturnStatus** member's value as the status that it returns to the thread that initiated the registry operation. (In such cases, the operating system also copies the **ReturnStatus** member's value to the **Status** member.) Otherwise, this member is ignored. This member is defined for Windows Vista and later versions of the Windows operating system.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined for Windows Vista and later versions of the Windows operating system.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined for Windows Vista and later versions of the Windows

operating system.

`Reserved`

This member is reserved for future use. This member is defined for Windows Vista and later versions of the Windows operating system.

Remarks

For more information about handling post-notifications, see Handling Notifications.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available on Microsoft Windows Server 2003 and later versions of the Windows operating system, but some structure members are available only for Windows Vista and later versions.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

REG_QUERY_VALUE_KEY_INFORMATION

RegistryCallback

REG_PRE_CREATE_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_PRE_OPEN_KEY_INFORMATION** structure contains the name of a registry key that is about to be opened.

Syntax

```
typedef struct _REG_PRE_CREATE_KEY_INFORMATION {
  PUNICODE_STRING CompleteName;
} REG_PRE_CREATE_KEY_INFORMATION, REG_PRE_OPEN_KEY_INFORMATION, *PREG_PRE_CREATE_KEY_INFORMATION,
*PREG_PRE_OPEN_KEY_INFORMATION;
```

Members

`CompleteName`

A pointer to a UNICODE_STRING structure that contains the complete path of the registry key.

Remarks

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available only on Microsoft Windows XP.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

REG_QUERY_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_QUERY_KEY_INFORMATION** structure describes the metadata that is about to be queried for a key.

Syntax

```
typedef struct _REG_QUERY_KEY_INFORMATION {
  PVOID                Object;
  KEY_INFORMATION_CLASS KeyInformationClass;
  PVOID                KeyInformation;
  ULONG                Length;
  PULONG               ResultLength;
  PVOID                CallContext;
  PVOID                ObjectContext;
  PVOID                Reserved;
} REG_QUERY_KEY_INFORMATION, *PREG_QUERY_KEY_INFORMATION;
```

Members

`Object`

A pointer to the registry key object for the key whose metadata is about to be queried.

`KeyInformationClass`

The KEY_INFORMATION_CLASS value that indicates the type of information to be returned by the system.

`KeyInformation`

A pointer to a buffer that contains the information to be returned by the system. The format of the buffer depends on the value of **KeyInformationClass**. For more information see KEY_INFORMATION_CLASS.

`Length`

Specifies the size, in bytes, of the **KeyInformation** buffer.

`ResultLength`

Pointer to a variable that receives (from the system) the amount of valid data, in bytes, in the **KeyInformation** buffer.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined for Windows Vista and later versions of the Windows operating system.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined for Windows Vista and later versions of the Windows operating system.

`Reserved`

This member is reserved for future use. This member is defined for Windows Vista and later versions of the

Windows operating system.

Remarks

The system passes this structure to the RegistryCallback routine every time a thread attempts to query the metadata for a key—for example, when a user-mode thread calls **RegQueryInfoKey** or when a driver calls ZwQueryKey.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available on Microsoft Windows XP and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

RegistryCallback

ZwQueryKey

REG_QUERY_KEY_NAME structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_QUERY_KEY_NAME** structure describes the full registry key name of an object being queried.

Syntax

```
typedef struct _REG_QUERY_KEY_NAME {
  PVOID                    Object;
  POBJECT_NAME_INFORMATION ObjectNameInfo;
  ULONG                    Length;
  PULONG                   ReturnLength;
  PVOID                    CallContext;
  PVOID                    ObjectContext;
  PVOID                    Reserved;
} REG_QUERY_KEY_NAME, *PREG_QUERY_KEY_NAME;
```

Members

`Object`

A pointer to the registry key object for the key whose metadata is about to be queried.

`ObjectNameInfo`

A pointer to an **OBJECT_NAME_INFORMATION** structure (see wdm.h) that contains the full registry key name to be returned by the system, as a Unicode string.

`Length`

Specifies the size, in bytes, of the **ObjectNameInfo** buffer.

`ReturnLength`

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext. It contains the key context for the key that is being queried.

`Reserved`

This member is reserved for future use.

Remarks

The system passes this structure to the RegistryCallback routine every time a thread attempts to query the full name of the registry key.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available on Microsoft Windows 10 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

RegistryCallback

REG_QUERY_KEY_SECURITY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_QUERY_KEY_SECURITY_INFORMATION** structure receives security information for a registry key object.

Syntax

```
typedef struct _REG_QUERY_KEY_SECURITY_INFORMATION {
  PVOID                 Object;
  PSECURITY_INFORMATION SecurityInformation;
  PSECURITY_DESCRIPTOR  SecurityDescriptor;
  PULONG                Length;
  PVOID                 CallContext;
  PVOID                 ObjectContext;
  PVOID                 Reserved;
} REG_QUERY_KEY_SECURITY_INFORMATION, *PREG_QUERY_KEY_SECURITY_INFORMATION;
```

Members

`Object`

A pointer to the registry key object for the key whose security information is being retrieved.

`SecurityInformation`

A pointer to a SECURITY_INFORMATION-typed value that identifies the type of security information that is being requested.

`SecurityDescriptor`

A pointer to a SECURITY_DESCRIPTOR structure that receives security information for the key object.

`Length`

The length, in bytes of the **SECURITY_DESCRIPTOR** structure that **SecurityDescriptor** points to.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined for Windows Vista and later versions of the Windows operating system.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined for Windows Vista and later versions of the Windows operating system.

`Reserved`

This member is reserved for future use. This member is defined for Windows Vista and later versions of the Windows operating system.

Remarks

The system passes the **REG_QUERY_KEY_SECURITY_INFORMATION** structure to the RegistryCallback routine every time a thread attempts to query a key's security information—for example, when a driver calls ZwQuerySecurityObject.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available on Windows Vista and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

REG_QUERY_MULTIPLE_VALUE_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_QUERY_MULTIPLE_VALUE_KEY_INFORMATION** structure describes the multiple value entries that are being retrieved for a key.

Syntax

```
typedef struct _REG_QUERY_MULTIPLE_VALUE_KEY_INFORMATION {
  PVOID            Object;
  PKEY_VALUE_ENTRY ValueEntries;
  ULONG            EntryCount;
  PVOID            ValueBuffer;
  PULONG           BufferLength;
  PULONG           RequiredBufferLength;
  PVOID            CallContext;
  PVOID            ObjectContext;
  PVOID            Reserved;
} REG_QUERY_MULTIPLE_VALUE_KEY_INFORMATION, *PREG_QUERY_MULTIPLE_VALUE_KEY_INFORMATION;
```

Members

`Object`

A pointer to the registry key object for the key whose value entries are being retrieved.

`ValueEntries`

A pointer to an array of KEY_VALUE_ENTRY structures, one for each value entry that is retrieved.

`EntryCount`

The number of entries in the **ValueEntries** array.

`ValueBuffer`

A pointer to a buffer that receives (from the system) the data for all the value entries specified by the **ValueEntries** array.

`BufferLength`

A pointer to a variable that contains the length, in bytes, of the **ValueBuffer** buffer.

`RequiredBufferLength`

A pointer to a variable that receives (from the system) the number of bytes required to hold the data for all the value entries that the **ValueEntries** array specifies. This member can be **NULL**.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined for Windows Vista and later versions of the Windows operating system.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined for Windows Vista and later versions of the Windows operating system.

`Reserved`

This member is reserved for future use. This member is defined for Windows Vista and later versions of the Windows operating system.

Remarks

The system passes this structure to the RegistryCallback routine every time a thread attempts to retrieve multiple value entries for a key at once—for example, when a user-mode thread calls **RegQueryMultipleValues**.

Each KEY_VALUE_ENTRY structure in the **ValueEntries** array describes one value entry in the **ValueBuffer** buffer. Specifically, the **DataOffset** member of **KEY_VALUE_ENTRY** contains the offset within **ValueBuffer** where the data for that value entry begins, and the **DataLength** member contains the length, in bytes, of the data for that value entry.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available on Microsoft Windows XP and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

RegistryCallback

REG_QUERY_VALUE_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_QUERY_VALUE_KEY_INFORMATION** structure contains information about a registry key's value entry that is being queried.

Syntax

```
typedef struct _REG_QUERY_VALUE_KEY_INFORMATION {
  PVOID                       Object;
  PUNICODE_STRING             ValueName;
  KEY_VALUE_INFORMATION_CLASS KeyValueInformationClass;
  PVOID                       KeyValueInformation;
  ULONG                       Length;
  PULONG                      ResultLength;
  PVOID                       CallContext;
  PVOID                       ObjectContext;
  PVOID                       Reserved;
} REG_QUERY_VALUE_KEY_INFORMATION, *PREG_QUERY_VALUE_KEY_INFORMATION;
```

Members

`Object`

A pointer to the registry key object for the key whose value entry is being queried.

`ValueName`

A pointer to a UNICODE_STRING structure that contains the name of the value entry to retrieve information for.

`KeyValueInformationClass`

The KEY_VALUE_INFORMATION_CLASS value that indicates the type of information to be returned by the system.

`KeyValueInformation`

A pointer to a buffer that contains the information to be returned by the system. The format of the buffer depends on the value of **KeyValueInformationClass**. For more information see KEY_VALUE_INFORMATION_CLASS.

`Length`

The size, in bytes, of the **KeyValueInformation** buffer.

`ResultLength`

A pointer to a variable that receives (from the system) the amount of valid data, in bytes, in the **KeyValueInformation** buffer.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined for Windows Vista and later versions of the Windows operating system.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined for Windows Vista and later versions of the Windows operating system.

`Reserved`

This member is reserved for future use. This member is defined for Windows Vista and later versions of the Windows operating system.

Remarks

The system passes this structure to a RegistryCallback routine every time a thread attempts to query a value entry for a key—for example, when a user-mode thread calls **RegQueryValue** or **RegQueryValueEx** or when a driver calls ZwDeleteKey.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available on Microsoft Windows XP and later versions of the Windows operating system.

REG_RENAME_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_RENAME_KEY_INFORMATION** structure contains the new name for a registry key whose name is about to be changed.

Syntax

```
typedef struct _REG_RENAME_KEY_INFORMATION {
  PVOID           Object;
  PUNICODE_STRING NewName;
  PVOID           CallContext;
  PVOID           ObjectContext;
  PVOID           Reserved;
} REG_RENAME_KEY_INFORMATION, *PREG_RENAME_KEY_INFORMATION;
```

Members

`Object`

A pointer to the registry key object for the key whose name is about to be changed.

`NewName`

A pointer to a UNICODE_STRING structure that contains the new name for the registry key.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined for Windows Vista and later versions of the Windows operating system.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined for Windows Vista and later versions of the Windows operating system.

`Reserved`

This member is reserved for future use. This member is defined for Windows Vista and later versions of the Windows operating system.

Remarks

Note that when a key is renamed, only the last component of the path can be changed.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available on Microsoft Windows XP and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

RegistryCallback

REG_REPLACE_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_REPLACE_KEY_INFORMATION** structure describes the metadata that is about to be replaced for a key.

Syntax

```
typedef struct _REG_REPLACE_KEY_INFORMATION {
  PVOID           Object;
  PUNICODE_STRING OldFileName;
  PUNICODE_STRING NewFileName;
  PVOID           CallContext;
  PVOID           ObjectContext;
  PVOID           Reserved;
} REG_REPLACE_KEY_INFORMATION, *PREG_REPLACE_KEY_INFORMATION;
```

Members

`Object`

A pointer to a registry key object for the key whose metadata is about to be replaced.

`OldFileName`

The name of the file that receives a backup copy of the registry information being replaced.

`NewFileName`

The name of the file with the registry information. This file is typically created by using the **RegSaveKey** function.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined for Windows Vista and later versions of the Windows operating system.

`ObjectContext`

A pointer to driver-defined context information, which the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined for Windows Vista and later versions of the Windows operating system.

`Reserved`

This member is reserved for future use. This member is defined for Windows Vista and later versions of the Windows operating system.

Remarks

The system passes this structure to the RegistryCallback routine every time a thread attempts to replace the metadata for a key.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available on Windows Vista SP2 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

RegistryCallback

REG_RESTORE_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_RESTORE_KEY_INFORMATION** structure contains the information for a registry key that is about to be restored.

Syntax

```
typedef struct _REG_RESTORE_KEY_INFORMATION {
  PVOID  Object;
  HANDLE FileHandle;
  ULONG  Flags;
  PVOID  CallContext;
  PVOID  ObjectContext;
  PVOID  Reserved;
} REG_RESTORE_KEY_INFORMATION, *PREG_RESTORE_KEY_INFORMATION;
```

Members

`Object`

A pointer to a registry key object for the key whose name is about to be changed.

`FileHandle`

A handle to the file from which the hive will be restored.

`Flags`

REG_FORCE_RESTORE

0x00000008L

If specified, the restore operation is executed even if open handles exist at or beneath the location in the registry hierarchy to which the *hKey* parameter points.

REG_WHOLE_HIVE_VOLATILE

0x00000001L

If specified, a new, volatile (memory-only) set of registry information, or *hive*, is created. If REG_WHOLE_HIVE_VOLATILE is specified, the key identified by the *hKey* parameter must be either the HKEY_USERS or HKEY_LOCAL_MACHINE value.

REG_REFRESH_HIVE

0x00000002

If set, the location of the subtree that the *hKey* parameter points to is restored to its state immediately following the last flush. The subtree must not be lazy flushed (by calling **RegRestoreKey** with REG_NO_LAZY_FLUSH specified as the value of this parameter); the caller must have the trusted computing base (TCB) privilege; and the handle to which the *hKey* parameter refers must point to the root of the subtree.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is

defined for Windows Vista and later versions of the Windows operating system.

`ObjectContext`

A pointer to driver-defined context information, which the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined for Windows Vista and later versions of the Windows operating system.

`Reserved`

This member is reserved for future use. This member is defined for Windows Vista and later versions of the Windows operating system.

Remarks

Note that when a key is restored, only the last component of the path can be changed.

The REG_REFRESH_HIVE flag is opaque and a filter should not attempt to change it.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available on Windows Vista SP2 and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

RegistryCallback

REG_SAVE_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_SAVE_KEY_INFORMATION** structure contains the information for a registry key that is about to be saved.

Syntax

```
typedef struct _REG_SAVE_KEY_INFORMATION {
  PVOID  Object;
  HANDLE FileHandle;
  ULONG  Format;
  PVOID  CallContext;
  PVOID  ObjectContext;
  PVOID  Reserved;
} REG_SAVE_KEY_INFORMATION, *PREG_SAVE_KEY_INFORMATION;
```

Members

`Object`

A pointer to a registry key object for the key whose information is about to be saved.

`FileHandle`

A handle to the file to which the hive information will be saved.

`Format`

The format in which the key or hive is saved. This member can have one of the following values.

VALUE	MEANING
REG_STANDARD_FORMAT	Save in standard format. The standard format is the only format supported by Windows 2000.
REG_LATEST_FORMAT	Save in the latest format. The latest format is supported starting with Windows XP. After the key is saved in this format, it cannot be loaded on an earlier version of Windows.
REG_NO_COMPRESSION	Save with no compression, for faster save operations. The registry key object must represent the root of a hive.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined starting with Windows Vista.

`ObjectContext`

A pointer to driver-defined context information, which the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined starting with Windows Vista.

`Reserved`

This member is reserved for future use. This member is defined starting with Windows Vista.

Remarks

Note that when a key is saved, only the last component of the path can be changed.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available starting with Windows Vista SP2.

RegistryCallback

REG_SET_INFORMATION_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_SET_INFORMATION_KEY_INFORMATION** structure describes a new setting for a key's metadata.

Syntax

```
typedef struct _REG_SET_INFORMATION_KEY_INFORMATION {
  PVOID                     Object;
  KEY_SET_INFORMATION_CLASS KeySetInformationClass;
  PVOID                     KeySetInformation;
  ULONG                     KeySetInformationLength;
  PVOID                     CallContext;
  PVOID                     ObjectContext;
  PVOID                     Reserved;
} REG_SET_INFORMATION_KEY_INFORMATION, *PREG_SET_INFORMATION_KEY_INFORMATION;
```

Members

`Object`

A pointer to the registry key object for the key whose metadata is about to be changed.

`KeySetInformationClass`

The KEY_SET_INFORMATION_CLASS value that indicates the type of information about to be changed.

`KeySetInformation`

A pointer to a buffer that contains the information about to be written. The format of the buffer depends on the value of **KeySetInformationClass**. For more information, see KEY_SET_INFORMATION_CLASS.

`KeySetInformationLength`

The size, in bytes, of the **KeySetInformation** buffer.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined for Windows Vista and later versions of the Windows operating system.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined for Windows Vista and later versions of the Windows operating system.

`Reserved`

This member is reserved for future use. This member is defined for Windows Vista and later versions of the Windows operating system.

Remarks

For more information about registry filtering operations, see Filtering Registry Calls.

RegistryCallback

REG_SET_KEY_SECURITY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_SET_KEY_SECURITY_INFORMATION** structure specifies security information for a registry key object.

Syntax

```
typedef struct _REG_SET_KEY_SECURITY_INFORMATION {
  PVOID                 Object;
  PSECURITY_INFORMATION SecurityInformation;
  PSECURITY_DESCRIPTOR  SecurityDescriptor;
  PVOID                 CallContext;
  PVOID                 ObjectContext;
  PVOID                 Reserved;
} REG_SET_KEY_SECURITY_INFORMATION, *PREG_SET_KEY_SECURITY_INFORMATION;
```

Members

`Object`

A pointer to the registry key object for the key whose security information is being set.

`SecurityInformation`

A pointer to a SECURITY_INFORMATION-typed variable that identifies the type of security information that is being set.

`SecurityDescriptor`

A pointer to a SECURITY_DESCRIPTOR structure that contains security information for the key object.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined for Windows Vista and later versions of the Windows operating system.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined for Windows Vista and later versions of the Windows operating system.

`Reserved`

This member is reserved for future use. This member is defined for Windows Vista and later versions of the Windows operating system.

Remarks

The system passes the **REG_SET_KEY_SECURITY_INFORMATION** structure to the RegistryCallback routine every time a thread attempts to set a key's security information—for example, when a driver calls ZwSetSecurityObject.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available on Windows Vista and later versions of the Windows operating system.

REG_SET_VALUE_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_SET_VALUE_INFORMATION** structure describes a new setting for a registry key's value entry.

Syntax

```
typedef struct _REG_SET_VALUE_KEY_INFORMATION {
  PVOID           Object;
  PUNICODE_STRING ValueName;
  ULONG           TitleIndex;
  ULONG           Type;
  PVOID           Data;
  ULONG           DataSize;
  PVOID           CallContext;
  PVOID           ObjectContext;
  PVOID           Reserved;
} REG_SET_VALUE_KEY_INFORMATION, *PREG_SET_VALUE_KEY_INFORMATION;
```

Members

`Object`

A pointer to the registry key object for the key whose value entry is about to be changed.

`ValueName`

A pointer to a UNICODE_STRING structure that contains the name of the value entry about to be changed.

`TitleIndex`

Reserved for system use. Drivers should ignore this member.

`Type`

The type of data that is about to be written. For more information about the possible values for this member, see the *Type* parameter of ZwSetValueKey.

`Data`

A pointer to a buffer that contains the data about to be written. The format of the buffer depends on the value of **Type**. For more information, see ZwSetValueKey.

`DataSize`

The size, in bytes, of the **Data** buffer.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined for Windows Vista and later versions of the Windows operating system.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined for Windows Vista and later versions of the Windows

operating system.

`Reserved`

This member is reserved for future use. This member is defined for Windows Vista and later versions of the Windows operating system.

Remarks

The system passes this structure to a RegistryCallback routine every time a thread attempts to set a value entry for a key—for example, when a user-mode thread calls **RegSetValue** or **RegSetValueEx** or when a driver calls ZwSetValueKey.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available on Microsoft Windows XP and later versions of the Windows operating system.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

RegistryCallback

ZwSetValueKey

REG_UNLOAD_KEY_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **REG_UNLOAD_KEY_INFORMATION** structure contains information that a driver's RegistryCallback routine can use when a registry hive is unloaded.

Syntax

```
typedef struct _REG_UNLOAD_KEY_INFORMATION {
  PVOID Object;
  PVOID UserEvent;
  PVOID CallContext;
  PVOID ObjectContext;
  PVOID Reserved;
} REG_UNLOAD_KEY_INFORMATION, *PREG_UNLOAD_KEY_INFORMATION;
```

Members

`Object`

A pointer to a registry key object. This object represents the root key of the hive that is being unloaded.

`UserEvent`

A pointer to an event object.

`CallContext`

Optional driver-defined context information that the driver's RegistryCallback routine can supply. This member is defined starting with Windows Vista.

`ObjectContext`

A pointer to driver-defined context information that the driver has associated with a registry object by calling CmSetCallbackObjectContext. This member is defined starting with Windows Vista.

`Reserved`

This member is reserved for future use. This member is defined starting with Windows Vista.

Remarks

This structure is used by the RegistryCallback routine. When the *Argument1* parameter to the *RegistryCallback* routine is **RegNtPreUnloadKey**, the *Argument2* parameter is a pointer to a **REG_UNLOAD_KEY_INFORMATION** structure.

The operating system passes the **REG_UNLOAD_KEY_INFORMATION** structure to the *RegistryCallback* routine every time a thread attempts to unload a key—for example, when a user-mode thread calls the RegUnloadKey function. In response to a **RegNtPreUnloadKey** notification, the *RegistryCallback* routine should free any resources the driver previously allocated for use with the hive before the hive is unloaded.

For more information about registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available starting with Windows Vista.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

RegistryCallback

RESOURCEMANAGER_BASIC_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **RESOURCEMANAGER_BASIC INFORMATION** structure contains information about a resource manager object.

Syntax

```
typedef struct _RESOURCEMANAGER_BASIC_INFORMATION {
  GUID  ResourceManagerId;
  ULONG DescriptionLength;
  WCHAR Description[1];
} RESOURCEMANAGER_BASIC_INFORMATION, *PRESOURCEMANAGER_BASIC_INFORMATION;
```

Members

`ResourceManagerId`

A GUID that KTM assigned to the resource manager.

`DescriptionLength`

The length, in bytes, of the character array that the **Description** member provides.

`Description`

A caller-allocated array of characters that receives a resource manager's description string.

Remarks

The **RESOURCEMANAGER_BASIC INFORMATION** structure is used with the ZwQueryInformationResourceManager routine.

The resource manager's description string, which the **Description** member receives, is the description that the resource manager previously specified when it called ZwCreateResourceManager.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ZwQueryInformationResourceManager

RESOURCEMANAGER_COMPLETION_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **RESOURCEMANAGER_COMPLETION_INFORMATION** structure is not used.

Syntax

```
typedef struct _RESOURCEMANAGER_COMPLETION_INFORMATION {
  HANDLE    IoCompletionPortHandle;
  ULONG_PTR CompletionKey;
} RESOURCEMANAGER_COMPLETION_INFORMATION, *PRESOURCEMANAGER_COMPLETION_INFORMATION;
```

Members

`IoCompletionPortHandle`

`CompletionKey`

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Header	wdm.h (include Wdm.h, Ntifs.h)

RESOURCEMANAGER_INFORMATION_CLASS Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **RESOURCEMANAGER_INFORMATION_CLASS** enumeration identifies the type of information that the ZwQueryInformationResourceManager routine can retrieve for a resource manager object.

Syntax

```
typedef enum _RESOURCEMANAGER_INFORMATION_CLASS {
  ResourceManagerBasicInformation,
  ResourceManagerCompletionInformation
} RESOURCEMANAGER_INFORMATION_CLASS;
```

Constants

ResourceManagerBasicInformation	Information about a resource manager object is stored in a RESOURCEMANAGER_BASIC_INFORMATION structure.
ResourceManagerCompletionInformation	Information about a resource manager object is stored in a RESOURCEMANAGER_COMPLETION_INFORMATION structure.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

RESOURCEMANAGER_BASIC_INFORMATION

RESOURCEMANAGER_COMPLETION_INFORMATION

ZwQueryInformationResourceManager

SCATTER_GATHER_LIST structure

1/30/2019 • 2 minutes to read • Edit Online

The **SCATTER_GATHER_LIST** structure describes the scatter/gather list for a DMA operation.

Syntax

```
typedef struct _SCATTER_GATHER_LIST {
  ULONG                  NumberOfElements;
  ULONG_PTR              Reserved;
  SCATTER_GATHER_ELEMENT Elements[];
} SCATTER_GATHER_LIST, *PSCATTER_GATHER_LIST;
```

Members

`NumberOfElements`

Specifies the number of elements in the **Elements** array.

`Reserved`

Reserved for future use.

`Elements`

Specifies an array of scatter/gather elements that comprise a scatter/gather list. Each array element is a structure of type **SCATTER_GATHER_ELEMENT**, which is defined as follows:

```
typedef struct _SCATTER_GATHER_ELEMENT {
  PHYSICAL_ADDRESS  Address;
  ULONG  Length;
  ULONG_PTR  Reserved;
} SCATTER_GATHER_ELEMENT, *PSCATTER_GATHER_ELEMENT;
```

The **SCATTER_GATHER_ELEMENT** structure specifies the length, in bytes, of a physically contiguous scatter/gather region and the starting physical address of this region.

Remarks

For a driver that performs scatter/gather DMA, the GetScatterGatherList or BuildScatterGatherList routine creates a scatter/gather list and passes this list to the driver's AdapterListControl routine. This scatter/gather list consists of a **SCATTER_GATHER_LIST** structure that is immediately followed in memory by a **SCATTER_GATHER_ELEMENT** array. The number of elements in this array is specified by the **NumberOfElements** member of the **SCATTER_GATHER_LIST** structure.

For more information about scatter/gather lists, see Using Scatter/Gather DMA.

SECTION_OBJECT_POINTERS structure

1/30/2019 • 2 minutes to read • Edit Online

The **SECTION_OBJECT_POINTERS** structure, allocated by a file system or a redirector driver, is used by the memory manager and cache manager to store file-mapping and cache-related information for a file stream.

Syntax

```
typedef struct _SECTION_OBJECT_POINTERS {
  PVOID DataSectionObject;
  PVOID SharedCacheMap;
  PVOID ImageSectionObject;
} SECTION_OBJECT_POINTERS;
```

Members

`DataSectionObject`

Opaque pointer to a data section object (that is, a **CONTROL_AREA** structure) that is used to track state information for a data file stream. Memory manager sets this member when the operating system first caches the data stream. A **NULL** value indicates that the data stream is currently not in memory; this value, however, can change at any time.

`SharedCacheMap`

Opaque pointer to a cache map object (that is, a **SHARED_CACHE_MAP** structure) that is used to track views that are mapped to the data file stream. Cache manager sets this member when the operating system first caches the stream. A **NULL** value indicates that the data stream is

```
currently
```

not cached; this value, however, can change at any time.

`ImageSectionObject`

Opaque pointer to an image section object (that is, a **CONTROL_AREA** structure) that is used to track state information for an executable file stream. Memory manager sets this member whenever an executable image section is created for the stream. A **NULL** value indicates that the executable image is currently not in memory; this value, however, can change at any time.

Remarks

The **SECTION_OBJECT_POINTERS** structure links a file object to a file stream's section object. That is, through its members, the **SECTION_OBJECT_POINTERS** structure connects a particular file object to virtual memory control structures that keep track of the stream's contents when they are in memory, and allow the operating system to fetch those contents when they are not.

There is a one-to-one relationship between a **SECTION_OBJECT_POINTERS** structure and a file stream. Multiple file objects can be associated with a particular file stream, each representing an open instance of the stream. However, only one **SECTION_OBJECT_POINTERS** structure can be associated with a given stream. If there are multiple file objects for a stream, the **SectionObjectPointer** member for all file objects must point to the

same **SECTION_OBJECT_POINTERS** structure (that is associated with the stream).

For the first file stream open request, the file system or the redirector driver must:

1. Allocate a **SECTION_OBJECT_POINTERS** structure from a nonpaged pool.
2. Initialize all members of the allocated **SECTION_OBJECT_POINTERS** structure to **NULL**.
3. Set the **SectionObjectPointer** member of the associate file object to point to the initialized **SECTION_OBJECT_POINTERS** structure.

For subsequent open requests to the same file stream, the file system or the redirector driver must set the **SectionObjectPointer** member of the associated file object to point to the previously allocated **SECTION_OBJECT_POINTERS** structure for the file stream.

> **Warning** File system filter drivers must treat the members of the **SECTION_OBJECT_POINTERS** structure as opaque because the underlying file system is responsible for the synchronization of the members and, therefore, could change their values at any time.

> **Note** A file is composed of one or more streams, depending on the file system. For more information, see File Streams, Stream Contexts, and Per-Stream Contexts.

Requirements

Minimum supported client	Available in all versions of Windows that Microsoft supports.

SLIST_ENTRY structure

1/30/2019 • 2 minutes to read • Edit Online

An **SLIST_ENTRY** structure describes an entry in a sequenced singly linked list.

Syntax

```
typedef struct _SLIST_ENTRY {
  struct _SLIST_ENTRY *Next;
} SLIST_ENTRY, *PSLIST_ENTRY;
```

Members

`Next`

Pointer to the next entry in the list, or **NULL** if there is no next entry in the list.

Remarks

A driver can access the **Next** member of a **SLIST_ENTRY**, but must only be updated by the system routines supplied for this purpose.

On 64-bit platforms, **SLIST_ENTRY** structures must be 16-byte aligned. Drivers can use DECLSPEC_ALIGN(MEMORY_ALLOCATION_ALIGNMENT) to ensure the proper alignment of **SLIST_ENTRY**.

For more information about how to use **SLIST_ENTRY** structures to implement a sequenced singly linked list, see Singly and Doubly Linked Lists.

SYSTEM_POWER_STATE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **SYSTEM_POWER_STATE** enumeration type is used to indicate a system power state.

Syntax

```
typedef enum _SYSTEM_POWER_STATE {
  PowerSystemUnspecified,
  PowerSystemWorking,
  PowerSystemSleeping1,
  PowerSystemSleeping2,
  PowerSystemSleeping3,
  PowerSystemHibernate,
  PowerSystemShutdown,
  PowerSystemMaximum
} SYSTEM_POWER_STATE, *PSYSTEM_POWER_STATE;
```

Constants

PowerSystemUnspecified	Indicates an unspecified system power state.
PowerSystemWorking	Indicates maximum system power, which corresponds to system working state S0.
PowerSystemSleeping1	Indicates a system sleeping state less than **PowerSystemWorking** and greater than **PowerSystemSleeping2**, which corresponds to system power state S1.
PowerSystemSleeping2	Indicates a system sleeping state less than **PowerSystemSleeping1** and greater than **PowerSystemSleeping3**, which corresponds to system power state S2.
PowerSystemSleeping3	Indicates a system sleeping state less than **PowerSystemSleeping2** and greater than **PowerSystemHibernate**, which corresponds to system power state S3.
PowerSystemHibernate	Indicates the lowest-powered sleeping state, which corresponds to system power state S4.
PowerSystemShutdown	Indicates the system is turned off, which corresponds to system shutdown state S5.
PowerSystemMaximum	The number of system power state values for this enumeration type that represents actual power states. This value is the number of elements in the **DeviceState** member of the DEVICE_CAPABILITIES structure for a device. The other system power state values are less than this value.

Remarks

A power state indicates the level of power consumption—and thus the extent of computing activity—by the system or by a single device. The power manager sets the power state of the system as a whole, where the system power state is indicated by one of the values of the **SYSTEM_POWER_STATE** enumeration type. Device drivers set the power state of their individual devices, where the device power state is indicated by one of the values of the DEVICE_POWER_STATE enumeration type.

For more information about system power states, see Handling System Power State Requests and for more information about device power states, see Managing Power for Individual Devices.

For more information about power management in general, see Introduction to Power Management.

SYSTEM_POWER_STATE_CONTEXT structure

1/30/2019 • 2 minutes to read • Edit Online

The **SYSTEM_POWER_STATE_CONTEXT** structure is a partially opaque system structure that contains information about the previous system power states of a computer.

Syntax

```
typedef struct _SYSTEM_POWER_STATE_CONTEXT {
  union {
    struct {
      ULONG Reserved1 : 8;
      ULONG TargetSystemState : 4;
      ULONG EffectiveSystemState : 4;
      ULONG CurrentSystemState : 4;
      ULONG IgnoreHibernationPath : 1;
      ULONG PseudoTransition : 1;
      ULONG KernelSoftReboot : 1;
      ULONG DirectedDripsTransition : 1;
      ULONG Reserved2 : 8;
    } DUMMYSTRUCTNAME;
    ULONG ContextAsUlong;
  } DUMMYUNIONNAME;
} SYSTEM_POWER_STATE_CONTEXT, *PSYSTEM_POWER_STATE_CONTEXT;
```

Members

`DUMMYUNIONNAME`

Unnamed union.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME`

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.Reserved1`

Opaque member. Reserved for system use.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.TargetSystemState`

The target system power state of the previous system power IRP that the driver received. This member is set to a SYSTEM_POWER_STATE enumeration value. Drivers should treat this member as read-only.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.EffectiveSystemState`

The effective previous system power state, as perceived by the user. This member is set to a **SYSTEM_POWER_STATE** enumeration value. Drivers should treat this member as read-only. This member value might not match the **TargetSystemState** member if, for example, the previous system power IRP indicated that the computer was about to enter hibernation, but a hybrid shutdown instead occurred to prepare the computer for a fast startup. For more information, see Remarks.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.CurrentSystemState`

Opaque member. Reserved for system use.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.IgnoreHibernationPath`

Opaque member. Reserved for system use.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.PseudoTransition`

Opaque member. Reserved for system use.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.KernelSoftReboot`

Opaque member. Reserved for system use.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.DirectedDripsTransition`

Opaque member. Reserved for system use.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.Reserved2`

Opaque member. Reserved for system use.

`DUMMYUNIONNAME.ContextAsUlong`

Opaque member. Reserved for system use.

Remarks

Starting with Windows Vista, the I/O stack location in a system power IRP contains a **SYSTEM_POWER_STATE_CONTEXT** structure. The **Power** member of the **IO_STACK_LOCATION** structure contains a **SystemPowerStateContext** member, which is a **SYSTEM_POWER_STATE_CONTEXT** structure. For more information, see IO_STACK_LOCATION.

The size of the **SYSTEM_POWER_STATE_CONTEXT** structure is four bytes. This structure is divided into bit fields, most of which are opaque to drivers and reserved exclusively for use by the operating system. However, two of these bit fields, **TargetSystemState** and **EffectiveSystemState**, can be read by kernel-mode drivers to distinguish a fast startup from a wake-from-hibernation startup. For more information, see Distinguishing Fast Startup from Wake-from-Hibernation.

Requirements

Minimum supported client	Available starting with Windows Vista.
Header	wdm.h (include Ntpoapi.h)

See Also

IO_STACK_LOCATION

SYSTEM_POWER_STATE

TARGET_DEVICE_CUSTOM_NOTIFICATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **TARGET_DEVICE_CUSTOM_NOTIFICATION** structure describes a custom device event.

Syntax

```
typedef struct _TARGET_DEVICE_CUSTOM_NOTIFICATION {
  USHORT       Version;
  USHORT       Size;
  GUID         Event;
  PFILE_OBJECT FileObject;
  LONG         NameBufferOffset;
  UCHAR        CustomDataBuffer[1];
} TARGET_DEVICE_CUSTOM_NOTIFICATION, *PTARGET_DEVICE_CUSTOM_NOTIFICATION;
```

Members

`Version`

Specifies the version of the data structure, currently 1.

`Size`

Specifies the size of the structure, in bytes, including the first three standard members plus the event-specific data.

`Event`

Specifies a GUID identifying the event. GUIDs for custom event notification are defined by the components that use this mechanism.

`FileObject`

Pointer to a file object for the device.

`NameBufferOffset`

Specifies the offset, in bytes, from beginning of **CustomDataBuffer** where text begins. A value of -1 indicates that there is no text.

`CustomDataBuffer`

A variable-length buffer, optionally containing binary data at the start of the buffer, followed by an optional text buffer (word-aligned).

Remarks

Kernel-mode components use this structure for custom event notification: to signal a custom event (**IoReportTargetDeviceChange**[**Asynchronous**]) and when handling a custom event (in a notification callback routine).

This structure accommodates both a variable-length binary data buffer and a variable-length Unicode text buffer. The *NameBufferOffset* must indicate where the text buffer begins, so the data can be delivered in the appropriate format (ANSI or Unicode) to user-mode applications that registered for handle-based notification with

RegisterDeviceNotification. See the Microsoft Windows SDK documentation for information about **RegisterDeviceNotification**.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

TARGET_DEVICE_REMOVAL_NOTIFICATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **TARGET_DEVICE_REMOVAL_NOTIFICATION** structure describes a device-removal event. The PnP manager sends this structure to a driver that registered a callback routine for notification of **EventCategoryTargetDeviceChange** events.

Syntax

```
typedef struct _TARGET_DEVICE_REMOVAL_NOTIFICATION {
  USHORT       Version;
  USHORT       Size;
  GUID         Event;
  PFILE_OBJECT FileObject;
} TARGET_DEVICE_REMOVAL_NOTIFICATION, *PTARGET_DEVICE_REMOVAL_NOTIFICATION;
```

Members

`Version`

Specifies the version of the data structure, currently set to 1.

`Size`

Specifies the size of the structure, in bytes, including the size of the standard first three members plus the event-specific data.

`Event`

Specifies a GUID identifying the event: GUID_TARGET_DEVICE_QUERY_REMOVE, GUID_TARGET_DEVICE_REMOVE_COMPLETE, or GUID_TARGET_DEVICE_REMOVE_CANCELLED. These GUIDs are defined in Wdmguid.h.

`FileObject`

Pointer to a file object for the device.

Requirements

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

See Also

TRACE_INFORMATION_CLASS Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **TRACE_INFORMATION_CLASS** enumeration type is used to indicate types of information associated with a WMI event tracing session.

Syntax

```
typedef enum _TRACE_INFORMATION_CLASS {
  TraceIdClass,
  TraceHandleClass,
  TraceEnableFlagsClass,
  TraceEnableLevelClass,
  GlobalLoggerHandleClass,
  EventLoggerHandleClass,
  AllLoggerHandlesClass,
  TraceHandleByNameClass,
  LoggerEventsLostClass,
  TraceSessionSettingsClass,
  LoggerEventsLoggedClass,
  DiskIoNotifyRoutinesClass,
  TraceInformationClassReserved1,
  FltIoNotifyRoutinesClass,
  TraceInformationClassReserved2,
  WdfNotifyRoutinesClass,
  MaxTraceInformationClass
} TRACE_INFORMATION_CLASS;
```

Constants

TraceIdClass	Retrieves the logger ID (ULONG) of an event tracing session given a caller-supplied Wnode.
TraceHandleClass	Retrieves a trace handle (TRACEHANDLE) for an event tracing session given a caller-supplied logger ID (ULONG).
TraceEnableFlagsClass	Retrieves the enable flags (ULONG) set on a caller-supplied event trace handle (TRACEHANDLE).
TraceEnableLevelClass	Retrieves the enable level (ULONG) set on a caller-supplied event trace handle (TRACEHANDLE).
GlobalLoggerHandleClass	Retrieves an event trace handle (TRACEHANDLE) for the global logger.
EventLoggerHandleClass	Reserved for use by the operating system.
AllLoggerHandlesClass	Retrieves an array of event trace handles (TRACEHANDLE array) for all valid loggers.
TraceHandleByNameClass	Retrieves an event trace handle (TRACEHANDLE) identified by a caller-supplied friendly name (UNICODE_STRING structure in buffer).

LoggerEventsLostClass	Retrieves the number (ULONG) of events lost for a logger session given a caller-supplied logger ID (ULONG).
TraceSessionSettingsClass	Retrieves the settings (**ETW_TRACE_SESSION_SETTINGS** structure) for a logger session given a caller-supplied trace handle (TRACEHANDLE).
LoggerEventsLoggedClass	Retrieves the number (ULONG) of events logged in a logger session given a caller-supplied logger ID (ULONG).
DiskIoNotifyRoutinesClass	Reserved for use by the operating system.
TraceInformationClassReserved1	Reserved for use by the operating system.
FltIoNotifyRoutinesClass	Reserved for use by the operating system.
TraceInformationClassReserved2	Reserved for use by the operating system.
WdfNotifyRoutinesClass	Reserved for use by the operating system.
MaxTraceInformationClass	The maximum value in this enumeration type.

Remarks

TRACE_INFORMATION_CLASS is provided primarily for use with the WmiQueryTraceInformation routine, which returns information about a WMI event tracing session.

Requirements

TRANSACTION_BASIC_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **TRANSACTION_BASIC_INFORMATION** structure contains information about a transaction object.

Syntax

```
typedef struct _TRANSACTION_BASIC_INFORMATION {
  GUID  TransactionId;
  ULONG State;
  ULONG Outcome;
} TRANSACTION_BASIC_INFORMATION, *PTRANSACTION_BASIC_INFORMATION;
```

Members

`TransactionId`

A GUID that KTM has assigned to the transaction object. This value is also known as the transaction's unit of work (UOW) identifier.

`State`

A TRANSACTION_STATE-typed value that specifies the transaction's current state.

`Outcome`

A TRANSACTION_OUTCOME-typed value that specifies the transaction's outcome (result).

Remarks

The **TRANSACTION_BASIC_INFORMATION** structure is used with the ZwQueryInformationTransaction routine. This routine fills in the structure's members.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

TRANSACTION_ENLISTMENT_PAIR structure

1/30/2019 • 2 minutes to read • Edit Online

The **TRANSACTION_ENLISTMENT_PAIR** structure contains information about an enlistment that is associated with a transaction object.

Syntax

```
typedef struct _TRANSACTION_ENLISTMENT_PAIR {
  GUID EnlistmentId;
  GUID ResourceManagerId;
} TRANSACTION_ENLISTMENT_PAIR, *PTRANSACTION_ENLISTMENT_PAIR;
```

Members

`EnlistmentId`

A GUID that KTM has assigned to the enlistment.

`ResourceManagerId`

A GUID that KTM has assigned to the resource manager that created the enlistment.

Remarks

The **TRANSACTION_ENLISTMENT_PAIR** structure is used as a member of the TRANSACTION_ENLISTMENTS_INFORMATION structure.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ZwQueryInformationTransaction

TRANSACTION_ENLISTMENTS_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **TRANSACTION_ENLISTMENTS_INFORMATION** structure contains information about the enlistments that are associated with a transaction object.

Syntax

```
typedef struct _TRANSACTION_ENLISTMENTS_INFORMATION {
  ULONG                      NumberOfEnlistments;
  TRANSACTION_ENLISTMENT_PAIR EnlistmentPair[1];
} TRANSACTION_ENLISTMENTS_INFORMATION, *PTRANSACTION_ENLISTMENTS_INFORMATION;
```

Members

`NumberOfEnlistments`

The number of enlistments that are associated with a transaction object. This is also the number of elements in the array that the **EnlistmentPair** member specifies.

`EnlistmentPair`

A caller-allocated array of TRANSACTION_ENLISTMENT_PAIR structures.

Remarks

The **TRANSACTION_ENLISTMENTS_INFORMATION** structure is used with the ZwQueryInformationTransaction routine. This routine fills in the structure's members.

Requirements

TRANSACTION_INFORMATION_CLASS

ZwQueryInformationTransaction

TRANSACTION_INFORMATION_CLASS Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **TRANSACTION_INFORMATION_CLASS** enumeration specifies the type of information that ZwSetInformationTransaction can set and ZwQueryInformationTransaction can retrieve for a transaction manager object.

Syntax

```
typedef enum _TRANSACTION_INFORMATION_CLASS {
  TransactionBasicInformation,
  TransactionPropertiesInformation,
  TransactionEnlistmentInformation,
  TransactionSuperiorEnlistmentInformation
} TRANSACTION_INFORMATION_CLASS;
```

Constants

TransactionBasicInformation	Information about a transaction manager object is stored in a TRANSACTION_BASIC_INFORMATION structure.
TransactionPropertiesInformation	Information about a transaction manager object is stored in a TRANSACTION_PROPERTIES_INFORMATION structure.
TransactionEnlistmentInformation	Information about a transaction manager object is stored in a TRANSACTION_ENLISTMENTS_INFORMATION structure.
TransactionSuperiorEnlistmentInformation	Information about a transaction manager object is stored in a **TRANSACTION_SUPERIOR_ENLISTMENT_INFORMATION** structure.

Requirements

Minimum supported client	Available starting with Windows Vista.

ZwSetInformationTransaction

TRANSACTION_OUTCOME Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **TRANSACTION_OUTCOME** enumeration defines the outcomes (results) that KTM can assign to a transaction.

Syntax

```
typedef enum _TRANSACTION_OUTCOME {
  TransactionOutcomeUndetermined,
  TransactionOutcomeCommitted,
  TransactionOutcomeAborted
} TRANSACTION_OUTCOME;
```

Constants

TransactionOutcomeUndetermined	The transaction has not yet been committed or rolled back.
TransactionOutcomeCommitted	The transaction has been committed.
TransactionOutcomeAborted	The transaction has been rolled back.

Remarks

The **TRANSACTION_OUTCOME** enumeration is used in the TRANSACTION_BASIC_INFORMATION structure.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

TRANSACTION_BASIC_INFORMATION

TRANSACTION_PROPERTIES_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **TRANSACTION_PROPERTIES_INFORMATION** structure contains a transaction object's properties.

Syntax

```
typedef struct _TRANSACTION_PROPERTIES_INFORMATION {
  ULONG         IsolationLevel;
  ULONG         IsolationFlags;
  LARGE_INTEGER Timeout;
  ULONG         Outcome;
  ULONG         DescriptionLength;
  WCHAR         Description[1];
} TRANSACTION_PROPERTIES_INFORMATION, *PTRANSACTION_PROPERTIES_INFORMATION;
```

Members

`IsolationLevel`

Reserved for future use.

`IsolationFlags`

Reserved for future use.

`Timeout`

A time-out value. If the transaction has not been committed by the time specified by this parameter, KTM rolls back the transaction. The time-out value is expressed in system time units (100-nanosecond intervals), and can specify either an absolute time or a relative time. If the value of the **Timeout** member is negative, the expiration time is relative to the current system time. Otherwise, the expiration time is absolute. Set this member to zero if no time-out is required. If **Timeout** is zero, the transaction never times out.

`Outcome`

A TRANSACTION_OUTCOME-typed value that identifies the transaction's outcome (result). You can obtain this value by calling ZwQueryInformationTransaction, but you cannot set the value with ZwSetInformationTransaction.

`DescriptionLength`

The size, in bytes, of the buffer that contains the **Description** member's array.

`Description`

A caller-allocated array of characters that contains or receives the transaction's description string. The TPS client can specify this string when it calls ZwCreateTransaction. The client can retrieve the string by calling by calling **ZwQueryInformationTransaction**, and it can modify the string by calling **ZwSetInformationTransaction**.

Remarks

The **TRANSACTION_PROPERTIES_INFORMATION** structure is used with the

ZwQueryInformationTransaction and ZwSetInformationTransaction routines.

Requirements

Minimum supported client	Available starting with Windows Vista.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

TRANSACTION_STATE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **TRANSACTION_STATE** enumeration defines the states that KTM can assign to a transaction.

Syntax

```
typedef enum _TRANSACTION_STATE {
  TransactionStateNormal,
  TransactionStateIndoubt,
  TransactionStateCommittedNotify
} TRANSACTION_STATE;
```

Constants

TransactionStateNormal	The transaction's state is neither in doubt nor committed.
TransactionStateIndoubt	The transaction's state is in doubt (that is, KTM cannot determine whether the transaction should be committed or rolled back). A transaction that has been prepared enters the "in doubt" state if its superior transaction manager becomes unavailable.
TransactionStateCommittedNotify	The transaction has been committed. Commit notifications might (or might not) have been delivered to all enlistments.

Remarks

The **TRANSACTION_STATE** enumeration is used in the TRANSACTION_BASIC_INFORMATION structure.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

TRANSACTION_BASIC_INFORMATION

TRANSACTIONMANAGER_BASIC_INFORMATION structure

1/30/2019 • 2 minutes to read • Edit Online

The **TRANSACTIONMANAGER_BASIC_INFORMATION** structure contains information about a transaction manager object.

Syntax

```
typedef struct _TRANSACTIONMANAGER_BASIC_INFORMATION {
  GUID          TmIdentity;
  LARGE_INTEGER VirtualClock;
} TRANSACTIONMANAGER_BASIC_INFORMATION, *PTRANSACTIONMANAGER_BASIC_INFORMATION;
```

Members

`TmIdentity`

A GUID that KTM has assigned to a transaction manager object.

`VirtualClock`

The virtual clock value that is currently associated with a transaction manager object.

Remarks

The **TRANSACTIONMANAGER_BASIC_INFORMATION** structure is used with the ZwQueryInformationTransactionManager routine.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.

TRANSACTIONMANAGER_INFORMATION_CLASS

ZwQueryInformationTransactionManager

WORK_QUEUE_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **WORK_QUEUE_TYPE** enumeration type indicates the type of system worker thread that handles a work item.

Syntax

```
typedef enum _WORK_QUEUE_TYPE {
  CriticalWorkQueue,
  DelayedWorkQueue,
  HyperCriticalWorkQueue,
  NormalWorkQueue,
  BackgroundWorkQueue,
  RealTimeWorkQueue,
  SuperCriticalWorkQueue,
  MaximumWorkQueue,
  CustomPriorityWorkQueue
} WORK_QUEUE_TYPE;
```

Constants

CriticalWorkQueue	Indicates a real-time system worker thread. The assigned priority level is 13.
DelayedWorkQueue	Indicates an ordinary worker thread. The assigned priority level is 12.
HyperCriticalWorkQueue	System priority level. The assigned priority level is 15.
NormalWorkQueue	System priority level. The assigned priority level is 8
BackgroundWorkQueue	System priority level. The assigned priority level is 7.
RealTimeWorkQueue	System priority level. The assigned priority level is18.
SuperCriticalWorkQueue	System priority level. The assigned priority level is 14.
MaximumWorkQueue	System priority maximum. No priority level assigned.
CustomPriorityWorkQueue	The queue has a custom priority level assigned by the caller. The **CustomPriorityWorkQueue** value is the base priority level for the custom priority queue. Work items are queued at a particular priority by setting *QueueType* to **CustomPriorityWorkQueue** + *Priority* where *Priority* is the **KPRIORITY** value for the work item. This queue type is valid starting with Windows 8.1.

Remarks

For drivers targeting Windows 8.1 or later versions of Windows, use of only **CustomPriorityWorkQueue** with a

custom priority level is recommended.

A work queue priority < 17 is advised since queuing
at a higher priority may interfere with work item processing by critical system components.

For more information about system worker threads, see System Worker Threads.

ALLOCATE_FUNCTION_EX callback function

1/25/2019 • 4 minutes to read • Edit Online

The *LookasideListAllocateEx* routine allocates the storage for a new lookaside-list entry when a client requests an entry from a lookaside list that is empty.

Syntax

```
ALLOCATE_FUNCTION_EX AllocateFunctionEx;

PVOID AllocateFunctionEx(
  POOL_TYPE PoolType,
  SIZE_T NumberOfBytes,
  ULONG Tag,
  PLOOKASIDE_LIST_EX Lookaside
)
{...}
```

Parameters

`PoolType`

Specifies the type of storage to allocate for the new lookaside-list entry. The caller sets this parameter to a valid POOL_TYPE enumeration value, and possibly bitwise ORs this value with one of the following flag bits:

- POOL_RAISE_IF_ALLOCATION_FAILURE
- POOL_QUOTA_FAIL_INSTEAD_OF_RAISE

For more information about the POOL_RAISE_IF_ALLOCATION_FAILURE flag, see ExAllocatePoolWithTag. For more information about the POOL_QUOTA_FAIL_INSTEAD_OF_RAISE flag, see ExAllocatePoolWithQuotaTag.

If, in the ExInitializeLookasideListEx call that initialized the lookaside list, the *Flags* parameter is zero, the *PoolType* parameter that the *LookasideListAllocateEx* routine receives is the same *PoolType* parameter value that was passed to **ExInitializeLookasideListEx**.

If, in the **ExInitializeLookasideListEx** call, *Flags* = EX_LOOKASIDE_LIST_EX_FLAGS_RAISE_ON_FAIL, the *PoolType* parameter that the *LookasideListAllocateEx* routine receives is the bitwise OR of POOL_RAISE_IF_ALLOCATION_FAILURE and the *PoolType* parameter value that was passed to **ExInitializeLookasideListEx**. The *LookasideListAllocateEx* routine can pass its *PoolType* parameter value, without modification, to the **ExAllocatePoolWithTag** routine.

If, in the **ExInitializeLookasideListEx** call, Flags = EX_LOOKASIDE_LIST_EX_FLAGS_FAIL_NO_RAISE, the *PoolType* parameter that the *LookasideListAllocateEx* routine receives is the bitwise OR of POOL_QUOTA_FAIL_INSTEAD_OF_RAISE and the *PoolType* value that was passed to **ExInitializeLookasideListEx**. The *LookasideListAllocateEx* routine can pass its *PoolType* parameter value, without modification, to the **ExAllocatePoolWithQuotaTag** routine.

`NumberOfBytes`

Specifies the size, in bytes, of the lookaside-list entry to allocate.

`Tag`

Specifies the four-byte pool tag to use to mark the allocated storage for the new lookaside-list entry. For more information about pool tags, see the description of the *Tag* parameter in ExAllocatePoolWithTag.

`Lookaside`

A pointer to a LOOKASIDE_LIST_EX structure that describes the lookaside list. This structure was previously initialized by the ExInitializeLookasideListEx routine.

Return Value

LookasideListAllocateEx returns a pointer to the allocated lookaside-list entry. If the routine cannot allocate an entry, it returns **NULL**.

Remarks

A driver that creates a lookaside list can implement a *LookasideListAllocateEx* routine to dynamically allocate buffers for the list. A buffer that is not in use is stored as an entry in the list. All entries in a lookaside list are buffers of a uniform size, which the driver specifies when the list is initialized.

The driver supplies a pointer to a custom *LookasideListAllocateEx* routine as an input parameter in the **ExInitializeLookasideListEx** call that initializes the lookaside list. If the driver sets this parameter to **NULL**, the lookaside list uses a default allocation routine instead.

A driver calls the ExAllocateFromLookasideListEx routine to allocate an entry from a lookaside list. If the list is empty (contains no entries), **ExAllocateFromLookasideListEx** calls *LookasideListAllocateEx* to dynamically allocate the storage for a new entry. *LookasideListAllocateEx* returns a pointer to the newly allocated entry if the allocation is successful. Otherwise, it returns **NULL**.

The *PoolType*, *NumberOfBytes*, *Tag*, and *Lookaside* parameters contain the same values that were passed as input parameters in the **ExInitializeLookasideListEx** call that initialized the lookaside list.

The *LookasideListAllocateEx* routine can use the *Lookaside* parameter to access private context data that the driver has associated with the lookaside list. For more information, see the code example in ExInitializeLookasideListEx.

For more information about lookaside lists, see Using Lookaside Lists.

The *LookasideListAllocateEx* routine is called at the same IRQL as the call to **ExAllocateFromLookasideListEx** that requests the entry. For a call that requests an entry that resides in paged memory, the caller must be running IRQL <= APC_LEVEL. For a call that requests an entry that resides in nonpaged memory, the caller must be running IRQL <= DISPATCH_LEVEL.

Examples

To define a *LookasideListAllocateEx* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *LookasideListAllocateEx* callback routine that is named `MyLookasideListAllocateEx`, use the FREE_FUNCTION_EX type as shown in this code example:

```
FREE_FUNCTION_EX MyLookasideListFreeEx;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyLookasideListFreeEx(
    PVOID  Buffer,
    PLOOKASIDE_LIST_EX  Lookaside
    )
  {
      // Function body
  }
```

The FREE_FUNCTION_EX function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the FREE_FUNCTION_EX function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Supported in Windows Vista and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	See Remarks section.

AppendTailList function

1/25/2019 • 3 minutes to read • Edit Online

The **AppendTailList** routine appends a doubly linked list of LIST_ENTRY structures to the tail of another doubly linked list of **LIST_ENTRY** structures.

Syntax

```
void AppendTailList(
  PLIST_ENTRY ListHead,
  PLIST_ENTRY ListToAppend
);
```

Parameters

`ListHead`

A pointer to the head of the list to which the list pointed to by *ListToAppend* is to be appended. This parameter must be a valid, non-NULL pointer to the LIST_ENTRY structure that is the head of a list. This list can be empty.

`ListToAppend`

A pointer to the first entry in the list to append to the list pointed to by *ListHead*. This parameter must be a valid, non-NULL pointer to the LIST_ENTRY structure that is the first entry in a headless list. For more information, see Remarks.

Return Value

None.

Remarks

This routine constructs a list that contains all the combined entries from the input *ListHead* and *ListToAppend* lists. When the routine returns, the LIST_ENTRY structure pointed to by the *ListHead* parameter is the head of the resulting combined list. The **LIST_ENTRY** structure pointed to by the *ListToAppend* parameter is an entry in the resulting combined list.

The caller sets the *ListToAppend* parameter to point to the first entry in the list to be appended. In this regard, *AppendTailList* does not conform to the convention followed by the other doubly linked list routines that use the **LIST_ENTRY** structure. In these other routines, a parameter that represents a list points to the list head instead of to the first entry in the list. If your driver code uses a list head to represent the list to be appended, the list head must be removed from this list before the list is passed as the *ListToAppend* parameter to **AppendTailList**. For a code example that shows how to remove this list head, see Examples.

AppendTailList can be used to insert a single entry at the tail of a list, but the **Flink** and **Blink** members of the **LIST_ENTRY** structure pointed to by *ListToAppend* must first be initialized—typically, by calling the InitializeListHead routine. In contrast, the InsertTailList routine does not require the **Flink** and **Blink** members of the **LIST_ENTRY** structure pointed to by the *Entry* parameter to be initialized before the **InsertTailList** call. For this reason, **InsertTailList** might be more convenient to use to insert a single entry at the tail of a list.

A driver can access the **Flink** and **Blink** members of a **LIST_ENTRY**, but the members must only be updated by

the system routines supplied for this purpose.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

Callers of **AppendTailList** can be running at any IRQL. If **AppendTailList** is called at IRQL >= DISPATCH_LEVEL, the storage for the list entries must be memory-resident.

Examples

The following code example shows how to write a function named `MyAppendTailList` that is similar to **AppendTailList**, but that treats the *ListToAppend* parameter as a pointer to a list head instead of as a pointer to the first entry in a (headless) list. Unlike **AppendTailList**, the `MyAppendTailList` function avoids including the **LIST_ENTRY** structure pointed to by the *ListToAppend* parameter in the entries that are appended to the list pointed to by the *ListHead* parameter.

```
VOID MyAppendTailList(
    _Inout_  PLIST_ENTRY ListHead,
    _Inout_  PLIST_ENTRY ListToAppend
    )
{
    PLIST_ENTRY entry = ListToAppend->Flink;

    if (!IsListEmpty(ListToAppend))
    {
        RemoveEntryList(ListToAppend);
        InitializeListHead(ListToAppend);
        AppendTailList(ListHead, entry);
    }
}
```

The `MyAppendTailList` function in this code example treats both the *ListHead* and *ListToAppend* parameters as pointers to list heads. When this function returns, the list pointed to by *ListToAppend* is empty; that is, it consists of a list head that has no associated list entries. All of the entries that were initially in this list have been appended to the list pointed to by *ListHead*.

Requirements

Minimum supported client	Available starting with Windows Vista.
Target Platform	Desktop

BOUND_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *BoundCallback* routine is executed whenever the system issues a bounds exception for a user-mode thread.

Syntax

```
BOUND_CALLBACK BoundCallback;

BOUND_CALLBACK_STATUS BoundCallback(

)
{...}
```

Parameters

This callback function has no parameters.

Return Value

A BOUND_CALLBACK_STATUS value that indicates how the bounds exception was processed by the callback function.

Remarks

Drivers can supply a *BoundCallback* that is called when the system issues a bounds exception.

Use KeRegisterBoundCallback to register a *BoundCallback* routine. A driver can subsequently remove the callback by using the KeDeregisterBoundCallback routine. If the driver can be unloaded, it must remove any registered callbacks in its Unload routine.

Requirements

Minimum supported client	Available starting with Windows 10.
Target Platform	Windows
Header	wdm.h

KeRegisterBoundCallback

ClfsAddLogContainer function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsAddLogContainer** routine adds a container to a CLFS log.

Syntax

```
CLFSUSER_API NTSTATUS ClfsAddLogContainer(
  PLOG_FILE_OBJECT plfoLog,
  PULONGLONG       pcbContainer,
  PUNICODE_STRING  puszContainerPath
);
```

Parameters

`plfoLog`

A pointer to a LOG_FILE_OBJECT structure that represents the log to which the container will be added. The caller previously obtained this pointer by calling ClfsCreateLogFile.

`pcbContainer`

A pointer to a ULONGLONG-typed variable. The role of this parameter depends on whether the log currently has at least one container.

- If the log currently has no containers, the caller supplies a positive integer that is the requested size, in bytes, of the new container. CLFS creates a container that is the requested size rounded up to a multiple of 512KB (for a dedicated log) or 1MB (for a multiplexed log).
- If the log currently has at least one container and this parameter is the **NULL** pointer, CLFS creates a new container that is the same size as the existing containers. (All containers in a log must be the same size.)
- If the log currently has at least one container and this parameter is a valid pointer, the caller supplies a positive integer that is the requested size, in bytes, of the new container. The requested size is rounded up to a multiple of 512KB (for a dedicated log) or 1MB (for a multiplexed log). If the rounded-up size is at least as large as the existing container size, CLFS creates a new container that is the same size as the existing containers. On successful return, this parameter receives the existing container size. If the rounded-up size is less than the existing container size, **ClfsAddLogContainer** fails.

`puszContainerPath`

A pointer to a UNICODE_STRING structure that supplies the path name for the new container. The path can be absolute or relative to the location of the base log file. Paths that are relative to the base log file must begin with CLFS_CONTAINER_RELATIVE_PREFIX, which is the string literal (L"%BLF%\").

Return Value

ClfsAddLogContainer returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

A container is a contiguous extent on stable storage. For example, a container could be a contiguous file on disk. A

log is a set of containers along with a base log file. For more information about containers, see CLFS Stable Storage.

A container specified by a path that is relative to the base log file must be in the same directory as the base log file or a subdirectory of the base log file. The directories "." and ".." are not allowed in a relative path.

A log can have some containers with absolute paths and other containers with relative paths.

Containers are created in a non-compressed mode and are initialized with zeros.

A log must have at least two containers before any I/O can be performed on it.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

ClfsAddLogContainerSet

ClfsRemoveLogContainer

ClfsAddLogContainerSet function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsAddLogContainerSet** routine atomically adds a set of containers to a CLFS log.

Syntax

```
CLFSUSER_API NTSTATUS ClfsAddLogContainerSet(
  PLOG_FILE_OBJECT plfoLog,
  USHORT           cContainers,
  PULONGLONG       pcbContainer,
  PUNICODE_STRING  rguszContainerPath
);
```

Parameters

`plfoLog`

A pointer to a LOG_FILE_OBJECT structure that represents the log to which the containers will be added. The caller previously obtained this pointer by calling ClfsCreateLogFile.

`cContainers`

The number of containers in the set. This is the number of elements in the *rguszContainerPath* array.

`pcbContainer`

A pointer to a ULONGLONG-typed variable. The role of this parameter depends on whether the log currently has at least one container.

- If the log currently has no containers, the caller supplies a positive integer that is the requested size, in bytes, of an individual container. CLFS creates containers that are the requested size rounded up to a multiple of 512KB (for a dedicated log) or 1MB (for a multiplexed log).
- If the log currently has at least one container and this parameter is the **NULL** pointer, CLFS creates new containers that are the same size as the existing containers. (All containers in a log must be the same size.)
- If the log currently has at least one container and this parameter is a valid pointer, the caller supplies a positive integer that is the requested size, in bytes, of an individual container. The requested size is rounded up to a multiple of 512KB (for a dedicated log) or 1MB (for a shared log). If the rounded-up size is at least as large as the existing container size, CLFS creates new containers that are the same size as the existing containers. On successful return, this parameter receives the existing container size. If the rounded-up size is less than the existing container size, **ClfsAddLogContainerSet** fails.

`rguszContainerPath`

A pointer to an array of UNICODE_STRING structures. Each string supplies the path name for one of the new containers. The number of elements in the array is given by *cContainers*. A given path can be absolute or relative to the location of the base log file. Paths that are relative to the base log file must begin with CLFS_CONTAINER_RELATIVE_PREFIX, which is the string literal (L"%BLF%\").

Return Value

ClfsAddLogContainer returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes

defined in Ntstatus.h.

Remarks

A container is a contiguous extent on stable storage. For example, a container could be a contiguous file on disk. A log is a set of containers along with a base log file. For more information about containers, see CLFS Stable Storage.

A container specified by a path that is relative to the base log file must be in the same directory as the base log file or a subdirectory of the base log file. The directories "." and ".." are not allowed in a relative path.

A log can have some containers with absolute paths and other containers with relative paths.

Containers are created in a non-compressed mode and are initialized with zeros.

A log must have at least two containers before any I/O can be performed on it.

For an explanation of CLFS concepts and terminology, see Common Log File System.

ClfsAddLogContainer

ClfsRemoveLogContainerSet

ClfsAdvanceLogBase function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsAdvanceLogBase** routine sets the base LSN of a CLFS stream.

Syntax

```
CLFSUSER_API NTSTATUS ClfsAdvanceLogBase(
  PVOID     pvMarshalContext,
  PCLFS_LSN plsnBase,
  ULONG     fFlags
);
```

Parameters

`pvMarshalContext`

A pointer to an opaque context that represents a marshalling area associated with a CLFS stream. The caller previously obtained this pointer by calling ClfsCreateMarshallingArea.

`plsnBase`

A pointer to a CLFS_LSN structure that contains the new base LSN. This parameter must be the LSN of one of the records in the stream. Also, this parameter must be greater than or equal to the stream's current base LSN and less than or equal to the stream's current last LSN.

`fFlags`

This parameter is reserved for system use. Callers must set this parameter to zero.

Return Value

ClfsAdvanceLogBase returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

ClfsAdvanceLogBase does not write any records to the CLFS log; the only updates to the log are in the metadata. If you want to update the base LSN and write a restart record to a stream at the same time, call ClfsWriteRestartArea.

Whenever possible, CLFS avoids writing queued log records that have LSNs less than the new base LSN to stable storage.

ClfsAdvanceLogBase does not check to see whether the LSN supplied in *plsnBase* is actually the LSN of one of the records in the stream. If the caller sets *plsnBase* to an LSN that is not the LSN of one of the records in the stream, the stream's base LSN will be set to a meaningless value.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys

ClfsAlignReservedLog function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsAlignReservedLog** routine calculates the size of the space that must be reserved for a specified set of records. The size calculation includes the space required for headers and the space required for sector alignment.

Syntax

```
CLFSUSER_API NTSTATUS ClfsAlignReservedLog(
  PVOID       pvMarshalContext,
  ULONG       cRecords,
  LONGLONG [] rgcbReservation,
  PLONGLONG   pcbAlignReservation
);
```

Parameters

`pvMarshalContext`

A pointer to an opaque context that represents a marshalling area associated with a CLFS stream. The caller previously obtained this pointer by calling ClfsCreateMarshallingArea.

`cRecords`

The number of elements in the array pointed to by *rgcbReservation*.

`rgcbReservation`

A pointer to an array of LONGLONG-typed variables that supplies a list of record sizes (in bytes).

`pcbAlignReservation`

A pointer to a LONGLONG-typed variable that receives the size, in bytes, of the required reservation.

Return Value

ClfsAlignReservedLog returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ClfsAllocReservedLog

ClfsAllocReservedLog function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsAllocReservedLog** routine reserves space in a marshalling area for a set of records.

Syntax

```
CLFSUSER_API NTSTATUS ClfsAllocReservedLog(
  PVOID     pvMarshalContext,
  ULONG     cRecords,
  PLONGLONG pcbAdjustment
);
```

Parameters

`pvMarshalContext`

A pointer to an opaque context that represents a marshalling area. The caller previously obtained this pointer by calling ClfsCreateMarshallingArea.

`cRecords`

The number of records in the set. This value must match the value of *cRecords* previously passed to ClfsAlignReservedLog.

`pcbAdjustment`

A pointer to a LONGLONG-typed variable that supplies the size, in bytes, of the reservation that will hold all the records in the set. The caller previously obtained this size by calling ClfsAlignReservedLog.

Return Value

ClfsAllocReservedLog returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.

ClfsAlignReservedLog

ClfsCloseAndResetLogFile function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsCloseAndResetLogFile** routine releases all references to a specified log file object and marks its associated stream for reset.

Syntax

```
CLFSUSER_API NTSTATUS ClfsCloseAndResetLogFile(
  PLOG_FILE_OBJECT plfoLog
);
```

Parameters

`plfoLog`

A pointer to a LOG_FILE_OBJECT structure for which references will be released. The caller previously obtained this pointer by calling ClfsCreateLogFile.

Return Value

ClfsCloseAndResetLogFile returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

ClfsCloseAndResetLogFile releases all references, acquired by CLFS, to the specified log file object. Typically, the client will not have acquired any additional references to the log file object. However, if the client has obtained additional refereces, it is the client's responsibility to release them.

ClfsCloseAndResetLogFile causes the specified log file object's reference count to drop to zero, at which time the log file object is closed (that is, its memory is deallocated). The stream represented by the log file object might not be reset, however, because there could be other log file objects that represent the same stream. The stream is reset after all log file objects that represent the stream are closed (for example by calls to ClfsCloseLogFileObject).

A reset stream is like a newly created stream that has never had any records written to it.

On return from this routine, *plfoLog* is invalid.

You can call **ClfsCloseAndResetLogFile** at most 124 times for a given stream.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop

Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

ClfsCloseLogFileObject

ClfsDeleteLogByPointer

ClfsDeleteLogFile

ClfsCloseLogFileObject function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsCloseLogFileObject** routine releases all references to a log file object.

Syntax

```
CLFSUSER_API NTSTATUS ClfsCloseLogFileObject(
  PLOG_FILE_OBJECT plfoLog
);
```

Parameters

`plfoLog`

A pointer to the LOG_FILE_OBJECT structure for which references will be released.The caller previously obtained this pointer by calling ClfsCreateLogFile.

Return Value

ClfsCloseLogFileObject returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

ClfsCloseLogFileObject releases all references, acquired by CLFS, to the specified log file object. Typically, the client will not have acquired any additional references to the log file object. However, if the client has obtained additional refereces, it is the client's responsibility to release them.

ClfsCloseLogFileObject causes the specified log file object's reference count to drop to zero, at which time the log file object is closed (that is, its memory is deallocated). The stream represented by the log file object might remain open, however, because there could be other log file objects that represent the same stream. The stream is closed after all log file objects that represent the stream are closed.

On return from this routine, *plfoLog* is invalid.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib

DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

ClfsCloseAndResetLogFile

ClfsCreateLogFile

ClfsCreateLogFile function

1/25/2019 • 6 minutes to read • Edit Online

The **ClfsCreateLogFile** routine creates or opens a CLFS stream. If necessary, **ClfsCreateLogFile** also creates the underlying physical log that holds the stream's records.

Syntax

```
CLFSUSER_API NTSTATUS ClfsCreateLogFile(
  PPLOG_FILE_OBJECT    pplfoLog,
  PUNICODE_STRING      puszLogFileName,
  ACCESS_MASK          fDesiredAccess,
  ULONG                dwShareMode,
  PSECURITY_DESCRIPTOR psdLogFile,
  ULONG                fCreateDisposition,
  ULONG                fCreateOptions,
  ULONG                fFlagsAndAttributes,
  ULONG                fLogOptionFlag,
  PVOID                pvContext,
  ULONG                cbContext
);
```

Parameters

`pplfoLog`

A pointer to a variable that receives a pointer to a LOG_FILE_OBJECT structure that represents an open instance of the stream.

`puszLogFileName`

A pointer to a UNICODE_STRING structure that supplies the name of the stream or the underlying physical log.

If the stream already exists and is the only stream of a dedicated log, the name has the form log:*physical log name*, where *physical log name* is the path name, on the underlying file system, of the existing physical log that contains the stream's records.

If the stream does not already exist and is to become the only stream of a dedicated log (that does not yet exist), the name has the form log:*physical log name*, where *physical log name* is the path name, on the underlying file system, of the physical log that will be created to hold the stream's records.

If the stream is (or is to become) one of the streams of a multiplexed log, the name has the form log:*physical log name*::*stream name*, where *physical log name* is the path name, on the underlying file system, of the physical log that holds the stream's records, and *stream name* is the name of a stream that shares (or will share) that physical log.

If you want to create a multiplexed log that has no streams for the moment, use a name of the form log:*physical log name*::, where *physical log name* is the path name, on the underlying file system, of the physical log to be created.

The following list gives some examples of valid names.

- "Log:c:\myLog" creates or opens a dedicated log and its one stream.
- "Log:c:\myCommonLog::" creates a multiplexed log that does not yet have any streams.

- "Log:c:\myCommonLog::Stream1" creates or opens one of the streams (Stream1) of a multiplexed log.

`fDesiredAccess`

An ACCESS_MASK that supplies the type of access the client will have (by using the pointer returned in *pplfoLog*) to the stream. If this parameter is zero, clients can query the stream for its attributes, but cannot read from or write to the stream. This parameter can be zero or any combination of the following flags:

FLAG	MEANING
GENERIC_READ	The client has read access to the stream.
GENERIC_WRITE	The client has write access to the stream.
DELETE	The client can mark the stream for deletion.

`dwShareMode`

The sharing mode of the stream, which can be zero (not shared) or any combination of the following flags:

FLAG	MEANING
FILE_SHARE_DELETE	Subsequent requests to open the stream with delete access will succeed.
FILE_SHARE_READ	Subsequent requests to open the stream with read access will succeed.
FILE_SHARE_WRITE	Subsequent requests to open the stream with write access will succeed.

`psdLogFile`

A pointer to a SECURITY_DESCRIPTOR structure that supplies security attributes for the stream. This parameter can be **NULL**.

`fCreateDisposition`

The action to take that depends on whether the stream already exists. This parameter must be set to one of the following values:

VALUE	MEANING
CREATE_NEW	Create a new stream if the stream does not already exits. Fail if the stream already exists.
OPEN_EXISTING	Open an existing stream. Fail if the stream does not already exist.
OPEN_ALWAYS	Open an existing stream. Create the stream if it does not already exist.

`fCreateOptions`

A set of flags that specify options to apply when creating or opening the stream. This parameter can be zero or a compatible combination of the following flags:

FLAG	MEANING
FILE_NO_INTERMEDIATE_BUFFERING	The stream's records cannot be cached in a driver's internal buffers.
FILE_SYNCHRONOUS_IO_ALERT	All operations on the stream are performed synchronously. Any wait on behalf of the caller is subject to premature termination from alerts. If this flag is set, the FILE_SYNCHRONOUS_IO_NONALERT flag must be cleared.
FILE_SYNCHRONOUS_IO_NONALERT	All operations on the stream are performed synchronously. Waits in the system that synchronize I/O queuing and completion are not subject to alerts. If this flag is set, the FILE_SYNCHRONOUS_IO_ALERT flag must be cleared.

`fFlagsAndAttributes`

A value that specifies whether the stream is opened for normal or read-only access. This parameter must be set to either

FILE_ATTRIBUTE_NORMAL or FILE_ATTRIBUTE_READONLY.

`fLogOptionFlag`

A hint about the relationship between CLFS and the component creating or opening the stream. This parameter must be set to one of the following values:

VALUE	MEANING
CLFS_FLAG_NO_FLAGS	CLFS and the creating component have the standard, normal relationship. Kernel-mode components use this value unless they fall into one of the three other categories listed in this table. If *pvContext* is not **NULL**, CLFS verifies that *cbContext* is greater than zero. Otherwise, *pvContext* and *cbContext* are ignored.
CLFS_FLAG_REENTRANT_FILE_SYSTEM	The creating component is the file system that provides the underlying storage for CLFS. CLFS uses the file system for allocating containers, and the file system uses CLFS streams. In this case, it is possible for the file system to call CLFS and for CLFS to make calls back into the file system on the same thread or different threads. If *pvContext* is not **NULL**, CLFS verifies that *cbContext* is greater than zero. Otherwise, *pvContext* and *cbContext* are ignored.
CLFS_FLAG_NON_REENTRANT_FILTER	The creating component is a file system filter driver that sends all of its CLFS I/O to a specified level below itself on the filter stack. This option allows a filter driver to create a CLFS log without seeing its own logging I/O. The caller passes the non-**NULL** target device object in the *pvContext* parameter with *cbContext* set to the appropriate size. CLFS uses the IoCreateFileSpecifyDeviceObjectHint routine to create containers at a targeted level in the I/O filter stack specified by the device object.

CLFS_FLAG_REENTRANT_FILTER	The creating component is a file system filter driver that sends all of its CLFS I/O to the top of the filter stack. The filter has a recursive relationship with CLFS because it filters its own logging I/O when CLFS performs any file system operation on its containers. The *pvContext* parameter provides a means for filters to associate a recognizable context with its CLFS containers as log I/O comes down the filter stack. The *cbContext* parameter specifies the size of the opaque context in bytes.
CLFS_FLAG_MINIFILTER_LEVEL	The creating component is a file system minifilter driver that sends all of its CLFS I/O to a specified level below itself on the filter stack. This option allows a minifilter to create a CLFS log without seeing its own logging I/O. The caller passes the non-**NULL** minifilter context object in the *pvContext* parameter with *cbContext* set to the appropriate size. CLFS uses the **IoCreateFileSpecifyDeviceObjectHint** routine to create containers at an altitude (specified within the minifilter context) in the filter manager's minifilter stack.

`pvContext`

A pointer to a context. The way the context is interpreted depends on the value passed to *fLogOptionsFlag*.

`cbContext`

The size, in bytes, of the context pointed to by *pvContext*. If *pvContext* is not **NULL**, this parameter must be greater than zero.

Return Value

ClfsCreateLogFile returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

When you create a CLFS stream, it is backed by an underlying physical CLFS log. The underlying log can be either dedicated (backs only one stream) or multiplexed (backs several streams). A dedicated log cannot be converted to a multiplexed log, and a multiplexed log cannot be converted to a dedicated log.

A physical CLFS log name does not include the .blf extension.

For an explanation of CLFS concepts and terminology, see Common Log File System.

ClfsCreateMarshallingArea function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsCreateMarshallingArea** routine creates a marshalling area for a CLFS stream and returns a pointer to an opaque context that represents the new marshalling area.

Syntax

```
CLFSUSER_API NTSTATUS ClfsCreateMarshallingArea(
  PLOG_FILE_OBJECT   plfoLog,
  POOL_TYPE          ePoolType,
  PALLOCATE_FUNCTION pfnAllocBuffer,
  PFREE_FUNCTION     pfnFreeBuffer,
  ULONG              cbMarshallingBuffer,
  ULONG              cMaxWriteBuffers,
  ULONG              cMaxReadBuffers,
  PVOID              *ppvMarshalContext
);
```

Parameters

`plfoLog`

A pointer to a LOG_FILE_OBJECT structure that represents a CLFS stream. The caller previously obtained this pointer by calling ClfsCreateLogFile.

`ePoolType`

A POOL_TYPE value that specifies the type of memory (paged, non-paged, for example) that the new marshalling area will use for its log I/O blocks.

`pfnAllocBuffer`

Either **NULL** or a pointer to a caller-supplied function that allocates a log I/O block for the marshalling area. The allocation function has the following prototype:

```
PVOID
(*PALLOCATE_FUNCTION) (
    IN POOL_TYPE PoolType,
    IN SIZE_T NumberOfBytes,
    IN ULONG Tag
    );
```

The return value of the allocation function is a pointer to the newly allocated log I/O block. `pfnFreeBuffer` Either **NULL** or a pointer to a caller-supplied function that frees a log I/O block that was previously allocated by *pfnAllocBuffer*. The function has the following prototype:

```
VOID
(*PFREE_FUNCTION) (
    IN PVOID Buffer
    );
```

`cbMarshallingBuffer`

The size, in bytes, of the individual log I/O blocks that the new marshalling area uses. This must be a multiple of the sector size on the stable storage medium. The sector size is the *lpBytesPerSector* value returned from **GetDiskFreeSpace**.

`cMaxWriteBuffers`

The maximum number of I/O blocks that can be allocated at one time for write operations. This parameter affects the frequency of data flushes. If you do not need to control the frequency of data flushes, set this parameter to INFINITE.

`cMaxReadBuffers`

The maximum number of log I/O blocks that can be allocated at one time for read operations.

`ppvMarshalContext`

A pointer to a variable that receives a pointer to an opaque context that represents the new marshalling area.

Return Value

ClfsCreateMarshallingArea returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

The *pfnAllocBuffer* and *pfnFreeBuffer* parameters must both point to caller-allocated functions, or they must both be **NULL**. If they are both **NULL**, CLFS provides default functions for allocating and freeing log I/O blocks.

Before calling **ClfsCreateMarshallingArea**, you must add at least two containers to the underlying log by calling ClfsAddLogContainer or ClfsAddLogContainerSet.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys

IRQL	"<= APC_LEVEL"

LOG_FILE_OBJECT

POOL_TYPE

ClfsCreateScanContext function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsCreateScanContext** routine creates a scan context that can be used to iterate over the containers of a specified CLFS log.

Syntax

```
CLFSUSER_API NTSTATUS ClfsCreateScanContext(
  PLOG_FILE_OBJECT   plfoLog,
  ULONG              cFromContainer,
  ULONG              cContainers,
  CLFS_SCAN_MODE     eScanMode,
  PCLFS_SCAN_CONTEXT pcxScan
);
```

Parameters

`plfoLog`

A pointer to a LOG_FILE_OBJECT structure that represents a CLFS stream. The scan context is created for the log that provides the underlying storage for that stream. The caller previously obtained this pointer by calling ClfsCreateLogFile.

`cFromContainer`

The index of the first container to be scanned. Containers are indexed starting at zero.

`cContainers`

The number of containers to be scanned with each call to ClfsScanLogContainers.

`eScanMode`

A set of flags that specify whether the scan context is set up for scanning forward or backward and whether the scan context should be reinitialized. The following three flags are available for callers of this routine.

VALUE	MEANING
CLFS_SCAN_FORWARD	Set up the scan context for scanning in the forward direction. For example, if container 5 is the most recently scanned container and *cContainers* is 2, then a forward scan would return descriptors for containers 6 and 7.
CLFS_SCAN_BACKWARD	Set up the scan context for scanning in the backward direction. For example, if container 5 is the most recently scanned container and *cContainers* is 2, then a backward scan would return descriptors for containers 4 and 3.
CLFS_SCAN_INIT	Reinitialize the scan context. The next time **ClfsScanLogContainers** is called, it will behave as if it were being called for the first time after the creation of the scan context.

If *pcxScan* points to a CLFS_SCAN_CONTEXT structure that is being passed to this routine for the first time, one of the direction flags (CLFS_SCAN_FORWARD or CLFS_SCAN_BACKWARD) must be set. The CLFS_SCAN_INIT flag must not be set.

If *pcxScan* points to a CLFS_SCAN_CONTEXT structure that has been passed to this routine previously, the CLFS_SCAN_INIT flag must be set. Also, one and only one of the direction flags (CLFS_SCAN_FORWARD or CLFS_SCAN_BACKWARD) must be set.

`pcxScan`

A pointer to a caller-allocated CLFS_SCAN_CONTEXT structure whose members are initialized by this routine. This structure is later passed to ClfsScanLogContainers.

Return Value

ClfsCreateScanContext returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes in Ntstatus.h.

Remarks

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys

ClfsScanLogContainers

ClfsDeleteLogByPointer function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsDeleteLogByPointer** routine marks a CLFS stream for deletion.

Syntax

```
CLFSUSER_API NTSTATUS ClfsDeleteLogByPointer(
  PLOG_FILE_OBJECT plfoLog
);
```

Parameters

`plfoLog`

A pointer to a LOG_FILE_OBJECT structure that represents an open instance of the stream to be deleted. The caller previously obtained this pointer by calling ClfsCreateLogFile.

Return Value

ClfsDeleteLogByPointer returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

ClfsDeleteLogByPointer marks a stream for deletion but does not close the log file object pointed to by *plfoLog*. To close a log file object, call ClfsCloseLogFileObject. A stream marked for deletion is deleted after all log file objects associated with the stream are closed.

A CLFS stream marked for deletion will refuse subsequent requests to open the stream.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

ClfsCreateLogFile

ClfsDeleteLogFile

ClfsDeleteLogFile function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsDeleteLogFile** routine marks a CLFS stream for deletion.

Syntax

```
CLFSUSER_API NTSTATUS ClfsDeleteLogFile(
  PUNICODE_STRING puszLogFileName,
  PVOID           pvReserved,
  ULONG           fLogOptionFlag,
  PVOID           pvContext,
  ULONG           cbContext
);
```

Parameters

`puszLogFileName`

A pointer to a UNICODE_STRING structure that supplies the name of the CLFS stream to be deleted.

If the stream to be deleted is the only stream of a dedicated log, the name has the form log:*physical log name*, where *physical log name* is the path name of the physical log on the underlying file system.

If the stream to be deleted is one of the streams of a multiplexed log, the name has the form log:*physical log name*::*stream name*, where *physical log name* is the path name of the physical log on the underlying file system and *stream name* is the unique name of the stream to be deleted.

`pvReserved`

Reserved.

`fLogOptionFlag`

A value that indicates the relationship between CLFS and the component that is deleting the log. For a list of possible values, see the description of the *fLogOptionFlag* parameter of the **ClfsCreateLogFile** routine.

`pvContext`

A pointer to a context. The way the context is interpreted depends on the value passed in *fLogOptionFlag*.

`cbContext`

The size, in bytes, of the context pointed to by *pvContext*. If *pvContext* is not **NULL**, this parameter must be greater than zero.

Return Value

ClfsDeleteLogFile returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

The Common Log File System (CLFS) uses the LOG_FILE_OBJECT structure to represent logs. The

ClfsCreateLogFile function returns a pointer to LOG_FILE_OBJECT, which clients then pass to other CLFS functions.

CLFS clients do not directly access the members of a LOG_FILE_OBJECT structure. For information about the members, see FILE_OBJECT.

ClfsDeleteLogFile marks a stream for deletion but does not close any log file objects that are currently open. To close a log file object, call ClfsCloseLogFileObject. A stream marked for deletion is deleted after all log file objects associated with the stream are closed.

A CLFS stream marked for deletion will refuse subsequent requests to open the stream.

The name of a physical CLFS log does not include the .blf extension.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys

ClfsCreateLogFile

ClfsDeleteLogByPointer

ClfsDeleteMarshallingArea function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsDeleteMarshallingArea** routine deletes a marshalling area.

Syntax

```
CLFSUSER_API NTSTATUS ClfsDeleteMarshallingArea(
  PVOID pvMarshalContext
);
```

Parameters

`pvMarshalContext`

A pointer to an opaque context that represents a marshalling area. The caller previously obtained this pointer by calling ClfsCreateMarshallingArea.

Return Value

ClfsDeleteMarshallingArea returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

Before deleting the marshalling area, **ClfsDeleteMarshallingArea** flushes all of the log I/O blocks associated with the marshalling area.

The marshalling area goes away only after all references to it go away. For example, the marshalling area remains in memory if it still has an open read context.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

ClfsCreateMarshallingArea

ClfsFlushBuffers function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsFlushBuffers** routine forces all log I/O blocks in a specified marshalling area to stable storage.

Syntax

```
CLFSUSER_API NTSTATUS ClfsFlushBuffers(
  PVOID pvMarshalContext
);
```

Parameters

`pvMarshalContext`

A pointer to an opaque context that represents a marshalling area. The caller previously obtained this pointer by calling ClfsCreateMarshallingArea.

Return Value

ClfsFlushBuffers returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

Calling **ClfsFlushBuffers** is equivalent to calling ClfsFlushToLsn with the *plsnFlush* parameter set to CLFS_LSN_NULL.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

ClfsFlushToLsn

ClfsFlushToLsn function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsFlushToLsn** routine forces, to stable storage, all records that have an LSN less than or equal to a specified LSN.

Syntax

```
CLFSUSER_API NTSTATUS ClfsFlushToLsn(
  PVOID     pvMarshalContext,
  PCLFS_LSN plsnFlush,
  PCLFS_LSN plsnLastFlushed
);
```

Parameters

`pvMarshalContext`

A pointer to an opaque context associated with a marshalling area. The caller previously obtained this pointer by calling ClfsCreateMarshallingArea.

`plsnFlush`

A pointer to a CLFS_LSN structure. All records that have an LSN less than or equal to *plsnFlush* are guaranteed to be forced to stable storage. If *plsnFlush* is equal to CLFS_LSN_NULL, then all records in the marshalling area are forced to stable storage.

`plsnLastFlushed`

A pointer to a **CLFS_LSN** structure that receives the LSN of the oldest record that was not flushed. This is the LSN of the record immediately following the last record flushed.

> **Note** On successful return, *plsnLastFlushed* is greater than the value supplied in *plsnFlush*. However, *plsnLastFlushed* does not necessarily point to a record in the stream. For example, if all records in the stream were flushed, *plsnLastFlushed* is the LSN that will be assigned to the next record written to the stream.

Return Value

ClfsFlushToLsn returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

ClfsFlushBuffers

ClfsGetContainerName function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsGetContainerName** routine returns the path name of a specified container.

Syntax

```
CLFSUSER_API NTSTATUS ClfsGetContainerName(
  PLOG_FILE_OBJECT  plfoLog,
  CLFS_CONTAINER_ID cidLogicalContainer,
  PUNICODE_STRING   puszContainerName,
  PULONG            pcActualLenContainerName
);
```

Parameters

`plfoLog`

A pointer to a LOG_FILE_OBJECT structure that represents a CLFS log. The caller previously obtained this pointer by calling ClfsCreateLogFile.

`cidLogicalContainer`

The logical identifier of a container in the CLFS log.

`puszContainerName`

A pointer to a UNICODE_STRING structure. The **Buffer** member of *puszContainerName* must point to a caller-allocated buffer that receives the path name of the container. The **MaximumLength** member must supply the size of the buffer.

`pcActualLenContainerName`

A pointer to a ULONG-typed variable that receives the actual length, in Unicode characters, of the container's path name. This parameter can be **NULL**.

Return Value

ClfsGetContainerName returns one of the status codes defined in Ntstatus.h. The following table gives the meanings of various return values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The **Buffer** member of *puszContainerName* receives the full path name of the container. If *pcActualLenContainerName* is not **NULL**, it receives the actual length, in Unicode characters, of the full path name.

STATUS_BUFFER_OVERFLOW	The actual length, in Unicode characters, of the full path name is larger than *puszContainerName*->**MaximumLength**. The **Buffer** member of *puszContainerName* receives the full path name of the container truncated to the number of characters specified by *puszContainerName*->**MaximumLength**. If *pcActualLenContainerName* is not **NULL**, it receives the actual length, in Unicode characters, of the full path name.
Other	On return, the contents of *puszContainerName*->**Buffer** and *pcActualLenContainerName* are undefined.

Remarks

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys

ClfsRemoveLogContainer

ClfsGetIoStatistics function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsGetIoStatistics** routine returns I/O statistics for a specified CLFS log.

Syntax

```
CLFSUSER_API NTSTATUS ClfsGetIoStatistics(
  PLOG_FILE_OBJECT   plfoLog,
  PVOID              pvStatsBuffer,
  ULONG              cbStatsBuffer,
  CLFS_IOSTATS_CLASS eStatsClass,
  PULONG             pcbStatsWritten
);
```

Parameters

`plfoLog`

A pointer to a LOG_FILE_OBJECT structure that represents a CLFS stream. The I/O statistics will be collected for the stream's underlying log on stable storage. The caller previously obtained this pointer by calling ClfsCreateLogFile.

`pvStatsBuffer`

A pointer to a CLFS_IO_STATISTICS structure that receives the I/O statistics data.

`cbStatsBuffer`

The size, in bytes, of the buffer pointed to by *pvStatsBuffer*. This parameter must be at least **sizeof**(CLFS_IO_STATISTICS_HEADER). If this parameter is less than **sizeof**(**CLFS_IO_STATISTICS**), *pvStatsBuffer* will receive only a portion of the available I/O statistics.

`eStatsClass`

This parameter is reserved for future use.

`pcbStatsWritten`

A pointer to a ULONG-typed variable that receives the number of bytes actually written to *pvStatsBuffer*. This parameter can be **NULL**.

Return Value

ClfsGetIoStatistics returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys

ClfsLsnBlockOffset function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsLsnBlockOffset** routine returns the sector-aligned block offset contained in a specified LSN.

Syntax

```
CLFSUSER_API ULONG ClfsLsnBlockOffset(
  const CLFS_LSN *plsn
);
```

Parameters

`plsn`

A pointer to a CLFS_LSN structure from which the block offset is retrieved.

Return Value

ClfsLsnBlockOffset returns the block offset contained in the LSN that is supplied by the caller.

Remarks

The block offset returned by this routine is a multiple of the sector size on the stable storage medium. For example, if the sector size is 1024 bytes, the block offset is a multiple of 1024.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.

ClfsLsnRecordSequence

ClfsLsnContainer function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsLsnContainer** routine returns the logical container identifier contained in a specified LSN.

Syntax

```
CLFSUSER_API CLFS_CONTAINER_ID ClfsLsnContainer(
  const CLFS_LSN *plsn
);
```

Parameters

`plsn`

A pointer to a CLFS_LSN structure from which the container identifier is retrieved.

Return Value

ClfsLsnContainer returns the logical container identifier contained in the LSN that is supplied by the caller. The logical container identifier is not necessarily the same as the identifier of the physical container on stable storage.

Remarks

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.

ClfsLsnRecordSequence

ClfsLsnCreate function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsLsnCreate** routine creates a log sequence number (LSN), given a container identifier, a block offset, and a record sequence number.

Syntax

```
CLFSUSER_API CLFS_LSN ClfsLsnCreate(
  CLFS_CONTAINER_ID cidContainer,
  ULONG             offBlock,
  ULONG             cRecord
);
```

Parameters

`cidContainer`

An integer in the range 0x0 through 0xFFFFFFFF that supplies the container identifier.

`offBlock`

The block offset. This parameter must be a multiple of 512.

`cRecord`

An integer in the range 0 - 511 that supplies the record sequence number.

Return Value

ClfsLsnCreate returns a CLFS_LSN structure that represents the container identifier, block offset, and record sequence number supplied by the caller.

Remarks

For an explanation of CLFS concepts and terminology, see Common Log File System.

ClfsLsnEqual function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsLsnEqual** routine determines whether two LSNs from the same stream are equal.

Syntax

```
CLFSUSER_API BOOLEAN ClfsLsnEqual(
  const CLFS_LSN *plsn1,
  const CLFS_LSN *plsn2
);
```

Parameters

`plsn1`

A pointer to a CLFS_LSN structure that supplies one of the LSNs to be compared.

`plsn2`

A pointer to a CLFS_LSN structure that supplies the other LSN to be compared.

Return Value

ClfsLsnEqual returns **TRUE** if the two LSNs are equal; otherwise, it returns **FALSE**.

Remarks

CLFS_LSN_NULL (the smallest LSN) and CLFS_LSN_INVALID (larger than any valid LSN) are valid arguments to **ClfsLsnEqual**.

LSNs from different streams are not comparable. Do not use **ClfsLsnEqual**, ClfsLsnGreater, and the like to compare LSNs from different streams.

ClfsLsnGreater function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsLsnGreater** routine determines whether one LSN is greater than another LSN. The two LSNs must be from the same stream.

Syntax

```
CLFSUSER_API BOOLEAN ClfsLsnGreater(
  const CLFS_LSN *plsn1,
  const CLFS_LSN *plsn2
);
```

Parameters

`plsn1`

A pointer to a CLFS_LSN structure that supplies one of the LSNs to be compared.

`plsn2`

A pointer to a CLFS_LSN structure that supplies the other LSN to be compared.

Return Value

ClfsLsnGreater returns **TRUE** if *plsn1* is strictly greater than *plsn2*; otherwise, it returns **FALSE**.

Remarks

CLFS_LSN_NULL (the smallest LSN) and CLFS_LSN_INVALID (larger than any valid LSN) are valid arguments to **ClfsLsnGreater**.

LSNs from different streams are not comparable. Do not use ClfsLsnEqual, **ClfsLsnGreater**, and the like to compare LSNs from different streams.

  const CLFS_LSN *plsn1,
  const CLFS_LSN *plsn2
);
```

Parameters

`plsn1`

A pointer to a CLFS_LSN structure that supplies one of the LSNs to be compared.

`plsn2`

A pointer to a CLFS_LSN structure that supplies the other LSN to be compared.

Return Value

ClfsLsnLess returns **TRUE** if *plsn1* is strictly less than *plsn2*; otherwise, it returns **FALSE**.

Remarks

CLFS_LSN_NULL (the smallest LSN) and CLFS_LSN_INVALID (larger than any valid LSN) are valid arguments to **ClfsLsnLess**.

ClfsMgmtDeregisterManagedClient function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsMgmtDeregisterManagedClient** routine removes the connection between a client and a log, so that the client no longer manages the log.

Syntax

```
CLFSUSER_API NTSTATUS ClfsMgmtDeregisterManagedClient(
  CLFS_MGMT_CLIENT ClientCookie
);
```

Parameters

`ClientCookie`

The cookie we give back to the caller for future use of the API.

Return Value

The **ClfsMgmtDeregisterManagedClient** routine returns one of the following NTSTATUS values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The client is no longer associated with the log.
STATUS_UNSUCCESSFUL	CLFS management was not able to deregister the client.
STATUS_INVALID_PARAMETER	A **NULL** value was supplied for the *Client* parameter.

STA **TUS** **_IN** **VAL** **ID_** **PAR** **AM** **ETE** **R_1**	The value that was supplied for the *Client* parameter does not represent a valid client.

Remarks

After calling the **ClfsMgmtDeregisterManagedClient** routine, a client's callback functions will no longer be invoked.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

See Also

ClfsMgmtRegisterManagedClient

ClfsMgmtHandleLogFileFull function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsMgmtHandleLogFileFull** routine attempts to make more space available in a log. It might make more space available by adding containers to the log, or it might ask clients to move their log tails.

Syntax

```
CLFSUSER_API NTSTATUS ClfsMgmtHandleLogFileFull(
  CLFS_MGMT_CLIENT Client
);
```

Parameters

`Client`

The client that is requesting CLFS management to make space available in the log. The value of this parameter should be the **CLFS_MGMT_CLIENT** structure that is obtained through a call to the ClfsMgmtRegisterManagedClient routine.

Return Value

The **ClfsMgmtHandleLogFileFull** routine returns one of the following NTSTATUS values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The client is not managing a log.
STATUS_INVALID_PARAMETER_1	The value that was supplied for the *Client* parameter either was **NULL** or does not represent a valid client.

STATUS_LOG_FULL_HANDLER_IN_PROGRESS	CLFS management is already attempting to resolve a log file full condition for this client.
STATUS_UNSUCCESSFUL	CLFS management was not able to process the request.
STATUS_PENDING	CLFS management is processing the request to create space in the log.
STATUS_SUCCESS	The requested amount of space is available in the log.

Remarks

To make more space available in the log, the **ClfsMgmtHandleLogFileFull** routine first tries to add more containers to the log in accordance with the growth rate, new container size, and maximum size policies. If more containers cannot be added, then the **ClfsMgmtHandleLogFileFull** routine tries to free existing space by invoking one or more clients' ClfsAdvanceTailCallback functions.

If the **ClfsMgmtHandleLogFileFull** routine returns STATUS_PENDING, the client's ClfsLogGrowthCompleteCallback function will be called when the request to make space in the log has been completed.

If the **ClfsMgmtHandleLogFileFull** routine returns STATUS_LOG_FULL_HANDLER_IN_PROGRESS, the client has already requested CLFS management to handle a log file full condition. The client's ClfsLogGrowthCompleteCallback function will not be called a second time.

If the **ClfsMgmtHandleLogFileFull** routine returns STATUS_SUCCESS, the call completed synchronously, and the client's ClfsLogGrowthCompleteCallback function will not be invoked.

If the **ClfsMgmtHandleLogFileFull** routine returns STATUS_PENDING, then CLFS management is in the process of trying to free space in the log, and will call the client's ClfsLogGrowthCompleteCallback function when the log file full condition has been handled. If the log is pinned, CLFS management will call the client's

ClfsLogGrowthCompleteCallback function with the *LogIsPinned* parameter set to **TRUE** before the **ClfsMgmtHandleLogFileFull** routine returns STATUS_PENDING.

> **Important** It is possible that the client's ClfsLogGrowthCompleteCallback function could be called before the call to **ClfsMgmtHandleLogFileFull** returns.

> **Important** If the **ClfsMgmtHandleLogFileFull** routine returns STATUS_PENDING, you should not call the **ClfsMgmtHandleLogFileFull** routine again for this client until the client's ClfsLogGrowthCompleteCallback function has been called.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

See Also

ClfsAdvanceTailCallback

ClfsLogGrowthCompleteCallback

ClfsMgmtRegisterManagedClient

ClfsMgmtInstallPolicy function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsMgmtInstallPolicy** routine adds a CLFS_MGMT_POLICY structure to a physical log.

Syntax

```
CLFSUSER_API NTSTATUS ClfsMgmtInstallPolicy(
  PLOG_FILE_OBJECT  LogFile,
  PCLFS_MGMT_POLICY Policy,
  ULONG             PolicyLength
);
```

Parameters

`LogFile`

A pointer to a LOG_FILE_OBJECT structure that represents the CLFS log that this instance of the **CLFS_MGMT_POLICY** structure will apply to. The policy applies to all streams within the log, even if a single stream within the log was specified.

`Policy`

A pointer to a CLFS_MGMT_POLICY structure that contains the policy to be installed.

`PolicyLength`

The length, in bytes, of the structure pointed to by the *Policy* parameter.

Return Value

The **ClfsMgmtInstallPolicy** routine returns one of the following NTSTATUS values:

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	The policy has been installed.
STA TUS _IN VAL ID_ PAR AM ETE R_1	A **NULL** value was supplied for the *LogFile* parameter.

STATUS_INVALID_PARAMETER_2	A **NULL** value was supplied for the *Policy* parameter.
STATUS_INVALID_PARAMETER_3	The value of the *PolicyLength* parameter is less than the size of an instance of the CLFS_MGMT_POLICY structure.
STATUS_NOT_SUPPORTED	The **PolicyFlags** member of the **CLFS_MGMT_POLICY_STRUCTURE** pointed to by the *Policy* parameter specifies any flag other than LOG_POLICY_OVERWRITE.
STATUS_INVALID_PARAMETER	One of the following conditions is true: • The *Policy* parameter's **Version** member is not equal to CLFS_MGMT_POLICY_VERSION. • The value of the *Policy*parameter is equal to **ClfsMgmtPolicyInvalid**. • The *Policy* parameter's **PolicyFlags** member specifies any flag other than LOG_POLICY_OVERWRITE.
STATUS_LOG_POLICY_ALREADY_INSTALLED	The log already has a policy of this type, and the LOG_POLICY_OVERWRITE flag is not set.

STA **TUS** **_IN** **SUF** **FICI** **ENT** **_RE** **SO** **URC** **ES**	There is insufficient memory to complete the operation.

This routine might also return other NTSTATUS Values.

Remarks

Policies are volatile. When all handles to the log are closed, the policies will be lost. You should install policies each time you register the first client.

You should only register a **CLFS_MGMT_POLICY** structure whose **PolicyType** member is equal to **ClfsMgmtPolicyNewContainerSize** before the first container in the log is created. Any subsequent registrations are ignored.

The log policy that is installed applies to the physical log, even if the *LogFile* parameter specifies a log stream.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

CLFS_MGMT_POLICY

ClfsMgmtQueryPolicy function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsMgmtQueryPolicy** routine retrieves a specific CLFS_MGMT_POLICY structure for a log.

Syntax

```
CLFSUSER_API NTSTATUS ClfsMgmtQueryPolicy(
  PLOG_FILE_OBJECT      LogFile,
  CLFS_MGMT_POLICY_TYPE PolicyType,
  PCLFS_MGMT_POLICY     Policy,
  PULONG                PolicyLength
);
```

Parameters

`LogFile`

A pointer to a LOG_FILE_OBJECT structure that represents the CLFS log whose policy is being retrieved.

`PolicyType`

A value of the CLFS_MGMT_POLICY_TYPE enumeration that identifies the type of policy to be retrieved.

`Policy`

An instance of the CLFS_MGMT_POLICY structure that contains the policy.

`PolicyLength`

The length of the *Policy* parameter.

Return Value

The **ClfsMgmtQueryPolicy** routine returns one of the following NTSTATUS values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	CLFS management has retrieved the requested policy.
STATUS_UNSUCCESSFUL	CLFS management was not able to process the request.

STATUS_INVALID_PARAMETER	The value of the *PolicyType* parameter is not valid for the **CLFS_MGMT_POLICY_TYPE** enumeration.
STATUS_INVALID_PARAMETER_1	A **NULL** value was supplied for the *LogFile* parameter.
STATUS_INVALID_PARAMETER_2	The value of the *PolicyLength* parameter is less than the size of an instance of the **CLFS_MGMT_POLICY** structure.
STATUS_INSUFFICIENT_RESOURCES	There is insufficient memory to complete the operation.
STATUS_LOG_POLICY_NOT_INSTALLED	No policy of this type has been registered for the log file.

This routine might also return other NTSTATUS Values.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

CLFS_MGMT_POLICY

CLFS_MGMT_POLICY_TYPE

ClfsMgmtRegisterManagedClient function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsMgmtRegisterManagedClient** routine creates a client that will manage a CLFS log.

Syntax

```
CLFSUSER_API NTSTATUS ClfsMgmtRegisterManagedClient(
  PLOG_FILE_OBJECT               LogFile,
  PCLFS_MGMT_CLIENT_REGISTRATION RegistrationData,
  PCLFS_MGMT_CLIENT              ClientCookie
);
```

Parameters

`LogFile`

A pointer to a LOG_FILE_OBJECT structure that represents the CLFS log stream that the client created by **ClfsMgmtRegisterManagedClient** will manage.

`RegistrationData`

An instance of the CLFS_MGMT_CLIENT_REGISTRATION structure that contains the functions that will be used to manage the log.

`ClientCookie`

The cookie we give back to the caller for future use of the API.

Return Value

The **ClfsMgmtRegisterManagedClient** routine returns one of the following NTSTATUS values:

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	A client has been created to manage the log.
STA TUS _UN SUC CES SFU L	CLFS management was not able to create a client to manage the log.

STA TUS _IN SUF FICI ENT _RE SO URC ES	There is insufficient memory to complete the operation.
STA TUS _IN VAL ID_ PAR AM ETE R	An input parameter is invalid.

This routine might also return other NTSTATUS Values.

Remarks

The *Client* parameter that is provided by the **ClfsMgmtRegisterManagedClient** routine is a required parameter for other CLFS management functions. You should store this value for later use.

A client application must be ready for its callback routine to be called as soon as it calls the **ClfsMgmtRegisterManagedClient** routine.

More than one client can register with a log stream.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

CLFS_MGMT_CLIENT_REGISTRATION

ClfsMgmtRemovePolicy function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsMgmtRemovePolicy** routine resets a log's CLFS_MGMT_POLICY structure to its default value.

Syntax

```
CLFSUSER_API NTSTATUS ClfsMgmtRemovePolicy(
  PLOG_FILE_OBJECT      LogFile,
  CLFS_MGMT_POLICY_TYPE PolicyType
);
```

Parameters

`LogFile`

A pointer to a LOG_FILE_OBJECT structure that represents the CLFS log whose policy is being removed.

`PolicyType`

A value of the CLFS_MGMT_POLICY_TYPE enumeration that supplies the type of the policy to be removed.

Return Value

The **ClfsMgmtRemovePolicy** routine returns one of the following NTSTATUS values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	CLFS management has removed the requested policy.
STATUS_UNSUCCESSFUL	CLFS management was not able to process the request.

STATUS_INVALID_PARAMETER_1	A **NULL** value was supplied for the *LogFile* parameter.
STATUS_INSUFFICIENT_RESOURCES	There is insufficient memory to complete the operation.
STATUS_INVALID_PARAMETER	The value of the *PolicyType* parameter is not a valid value for the **CLFS_MGMT_POLICY_TYPE** enumeration.
STATUS_LOG_POLICY_NOT_INSTALLED	No policy of this type has been registered for the log file.

This routine might also return other NTSTATUS Values.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

CLFS_MGMT_POLICY

CLFS_MGMT_POLICY_TYPE

ClfsMgmtSetLogFileSize function

1/25/2019 • 3 minutes to read • Edit Online

The **ClfsMgmtSetLogFileSize** routine adds containers to a log or deletes containers from a log.

Syntax

```
CLFSUSER_API NTSTATUS ClfsMgmtSetLogFileSize(
  PLOG_FILE_OBJECT                    LogFile,
  PULONGLONG                          NewSizeInContainers,
  PULONGLONG                          ResultingSizeInContainers,
  PCLFS_SET_LOG_SIZE_COMPLETE_CALLBACK CompletionRoutine,
  PVOID                               CompletionRoutineData
);
```

Parameters

`LogFile`

A pointer to a LOG_FILE_OBJECT structure that represents the CLFS log, or a stream within the log, to which containers are being added or deleted.

`NewSizeInContainers`

A pointer to the requested log size. The caller sets this parameter to one of the following values.

VALUE	MEANING
0	Enforce the minimum size policy. For more information about this policy, see ClfsMgmtInstallPolicy. If a minimum size policy is not installed, one of the following occurs: • If the log currently has less than 2 containers, the log will be expanded to a size of 2 containers. • If the log currently has 2 or more containers, no changes are made and the call succeeds. If a minimum size policy is installed, one of the following occurs: • If the log currently has less than the minimum number of containers specified by the minimum size policy, the log expands to the policy-specified minimum number of containers. • If the number of containers in the log is greater than or equal to the minimum number of containers specified by the minimum size policy, no changes are made and the call succeeds with no error.
1	Invalid value. The call fails and returns STATUS_INVALID_VALUE.

2 to 1023	The desired size of the log, expressed as the number of containers. If this number is smaller than the minimum number of containers specified by the installed policy, the call fails with ERROR_COULD_NOT_RESIZE_LOG. If this number is larger than the maximum number of containers specified by the installed policy, the log expands only as far as the policy-specified maximum number of containers, and the call succeeds with no error.
1024 to MAXULONGLONG	If no maximum size policy is installed, the call fails and returns ERROR_LOG_POLICY_CONFLICT. If a maximum size policy is installed, the log expands to the maximum number of containers specified by the maximum size policy and the call succeeds with no error.

To determine the actual log size, which might be different from the requested size, use the *ResultingSizeInContainers* parameter.

`ResultingSizeInContainers`

A pointer to the resulting log size. If successful, the routine writes the actual size of the log, expressed as the number of containers in the log, to the location pointed to by this parameter.

`CompletionRoutine`

Not used. Set to NULL.

`CompletionRoutineData`

Not used. Set to NULL.

Return Value

The **ClfsMgmtSetLogFileSize** routine returns one of the following NTSTATUS values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The log file size has been set. The *ResultingSizeInContainers* parameter contains the current size of the log.
STATUS_UNSUCCESSFUL	CLFS management was not able to set the log file size.

STATUS_INVALID_PARAMETER_1	The value of the *LogFile* parameter is **NULL**, or the contents of the *NewSizeInContainers* parameter is 1.
STATUS_INVALID_PARAMETER_2	The value of the *NewSizeInContainers* parameter is **NULL**.
STATUS_LOG_POLICY_INVALID	There is a conflict between the maximum size and minimum size policies for the log.
STATUS_COULD_NOT_RESIZE_LOG	CLFS management could not delete enough containers to reach *NewSizeInContainers*.
STATUS_LOG_POLICY_CONFLICT	CLFS management could not add enough containers to the log to reach *NewSizeInContainers*. This might be due to a conflict with a policy that the client set.

This routine might also return other NTSTATUS Values.

Remarks

The **ClfsMgmtSetLogFileSize** routine is typically used only when a client starts or stops. Do not call the **ClfsMgmtSetLogFileSize** routine from within your ClfsAdvanceTailCallback function.

Requirements

Minimum supported client	Available starting with Windows Server 2003 R2 and Windows Vista.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

See Also

CLFS_MGMT_POLICY_TYPE

ClfsMgmtInstallPolicy

ClfsMgmtSetLogFileSizeAsClient function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsMgmtSetLogFileSizeAsClient** routine sets the log file size by adding containers to a client log or deleting containers from a client log.

Syntax

```
CLFSUSER_API NTSTATUS ClfsMgmtSetLogFileSizeAsClient(
  PLOG_FILE_OBJECT                    LogFile,
  PCLFS_MGMT_CLIENT                   ClientCookie,
  PULONGLONG                          NewSizeInContainers,
  PULONGLONG                          ResultingSizeInContainers,
  PCLFS_SET_LOG_SIZE_COMPLETE_CALLBACK CompletionRoutine,
  PVOID                               CompletionRoutineData
);
```

Parameters

`LogFile`

A pointer to a LOG_FILE_OBJECT structure that represents the Common Log File System (CLFS) log, or a stream within the log, to which containers are being added or deleted. The value of this parameter is obtained through a call to the ClfsCreateLogFile routine.

`ClientCookie`

A pointer to a client-supplied cookie. The value of this parameter should be the **CLFS_MGMT_CLIENT** structure that is obtained through a call to the ClfsMgmtRegisterManagedClient routine.

`NewSizeInContainers`

The desired size of the log, expressed in the number of containers. There can be at most 1,024 containers for a log file.

`ResultingSizeInContainers`

The actual size of the log, expressed in the number of containers.

`CompletionRoutine`

Not used.

`CompletionRoutineData`

Not used.

Return Value

The **ClfsMgmtSetLogFileSizeAsClient** routine returns an NTSTATUS value.

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	The log file size has been set.
STATUS_INVALID_PARAMETER_1	The value of the *LogFile* parameter is **NULL**, or the contents of the *NewSizeInContainers* parameter is 1.
STATUS_INVALID_PARAMETER_2	The value of the *NewSizeInContainers* parameter is **NULL**.
STATUS_LOG_POLICY_INVALID	The installed set of policies on the log is invalid. This might be due to an invalid ClfsMgmtPolicyAutoShrink policy or ClfsMgmtPolicyMaximumSize policy.
STATUS_COULD_NOT_RESIZE_LOG	CLFS management could not delete enough containers to reach the value in *NewSizeInContainers*.

STA TUS _LO G_P OLI CY_ CO NFL ICT	A policy on the specified log prevented the operation from completing. This may occur if CLFS management could not add enough containers to the log to reach the value in *NewSizeInContainers*. This might be due to a conflict with a policy that the client set.

This routine might also return other NTSTATUS values.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Desktop
Header	wdm.h
DLL	Clfs.sys

See Also

CLFS Management Library Routines

ClfsMgmtTailAdvanceFailure function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsMgmtTailAdvanceFailure** routine notifies CLFS management that the client could not advance the log's tail.

Syntax

```
CLFSUSER_API NTSTATUS ClfsMgmtTailAdvanceFailure(
  CLFS_MGMT_CLIENT Client,
  NTSTATUS         Reason
);
```

Parameters

`Client`

A pointer to the client. This is the value that was obtained through a call to the ClfsMgmtRegisterManagedClient routine.

`Reason`

A value that indicates why the log's tail could not be advanced.

Return Value

The **ClfsMgmtTailAdvanceFailure** routine returns one of the following NTSTATUS values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	CLFS management has processed the notification that the log's tail could not be advanced.
STATUS_INVALID_PARAMETER	A **NULL** value was supplied for the *Client* parameter.

STA **TUS** **_IN** **VAL** **ID_** **PAR** **AM** **ETE** **R_1**	The value that was supplied for the *Client* parameter does not represent a valid client.

Remarks

If a client cannot advance its log's tail to or beyond the requested LSN, then the client must call the **ClfsMgmtTailAdvanceFailure** routine to indicate that it is not able to advance its tail. Until the client either moves its tail as requested or calls the **ClfsMgmtTailAdvanceFailure** routine, the client will not receive any further requests to move its tail.

The value of the *Reason* parameter is passed back to the client as the value of the *OperationStatus* parameter when the ClfsLogGrowthCompleteCallback function is invoked.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

ClfsMgmtRegisterManagedClient

ClfsQueryLogFileInformation function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsQueryLogFileInformation** routine returns metadata and state information for a specified CLFS stream or its underlying physical log or both.

Syntax

```
CLFSUSER_API NTSTATUS ClfsQueryLogFileInformation(
  PLOG_FILE_OBJECT           plfoLog,
  CLFS_LOG_INFORMATION_CLASS eInformationClass,
  PVOID                      pinfoInputBuffer,
  ULONG                      cbinfoInputBuffer,
  PVOID                      pinfoBuffer,
  PULONG                     pcbInfoBuffer
);
```

Parameters

`plfoLog`

A pointer to a LOG_FILE_OBJECT structure that represents a CLFS stream. The caller previously obtained this pointer by calling ClfsCreateLogFile.

`eInformationClass`

A value from the CLFS_LOG_INFORMATION_CLASS enumeration that specifies the type of information being requested.

`pinfoInputBuffer`

Optional input buffer which is required for some information classes.

`cbinfoInputBuffer`

Length in bytes of pinfoInputBuffer.

`pinfoBuffer`

A pointer to a buffer that receives the log information. The structure of this buffer depends on the value of *eInformationClass*. The following table shows the relationship between the information class and the data type of the buffer.

VALUE OF *EINFORMATIONCLASS*	TYPE OF BUFFER POINTED TO BY *PINFOBUFFER*
ClfsLogBasicInformation	CLFS_INFORMATION
ClfsLogBasicInformationPhysical	CLFS_INFORMATION
ClfsLogNameInformation	CLFS_LOG_NAME_INFORMATION
ClfsLogPhysicalNameInformation	CLFS_LOG_NAME_INFORMATION

ClfsLogStreamIdentifierInformation	CLFS_STREAM_ID_INFORMATION

`pcbInfoBuffer`

Length in bytes of the incoming information buffer.

Return Value

ClfsQueryLogFileInformation returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

ClfsSetLogFileInformation

ClfsReadLogRecord function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsReadLogRecord** routine reads a target record in a CLFS stream and returns a read context that the caller can use to read the records preceding or following it in the stream.

Syntax

```
CLFSUSER_API NTSTATUS ClfsReadLogRecord(
  PVOID             pvMarshalContext,
  PCLFS_LSN         plsnFirst,
  CLFS_CONTEXT_MODE peContextMode,
  PVOID             *ppvReadBuffer,
  PULONG            pcbReadBuffer,
  PCLFS_RECORD_TYPE peRecordType,
  PCLFS_LSN         plsnUndoNext,
  PCLFS_LSN         plsnPrevious,
  PVOID             *ppvReadContext
);
```

Parameters

`pvMarshalContext`

A pointer to an opaque context that represents a marshalling area. The caller previously obtained this pointer by calling ClfsCreateMarshallingArea.

`plsnFirst`

A pointer to a CLFS_LSN structure that supplies the LSN of the target record in the log.

`peContextMode`

A value from the CLFS_CONTEXT_MODE enumeration that specifies the initial mode (ClfsContextUndoNext, ClfsContextPrevious, or ClfsContextForward) of the read context returned in *ppvReadContext*.

`ppvReadBuffer`

A pointer to a variable that receives a pointer to the data buffer of the target record.

`pcbReadBuffer`

A pointer to a ULONG-typed variable that receives the size, in bytes, of the buffer pointed to by **ppvReadBuffer*. This is the length of the data buffer of the target record.

`peRecordType`

A pointer to a variable of type CLFS_RECORD_TYPE that receives one of the following values.

VALUE	MEANING
ClfsDataRecord	The target record is a data record.
ClfsRestartRecord	The target record is a restart record.

`plsnUndoNext`

A pointer to a **CLFS_LSN** structure that receives the undo-next LSN of the target record.

`plsnPrevious`

A pointer to a **CLFS_LSN** structure that receives the previous LSN of the target record.

`ppvReadContext`

A pointer to a variable that receives a pointer to an opaque read context. The client repeatedly passes this context to ClfsReadNextLogRecord to read the remaining records in a sequence. After the client has read all the records in the sequence, it calls ClfsTerminateReadLog to free the read context.

Return Value

ClfsReadLogRecord returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

You must call **ClfsTerminateReadLog** when you have finished using the read context in order to avoid a memory leak.

For an explanation of CLFS concepts and terminology, see Common Log File System.

For information about reading records from CLFS streams, see Reading Data Records from a CLFS Stream and Reading Restart Records from a CLFS Stream.

Read contexts are not thread-safe. Clients are responsible for serializing access to read contexts.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

ClfsReadNextLogRecord

ClfsTerminateReadLog

ClfsReadNextLogRecord function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsReadNextLogRecord** routine reads the next record in a sequence, relative to the current record in a read context.

Syntax

```
CLFSUSER_API NTSTATUS ClfsReadNextLogRecord(
  PVOID             pvReadContext,
  PVOID             *ppvBuffer,
  PULONG            pcbBuffer,
  PCLFS_RECORD_TYPE peRecordType,
  PCLFS_LSN         plsnUser,
  PCLFS_LSN         plsnUndoNext,
  PCLFS_LSN         plsnPrevious,
  PCLFS_LSN         plsnRecord
);
```

Parameters

`pvReadContext`

A pointer to a read context that the caller previously obtained by calling ClfsReadLogRecord or ClfsReadRestartArea.

`ppvBuffer`

A pointer to a variable that receives a pointer to a buffer that contains the record data.

`pcbBuffer`

A pointer to a ULONG-typed variable that receives the size, in bytes, of the buffer pointed to by **ppvBuffer*. This is the length of the data buffer of the record read.

`peRecordType`

A pointer to a variable of type CLFS_RECORD_TYPE. The caller must set this parameter to one of the following values.

VALUE	RECORD THAT WILL BE READ
ClfsDataRecord	The next data record.
ClfsRestartRecord	The next restart record.
ClfsClientRecord	The next record that is either a data record or a restart record.

`plsnUser`

A pointer to a CLFS_LSN structure that supplies the LSN of the record to be read. The specified record is read instead of the record that would have been read according to the mode (**ClfsContextUndoNext**, **ClfsContextPrevious**, or **ClfsContextForward**) of the read context (*pvReadContext*). The LSN supplied in

plsnUser must be less than the current LSN of the read context. This parameter can be **NULL**.

`plsnUndoNext`

A pointer to a **CLFS_LSN** structure that receives the undo-next LSN of the record that is read.

`plsnPrevious`

A pointer to a **CLFS_LSN** structure that receives the previous LSN of the record that was read.

`plsnRecord`

A pointer to a **CLFS_LSN** structure that receives the LSN of the record that was read.

Return Value

ClfsReadNextLogRecord returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

For an explanation of CLFS concepts and terminology, see Common Log File System.

For information about reading records from CLFS streams, see Reading Data Records from a CLFS Stream and Reading Restart Records from a CLFS Stream.

Read contexts are not thread-safe. Clients are responsible for serializing access to read contexts.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

See Also

CLFS_LSN

ClfsReadLogRecord

ClfsReadRestartArea

ClfsReadPreviousRestartArea function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsReadPreviousRestartArea** routine reads the previous restart record relative to the current record in a read context.

Syntax

```
CLFSUSER_API NTSTATUS ClfsReadPreviousRestartArea(
  PVOID     pvReadContext,
  PVOID     *ppvRestartBuffer,
  PULONG    pcbRestartBuffer,
  PCLFS_LSN plsnRestart
);
```

Parameters

`pvReadContext`

A pointer to a read context obtained by a previous call to ClfsReadRestartArea.

`ppvRestartBuffer`

A pointer to a variable that receives a pointer to the data buffer of the restart record that is read.

`pcbRestartBuffer`

A pointer to a ULONG-typed variable that receives the size, in bytes, of the buffer pointed to by **ppvRestartBuffer*. This is the length of the data buffer of the restart record that is read.

`plsnRestart`

A pointer to a CLFS_LSN structure that receives the previous LSN of the restart record that was read.

Return Value

ClfsReadPreviousRestartArea returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h. If there are no previous restart areas, the return value is STATUS_LOG_START_OF_LOG.

Remarks

For an explanation of CLFS concepts and terminology, see Common Log File System.

For information about reading records from CLFS streams, see Reading Data Records from a CLFS Stream and Reading Restart Records from a CLFS Stream.

Read contexts are not thread-safe. Clients are responsible for serializing access to read contexts.

Clients append restart records to a CLFS log by calling ClfsWriteRestartArea.

With the **ReadPreviousLogRestartArea** routine, clients can implement a form of fuzzy checkpointing. For example, the checkpoint state could consist of the log records delimited by two or more restart records.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

CLFS_LSN

ClfsReadRestartArea

ClfsWriteRestartArea

ClfsReadRestartArea function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsReadRestartArea** routine reads the restart record that was most recently written to a specified CLFS stream.

Syntax

```
CLFSUSER_API NTSTATUS ClfsReadRestartArea(
  PVOID     pvMarshalContext,
  PVOID     *ppvRestartBuffer,
  PULONG    pcbRestartBuffer,
  PCLFS_LSN plsn,
  PVOID     *ppvReadContext
);
```

Parameters

`pvMarshalContext`

A pointer to an opaque context that represents a marshalling area associated with a CLFS stream. The caller previously obtained this pointer by calling ClfsCreateMarshallingArea.

`ppvRestartBuffer`

A pointer to a variable that receives a pointer to the data buffer of the restart record.

`pcbRestartBuffer`

A pointer to a ULONG-typed variable that receives the size, in bytes, of the data buffer pointed to by *pcbRestartBuffer*. This is the length of the data buffer of the restart record.

`plsn`

A pointer to a CLFS_LSN structure that receives the LSN of the restart record that was read.

`ppvReadContext`

A pointer to a variable that receives a pointer to an opaque read context. The caller can pass this context to ClfsReadPreviousRestartArea or ClfsReadNextLogRecord. When the caller has finished using the read context, it must free the context by calling ClfsTerminateReadLog.

Return Value

ClfsReadRestartArea returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

For an explanation of CLFS concepts and terminology, see Common Log File System.

For information about reading records from CLFS streams, see Reading Data Records from a CLFS Stream and Reading Restart Records from a CLFS Stream.

Read contexts are not thread-safe. Clients are responsible for serializing access to read contexts.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop

ClfsReadPreviousRestartArea

ClfsTerminateReadLog

ClfsRemoveLogContainer function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsRemoveLogContainer** routine removes a container from a CLFS log.

Syntax

```
CLFSUSER_API NTSTATUS ClfsRemoveLogContainer(
  PLOG_FILE_OBJECT plfoLog,
  PUNICODE_STRING  puszContainerPath,
  BOOLEAN          fForce
);
```

Parameters

`plfoLog`

A pointer to a LOG_FILE_OBJECT structure that represents a CLFS log from which the container will be removed. The caller previously obtained this pointer by calling ClfsCreateLogFile.

`puszContainerPath`

A pointer to a UNICODE_STRING structure that supplies the path name for the container to be removed. The path name was created in a previous call to ClfsAddLogContainer or ClfsAddLogContainerSet. The path can be absolute or relative to the location of the base log file for the CLFS log that is represented by *plfoLog*. Paths that are relative to the base log file must begin with CLFS_CONTAINER_RELATIVE_PREFIX, which is the string literal (L"%BLF%\"). The directories "." and ".." are not allowed in a relative path.

`fForce`

A Boolean value that specifies whether the container removal is forced (**TRUE**) or lazy (**FALSE**).

Return Value

ClfsRemoveLogContainer returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

Forced container removal (*fForce* = **TRUE**) succeeds only if the container to be removed is not part of the active log.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.

Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys

LOG_FILE_OBJECT

UNICODE_STRING

ClfsRemoveLogContainerSet function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsRemoveLogContainerSet** routine atomically removes a set of containers from a CLFS log.

Syntax

```
CLFSUSER_API NTSTATUS ClfsRemoveLogContainerSet(
  PLOG_FILE_OBJECT plfoLog,
  USHORT           cContainers,
  PUNICODE_STRING  rgwszContainerPath,
  BOOLEAN          fForce
);
```

Parameters

`plfoLog`

A pointer to a LOG_FILE_OBJECT structure that represents the CLFS log from which the containers will be removed. The caller previously obtained this pointer by calling ClfsCreateLogFile.

`cContainers`

The number of containers in the set. This is the number of elements in the *rgwszContainerPath* array.

`rgwszContainerPath`

A pointer to an array of UNICODE_STRING structures, each of which supplies the path name for one of the containers to be removed. The number of elements in the array is given by *cContainers*. A given path can be absolute or relative to the location of the base log file for the CLFS log represented by *plfoLog*. Paths that are relative to the base log file must begin with CLFS_CONTAINER_RELATIVE_PREFIX, which is the string literal (L"%BLF%\"). The directories "." and ".." are not allowed in a relative path.

`fForce`

A Boolean value that specifies whether the container removal is forced (**TRUE**) or lazy (**FALSE**).

Return Value

ClfsRemoveLogContainerSet returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

Forced container removal (*fForce* = **TRUE**) succeeds only if the containers to be removed are not part of the active log.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)

LOG_FILE_OBJECT

UNICODE_STRING

ClfsReserveAndAppendLog function

1/25/2019 • 3 minutes to read • Edit Online

The **ClfsReserveAndAppendLog** routine reserves space in a marshalling area or appends a record to a marshalling area or does both atomically.

Syntax

```
CLFSUSER_API NTSTATUS ClfsReserveAndAppendLog(
  PVOID             pvMarshalContext,
  PCLFS_WRITE_ENTRY rgWriteEntries,
  ULONG             cWriteEntries,
  PCLFS_LSN         plsnUndoNext,
  PCLFS_LSN         plsnPrevious,
  ULONG             cReserveRecords,
  PLONGLONG         rgcbReservation,
  ULONG             fFlags,
  PCLFS_LSN         plsn
);
```

Parameters

`pvMarshalContext`

A pointer to an opaque context that represents a marshalling area associated with a CLFS stream. The caller previously obtained this pointer by calling ClfsCreateMarshallingArea.

`rgWriteEntries`

A pointer to an array of CLFS_WRITE_ENTRY structures, each of which holds a pointer to a buffer of data that will become part of the record that is appended to the log. This parameter can be **NULL** if *cWriteEntries* is zero.

`cWriteEntries`

The number of elements in the array pointed to by *rgWriteEntries*. This parameter must be zero if *rgWriteEntries* is **NULL**.

`plsnUndoNext`

A pointer to a CLFS_LSN structure that supplies the undo-next LSN of the record to be appended.

`plsnPrevious`

A pointer to a CLFS_LSN structure that supplies the previous LSN of the record to be appended.

`cReserveRecords`

The number of elements in the array pointed to by *rgcbReservation*. This parameter must be zero if *rgcbReservation* is **NULL** or the CLFS_FLAG_USE_RESERVATION flag of *fFlags* is set.

`rgcbReservation`

A pointer to an array of LONGLONG-typed variables. The caller sets each element of the array to the size, in bytes, of a record that must have space reserved for it. On return, each array element receives that actual size of the space reserved for the record. This includes the space required for headers and alignment. If the reservation value is

negative, a reserved record that most nearly matches the absolute value of the provided negative value will be freed. This parameter can be **NULL** if *cReserveRecords* is zero and must be **NULL** if the CLFS_FLAG_USE_RESERVATION flag of *fFlags* is set.

`fFlags`

This parameter can be zero or any combination of the following flags.

FLAG	MEANING
CLFS_FLAG_FORCE_APPEND	After the current record is appended to a log I/O block, the block is queued, in LSN sequence, to stable storage. This flag provides no guarantee that the record is forced to stable storage (see CLFS_FLAG_FORCE_FLUSH).
CLFS_FLAG_FORCE_FLUSH	After the current record is appended to a log I/O block, the block is forced to stable storage.
CLFS_FLAG_USE_RESERVATION	The current record is placed in reserved space in a log I/O block within the marshalling area. The number of reserved records in the marshalling area is reduced by one. If this flag is set, *cReserveRecords* must be zero and *rgcbReservation* must be **NULL**.

`plsn`

A pointer to a CLFS_LSN structure that receives the LSN of the appended record. This parameter can be **NULL** if *cWriteEntries* is zero.

Return Value

ClfsReserveAndAppendLog returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

The **ClfsReserveAndAppendLog** routine changes its fundamental behavior based on the presence of optional parameters and the state of the CLFS_USE_RESERVATION flag. The following table summarizes common scenarios.

PARAMETER AND FLAG VALUES	ACTIONS PERFORMED
cWriteEntries = 0. *rgWriteEntries* = **NULL**. *plsn* = **NULL**.	Reserves space for a set of records, but does not append the records to the marshalling area. The *rgcbReservation* parameter gives the size of the data portion of each record that needs space reserved.
cWriteEntries > 0. *rgWriteEntries* is not **NULL**. *plsn* is not **NULL**. *cReserveRecords* = 0. *rgcbReservation* is **NULL**. CLFS_USE_RESERVATION is set.	Appends a record to the marshalling area by using space that has already been reserved. Reduces the number of reserved record spaces by one.
cWriteEntries > 0. *rgWriteEntries* is not **NULL**. *plsn* is not **NULL**. *cReserveRecords* = 0. *rgcbReservation* is **NULL**. CLFS_USE_RESERVATION is cleared.	Appends a record to the marshalling area by reserving new space. Leaves the number of reserved record spaces unchanged.

cWriteEntries > 0. *rgWriteEntries* is not **NULL**. *plsn* is not **NULL**. *cReserveRecords* > 0. rgcbReservation is not **NULL**. CLFS_USE_RESERVATION flag is cleared.	Appends a record to the marshalling area by reserving new space. Also reserves space for a set of records that are not appended at this time. The *rgcbReservation* parameter gives the size of each record that needs space reserved. Increases the number of reserved record spaces by the value of *cReserveRecords*.

Calling **ClfsReserveAndAppendLog** is equivalent to calling ClfsReserveAndAppendLogAligned with the *cbEntryAlignment* parameter set to one.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

CLFS_LSN

CLFS_WRITE_ENTRY

ClfsCreateMarshallingArea

ClfsReserveAndAppendLogAligned

ClfsReserveAndAppendLogAligned function

1/25/2019 • 4 minutes to read • Edit Online

The **ClfsReserveAndAppendLogAligned** routine reserves space in a marshalling area or appends a record to a marshalling area or does both atomically. The record's data is aligned on specified boundaries.

Syntax

```
CLFSUSER_API NTSTATUS ClfsReserveAndAppendLogAligned(
  PVOID             pvMarshalContext,
  PCLFS_WRITE_ENTRY rgWriteEntries,
  ULONG             cWriteEntries,
  ULONG             cbEntryAlignment,
  PCLFS_LSN         plsnUndoNext,
  PCLFS_LSN         plsnPrevious,
  ULONG             cReserveRecords,
  PLONGLONG         rgcbReservation,
  ULONG             fFlags,
  PCLFS_LSN         plsn
);
```

Parameters

`pvMarshalContext`

A pointer to an opaque context that represents a marshalling area associated with a CLFS stream. The caller previously obtained this pointer by calling ClfsCreateMarshallingArea.

`rgWriteEntries`

A pointer to an array of CLFS_WRITE_ENTRY structures, each of which holds a pointer to a buffer of data that will become part of the record that is appended to the log. This parameter can be **NULL** if *cWriteEntries* is zero.

`cWriteEntries`

The number of elements in the array pointed to by *rgWriteEntries*. This parameter must be zero if *rgWriteEntries* is **NULL**.

`cbEntryAlignment`

The byte alignment of the data entries pointed to by *rgWriteEntries* as they are marshaled into a single record. A value of one specifies simple concatenation (see ClfsReserveAndAppendLog). A value larger than one can result in zeros being placed between entries in the record. The value of this parameter must be greater than zero.

`plsnUndoNext`

A pointer to a CLFS_LSN structure that supplies the undo-next LSN of the record to be appended.

`plsnPrevious`

A pointer to a CLFS_LSN structure that supplies the previous LSN of the record to be appended.

`cReserveRecords`

The number of elements in the array pointed to by *rgcbReservation*. This parameter must be zero if

rgcbReservation is **NULL** or the CLFS_FLAG_USE_RESERVATION flag of *fFlags* is set.

`rgcbReservation`

A pointer to an array of LONGLONG-typed variables. The caller sets each element of the array to the size, in bytes, of a record that must have space reserve for it. On return, each array element receives that actual size of the space reserved for the record. This includes the space required for headers and alignment. If the reservation value is negative, a reserved record that most nearly matches the absolute value of the provided negative value will be freed. This parameter can be **NULL** if *cReserveRecords* is zero and must be **NULL** if the CLFS_FLAG_USE_RESERVATION flag of *fFlags* is set.

`fFlags`

This parameter can be any combination of the following flags.

FLAG	MEANING
CLFS_FLAG_FORCE_APPEND	After the current record is appended to a log I/O block, the block is queued, in LSN sequence, to stable storage. This flag provides no guarantee that the record is forced to stable storage (see CLFS_FLAG_FORCE_FLUSH).
CLFS_FLAG_FORCE_FLUSH	After the current record is appended to a log I/O block, the block is forced to stable storage.
CLFS_FLAG_USE_RESERVATION	The current record is placed in reserved space in an I/O block. The number of reserved records in the marshalling area is reduced by one. If this flag is set, *cReserveRecords* must be zero and *rgcbReservation* must be **NULL**.

`plsn`

A pointer to a CLFS_LSN structure that receives the LSN of the appended record. This parameter can be **NULL** if *cWriteEntries* is zero.

Return Value

ClfsReserveAndAppendLogAligned returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

The **ClfsReserveAndAppendLogAligned** routine changes its fundamental behavior based on the presence of optional parameters and the state of the CLFS_USE_RESERVATION flag. The following table summarizes common scenarios.

PARAMETER AND FLAG VALUES	ACTIONS PERFORMED
cWriteEntries = 0. *rgWriteEntries* = **NULL**. *plsn* = **NULL**.	Reserves space for a set of records, but does not append the records to the marshalling area. The *rgcbReservation* parameter gives the size of the data portion of each record that needs space reserved.
cWriteEntries > 0. *rgWriteEntries* is not **NULL**. *plsn* is not **NULL**. *cReserveRecords* = 0. *rgcbReservation* is **NULL**. CLFS_USE_RESERVATION is set.	Appends a record to the marshalling area by using space that has already been reserved. Reduces the number of reserved record spaces by one.

cWriteEntries > 0. *rgWriteEntries* is not **NULL**. *plsn* is not **NULL**. *cReserveRecords* = 0. *rgcbReservation* is **NULL**. CLFS_USE_RESERVATION is cleared.	Appends a record to the marshalling area by reserving new space. Leaves the number of reserved record spaces unchanged.
cWriteEntries > 0. *rgWriteEntries* is not **NULL**. *plsn* is not **NULL**. *cReserveRecords* > 0. *rgcbReservation* is not **NULL**. CLFS_USE_RESERVATION flag is cleared.	Appends a record to the marshalling area by reserving new space. Also reserves space for a set of records that are not appended at this time. The *rgcbReservation* parameter gives the size of each record that needs space reserved. Increases the number of reserved record spaces by the value of *cReserveRecords*.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)

CLFS_WRITE_ENTRY

ClfsCreateMarshallingArea

ClfsReserveAndAppendLog

ClfsScanLogContainers function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsScanLogContainers** routine retrieves descriptive information for a sequence of containers that belong to a particular CLFS log.

Syntax

```
CLFSUSER_API NTSTATUS ClfsScanLogContainers(
  PCLFS_SCAN_CONTEXT pcxScan,
  CLFS_SCAN_MODE     eScanMode
);
```

Parameters

`pcxScan`

A pointer to a CLFS_SCAN_CONTEXT structure. The caller previously allocated the structure and initialized it by calling ClfsCreateScanContext. In particular, the **pInfoContainer** member was initialized to point to an array of CLFS_CONTAINER_INFORMATION structures, and the **cContainers** member was initialized to the number of elements in the array. On return, the structures in the array receive descriptive information for the containers in the sequence.

`eScanMode`

A set of flags that specify the direction of the scan and whether the scan context should be closed. The following flags are available to callers of this routine.

VALUE	MEANING
CLFS_SCAN_FORWARD	Scan in the forward direction. For example, if container 5 is the most recently scanned container and *pxcScan*->**cContainers** is equal to two, this routine will return descriptors for containers 6 and 7.
CLFS_SCAN_BACKWARD	Scan in the backward direction. For example, if container 5 is the most recently scanned container and *pxcScan*->**cContainers** is equal to two, this routine will return descriptors for containers 4 and 3.
CLFS_SCAN_CLOSE	Free all resources associated with the scan context pointed to by *pcxScan*.

If the CLFS_SCAN_CLOSE flag is set, both the CLFS_SCAN_FORWARD and CLFS_SCAN_BACKWARD flags must be clear.

If the CLFS_SCAN_CLOSE flag is clear, only one of the direction flags (CLFS_SCAN_FORWARD or CLFS_SCAN_BACKWARD) must be set.

Return Value

ClfsScanLogContainers returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes

defined in Ntstatus.h.

Remarks

CLFS uses the CLFS_SCAN_CONTEXT structure to track where a container scan starts (the **cIndex** member) and how many containers are scanned in each call to **ClfsScanLogContainers**. The value N of the **cContainers** member specifies that each time **ClfsScanLogContainers** is called, the next N containers are scanned.

The **cContainersReturned** member of the **CLFS_SCAN_CONTEXT** structure receives the number of containers actually scanned in a single call to **ClfsScanLogContainers**.

When **ClfsScanLogContainers** returns STATUS_NO_MORE_ENTRIES, there are no more containers to be scanned.

When you have finished using the scan context pointed to by *pcxScan*, you must call **ClfsScanLogContainers**, with *eScanMode* equal to CLFS_SCAN_CLOSE, to free any resources associated with the scan context.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.

ClfsCreateScanContext

ClfsSetArchiveTail function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsSetArchiveTail** routine sets the archive tail of a CLFS log to a specified LSN.

Syntax

```
CLFSUSER_API NTSTATUS ClfsSetArchiveTail(
  PLOG_FILE_OBJECT plfoLog,
  PCLFS_LSN        plsnArchiveTail
);
```

Parameters

`plfoLog`

A pointer to a LOG_FILE_OBJECT structure that represents a CLFS log. The caller previously obtained this pointer by calling ClfsCreateLogFile.

`plsnArchiveTail`

A pointer to a CLFS_LSN structure that specifies the LSN that is to become the new archive tail. This must be the exact LSN of a record in the log.

Return Value

ClfsSetArchiveTail returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

The *plsnArchiveTail* value specifies where archiving starts in the log. The next archiving will start at or before this LSN.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys

ClfsAdvanceLogBase

ClfsCreateLogFile

ClfsSetEndOfLog

LOG_FILE_OBJECT

ClfsSetEndOfLog function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsSetEndOfLog** routine truncates a CLFS stream.

Syntax

```
CLFSUSER_API NTSTATUS ClfsSetEndOfLog(
  PLOG_FILE_OBJECT plfoLog,
  PCLFS_LSN        plsnEnd
);
```

Parameters

`plfoLog`

A pointer to a LOG_FILE_OBJECT structure that represents a CLFS stream. This stream must be the only stream of a dedicated log. The caller previously obtained this pointer by calling ClfsCreateLogFile.

`plsnEnd`

A pointer to a CLFS_LSN structure that supplies the LSN of the record that is to become the last record of the stream. This must be the exact LSN of one of the records in the stream.

Return Value

ClfsSetEndOfLog returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

The LSN supplied in the *plsnEnd* value is not validated. It is the responsibility of the caller to provide a valid LSN; that is, one that is the exact LSN of a record in the stream.

This stream represented by *plfoLog* must be from a dedicated log. This routine does not support streams from multiplexed logs.

For an explanation of CLFS concepts and terminology, see Common Log File System.

The kernel-mode routine **ClfsSetEndOfLog** is reserved for future use and currently always returns STATUS_NOT_SUPPORTED. However, the user-mode routine **SetEndOfLog** is currently supported.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop

Header	wdm.h (include Wdm.h)

LOG_FILE_OBJECT

ClfsSetLogFileInformation function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsSetLogFileInformation** routine sets metadata and state information for a specified stream and its underlying physical log.

Syntax

```
CLFSUSER_API NTSTATUS ClfsSetLogFileInformation(
  PLOG_FILE_OBJECT           plfoLog,
  CLFS_LOG_INFORMATION_CLASS eInformationClass,
  PVOID                      pinfoBuffer,
  ULONG                      cbBuffer
);
```

Parameters

`plfoLog`

A pointer to a LOG_FILE_OBJECT structure that represents a CLFS stream. The caller previously obtained this pointer by calling ClfsCreateLogFile.

`eInformationClass`

A CLFS_LOG_INFORMATION_CLASS value that specifies the class of information being set.

`pinfoBuffer`

A pointer to a buffer that supplies the log information. The structure of this buffer varies according to the class of information specified by *eInformationClass*. The following table shows the relationship between the information class and the buffer type.

VALUE OF EINFORMATIONCLASS	TYPE OF BUFFER POINTED TO BY *PINFOBUFFER*
ClfsLogBasicInformation	CLFS_INFORMATION
ClfsLogBasicInformationPhysical	CLFS_INFORMATION
ClfsLogNameInformation	CLFS_LOG_NAME_INFORMATION
ClfsLogPhysicalNameInformation	CLFS_LOG_NAME_INFORMATION
ClfsLogStreamIdentifierInformation	CLFS_STREAM_ID_INFORMATION

`cbBuffer`

The size, in bytes, of the buffer pointed to by *pinfoBuffer*.

Return Value

ClfsSetLogFileInformation returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys

LOG_FILE_OBJECT

ClfsTerminateReadLog function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsTerminateReadLog** routine invalidates a specified read context after freeing resources associated with the context.

Syntax

```
CLFSUSER_API NTSTATUS ClfsTerminateReadLog(
  PVOID pvCursorContext
);
```

Parameters

`pvCursorContext`

A pointer to the read context to be invalidated. The caller previously obtained this pointer by calling ClfsReadLogRecord or ClfsReadRestartArea.

Return Value

ClfsTerminateReadLog returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

> **Warning** Failure to call this routine can lead to memory leaks, premature exhaustion of log I/O blocks, and increased frequency of log flushes.
>
> Attempting to use *pvCursorContext* after it is freed is equivalent to accessing freed memory and can lead to unexpected behavior.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys

IRQL	"<= APC_LEVEL"

ClfsReadLogRecord

ClfsReadRestartArea

ClfsWriteRestartArea function

1/25/2019 • 2 minutes to read • Edit Online

The **ClfsWriteRestartArea** routine atomically appends a new restart record to a CLFS stream, flushes the restart record to stable storage, and optionally updates the base LSN of the stream.

Syntax

```
CLFSUSER_API NTSTATUS ClfsWriteRestartArea(
  PVOID     pvMarshalContext,
  PVOID     pvRestartBuffer,
  ULONG     cbRestartBuffer,
  PCLFS_LSN plsnBase,
  ULONG     fFlags,
  PULONG    pcbWritten,
  PCLFS_LSN plsnNext
);
```

Parameters

`pvMarshalContext`

A pointer to an opaque context that represents a marshalling area associated with a CLFS stream. The caller previously obtained this pointer by calling ClfsCreateMarshallingArea.

`pvRestartBuffer`

A pointer to a buffer that contains the data for the restart record.

`cbRestartBuffer`

The size, in bytes, of the buffer pointed to by *pvRestartBuffer*. This is the size of the restart data.

`plsnBase`

A pointer to a CLFS_LSN structure that specifies a new base LSN for the stream. If this parameter is **NULL**, the base LSN is not changed.

`fFlags`

This parameter must be one of the following values.

VALUE	MEANING
0	The restart record is placed in newly allocated space in an I/O block. The number of reserved records in the marshalling area is not changed.
CLFS_FLAG_USE_RESERVATION	The restart record is placed in previously reserved space in an I/O block. The number of reserved records in the marshalling area is reduced by one.

`pcbWritten`

A pointer to a ULONG-typed variable that receives the number of bytes actually forced to stable storage. This

parameter can be **NULL**.

`plsnNext`

A pointer to a **CLFS_LSN** structure that receives the LSN of the newly written restart record.

Return Value

ClfsWriteRestartArea returns STATUS_SUCCESS if it succeeds; otherwise, it returns one of the error codes defined in Ntstatus.h.

Remarks

Typically ClfsWriteRestartArea is called as the last act of a client checkpoint.

ClfsWriteRestartArea is a relatively expensive operation because it causes a flush of all records currently in the marshalling area along with a flush of stream and log metadata.

At any one time, only one marshalling area should be used to write data to a stream. Having two marshalling areas writing into the stream might result in stream corruption.

If you just want to set the base LSN of a stream, use ClfsAdvanceLogBase, which does not necessarily flush any data to stable storage.

For an explanation of CLFS concepts and terminology, see Common Log File System.

Requirements

Minimum supported client	Available in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
Library	Clfs.lib
DLL	Clfs.sys
IRQL	"<= APC_LEVEL"

CM_POWER_DATA structure

1/25/2019 • 2 minutes to read • Edit Online

The **CM_POWER_DATA** structure contains information about a device's power management state and capabilities.

Syntax

```
typedef struct CM_Power_Data_s {
  ULONG              PD_Size;
  DEVICE_POWER_STATE PD_MostRecentPowerState;
  ULONG              PD_Capabilities;
  ULONG              PD_D1Latency;
  ULONG              PD_D2Latency;
  ULONG              PD_D3Latency;
  DEVICE_POWER_STATE PD_PowerStateMapping[POWER_SYSTEM_MAXIMUM];
  SYSTEM_POWER_STATE PD_DeepestSystemWake;
} CM_POWER_DATA, *PCM_POWER_DATA;
```

Members

`PD_Size`

The size, in bytes, of this structure.

`PD_MostRecentPowerState`

A DEVICE_POWER_STATE value representing the device's most recent power state.

`PD_Capabilities`

The device's power capabilities, represented by a combination of the following bit flags:

PDCAP_D0_SUPPORTED

PDCAP_D1_SUPPORTED

PDCAP_D2_SUPPORTED

PDCAP_D3_SUPPORTED

PDCAP_WAKE_FROM_D0_SUPPORTED

PDCAP_WAKE_FROM_D1_SUPPORTED

PDCAP_WAKE_FROM_D2_SUPPORTED

PDCAP_WAKE_FROM_D3_SUPPORTED

PDCAP_WARM_EJECT_SUPPORTED

`PD_D1Latency`

The device's latency when returning the D0 state from the D1 state. For more information, see the **D1Latency** member of DEVICE_CAPABILITIES.

`PD_D2Latency`

The device's latency when returning the D0 state from the D2 state. For more information, see the **D2Latency** member of **DEVICE_CAPABILITIES**.

`PD_D3Latency`

The device's latency when returning the D0 state from the D3 state. For more information, see the **D3Latency** member of **DEVICE_CAPABILITIES**.

`PD_PowerStateMapping`

An array of **DEVICE_POWER_STATE** values representing the maximum device power state achievable for each system power state. For more information, see the **DeviceState** member of DEVICE_CAPABILITIES.

`PD_DeepestSystemWake`

Specifies the least-powered system state from which the device can wake the system. **PD_DeepestSystemWake** typically indicates one of the system sleeping states, S1, S2, or S3 (as specified by **PowerSystemSleeping1**, **PowerSystemSleeping2**, and **PowerSystemSleeping3**, respectively). Note, however, that some devices might be able to wake the system from the system hibernate state, S4 (as specified by **PowerSystemHibernate**), or even from the system shutdown state, S5 (as specified by **PowerSystemShutdown**).

Requirements

Minimum supported client	Available in Microsoft Windows XP and later versions of the Windows operating system.
Header	wdm.h (include Ntddk.h, Ntpoapi.h)

DEVICE_POWER_STATE

SetupDiGetDeviceRegistryProperty

CmCallbackGetKeyObjectID function

1/25/2019 • 2 minutes to read • Edit Online

The **CmCallbackGetKeyObjectID** routine retrieves the unique identifier and object name that are associated with a specified registry key object.

> **Note** Starting with Windows 8, registry filter drivers should call the CmCallbackGetKeyObjectIDEx routine instead of **CmCallbackGetKeyObjectID**. For more information, see Remarks.

Syntax

```
NTSTATUS CmCallbackGetKeyObjectID(
  PLARGE_INTEGER   Cookie,
  PVOID            Object,
  PULONG_PTR       ObjectID,
  PCUNICODE_STRING *ObjectName
);
```

Parameters

`Cookie`

The cookie value that the driver previously obtained by calling the CmRegisterCallback or CmRegisterCallbackEx routine.

`Object`

The pointer value that the driver's RegistryCallback callback routine received in the **Object** member of one of the **REG_*XXX*_KEY_INFORMATION** structures.

> **Warning** In certain circumstances registry callback notification structures may contain invalid non-NULL object pointers. Registry filtering drivers must not pass such pointers to this routine. For more information, see Invalid Key Object Pointers in Registry Notifications.

`ObjectID`

A pointer to a location that receives a pointer to the unique identifier that represents the registry key that *Object* specifies. This parameter is optional and can be **NULL**.

`ObjectName`

A pointer to a location that receives a pointer to a UNICODE_STRING structure. This structure contains the object name of the registry key object that *Object* specifies. The object name is actually the full path name of the registry key that the object represents. The caller must not write to this **UNICODE_STRING** structure or free it. This parameter is optional and can be **NULL**.

Return Value

CmCallbackGetKeyObjectID returns STATUS_SUCCESS if the operation succeeds. Possible error return values include the following status code.

RETURN CODE	DESCRIPTION
STA TUS _IN VAL ID_ PAR AM ETE R	The *Cookie* or *Object* parameter is invalid.

Remarks

The **CmCallbackGetKeyObjectID** routine is available starting with Windows Vista. An improved version of this routine, CmCallbackGetKeyObjectIDEx, is available starting with Windows 8. Drivers that run only in Windows 8 and later versions of Windows should call **CmCallbackGetKeyObjectIDEx** instead of **CmCallbackGetKeyObjectID**.

Drivers can use **CmCallbackGetKeyObjectID** to obtain the registry key identifier, the object name, or both, by supplying non-**NULL** values for the *ObjectID* or *ObjectName* parameters.

After the driver has obtained the identifier or name, the identifier or name is valid until the driver's *RegistryCallback* routine receives pre-notification of handle closure.

The driver must not modify the object name.

If two registry key objects represent the same registry key, the key identifiers for both objects are identical.

For more information about **CmCallbackGetKeyObjectID** and registry filtering operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available starting with Windows Vista.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

CmCallbackGetKeyObjectIDEx

CmRegisterCallback

CmRegisterCallbackEx

RegistryCallback

UNICODE_STRING

CmCallbackGetKeyObjectIDEx function

1/25/2019 • 3 minutes to read • Edit Online

The **CmCallbackGetKeyObjectIDEx** routine retrieves the unique identifier and object name that are associated with a specified registry key object.

> **Note** This routine is available starting with Windows 8. In earlier versions of Windows, use the CmCallbackGetKeyObjectID routine instead. For more information, see Remarks.

Syntax

```
NTSTATUS CmCallbackGetKeyObjectIDEx(
  PLARGE_INTEGER   Cookie,
  PVOID            Object,
  PULONG_PTR       ObjectID,
  PCUNICODE_STRING *ObjectName,
  ULONG            Flags
);
```

Parameters

`Cookie`

A cookie value that represents the caller's registration to receive registry filter callbacks. The driver previously obtained this cookie value from the CmRegisterCallback or CmRegisterCallbackEx routine.

`Object`

A pointer to the registry key object. This parameter is the pointer value that the driver's RegistryCallback callback routine received in the **Object** member of one of the **REG_*XXX*_KEY_INFORMATION** structures.

> **Warning** In certain circumstances registry callback notification structures may contain invalid non-NULL object pointers. Registry filtering drivers must not pass such pointers to this routine. For more information, see Invalid Key Object Pointers in Registry Notifications.

`ObjectID`

A pointer to a location that receives a pointer to the key identifier for the registry key that *Object* represents. This identifier is unique across all keys in the registry. This parameter is optional and can be **NULL**. For more information, see Remarks.

`ObjectName`

A pointer to a location that receives a pointer to a UNICODE_STRING structure. This structure contains the object name of the registry key object that *Object* specifies. The object name is actually the full path name of the registry key that the object represents. The caller is responsible for freeing this structure by calling the CmCallbackReleaseKeyObjectIDEx routine. This parameter is optional and can be **NULL**. For more information, see Remarks.

`Flags`

Reserved. Set to zero.

Return Value

CmCallbackGetKeyObjectIDEx returns STATUS_SUCCESS if the operation succeeds. Possible error return values include the following status code.

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The *Cookie*, *Object*, or *Flags* parameter is invalid.

Remarks

Drivers can use **CmCallbackGetKeyObjectIDEx** to obtain the registry key identifier, the object name, or both, by supplying non-**NULL** values for the *ObjectID* or *ObjectName* parameters.

The caller can obtain the key identifier through the *ObjectID* parameter. If two registry key objects represent the same registry key, the key identifiers obtained from **CmCallbackGetKeyObjectIDEx** for the two objects are identical. If the name of the registry key changes, the key identifier obtained from **CmCallbackGetKeyObjectIDEx** does not change. The caller can use the key identifier to reliably track accesses that are made to a particular registry key through multiple key objects, and even across changes to the registry key name.

The caller can obtain the object name through the *ObjectName* parameter. The storage for the UNICODE_STRING structure that contains the object name remains valid until the caller calls CmCallbackReleaseKeyObjectIDEx to free the structure.

CmCallbackGetKeyObjectIDEx is an improved version of the CmCallbackGetKeyObjectID routine, which is available starting with Windows Vista. Drivers that run in versions of Windows earlier than Windows 8 should call **CmCallbackGetKeyObjectID** instead of **CmCallbackGetKeyObjectIDEx**. Drivers that run only in Windows 8 and later versions of Windows should call **CmCallbackGetKeyObjectIDEx** instead of **CmCallbackGetKeyObjectID**.

CmCallbackGetKeyObjectIDEx has two important features that are not available from **CmCallbackGetKeyObjectID**.

First, **CmCallbackGetKeyObjectIDEx** enables a registry filter driver to explicitly control the lifetime of the *ObjectName* structure. The driver can call **CmCallbackReleaseKeyObjectIDEx** at any time to free this structure. In contrast, the driver cannot explicitly free the *ObjectName* structure received from **CmCallbackGetKeyObjectID**. This structure is automatically released when all handles to the key are closed.

Second, if a registry filter driver calls **CmCallbackReleaseKeyObjectID** to get an *ObjectName* structure pointer, and, after this call, the name of the registry key changes, subsequent calls to **CmCallbackGetKeyObjectID** get a pointer to a stale copy of the *ObjectName* structure, which contains the old key name. The stale copy of this structure persists until all handles to the key are closed. In contrast, the *ObjectName* structure obtained from **CmCallbackGetKeyObjectIDEx** always contains the most up-to-date key name.

For more information about registry filter drivers, see Filtering Registry Calls.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal

UNICODE_STRING

CmCallbackReleaseKeyObjectIDEx function

1/25/2019 • 2 minutes to read • Edit Online

The **CmCallbackReleaseKeyObjectIDEx** routine frees an object name string obtained from the CmCallbackGetKeyObjectIDEx routine.

Syntax

```
void CmCallbackReleaseKeyObjectIDEx(
  PCUNICODE_STRING ObjectName
);
```

Parameters

`ObjectName`

A pointer to a UNICODE_STRING structure that contains the object name string. The driver previously obtained this pointer by calling CmCallbackGetKeyObjectIDEx.

Return Value

None.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

UNICODE_STRING

CmGetBoundTransaction function

1/25/2019 • 2 minutes to read • Edit Online

The **CmGetBoundTransaction** routine returns a pointer to the transaction object that represents the transaction, if any, that is associated with a specified registry key object.

Syntax

```
PVOID CmGetBoundTransaction(
  PLARGE_INTEGER Cookie,
  PVOID          Object
);
```

Parameters

`Cookie`

The cookie value that the driver previously obtain by calling CmRegisterCallback or CmRegisterCallbackEx.

`Object`

The pointer value that the driver's RegistryCallback callback routine received in one of the **REG_*XXX*_KEY_INFORMATION** structures.

Return Value

CmGetBoundTransaction returns a pointer to a transaction object, if the key object that the *Object* parameter specifies is associated with a transaction. Otherwise, the routine returns **NULL**.

Remarks

The **CmGetBoundTransaction** routine is available on Windows Vista and later versions of Windows.

For more information about **CmGetBoundTransaction** and filtering registry operations, see Filtering Registry Calls.

For more information about transactions, see Kernel Transaction Manager Design Guide.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.

CmRegisterCallback

CmRegisterCallbackEx

RegistryCallback

CmGetCallbackVersion function

1/25/2019 • 2 minutes to read • Edit Online

The **CmGetCallbackVersion** routine retrieves the major and minor version numbers for the current version of the configuration manager's registry callback feature.

Syntax

```
void CmGetCallbackVersion(
  PULONG Major,
  PULONG Minor
);
```

Parameters

`Major`

A pointer to a location that receives the major version number.

`Minor`

A pointer to a location that receives the minor version number.

Return Value

None

Remarks

The **CmGetCallbackVersion** routine is available starting with Windows Vista.

For Windows Vista, the major version number is 1 and the minor version number is 0.

Starting with Windows 7, the major version number is 1 and the minor version number is 1.

Version 1.1 contains two changes from version 1.0.

First, in version 1.0, if multiple registry filter drivers are active on the computer at the same time, the **REG_POST_*XXX*_KEY_INFORMATION** structure passed to a driver's registry callback routine during the post-notification phase for a create-key or open-key operation might contain a non-NULL **Object** member, even though the operation failed and the **Status** member contains an error status. In version 1.1, the **Object** member is always NULL if the **Status** member is set to an error status value to indicate that the operation failed.

Second, in version 1.0, an uncaught exception in a registry callback routine is quietly accepted by the operating system. In version 1.1, this exception causes the computer to bug check.

For more information on the differences between versions, see Filtering Registry Calls.

Requirements

Minimum supported client	Available starting with Windows Vista.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

CmRegisterCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **CmRegisterCallback** routine is **obsolete** for Windows Vista and later operating system versions. Use CmRegisterCallbackEx instead.

The **CmRegisterCallback** routine registers a RegistryCallback routine.

Syntax

```
NTSTATUS CmRegisterCallback(
  PEX_CALLBACK_FUNCTION Function,
  PVOID                 Context,
  PLARGE_INTEGER        Cookie
);
```

Parameters

`Function`

A pointer to the RegistryCallback routine to register.

`Context`

A driver-defined value that the configuration manager will pass as the *CallbackContext* parameter to the *RegistryCallback* routine

`Cookie`

A pointer to a LARGE_INTEGER variable that receives the value that identifies the callback routine. When you unregister the callback routine, pass this value as the *Cookie* parameter to CmUnRegisterCallback.

Return Value

CmRegisterCallback returns STATUS_SUCCESS if the operation succeeds or the appropriate NTSTATUS error code if it fails.

Remarks

The **CmRegisterCallback** routine is available on Windows XP and later operating system versions. For Windows Vista and later operating system versions, you should use CmRegisterCallbackEx instead.

A driver calls **CmRegisterCallback** to register a RegistryCallback routine, which is called every time a thread performs an operation on the registry.

Call CmUnRegisterCallback to unregister a callback routine that **CmRegisterCallback** registered.

For more information about **CmRegisterCallback** and filtering registry operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

CmRegisterCallbackEx

CmUnRegisterCallback

RegistryCallback

CmRegisterCallbackEx function

1/25/2019 • 2 minutes to read • Edit Online

The **CmRegisterCallbackEx** routine registers a RegistryCallback routine.

Syntax

```
NTSTATUS CmRegisterCallbackEx(
  PEX_CALLBACK_FUNCTION Function,
  PCUNICODE_STRING      Altitude,
  PVOID                 Driver,
  PVOID                 Context,
  PLARGE_INTEGER        Cookie,
  PVOID                 Reserved
);
```

Parameters

`Function`

A pointer to the RegistryCallback routine to register.

`Altitude`

A pointer to a UNICODE_STRING structure. This structure must contain a string that represents the altitude of the calling minifilter driver. For more information, see Remarks.

`Driver`

A pointer to the DRIVER_OBJECT structure that represents the driver.

`Context`

A driver-defined value that the configuration manager will pass as the *CallbackContext* parameter to the *RegistryCallback* routine.

`Cookie`

A pointer to a LARGE_INTEGER variable that receives the value that identifies the callback routine. When you unregister the callback routine, pass this value as the *Cookie* parameter to CmUnRegisterCallback.

`Reserved`

This parameter is reserved for future use.

Return Value

CmRegisterCallbackEx returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following NTSTATUS values:

RETURN CODE	DESCRIPTION

STA TUS _FLT _IN STA NCE _AL TIT UDE _CO LLIS ION	The calling driver or another driver has already registered a RegistryCallback routine for the specified altitude.
STA TUS _IN SUF FICI ENT _RE SO URC ES	An attempt to allocate memory failed.

Remarks

The **CmRegisterCallbackEx** routine is available starting with Windows Vista.

A driver can call CmRegisterCallback or **CmRegisterCallbackEx** to register a RegistryCallback routine, which is called every time a thread performs an operation on the registry.

The *Altitude* parameter defines the position of the minifilter driver relative to other minifilters in the I/O stack when the minifilter is loaded. Allocation of altitudes to minifilters is managed by Microsoft. For more information about altitudes, see Load Order Groups and Altitudes for Minifilter Drivers.

Call CmUnRegisterCallback to unregister a callback routine that **CmRegisterCallbackEx** registered.

For more information about **CmRegisterCallbackEx** and filtering registry operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available starting with Windows Vista.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

DRIVER_OBJECT

RegistryCallback

UNICODE_STRING

CmSetCallbackObjectContext function

1/25/2019 • 2 minutes to read • Edit Online

The **CmSetCallbackObjectContext** routine associates specified context information with a specified registry object.

Syntax

```
NTSTATUS CmSetCallbackObjectContext(
  PVOID          Object,
  PLARGE_INTEGER Cookie,
  PVOID          NewContext,
  PVOID          *OldContext
);
```

Parameters

`Object`

A pointer to the registry key object that the driver is providing context information for. The driver obtains this pointer from the **ResultObject** member of one of the following structures:

REG_CREATE_KEY_INFORMATION REG_CREATE_KEY_INFORMATION_V1 REG_OPEN_KEY_INFORMATION REG_OPEN_KEY_INFORMATION_V1

`Cookie`

A pointer to a LARGE_INTEGER value that identifies the callback routine to associate the context with. The CmRegisterCallbackEx routine provided this value when you registered the callback routine.

`NewContext`

A pointer to driver-defined context information.

`OldContext`

A pointer to a location that receives a pointer to context information that the driver previously associated with the specified object and cookie. This parameter is optional and can be **NULL**.

Return Value

CmSetCallbackObjectContext returns STATUS_SUCCESS or another appropriate NTSTATUS-typed value.

Remarks

The **CmSetCallbackObjectContext** routine is available starting with Windows Vista.

A driver's RegistryCallback routine can call **CmSetCallbackObjectContext** for any registry key object after the object has been created or opened (that is, during a post-notification for a create operation, an open operation, or any subsequent notification up to the pre-notification of handle closure).

If a driver calls **CmSetCallbackObjectContext**, the driver's *RegistryCallback* routine will receive a **RegNtCallbackObjectContextCleanup** notification after the key object's handle has been closed or after the

driver calls CmUnRegisterCallback to unregister the *RegistryCallback* routine. When the *RegistryCallback* routine receives this notification, the routine should release any resources that it allocated for the object's context.

For more information about **CmSetCallbackObjectContext** and filtering registry operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available starting with Windows Vista.

RegistryCallback

CmUnRegisterCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **CmUnRegisterCallback** routine unregisters a RegistryCallback routine that a CmRegisterCallback or CmRegisterCallbackEx routine previously registered.

Syntax

```
NTSTATUS CmUnRegisterCallback(
  LARGE_INTEGER Cookie
);
```

Parameters

`Cookie`

A LARGE_INTEGER value that identifies the callback routine to unregister. **CmRegisterCallback** provided this value when you registered the callback routine.

Return Value

CmUnRegisterCallback returns STATUS_SUCCESS if it succeeds or the appropriate NTSTATUS error code if it fails. If the *Cookie* parameter does not match any registered callback routines, **CmUnRegisterCallback** returns STATUS_INVALID_PARAMETER.

Remarks

A driver that calls **CmRegisterCallback** or **CmRegisterCallbackEx** should call **CmUnRegisterCallback** before the driver is unloaded.

> **Note** A driver must not call **CmRegisterCallback** from its implementation of the RegistryCallback routine. That call will result in a deadlock.

For more information about **CmUnRegisterCallback** and filtering registry operations, see Filtering Registry Calls.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.

RegistryCallback

DMA_COMPLETION_ROUTINE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *DmaCompletionRoutine* callback routine notifies the driver that previously requested a system DMA transfer that this transfer is complete.

Syntax

```
DMA_COMPLETION_ROUTINE DmaCompletionRoutine;

void DmaCompletionRoutine(
  PDMA_ADAPTER DmaAdapter,
  PDEVICE_OBJECT DeviceObject,
  PVOID CompletionContext,
  DMA_COMPLETION_STATUS Status
)
{...}
```

Parameters

`DmaAdapter`

A pointer to a DMA_ADAPTER structure. This structure is the adapter object that represents the driver's system DMA channel.

`DeviceObject`

A pointer to a DEVICE_OBJECT structure. This structure is the physical device object (PDO) that represents the target device for the requested DMA operation.

`CompletionContext`

A pointer to a driver-determined context for the *DmaCompletionRoutine* routine. This context is the *CompletionContext* parameter value that the driver previously passed to the MapTransferEx call that initiated the system DMA transfer.

`Status`

The completion status of the DMA transfer. This parameter is a DMA_COMPLETION_STATUS enumeration value that indicates whether the DMA transfer completed successfully.

Return Value

None.

Remarks

As an option, a driver can implement a *DmaCompletionRoutine* routine. When the driver requests a system DMA transfer, the driver can supply a pointer to this routine with the request. After the DMA transfer completes, the *DmaCompletionRoutine* routine is automatically called to notify the driver.

A driver's *DmaCompletionRoutine* routine is called only if the DMA transfer requested by the driver uses a system DMA controller that can generate an interrupt after a DMA transfer completes. A driver that uses a bus-master

DMA device, or that uses a system DMA controller that does not generate interrupts, must use other means to determine when a DMA transfer completes. For example, this driver might use a timer interrupt to periodically poll the status of the DMA transfer.

A driver can supply a pointer to a *DmaCompletionRoutine* routine as an optional parameter to the MapTransferEx routine.

Examples

To define a *DmaCompletionRoutine* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *DmaCompletionRoutine* callback routine that is named `MyDmaCompletionRoutine`, use the DMA_COMPLETION_ROUTINE type as shown in this code example:

```
DMA_COMPLETION_ROUTINE MyDmaCompletionRoutine;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyDmaCompletionRoutine(
    PDMA_ADAPTER DmaAdapter,
    PDEVICE_OBJECT DeviceObject,
    PVOID CompletionContext,
    DMA_COMPLETION_STATUS Status
    )
  {
      // Function body
  }
```

The DMA_COMPLETION_ROUTINE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the DMA_COMPLETION_ROUTINE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at DISPATCH_LEVEL.

DRIVER_ADD_DEVICE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *AddDevice* routine is responsible for creating functional device objects (FDO) or filter device objects (filter DO) for devices enumerated by the Plug and Play (PnP) manager.

Syntax

```
DRIVER_ADD_DEVICE DriverAddDevice;

NTSTATUS DriverAddDevice(
  _DRIVER_OBJECT *DriverObject,
  _DEVICE_OBJECT *PhysicalDeviceObject
)
{...}
```

Parameters

`*DriverObject`

Caller-supplied pointer to a DRIVER_OBJECT structure. This is the driver's driver object.

`*PhysicalDeviceObject`

Caller-supplied pointer to a DEVICE_OBJECT structure representing a physical device object (PDO) created by a lower-level driver.

Return Value

If the routine succeeds, it must return STATUS_SUCCESS. Otherwise, it must return one of the error status values defined in Ntstatus.h.

Remarks

All kernel-mode drivers that support PnP must provide an *AddDevice* routine.

A driver's *AddDevice* routine should be named *Xxx* `AddDevice`, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *AddDevice* routine's address in **DriverObject->DriverExtension->AddDevice**.

An *AddDevice* routine's primary responsibilities are calling IoCreateDevice to create a device object, then calling IoAttachDeviceToDeviceStack to attach the device object to the device stack. For detailed information about implementing a driver's *AddDevice* routine, see Writing an AddDevice Routine.

An *AddDevice* routine runs in a system thread context at IRQL = PASSIVE_LEVEL.

Examples

To define an *AddDevice* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define an *AddDevice* callback routine that is named `MyAddDevice`, use the DRIVER_ADD_DEVICE

type as shown in this code example:

```
DRIVER_ADD_DEVICE MyAddDevice;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
NTSTATUS
  MyAddDevice(
    struct _DRIVER_OBJECT  *DriverObject,
    struct _DEVICE_OBJECT  *PhysicalDeviceObject
    )
  {
      // Function body
  }
```

The DRIVER_ADD_DEVICE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the DRIVER_ADD_DEVICE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at PASSIVE_LEVEL (see Remarks section).

DRIVER_CANCEL callback function

1/25/2019 • 2 minutes to read • Edit Online

The *Cancel* routine cancels an I/O operation.

Syntax

```
DRIVER_CANCEL DriverCancel;

void DriverCancel(
  _DEVICE_OBJECT *DeviceObject,
  _IRP *Irp
)
{...}
```

Parameters

`*DeviceObject`

Caller-supplied pointer to a DEVICE_OBJECT structure. This is the device object for the target device, previously created by the driver's AddDevice routine.

`*Irp`

Caller-supplied pointer to an IRP structure that describes the I/O operation to be canceled.

Return Value

None

Remarks

When a driver or other system component calls IoCancelIrp, the I/O manager calls the IRP's *Cancel* routine, if one has been registered for the IRP.

To register a *Cancel* routine for an IRP, a driver can use either of the following two methods:

1. A driver that provides a StartIo routine and uses the I/O manager-supplied device queue can specify a *Cancel* routine when calling IoStartPacket.
2. A driver that creates and manages supplemental device queues can register a *Cancel* routine by calling IoSetCancelRoutine.

Only one *Cancel* routine can be registered for an IRP at one time.

The I/O manager calls IoAcquireCancelSpinLock before calling a driver's *Cancel* routine, so the *Cancel* routine must call IoReleaseCancelSpinLock at some point. The routine should not hold the spin lock longer than necessary.

The *Cancel* routine executes in an arbitrary thread context at IRQL = DISPATCH_LEVEL until it calls **IoReleaseCancelSpinLock**, which changes the IRQL to a caller-supplied value. The driver should specify **Irp->CancelIrql** for this value.

The *Cancel* routine must set the I/O status block's **Status** member to STATUS_CANCELLED, and set its

Information member to zero. The routine must then complete the specified IRP by calling IoCompleteRequest.

For detailed information about implementing a driver's *Cancel* routine, see Canceling IRPs.

Examples

To define a *Cancel* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *Cancel* callback routine that is named `MyCancel`, use the DRIVER_CANCEL type as shown in this code example:

```
DRIVER_CANCEL MyCancel;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyCancel(
    struct _DEVICE_OBJECT  *DeviceObject,
    struct _IRP  *Irp
    )
  {
      // Function body
  }
```

The DRIVER_CANCEL function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the DRIVER_CANCEL function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at DISPATCH_LEVEL (see Remarks section).

DRIVER_CONTROL callback function

1/25/2019 • 2 minutes to read • Edit Online

This routine starts a DMA data-transfer or a data transfer operation.

Syntax

```
DRIVER_CONTROL DriverControl;

IO_ALLOCATION_ACTION DriverControl(
  _DEVICE_OBJECT *DeviceObject,
  _IRP *Irp,
  PVOID MapRegisterBase,
  PVOID Context
)
{...}
```

Parameters

`DeviceObject`

Caller-supplied pointer to a DEVICE_OBJECT structure. This is the device object for the target device, previously created by the driver's *AddDevice* routine.

`Irp`

Caller-supplied pointer to an IRP structure. *Irp* is equal to the value of the **CurrentIrp** member of *DeviceObject* when the callback routine was registered.

`MapRegisterBase`

In the case of *AdapterControl*, this is a caller-supplied opaque value that represents the map registers that the system has assigned for this transfer operation. The driver passes this value to FlushAdapterBuffers, FreeMapRegisters, and MapTransfer.

In the case of *ControllerControl*, this is not used.

`Context`

Caller-supplied pointer to driver-defined context information, specified in a previous call to AllocateAdapterChannel.

Return Value

The routine must return one of the values defined by the IO_ALLOCATION_ACTION enumeration. Drivers of bus-master devices return either **DeallocateObject** or **DeallocateObjectKeepRegisters**; drivers that use system DMA return **KeepObject**.

Remarks

About implementing *AdapterControl*:

To register an *AdapterControl* routine for a specific device object, a driver must call IoGetDmaAdapter to obtain an

adapter object, then call AllocateAdapterChannel to request use of the adapter and to supply the *AdapterControl* routine's address. When the adapter is free, the system calls the *AdapterControl* routine.

If *AdapterControl* has been registered by a StartIo routine, then the *Irp* parameter is guaranteed to point to the IRP currently being processed by the *StartIo* routine. Otherwise, drivers must set the **CurrentIrp** member of the device object structure before calling **AllocateAdapterChannel**.

For detailed information about implementing an *AdapterControl* routine, see Writing AdapterControl Routines.

About implementing *ControllerControl*: A driver's *ControllerControl* routine executes in an arbitrary thread context at IRQL = DISPATCH_LEVEL.

To register a *ControllerControl* routine for a specific device object, a driver must call IoCreateController to obtain a controller object, then call IoAllocateController to request use of the controller and to supply the *ControllerControl* routine's address. When the controller is free, the system calls the *ControllerControl* routine.

For detailed information about implementing a *ControllerControl* routine, see Writing ControllerControl Routines. Also see Controller Objects.

The DRIVER_CONTROL function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the DRIVER_CONTROL function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Examples

To define a callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define an *AdapterControl* callback routine that is named `MyAdapterControl`, use the DRIVER_CONTROL type as shown in this code example:

```
DRIVER_CONTROL MyAdapterControl;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
IO_ALLOCATION_ACTION
 MyAdapterControl(
    struct _DEVICE_OBJECT  *DeviceObject,
    struct _IRP  *Irp,
    PVOID  MapRegisterBase,
    PVOID  Context
    )
  {
      // Function body
  }
```

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at DISPATCH_LEVEL.

AllocateAdapterChannel

DRIVER_DISPATCH callback function

1/25/2019 • 4 minutes to read • Edit Online

The callback routine services various IRPs. For a list of function codes, see Remarks.

Syntax

```
DRIVER_DISPATCH DriverDispatch;

NTSTATUS DriverDispatch(
  _DEVICE_OBJECT *DeviceObject,
  _IRP *Irp
)
{...}
```

Parameters

`*DeviceObject`

Caller-supplied pointer to a DEVICE_OBJECT structure. This is the device object for the target device, previously created by the driver's AddDevice routine.

`*Irp`

Caller-supplied pointer to an IRP structure that describes the requested I/O operation.

Return Value

If the routine succeeds, it must return STATUS_SUCCESS. Otherwise, it must return one of the error status values defined in Ntstatus.h.

Remarks

Input parameters for all *Dispatch* routines are supplied in the IRP structure pointed to by *Irp*. Additional parameters are supplied in the driver's associated I/O stack location, which is described by the IO_STACK_LOCATION structure and can be obtained by calling IoGetCurrentIrpStackLocation.

Generally, all *Dispatch* routines execute in an arbitrary thread context at IRQL = PASSIVE_LEVEL, but there are exceptions. For more information, see Dispatch Routines and IRQLs.

For more information about dispatch routines, see Writing Dispatch Routines. For more information about IRPs, see Handling IRPs.

IRP	ABOUT IMPLEMENTING THE CALLBACK
IRP_MJ_CLEANUP	A driver's *DispatchCleanup* routine should be named *Xxx* DispatchCleanup, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchCleanup* routine's address in *DriverObject*->**MajorFunction**[IRP_MJ_CLEANUP].

IRP_MJ_CLOSE	A driver's *DispatchClose* routine should be named ***Xxx*DispatchClose**, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchClose* routine's address in *DriverObject*->**MajorFunction**[IRP_MJ_CLOSE].
IRP_MJ_CREATE	A driver's *DispatchCreate* routine should be named *Xxx* DispatchCreate, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchCreate* routine's address in *DriverObject*->**MajorFunction**[IRP_MJ_CREATE].
IRP_MJ_CREATE or IRP_MJ_CLOSE	A driver can provide a single *DispatchCreateClose* routine instead of separate DispatchCreate and DispatchClose routines. A driver's *DispatchCreateClose* routine should be named ***Xxx*DispatchCreateClose**, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchCreateClose* routine's address in *DriverObject*->**MajorFunction**[IRP_MJ_CREATE] and in *DriverObject*->**MajorFunction**[IRP_MJ_CLOSE].
IRP_MJ_DEVICE_CONTROL	A driver's *DispatchDeviceControl* routine should be named ***Xxx*DispatchDeviceControl**, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchDeviceControl* routine's address in *DriverObject*->**MajorFunction**[IRP_MJ_DEVICE_CONTROL]. The system uses the FILE_*XXX* flags in the I/O control code to determine whether the IRP sender has the privileges to send the IRP to the device object. Drivers for Windows Server 2003 and later versions of Windows can use the IoValidateDeviceIoControlAccess routine to perform stricter access checks within *DispatchDeviceControl*.
IRP_MJ_FLUSH_BUFFERS	A driver's *DispatchFlushBuffers* routine should be named *Xxx* DispatchFlushBuffers, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchFlushBuffers* routine's address in *DriverObject*->**MajorFunction**[IRP_MJ_FLUSH_BUFFERS].
IRP_MJ_INTERNAL_DEVICE_CONTROL	A driver's *DispatchInternalDeviceControl* routine should be named ***Xxx*DispatchInternalDeviceControl**, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchInternalDeviceControl* routine's address in *DriverObject*->**MajorFunction**[**IRP_MJ_INTERNAL_DEVICE_CONTROL**].
IRP_MJ_PNP	A driver's *DispatchPnP* routine should be named *Xxx* DispatchPnP, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchPnP* routine's address in *DriverObject*->**MajorFunction**[IRP_MJ_PNP].
IRP_MJ_POWER	A driver's *DispatchPower* routine should be named ***Xxx*DispatchPower**, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchPower* routine's address in *DriverObject*->**MajorFunction**[**IRP_MJ_POWER**].

IRP_MJ_QUERY_INFORMATION	A driver's *DispatchQueryInformation* routine should be named ***Xxx*DispatchQueryInformation**, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchQueryInformation* routine's address in *DriverObject*->**MajorFunction**[IRP_MJ_QUERY_INFORMATION].
IRP_MJ_READ	A driver's *DispatchRead* routine should be named ***Xxx*DispatchRead**, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchRead* routine's address in *DriverObject*->**MajorFunction**[IRP_MJ_READ].
IRP_MJ_READ or IRP_MJ_WRITE	A driver can provide a single *DispatchReadWrite* routine instead of separate DispatchRead and DispatchWrite routines. A driver's *DispatchReadWrite* routine should be named ***Xxx*DispatchReadWrite**, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchReadWrite* routine's address in *DriverObject*->**MajorFunction**[**IRP_MJ_READ**] and in *DriverObject*->**MajorFunction**[**IRP_MJ_WRITE**].
IRP_MJ_SET_INFORMATION	A driver's *DispatchSetInformation* routine should be named ***Xxx*DispatchSetInformation**, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchSetInformation* routine's address in *DriverObject*->**MajorFunction**[IRP_MJ_SET_INFORMATION].
IRP_MJ_SHUTDOWN	A driver's *DispatchShutdown* routine should be named ***Xxx*DispatchShutdown**, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchShutdown* routine's address in *DriverObject*->**MajorFunction**[IRP_MJ_SHUTDOWN]. Additionally, in order to receive **IRP_MJ_SHUTDOWN** requests, a driver must call IoRegisterShutdownNotification or IoRegisterLastChanceShutdownNotification to register its *DispatchShutdown* routine with the system.
IRP_MJ_SYSTEM_CONTROL	A driver's *DispatchSystemControl* routine should be named ***Xxx*DispatchSystemControl**, where ***Xxx*** is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchSystemControl* routine's address in *DriverObject*->**MajorFunction**[IRP_MJ_SYSTEM_CONTROL].
IRP_MJ_WRITE	A driver's *DispatchWrite* routine should be named ***Xxx*DispatchWrite**, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *DispatchWrite* routine's address in *DriverObject*->**MajorFunction**[IRP_MJ_WRITE].

Examples

To define a callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *DispatchCleanup* callback routine that is named `MyDispatchCleanup`, use the DRIVER_DISPATCH type as shown in this code example:

```
DRIVER_DISPATCH MyDispatchCleanup;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
NTSTATUS
  MyDispatchCleanup(
    struct _DEVICE_OBJECT  *DeviceObject,
    struct _IRP  *Irp
    )
  {
      // Function body
  }
```

The DRIVER_DISPATCH function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the DRIVER_DISPATCH function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at PASSIVE_LEVEL (see Remarks section).

DRIVER_INITIALIZE callback function

1/25/2019 • 2 minutes to read • Edit Online

DriverEntry is the first routine called after a driver is loaded, and is responsible for initializing the driver.

Syntax

```
DRIVER_INITIALIZE DriverInitialize;

NTSTATUS DriverInitialize(
  _DRIVER_OBJECT *DriverObject,
  PUNICODE_STRING RegistryPath
)
{...}
```

Parameters

`*DriverObject`

A pointer to a DRIVER_OBJECT structure. This is the driver's driver object.

`RegistryPath`

A pointer to a counted Unicode string specifying the path to the driver's registry key.

Return Value

If the routine succeeds, it must return STATUS_SUCCESS. Otherwise, it must return one of the error status values defined in Ntstatus.h.

Remarks

The *DriverObject* parameter supplies the **DriverEntry** routine with a pointer to the driver's driver object, which is allocated by the I/O manager. The **DriverEntry** routine must fill in the driver object with entry points for the driver's standard routines.

The *DriverObject* pointer gives the driver access to *DriverObject*->**HardwareDatabase**, which points to a counted Unicode string that specifies a path to the registry's **\Registry\Machine\Hardware** tree.

The registry path string pointed to by *RegistryPath* is of the form **\Registry\Machine\System\CurrentControlSet\Services<i>DriverName**. A driver can use this path to store driver-specific information; see Registry Keys for Drivers. The **DriverEntry** routine should save a copy of the Unicode string, not the pointer, since the I/O manager frees the *RegistryPath* buffer after **DriverEntry** returns.

For more information about implementing a **DriverEntry** routine, see Writing a DriverEntry Routine.

While it is possible to name this routine something other than **DriverEntry**, doing so is not recommended. The DDK-supplied build tools automatically inform the linker that the driver's entry point is called **DriverEntry**, so giving the routine another name requires you to modify the build tools. For more information about build tools, see Building a Driver.

Examples

To define a **DriverEntry** callback routine, you must first provide a function declaration that identifies the type of

callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

To define a **DriverEntry** callback routine, use the DRIVER_INITIALIZE type as shown in this code example:

```
DRIVER_INITIALIZE DriverEntry;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
NTSTATUS
  DriverEntry(
    struct _DRIVER_OBJECT  *DriverObject,
    PUNICODE_STRING  RegistryPath
    )
  {
      // Function body
  }
```

The DRIVER_INITIALIZE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the DRIVER_INITIALIZE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Mcd.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
IRQL	Called at PASSIVE_LEVEL.

See Also

DRIVER_OBJECT

DRIVER_LIST_CONTROL callback function

1/25/2019 • 2 minutes to read • Edit Online

The *AdapterListControl* routine starts a direct memory access (DMA) scatter/gather operation.

Syntax

```
DRIVER_LIST_CONTROL DriverListControl;

void DriverListControl(
  _DEVICE_OBJECT *DeviceObject,
  _IRP *Irp,
  PSCATTER_GATHER_LIST ScatterGather,
  PVOID Context
)
{...}
```

Parameters

`DeviceObject`

Caller-supplied pointer to a DEVICE_OBJECT structure. This is the device object for the target device, previously created by the driver's AddDevice routine.

`Irp`

Caller-supplied pointer to an IRP structure that describes the I/O operation, if the driver has a StartIo routine. Otherwise, not used.

`ScatterGather`

Caller-supplied pointer to a SCATTER_GATHER_LIST structure describing scatter/gather regions.

`Context`

Caller-supplied pointer to driver-defined context information, specified in a previous call to AllocateAdapterChannel.

Return Value

None

Remarks

To register an *AdapterListControl* routine for a specific device object, a driver must call IoGetDmaAdapter to obtain an adapter object, then call GetScatterGatherList to request use of the adapter and to supply the *AdapterListControl* routine's address. When the adapter is free, the system calls the *AdapterListControl* routine.

Examples

To define an *AdapterListControl* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define an *AdapterListControl* callback routine that is named `MyAdapterListControl`, use the DRIVER_LIST_CONTROL type as shown in this code example:

```
DRIVER_LIST_CONTROL MyAdapterListControl;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyAdapterListControl(
    struct _DEVICE_OBJECT  *DeviceObject,
    struct _IRP  *Irp,
    PSCATTER_GATHER_LIST  ScatterGather,
    PVOID  Context
    )
  {
      // Function body
  }
```

The DRIVER_LIST_CONTROL function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the DRIVER_LIST_CONTROL function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior. For detailed information about implementing an *AdapterListControl* routine, see Using Scatter/Gather DMA.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at DISPATCH_LEVEL.

DRIVER_STARTIO callback function

1/25/2019 • 2 minutes to read • Edit Online

The *StartIo* routine starts the I/O operation described by an IRP.

Syntax

```
DRIVER_STARTIO DriverStartio;

void DriverStartio(
  _DEVICE_OBJECT *DeviceObject,
  _IRP *Irp
)
{...}
```

Parameters

`*DeviceObject`

Caller-supplied pointer to a DEVICE_OBJECT structure. This is the device object for the target device, previously created by the driver's AddDevice routine.

`*Irp`

Caller-supplied pointer to an IRP structure that describes the requested I/O operation.

Return Value

None

Remarks

A driver's *StartIo* routine executes in an arbitrary thread context at IRQL = DISPATCH_LEVEL.

The *StartIo* routine is optional. A driver's *StartIo* routine, if supplied, should be named *Xxx***StartIo**, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *StartIo* routine's address in **DriverObject->DriverStartIo**. (If no routine is supplied, this pointer must be **NULL**.)

A driver can use IoSetStartIoAttributes to set attributes on when its *StartIo* routine is called.

For detailed information about implementing a driver's *StartIo* routine, see Writing a StartIo Routine.

Examples

To define a *StartIo* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *StartIo* callback routine that is named `MyStartIo`, use the DRIVER_STARTIO type as shown in this code example:

```
```

```
DRIVER_STARTIO MyStartIo;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyStartIo(
    struct _DEVICE_OBJECT  *DeviceObject,
    struct _IRP  *Irp
    )
  {
      // Function body
  }
```

The DRIVER_STARTIO function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the DRIVER_STARTIO function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at DISPATCH_LEVEL.

DRIVER_UNLOAD callback function

1/25/2019 • 2 minutes to read • Edit Online

The *Unload* routine performs any operations that are necessary before the system unloads the driver.

Syntax

```
DRIVER_UNLOAD DriverUnload;

void DriverUnload(
  _DRIVER_OBJECT *DriverObject
)
{...}
```

Parameters

`*DriverObject`

Caller-supplied pointer to a DRIVER_OBJECT structure. This is the driver's driver object.

Return Value

None

Remarks

A driver's *Unload* routine executes in a system thread context at IRQL = PASSIVE_LEVEL.

The *Unload* routine is required for WDM drivers and optional for non-WDM drivers. A driver's *Unload* routine, if supplied, should be named *Xxx***Unload**, where *Xxx* is a driver-specific prefix. The driver's DriverEntry routine must store the *Unload* routine's address in **DriverObject->DriverUnload**. (If no routine is supplied, this pointer must be **NULL**.)

For detailed information about implementing a driver's *Unload* routine, see Writing an Unload Routine.

Examples

To define an *Unload* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define an *Unload* callback routine that is named `MyUnload`, use the DRIVER_UNLOAD type as shown in this code example:

```
DRIVER_UNLOAD MyUnload;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyUnload(
    struct _DRIVER_OBJECT  *DriverObject
    )
  {
      // Function body
  }
```

The DRIVER_UNLOAD function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the DRIVER_UNLOAD function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at PASSIVE_LEVEL.

EX_CALLBACK_FUNCTION callback function

1/25/2019 • 5 minutes to read • Edit Online

A filter driver's *RegistryCallback* routine can monitor, block, or modify a registry operation.

Syntax

```
EX_CALLBACK_FUNCTION ExCallbackFunction;

NTSTATUS ExCallbackFunction(
  PVOID CallbackContext,
  PVOID Argument1,
  PVOID Argument2
)
{...}
```

Parameters

`CallbackContext`

The value that the driver passed as the *Context* parameter to CmRegisterCallback or CmRegisterCallbackEx when it registered this *RegistryCallback* routine.

`Argument1`

A REG_NOTIFY_CLASS-typed value that identifies the type of registry operation that is being performed and whether the *RegistryCallback* routine is being called before or after the registry operation is performed.

`Argument2`

A pointer to a structure that contains information that is specific to the type of registry operation. The structure type depends on the REG_NOTIFY_CLASS-typed value for *Argument1*, as shown in the following table. For information about which REG_NOTIFY_CLASS-typed values are available for which operating system versions, see REG_NOTIFY_CLASS.

REG_NOTIFY_CLASS VALUE	STRUCTURE TYPE
RegNtDeleteKey	REG_DELETE_KEY_INFORMATION
RegNtPreDeleteKey	REG_DELETE_KEY_INFORMATION
RegNtPostDeleteKey	REG_POST_OPERATION_INFORMATION
RegNtSetValueKey	REG_SET_VALUE_KEY_INFORMATION
RegNtPreSetValueKey	REG_SET_VALUE_KEY_INFORMATION
RegNtPostSetValueKey	REG_POST_OPERATION_INFORMATION
RegNtDeleteValueKey	REG_DELETE_VALUE_KEY_INFORMATION

REG_NOTIFY_CLASS VALUE	STRUCTURE TYPE
RegNtPreDeleteValueKey	REG_DELETE_VALUE_KEY_INFORMATION
RegNtPostDeleteValueKey	REG_POST_OPERATION_INFORMATION

RegNtCallbackObjectContextCleanup	REG_CALLBACK_CONTEXT_CLEANUP_INFORMATION
RegNtPreRestoreKey	REG_RESTORE_KEY_INFORMATION
RegNtPostRestoreKey	REG_RESTORE_KEY_INFORMATION
RegNtPreSaveKey	REG_SAVE_KEY_INFORMATION
RegNtPostSaveKey	REG_SAVE_KEY_INFORMATION
RegNtPreReplaceKey	REG_REPLACE_KEY_INFORMATION

REG_NOTIFY_CLASS VALUE	STRUCTURE TYPE
RegNtPostReplaceKey	REG_REPLACE_KEY_INFORMATION
RegNtPreQueryKeyName	REG_QUERY_KEY_NAME
RegNtPostQueryKeyName	REG_POST_OPERATION_INFORMATION

** Starting with Windows 7, the actual data structure passed in when the notify class is RegNtPreCreateKeyEx or RegNtPreOpenKeyEx is the V1 version of this structure, REG_CREATE_KEY_INFORMATION_V1 or REG_OPEN_KEY_INFORMATION_V1 , respectively. Check the Reserved member to determine the version of the structure.

VERSION NUMBER	STRUCTURE NAME
0	REG_CREATE_KEY_INFORMATION and REG_OPEN_KEY_INFORMATION
1	REG_CREATE_KEY_INFORMATION_V1 and REG_OPEN_KEY_INFORMATION_V1

Return Value

For more information about when a *RegistryCallback* routine should return each of these status values, see Filtering Registry Calls.

Remarks

To be notified of registry operations, a kernel-mode component (such as the driver component of an antivirus software package) can call CmRegisterCallback or CmRegisterCallbackEx to register a *RegistryCallback* routine.

The *RegistryCallback* routine can inspect the contents of the input and output buffers that are supplied for registry operations. A registry operation can be initiated by a user-mode application that calls a user-mode registry routine (such as RegCreateKeyEx or RegOpenKeyEx) or by a driver that calls a kernel-mode registry routine (such as ZwCreateKey or ZwOpenKey). An *input buffer* is a memory buffer supplied by the initiator from which the registry reads input data for the operation. An *output buffer* is a buffer supplied by the initiator into which the registry writes output data requested by the initiator.

Before calling the *RegistryCallback* routine, the kernel probes (to verify alignment and accessibility) all members of the *Argument2* structures that point to output buffers in user-mode memory, but does not capture user-mode output buffers in system memory. The callback routine must enclose any access of an output buffer in a **try**/**except** block. If the callback routine needs to pass an output buffer pointer to a system routine (for example, ZwOpenKey), and the buffer is in user-mode memory, the callback routine must first capture the buffer.

The handling of input buffers depends on the Windows version. Starting with Windows 8, the kernel captures all input buffers pointed to by members of the *Argument2* structures in system memory before calling the *RegistryCallback* routine. In versions of Windows before Windows 8, the kernel probes all members of the *Argument2* structures that point to input buffers in user-mode memory, but captures only some of these buffers in system memory. In these earlier versions of Windows, the callback routine must enclose any access of an input buffer in a **try**/**except** block. Additionally, if the callback routine needs to pass an input buffer pointer to a system routine (for example, **ZwOpenKey**), and the buffer is in user-mode memory, the callback routine must first capture the buffer.

The following table summarizes the requirements for buffer accesses by the *RegistryCallback* routine.

BUFFER TYPE	WINDOWS VERSION	BUFFER POINTER PASSED TO CALLBACK ROUTINE	SAFE FOR CALLBACK ROUTINE TO DIRECTLY ACCESS?	SAFE TO PASS TO SYSTEM ROUTINES (SUCH AS ZWOPENKEY)?
User-mode input	Windows 8 and later	Points to captured data.	Yes	Yes
User-mode input	Windows 7 and earlier	Points to captured data or original user-mode buffer.	No. Must read under try/except.	No. Must allocate kernel memory, copy data from the original buffer under try/except, and pass the copied data to the system routine.
User-mode output	All	Points to original user-mode buffer.	No. Must write under try/except.	No. Must allocate kernel memory, pass kernel memory to the system routine, and copy the results back to the original buffer under try/except.
Kernel-mode input and output	All	Points to original kernel-mode buffer.	Yes	Yes

For more information about *RegistryCallback* routines and registry filter drivers, see Filtering Registry Calls.

A *RegistryCallback* executes at IRQL = PASSIVE_LEVEL and in the context of the thread that is performing the registry operation.

Examples

To define a *RegistryCallback* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *RegistryCallback* callback routine that is named `MyRegistryCallback`, use the EX_CALLBACK_FUNCTION type as shown in this code example:

```
EX_CALLBACK_FUNCTION MyRegistryCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
NTSTATUS
  MyRegistryCallback(
    PVOID  CallbackContext,
    PVOID  Argument1,
    PVOID  Argument2
    )
  {
      // Function body
  }
```

The EX_CALLBACK_FUNCTION function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the EX_CALLBACK_FUNCTION function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Supported starting with Windows XP (see Return Value section).
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at PASSIVE_LEVEL (see Remarks section).

ZwOpenKey

ExAcquireResourceExclusiveLite function

1/25/2019 • 2 minutes to read • Edit Online

The **ExAcquireResourceExclusiveLite** routine acquires the given resource for exclusive access by the calling thread.

Syntax

```
BOOLEAN ExAcquireResourceExclusiveLite(
  PERESOURCE Resource,
  BOOLEAN    Wait
);
```

Parameters

`Resource`

A pointer to the resource to acquire.

`Wait`

Specifies the routine's behavior whenever the resource cannot be acquired immediately. If**TRUE**, the caller is put into a wait state until the resource can be acquired. If **FALSE**, the routine immediately returns, regardless of whether the resource can be acquired.

Return Value

ExAcquireResourceExclusiveLite returns **TRUE** if the resource is acquired. This routine returns **FALSE** if the input *Wait* is **FALSE** and exclusive access cannot be granted immediately.

Remarks

The following list describes whether and when a caller is given exclusive access to a given resource:

- If the resource is currently not owned, exclusive access is granted immediately to the current thread.
- If the caller already had acquired the resource for exclusive access, the current thread is granted the same type of access recursively.
- If the caller has shared access to the resource, the caller must release the lock before it attempts to reacquire it exclusively.
- If the resource is currently owned as exclusive by another thread, or if the caller only has shared access to the resource, the current thread is put into a wait state until the resource can be acquired.

> **Note** If two threads each hold a shared lock on the same resource and both attempt to acquire the lock exclusively without releasing their shared lock, they will deadlock. This means that each thread will wait for the other to release its shared hold on the lock, and neither will release its shared hold until the other does.

The caller can release the resource by calling either ExReleaseResourceLite or ExReleaseResourceForThreadLite.

Normal kernel APC delivery must be disabled before calling this routine. Disable normal kernel APC delivery by

calling KeEnterCriticalRegion. Delivery must remain disabled until the resource is released, at which point it can be reenabled by calling KeLeaveCriticalRegion. For more information, see Disabling APCs.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

ExAcquireResourceSharedLite function

1/25/2019 • 2 minutes to read • Edit Online

The **ExAcquireResourceSharedLite** routine acquires the given resource for shared access by the calling thread.

Syntax

```
BOOLEAN ExAcquireResourceSharedLite(
  PERESOURCE Resource,
  BOOLEAN    Wait
);
```

Parameters

`Resource`

A pointer to the resource to acquire.

`Wait`

Specifies the routine's behavior whenever the resource cannot be acquired immediately. If**TRUE**, the caller is put into a wait state until the resource can be acquired. If **FALSE**, the routine immediately returns, regardless of whether the resource can be acquired.

Return Value

The caller can release the resource by calling either ExReleaseResourceLite or ExReleaseResourceForThreadLite.

ExAcquireResourceSharedLite returns **TRUE** if (or when) the resource is acquired. This routine returns **FALSE** if the input *Wait* is **FALSE** and shared access cannot be granted immediately.

Remarks

Whether or when the caller is given shared access to the given resource depends on the following:

- If the resource is currently unowned, shared access is granted immediately to the current thread.
- If the caller already has acquired the resource (for shared or exclusive access), the current thread is granted the same type of access recursively. Note that making this call does not convert a caller's exclusive access of a given resource to shared access.
- If the resource is currently owned as shared by another thread and no thread is waiting for exclusive access to the resource, shared access is granted to the caller immediately. The caller is put into a wait state if there is an exclusive waiter.
- If the resource is currently owned as exclusive by another thread or if there is another thread waiting for exclusive access and the caller does not already have shared access to the resource, the current thread either is put into a wait state (*Wait* set to **TRUE**) or **ExAcquireResourceSharedLite** returns **FALSE**.

Normal kernel APC delivery must be disabled before calling this routine. Disable normal kernel APC delivery by calling KeEnterCriticalRegion. Delivery must remain disabled until the resource is released, at which point it can be reenabled by calling KeLeaveCriticalRegion. For more information, see Disabling APCs.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ExAcquireRundownProtection function

1/25/2019 • 2 minutes to read • Edit Online

The **ExAcquireRundownProtection** routine tries to acquire run-down protection on a shared object so the caller can safely access the object.

Syntax

```
BOOLEAN ExAcquireRundownProtection(
  PEX_RUNDOWN_REF RunRef
);
```

Parameters

`RunRef`

A pointer to an EX_RUNDOWN_REF structure that was initialized by a previous call to the ExInitializeRundownProtection routine. The run-down protection routines use this structure to track the run-down status of the associated shared object. This structure is opaque to drivers.

Return Value

ExAcquireRundownProtection returns **TRUE** if the routine successfully acquires run-down protection for the caller. Otherwise, it returns **FALSE**. A return value of **FALSE** indicates that the run down of the object has started and that the object must be treated as invalid.

Remarks

To safely access a shared object, a driver calls **ExAcquireRundownProtection** to acquire run-down protection on the object. The routine returns **TRUE** to indicate that run-down protection is in effect. When run-down protection is in effect, the driver can safely access the object without risk that the object will be deleted before the access completes.

After completing the access, the driver calls ExReleaseRundownProtection to release the previously acquired run-down protection.

If **ExAcquireRundownProtection** returns **FALSE**, the object is no longer accessible. For example, if the object is to be replaced with a new one, the caller must wait for the object owner to create the new object, and then negotiate access to the new object.

For more information, see Run-Down Protection.

Requirements

Minimum supported client	Available starting with Windows XP.
Target Platform	Universal

Header	wdm.h (include Wdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"
DDI compliance rules	HwStorPortProhibitedDDIs

EX_RUNDOWN_REF

ExInitializeRundownProtection

ExReleaseRundownProtection

ExAcquireRundownProtectionEx function

1/25/2019 • 2 minutes to read • Edit Online

The **ExAcquireRundownProtectionEx** routine tries to acquire run-down protection on a shared object so the caller can safely access the object.

Syntax

```
BOOLEAN ExAcquireRundownProtectionEx(
  PEX_RUNDOWN_REF RunRef,
  ULONG           Count
);
```

Parameters

`RunRef`

A pointer to an EX_RUNDOWN_REF structure that was initialized by a previous call to the ExInitializeRundownProtection routine. The run-down protection routines use this structure to track the run-down status of the associated shared object. This structure is opaque to drivers.

`Count`

The amount by which to increment to the run-down instance count of the object. The count is incremented only if the routine returns **TRUE**. For more information, see Remarks

Return Value

ExAcquireRundownProtectionEx returns **TRUE** if the routine successfully acquires run-down protection for the caller. Otherwise, it returns **FALSE**. A return value of **FALSE** indicates that the run down of the object has started and that the object must be treated as invalid.

Remarks

To safely access a shared object, a driver calls **ExAcquireRundownProtectionEx** to acquire run-down protection on the object.

The *RunRef* parameter points to an EX_RUNDOWN_REF structure that tracks the run-down status of the associated object. This status information includes a count of instances of run-down protection that are currently in effect on the object. The **ExAcquireRundownProtectionEx** and ExReleaseRundownProtectionEx routines increment and decrement this count by arbitrary amounts. Two related routines, ExAcquireRundownProtection and ExReleaseRundownProtection, increment and decrement this count by one.

For more information, see Run-Down Protection.

Requirements

Minimum supported client	Available starting with Windows Server 2003.

Target Platform	Universal
Header	wdm.h (include Wdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"
DDI compliance rules	HwStorPortProhibitedDDIs

ExReleaseRundownProtectionEx

ExAcquireSharedStarveExclusive function

1/25/2019 • 2 minutes to read • Edit Online

The **ExAcquireSharedStarveExclusive** routine acquires a given resource for shared access without waiting for any pending attempts to acquire exclusive access to the same resource.

Syntax

```
BOOLEAN ExAcquireSharedStarveExclusive(
  PERESOURCE Resource,
  BOOLEAN    Wait
);
```

Parameters

`Resource`

A pointer to the resource to be acquired for shared access.

`Wait`

Specifies the routine's behavior whenever the resource cannot be acquired immediately. If**TRUE**, the caller is put into a wait state until the resource can be acquired. If **FALSE**, the routine immediately returns, regardless of whether the resource can be acquired.

Return Value

The caller can release the resource by calling either ExReleaseResourceLite or ExReleaseResourceForThreadLite.

ExAcquireSharedStarveExclusive returns **TRUE** if the requested access is granted. This routine returns **FALSE** if the input *Wait* is **FALSE** and shared access cannot be granted immediately.

Remarks

Whether or when the caller is given shared access to the given resource depends on the following:

- If the resource is currently unowned, shared access is granted immediately to the current thread.
- If the caller already has acquired the resource (for shared or exclusive access), the current thread is granted the same type of access recursively. Note that making this call does not convert a caller's exclusive access of a given resource to shared access.
- If the resource is currently owned as shared by another thread, shared access is granted to the caller immediately, even if another thread is waiting for exclusive access to that resource.
- If the resource is currently owned as exclusive by another thread, the caller either is put into a wait state (*Wait* set to **TRUE**) or **ExAcquireSharedStarveExclusive** returns **FALSE**.

Callers of **ExAcquireSharedStarveExclusive** usually need quick access to a shared resource in order to save an exclusive accessor from doing redundant work. For example, a file system might call this routine to modify a cached resource, such as a BCB pinned in the cache, before the cache manager can acquire exclusive access to the resource and write the cache out to disk.

Normal kernel APC delivery must be disabled before calling this routine. Disable normal kernel APC delivery by calling KeEnterCriticalRegion. Delivery must remain disabled until the resource is released, at which point it can be reenabled by calling KeLeaveCriticalRegion. For more information, see Disabling APCs.

Requirements

ExGetExclusiveWaiterCount

ExIsResourceAcquiredExclusiveLite

ExIsResourceAcquiredSharedLite

ExAcquireSharedWaitForExclusive function

1/25/2019 • 2 minutes to read • Edit Online

The **ExAcquireSharedWaitForExclusive** routine acquires the given resource for shared access if shared access can be granted and there are no exclusive waiters.

Syntax

```
BOOLEAN ExAcquireSharedWaitForExclusive(
  PERESOURCE Resource,
  BOOLEAN    Wait
);
```

Parameters

`Resource`

A pointer to the resource to be acquired for shared access.

`Wait`

Specifies the routine's behavior whenever the resource cannot be acquired immediately. If**TRUE**, the caller is put into a wait state until the resource can be acquired. If **FALSE**, the routine immediately returns, regardless of whether the resource can be acquired.

Return Value

ExAcquireSharedWaitForExclusive returns **TRUE** if the requested access is granted or an exclusive owner releases the resource. This routine returns **FALSE** if the input *Wait* is **FALSE** and shared access cannot be granted immediately.

Remarks

Most drivers should use ExAcquireResourceSharedLite instead of **ExAcquireSharedWaitForExclusive**.

The caller can release the resource by calling either ExReleaseResourceLite or ExReleaseResourceForThreadLite.

If shared access cannot be granted immediately, the caller can wait for other threads to acquire and release exclusive ownership of the resource.

Whether or when the caller is given shared access to the given resource depends on the following:

- If the resource is currently unowned, shared access is granted immediately to the current thread.
- If the caller already has exclusive access to the resource, the current thread is granted the same type of access recursively.
- If the resource is currently owned as shared and there are no pending attempts to acquire exclusive access, shared access is granted to the caller immediately.
- If the resource is currently owned as shared but there is a pending attempt to acquire exclusive access, the caller either is put into a wait state (*Wait* set to **TRUE**) or **ExAcquireSharedWaitForExclusive** returns **FALSE**.

When the current thread waits to acquire the resource until after a pending exclusive ownership has been released, **ExAcquireSharedWaitForExclusive** returns **TRUE** when the current thread is granted shared access to the resource and resumes execution.

The behavior of **ExAcquireSharedWaitForExclusive** is identical to that of ExAcquireResourceSharedLite unless the calling thread already owns the resource as shared and there are exclusive waiters. In that case, **ExAcquireSharedWaitForExclusive** allows the exclusive waiters to acquire exclusive ownership of the resource.

If the caller specifies **TRUE** for the *Wait* parameter, the caller blocks until another thread frees the resource on behalf of the caller, using ExReleaseResourceForThread. Driver writers must be careful to ensure that another thread actually releases the resource; otherwise the caller is deadlocked. **ExAcquireResourceSharedLite** does not have this property, so drivers should use that routine unless they require the particular behavior of **ExAcquireSharedWaitForExclusive**.

Normal kernel APC delivery must be disabled before calling this routine. Disable normal kernel APC delivery by calling KeEnterCriticalRegion. Delivery must remain disabled until the resource is released, at which point it can be reenabled by calling KeLeaveCriticalRegion. For more information, see Disabling APCs.

Requirements

ExAllocateFromLookasideListEx function

1/25/2019 • 2 minutes to read • Edit Online

The **ExAllocateFromLookasideListEx** routine removes the first entry from the specified lookaside list, or, if the list is empty, dynamically allocates the storage for a new entry.

Syntax

```
PVOID ExAllocateFromLookasideListEx(
  PLOOKASIDE_LIST_EX Lookaside
);
```

Parameters

`Lookaside`

A pointer to a LOOKASIDE_LIST_EX structure that describes a lookaside list. This structure was previously initialized by the ExInitializeLookasideListEx routine.

Return Value

ExAllocateFromLookasideListEx returns a pointer to a lookaside-list entry, if an entry is available in the list or can be dynamically allocated. Otherwise, this routine returns **NULL**.

Remarks

This routine removes the first entry, if an entry is available, from the specified lookaside list and returns a pointer to this entry. If the list is empty, the routine allocates storage for a new entry and returns a pointer to this entry. If this allocation fails, the routine returns **NULL**.

If the lookaside list is empty, **ExAllocateFromLookasideListEx** calls the LookasideListAllocateEx routine to allocate storage for a new entry, if the driver has provided such a routine. Otherwise, a default allocation routine is used to allocate the entry.

After the caller finishes using the entry, it should free the entry by calling the ExFreeToLookasideListEx routine.

In the current implementation, a lookaside list operates as a last-in, first-out (LIFO) stack. Thus, the last entry to be freed (and pushed onto the stack) is the next entry to be allocated (popped) from the list.

For more information about lookaside lists, see Using Lookaside Lists.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

LookasideListAllocateEx

ExAllocateFromNPagedLookasideList function

1/25/2019 • 2 minutes to read • Edit Online

The **ExAllocateFromNPagedLookasideList** routine returns a pointer to a nonpaged entry from the given lookaside list, or it returns a pointer to a newly allocated nonpaged entry.

Syntax

```
PVOID ExAllocateFromNPagedLookasideList(
  PNPAGED_LOOKASIDE_LIST Lookaside
);
```

Parameters

`Lookaside`

A pointer to the NPAGED_LOOKASIDE_LIST structure for the lookaside list, which the caller already initialized with ExInitializeNPagedLookasideList.

Return Value

ExAllocateFromNPagedLookasideList returns a pointer to an entry if one can be allocated. Otherwise, it returns **NULL**.

Remarks

If the given lookaside list is not empty, **ExAllocateFromNPagedLookasideList** removes the first entry from the list and returns a pointer to this entry. Otherwise, **ExAllocateFromNPagedLookasideList** either calls the *Allocate* routine specified at list initialization or ExAllocatePoolWithTag to return an entry pointer.

The caller can then set up the returned entry with any caller-determined data. For example, a driver might use each such fixed-size entry to set up command blocks, like SCSI SRBs, to peripheral devices on a particular type of I/O bus. The caller should release each entry with ExFreeToNPagedLookasideList when it is no longer in use.

For more information, see Using Lookaside Lists.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IRQL	"<= DISPATCH_LEVEL"

ExFreeToNPagedLookasideList

ExInitializeNPagedLookasideList

NPAGED_LOOKASIDE_LIST

ExAllocateFromPagedLookasideList function

1/25/2019 • 2 minutes to read • Edit Online

The **ExAllocateFromPagedLookasideList** routine returns a pointer to a paged entry from the given lookaside list, or it returns a pointer to a newly allocated paged entry.

Syntax

```
PVOID ExAllocateFromPagedLookasideList(
  PPAGED_LOOKASIDE_LIST Lookaside
);
```

Parameters

`Lookaside`

A pointer to the PAGED_LOOKASIDE_LIST structure for the lookaside list, which the caller already initialized with ExInitializePagedLookasideList.

Return Value

ExAllocateFromPagedLookasideList returns a pointer to an entry if one can be allocated. Otherwise, it returns **NULL**.

Remarks

If the given lookaside list is not empty, **ExAllocateFromPagedLookasideList** removes the first entry from the list and returns a pointer to this entry. Otherwise, **ExAllocateFromPagedLookasideList** either calls the *Allocate* routine specified at list initialization or ExAllocatePoolWithTag to return an entry pointer.

The caller can then set up the returned entry with any caller-determined data. The caller should release each entry with ExFreeToPagedLookasideList when it is no longer in use.

Because the entries in a paged lookaside list are allocated from pageable memory, they must not be accessed at an IRQL >= DISPATCH_LEVEL. You can use ExAllocateFromNPagedLookasideList to create a lookaside list with non-pageable entries.

On Windows 2000, drivers must use the **-D_WIN2K_COMPAT_SLIST_USAGE** switch to successfully link code that uses **ExAllocateFromPagedLookasideList**.

For more information, see Using Lookaside Lists.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

ExFreeToPagedLookasideList

ExInitializePagedLookasideList

PAGED_LOOKASIDE_LIST

ExAllocatePool function

1/25/2019 • 2 minutes to read • Edit Online

The **ExAllocatePool** routine is obsolete, and is exported only for existing binaries. Use ExAllocatePoolWithTag instead.

ExAllocatePool allocates pool memory of the specified type and returns a pointer to the allocated block.

Syntax

```
PVOID ExAllocatePool(
  __drv_strictTypeMatch(__drv_typeExpr)POOL_TYPE PoolType,
  SIZE_T                                         NumberOfBytes
);
```

Parameters

`PoolType`

Specifies the type of pool memory to allocate. For a description of the available pool memory types, see POOL_TYPE.

You can modify *PoolType* by using a bitwise OR with the POOL_COLD_ALLOCATION flag as a hint to the kernel to allocate the memory from pages that are likely to be paged out quickly. To reduce the amount of resident pool memory as much as possible, you should not reference these allocations frequently. The POOL_COLD_ALLOCATION flag is only advisory and is available for Windows XP and later versions of the Windows operating system.

`NumberOfBytes`

Specifies the number of bytes to allocate.

Return Value

ExAllocatePool returns **NULL** if there is insufficient memory in the free pool to satisfy the request. Otherwise the routine returns a pointer to the allocated memory.

Remarks

This routine is used for the general pool allocation of memory.

If *NumberOfBytes* is PAGE_SIZE or greater, a page-aligned buffer is allocated. Memory allocations of PAGE_SIZE or less do not cross page boundaries. Memory allocations of less than PAGE_SIZE are not necessarily page-aligned but are aligned to 8-byte boundaries in 32-bit systems and to 16-byte boundaries in 64-bit systems.

A successful allocation requesting *NumberOfBytes* < PAGE_SIZE of nonpaged pool gives the caller exactly the number of requested bytes of memory. If an allocation request for *NumberOfBytes* > PAGE_SIZE succeeds and *NumberOfBytes* is not an exact multiple of PAGE_SIZE, the last page in the allocation contains bytes that are not part of the caller's allocation. If possible, the pool allocator uses these bytes. To avoid corrupting data that belongs to other kernel-mode components, drivers must access only storage addresses that they have explicitly allocated.

If **ExAllocatePool** returns **NULL**, the caller should return the NTSTATUS value

STATUS_INSUFFICIENT_RESOURCES or should delay processing to another point in time.

Callers of **ExAllocatePool** must be executing at IRQL <= DISPATCH_LEVEL. A caller executing at DISPATCH_LEVEL must specify a **NonPaged***Xxx* value for *PoolType*. A caller executing at IRQL <= APC_LEVEL can specify any **POOL_TYPE** value, but the IRQL and environment must also be considered for determining the page type.

> **Note** Do not set *NumberOfBytes* = 0. Avoid zero-length allocations because they waste pool header space and, in many cases, indicate a potential validation issue in the calling code. For this reason, Driver Verifier flags such allocations as possible errors.

The system automatically sets certain standard event objects when the amount of pool (paged or nonpaged) is high or low. Drivers can wait for these events to tune their pool usage. For more information, see Standard Event Objects.

> **Note** Memory that **ExAllocatePool** allocates is uninitialized. A kernel-mode driver must first zero this memory if it is going to make it visible to user-mode software (to avoid leaking potentially privileged contents).

Requirements

Minimum supported client	Obsolete. This routine is exported only for existing binaries. Use ExAllocatePoolWithTag instead.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Classpnp.h, Smcnt.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL (see Remarks section)"
DDI compliance rules	HwStorPortProhibitedDDIs, SpNoWait, StorPortStartIo

ExAllocatePoolWithTag

ExFreePool

POOL_TYPE

ExAllocatePoolWithQuota function

1/25/2019 • 2 minutes to read • Edit Online

The **ExAllocatePoolWithQuota** routine is obsolete, and is exported only for existing driver binaries. Use ExAllocatePoolWithQuotaTag instead.

ExAllocatePoolWithQuota allocates pool memory, charging quota against the current process.

Syntax

```
PVOID ExAllocatePoolWithQuota(
  __drv_strictTypeMatch(__drv_typeExpr)POOL_TYPE PoolType,
  SIZE_T                                         NumberOfBytes
);
```

Parameters

`PoolType`

Specifies the type of pool memory to allocate. For a description of the available pool memory types, see POOL_TYPE.

You can modify *PoolType* by using a bitwise OR with the POOL_COLD_ALLOCATION flag as a hint to the kernel to allocate the memory from pages that are likely to be paged out quickly. To reduce the amount of resident pool memory as much as possible, you should not reference these allocations frequently. The POOL_COLD_ALLOCATION flag is only advisory and is available for Windows XP and later versions of the Windows operating system.

`NumberOfBytes`

Specifies the number of bytes to allocate.

Return Value

ExAllocatePoolWithQuota returns a pointer to the allocated pool.

If the request cannot be satisfied, **ExAllocatePoolWithQuota** raises an exception.

Remarks

This routine is called by highest-level drivers that allocate memory to satisfy a request in the context of the process that originally made the I/O request. Lower-level drivers call ExAllocatePoolWithTag instead.

If *NumberOfBytes* is PAGE_SIZE or greater, a page-aligned buffer is allocated. Quota is not charged to the process for allocations of PAGE_SIZE or greater.

Memory allocations of less than PAGE_SIZE are allocated within a page and do not cross page boundaries. Memory allocations of PAGE_SIZE or less are not necessarily page-aligned but are aligned to 8-byte boundaries in 32-bit systems and to 16-byte boundaries in 64-bit systems.

Note Do not set *NumberOfBytes* = 0. Avoid zero-length allocations because they waste pool header space and, in many cases, indicate a potential validation issue in the calling code. For this reason, Driver Verifier flags such allocations as possible errors.

The system automatically sets certain standard event objects when the amount of pool (paged or nonpaged) is high or low. Drivers can wait for these events to tune their pool usage. For more information, see Standard Event Objects.

Note Memory that **ExAllocatePoolWithQuota** allocates is uninitialized. A kernel-mode driver must first zero this memory if it is going to make it visible to user-mode software (to avoid leaking potentially privileged contents).

Callers of **ExAllocatePoolWithQuota** must be executing at IRQL <= DISPATCH_LEVEL. A caller executing at DISPATCH_LEVEL must specify a **NonPaged***Xxx* value for *PoolType*. A caller executing at IRQL <= APC_LEVEL can specify any **POOL_TYPE** value, but the IRQL and environment must also be considered for determining the pool type.

Requirements

Minimum supported client	Obsolete. This routine is exported only for existing driver binaries. Use ExAllocatePoolWithQuotaTag instead.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Classpnp.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL (see Remarks section)"

ExAllocatePoolWithQuotaTag

ExAllocatePoolWithTag

ExFreePool

POOL_TYPE

ExAllocatePoolWithQuotaTag function

1/25/2019 • 3 minutes to read • Edit Online

The **ExAllocatePoolWithQuotaTag** routine allocates pool memory, charging the quota against the current process.

Syntax

```
PVOID ExAllocatePoolWithQuotaTag(
  __drv_strictTypeMatch(__drv_typeExpr)POOL_TYPE PoolType,
  SIZE_T                                         NumberOfBytes,
  ULONG                                          Tag
);
```

Parameters

`PoolType`

Specifies the type of pool memory to allocate. For a description of the available pool memory types, see POOL_TYPE.

You can modify the *PoolType* value by bitwise-ORing this value with the POOL_QUOTA_FAIL_INSTEAD_OF_RAISE flag. This flag causes the routine to return a **NULL** value if the request cannot be satisfied.

Similarly, you can modify the *PoolType* value by bitwise-ORing this value with the POOL_COLD_ALLOCATION flag as a hint to the kernel to allocate the memory from pages that are likely to be paged out quickly. To reduce the amount of resident pool memory as much as possible, you should not reference these allocations frequently. The POOL_COLD_ALLOCATION flag is only advisory and is supported in Windows XP and later versions of the Windows operating system.

`NumberOfBytes`

Specifies the number of bytes to allocate.

`Tag`

Specifies the pool tag for the allocated memory. For more information, see the *Tag* parameter of ExAllocatePoolWithTag.

Return Value

ExAllocatePoolWithQuotaTag returns a pointer to the allocated pool.

If the request cannot be satisfied, **ExAllocatePoolWithQuotaTag** raises an exception unless POOL_QUOTA_FAIL_INSTEAD_OF_RAISE is specified. Using POOL_QUOTA_FAIL_INSTEAD_OF_RAISE is preferred for performance reasons.

Remarks

This routine is called by highest-level drivers that allocate memory to satisfy a request in the context of the process that originally made the I/O request. Lower-level drivers call ExAllocatePoolWithTag instead.

If *NumberOfBytes* is PAGE_SIZE or greater, a page-aligned buffer is allocated. Memory allocations of PAGE_SIZE or less are allocated within a page and do not cross page boundaries. Memory allocations of less than PAGE_SIZE are not necessarily page-aligned but are aligned to 8-byte boundaries in 32-bit systems and to 16-byte boundaries in 64-bit systems.

The system associates the pool tag with the allocated memory. Programming tools, such as WinDbg, can display the pool tag associated with each allocated buffer. The value of *Tag* is normally displayed in reversed order. For example, if a caller passes 'Fred' as a *Tag*, it would appear as 'derF' if the pool is dumped or when tracking pool usage in the debugger.

The allocated buffer can be freed with either ExFreePool or ExFreePoolWithTag.

> **Note** Do not set *NumberOfBytes* = 0. Avoid zero-length allocations because they waste pool header space and, in many cases, indicate a potential validation issue in the calling code. For this reason, Driver Verifier flags such allocations as possible errors.

The system automatically sets certain standard event objects when the amount of pool (paged or nonpaged) is high or low. Drivers can wait for these events to tune their pool usage. For more information, see Standard Event Objects.

In a non-uniform memory access (NUMA) multiprocessor architecture, **ExAllocatePoolWithQuotaTag** tries to allocate memory that is local to the processor that is calling **ExAllocatePoolWithQuotaTag**. If no local memory is available, **ExAllocatePoolWithQuotaTag** allocates the closest available memory.

> **Note** Memory that **ExAllocatePoolWithQuotaTag** allocates is uninitialized. A kernel-mode driver must first zero this memory if it is going to make it visible to user-mode software (to avoid leaking potentially privileged contents).

Callers of **ExAllocatePoolWithQuotaTag** must be executing at IRQL <= DISPATCH_LEVEL. A caller executing at DISPATCH_LEVEL must specify a **NonPaged***Xxx* value for *PoolType*. A caller executing at IRQL <= APC_LEVEL can specify any **POOL_TYPE** value, but the IRQL and environment must also be considered for determining the pool type.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ExAllocatePoolWithTag

ExFreePool

ExFreePoolWithTag

POOL_TYPE

ExAllocatePoolWithTag function

1/25/2019 • 3 minutes to read • Edit Online

The **ExAllocatePoolWithTag** routine allocates pool memory of the specified type and returns a pointer to the allocated block.

Syntax

```
PVOID ExAllocatePoolWithTag(
  __drv_strictTypeMatch(__drv_typeExpr)POOL_TYPE PoolType,
  SIZE_T                                         NumberOfBytes,
  ULONG                                          Tag
);
```

Parameters

`PoolType`

The type of pool memory to allocate. For a description of the available pool memory types, see POOL_TYPE.

You can modify the *PoolType* value by bitwise-ORing this value with the POOL_RAISE_IF_ALLOCATION_FAILURE flag. This flag causes an exception to be raised if the request cannot be satisfied. Use of the POOL_RAISE_IF_ALLOCATION_FAILURE flag is not recommended because it is costly.

Similarly, you can modify the *PoolType* value by bitwise-ORing this value with the POOL_COLD_ALLOCATION flag as a hint to the kernel to allocate the memory from pages that are likely to be paged out quickly. To reduce the amount of resident pool memory as much as possible, you should not reference these allocations frequently. The POOL_COLD_ALLOCATION flag is only advisory and is supported starting with Windows XP.

`NumberOfBytes`

The number of bytes to allocate.

`Tag`

The pool tag to use for the allocated memory. Specify the pool tag as a character literal of up to four characters delimited by single quotation marks (for example, 'Tag1'). The string is usually specified in reverse order (for example, '1gaT'). Each ASCII character in the tag must be a value in the range 0x20 (space) to 0x7E (tilde). Each allocation code path should use a unique pool tag to help debuggers and verifiers identify the code path.

Return Value

ExAllocatePoolWithTag returns **NULL** if there is insufficient memory in the free pool to satisfy the request. Otherwise, the routine returns a pointer to the allocated memory.

Remarks

This routine is used for the general pool allocation of memory.

If *NumberOfBytes* is PAGE_SIZE or greater, a page-aligned buffer is allocated. Memory allocations of PAGE_SIZE or less are allocated within a page and do not cross page boundaries. Memory allocations of less than PAGE_SIZE are not necessarily page-aligned but are aligned to 8-byte boundaries in 32-bit systems and to 16-byte boundaries

in 64-bit systems.

A successful allocation requesting *NumberOfBytes* < PAGE_SIZE of nonpaged pool gives the caller exactly the number of requested bytes of memory. If an allocation request for *NumberOfBytes* > PAGE_SIZE succeeds and *NumberOfBytes* is not an exact multiple of PAGE_SIZE, the last page in the allocation contains bytes that are not part of the caller's allocation. If possible, the pool allocator uses these bytes. To avoid corrupting data that belongs to other kernel-mode components, drivers must access only storage addresses that they have explicitly allocated.

The system associates the pool tag with the allocated memory. Programming tools, such as WinDbg, can display the pool tag associated with each allocated buffer. Gflags, a tool included in Debugging Tools for Windows, turns on a system feature that requests allocation from special pool for a particular pool tag. Poolmon, which is included in the WDK, tracks memory by pool tag.

The value of *Tag* is stored, and sometimes displayed, in reverse (little-endian) order. For example, if a caller passes 'Fred' as a *Tag*, it appears as "derF" in a pool dump and in pool usage tracking in the debugger, and as 0x64657246 in the registry and in tool displays.

The allocated buffer can be freed with either ExFreePool or ExFreePoolWithTag.

The system automatically sets certain standard event objects when the amount of pool (paged or nonpaged) is high or low. Drivers can wait for these events to tune their pool usage. For more information, see Standard Event Objects.

Callers of **ExAllocatePoolWithTag** must be executing at IRQL <= DISPATCH_LEVEL. A caller executing at DISPATCH_LEVEL must specify a **NonPaged***Xxx* value for *PoolType*. A caller executing at IRQL <= APC_LEVEL can specify any **POOL_TYPE** value, but the IRQL and environment must also be considered for determining the page type.

> **Note** Do not set *NumberOfBytes* = 0. Avoid zero-length allocations because they waste pool header space and, in many cases, indicate a potential validation issue in the calling code. For this reason, Driver Verifier flags such allocations as possible errors.

In a non-uniform memory access (NUMA) multiprocessor architecture, **ExAllocatePoolWithTag** tries to allocate memory that is local to the processor that is calling **ExAllocatePoolWithTag**. If no local memory is available, **ExAllocatePoolWithTag** allocates the closest available memory.

> **Note** Memory that **ExAllocatePoolWithTag** allocates is uninitialized. A kernel-mode driver must first zero this memory if it is going to make it visible to user-mode software (to avoid leaking potentially privileged contents).

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL (see Remarks section)"

ExAllocatePoolWithQuotaTag

ExAllocatePoolWithTagPriority

ExFreePool

ExFreePoolWithTag

POOL_TYPE

ExAllocatePoolWithTagPriority function

1/25/2019 • 3 minutes to read • Edit Online

The **ExAllocatePoolWithTagPriority** routine allocates pool memory of the specified type.

Syntax

```
PVOID ExAllocatePoolWithTagPriority(
  __drv_strictTypeMatch(__drv_typeCond)POOL_TYPE        PoolType,
  SIZE_T                                                NumberOfBytes,
  ULONG                                                 Tag,
  __drv_strictTypeMatch(__drv_typeExpr)EX_POOL_PRIORITY Priority
);
```

Parameters

`PoolType`

The type of pool memory to allocate. For a description of the available pool memory types, see POOL_TYPE.

You can modify the *PoolType* value by bitwise-ORing this value with the POOL_RAISE_IF_ALLOCATION_FAILURE flag. This flag causes an exception to be raised if the request cannot be satisfied.

Similarly, you can modify the *PoolType* value by bitwise-ORing this value with the POOL_COLD_ALLOCATION flag as a hint to the kernel to allocate the memory from pages that are likely to be paged out quickly. To reduce the amount of resident pool memory as much as possible, you should not reference these allocations frequently. The POOL_COLD_ALLOCATION flag is only advisory and is available starting with Windows XP.

`NumberOfBytes`

The number of bytes to allocate.

`Tag`

The pool tag to use for the allocated memory. For more information, see the *Tag* parameter of ExAllocatePoolWithTag.

`Priority`

The priority of this request. Set this parameter to one of the following **EX_POOL_PRIORITY** enumeration values.

PRIORITY VALUE	DESCRIPTION
LowPoolPriority	Specifies that the system may fail the request when it runs low on resources. Driver allocations that can recover from an allocation failure use this priority.
NormalPoolPriority	Specifies that the system may fail the request when it runs very low on resources. Most drivers should use this value.

HighPoolPriority	Specifies that the system must not fail the request, unless it is completely out of resources. Drivers only use this value when it is critically important for the request to succeed.

The **EX_POOL_PRIORITY** enumeration defines ***Xxx*SpecialPoolOverrun** and ***Xxx*SpecialPoolUnderrun** variants to specify how memory should be allocated when Driver Verifier (or special pool) is enabled. If the driver specifies ***Xxx*SpecialPoolUnderrun**, when the memory manager allocates memory from special pool, it allocates it at the start of a physical page. If the driver specifies ***Xxx*SpecialPoolOverrun**, the memory manager allocates it at the end of a physical page.

Return Value

ExAllocatePoolWithTagPriority returns **NULL** if there is insufficient memory in the free pool to satisfy the request unless POOL_RAISE_IF_ALLOCATION_FAILURE is specified. Otherwise, the routine returns a pointer to the allocated memory.

Remarks

Callers of **ExAllocatePoolWithTagPriority** must be executing at IRQL <= DISPATCH_LEVEL. A caller executing at DISPATCH_LEVEL must specify a **NonPaged***Xxx* value for *PoolType*. A caller executing at IRQL <= APC_LEVEL can specify any **POOL_TYPE** value, but the IRQL and environment must also be considered for determining the page type.

If *NumberOfBytes* is PAGE_SIZE or greater, a page-aligned buffer is allocated. Memory allocations of PAGE_SIZE or less are allocated within a page and do not cross page boundaries. Memory allocations of less than PAGE_SIZE are not necessarily page-aligned but are aligned to 8-byte boundaries in 32-bit systems and to 16-byte boundaries in 64-bit systems.

> **Note** Do not set *NumberOfBytes* = 0. Avoid zero-length allocations because they waste pool header space and, in many cases, indicate a potential validation issue in the calling code. For this reason, Driver Verifier flags such allocations as possible errors.

The system automatically sets certain standard event objects when the amount of pool (paged or nonpaged) is high or low. Drivers can wait for these events to tune their pool usage. For more information, see Standard Event Objects. In a non-uniform memory access (NUMA) multiprocessor architecture, **ExAllocatePoolWithTagPriority** tries to allocate memory that is local to the processor that is calling **ExAllocatePoolWithTagPriority**. If no local memory is available, **ExAllocatePoolWithTagPriority** allocates the closest available memory.

> **Note** Memory that **ExAllocatePoolWithTagPriority** allocates is uninitialized. A kernel-mode driver must first zero this memory if it is going to make it visible to user-mode software (to avoid leaking potentially privileged contents).

Requirements

ExAllocatePoolWithTag

ExFreePool

POOL_TYPE

ExAllocateTimer function

1/25/2019 • 3 minutes to read • Edit Online

The **ExAllocateTimer** routine allocates and initializes a timer object.

Syntax

```
PEX_TIMER ExAllocateTimer(
  PEXT_CALLBACK Callback,
  PVOID         CallbackContext,
  ULONG         Attributes
);
```

Parameters

`Callback`

A pointer to a driver-implemented ExTimerCallback callback routine. The operating system calls this routine when the timer expires. This parameter is optional and can be **NULL** if no callback routine is needed.

`CallbackContext`

A context value for the callback routine pointed to by the *Callback* parameter. The operating system passes this value as a parameter to the *ExTimerCallback* callback routine, if one is specified. This parameter is typically a pointer to a caller-defined structure that contains context information used by the callback routine. This parameter is optional and can be set to **NULL** if no context information is needed.

`Attributes`

The timer attributes. Set this parameter to zero or to the bitwise-OR of one or more of the following timer flag bits.

TIMER FLAG BIT	DESCRIPTION
EX_TIMER_HIGH_RESOLUTION	High-resolution timer. Make the timer more precise by using a higher-resolution clock to drive the timer.
EX_TIMER_NO_WAKE	No-wake timer. Make the timer delay waking the processor to expire until the timer's expiration time plus its delay tolerance is exceeded.
EX_TIMER_NOTIFICATION	Notification timer. Make the timer a notification timer instead of a synchronization timer. If this flag is not set, the timer is a synchronization timer.

The EX_TIMER_NOTIFICATION flag bit can be set regardless of what other flag bits are set.

The EX_TIMER_HIGH_RESOLUTION and EX_TIMER_NO_WAKE flag bits are mutually exclusive. If the caller sets both of these flag bits, the routine bug checks.

For more information about timer attributes, see Remarks.

Return Value

This routine returns a pointer to an EX_TIMER structure, if the call is successful. This structure is the timer object that the routine has allocated and initialized. If the call fails, the routine returns **NULL**.

Remarks

This routine returns a pointer to the new timer object. To use the timer, the calling driver supplies this pointer in subsequent calls to the ExSetTimer, ExCancelTimer, and ExDeleteTimer routines. If the driver supplies a pointer to an ExTimerCallback callback routine as an input parameter to the **ExAllocateTimer** routine, the operating system passes this timer object as an input parameter to the *ExTimerCallback* routine.

A timer can be a notification timer or a synchronization timer. When a notification timer is signaled, all waiting threads have their wait satisfied. The state of this timer remains signaled until it is explicitly reset. When a synchronization timer expires, its state is set to signaled until a single waiting thread is released. Then, the timer is reset to the not-signaled state.

If the EX_TIMER_HIGH_RESOLUTION flag bit is set in *Attributes*, the operating system increases the resolution of the system clock, as necessary, so that the times at which the timer expires more precisely corresponds to the nominal expiration times specified in the *DueTime* and *Period* parameters to the **ExSetTimer** routine. For more information, see High-Resolution Timers.

If the EX_TIMER_NO_WAKE flag bit is set in *Attributes*, the timer avoids unnecessarily waking the processor from a low-power state. For more information, see No-Wake Timers.

ExAllocateTimer allocates the storage for the timer object. When this object is no longer needed, the caller is responsible for freeing this object by calling the **ExDeleteTimer** routine.

The *Callback* parameter is optional. A driver that does not supply an *ExTimerCallback* routine can instead initiate a wait operation on the timer object. A driver thread can call a routine such as KeWaitForSingleObject or KeWaitForMultipleObjects to wait for the timer to expire. When the timer expires, the timer object is signaled.

For more information, see ExXxxTimer Routines and EX_TIMER Objects.

Requirements

Minimum supported client	Available starting with Windows 8.1.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Ntoskrnl.lib
IRQL	"<= DISPATCH_LEVEL"

EX_TIMER

ExCancelTimer

ExDeleteTimer

ExSetTimer

ExTimerCallback

ExCancelTimer function

1/25/2019 • 2 minutes to read • Edit Online

The **ExCancelTimer** routine cancels a timer that was set by a previous call to the ExSetTimer routine.

Syntax

```
BOOLEAN ExCancelTimer(
  PEX_TIMER              Timer,
  PEXT_CANCEL_PARAMETERS Parameters
);
```

Parameters

`Timer`

A pointer to an EX_TIMER structure. This structure is a timer object that was previously allocated by the ExAllocateTimer routine.

`Parameters`

Drivers must set this parameter to **NULL**.

Return Value

This routine returns **TRUE** if the timer was canceled. Otherwise, the routine returns **FALSE**.

Remarks

After your driver calls the ExSetTimer routine to set the timer, the timer might be canceled before it expires. The driver can call the **ExCancelTimer** routine to explicitly cancel a pending timer. Also, if the driver calls the **ExSetTimer** routine to set a new timer on a timer object before a previously set timer on this object expires, this **ExSetTimer** call implicitly cancels the previous timer and then starts the new timer.

A return value of **TRUE** indicates that the timer was set when **ExCancelTimer** was called. In this case, the routine cancels the timer. A return value of **FALSE** indicates that the timer was not set, which might mean that the timer was never set, that the timer had already been canceled, or that the timer had already expired.

When a timer expires, the operating system signals the timer object. As an option, a driver can supply an ExTimerCallback callback routine that is called when the timer expires. If the driver supplies this callback routine, this routine is guaranteed to be called if the timer object is signaled. If the timer is canceled before it expires, the timer object is not signaled and the callback routine is not called.

For more information, see ExXxxTimer Routines and EX_TIMER Objects.

Requirements

Minimum supported client	Available starting with Windows 8.1.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Ntoskrnl.lib

ExSetTimer

ExConvertExclusiveToSharedLite function

1/25/2019 • 2 minutes to read • Edit Online

The **ExConvertExclusiveToSharedLite** routine converts a given resource from acquired for exclusive access to acquired for shared access.

Syntax

```
void ExConvertExclusiveToSharedLite(
  PERESOURCE Resource
);
```

Parameters

`Resource`

A pointer to the resource for which the access should be converted.

Return Value

None

Remarks

The caller must have exclusive access to the given resource. During this conversion, the current thread and any other threads waiting for shared access to the resource are given shared access.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"
DDI compliance rules	IrqlExApcLte3, HwStorPortProhibitedDDIs

See Also

ExIsResourceAcquiredExclusiveLite

ExCreateCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **ExCreateCallback** routine either creates a new callback object or opens an existing callback object on behalf of the caller.

Syntax

```
NTSTATUS ExCreateCallback(
  PCALLBACK_OBJECT   *CallbackObject,
  POBJECT_ATTRIBUTES ObjectAttributes,
  BOOLEAN            Create,
  BOOLEAN            AllowMultipleCallbacks
);
```

Parameters

`CallbackObject`

A pointer to a location that receives a pointer to a callback object, which is an opaque, system structure. If the **ExCreateCallback** call succeeds, the routine writes the address of the newly created or opened callback object to this location. The callback object pointer obtained from this routine can be supplied as a parameter to the ExRegisterCallback or ExNotifyCallback routine.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that contains the callback object's attributes. This structure was previously initialized by the InitializeObjectAttributes routine.

`Create`

Whether to create a callback object. Set to **TRUE** to create a new callback object if the requested object cannot be opened. Otherwise, set to **FALSE**.

`AllowMultipleCallbacks`

Whether a newly created callback object should allow multiple registered callback routines. Set to **TRUE** to allow multiple registered callback routines. Otherwise, set to **FALSE**. This parameter is ignored when *Create* is **FALSE** or when opening an existing object.

Return Value

ExCreateCallback returns STATUS_SUCCESS if a callback object was opened or created. Otherwise, it returns an NTSTATUS error code to indicate the nature of the failure.

Remarks

A driver calls **ExCreateCallback** to create a new callback object or to open an existing callback object. After the object has been created or opened, other components can call the ExRegisterCallback routine to register callback routines with the callback object.

Before calling **ExCreateCallback**, the driver must call InitializeObjectAttributes to initialize the

OBJECT_ATTRIBUTES structure for the callback object. Unnamed callback objects are not permitted. The caller must specify a name for the object; otherwise, the call fails with STATUS_UNSUCCESSFUL. The caller should specify the OBJ_PERMANENT attribute in the callback object to prevent the object from being deleted before it can be registered with the object manager. The caller should also specify any other attributes, such as OBJ_CASE_INSENSITIVE, that might be needed.

When all operations have been completed with the callback object, the driver must delete the object to prevent a memory leak. For information about deleting an object that was created with the OBJ_PERMANENT object attribute, see ObDereferenceObject.

The following table shows the callback objects that the operating system creates for use by drivers.

CALLBACK OBJECT NAME	USAGE
\Callback\SetSystemTime	The operating system calls any callback routines registered for this object whenever the system time changes.
\Callback\PowerState	The operating system calls any callback routines registered for this object whenever certain system power characteristics change. When a driver registers for callback notification (by calling **ExRegisterCallback**), it can specify the changes for which it should be notified.

For more information about callback objects, see Callback Objects.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ExDeleteLookasideListEx function

1/25/2019 • 2 minutes to read • Edit Online

The **ExDeleteLookasideListEx** routine deletes a lookaside list.

Syntax

```
void ExDeleteLookasideListEx(
  PLOOKASIDE_LIST_EX Lookaside
);
```

Parameters

`Lookaside`

A pointer to a LOOKASIDE_LIST_EX structure that describes a lookaside list. This structure was previously initialized by the ExInitializeLookasideListEx routine.

Return Value

None

Remarks

ExDeleteLookasideListEx is the reciprocal of the **ExInitializeLookasideListEx** routine. It frees any remaining entries in the specified lookaside list and then removes the list from the system-wide set of active lookaside lists.

On return from **ExDeleteLookasideListEx**, the caller is responsible for releasing, if necessary, the caller-supplied storage for the **LOOKASIDE_LIST_EX** structure.

For more information about lookaside lists, see Using Lookaside Lists.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ExDeleteNPagedLookasideList function

1/25/2019 • 2 minutes to read • Edit Online

The **ExDeleteNPagedLookasideList** routine destroys a nonpaged lookaside list.

Syntax

```
void ExDeleteNPagedLookasideList(
  PNPAGED_LOOKASIDE_LIST Lookaside
);
```

Parameters

`Lookaside`

A pointer to the NPAGED_LOOKASIDE_LIST structure for the lookaside list, which the caller originally set up with ExInitializeNPagedLookasideList.

Return Value

None

Remarks

ExDeleteNPagedLookasideList is the reciprocal of **ExInitializeNPagedLookasideList**. It frees any remaining entries in the specified lookaside list and then removes the list from the system-wide set of active lookaside lists.

The caller of **ExDeleteNPagedLookasideList** is responsible for subsequently releasing the memory that the caller provided to contain the list head.

For more information, see Using Lookaside Lists.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

1/25/2019 • 2 minutes to read • Edit Online

The **ExDeletePagedLookasideList** routine destroys a paged lookaside list.

Syntax

```
void ExDeletePagedLookasideList(
  PPAGED_LOOKASIDE_LIST Lookaside
);
```

Parameters

`Lookaside`

A pointer to the PAGED_LOOKASIDE_LIST structure for the lookaside list, which the caller already initialized with ExInitializePagedLookasideList, which the caller originally set up with **ExInitializePagedLookasideList**.

Return Value

None

Remarks

ExDeletePagedLookasideList is the reciprocal of **ExInitializePagedLookasideList**. It frees any remaining entries in the specified lookaside list and then removes the list from the system-wide set of active lookaside lists.

The caller of **ExDeletePagedLookasideList** is responsible for subsequently releasing the memory that the caller provided to contain the list head.

For more information, see Using Lookaside Lists.

Requirements

PAGED_LOOKASIDE_LIST

ExDeleteResourceLite function

1/25/2019 • 2 minutes to read • Edit Online

The **ExDeleteResourceLite** routine deletes a given resource from the system's resource list.

Syntax

```
NTSTATUS ExDeleteResourceLite(
  PERESOURCE Resource
);
```

Parameters

`Resource`

A pointer to the caller-supplied storage for the initialized resource variable to be deleted.

Return Value

ExDeleteResourceLite returns STATUS_SUCCESS if the resource was deleted.

Remarks

After calling **ExDeleteResourceLite**, the caller can free the memory it allocated for its resource.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

ExReinitializeResourceLite

ExDeleteTimer function

1/25/2019 • 2 minutes to read • Edit Online

The **ExDeleteTimer** routine deletes a timer object that was previously allocated by the ExAllocateTimer routine.

Syntax

```
BOOLEAN ExDeleteTimer(
  PEX_TIMER              Timer,
  BOOLEAN                Cancel,
  BOOLEAN                Wait,
  PEXT_DELETE_PARAMETERS Parameters
);
```

Parameters

`Timer`

A pointer to an EX_TIMER structure. This structure is a timer object that was previously allocated by the ExAllocateTimer routine.

`Cancel`

Whether to cancel the timer if it is currently set. If **TRUE**, the routine cancels the timer if the timer is set. If **FALSE**, the routine does not cancel the timer if it is set. If the caller sets *Wait* to **TRUE**, *Cancel* must also be **TRUE**; otherwise, a bug check occurs.

`Wait`

Whether to wait for the timer to finish expiring if the timer has already started the process of expiring. If **TRUE**, the routine waits for the timer to expire. If **FALSE**, the routine does not wait. For more information, see Remarks.

`Parameters`

A pointer to an EXT_DELETE_PARAMETERS structure. The calling driver previously called the ExInitializeDeleteTimerParameters routine to initialize this structure.

Return Value

This routine returns **TRUE** if *Cancel* is **TRUE** and the timer was canceled. Otherwise, the routine returns **FALSE**. For more information, see Remarks.

Remarks

After your driver calls this routine, the timer object pointed to by *Timer* might no longer be valid. However, the *Timer* parameter value passed to an ExTimerCallback callback routine, if the driver implements this routine, is always a valid pointer to a timer object.

If *Cancel* is **TRUE**, a return value of **FALSE** indicates that the timer was never set, or that the timer was set but expired before it could be canceled. If *Cancel* is **FALSE**, the routine always returns **FALSE**.

This routine can block if *Wait* is **TRUE**. If **ExDeleteTimer** is called from the driver's *ExTimerCallback* routine, which is called at DISPATCH_LEVEL, the *Wait* parameter in this call must be **FALSE**.

If *Wait* is **TRUE**, the routine must be called at IRQL <= APC_LEVEL. If *Wait* is **FALSE**, the routine can be called at IRQL <= DISPATCH_LEVEL.

For more information, see Deleting a System-Allocated Timer Object.

Requirements

Minimum supported client	Available starting with Windows 8.1.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Ntoskrnl.lib
IRQL	See Remarks.

ExFlushLookasideListEx function

1/25/2019 • 2 minutes to read • Edit Online

The **ExFlushLookasideListEx** routine flushes all entries from the specified lookaside list and frees the allocated storage for each entry.

Syntax

```
void ExFlushLookasideListEx(
  PLOOKASIDE_LIST_EX Lookaside
);
```

Parameters

`Lookaside`

A pointer to a LOOKASIDE_LIST_EX structure that describes a lookaside list. This structure was previously initialized by the ExInitializeLookasideListEx routine.

Return Value

None

Remarks

On return from this routine, the lookaside list is empty and the allocated storage for all its entries has been freed.

For more information about lookaside lists, see Using Lookaside Lists.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ExFreePool function

1/25/2019 • 2 minutes to read • Edit Online

The **ExFreePool** routine deallocates a block of pool memory.

Syntax

```
void ExFreePool(
  PVOID P
);
```

Parameters

P

Return Value

None

Remarks

This routine releases memory allocated by ExAllocatePool, ExAllocatePoolWithTag, ExAllocatePoolWithQuota, or ExAllocatePoolWithQuotaTag. The memory block must not be accessed after it is freed.

Drivers can also use the **ExFreePoolWithTag** routine to free buffers allocated by ExAllocatePoolWithTag and ExAllocatePoolWithQuotaTag.

Callers of **ExFreePool** must be running at IRQL <= DISPATCH_LEVEL. A caller at DISPATCH_LEVEL must have specified a **NonPaged***XxxPoolType* when the memory was allocated. Otherwise, the caller must be running at IRQL <= APC_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ExFreePoolWithTag

ExFreePoolWithTag function

1/25/2019 • 2 minutes to read • Edit Online

The **ExFreePoolWithTag** routine deallocates a block of pool memory allocated with the specified tag.

Syntax

```
void ExFreePoolWithTag(
  PVOID P,
  ULONG Tag
);
```

Parameters

`P`

Specifies the beginning address of a block of pool memory allocated by either ExAllocatePoolWithTag or ExAllocatePoolWithQuotaTag.

`Tag`

Specifies the tag value passed to ExAllocatePoolWithTag or ExAllocatePoolWithQuotaTag when the block of memory was originally allocated.

NOTE

Tag must be a value from 0x20 (space) to 0x126 (tilde).

Return Value

None

Remarks

Callers of **ExFreePoolWithTag** must be running at IRQL <= DISPATCH_LEVEL. A caller at DISPATCH_LEVEL must have specified a **NonPaged***XxxPoolType* when the memory was allocated. Otherwise, the caller must be running at IRQL <= APC_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ExFreeToLookasideListEx function

1/25/2019 • 2 minutes to read • Edit Online

The **ExFreeToLookasideListEx** routine inserts an entry into a lookaside list, or, if the list is full, frees the allocated storage for the entry.

Syntax

```
void ExFreeToLookasideListEx(
  PLOOKASIDE_LIST_EX Lookaside,
  PVOID              Entry
);
```

Parameters

`Lookaside`

A pointer to a LOOKASIDE_LIST_EX structure that describes a lookaside list. This structure was previously initialized by the ExInitializeLookasideListEx routine.

`Entry`

A pointer to the lookaside-list entry that is being freed.

Return Value

None

Remarks

This routine frees a lookaside-list entry that was allocated by a previous call to the ExAllocateFromLookasideListEx routine. **ExFreeToLookasideListEx** inserts the entry into the specified lookaside list, if space for the entry is available in the list. If the list is full (that is, it already contains the maximum number of entries, as determined by the operating system), **ExFreeToLookasideListEx** calls the LookasideListFreeEx routine to free the storage for the specified entry, if the driver has provided such a routine. Otherwise, a default deallocation routine is used to free the entry.

For more information about lookaside lists, see Using Lookaside Lists.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

See Also

ExAllocateFromLookasideListEx

ExInitializeLookasideListEx

LOOKASIDE_LIST_EX

ExFreeToNPagedLookasideList function

1/25/2019 • 2 minutes to read • Edit Online

The **ExFreeToNPagedLookasideList** routine returns a nonpaged entry to the given lookaside list or to nonpaged pool.

Syntax

```
void ExFreeToNPagedLookasideList(
  PNPAGED_LOOKASIDE_LIST Lookaside,
  PVOID                  Entry
);
```

Parameters

`Lookaside`

A pointer to the NPAGED_LOOKASIDE_LIST structure for the lookaside list, which the caller already initialized with ExInitializeNPagedLookasideList.

`Entry`

A pointer to the entry to be freed. The caller obtained this pointer from a preceding call to ExAllocateFromNPagedLookasideList.

Return Value

None

Remarks

ExFreeToNPagedLookasideList is the reciprocal of **ExAllocateFromNPagedLookasideList**. It releases a caller-allocated entry back to the caller's lookaside list or to nonpaged pool when that entry is no longer in use.

The same entry can be reallocated or another entry allocated later with a subsequent call to **ExAllocateFromNPagedLookasideList**. The user of the lookaside list can allocate and free such entries dynamically on an as-needed basis until it calls **ExDeleteNPagedLookasideList**, which releases any outstanding entries in the list before it clears the system state for the given lookaside list and returns control.

If the specified lookaside list has not yet reached the system-determined maximum number of entries, **ExFreeToNPagedLookasideList** inserts the given entry at the front of the list. Otherwise, the buffer at *Entry* is released to nonpaged pool using the caller-supplied *Free* routine, if any, that was set up when the lookaside list was initialized or **ExFreePool**.

For more information, see Using Lookaside Lists.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ExFreeToPagedLookasideList function

1/25/2019 • 2 minutes to read • Edit Online

The **ExFreeToPagedLookasideList** routine returns a pageable entry to the given lookaside list or to paged pool.

Syntax

```
void ExFreeToPagedLookasideList(
  PPAGED_LOOKASIDE_LIST Lookaside,
  PVOID                 Entry
);
```

Parameters

`Lookaside`

A pointer to the PAGED_LOOKASIDE_LIST structure for the lookaside list, which the caller already initialized with ExInitializePagedLookasideList, which the caller already initialized with **ExInitializePagedLookasideList**.

`Entry`

A pointer to the entry to be freed. The caller obtained this pointer from a preceding call to ExAllocateFromPagedLookasideList.

Return Value

None

Remarks

ExFreeToPagedLookasideList is the reciprocal of **ExAllocateFromPagedLookasideList**. It releases a caller-allocated entry back to the caller's lookaside list or to paged pool when that entry is no longer in use.

The same entry can be reallocated or another entry can be allocated later with a subsequent call to **ExAllocateFromPagedLookasideList**. The user of a lookaside list can allocate and free such entries dynamically, as needed, until it calls **ExDeletePagedLookasideList**. **ExDeletePagedLookasideList** releases any outstanding entries in the list before it clears the system state for the given lookaside list and returns control.

If the specified lookaside list has not yet reached the system-determined maximum number of entries, **ExFreeToPagedLookasideList** inserts the given entry at the front of the list. Otherwise, the buffer at *Entry* is released back to paged pool using the caller-supplied *Free* routine, if any, that was set up when the lookaside list was initialized or **ExFreePool**.

On Windows 2000, drivers must use the **-D_WIN2K_COMPAT_SLIST_USAGE** switch to successfully link code that uses **ExFreeToPagedLookasideList**.

For more information, see Using Lookaside Lists.

Requirements

ExGetExclusiveWaiterCount function

1/25/2019 • 2 minutes to read • Edit Online

The **ExGetExclusiveWaiterCount** routine returns the number of waiters on exclusive access to a given resource.

Syntax

```
ULONG ExGetExclusiveWaiterCount(
  PERESOURCE Resource
);
```

Parameters

`Resource`

A pointer to the resource to be tested.

Return Value

ExGetExclusiveWaiterCount returns the number of threads currently waiting to acquire the given resource for exclusive access.

Remarks

ExGetExclusiveWaiterCount can be called to get an estimate of how many other threads might be waiting to modify the data protected by a particular resource variable. The caller cannot assume that the returned value remains constant for any particular interval.

Requirements

Minimum supported client	Available starting with Windows 2000.

ExGetFirmwareEnvironmentVariable function

1/25/2019 • 3 minutes to read • Edit Online

The **ExGetFirmwareEnvironmentVariable** routine gets the value of the specified system firmware environment variable.

Syntax

```
NTSTATUS ExGetFirmwareEnvironmentVariable(
  PUNICODE_STRING VariableName,
  LPGUID          VendorGuid,
  PVOID           Value,
  PULONG          ValueLength,
  PULONG          Attributes
);
```

Parameters

`VariableName`

A pointer to a UNICODE_STRING structure that contains the name of the specified environment variable.

`VendorGuid`

A pointer to a GUID that identifies the vendor associated with the specified environment variable. Environment variables are grouped into namespaces based on their vendor GUIDs. Some hardware platforms might not support vendor GUIDs. On these platforms, all variables are grouped into one, common namespace, and the *VendorGuid* parameter is ignored.

`Value`

A pointer to a caller-allocated buffer to which the routine writes the value of the specified environment variable.

`ValueLength`

A pointer to a location that contains the buffer size. On entry, the location pointed to by this parameter contains the size, in bytes, of the caller-supplied *Value* buffer. Before exiting, the routine writes to this location the size, in bytes, of the variable value. If the routine returns STATUS_SUCCESS, the **ValueLength* output value is the number of bytes of data written to the *Value* buffer. If the routine returns STATUS_BUFFER_TOO_SMALL, **ValueLength* is the required buffer size.

`Attributes`

A pointer to a location to which the routine writes the attributes of the specified environment variable. This parameter is optional and can be set to NULL if the caller does not need the attributes. For more information, see Remarks.

Return Value

ExGetFirmwareEnvironmentVariable returns STATUS_SUCCESS if it is successful. Possible return values include the following error status codes.

RETURN CODE	DESCRIPTION

STATUS_INSUFFICIENT_RESOURCES	Available system resources are insufficient to complete the requested operation.
STATUS_BUFFER_TOO_SMALL	The *Value* buffer is too small.
STATUS_VARIABLE_NOT_FOUND	The requested variable does not exist.
STATUS_INVALID_PARAMETER	One of the parameters is not valid.
STATUS_NOT_IMPLEMENTED	This routine is not supported on this platform.

STATUS_UNSUCCESSFUL	The firmware returned an unrecognized error.

Remarks

System firmware environment variables contain data values that are passed between the boot firmware environment implemented in the hardware platform and the operating-system loaders and other software that runs in the firmware environment.

The set of firmware environment variables that is available in a hardware platform depends on the boot firmware. The location of these environment variables is also specified by the firmware. For example, on a UEFI-based platform, NVRAM contains firmware environment variables that specify system boot settings. For information about specific variables used, see the Unified Extensible Firmware Interface Specification at the UEFI website. For more information about UEFI and Windows, see UEFI and Windows.

Firmware environment variables are not supported on a legacy BIOS-based platform. Calls to **ExGetFirmwareEnvironmentVariable** always fail on a legacy BIOS-based platform; they also fail if Windows was installed using the legacy BIOS on a platform that supports both legacy BIOS and UEFI. To identify these conditions, call the function with a dummy *VariableName* string (for example, an empty string) and a dummy GUID such as

```
"{00000000-0000-0000-0000-000000000000}"
```

for the *VendorGuid* parameter. On a legacy BIOS-based platform, or on a platform that supports both legacy BIOS and UEFI but in which Windows was installed using the legacy BIOS, the function will fail with STATUS_NOT_IMPLEMENTED. On a UEFI-based platform, the function will fail with an error specific to the firmware, such as STATUS_VARIABLE_NOT_FOUND, to indicate that the dummy GUID namespace does not exist.

If the caller specifies a non-NULL *Attributes* parameter, the routine writes the attributes of the specified system firmware environment variable to the location pointed to by *Attributes*. Version 2.3.1 of the UEFI specification defines the following attributes for firmware environment variables.

VARIABLE NAME	VALUE
EFI_VARIABLE_NON_VOLATILE	0x00000001
EFI_VARIABLE_BOOTSERVICE_ACCESS	0x00000002
EFI_VARIABLE_RUNTIME_ACCESS	0x00000004
EFI_VARIABLE_HARDWARE_ERROR_RECORD	0x00000008
EFI_VARIABLE_AUTHENTICATED_WRITE_ACCESS	0x00000010
EFI_VARIABLE_TIME_BASED_AUTHENTICATED_WRITE_ACCESS	0x00000020
EFI_VARIABLE_APPEND_WRITE	0x00000040

These attribute values are defined as flag bits. The value written to the ULONG variable pointed to by *Attributes* is

either zero or the bitwise OR of one or more attributes in the preceding table. For more information, see the UEFI specification at the UEFI website.

If you create a backup datastore, you can use this function to save all the boot settings for the platform so they can be restored by calling the ExSetFirmwareEnvironmentVariable routine if needed.

ExGetFirmwareEnvironmentVariable is the kernel-mode equivalent of the Win32 GetFirmwareEnvironmentVariable function.

ExGetFirmwareType function

1/25/2019 • 2 minutes to read • Edit Online

Returns the system firmware type.

Syntax

```
FIRMWARE_TYPE ExGetFirmwareType(

);
```

Parameters

This function has no parameters.

Return Value

Returns a FIRMWARE_TYPE-type value that indicates the type of firmware.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	wdm.h
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode)
IRQL	"<=APC_LEVEL"

ExGetPreviousMode function

1/25/2019 • 2 minutes to read • Edit Online

The **ExGetPreviousMode** routine returns the previous processor mode for the current thread.

Syntax

```
KPROCESSOR_MODE ExGetPreviousMode(

);
```

Parameters

This function has no parameters.

Return Value

ExGetPreviousMode returns a **KPROCESSOR_MODE** value, one of **KernelMode** or **UserMode**. This value specifies the previous processor mode for the current thread.

Remarks

If an I/O request can originate either in user mode or kernel mode and the caller passes pointers to data structures used for I/O, the driver must be able to determine whether the caller's pointers are valid in user mode or kernel mode.

If drivers are processing I/O requests using the normal IRP-based I/O dispatch method, they can determine the previous processor mode by checking the *RequestorMode* parameter in the IRP header. (The *RequestorMode* parameter is set by the I/O manager.)

Alternatively, **ExGetPreviousMode** can be used to determine the previous processor mode. This routine is particularly useful in situations where a previous mode parameter is not available, for example, in a file driver that uses fast I/O.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

ExGetSharedWaiterCount function

1/25/2019 • 2 minutes to read • Edit Online

The **ExGetSharedWaiterCount** routine returns the number of waiters on shared access to a given resource.

Syntax

```
ULONG ExGetSharedWaiterCount(
  PERESOURCE Resource
);
```

Parameters

`Resource`

A pointer to the resource to be tested.

Return Value

ExGetSharedWaiterCount returns the number of threads currently waiting to acquire the given resource for shared access.

Remarks

ExGetSharedWaiterCount can be called to get an estimate of how many other threads might be waiting to read the data protected by a particular resource variable. The caller cannot assume that the returned value remains constant for any particular interval.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ExInitializeDeleteTimerParameters function

1/25/2019 • 2 minutes to read • Edit Online

The **ExInitializeDeleteTimerParameters** routine initializes an EXT_DELETE_PARAMETERS structure.

Syntax

```
void ExInitializeDeleteTimerParameters(
  PEXT_DELETE_PARAMETERS Parameters
);
```

Parameters

`Parameters`

A pointer to the **EXT_DELETE_PARAMETERS** structure that is to be initialized.

Return Value

None.

Remarks

Your driver must call **ExInitializeDeleteTimerParameters** to initialize an **EXT_DELETE_PARAMETERS** structure before the driver passes this structure to the ExDeleteTimer routine. For more information about the member values that **ExInitializeDeleteTimerParameters** writes to the members of this structure, see EXT_DELETE_PARAMETERS.

Requirements

Minimum supported client	Available starting with Windows 8.1.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Any level.

EXT_DELETE_PARAMETERS

ExDeleteTimer

ExInitializeFastMutex function

1/25/2019 • 2 minutes to read • Edit Online

The **ExInitializeFastMutex** routine initializes a fast mutex variable, used to synchronize mutually exclusive access by a set of threads to a shared resource.

Syntax

```
void ExInitializeFastMutex(
  PFAST_MUTEX FastMutex
);
```

Parameters

`FastMutex`

A pointer to a caller-allocated FAST_MUTEX structure, which represents the fast mutex, in the nonpaged memory pool. The allocation must be 4-byte aligned on 32-bit platforms, and 8-byte aligned on 64-bit platforms.

Return Value

None

Remarks

ExInitializeFastMutex must be called before any calls to other **Ex*Xxx*FastMutex** routines occur.

Although the caller supplies the storage for the given fast mutex, the **FAST_MUTEX** structure is opaque: that is, its members are reserved for system use.

For better performance, use the **Ex*Xxx*FastMutex** routines instead of the **Ke*Xxx*Mutex** routines. However, a fast mutex cannot be acquired recursively, as a kernel mutex can.

For more information about fast mutexes, see Fast Mutexes and Guarded Mutexes.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ExInitializeLookasideListEx function

1/25/2019 • 7 minutes to read • Edit Online

The **ExInitializeLookasideListEx** routine initializes a lookaside list.

Syntax

```
NTSTATUS ExInitializeLookasideListEx(
  PLOOKASIDE_LIST_EX    Lookaside,
  PALLOCATE_FUNCTION_EX Allocate,
  PFREE_FUNCTION_EX     Free,
  POOL_TYPE             PoolType,
  ULONG                 Flags,
  SIZE_T                Size,
  ULONG                 Tag,
  USHORT                Depth
);
```

Parameters

`Lookaside`

A pointer to the LOOKASIDE_LIST_EX structure to initialize. On return, this structure describes an empty lookaside list. The caller must use nonpaged system space for this structure, regardless of whether the entries in the lookaside list are allocated from paged or nonpaged memory. On 64-bit platforms, this structure must be 16-byte aligned.

`Allocate`

A pointer to a caller-supplied LookasideListAllocateEx routine that allocates a new lookaside-list entry. The ExAllocateFromLookasideListEx routine calls this *LookasideListAllocateEx* routine if the lookaside list is empty (contains no entries). This parameter is optional and can be specified as **NULL** if a custom allocation routine is not required. If this parameter is **NULL**, calls to **ExAllocateFromPagedLookasideList** automatically allocate the paged or nonpaged storage (as determined by the *PoolType* parameter) for the new entries.

`Free`

A pointer to a caller-supplied LookasideListFreeEx routine that frees a previously allocated lookaside-list entry. The ExFreeToPagedLookasideList routine calls this *LookasideListFreeEx* routine if the lookaside list is full (that is, the list already contains the maximum number of entries, as determined by the operating system). This parameter is optional and can be specified as **NULL** if a custom deallocation routine is not required. If this parameter is **NULL**, calls to **ExFreeToPagedLookasideList** automatically free the storage for the specified entries.

`PoolType`

Specifies the pool type of the entries in the lookaside list. Set this parameter to a valid POOL_TYPE enumeration value.

`Flags`

Specifies an optional flag value to modify the default behavior of the *LookasideListAllocateEx* routine. Set this parameter to zero or to one of the following EX_LOOKASIDE_LIST_EX_FLAGS_*XXX* flag bits.

FLAG BIT	MEANING
EX_LOOKASIDE_LIST_EX_FLAGS_RAISE_ON_FAIL	If the allocation fails, raise an exception.
EX_LOOKASIDE_LIST_EX_FLAGS_FAIL_NO_RAISE	If the allocation fails, return **NULL** instead of raising an exception. This flag is intended for use with an allocation routine, such as ExAllocatePoolWithQuotaTag, that charges quotas for pool usage.

These two flag bits are mutually exclusive.

If *Allocate* is **NULL**, set *Flags* to either zero or EX_LOOKASIDE_LIST_EX_FLAGS_RAISE_ON_FAIL, but not to EX_LOOKASIDE_LIST_EX_FLAGS_FAIL_NO_RAISE. Otherwise, the behavior of the default allocation routine is undefined.

If *Flags* = EX_LOOKASIDE_LIST_EX_FLAGS_RAISE_ON_FAIL, the *PoolType* parameter value is bitwise ORed with the POOL_RAISE_IF_ALLOCATION_FAILURE flag bit to form the *PoolType* parameter value that is passed to the *LookasideListAllocateEx* routine. The *LookasideListAllocateEx* routine can pass this *PoolType* value, without modification, to the **ExAllocatePoolWithTag** routine. For more information about the POOL_RAISE_IF_ALLOCATION_FAILURE flag, see ExAllocatePoolWithTag.

If *Flags* = EX_LOOKASIDE_LIST_EX_FLAGS_FAIL_NO_RAISE, the *PoolType* parameter value is bitwise ORed with the POOL_QUOTA_FAIL_INSTEAD_OF_RAISE flag bit to form the *PoolType* parameter value that is passed to the *LookasideListAllocateEx* routine. The *LookasideListAllocateEx* routine can pass this *PoolType* value, without modification, to the **ExAllocatePoolWithQuotaTag** routine. For more information about the POOL_QUOTA_FAIL_INSTEAD_OF_RAISE flag, see ExAllocatePoolWithQuotaTag.

`Size`

Specifies the size, in bytes, of each entry in the lookaside list.

`Tag`

Specifies the four-byte pool tag to use to mark the allocated storage for lookaside-list entries. For more information about pool tags, see the description of the *Tag* parameter in **ExAllocatePoolWithTag**.

`Depth`

Reserved. Always set this parameter to zero.

Return Value

ExInitializeLookasideListEx returns STATUS_SUCCESS if the call is successful. Possible return values include the following error code:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER_4	The *PoolType* parameter value is not valid.

STA TUS _IN VAL ID_ PAR AM ETE R_5	The *Flags* parameter value is not valid.

Remarks

A driver must call this routine to initialize a lookaside list before the driver can begin to use the list. A lookaside list is a pool of fixed-size buffers that the driver can manage locally to reduce the number of calls to system allocation routines and, thereby, to improve performance. The buffers are stored as entries in the lookaside list. All entries in the list are of the same, uniform size, which is specified by the *Size* parameter.

After **ExInitializeLookasideListEx** returns, the lookaside list is initialized but contains no entries. When a client calls the ExAllocateFromLookasideListEx routine to request an entry, this routine determines that the lookaside list is empty and calls the driver-supplied LookasideListAllocateEx routine to dynamically allocate storage for a new entry. Additional entries might be allocated in response to similar requests from clients. Later, when clients call the ExFreeToLookasideListEx to release these entries, this routine inserts the entries into the lookaside list. If the number of entries in the list reaches a limit that is determined by the operating system, **ExFreeToLookasideListEx** ceases to add further entries to the list and instead passes these entries to the driver-supplied LookasideListFreeEx routine to be freed.

If the driver does not supply *LookasideListAllocateEx* and *LookasideListFreeEx* routines, the **ExAllocateFromLookasideListEx** and **ExFreeToLookasideListEx** routines use default allocation and deallocation routines instead.

There is no benefit to providing *LookasideListAllocateEx* and *LookasideListFreeEx* routines that do nothing but call ExAllocatePoolWithTag and ExFreePool. The same effect can be achieved with better performance by simply setting the *Allocate* and *Free* parameters to **NULL**.

Before a driver unloads, it must explicitly free any lookaside lists it created. Failure to do so is a serious programming error. Call the ExDeleteLookasideListEx routine to free a lookaside list. This routine frees the storage for any remaining entries in the specified lookaside list and then removes the list from the system-wide set of active lookaside lists.

The operating system keeps track of all lookaside lists that are currently in use. As both the amount of available nonpaged memory and the demand for lookaside list entries vary over time, the operating system dynamically adjusts its limits for the maximum number of entries in each nonpaged lookaside list.

In Windows 2000 and later versions of Windows, a lookaside list that contains paged or nonpaged entries can be described by a PAGED_LOOKASIDE_LIST or NPAGED_LOOKASIDE_LIST structure, respectively.

For more information about lookaside lists, see Using Lookaside Lists.

Callers of **ExInitializeLookasideListEx** can be running at IRQL <= DISPATCH_LEVEL, but are typically running at IRQL = PASSIVE_LEVEL.

Examples

The driver-supplied *LookasideListAllocateEx* and *LookasideListFreeEx* routines both receive *Lookaside* parameters that point to the **LOOKASIDE_LIST_EX** structure that describes the lookaside list. The routines can use this parameter to access private data that the driver has associated with the lookaside list. For example, the driver might allocate an instance of the following structure to collect private data for each lookaside list that it creates:

```
typedef struct
{
  ULONG NumberOfAllocations;  // number of entries allocated
  ULONG NumberOfFrees;        // number of entries freed
  LOOKASIDE_LIST_EX LookasideField;
} MY_PRIVATE_DATA;
```

The driver can initialize a lookaside list as shown in the following code example:

```
#define ENTRY_SIZE  256
#define MY_POOL_TAG  'tsLL'
MY_PRIVATE_DATA *MyContext;
NTSTATUS status = STATUS_SUCCESS;

MyContext = ExAllocatePoolWithTag(NonPagedPool, sizeof(MY_PRIVATE_DATA), MY_POOL_TAG);
if (MyContext)
{
    MyContext.NumberOfAllocations = 0;
    MyContext.NumberOfFrees = 0;

    status = ExInitializeLookasideListEx(
                &MyContext.LookasideField,
                MyLookasideListAllocateEx,
                MyLookasideListFreeEx,
                NonPagedPool,
                0,
                ENTRY_SIZE,
                MY_POOL_TAG,
                0);
}
else
{
    status = STATUS_INSUFFICIENT_RESOURCES;
}
```

The following code example shows how the *LookasideListAllocateEx* routine can use its *Lookaside* parameter to access the private data that is associated with the lookaside list:

```
PVOID
  MyLookasideListAllocateEx(
    __in POOL_TYPE  PoolType,
    __in SIZE_T  NumberOfBytes,
    __in ULONG  Tag,
    __inout PLOOKASIDE_LIST_EX  Lookaside)
{
    MY_PRIVATE_DATA *MyContext;
    PVOID NewEntry;

    MyContext = CONTAINING_RECORD(Lookaside, MY_PRIVATE_DATA, LookasideField);

    NewEntry = ExAllocatePoolWithTag(PoolType, NumberOfBytes, Tag);

    if (NewEntry)
    {
        MyContext->NumberOfAllocations = InterlockedIncrement(MyContext->NumberOfAllocations);
    }

    return NewEntry;
}
```

The CONTAINING_RECORD macro is defined in the Ntdef.h header file. The *LookAsideListFreeEx* routine can similarly use its *Lookaside* parameter to access private data. After the `MyLookasideListAllocateEx` routine in this example returns, **ExAllocateFromLookasideListEx** inserts the buffer pointed to by the `NewEntry` variable into the lookaside list. To make this insertion operation thread-safe, **ExAllocateFromLookasideListEx** synchronizes its access of the lookaside list with other list insertion and removal operations that might be performed by other threads. Similarly, when **ExFreeFromLookasideListEx** removes a buffer from the lookaside list, it synchronizes its access to the list. **ExAllocateFromLookasideListEx** and **ExFreeFromLookasideListEx** do not synchronize their calls to driver-supplied LookasideListAllocateEx and LookasideListFreeEx routines. Thus, if the `MyLookasideListAllocateEx` and `MyLookasideListFreeEx` routines in the preceding code examples must be thread-safe, the driver must provide the necessary synchronization. The example routine, `MyLookasideListAllocateEx`, synchronizes its access of the `MyContext->NumberOfAllocations` variable with other threads that might increment and decrement this variable. To provide this synchronization, `MyLookasideListAllocateEx` calls the InterlockedIncrement routine to atomically increment this variable. Similarly, the `MyLookasideListFreeEx` routine (not shown) can call the InterlockedDecrement routine to atomically decrement this variable. However, if the sole purpose of the `MyContext->NumberOfAllocations` variable in the preceding code example is simply to gather statistics on lookaside list allocations, atomic increments and decrements are hardly necessary. In this case, the remote possibility of a missed increment or decrement should not be a concern. For more information about thread safety for lookaside lists, see Using Lookaside Lists.

Requirements

ExInitializeNPagedLookasideList function

1/25/2019 • 4 minutes to read • Edit Online

The **ExInitializeNPagedLookasideList** routine initializes a lookaside list for nonpaged entries of the specified size.

Syntax

```
void ExInitializeNPagedLookasideList(
  PNPAGED_LOOKASIDE_LIST Lookaside,
  PALLOCATE_FUNCTION     Allocate,
  PFREE_FUNCTION         Free,
  ULONG                  Flags,
  SIZE_T                 Size,
  ULONG                  Tag,
  USHORT                 Depth
);
```

Parameters

`Lookaside`

A pointer to the NPAGED_LOOKASIDE_LIST structure to initialize. The caller must use nonpaged system space for the structure. On 64-bit platforms, this structure must be 16-byte aligned.

`Allocate`

A pointer to either a caller-supplied function for allocating an entry when the lookaside list is empty, or to **NULL**. If non-**NULL**, the pointer is to a function with the prototype:

```
PVOID XxxAllocate(
  __in POOL_TYPE  PoolType,           // NonPagedPool
  __in SIZE_T  NumberOfBytes,         // value of Size
  __in ULONG  Tag                     // value of Tag
);
```

If the *Allocate* parameter is **NULL**, subsequent calls to ExAllocateFromNPagedLookasideList automatically allocate entries whenever the lookaside list is empty.

`Free`

A pointer to either a caller-supplied function for freeing an entry whenever the lookaside list is full, or to **NULL**. If non-**NULL**, the pointer is to a function with the prototype:

```
VOID XxxFree(
  __in PVOID  Buffer
);
```

If the *Free* parameter is **NULL**, subsequent calls to ExFreeToNPagedLookasideList automatically release the given entry back to nonpaged pool whenever the list is full, that is, currently holding the system-determined maximum number of entries.

`Flags`

Starting in Windows 8, this parameter specifies an optional flag value to modify the default behavior of the **ExInitializeNPagedLookasideList** routine. Compatible flag bits include the following.

FLAG BIT	MEANING
POOL_NX_ALLOCATION	Allocate non-executable memory.
POOL_RAISE_IF_ALLOCATION_FAILURE	If the allocation fails, raise an exception.

Before Windows 8, this parameter is not used and must be zero.

`Size`

Specifies the size, in bytes, for each nonpaged entry to be allocated subsequently. This parameter must not be less than the required minimum size, LOOKASIDE_MINIMUM_BLOCK_SIZE, which is defined in the Wdm.h header file.

`Tag`

Specifies the pool tag to use when allocating lookaside list entries. For more information about pool tags, see the *Tag* parameter of ExAllocatePoolWithTag.

`Depth`

Reserved. Must be zero.

Return Value

None

Remarks

After calling **ExInitializeNPagedLookasideList**, memory blocks of the caller-specified *Size* can be allocated from and freed to the lookaside list with calls to ExAllocateFromNPagedLookasideList and ExFreeToNPagedLookasideList, respectively. Such dynamically allocated and freed entries can be any data structure or fixed-size buffer that the caller uses while the system is running, particularly if the caller cannot predetermine how many such entries will be in use at any given moment. The layout and contents of each fixed-size entry are caller-determined.

ExInitializeNPagedLookasideList initializes the system state to track usage of the given lookaside list, as follows:

- Zero-initializes the counters to be maintained for entries.
- Stores the entry points of the caller-supplied ***Xxx*Allocate** and ***Xxx*Free** routines, if any, or sets these entry points to ExAllocatePoolWithTag and ExFreePool, respectively.

- Initializes a system spin lock to control allocations from and frees to the lookaside list in a multiprocessor-safe manner if necessary.
- Stores the caller-supplied entry *Size* and list *Tag*.
- Sets up the system-determined limits (minimum and maximum) on the number of entries to be held in the lookaside list, which can be adjusted subsequently if system-wide demand for entries is higher or lower than anticipated.
- Sets up the system-determined flags, which control the type of memory from which entries will be allocated subsequently.

The system maintains a set of all lookaside lists currently in use. As demand for lookaside list entries and on available nonpaged memory varies while the system runs, the system adjusts its limits for the number of entries to be held in each nonpaged lookaside list dynamically.

Drivers must always explicitly free any lookaside lists they create before unloading. To do otherwise is a serious programming error. Use ExDeleteNPagedLookasideList to free the list.

ExInitializeNPagedLookasideList sets up the opaque list head at the caller-supplied location but preallocates no memory for list entries. Subsequently, the initial entries are allocated dynamically as calls to **ExAllocateFromNPagedLookasideList** occur, and these initial entries are held in the lookaside list as reciprocal calls to **ExFreeToNPagedLookasideList** occur. Entries collect in the given lookaside list until the system-determined maximum is reached, whereupon any additional entries are returned to nonpaged pool as they are freed. If the list becomes empty, allocate requests are satisfied by the ***Xxx*Allocate** function specified at list initialization or by ExAllocatePoolWithTag.

It is more efficient to pass **NULL** pointers for the *Allocate* and *Free* parameters of **ExInitializeNPagedLookasideList** whenever the user of a lookaside list does nothing more than allocate and release fixed-size entries. However, any component that uses a lookaside list might supply these functions to do additional caller-determined processing, such as tracking its own dynamic memory usage by maintaining state about the number of entries it allocates and frees.

If the caller of **ExInitializeNPagedLookasideList** supplies an ***Xxx*Allocate** function, that routine must allocate entries for the lookaside list using the given input parameters when it calls **ExAllocatePoolWithTag.**

Starting with Windows Vista, a similar routine, ExInitializeLookasideListEx, initializes a lookaside list that is described by a LOOKASIDE_LIST_EX structure. Unlike the ***Xxx*Allocate** and ***Xxx*Free** routines for a lookaside list that uses an **NPAGED_LOOKASIDE_LIST** structure, the allocation and deallocation routines for a lookaside list that uses the **LOOKASIDE_LIST_EX** structure receive a context pointer as an input parameter. These routines can use this context to store private data for the lookaside list. If your driver is intended to run only in Windows Vista and later versions of Windows, consider using **ExInitializeLookasideListEx** instead of **ExInitializeNPagedLookasideList**. For more information, see Using Lookaside Lists.

Callers of **ExInitializeNPagedLookasideList** can be running at IRQL <= DISPATCH_LEVEL, but are typically running at IRQL = PASSIVE_LEVEL.

Requirements

LOOKASIDE_LIST_EX

NPAGED_LOOKASIDE_LIST

ExInitializePagedLookasideList function

1/25/2019 • 4 minutes to read • Edit Online

The **ExInitializePagedLookasideList** routine initializes a lookaside list for pageable entries of the specified size.

Syntax

```
void ExInitializePagedLookasideList(
  PPAGED_LOOKASIDE_LIST Lookaside,
  PALLOCATE_FUNCTION    Allocate,
  PFREE_FUNCTION        Free,
  ULONG                 Flags,
  SIZE_T                Size,
  ULONG                 Tag,
  USHORT                Depth
);
```

Parameters

`Lookaside`

A pointer to the PAGED_LOOKASIDE_LIST structure to initialize. The caller must use nonpaged system space for the structure, even though the entries in this lookaside list will be allocated from pageable memory. On 64-bit platforms, this structure must be 16-byte aligned.

`Allocate`

A pointer to either a caller-supplied function for allocating an entry when the lookaside list is empty, or to **NULL**. If non-**NULL**, the pointer is to a function with the prototype:

```
PVOID XxxAllocate(
  __in POOL_TYPE  PoolType,           // PagedPool
  __in SIZE_T  NumberOfBytes,         // value of Size
  __in ULONG  Tag                     // value of Tag
);
```

If the *Allocate* parameter is **NULL**, subsequent calls to **ExAllocateFromPagedLookasideList** automatically allocate entries whenever the lookaside list is empty.

`Free`

A pointer to either a caller-supplied function for freeing an entry whenever the lookaside list is full, or to **NULL**. If non-**NULL**, the pointer is to a function with the prototype:

```
VOID XxxFree(
  __in PVOID  Buffer
);
```

If the *Free* parameter is **NULL**, subsequent calls to **ExFreeToPagedLookasideList** automatically release the given entry back to paged pool whenever the list is full, that is, currently holding the system-determined maximum number of entries.

`Flags`

Starting in Windows 8, this parameter specifies an optional flag value to modify the default behavior of the **ExInitializePagedLookasideList** routine. Compatible flag bits include the following.

FLAG BIT	MEANING
POOL_NX_ALLOCATION	Allocate non-executable memory.
POOL_RAISE_IF_ALLOCATION_FAILURE	If the allocation fails, raise an exception.

Before Windows 8, this parameter is not used and must be zero.

`Size`

Specifies the size in bytes of each entry in the lookaside list.

`Tag`

Specifies the pool tag to use when allocating lookaside list entries. For more information about pool tags, see the *Tag* parameter of ExAllocatePoolWithTag.

`Depth`

Reserved. Must be zero.

Return Value

None

Remarks

After calling **ExInitializePagedLookasideList**, blocks of the caller-specified *Size* can be allocated from and freed to the lookaside list with calls to ExAllocateFromPagedLookasideList and ExFreeToPagedLookasideList, respectively. Such dynamically allocated and freed entries can be any data structure or fixed-size buffer that the caller uses while the system is running, particularly if the caller cannot predetermine how many such entries will be in use at any given moment. The layout and contents of each fixed-size entry are caller-determined.

ExInitializePagedLookasideList initializes the system state to track usage of the given lookaside list, as follows:

- Zero-initializes the counters to be maintained for entries.
- Stores the entry points of the caller-supplied ***Xxx*Allocate** and ***Xxx*Free** routines, if any, or sets these entry points to ExAllocatePoolWithTag and ExFreePool, respectively.
- Initializes a system spin lock to control allocations from and frees to the lookaside list in a multiprocessor-safe manner if necessary.

- Stores the caller-supplied entry *Size* and list *Tag*.
- Sets up the system-determined limits (minimum and maximum) on the number of entries to be held in the lookaside list, which can be adjusted subsequently if system-wide demand for entries is higher or lower than anticipated.
- Sets up the system-determined flags, which control the type of memory from which entries will be allocated subsequently.

The system maintains a set of all lookaside lists in use. As demand for lookaside list entries and on available paged memory varies while the system runs, the system adjusts its limits for the number of entries to be held in each paged lookaside list dynamically.

Drivers must always use explicitly free any lookaside lists they create before unloading. To do otherwise is a serious programming error. Use ExDeletePagedLookasideList to free the list.

ExInitializePagedLookasideList sets up the opaque list head at the caller-supplied location but preallocates no memory for list entries. Subsequently, the initial entries are allocated dynamically as calls to **ExAllocateFromPagedLookasideList** occur, and these initial entries are held in the lookaside list as reciprocal calls to **ExFreeToPagedLookasideList** occur. Entries collect in the given lookaside list until the system-determined maximum is reached, whereupon any additional entries are returned to paged pool as they are freed. If the list becomes empty, allocate requests are satisfied by the ***Xxx*Allocate** function specified at list initialization or by **ExAllocatePoolWithTag**.

It is more efficient to pass **NULL** pointers for the *Allocate* and *Free* parameters of **ExInitializePagedLookasideList** whenever the user of a lookaside list does nothing more than allocate and release fixed-size entries. However, any component that uses a lookaside list might supply these functions to do additional caller-determined processing, such as tracking its own dynamic memory usage by maintaining state about the number of entries it allocates and frees.

If the caller of **ExInitializePagedLookasideList** supplies an ***Xxx*Allocate** function, that function must allocate entries for the lookaside list using the given input parameters when it calls **ExAllocatePoolWithTag.**

Starting with Windows Vista, a similar routine, ExInitializeLookasideListEx, initializes a lookaside list that is described by a LOOKASIDE_LIST_EX structure. Unlike the ***Xxx*Allocate** and ***Xxx*Free** routines for a lookaside list that uses a **PAGED_LOOKASIDE_LIST** structure, the allocation and deallocation routines for a lookaside list that uses the **LOOKASIDE_LIST_EX** structure receive a context pointer as an input parameter. These routines can use this context to store private data for the lookaside list. If your driver is intended to run only in Windows Vista and later versions of Windows, consider using **ExInitializeLookasideListEx** instead of **ExInitializePagedLookasideList**. For more information, see Using Lookaside Lists.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ExInitializeResourceLite function

1/25/2019 • 2 minutes to read • Edit Online

The **ExInitializeResourceLite** routine initializes a resource variable.

Syntax

```
NTSTATUS ExInitializeResourceLite(
  PERESOURCE Resource
);
```

Parameters

`Resource`

A pointer to the caller-supplied storage, which must be at least **sizeof**(**ERESOURCE**), for the resource variable being initialized. The storage must be 4-byte aligned on 32-bit platforms, and 8-byte aligned on 64-bit platforms.

Return Value

ExInitializeResourceLite returns STATUS_SUCCESS.

Remarks

The storage for **ERESOURCE** must be allocated from nonpaged pool.

The resource variable can be used for synchronization by a set of threads. Although the caller provides the storage for the resource variable, the **ERESOURCE** structure is opaque: that is, its members are reserved for system use.

Call **ExDeleteResourceLite** before freeing the memory for the resource.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"
DDI compliance rules	HwStorPortProhibitedDDIs

ExInitializeRundownProtection function

1/25/2019 • 2 minutes to read • Edit Online

The **ExInitializeRundownProtection** routine initializes run-down protection on a shared object.

Syntax

```
void ExInitializeRundownProtection(
  PEX_RUNDOWN_REF RunRef
);
```

Parameters

`RunRef`

A pointer to a caller-allocated EX_RUNDOWN_REF structure that is to be initialized. The allocation must be 4-byte aligned on 32-bit platforms, and 8-byte aligned on 64-bit platforms. For more information, see Remarks.

Return Value

None.

Remarks

This routine is called by the driver that owns an object that resides in shared memory and is that accessed by other drivers.

ExInitializeRundownProtection must be called to initialize an **EX_RUNDOWN_REF** structure before it is passed as a parameter to any other run-down protection routine.

The run-down protection routines use the **EX_RUNDOWN_REF** structure to track the run-down status of a shared object that is associated with the structure. This status information includes a count of instances of run-down protection that are currently in effect on the object. **ExInitializeRundownProtection** initializes this count to zero.

After an **EX_RUNDOWN_REF** structure is initialized, other drivers that access the associated object can call the ExAcquireRundownProtection and ExReleaseRundownProtection routines to acquire and release run-down protection on the object.

For more information, see Run-Down Protection.

Requirements

Minimum supported client	Available starting with Windows XP.
Target Platform	Universal
Header	wdm.h (include Wdm.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

ExInitializeSetTimerParameters function

1/25/2019 • 2 minutes to read • Edit Online

The **ExInitializeSetTimerParameters** routine initializes an EXT_SET_PARAMETERS structure.

Syntax

```
void ExInitializeSetTimerParameters(
  PEXT_SET_PARAMETERS Parameters
);
```

Parameters

`Parameters`

A pointer to the **EXT_SET_PARAMETER** structure that is to be initialized.

Return Value

None.

Remarks

Your driver must call **ExInitializeSetTimerParameters** to initialize an **EXT_SET_PARAMETERS** structure before the driver passes this structure to the ExSetTimer routine. For more information about the member values that **ExInitializeSetTimerParameters** writes to the members of this structure, see EXT_SET_PARAMETERS.

Requirements

Minimum supported client	Available starting with Windows 8.1.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Any level.

EXT_SET_PARAMETERS

ExSetTimer

ExInterlockedAddLargeInteger function

1/25/2019 • 2 minutes to read • Edit Online

The **ExInterlockedAddLargeInteger** routine adds a large integer value to the specified variable as an atomic operation.

Syntax

```
LARGE_INTEGER ExInterlockedAddLargeInteger(
  PLARGE_INTEGER Addend,
  LARGE_INTEGER  Increment,
  PKSPIN_LOCK    Lock
);
```

Parameters

`Addend`

A pointer to the variable to be adjusted by the *Increment* value.

`Increment`

Specifies a value to be added to *Addend*.

`Lock`

A pointer to a spin lock to be used to synchronize access to *Addend*.

Return Value

ExInterlockedAddLargeInteger returns the initial value of the *Addend*parameter.

Remarks

Support routines that do interlocked operations are assumed to be incapable of causing a page fault. That is, neither their code nor any of the data they touch can cause a page fault without bringing down the system. They use spin locks to achieve atomicity on symmetric multiprocessor machines. The caller must provide resident storage for the *Lock*, which must be initialized with **KeInitializeSpinLock** before the initial call to an **ExInterlocked*Xxx***.

The *Lock* passed to **ExInterlockedAddLargeInteger** is used to assure that the add operation on *Addend* is atomic with respect to any other operations on the same value which synchronize with this same spin lock.

ExInterlockedAddLargeInteger masks interrupts. Consequently, it can be used for synchronization between an ISR and other device driver code, provided that the same *Lock* is never reused in a call to a routine that runs at IRQL = DISPATCH_LEVEL.

Note that calls to **Interlocked*Xxx*** are guaranteed to be atomic with respect to other **Interlocked*Xxx*** calls without caller-supplied spin locks.

Callers of **ExInterlockedAddLargeInteger** run at any IRQL. The storage for the *Addend* parameter must be resident at all IRQLs.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows. Not available in Windows 98 or Windows Me.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

InterlockedDecrement

InterlockedIncrement

KeInitializeSpinLock

ExInterlockedAddLargeStatistic macro

1/25/2019 • 2 minutes to read • Edit Online

The **ExInterlockedAddLargeStatistic** routine performs an interlocked addition of a ULONG increment value to a LARGE_INTEGER variable.

Syntax

```
void ExInterlockedAddLargeStatistic(
   Addend,
   Increment
);
```

Parameters

`Addend`

A pointer to the LARGE_INTEGER variable that is incremented by the value of *Increment*.

`Increment`

Specifies a ULONG value that is added to the variable that *Addend* points to.

Return Value

None

Remarks

Support routines that do interlocked operations must not cause a page fault. Neither their code nor any of the data they access can cause a page fault without bringing down the system.

ExInterlockedAddLargeStatistic masks interrupts, and can be safely used to synchronize an ISR with other driver code.

ExInterlockedAddLargeStatistic runs at any IRQL. The storage for the *Addend* parameter must be resident at all IRQLs.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

See Also

ExInterlockedAddLargeInteger

ExInterlockedAddUlong

ExInterlockedAddUlong function

1/25/2019 • 2 minutes to read • Edit Online

The **ExInterlockedAddUlong** routine adds an unsigned long value to a given unsigned integer as an atomic operation.

Syntax

```
ULONG ExInterlockedAddUlong(
  PULONG      Addend,
  ULONG       Increment,
  PKSPIN_LOCK Lock
);
```

Parameters

`Addend`

A pointer to an unsigned long integer whose value is to be adjusted by the *Increment* value.

`Increment`

Specifies an unsigned long integer to be added.

`Lock`

A pointer to a spin lock to be used to synchronize access to the *Addend*.

Return Value

ExInterlockedAddUlong returns the original (unsummed) value of the *Addend*.

Remarks

Consider using **InterlockedExchangeAdd** instead of this routine. **InterlockedExchangeAdd** can be more efficient because it does not use a spin lock and it is inlined by the compiler.

Support routines that do interlocked operations are assumed to be incapable of causing a page fault. That is, neither their code nor any of the data they touch can cause a page fault without bringing down the system. They use spin locks to achieve atomicity on symmetric multiprocessor machines. The caller must provide resident storage for the *Lock*, which must be initialized with **KeInitializeSpinLock** before the initial call to an **ExInterlocked*Xxx***.

The *Lock* passed to **ExInterlockedAddULong** is used to assure that the add operation on *Addend* is atomic with respect to any other operations on the same value which synchronize with this same spin lock.

ExInterlockedAddUlong masks interrupts. Consequently, it can be used for synchronization between an ISR and other driver code, provided that the same *Lock* is never reused in a call to a routine that runs at IRQL = DISPATCH_LEVEL.

Note that calls to **Interlocked*Xxx*** are guaranteed to be atomic with respect to other **Interlocked*Xxx*** calls without caller-supplied spin locks.

Callers of **ExInterlockedAddUlong** run at any IRQL. The storage for the *Addend* parameter must be resident at all IRQLs.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeInitializeSpinLock

ExInterlockedCompareExchange64 macro

1/25/2019 • 2 minutes to read • Edit Online

The **ExInterlockedCompareExchange64** routine compares one integer variable to another and, if they are equal, sets the first variable to a caller-supplied value.

Syntax

```
void ExInterlockedCompareExchange64(
   Destination,
   Exchange,
   Comperand,
   Lock
);
```

Parameters

`Destination`

A pointer to an integer that will be compared and possibly replaced.

`Exchange`

A pointer to an integer that will replace the one at *Destination* if the comparison results in equality.

`Comperand`

A pointer to an integer with which the value at *Destination* will be compared.

`Lock`

A pointer to a caller-allocated spin-lock that is used if the host system does not support an 8-byte atomic compare-and-exchange operation.

Return Value

This macro wraps **InterlockedCompareExchange64** or **ExfInterlockedCompareExchange64** and assumes the return value of the type LONGLONG.

Remarks

ExInterlockedCompareExchange64 tests and, possibly, replaces the value of a given variable. For most underlying microprocessors, this routine is implemented inline by the compiler to execute as an atomic operation. If a spin lock is used, this routine can only be safely used on nonpaged parameters.

If the *Destination* and *Comparand* are unequal, **ExInterlockedCompareExchange64** simply returns the value of *Destination*.

ExInterlockedCompareExchange64 is atomic only with respect to other **(Ex)Interlocked*Xxx*** calls.

Callers of **ExInterlockedCompareExchange64** can be running at any IRQL. The storage for the *Destination*, Comparand, and *Exchange* parameter and the list entries must be resident at all IRQLs.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

ExInterlockedFlushSList macro

1/25/2019 • 2 minutes to read • Edit Online

The **ExInterlockedFlushSList** routine atomically removes all entries from a sequenced singly linked list.

Syntax

```
void ExInterlockedFlushSList(
   Head
);
```

Parameters

`Head`

Return Value

If there were entries on the specified list, **ExInterlockedFlushSList** returns a pointer to the first **SLIST_ENTRY** structure that was entry on the list; otherwise, it returns NULL.

Remarks

ExInterlockedFlushSList does not delete the SLIST_ENTRY structures that made up the list; it only sets the internal pointer of *ListHead* to the beginning of the list to **NULL**. The driver must free the entries explicitly.

The routine returns a pointer to the first **SLIST_ENTRY** structure that was on the list. The driver can use this pointer to iterate through the entries.

For more information about using this routine to implement a sequenced singly linked list, see Singly and Doubly Linked Lists.

Callers of **ExInterlockedFlushSList** can be running at any IRQL. The storage for the *ListHead* parameter and the list entries must be resident at all IRQLs.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

ExInitializeSListHead

ExInterlockedInsertHeadList function

1/25/2019 • 2 minutes to read • Edit Online

The **ExInterlockedInsertHeadList** routine atomically inserts an entry at the beginning of a doubly linked list of LIST_ENTRY structures.

Syntax

```
PLIST_ENTRY ExInterlockedInsertHeadList(
  PLIST_ENTRY                  ListHead,
  __drv_aliasesMem PLIST_ENTRY ListEntry,
  PKSPIN_LOCK                  Lock
);
```

Parameters

`ListHead`

A pointer to the LIST_ENTRY structure that serves as the list header.

`ListEntry`

A pointer to the LIST_ENTRY structure that represents the entry to be inserted into the list.

`Lock`

A pointer to a **KSPIN_LOCK** structure that serves as the spin lock used to synchronize access to the list. The storage for the spin lock must be resident and must have been initialized by calling KeInitializeSpinLock. You must use this spin lock only with the **ExInterlocked*Xxx*List** routines.

Return Value

ExInterlockedInsertHeadList returns a pointer to the first entry of the list before the new entry was inserted. If the list was empty, the routine returns **NULL**.

Remarks

ExInterlockedInsertHeadList performs the same operation as InsertHeadList, but atomically. Do not mix atomic and non-atomic calls on the same list.

For more information about using this routine to implement a doubly linked list, see Singly and Doubly Linked Lists.

The **ExInterlockedInsertHeadList** routine can be called at any IRQL. The storage for the *ListHead* parameter and the list entries must be resident at all IRQLs.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal

InitializeListHead

InsertHeadList

KeInitializeSpinLock

ExInterlockedInsertTailList function

1/25/2019 • 2 minutes to read • Edit Online

The **ExInterlockedInsertTailList** routine atomically inserts an entry at the end of a doubly linked list of LIST_ENTRY structures.

Syntax

```
PLIST_ENTRY ExInterlockedInsertTailList(
  PLIST_ENTRY                  ListHead,
  __drv_aliasesMem PLIST_ENTRY ListEntry,
  PKSPIN_LOCK                  Lock
);
```

Parameters

`ListHead`

A pointer to the LIST_ENTRY structure that serves as the list header.

`ListEntry`

A pointer to the LIST_ENTRY structure that represents the entry to be inserted into the list.

`Lock`

A pointer to a **KSPIN_LOCK** structure that serves as the spin lock used to synchronize access to the list. The storage for the spin lock must be resident and must have been initialized by calling KeInitializeSpinLock. You must use this spin lock only with the **ExInterlocked*Xxx*List** routines.

Return Value

ExInterlockedInsertTailList returns a pointer to the last entry of the list before the new entry was inserted. If the list was empty, the routine returns **NULL**.

Remarks

ExInterlockedInsertTailList performs the same operation as InsertTailList, but atomically. Do not mix atomic and non-atomic calls on the same list.

For more information about using this routine to implement a doubly linked list, see Singly and Doubly Linked Lists.

The **ExInterlockedInsertTailList** routine can be called at any IRQL. The storage for the *ListHead* parameter and the list entries must be resident at all IRQLs.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal

ExInterlockedPopEntryList function

1/25/2019 • 2 minutes to read • Edit Online

The **ExInterlockedPopEntryList** routine atomically removes an entry from the beginning of a singly linked list of SINGLE_LIST_ENTRY structures.

Syntax

```
PSINGLE_LIST_ENTRY ExInterlockedPopEntryList(
  PSINGLE_LIST_ENTRY ListHead,
  PKSPIN_LOCK        Lock
);
```

Parameters

`ListHead`

A pointer to the SINGLE_LIST_ENTRY structure that serves as the list header.

`Lock`

A pointer to a **KSPIN_LOCK** structure that serves as the spin lock used to synchronize access to the list. The storage for the spin lock must be resident and must have been initialized by calling KeInitializeSpinLock. You must use this spin lock only with the **ExInterlocked*Xxx*List** routines.

Return Value

ExInterlockedPopEntryList returns a pointer to the SINGLE_LIST_ENTRY structure removed from the list. If the list was empty, the routine returns **NULL**.

Remarks

ExInterlockedPopEntryList performs the same operation as PopEntryList, but atomically. Do not mix atomic and non-atomic calls on the same list.

For more information about using this routine to implement a singly linked list, see Singly and Doubly Linked Lists.

The **ExInterlockedPopEntryList** routine can be called at any IRQL. The storage for the *ListHead* parameter must be resident at all IRQLs.

Requirements

KeInitializeSpinLock

ExInterlockedPushEntryList function

1/25/2019 • 2 minutes to read • Edit Online

The **ExInterlockedPushEntryList** routine atomically inserts an entry at the beginning of a singly linked list of SINGLE_LIST_ENTRY structures.

Syntax

```
PSINGLE_LIST_ENTRY ExInterlockedPushEntryList(
  PSINGLE_LIST_ENTRY                  ListHead,
  __drv_aliasesMem PSINGLE_LIST_ENTRY ListEntry,
  PKSPIN_LOCK                         Lock
);
```

Parameters

`ListHead`

A pointer to the SINGLE_LIST_ENTRY structure that serves as the list header.

`ListEntry`

A pointer to the SINGLE_LIST_ENTRY structure that represents the entry to be inserted into the list.

`Lock`

A pointer to a **KSPIN_LOCK** structure that serves as the spin lock used to synchronize access to the list. The storage for the spin lock must be resident and must have been initialized by calling KeInitializeSpinLock. You must use this spin lock only with the **ExInterlocked*Xxx*List** routines.

Return Value

ExInterlockedPushEntryList returns a pointer to the first entry of the list before the new entry was inserted. If the list was empty, the routine returns **NULL**.

Remarks

ExInterlockedPushEntryList performs the same operation as PushEntryList, but atomically. Do not mix atomic and non-atomic calls on the same list.

For more information about using this routine to implement a singly linked list, see Singly and Doubly Linked Lists.

The **ExInterlockedPushEntryList** routine can be called at any IRQL. The storage for the *ListHead* parameter and the list entries must be resident at all IRQLs.

ExInterlockedRemoveHeadList function

1/25/2019 • 2 minutes to read • Edit Online

The **ExInterlockedRemoveHeadList** routine removes an entry from the beginning of a doubly linked list of LIST_ENTRY structures.

Syntax

```
PLIST_ENTRY ExInterlockedRemoveHeadList(
  PLIST_ENTRY ListHead,
  PKSPIN_LOCK Lock
);
```

Parameters

`ListHead`

A pointer to the LIST_ENTRY structure that serves as the list header.

`Lock`

A pointer to a **KSPIN_LOCK** structure that serves as the spin lock used to synchronize access to the list. The storage for the spin lock must be resident and must have been initialized by calling KeInitializeSpinLock. You must use this spin lock only with the **ExInterlocked*Xxx*List** routines.

Return Value

ExInterlockedRemoveHeadList returns a pointer to the LIST_ENTRY structure removed from the list. If the list was empty, the routine returns **NULL**.

Remarks

ExInterlockedRemoveHeadList performs a similar operation as RemoveHeadList, but atomically. Do not mix atomic and non-atomic calls on the same list.

For more information about using this routine to implement a doubly linked list, see Singly and Doubly Linked Lists.

The **ExInterlockedRemoveHeadList** routine can be called at any IRQL. The storage for the *ListHead* parameter must be resident at all IRQLs.

The **ExIsProcessorFeaturePresent** routine queries for the existence of a specified processor feature.

Syntax

```
BOOLEAN ExIsProcessorFeaturePresent(
  ULONG ProcessorFeature
);
```

Parameters

`ProcessorFeature`

Specifies one of the following constant values:

PF_FLOATING_POINT_PRECISION_ERRATA

The processor has the Pentium floating-point divide bug.

PF_FLOATING_POINT_EMULATED

The processor does not have floating-point hardware.

PF_COMPARE_EXCHANGE_DOUBLE

The processor has an 8-byte, memory-locked compare and exchange (CMPXCHG8B) instruction.

PF_MMX_INSTRUCTIONS_AVAILABLE

The processor supports MMX instructions in hardware.

PF_XMMI_INSTRUCTIONS_AVAILABLE

The processor supports SSE instructions in hardware.

PF_3DNOW_INSTRUCTIONS_AVAILABLE

The processor supports AMD 3DNow instructions.

PF_RDTSC_INSTRUCTION_AVAILABLE

The processor supports a read-timestamp-counter (RDTSC) instruction.

PF_PAE_ENABLED

The processor implements Physical Address Extension (PAE) support.

PF_XMMI64_INSTRUCTIONS_AVAILABLE

The processor supports SSE2 instructions in hardware. This parameter value is supported only in Windows XP and later versions of Windows.

PF_SSE_DAZ_MODE_AVAILABLE

The processor supports the denormals-are-zero (DAZ) mode for SSE instructions. This parameter value is supported only in Windows Vista and later versions of Windows.

PF_NX_ENABLED

Data execution prevention is enabled. This parameter value is supported only in Windows Vista and later versions of Windows.

PF_SSE3_INSTRUCTIONS_AVAILABLE

The processor supports SSE3 instructions. This parameter value is supported only in Windows Vista and later

versions of Windows.

PF_COMPARE_EXCHANGE128

The atomic compare and exchange 128-bit operation (CMPXCHG16B) is available. This parameter value is supported only in Windows Vista and later versions of Windows.

PF_COMPARE64_EXCHANGE128

The atomic compare 64-bit and exchange 128-bit operation (CMP8XCHG16) is available. This parameter value is supported only in Windows Vista and later versions of Windows.

PF_XSAVE_ENABLED

The processor supports the XSAVE and XRSTOR instructions. This parameter value is supported only in Windows 7 and later versions of Windows.

Return Value

ExIsProcessorFeaturePresent returns **TRUE** if the specified processor feature is present; otherwise, it returns **FALSE**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	IrqlExPassive, PowerIrpDDis, HwStorPortProhibitedDDIs

ExIsResourceAcquiredExclusiveLite function

1/25/2019 • 2 minutes to read • Edit Online

The **ExIsResourceAcquiredExclusiveLite** routine returns whether the current thread has exclusive access to a given resource.

Syntax

```
BOOLEAN ExIsResourceAcquiredExclusiveLite(
  PERESOURCE Resource
);
```

Parameters

`Resource`

A pointer to the resource to be queried.

Return Value

ExIsResourceAcquiredExclusiveLite returns **TRUE** if the caller already has exclusive access to the given resource.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"
DDI compliance rules	HwStorPortProhibitedDDIs

See Also

ExAcquireResourceExclusiveLite

ExIsResourceAcquiredSharedLite

ExIsResourceAcquiredSharedLite function

1/25/2019 • 2 minutes to read • Edit Online

The **ExIsResourceAcquiredSharedLite** routine returns whether the current thread has access (either shared or exclusive) to a given resource.

Syntax

```
ULONG ExIsResourceAcquiredSharedLite(
  PERESOURCE Resource
);
```

Parameters

`Resource`

A pointer to the resource to be queried.

Return Value

ExIsResourceAcquiredSharedLite returns the number of times the caller has acquired the given resource for shared or exclusive access.

Remarks

The system considers exclusive access to be a subset of shared access. Therefore, a thread that has exclusive access to a resource also has shared access to the resource.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"
DDI compliance rules	HwStorPortProhibitedDDIs

ExIsSoftBoot function

1/25/2019 • 2 minutes to read • Edit Online

Determines whether the system has gone through a soft restart.

Syntax

```
BOOLEAN ExIsSoftBoot(

);
```

Parameters

This function has no parameters.

Return Value

TRUE indicates a soft restart; FALSE otherwise.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	wdm.h
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode)
IRQL	"<=APC_LEVEL"

ExLocalTimeToSystemTime function

1/25/2019 • 2 minutes to read • Edit Online

The **ExLocalTimeToSystemTime** routine converts a system time value for the current time zone to an unbiased, GreenGMT value.

Syntax

```
void ExLocalTimeToSystemTime(
  PLARGE_INTEGER LocalTime,
  PLARGE_INTEGER SystemTime
);
```

Parameters

`LocalTime`

A pointer to a variable set to the locale-specific time.

`SystemTime`

A pointer to the returned value for GMT system time.

Return Value

None

Remarks

ExLocalTimeToSystemTime adds the time-zone bias at the current locale to compute the corresponding GMT system time value.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

See Also

ExSystemTimeToLocalTime

ExNotifyCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **ExNotifyCallback** routine causes all callback routines registered for the given object to be called.

Syntax

```
void ExNotifyCallback(
  PVOID CallbackObject,
  PVOID Argument1,
  PVOID Argument2
);
```

Parameters

`CallbackObject`

A pointer to the callback object for which all registered callback routines will be called.

`Argument1`

Specifies the parameter that is passed as *Argument1* of the callback routine.

`Argument2`

Specifies the parameter that is passed as *Argument2* of the callback routine.

Return Value

None

Remarks

Driver writers must not call **ExNotifyCallback** for any of the system-defined callback objects listed in **ExCreateCallback**.

The system calls callback routines in order of their registration.

For more information about callback objects, see Callback Objects.

Callers of this routine must be running at IRQL <= DISPATCH_LEVEL. The system calls all registered callback routines at the caller's IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL (see Remarks section)"

See Also

ExCreateCallback

ExRegisterCallback

ExQueryDepthSList function

1/25/2019 • 2 minutes to read • Edit Online

The **ExQueryDepthSList** routine returns the number of entries currently in a given sequenced singly linked list.

Syntax

```
USHORT ExQueryDepthSList(
  PSLIST_HEADER SListHead
);
```

Parameters

`SListHead`

A pointer to the SLIST_HEADER structure that serves as the header for the sequenced singly linked list. *SListHead* must have been initialized by calling ExInitializeSListHead.

Return Value

ExQueryDepthSList returns the current number of entries in the list.

Remarks

For more information about using this routine to implement a sequenced singly linked list, see Singly and Doubly Linked Lists.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

See Also

ExInitializeSListHead

ExInterlockedPopEntrySList

ExInterlockedPushEntrySList

ExQueryTimerResolution function

1/25/2019 • 2 minutes to read • Edit Online

The **ExQueryTimerResolution** routine reports the range of timer resolutions that are supported by the system clock.

Syntax

```
void ExQueryTimerResolution(
  PULONG MaximumTime,
  PULONG MinimumTime,
  PULONG CurrentTime
);
```

Parameters

`MaximumTime`

A pointer to a location to which the routine writes the maximum time interval, in 100-nanosecond units, between successive ticks of the system clock. A *tick* is an interrupt caused by the system clock timer.

`MinimumTime`

A pointer to a location to which the routine writes the minimum time interval, in 100-nanosecond units, between successive ticks of the system clock.

`CurrentTime`

A pointer to a location to which the routine writes the current time interval, in 100-nanosecond units, between successive ticks of the system clock.

Return Value

None.

Remarks

If your driver calls the ExSetTimerResolution routine to change the time interval between successive system clock interrupts, the driver can first call **ExQueryTimerResolution** to determine the range of intervals supported by the system clock.

When your driver calls a routine such as KeSetTimerEx to set a timer, the accuracy of the timer depends on the resolution of the system clock. For more information, see Timer Accuracy.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Ntoskrnl.lib
IRQL	Any level.

See Also

ExSetTimerResolution

KeSetTimerEx

ExRaiseStatus function

1/25/2019 • 2 minutes to read • Edit Online

The **ExRaiseStatus** routine is called by drivers that supply structured exception handlers to handle particular errors that occur while they are processing I/O requests.

Syntax

```
void ExRaiseStatus(
  NTSTATUS Status
);
```

Parameters

`Status`

Specifies one of the system-defined STATUS_*XXX* values.

Return Value

None

Remarks

Highest-level drivers, particularly file systems, can call **ExRaiseStatus**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=APC_LEVEL"
DDI compliance rules	IrqlExPassive, HwStorPortProhibitedDDIs

ExRaiseDatatypeMisalignment

IoAllocateErrorLogEntry

KeBugCheckEx

ExRegisterCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **ExRegisterCallback** routine registers a given callback routine with a given callback object.

Syntax

```
PVOID ExRegisterCallback(
  PCALLBACK_OBJECT   CallbackObject,
  PCALLBACK_FUNCTION CallbackFunction,
  PVOID              CallbackContext
);
```

Parameters

`CallbackObject`

A pointer to a callback object obtained from the ExCreateCallback routine.

`CallbackFunction`

A pointer to a driver-implemented callback routine, which must be nonpageable. The callback routine must conform to the following prototype:

```
VOID
(*PCALLBACK_FUNCTION ) (
    IN PVOID CallbackContext,
    IN PVOID Argument1,
    IN PVOID Argument2
    );
```

The callback routine parameters are as follows:

CallbackContext

A pointer to a driver-supplied context area as specified in the *CallbackContext* parameter of **ExRegisterCallback**.

Argument1

A pointer to a parameter defined by the callback object.

Argument2

A pointer to a parameter defined by the callback object.

`CallbackContext`

A pointer to a caller-defined structure of data items to be passed as the context parameter of the callback routine each time it is called. Typically the context is part of the caller's device object extension.

Return Value

ExRegisterCallback returns a pointer to a callback registration handle that should be treated as opaque and reserved for system use. This pointer is **NULL** if **ExRegisterCallback** completes with an error.

Remarks

A driver calls **ExRegisterCallback** to register a callback routine with a specified callback object.

If the object allows only one registered callback routine, and such a routine is already registered, **ExRegisterCallback** returns **NULL**.

Callers of **ExRegisterCallback** must save the returned pointer for use later in a call to ExUnregisterCallback. The pointer is required when removing the callback routine from the list of registered callback routines for the callback object.

The meanings of *Argument1* and *Argument2* of the registered callback routine depend on the callback object and are defined by the component that created it. The following are the parameters for the system-defined callback objects:

Starting with Windows Vista, the **\Callback\ProcessorAdd** callback object is available to dynamically track changes in the processor population. The KeRegisterProcessorChangeCallback routine provides similar information, but additionally supports a KE_PROCESSOR_CHANGE_ADD_EXISTING flag that a driver can use to enumerate the processors in the initial multiprocessor system configuration. For drivers that run in Windows Server 2008 and later versions of Windows, use **KeRegisterProcessorChangeCallback** instead of the **\Callback\ProcessorAdd** callback object, if possible.

For more information about callback objects, see Callback Objects.

The operating system calls registered callback routines at the same IRQL at which the driver that created the callback called the ExNotifyCallback routine.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"
DDI compliance rules	IrqlExApcLte2, HwStorPortProhibitedDDIs

KeRegisterProcessorChangeCallback

ExReinitializeResourceLite function

1/25/2019 • 2 minutes to read • Edit Online

The **ExReinitializeResourceLite** routine reinitializes an existing resource variable.

Syntax

```
NTSTATUS ExReinitializeResourceLite(
  PERESOURCE Resource
);
```

Parameters

`Resource`

A pointer to the caller-supplied resource variable to be reinitialized.

Return Value

ExReinitializeResourceLite returns STATUS_SUCCESS.

Remarks

With a single call to **ExReinitializeResource**, a driver writer can replace three calls: one to **ExDeleteResourceLite**, another to **ExAllocatePool**, and a third to **ExInitializeResourceLite**. As contention for a resource variable increases, memory is dynamically allocated and attached to the resource in order to track this contention. As an optimization, **ExReinitializeResourceLite** retains and zeros this previously allocated memory.

The **ERESOURCE** structure is opaque; that is, the members are reserved for system use.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"
DDI compliance rules	HwStorPortProhibitedDDIs

ExReInitializeRundownProtection function

1/25/2019 • 2 minutes to read • Edit Online

The **ExReInitializeRundownProtection** routine reinitializes an EX_RUNDOWN_REF structure after the associated object is run down.

Syntax

```
void ExReInitializeRundownProtection(
  PEX_RUNDOWN_REF RunRef
);
```

Parameters

`RunRef`

A pointer to an **EX_RUNDOWN_REF** structure that was initialized by a previous call to the ExInitializeRundownProtection routine. The run-down protection routines use this structure to track the run-down status of the associated shared object. This structure is opaque to drivers.

Return Value

None.

Remarks

This routine is called by the driver that owns an object that resides in shared memory and that is accessed by other drivers.

ExReInitializeRundownProtection enables a previously used EX_RUNDOWN_REF structure to be associated with a new object, and initializes run-down protection on this object. After the **ExReInitializeRundownProtection** call, drivers can call ExAcquireRundownProtection to acquire run-down protection on the new object.

An **ExReInitializeRundownProtection** call must be preceded by a call to the ExWaitForRundownProtectionRelease routine that runs down the old object. Between the **ExWaitForRundownProtectionRelease** and **ExReInitializeRundownProtection** calls, the driver might call the ExRundownCompleted routine to indicate that the run down of the old object has completed.

On entry, the status information in the **EX_RUNDOWN_REF** structure must indicate that the old object was run down. Otherwise, **ExReInitializeRundownProtection** bug checks in checked builds.

For more information, see Run-Down Protection.

Requirements

Minimum supported client	Available starting with Windows XP.

Target Platform	Universal
Header	wdm.h (include Wdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

ExReleaseResourceForThreadLite function

1/25/2019 • 2 minutes to read • Edit Online

The **ExReleaseResourceForThreadLite** routine releases the input resource of the indicated thread.

Syntax

```
void ExReleaseResourceForThreadLite(
  PERESOURCE       Resource,
  ERESOURCE_THREAD ResourceThreadId
);
```

Parameters

`Resource`

`ResourceThreadId`

Identifies the thread that originally acquired the resource. If this is not the currently executing thread, the caller must have transferred ownership of the resource by calling the ExSetResourceOwnerPointerEx routine first on the thread that originally acquired the resource.

Return Value

None

Remarks

If this is not the currently executing thread, the caller must have transferred ownership of the resource by calling the ExSetResourceOwnerPointerEx routine first on the thread that originally acquired the resource. This is to ensure that thread A does not get terminated or deleted before thread B has a chance to release the resource.

Unless the caller is running in a system thread, the caller must explicitly disable the delivery of normal kernel APCs before calling this routine. This requirement prevents threads from being suspended while they manipulate or hold a resource. The caller can disable normal kernel APC delivery by calling the KeEnterCriticalRegion routine. Delivery must remain disabled until the resource is released, at which point it can be reenabled by calling the KeLeaveCriticalRegion routine. For more information, see Disabling APCs.

This requirement does not apply to calls made to **ExReleaseResourceForThreadLite** from a system thread. A caller running in a system thread does not need to explicitly disable APCs before calling this routine.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"
DDI compliance rules	ExclusiveResourceAccess, WithinCriticalRegion, HwStorPortProhibitedDDIs, WithinCriticalRegion(storport)

ExInitializeResourceLite

ExReinitializeResourceLite

ExReleaseResourceLite function

1/25/2019 • 2 minutes to read • Edit Online

The **ExReleaseResourceLite** routine releases a specified executive resource owned by the current thread.

Syntax

```
void ExReleaseResourceLite(
  PERESOURCE Resource
);
```

Parameters

`Resource`

A pointer to an executive resource owned by the current thread.

Return Value

None

Remarks

Normal kernel APC delivery must be disabled before calling this routine. Disable normal kernel APC delivery by calling KeEnterCriticalRegion. Delivery must remain disabled until the resource is released, at which point it can be reenabled by calling KeLeaveCriticalRegion. For more information, see Disabling APCs.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ExReleaseRundownProtection function

1/25/2019 • 2 minutes to read • Edit Online

The **ExReleaseRundownProtection** routine releases run-down protection that the caller previously acquired by calling the ExAcquireRundownProtection routine.

Syntax

```
void ExReleaseRundownProtection(
  PEX_RUNDOWN_REF RunRef
);
```

Parameters

`RunRef`

A pointer to an EX_RUNDOWN_REF structure that was initialized by a previous call to the ExInitializeRundownProtection routine. The run-down protection routines use this structure to track the run-down status of the associated shared object. This structure is opaque to drivers.

Return Value

None.

Remarks

A driver that calls ExAcquireRundownProtection to acquire run-time protection for an object access is responsible for calling **ExReleaseRundownProtection** to release the run-time protection when the access is finished.

For more information, see Run-Down Protection.

Requirements

Minimum supported client	Available starting with Windows XP.
Target Platform	Universal
Header	wdm.h (include Wdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"
DDI compliance rules	HwStorPortProhibitedDDIs

EX_RUNDOWN_REF

ExAcquireRundownProtection

ExInitializeRundownProtection

ExReleaseRundownProtectionEx function

1/25/2019 • 2 minutes to read • Edit Online

The **ExReleaseRundownProtectionEx** routine releases run-down protection that the caller previously acquired by calling the ExAcquireRundownProtectionEx routine.

Syntax

```
void ExReleaseRundownProtectionEx(
  PEX_RUNDOWN_REF RunRef,
  ULONG           Count
);
```

Parameters

`RunRef`

A pointer to an EX_RUNDOWN_REF structure that was initialized by a previous call to the ExInitializeRundownProtection routine. The run-down protection routines use this structure to track the run-down status of the associated shared object. This structure is opaque to drivers.

`Count`

The amount by which to decrement to the run-down instance count of the object. For more information, see Remarks.

Return Value

None.

Remarks

The *RunRef* parameter points to an EX_RUNDOWN_REF structure that tracks the run-down status of the associated object. This status information includes a count of the instances of run-down protection that are currently in effect on the object. The ExAcquireRundownProtectionEx and **ExReleaseRundownProtectionEx** routines increment and decrement this count by arbitrary amounts. Two related routines, ExAcquireRundownProtection and ExReleaseRundownProtection, increment and decrement this count by one.

For more information, see Run-Down Protection.

Requirements

Minimum supported client	Available starting with Windows Server 2003.
Target Platform	Universal
Header	wdm.h (include Wdm.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ExReleaseSpinLockExclusive function

1/25/2019 • 2 minutes to read • Edit Online

The **ExReleaseSpinLockExclusive** routine releases a spin lock that the caller previously acquired for exclusive access, and restores the IRQL to its original value.

Syntax

```
void ExReleaseSpinLockExclusive(
  PEX_SPIN_LOCK SpinLock,
  KIRQL         OldIrql
);
```

Parameters

`SpinLock`

`OldIrql`

The interrupt request level (IRQL) to restore. Set this parameter to the KIRQL value that was returned by the ExAcquireSpinLockExclusive call that acquired the spin lock.

Return Value

None.

Remarks

This routine must be called only for a spin lock that is owned by the caller.

On entry to this routine, the caller must be running at IRQL = DISPATCH_LEVEL. Before exiting, **ExReleaseSpinLockExclusive** restores the IRQL to the value specified by the *OldIrql* parameter.

The caller should hold the spin lock only briefly before releasing it. For more information, see Introduction to Spin Locks.

Requirements

Minimum supported client	Available starting with Windows Vista with SP1.
Target Platform	Universal
Header	wdm.h
IRQL	DISPATCH_LEVEL (See Remarks.)

See Also

ExAcquireSpinLockExclusive

ExReleaseSpinLockShared function

1/25/2019 • 2 minutes to read • Edit Online

The **ExReleaseSpinLockShared** routine releases ownership of a spin lock that the caller previously acquired for shared access, and restores the IRQL to its original value.

Syntax

```
void ExReleaseSpinLockShared(
  PEX_SPIN_LOCK SpinLock,
  KIRQL         OldIrql
);
```

Parameters

`SpinLock`

`OldIrql`

The interrupt request level (IRQL) to restore. Set this parameter to the KIRQL value that was returned by the ExAcquireSpinLockShared call that acquired the spin lock.

Return Value

None.

Remarks

This routine must be called only for a spin lock that is owned by the caller.

On entry to this routine, the caller must be running at IRQL = DISPATCH_LEVEL. Before exiting, **ExReleaseSpinLockShared** restores the IRQL to the value specified by the *OldIrql* parameter.

The caller should hold the spin lock only briefly before releasing it. For more information, see Introduction to Spin Locks.

Requirements

Minimum supported client	Available starting with Windows Vista with SP1.
Target Platform	Universal
Header	wdm.h
IRQL	DISPATCH_LEVEL (See Remarks.)

ExAcquireSpinLockShared

ExRundownCompleted function

1/25/2019 • 2 minutes to read • Edit Online

The **ExRundownCompleted** routine updates the run-down status of a shared object to indicate that the run down of the object has completed.

Syntax

```
void ExRundownCompleted(
  PEX_RUNDOWN_REF RunRef
);
```

Parameters

`RunRef`

A pointer to an EX_RUNDOWN_REF structure that was initialized by a previous call to the ExInitializeRundownProtection routine. The run-down protection routines use this structure to track the run-down status of the associated shared object. This structure is opaque to drivers.

Return Value

None.

Remarks

This routine is called by the driver that owns an object that resides in shared memory and that is accessed by other drivers. The **ExRundownCompleted** call must be preceded by a call to the ExWaitForRundownProtectionRelease routine that runs down the object.

After an **ExRundownCompleted** call, additional calls to **ExWaitForRundownProtectionRelease** to run down the associated object return immediately without waiting. However, calls to ExAcquireRundownProtection to acquire run-down protection on the associated object fail (return **FALSE**).

After an **ExRundownCompleted** call, the driver can call the ExReInitializeRundownProtection routine to associate the EX_RUNDOWN_REF structure with a new object and to initialize run-down protection on this object. After the **ExReInitializeRundownProtection** call, drivers can call **ExAcquireRundownProtection** to acquire run-down protection on the new object.

On entry, the status information in the **EX_RUNDOWN_REF** structure must indicate that the object that was associated with this structure was run down. Otherwise, **ExReInitializeRundownProtection** bug checks in checked builds.

For more information, see Run-Down Protection.

Requirements

Minimum supported client	Available starting with Windows XP.

Target Platform	Universal
Header	wdm.h (include Wdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

EX_RUNDOWN_REF

ExInitializeRundownProtection

ExSetFirmwareEnvironmentVariable function

1/25/2019 • 2 minutes to read • Edit Online

The **ExSetFirmwareEnvironmentVariable** routine sets the value of the specified system firmware environment variable.

Syntax

```
NTSTATUS ExSetFirmwareEnvironmentVariable(
  PUNICODE_STRING VariableName,
  LPGUID          VendorGuid,
  PVOID           Value,
  ULONG           ValueLength,
  ULONG           Attributes
);
```

Parameters

`VariableName`

A pointer to a UNICODE_STRING structure that contains the name of the specified environment variable.

`VendorGuid`

A pointer to a GUID that identifies the vendor associated with the specified environment variable. Environment variables are grouped into namespaces based on their vendor GUIDs. Some hardware platforms might not support vendor GUIDs. On these platforms, all variables are grouped into one, common namespace, and the *VendorGuid* parameter is ignored.

`Value`

A pointer to a caller-allocated buffer that contains the data value to write to the specified environment variable.

`ValueLength`

The size, in bytes, of the data value contained in the *Value* buffer.

`Attributes`

The attributes to assign to the specified environment variable. The VARIABLE_ATTRIBUTE_NON_VOLATILE attribute bit must be set or this call will fail. For more information about the attribute bits that are defined for this parameter, see Remarks in ExGetFirmwareEnvironmentVariable.

Return Value

ExSetFirmwareEnvironmentVariable returns STATUS_SUCCESS if it is successful. Possible return values include the following error status codes.

RETURN CODE	DESCRIPTION

STATUS_INSUFFICIENT_RESOURCES	Available system resources are insufficient to complete the requested operation.
STATUS_INVALID_PARAMETER	One of the parameters is not valid.
STATUS_NOT_IMPLEMENTED	This routine is not supported on this platform.
STATUS_UNSUCCESSFUL	The firmware returned an unrecognized error.

Remarks

The caller requires the system environment privilege (SE_SYSTEM_ENVIRONMENT_PRIVILEGE) to use this routine.

System firmware environment variables contain data values that are passed between the boot firmware environment implemented in the hardware platform and the operating-system loaders and other software that runs in the firmware environment. For more information, see Remarks in ExGetFirmwareEnvironmentVariable.

If you create a backup datastore, you can use the ExGetFirmwareEnvironmentVariable routine to save all the boot settings for the platform. Later, you can use **ExSetFirmwareEnvironmentVariable** to restore these settings if needed.

ExSetFirmwareEnvironmentVariable is the kernel-mode equivalent of the Win32 SetFirmwareEnvironmentVariable function.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

UNICODE_STRING

ExSetResourceOwnerPointer function

1/25/2019 • 2 minutes to read • Edit Online

The **ExSetResourceOwnerPointer** routine sets the owner thread pointer for an executive resource.

Syntax

```
void ExSetResourceOwnerPointer(
  PERESOURCE Resource,
  PVOID      OwnerPointer
);
```

Parameters

`Resource`

A pointer to an executive resource owned by the current thread.

`OwnerPointer`

A pointer to an owner thread pointer of type ERESOURCE_THREAD (for additional requirements, see the following Remarks section).

Return Value

None

Remarks

ExSetResourceOwnerPointer, used in conjunction with **ExReleaseResourceForThreadLite**, provides a means for one thread (acting as an resource manager thread) to acquire and release resources for use by another thread (acting as a resource user thread).

After calling **ExSetResourceOwnerPointer** for a specific resource, the only other routine that can be called for that resource is **ExReleaseResourceForThreadLite**.

The resource manager thread acquires ownership of the resource and passes ownership to the user thread by calling **ExSetResourceOwnerPointer**. The caller must allocate the memory for the ERESOURCE_THREAD value pointed to by *OwnerPointer* in system memory, and this memory must remain allocated until **ExReleaseResourceForThreadLite** returns. The caller must also set the two low-order bits of the ERESOURCE_THREAD value pointed to by *OwnerPointer* to one — this encoding is used internally by the resource services to distinguish between owner and thread addresses.

When the user thread is done with the resource, the resource manager thread releases the user thread's ownership of the resource by calling **ExReleaseResourceForThreadLite**. The *ResourceThreadId* input parameter is set to the value of the *OwnerPointer* parameter used in the previous call to **ExSetResourceOwnerPointer** that gave the worker thread ownership of the resource.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ExReleaseResourceForThreadLite

ExSetResourceOwnerPointerEx function

1/25/2019 • 3 minutes to read • Edit Online

The **ExSetResourceOwnerPointerEx** routine transfers the ownership of an executive resource from the calling thread to an owner pointer, which is a system address that identifies the resource owner.

Syntax

```
void ExSetResourceOwnerPointerEx(
  PERESOURCE Resource,
  PVOID      OwnerPointer,
  ULONG      Flags
);
```

Parameters

`Resource`

A pointer to an executive resource (an opaque ERESOURCE structure) that is owned by the calling thread. The caller previously allocated this structure and initialized it by calling the ExInitializeResourceLite routine. For more information, see the following Remarks section.

`OwnerPointer`

A pointer value that identifies the resource owner. This parameter value is nominally a pointer to a value of type ERESOURCE_THREAD but is cast to type PVOID. The caller must set the two least significant bits of this pointer value to ones. For more information, see the following Remarks section.

`Flags`

A set of flags that can modify the operation of this routine. Set this parameter either to zero or to the following flag value:

- FLAG_OWNER_POINTER_IS_THREAD

If *Flags* = FLAG_OWNER_POINTER_IS_THREAD, *OwnerPointer* must point to a value of type ERESOURCE_THREAD, which is a pointer to an opaque thread object. If *Flags* = 0, *OwnerPointer* must point to a storage object in system memory that remains allocated until the resource is released. For more information, see the following Remarks section.

Return Value

None

Remarks

This routine is available in Windows 7 and later versions of the Windows operating system.

ExSetResourceOwnerPointerEx enables a thread, which acts as a resource manager, to transfer ownership of an executive resource, which the thread has already acquired, to another thread, which then uses the resource. The executive resource is represented by an ERESOURCE structure.

The caller must set the two least significant bits of the *OwnerPointer* parameter value to ones. The operating system uses these bits internally to distinguish an owner pointer that has been set by an **ExSetResourceOwnerPointerEx** call from a thread that has acquired a resource by calling the ExAcquireResourceExclusiveLite or ExAcquireResourceSharedLite routine.

The thread that calls **ExSetResourceOwnerPointerEx** to transfer ownership of a resource must be the same thread that previously called the **ExAcquireResource*Xxx*Lite** routine to acquire the resource.

If the resource-manager thread acquired the resource for exclusive access (by calling **ExAcquireResourceExclusiveLite**), the **ExSetResourceOwnerPointerEx** call transfers exclusive-access ownership to the resource-user thread. If the resource-manager thread acquired the resource for shared access (by calling **ExAcquireResourceSharedLite**), the **ExSetResourceOwnerPointerEx** call transfers shared-access ownership to the resource-user thread.

When the resource-user thread no longer needs the resource, the resource should be released. Typically, the resource-user thread releases the resource. To do so, it must call the ExReleaseResourceForThreadLite routine. In this call, the *ThreadId* parameter value must match the value of the *OwnerPointer* parameter (including the two least significant bits) in the previous **ExSetResourceOwnerPointerEx** call that transferred ownership of the resource.

After a **ExSetResourceOwnerPointerEx** call transfers ownership of a resource, the only other ERESOURCE routine that a driver can call for the specified resource is **ExReleaseResourceForThreadLite**. An attempt to call another **ERESOURCE** routine, such as ExReleaseResourceLite, for this resource is an error.

ExSetResourceOwnerPointerEx can operate in two significantly different modes. The mode is specified by the *Flags* parameter. To select the more versatile of the two modes, set *Flags* = FLAG_OWNER_POINTER_IS_THREAD. This *Flags* value informs the operating system that the *OwnerPointer* parameter is a pointer to the thread object of the resource-manager thread. The operating system can, if necessary, use this information to temporarily boost the priority of this thread to avoid priority inversion. To obtain the thread object pointer to use for the *OwnerPointer* value, a driver can call the ExGetCurrentResourceThread routine. Remember to set the two least significant bits of the *OwnerPointer* value to ones.

If *Flags* is zero, the behavior of **ExSetResourceOwnerPointerEx** is the same as that of the legacy ExSetResourceOwnerPointer routine, which is available in Windows 2000 and later versions of the Windows operating system. That is, the *OwnerPointer* parameter points to a storage object that the resource-manager thread allocates in system memory before it calls **ExSetResourceOwnerPointerEx**. In this case, the object type and value are not relevant because **ExSetResourceOwnerPointerEx** does not attempt to access the object itself. Instead, the routine simply uses the memory address of the object to identify the resource owner. The storage for the object must begin at an even four-byte boundary in memory. To prevent two drivers from inadvertently using the same owner pointer at the same time, the resource-manager thread must not release the storage for the object until the resource is released.

For more information about managing executive resources, see Introduction to ERESOURCE Routines.

ExSetResourceOwnerPointer

ExSetTimer function

1/25/2019 • 3 minutes to read • Edit Online

The **ExSetTimer** routine starts a timer operation and sets the timer to expire at the specified due time.

Syntax

```
BOOLEAN ExSetTimer(
  PEX_TIMER           Timer,
  LONGLONG            DueTime,
  LONGLONG            Period,
  PEXT_SET_PARAMETERS Parameters
);
```

Parameters

`Timer`

A pointer to an EX_TIMER structure. This structure is a timer object that was previously allocated by the ExAllocateTimer routine.

`DueTime`

The absolute or relative time at which the timer is to expire. If the value of the *DueTime* parameter is negative, the expiration time is relative to the current system time. Otherwise, the expiration time is absolute. The expiration time is expressed in system time units (100-nanosecond intervals). Absolute expiration times track any changes in the system time; relative expiration times are not affected by system time changes. An absolute time is expressed as the amount of time passed, in system time units, since the start of the year 1601.

The *DueTime* parameter for a high-resolution timer must be a relative time (negative value), or the routine bug checks.

`Period`

An optional period for the timer in system time units (100-nanosecond intervals). Must be less than or equal to MAXLONG. For a timer that is one-shot instead of periodic, set *Period* to zero.

`Parameters`

A pointer to an EXT_SET_PARAMETERS structure. The calling driver previously called the ExInitializeSetTimerParameters routine to initialize this structure.

Return Value

This routine returns **TRUE** if it cancels a timer that was pending at the time that the routine was called. Otherwise, the routine returns **FALSE**. For more information, see Remarks.

Remarks

Your driver can call this routine to set a timer to expire at a future time. The driver can then wait for the timer to expire. Or, the driver can implement a callback routine that is called when the timer expires.

After a driver calls **ExSetTimer**, the driver can call a routine such as KeWaitForSingleObject or or

KeWaitForMultipleObjects to wait for the timer to expire. When the timer expires, the operating system signals the timer object.

As an option, the driver can implement an ExTimerCallback callback routine, and supply a pointer to this routine as an input parameter to the ExAllocateTimer routine. When the timer expires, the operating system calls the *ExTimerCallback* routine.

An **ExSetTimer** call implicitly cancels any previously started set-timer operation on the timer object specified by *Timer*. If your driver previously called **ExSetTimer** to set a timer that uses *Timer*, and this timer has not yet expired when **ExSetTimer** is called a second time, the second call cancels the timer from the first call and then starts the new timer. In this case, the second call returns **TRUE**. However, if the timer started by the first call expires before the second call can cancel this timer, the second call starts the new timer and returns **FALSE**.

If the *Period* parameter is nonzero, the timer is periodic. For a periodic timer, the *DueTime* parameter specifies the time of the initial timer expiration, and *Period* specifies the interval between subsequent expirations.

The hardware timer used for the system clock signals interrupt requests at uniform intervals, but the handling of these interrupts might be delayed by interrupt processing for other devices. Thus, for a periodic timer, the delay from a periodic expiration time to the time at which the timer object is signaled or the *ExTimerCallback* routine runs might vary from one period to the next. For more information, see Timer Accuracy.

A periodic timer can expire no more than once per system clock tick. Setting the period of a timer to a value smaller than the interval between system clock ticks does not cause the timer to expire more than once per system clock tick, but might cause the intervals between successive expirations to vary if the system clock rate changes. For example, the operating system might temporarily increase the system clock rate to meet the timing requirements of a high-resolution timer. For more information, see High-Resolution Timers.

For a periodic timer that is not a high-resolution timer, a driver can achieve relatively uniform periodic expirations by setting *Period* to an integer multiple of the default interval between system clock ticks.

To avoid excessive power consumption, a driver should not set the period of a long-running high-resolution timer to a value less than the default interval between system clock ticks. Otherwise, the system clock timer will continuously generate interrupts at the maximum allowed system clock rate.

For more information, see ExXxxTimer Routines and EX_TIMER Objects.

Requirements

Minimum supported client	Available starting with Windows 8.1.

ExSetTimerResolution function

1/25/2019 • 2 minutes to read • Edit Online

The **ExSetTimerResolution** routine modifies the frequency at which the system clock interrupts. Use this routine with extreme caution (see the following Remarks section).

Syntax

```
ULONG ExSetTimerResolution(
  ULONG   DesiredTime,
  BOOLEAN SetResolution
);
```

Parameters

`DesiredTime`

Specifies the amount of time that should elapse between each timer interrupt, in 100-nanosecond units. The minimum value is approximately 10,000 (1 millisecond) but can vary slightly by platform. (This parameter is ignored if *SetResolution* is **FALSE**.)

`SetResolution`

If **TRUE**, the call is a request to set the clock interrupt frequency to the value specified by *DesiredTime*. If **FALSE**, the call is a request to restore the clock interrupt frequency to the system's default value, which is platform-specific.

Return Value

ExSetTimerResolution returns the new timer resolution, in 100-nanosecond units.

Remarks

To set the timer resolution, a driver calls this routine passing **TRUE** as the parameter for *SetResolution*. The following rules apply:

- The routine changes the clock interrupt frequency only if the specified *DesiredTime* value is less than the current setting.
- If a driver requests a *DesiredTime* value that is greater than what is currently set, the routine just returns the current setting.
- If a driver requests a *DesiredTime* value that is less than the system clock can support, the routine uses the smallest resolution the system can support, and returns that value.

If you use this routine to change the clock interrupt frequency, your driver must restore the default interrupt frequency, typically by making the following call before being unloaded:

```
ExSetTimerResolution (0, FALSE);
```

(If multiple drivers have attempted to modify the clock interrupt frequency, the system does not restore the default frequency until all of these drivers have called this routine with a *SetResolution* value of **FALSE**.)

Note that the result of changing the clock interrupt frequency is system-wide and can have a severely negative effect on system performance. Also note that higher clock interrupt frequencies can shorten a system's battery life.

During the processing of an IRP_MJ_POWER request, the power manager holds a lock on a resource that **ExSetTimerResolution** must acquire to complete. Consequently, a deadlock will occur if a driver directly or indirectly calls **ExSetTimerResolution** while processing a power request, and then waits for the call to **ExSetTimerResolution** to return before the driver completes the power request. For more information about safely calling **ExSetTimerResolution** while processing a power IRP, see Calling ExSetTimerResolution While Processing a Power IRP.

ExSystemTimeToLocalTime function

1/25/2019 • 2 minutes to read • Edit Online

The **ExSystemTimeToLocalTime** routine converts a GMT system time value to the local system time for the current time zone.

Syntax

```
void ExSystemTimeToLocalTime(
  PLARGE_INTEGER SystemTime,
  PLARGE_INTEGER LocalTime
);
```

Parameters

`SystemTime`

A pointer to a variable set to the unbiased, GMT system time.

`LocalTime`

A pointer to the returned value for the current locale.

Return Value

None

Remarks

ExSystemTimeToLocalTime subtracts the time-zone bias from the GMT system time value to compute the corresponding time at the current locale.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ExLocalTimeToSystemTime

EXT_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

An *ExTimerCallback* callback routine runs after an EX_TIMER timer object's time interval expires.

Syntax

```
EXT_CALLBACK ExtCallback;

void ExtCallback(
  PEX_TIMER Timer,
  PVOID Context
)
{...}
```

Parameters

`Timer`

A pointer to an EX_TIMER structure. This structure is a timer object that was previously allocated by the ExAllocateTimer routine.

`Context`

The context value that your driver previously supplied as the *CallbackContext* parameter of the ExAllocateTimer routine.

Return Value

None.

Remarks

As an option, your driver can supply a pointer to an *ExTimerCallback* routine in the *Callback* parameter that your driver passes to the ExAllocateTimer routine. After the timer expires, the operating system calls the *ExTimerCallback* routine.

To start a timer operation, the driver passes the timer object as an input parameter to the ExSetTimer routine. After the timer expires, the operating system schedules the *ExTimerCallback* routine to run.

A timer object is a waitable object. A driver thread can call a routine such as KeWaitForSingleObject or KeWaitForMultipleObjects to wait for the timer to expire. When the timer expires, the operating system signals the timer object.

A timer might be canceled before it expires. The driver can call the ExCancelTimer routine to explicitly cancel a timer. If the driver calls the ExSetTimer routine to start a new timer on a timer object before a previously set timer on this object expires, this call implicitly cancels the previous timer and then starts the new timer.

An *ExTimerCallback* routine can call a routine such as **ExSetTimer** or ExDeleteTimer. If an *ExTimerCallback* routine calls **ExDeleteTimer**, the *Wait* parameter supplied in this call must be **FALSE**. For more information, see Deleting a System-Allocated Timer Object.

In a multiprocessor system, *ExTimerCallback* callbacks for two successive expirations of a periodic timer might

simultaneously run on two different processors.

For more information, see ExXxxTimer Routines and EX_TIMER Objects.

Examples

To define an *ExTimerCallback* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function type helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define an *ExTimerCallback* callback routine that is named `MyExTimerCallback`, use the EXT_CALLBACK function type, as shown in this code example:

```
EXT_CALLBACK  MyExTimerCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyExTimerCallback(
    PEX_TIMER  Timer,
    PVOID  Context
    )
  {...}
```

The EXT_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the ***Use_decl_annotations*** annotation to your function definition. The ***Use_decl_annotations*** annotation ensures that the annotations that are applied to the EXT_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions Using Function Role Types for WDM Drivers. For more information about ***Use_decl_annotations***, see Annotating Function Behavior.

Requirements

Minimum supported client	Available starting with Windows 8.1.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at DISPATCH_LEVEL.

EXT_DELETE_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

An *ExTimerDeleteCallback* callback routine runs when the operating system deletes an EX_TIMER timer object.

Syntax

```
EXT_DELETE_CALLBACK ExtDeleteCallback;

void ExtDeleteCallback(
  PVOID Context
)
{...}
```

Parameters

`Context`

The context value from the *DeleteContext* member of the EXT_DELETE_PARAMETERS structure that your driver previously passed as an input parameter to the ExDeleteTimer routine.

Return Value

None.

Remarks

As an option, your driver can supply a pointer to an *ExTimerDeleteCallback* routine in the *DeleteCallback* member of the EXT_DELETE_PARAMETERS structure that your driver passes as an input parameter to the ExDeleteTimer routine. The *ExTimerDeleteCallback* routine can free any storage or other system resources that the driver might have previously allocated to use with the timer object that is being deleted.

If the driver supplies an *ExTimerDeleteCallback* routine, and the *Wait* parameter in the **ExDeleteRoutine** call is **TRUE**, the *ExTimerDeleteCallback* routine runs before **ExDeleteTimer** returns. Otherwise, the *ExTimerDeleteCallback* routine might run before or after the **ExDeleteTimer** call returns. The *ExTimerDeleteCallback* routine is called only after the timer object has been disabled to prevent further timer operations and any pending timer operation on the timer object is canceled or completed. The timer object (an EX_TIMER structure) that the driver passes as an input parameter to the **ExDeleteTimer** routine might no longer be valid by the time the *ExTimerDeleteCallback* routine runs.

For more information, see ExXxxTimer Routines and EX_TIMER Objects.

Examples

To define an *ExTimerDeleteCallback* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function type helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define an *ExTimerDeleteCallback* callback routine that is named `MyExTimerDeleteCallback`, use the EXT_DELETE_CALLBACK function type, as shown in this code example:

```
EXT_DELETE_CALLBACK  MyExTimerDeleteCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyExTimerDeleteCallback(
    PVOID  Context
    )
  {...}
```

The EXT_DELETE_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the ***Use_decl_annotations*** annotation to your function definition. The ***Use_decl_annotations*** annotation ensures that the annotations that are applied to the EXT_DELETE_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions Using Function Role Types for WDM Drivers. For more information about ***Use_decl_annotations***, see Annotating Function Behavior.

ExTryConvertSharedSpinLockExclusive function

1/25/2019 • 2 minutes to read • Edit Online

The **ExTryConvertSharedSpinLockExclusive** routine attempts to convert the access state of a spin lock from *acquired for shared access* to *exclusive access*.

Syntax

```
LOGICAL ExTryConvertSharedSpinLockExclusive(
  PEX_SPIN_LOCK SpinLock
);
```

Parameters

`SpinLock`

A pointer to the spin lock whose access state is to be converted to exclusive access. The caller must already own this spin lock for shared access.

Return Value

ExTryConvertSharedSpinLockExclusive returns TRUE if the conversion succeeds; otherwise, it returns FALSE.

Remarks

If the caller acquired the shared spin lock by calling the ExAcquireSpinLockSharedAtDpcLevel routine, the caller should release the converted spin lock by calling the ExReleaseSpinLockExclusiveFromDpcLevel routine. If the caller acquired the shared spin lock by calling the ExAcquireSpinLockShared routine, the caller should release the converted spin lock by calling the ExReleaseSpinLockExclusive routine, and the *OldIrql* value supplied as an input parameter to this routine should be the KIRQL value returned by **ExAcquireSpinLockShared**.

Requirements

Minimum supported client	Available starting with Windows Vista with SP1.

ExCreateCallback

ExRegisterCallback

ExWaitForRundownProtectionRelease function

1/25/2019 • 2 minutes to read • Edit Online

The **ExWaitForRundownProtectionRelease** routine waits until all drivers that have already been granted run-down protection complete their accesses of the shared object.

Syntax

```
void ExWaitForRundownProtectionRelease(
  PEX_RUNDOWN_REF RunRef
);
```

Parameters

`RunRef`

A pointer to an EX_RUNDOWN_REF structure that was initialized by a previous call to the ExInitializeRundownProtection routine. The run-down protection routines use this structure to track the run-down status of the associated shared object. This structure is opaque to drivers.

Return Value

None.

Remarks

This routine is called by the driver that owns an object that resides in shared memory and that is accessed by other drivers. Before deleting this object, the owning driver must call this routine to wait for any outstanding accesses of the object to complete. After **ExWaitForRundownProtectionRelease** returns, the owning driver can safely delete the object.

After **ExWaitForRundownProtectionRelease** is called, the ExAcquireRundownProtection routine grants no further requests for run-down protection from drivers that are trying to access the shared object. The routine waits to return until all drivers that were previously granted run-down protection finish accessing the object. As each driver finishes, it calls the ExReleaseRundownProtection routine to release the previously acquired run-down protection. When all outstanding accesses are completed, **ExWaitForRundownProtectionRelease** returns and the object can be safely deleted.

If **ExWaitForRundownProtectionRelease** is called when all drivers that were previously granted run-down protection have already finished accessing the shared object, the routine changes the object status to *run down*, and returns immediately, without waiting.

If **ExWaitForRundownProtectionRelease** is called to run down a shared object, but the *RunRef* parameter indicates that this object is already run down, the call has no effect but is not treated as an error.

For more information, see Run-Down Protection.

FIELD_OFFSET macro

1/25/2019 • 2 minutes to read • Edit Online

The **FIELD_OFFSET** macro returns the byte offset of a named field in a known structure type.

Syntax

```
void FIELD_OFFSET(
   type,
   field
);
```

Parameters

`type`

Specifies the name of a known structure type containing *Field*.

`field`

Specifies the name of a field in a structure of type *Type*.

Return Value

None

Remarks

Used by device driver writers to symbolically determine the offset of a known field in a known structure type.

Requirements

Minimum supported client	Available starting with Windows 2000.

CONTAINING_RECORD

FirstEntrySList function

1/25/2019 • 2 minutes to read • Edit Online

The **FirstEntrySList** routine returns the first entry in a sequenced singly linked list.

Syntax

```
PSLIST_ENTRY FirstEntrySList(
  PSLIST_HEADER SListHead
);
```

Parameters

`SListHead`

Pointer to the SLIST_HEADER structure that serves as the header for the sequenced singly linked list.

Return Value

FirstEntrySList returns a pointer to the first SLIST_ENTRY structure on the list. If the list is empty, the routine returns **NULL**.

Remarks

Unlike other sequenced singly linked list routines, the **FirstEntrySList** routine is not atomic. For more information about sequenced singly linked lists, see Sequenced Singly Linked Lists. Callers of this routine can run at any level. If called at IRQL >= DISPATCH_LEVEL, the storage for **ListHead** must be resident.

Requirements

Target Platform	Universal

FREE_FUNCTION_EX callback function

1/25/2019 • 2 minutes to read • Edit Online

The *LookasideListFreeEx* routine frees the storage for a lookaside-list entry when a client tries to insert the entry into a lookaside list that is full.

Syntax

```
FREE_FUNCTION_EX FreeFunctionEx;

void FreeFunctionEx(
  PVOID Buffer,
  PLOOKASIDE_LIST_EX Lookaside
)
{...}
```

Parameters

`Buffer`

A pointer to the lookaside-list entry that is to be freed.

`Lookaside`

A pointer to a LOOKASIDE_LIST_EX structure that describes the lookaside list. This structure was previously initialized by the ExInitializeLookasideListEx routine.

Return Value

None

Remarks

A driver that creates a lookaside list can implement a *LookasideListFreeEx* routine to free previously allocated buffers when the list becomes full and can contain no more buffers. A buffer that is not in use is stored as an entry in the list. All entries in a lookaside list are buffers of a uniform size, which the driver specifies when the list is initialized.

The driver supplies a pointer to a custom *LookasideListFreeEx* routine as an input parameter in the **ExInitializeLookasideListEx** call that initializes the lookaside list. If the driver sets this parameter to **NULL**, the lookaside list uses a default deallocation routine instead.

A driver calls the ExFreeToLookasideListEx routine to insert a previously allocated entry into a lookaside list. If the list is full (that is, if the list already contains the system-determined maximum number of entries), **ExFreeToLookasideListEx** calls *LookasideListFreeEx* to free the storage for the entry.

The *LookasideListFreeEx* routine can use the *Lookaside* parameter to access private context data that the driver has associated with the lookaside list. For more information, see the code example in ExInitializeLookasideListEx.

For more information about lookaside lists, see Using Lookaside Lists.

The *LookasideListFreeEx* routine is called at the same IRQL as the call to **ExFreeToLookasideListEx** that frees the entry. For a call to free an entry that resides in paged memory, the caller must be running IRQL <= APC_LEVEL.

For a call to free an entry that resides in nonpaged memory, the caller must be running IRQL <= DISPATCH_LEVEL.

Examples

To define a *LookasideListFreeEx* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *LookasideListFreeEx* callback routine that is named `MyLookasideListFreeEx`, use the FREE_FUNCTION_EX type as shown in this code example:

```
FREE_FUNCTION_EX MyLookasideListFreeEx;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyLookasideListFreeEx(
    PVOID  Buffer,
    PLOOKASIDE_LIST_EX  Lookaside
    )
  {
      // Function body
  }
```

The FREE_FUNCTION_EX function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the FREE_FUNCTION_EX function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Supported in Windows Vista and later versions of Windows.

LOOKASIDE_LIST_EX

GET_D3COLD_CAPABILITY callback function

1/25/2019 • 2 minutes to read • Edit Online

The *GetBusDriverD3ColdSupport* routine enables the driver for a device to query whether the enumerating bus driver supports the D3cold device power state.

Syntax

```
GET_D3COLD_CAPABILITY GetD3coldCapability;

NTSTATUS GetD3coldCapability(
  PVOID Context,
  PBOOLEAN D3ColdSupported
)
{...}
```

Parameters

`Context`

A pointer to interface-specific context information. The caller sets this parameter to the value of the **Context** member of the D3COLD_SUPPORT_INTERFACE structure for the interface.

`D3ColdSupported`

A pointer to a BOOLEAN variable to which the routine writes a value to indicate whether the bus driver supports the D3cold. If this value is **TRUE**, the bus driver supports D3cold. If **FALSE**, the bus driver does not support D3cold. If the call fails, the routine returns an error status code and does not write anything to this variable.

Return Value

The *GetBusDriverD3ColdSupport* routine returns STATUS_SUCCESS if it is successful. Otherwise, it returns an appropriate error status code.

Remarks

The driver for the device calls the version of this routine that is implemented by the Windows ACPI driver, Acpi.sys. This routine checks the parent bus driver for the device to determine whether this bus driver supports the D3cold power state.

For example, starting with Windows 8, Microsoft supplies an inbox USB 3.0 eXtensible Host Controller Interface (xHCI) driver that supports D3cold. Some third-party hardware vendors supply Windows drivers for their xHCI controllers, but these drivers might not support D3cold. The driver for a USB 3.0 device can call the *GetBusDriverD3ColdSupport* routine to determine whether the parent xHCI controller driver supports D3cold.

A bus driver supports D3cold if all of the following are true:

- The bus driver implements the GUID_D3COLD_SUPPORT_INTERFACE driver interface.
- The bus driver implements the *GetBusDriverD3ColdSupport* routine in this interface.
- The output value from the *GetBusDriverD3ColdSupport* routine indicates that the bus driver supports D3cold.

The driver for a device can call the GetIdleWakeInfo routine to determine whether the underlying bus drivers and ACPI

system firmware support D3cold for the device. If this call fails and returns an error status code, the device driver can call the *GetBusDriverD3ColdSupport* routine to determine whether the failure is caused by lack of D3cold support by the parent bus driver.

A device on a bus can make a transition to the D3cold substate only if the bus driver supports this transition. If the bus driver does not support D3cold, the device never enters D3cold, even if the function driver for the device calls the SetD3ColdSupport routine to enable the transition to D3cold. In this case, *SetD3ColdSupport* calls have no effect, but are harmless.

For this reason, most device drivers never need to call the *GetBusDriverD3ColdSupport* routine.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)

SetD3ColdSupport

GET_D3COLD_LAST_TRANSITION_STATUS callback function

1/25/2019 • 2 minutes to read • Edit Online

The *GetLastTransitionStatus* routine enables the driver for a device to query whether the most recent transition to the D3hot substate was followed by a transition to the D3cold substate.

Syntax

```
GET_D3COLD_LAST_TRANSITION_STATUS GetD3coldLastTransitionStatus;

void GetD3coldLastTransitionStatus(
  PVOID Context,
  PD3COLD_LAST_TRANSITION_STATUS LastTransitionStatus
)
{...}
```

Parameters

`Context`

A pointer to interface-specific context information. The caller sets this parameter to the value of the **Context** member of the D3COLD_SUPPORT_INTERFACE structure for the interface.

`LastTransitionStatus`

A pointer to a variable into which the routine writes one of the following D3COLD_LAST_TRANSITION_STATUS enumeration values:

- **LastDStateTransitionStatusUnknown**
- **LastDStateTransitionD3hot**
- **LastDStateTransitionD3cold**

The **LastDStateTransitionD3cold** value indicates that the most recent transition to D3hot was followed by a transition to D3cold. For more information, see Remarks.

Return Value

None.

Remarks

This routine tries to get the information needed to answer the caller's query from the parent bus driver and platform firmware. If this information is not available, the routine writes the value **LastDStateTransitionStatusUnknown** to the location pointed to by *the LastTransitionStatus* parameter.

For more information, see D3COLD_LAST_TRANSITION_STATUS.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
IRQL	PASSIVE_LEVEL

See Also

D3COLD_SUPPORT_INTERFACE

GET_DMA_ADAPTER callback function

1/25/2019 • 2 minutes to read • Edit Online

The *GetDmaAdapter* routine returns a DMA_ADAPTER structure for the target device.

Syntax

```
GET_DMA_ADAPTER GetDmaAdapter;

_DMA_ADAPTER * GetDmaAdapter(
  PVOID Context,
  _DEVICE_DESCRIPTION *DeviceDescriptor,
  PULONG NumberOfMapRegisters
)
{...}
```

Parameters

`Context`

A pointer to interface-specific context information. The caller passes the value that is passed as the **Context** member of the BUS_INTERFACE_STANDARD structure for the interface.

`DeviceDescriptor`

A pointer to a DEVICE_DESCRIPTION structure that describes the attributes of the physical device.

`NumberOfMapRegisters`

A pointer to, on output, the maximum number of map registers that the driver can allocate for any DMA transfer operation. The caller must allocate a **LONG** variable to receive this data.

Return Value

The *GetDmaAdapter* routine returns a pointer to a DMA_ADAPTER structure when successful. If an adapter structure cannot be allocated, the routine returns **NULL**.

Remarks

If the driver is executing at IRQL = PASSIVE_LEVEL, it should obtain a device's DMA adapter object by calling the IoGetDmaAdapter function. **IoGetDmaAdapter** detects whether the bus driver supports the BUS_INTERFACE_STANDARD interface; if it does, **IoGetDmaAdapter** calls the routine pointed to by the *GetDmaAdapter* member of this interface to obtain the adapter object. Otherwise, **IoGetDmaAdapter** calls an equivalent legacy routine.

However, if a driver must obtain an adapter object while running at IRQL ≥ DISPATCH_LEVEL, it cannot do so with the IoGetDmaAdapter function. In such a case, the driver must query for the BUS_INTERFACE_STANDARD interface while still at IRQL = PASSIVE_LEVEL by issuing an IRP_MN_QUERY_INTERFACE request.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Ntddk.h, Wdm.h)
IRQL	PASSIVE_LEVEL

IoGetDmaAdapter

GET_IDLE_WAKE_INFO callback function

1/25/2019 • 5 minutes to read • Edit Online

The *GetIdleWakeInfo* routine enables the driver for a device to discover the device power states from which the device can signal a wake event.

Syntax

```
GET_IDLE_WAKE_INFO GetIdleWakeInfo;

NTSTATUS GetIdleWakeInfo(
  PVOID Context,
  SYSTEM_POWER_STATE SystemPowerState,
  PDEVICE_WAKE_DEPTH DeepestWakeableDstate
)
{...}
```

Parameters

`Context`

A pointer to interface-specific context information. The caller sets this parameter to the value of the **Context** member of the D3COLD_SUPPORT_INTERFACE structure for the interface.

`SystemPowerState`

System power state. Set this parameter to one of the following SYSTEM_POWER_STATE enumeration values:

- **PowerSystemWorking**
- **PowerSystemSleeping1**
- **PowerSystemSleeping2**
- **PowerSystemSleeping3**
- **PowerSystemHibernate**

These values represent system power states S0 (system working state) through S4. For the *SystemPowerState* value supplied by the caller, the routine determines the deepest device power state from which the device can issue a wake signal.

`DeepestWakeableDstate`

Deepest wakeable Dx state. This parameter is a pointer to a DEVICE_WAKE_DEPTH variable. If the call is successful, the routine writes one of the following enumeration values to this variable:

- **DeviceWakeDepthNotWakeable**
- **DeviceWakeDepthD0**
- **DeviceWakeDepthD1**
- **DeviceWakeDepthD2**
- **DeviceWakeDepthD3hot**
- **DeviceWakeDepthD3cold**

A value in the range **DeviceWakeDepthD0** to **DeviceWakeDepthD3cold** indicates the lowest-powered Dx state from which the device can send a wake signal when the computer is in the system power state specified by the

SystemPowerState parameter. **DeviceWakeDepthNotWakeable** indicates that there is no device power state from which the device can send a wake signal when the computer is in the system power state specified by *SystemPowerState*.

If the routine cannot determine the deepest wakeable device state (perhaps because the platform firmware does not contain this information), the call fails and the routine returns an error status code. If a *GetIdleWakeInfo* call fails for any *SystemPowerState* parameter value in the range **PowerSystemWorking** to **PowerSystemHibernate**, it will fail for all such values.

Return Value

The *GetIdleWakeInfo* routine returns STATUS_SUCCESS if it successfully retrieves the deepest wakeable device state. Otherwise, it returns an appropriate error status code.

Remarks

For the system power state specified by the caller, this routine tries to determine the lowest-powered device power state from which the device can signal a wake event to the processor. If successful, the routine writes the device power state to the location pointed to by the *DeepestWakeableDstate* parameter, and returns STATUS_SUCCESS. Or, if the routine determines that the device cannot signal a wake event from any device power state, the routine writes the value **DeviceWakeDepthNotWakeable** to this location, and returns STATUS_SUCCESS.

The driver for a device uses the information supplied by the *GetIdleWakeInfo* routine to determine the conditions under which the device can signal a wake event. A device that needs to be able to signal certain wake events should not enter a device power state from which it cannot signal these events. For some types of devices, the wake signals that the device should send when the computer is in the S0 (working) system power state differ from those that the device should send when the computer appears to be off.

For example, when a card is inserted into a PCI Express card slot, and the PCI Express hot-plug controller device for the slot is in the D0 device power state, this device signals an interrupt to the processor. However, if the controller device is in a low-power Dx state when the card is inserted, the system power state of the computer might determine whether this device should signal a wake event to the processor. Ideally, the controller device should behave as follows:

- If the computer is in the S0 (working) system power state, the device should signal a wake event to the processor.
- If the computer is sleeping (in a low-power Sx state), the device should not signal a wake event.

Some older devices might not support this ideal behavior. If the PCI Express hot-plug controller device in this example can signal a wake event only when the computer is in the S3 state, the driver (which, in this case, is the inbox Pci.sys driver) for the controller should keep the controller in D0 when the computer is in S0 (and is not preparing to enter a sleeping state).

The driver in this example can call the *GetIdleWakeInfo* routine to determine whether the hot-plug controller device should leave the D0 state while the computer is in S0. For this call, the driver sets *SystemPowerState* = **PowerSystemWorking**. This device should not leave the D0 state (when the computer is in S0) in either of the following cases:

- The *GetIdleWakeInfo* call sets the output parameter to either **DeviceWakeDepthNotWakeable** or **DeviceWakeDepthD0** and returns STATUS_SUCCESS.
- The *GetIdleWakeInfo* call fails and returns an error status code.

The driver should interpret either of these results to mean that the device cannot signal a wake event when the computer is in S0. Based on this information, the driver should keep the device in D0 until the computer prepares to exit S0.

The drivers for most devices can treat an output value of **DeviceWakeDepthD0** the same as **DeviceWakeDepthNotWakeable**. Only a few drivers might have a reason to arm a wake signal when their devices are in D0. These are drivers for simple devices that monitor external events that trigger wake signals regardless of the whether the devices are in D0 or low-power Dx states. An example of such a device is a power button or a sleep button on a computer.

The *GetIdleWakeInfo* routine queries the underlying bus driver and ACPI system firmware to determine the lowest device power state from which the device can signal a wake event. If the bus driver and firmware cannot supply this information, the routine fails and returns an error status code.

The DEVICE_CAPABILITIES structure includes a **DeviceWake** member that provides information similar to that available from the *GetIdleWakeInfo* routine. However, the information in the **DeviceWake** member applies only to the system low-power states S1 to S4. For some devices, the information in the **DeviceWake** member might also apply to the S0 system power state, but drivers should not rely on such behavior. Only the *GetIdleWakeInfo* routine reliably reports the ability of a device to signal a wake event if the computer is in S0.

An inline helper function, **MapWakeDepthToDstate**, is provided to convert the DEVICE_WAKE_DEPTH output value from the *GetIdleWakeInfo* routine to a DEVICE_POWER_STATE value that can be used as an input parameter by the PoRequestPowerIrp routine.

GET_SDEV_IDENTIFIER callback function

1/25/2019 • 2 minutes to read • Edit Online

This material is not yet available. This placeholder topic is provided as an example of documentation that may be included in a later release.

Syntax

```
GET_SDEV_IDENTIFIER GetSdevIdentifier;

ULONGLONG GetSdevIdentifier(
  PVOID InterfaceContext
)
{...}
```

Parameters

`InterfaceContext`

Return Value

None

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	wdm.h (include Wdm.h)

GET_SET_DEVICE_DATA callback function

1/25/2019 • 2 minutes to read • Edit Online

The *GetBusData* routine reads data from the device's configuration space.

Syntax

```
GET_SET_DEVICE_DATA GetSetDeviceData;

ULONG GetSetDeviceData(
  PVOID Context,
  ULONG DataType,
  PVOID Buffer,
  ULONG Offset,
  ULONG Length
)
{...}
```

Parameters

`Context`

A pointer to interface-specific context information. The caller passes the value that is passed as the **Context** member of the BUS_INTERFACE_STANDARD structure for the interface.

`DataType`

The type of bus data to read. For more information, see the discussion of the *WhichSpace* parameter in IRP_MN_READ_CONFIG.

`Buffer`

A pointer to the buffer that holds the configuration information to be read from the device's configuration space.

`Offset`

The offset into the bus-specific device data where this read operation begins. For example, if the *DataType* parameter is **PCI_WHICHSPACE_CONFIG**, the *Offset* parameter value is the offset into PCI Configuration Space.

`Length`

The length, in bytes, of data to read.

Return Value

The *GetBusData* routine returns the length, in bytes, of the configuration data that is read after a successful read operation. If the read operation is unsuccessful, a value of zero is returned.

Remarks

Depending on the value of the *DataType* parameter, the *GetBusData* routine can be called only from the interrupt request levels (IRQLs) that are defined in the following table.

***DATATYPE* VALUE**	**IRQL**

PCI_WHICHSPACE_CONFIG	<= DIRQL
PCI_WHICHSPACE_ROM	<= APC_LEVEL
PCCARD_COMMON_MEMORY **PCCARD_COMMON_MEMORY_INDIRECT**	<= DISPATCH_LEVEL
PCCARD_ATTRIBUTE_MEMORY **PCCARD_ATTRIBUTE_MEMORY_INDIRECT**	<= DISPATCH_LEVEL
PCCARD_PCI_CONFIGURATION_SPACE	<= DIRQL

The following remarks apply to drivers for PCI Express (PCIe) virtual functions (VFs) on devices that support the single root I/O virtualization (SR-IOV) interface:

- Drivers for PCIe VFs should call the *GetBusData* routine at IRQL <= APC_LEVEL.
- In order to read PCI Configuration data for the VF at IRQL = DISPATCH_LEVEL, the driver must issue I/O requests of IRP_MN_READ_CONFIG.

Requirements

Target Platform	Desktop
Header	wdm.h (include Ntddk.h)
IRQL	See Remarks section.

InitializeListHead function

1/25/2019 • 2 minutes to read • Edit Online

The **InitializeListHead** routine initializes a LIST_ENTRY structure that represents the head of a doubly linked list.

Syntax

```
void InitializeListHead(
  PLIST_ENTRY ListHead
);
```

Parameters

`ListHead`

Pointer to a LIST_ENTRY structure that serves as the list header.

Return Value

None

Remarks

The **InitializeListHead** routine sets the **Flink** and **Blink** members of *ListHead* to point to *ListHead*.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

Callers of **InitializeListHead** can be running at any IRQL. If **InitializeListHead** is called at IRQL >= DISPATCH_LEVEL the storage for *ListHead* must be resident.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop

InitializeSListHead function

1/25/2019 • 2 minutes to read • Edit Online

The **InitializeSListHead** routine (or ExInitializeSListHead) initializes an SLIST_HEADER structure that represents the head of a sequenced singly linked list.

Syntax

```
void InitializeSListHead(
  PSLIST_HEADER SListHead
);
```

Parameters

`SListHead`

A pointer to the SLIST_HEADER structure to initialize. The structure must be 16-byte aligned on 64-bit platforms.

Return Value

None

Remarks

For more information about using this routine to implement a sequenced singly linked list, see Singly and Doubly Linked Lists.

Callers of **InitializeSListHead or ExInitializeSListHead** can be running at any IRQL. If **ExInitializeSListHead** is called at IRQL >= DISPATCH_LEVEL the storage for *SListHead* must be resident.

Requirements

Minimum supported client	Available starting with Windows 2000.

InsertHeadList function

1/25/2019 • 2 minutes to read • Edit Online

The **InsertHeadList** routine inserts an entry at the head of a doubly linked list of LIST_ENTRY structures.

Syntax

```
void InsertHeadList(
  PLIST_ENTRY                 ListHead,
  __drv_aliasesMem PLIST_ENTRY Entry
);
```

Parameters

`ListHead`

Pointer to the LIST_ENTRY structure that represents the head of the list.

`Entry`

Pointer to a LIST_ENTRY structure that represents the entry to be inserted into the list.

Return Value

None

Remarks

InsertHeadList updates *ListHead*->**Flink** to point to *Entry*. It updates *Entry*->**Flink** to point to the old first entry in the list, and sets *Entry*->**Blink** to *ListHead*. The **Blink** field of the original first entry is also updated to point to *Entry*.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

Callers of **InsertHeadList** can be running at any IRQL. If **InsertHeadList** is called at IRQL >= DISPATCH_LEVEL, the storage for *ListHead* and the list entries must be resident.

Requirements

The **InsertTailList** routine inserts an entry at the tail of a doubly linked list of LIST_ENTRY structures.

Syntax

```
void InsertTailList(
  PLIST_ENTRY                 ListHead,
  __drv_aliasesMem PLIST_ENTRY Entry
);
```

Parameters

`ListHead`

Pointer to the LIST_ENTRY structure that represents the head of the list.

`Entry`

Pointer to a LIST_ENTRY structure that represents the entry to be inserted in the list.

Return Value

None

Remarks

InsertTailList updates *ListHead*->**Blink** to point to *Entry*. It updates *Entry*->**Blink** to point to the old last entry in the list, and sets *Entry*->**Flink** to *ListHead*. The **Flink** of the previous last entry is updated to point to *Entry* as well.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

Callers of **InsertTailList** can be running at any IRQL. If **InsertTailList** is called at IRQL >= DISPATCH_LEVEL, the storage for *ListHead* and the list entries must be resident.

InterlockedAnd function

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedAnd** macro atomically computes a bitwise AND operation.

Syntax

```
LONG InterlockedAnd(
  LONG volatile *Destination,
  LONG          Value
);
```

Parameters

`Destination`

A pointer to the variable to be ANDed with *Value*. The result of the operation is stored in the variable.

`Value`

Specifies the value to be ANDed with the variable that is pointed to by *Destination*.

Return Value

InterlockedAnd returns the original value stored in the variable pointed to by *Destination*.

Remarks

InterlockedAnd atomically computes ***Destination*&=*Value***.

Interlocked operations cannot be used on non-cached memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
IRQL	Any level

InterlockedOr

InterlockedXor

InterlockedCompareExchange function

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedCompareExchange** routine performs an atomic operation that compares the input value pointed to by *Destination* with the value of *Comperand*.

Syntax

```
LONG CDECL_NON_WVMPURE InterlockedCompareExchange(
  LONG volatile *Destination,
  LONG          ExChange,
  LONG          Comperand
);
```

Parameters

`Destination`

A pointer to the input value that is compared with the value of *Comperand*.

`ExChange`

Specifies the output value pointed to by *Destination* if the input value pointed to by *Destination* equals the value of *Comperand*.

`Comperand`

Specifies the value that is compared with the input value pointed to by *Destination*.

Return Value

InterlockedCompareExchange returns the original value of **Destination*.

Remarks

If *Comperand* is equal to **Destination*, then **Destination* is set to equal *Exchange*. Otherwise, **Destination* is unchanged.

InterlockedCompareExchange provides a fast, atomic way to synchronize the testing and updating of a variable that is shared by multiple threads. If the input value pointed to by *Destination* equals the value of *Comperand*, the output value of *Destination* is set to the value of *Exchange*.

InterlockedCompareExchange is designed for speed and, typically, is implemented inline by a compiler. **InterlockedCompareExchange** is atomic only with respect to other **Interlocked*Xxx*** calls. It does not use a spin lock and can be safely used on pageable data.

Interlocked operations cannot be used on non-cached memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
Library	OneCoreUAP.lib on Windows 10

InterlockedDecrement

InterlockedExchange

InterlockedExchangePointer

InterlockedIncrement

InterlockedCompareExchangePointer function

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedCompareExchangePointer** routine performs an atomic operation that compares the input pointer value pointed to by *Destination* with the pointer value *Comperand*.

Syntax

```
PVOID InterlockedCompareExchangePointer(
  PVOID volatile *Destination,
  PVOID          Exchange,
  PVOID          Comperand
);
```

Parameters

`Destination`

A pointer to a PVOID value. If (*Destination) = Comperand, then the routine sets (Destination*) to *Exchange*.

`Exchange`

Specifies the PVOID value to set (**Destination*) to.

`Comperand`

Return Value

InterlockedCompareExchangePointer returns the original value of the pointer at **Destination* (that is, the value of this pointer at entry to the routine).

Remarks

If *Comperand* is equal to **Destination*, then **Destination* is set to equal *Exchange*. Otherwise, **Destination* is unchanged.

InterlockedCompareExchangePointer provides a fast, atomic way to synchronize the testing and updating of a pointer variable that is shared by multiple threads. If the input value pointed to by *Destination* equals the value of *Comperand*, the value pointed to by *Destination* is set to the value of *Exchange*.

InterlockedCompareExchangePointer is designed for speed and, typically, is implemented inline by a compiler. **InterlockedCompareExchangePointer** is atomic only with respect to other **Interlocked*Xxx*** calls. It does not use a spin lock and can be safely used on pageable data.

The **InterlockedCompareExchangePointer** routine is atomic only with respect to other **Interlocked*Xxx*** calls.

Interlocked operations cannot be used on non-cached memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
IRQL	Any level

InterlockedExchange

InterlockedExchangePointer

InterlockedDecrement function

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedDecrement** routine decrements a caller-supplied variable of type LONG as an atomic operation.

Syntax

```
LONG CDECL_NON_WVMPURE InterlockedDecrement(
  LONG volatile *Addend
);
```

Parameters

`Addend`

A pointer to a variable to be decremented.

Return Value

InterlockedDecrement returns the decremented value.

Remarks

InterlockedDecrement should be used instead of **ExInterlockedDecrementLong** because it is both more efficient and faster.

InterlockedDecrement is implemented inline by the compiler when appropriate and possible. It does not require a spin lock and can therefore be safely used on pageable data.

InterlockedDecrement is atomic only with respect to other **Interlocked*Xxx*** calls.

Interlocked operations cannot be used on non-cached memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
Library	OneCoreUAP.lib on Windows 10

InterlockedExchange

InterlockedIncrement

InterlockedExchange function

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedExchange** routine sets an integer variable to a given value as an atomic operation.

Syntax

```
LONG InterlockedExchange(
  LONG volatile *Target,
  LONG          Value
);
```

Parameters

`Target`

A pointer to a variable to be set to the supplied *Value* as an atomic operation.

`Value`

Specifies the value to which the variable will be set.

Return Value

InterlockedExchange returns the value of the variable at *Target* when the call occurred.

Remarks

InterlockedExchange should be used instead of **ExInterlockedExchangeUlong**, because it is both faster and more efficient.

InterlockedExchange is implemented inline by the compiler when appropriate and possible. It does not require a spin lock and can therefore be safely used on pageable data.

A call to **InterlockedExchange** routine is atomic only with respect to other **Interlocked*Xxx*** calls.

Interlocked operations cannot be used on non-cached memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)

InterlockedDecrement

InterlockedIncrement

InterlockedExchangeAdd function

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedExchangeAdd** routine adds a value to a given integer as an atomic operation and returns the original value of the given integer.

Syntax

```
LONG InterlockedExchangeAdd(
  LONG volatile *Addend,
  LONG          Value
);
```

Parameters

`Addend`

A pointer to an integer variable.

`Value`

Specifies the value to be added to *Addend*.

Return Value

InterlockedExchangeAdd returns the original value of the *Addend* variable when the call occurred.

Remarks

InterlockedExchangeAdd should be used instead of **ExInterlockedAddUlong** because it is both faster and more efficient.

InterlockedExchangeAdd is implemented inline by the compiler when appropriate and possible. It does not require a spin lock and can therefore be safely used on pageable data.

InterlockedExchangeAdd is atomic only with respect to other **InterlockedXxx** calls.

Interlocked operations cannot be used on non-cached memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
Library	OneCoreUAP.lib on Windows 10

IRQL	Any level

InterlockedDecrement

InterlockedIncrement

InterlockedExchangePointer function

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedExchangePointer** routine performs an atomic operation that sets a pointer to a new value.

Syntax

```
PVOID InterlockedExchangePointer(
  PVOID volatile *Target,
  PVOID          Value
);
```

Parameters

`Target`

A pointer to a PVOID value. The routine sets (**Target*) to *Value*.

`Value`

Specifies the PVOID value to set (**Target*) to.

Return Value

InterlockedExchangePointer returns the original value of the pointer at **Target* (that is, the value of this pointer at entry to the routine).

Remarks

InterlockedExchangePointer provides a fast, atomic way to synchronize updating a pointer variable that is shared by multiple threads.

InterlockedExchangePointer is designed for speed and, typically, is implemented inline by a compiler. **InterlockedExchangePointer** is atomic only with respect to other **Interlocked*Xxx*** calls. It does not use a spin lock and can be safely used on pageable data.

The *Target* parameter should be aligned on either a 32-bit or 64-bit boundary, depending on the system type, for better performance.

A call to **InterlockedExchangePointer** is atomic only with respect to other **Interlocked*Xxx*** calls.

Interlocked operations cannot be used on non-cached memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
IRQL	Any level

InterlockedOr function

1/25/2019 • 2 minutes to read • Edit Online

The **InterlockedOr** routine atomically computes a bitwise OR operation.

Syntax

```
LONG InterlockedOr(
  LONG volatile *Destination,
  LONG          Value
);
```

Parameters

`Destination`

A pointer to the variable to be ORed with *Value*. The result of the operation is stored in the variable.

`Value`

Specifies the value to be ORed with the variable that is pointed to by *Destination*.

Return Value

InterlockedOr returns the original value stored in the variable pointed to by *Destination*.

Remarks

InterlockedOr atomically computes ***Destination*|=*Value***.

Interlocked operations cannot be used on non-cached memory.

Requirements

IO_COMPLETION_ROUTINE callback function

1/25/2019 • 3 minutes to read • Edit Online

The *IoCompletion* routine completes the processing of I/O operations.

Syntax

```
IO_COMPLETION_ROUTINE IoCompletionRoutine;

NTSTATUS IoCompletionRoutine(
  PDEVICE_OBJECT DeviceObject,
  PIRP Irp,
  PVOID Context
)
{...}
```

Parameters

`DeviceObject`

Caller-supplied pointer to a DEVICE_OBJECT structure. This is the device object for the target device, previously created by the driver's AddDevice routine.

`Irp`

Caller-supplied pointer to an IRP structure that describes the I/O operation.

`Context`

Caller-supplied pointer to driver-specific context information, previously supplied when calling IoSetCompletionRoutine or IoSetCompletionRoutineEx. Context information must be stored in nonpaged memory, since an *IoCompletion* routine can be called at DISPATCH_LEVEL. For more information, see the following Remarks section.

Return Value

If the *IoCompletion* routine determines that additional processing is required for the IRP, it must return STATUS_MORE_PROCESSING_REQUIRED. For more information, see the following Remarks section. Otherwise, it should return STATUS_SUCCESS. (The I/O manager only checks for the presence or absence of STATUS_MORE_PROCESSING_REQUIRED.)

Remarks

A driver's *IoCompletion* routine executes in an arbitrary thread or DPC context, and at an IRQL that is less than or equal to DISPATCH_LEVEL. Because code written to execute at DISPATCH_LEVEL will also execute at lower levels, *IoCompletion* routines should be designed for execution at DISPATCH_LEVEL. However, because these routines are not guaranteed to run at DISPATCH_LEVEL, they must not call system routines that actually require execution at DISPATCH_LEVEL. (For more information about IRQLs, see Managing Hardware Priorities.)

To register an *IoCompletion* routine for a specific IRP, a driver must call IoSetCompletionRoutine or IoSetCompletionRoutineEx, which stores the *IoCompletion* routine's address in the next-lower driver's I/O stack location. (Thus, a lowest-level driver cannot register an *IoCompletion* routine.) A driver typically calls

IoSetCompletionRoutine or **IoSetCompletionRoutineEx** from one of its dispatch routines, each time an IRP is received. Most drivers, including all PnP drivers, can use **IoSetCompletionRoutine** to register their *IoCompletion* routine. Non-PnP drivers that may be unloaded before their *IoCompletion* routine executes should use **IoSetCompletionRoutineEx** instead.

When any driver completes an IRP, it calls IoCompleteRequest, which in turn calls the *IoCompletion* routine of each higher-level driver, from the next-highest to the highest, until all higher *IoCompletion* routines have been called or until one routine returns STATUS_MORE_PROCESSING_REQUIRED.

When you create the IRP, allocate a stack location for the current driver as well as any lower drivers. If you do not allocate sufficient stack locations, the *DeviceObject* pointer might be set to **NULL** when the completion routine is called. You can avoid allocating extra stack location for the current driver if you use the *Context* field to pass information to *IoCompletion* rather then relying on the *DeviceObject* parameter.

If an *IoCompletion* routine returns STATUS_MORE_PROCESSING_REQUIRED, the lower driver's call to **IoCompleteRequest** immediately returns. In this case, a higher-level driver will have to call **IoCompleteRequest** to complete the IRP.

For more information about implementing *IoCompletion* routines, see Completing IRPs.

Examples

To define an *IoCompletion* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define an *IoCompletion* callback routine that is named `MyIoCompletion`, use the IO_COMPLETION_ROUTINE type as shown in this code example:

```
IO_COMPLETION_ROUTINE MyIoCompletion;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
NTSTATUS
  MyIoCompletion(
    PDEVICE_OBJECT  DeviceObject,
    PIRP  Irp,
    PVOID  Context
    )
  {
      // Function body
  }
```

The IO_COMPLETION_ROUTINE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the IO_COMPLETION_ROUTINE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at IRQL <= DISPATCH_LEVEL (see Remarks section).

IO_CSQ_ACQUIRE_LOCK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *CsqAcquireLock* routine is used by the system to acquire the lock for a driver-implemented, cancel-safe IRP queue.

Syntax

```
IO_CSQ_ACQUIRE_LOCK IoCsqAcquireLock;

void IoCsqAcquireLock(
  PIO_CSQ Csq,
  PKIRQL Irql
)
{...}
```

Parameters

`Csq`

Pointer to the IO_CSQ structure for the cancel-safe IRP queue.

`Irql`

Pointer to a variable that the *CsqAcquireLock* routine can use to store the current IRQL. The system passes the stored value CsqReleaseLock when it releases the lock.

Return Value

None

Remarks

The driver specifies the *CsqAcquireLock* routine for a cancel-safe IRP queue when it initializes the queue's **IO_CSQ** structure. The driver specifies the routine as the *CsqAcquireLock* parameter of IoCsqInitialize or IoCsqInitializeEx when it initializes **IO_CSQ**. For more information, see Cancel-Safe IRP Queues.

The system calls this routine to acquire a lock on the driver's IRP queue before attempting to insert or remove an IRP from the queue. The system calls the CsqReleaseLock routine to release the lock.

If the driver uses a spin lock to implement locking for the queue, it must store the current IRQL for when it releases the spin lock. The system passes a pointer to an IRQL variable that the driver can use to store the current IRQL. The system passes the stored value as the *Irql* parameter to *CsqReleaseLock* when it releases the lock. Otherwise the driver can ignore the *Irql* parameter. For information about spin locks, see Spin Locks.

Drivers can use any locking mechanism to lock the queue, such as mutexes. For more information about mutexes, see Mutex Objects.

Examples

To define a *CsqAcquireLock* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification

tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *CsqAcquireLock* callback routine that is named `MyCsqAcquireLock`, use the IO_CSQ_ACQUIRE_LOCK type as shown in this code example:

```
IO_CSQ_ACQUIRE_LOCK MyCsqAcquireLock;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
 MyCsqAcquireLock(
    PIO_CSQ  Csq,
    PKIRQL  Irql
    )
  {
      // Function body
  }
```

The IO_CSQ_ACQUIRE_LOCK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the IO_CSQ_ACQUIRE_LOCK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	See Remarks section.

IO_CSQ_COMPLETE_CANCELED_IRP callback function

1/25/2019 • 2 minutes to read • Edit Online

The *CsqCompleteCanceledIrp* routine is used by the system to signal to the driver that it can complete a canceled IRP.

Syntax

```
IO_CSQ_COMPLETE_CANCELED_IRP IoCsqCompleteCanceledIrp;

void IoCsqCompleteCanceledIrp(
  PIO_CSQ Csq,
  PIRP Irp
)
{...}
```

Parameters

`Csq`

Pointer to the IO_CSQ structure for the cancel-safe IRP queue.

`Irp`

Pointer to the IRP to be canceled.

Return Value

None

Remarks

The driver specifies the *CsqCompleteCanceledIrp* routine for a cancel-safe IRP queue when it initializes the queue's **IO_CSQ** structure. The driver specifies the routine as the *CsqCompleteCanceledIrp* parameter of IoCsqInitialize or IoCsqInitializeEx when it initializes **IO_CSQ**. For more information, see Cancel-Safe IRP Queues.

The system calls this routine to complete a canceled IRP that has been removed from the driver's queue. Normally, drivers just call IoCompleteRequest for the IRP with a status of STATUS_CANCELLED.

Drivers are not required to remove the IRP from the queue before completing it as canceled: the system always calls the queue's CsqRemoveIrp routine to remove the IRP from the queue before calling *CsqCompleteCanceledIrp*.

Examples

To define a *CsqCompleteCanceledIrp* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *CsqCompleteCanceledIrp* callback routine that is named `MyCsqCompleteCanceledIrp`, use the IO_CSQ_COMPLETE_CANCELED_IRP type as shown in this code example:

```
IO_CSQ_COMPLETE_CANCELED_IRP MyCsqCompleteCanceledIrp;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
 MyCsqCompleteCanceledIrp(
    _In_ PIO_CSQ  Csq,
    _In_ PIRP  Irp
    )
  {
      // Function body
  }
```

The IO_CSQ_COMPLETE_CANCELED_IRP function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the IO_CSQ_COMPLETE_CANCELED_IRP function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

IO_CSQ_INSERT_IRP callback function

1/25/2019 • 2 minutes to read • Edit Online

The *CsqInsertIrp* routine is used by the system to insert an IRP into a driver-implemented, cancel-safe IRP queue.

Syntax

```
IO_CSQ_INSERT_IRP IoCsqInsertIrp;

void IoCsqInsertIrp(
  _IO_CSQ *Csq,
  PIRP Irp
)
{...}
```

Parameters

`*Csq`

Pointer to the IO_CSQ structure for the cancel-safe IRP queue.

`Irp`

Pointer to the IRP to insert into the IRP queue.

Return Value

None

Remarks

The driver specifies the *CsqInsertIrp* routine for a cancel-safe IRP queue when it initializes the queue's **IO_CSQ** structure. The driver specifies the routine as the *CsqInsertIrp* parameter of IoCsqInitialize when it initializes **IO_CSQ**. For more information, see Cancel-Safe IRP Queues.

The IoCsqInsertIrp and IoCsqInsertIrpEx routines call *CsqInsertIrp* to insert the IRP into the queue.

Examples

To define a *CsqInsertIrp* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *CsqInsertIrp* callback routine that is named `MyCsqInsertIrp`, use the IO_CSQ_INSERT_IRP type as shown in this code example:

```
IO_CSQ_INSERT_IRP MyCsqInsertIrp;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
NTSTATUS
 MyCsqInsertIrp(
    struct _IO_CSQ  *Csq,
    PIRP  Irp
    )
  {
      // Function body
  }
```

The IO_CSQ_INSERT_IRP function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the IO_CSQ_INSERT_IRP function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

IO_CSQ_INSERT_IRP_EX callback function

1/25/2019 • 2 minutes to read • Edit Online

The *CsqInsertIrpEx* routine is used by the system to insert an IRP into a driver-implemented, cancel-safe IRP queue.

Syntax

```
IO_CSQ_INSERT_IRP_EX IoCsqInsertIrpEx;

NTSTATUS IoCsqInsertIrpEx(
  _IO_CSQ *Csq,
  PIRP Irp,
  PVOID InsertContext
)
{...}
```

Parameters

`*Csq`

Pointer to the IO_CSQ structure for the cancel-safe IRP queue.

`Irp`

Pointer to the IRP to insert into the IRP queue.

`InsertContext`

Pointer to driver-defined context for the insert operation.

Return Value

CsqInsertIrpEx returns STATUS_SUCCESS if the IRP has been successfully inserted, or the appropriate error code on failure.

Remarks

The driver specifies the *CsqInsertIrpEx* routine for a cancel-safe IRP queue when it initializes the queue's **IO_CSQ** structure. The driver specifies the routine as the *CsqInsertIrp* parameter of IoCsqInitializeEx when it initializes **IO_CSQ**. For more information, see Cancel-Safe IRP Queues.

The IoCsqInsertIrpEx routine calls *CsqInsertIrpEx* to insert the IRP into the queue. The *InsertContext* parameter of **IoCsqInsertIrpEx** is passed as the *InsertContext* parameter of *CsqInsertIrpEx*.

Examples

To define a *CsqInsertIrpEx* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *CsqInsertIrpEx* callback routine that is named `MyCsqInsertIrpEx`, use the IO_CSQ_INSERT_IRP_EX type as shown in this code example:

```
IO_CSQ_INSERT_IRP_EX MyCsqInsertIrpEx;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
NTSTATUS
 MyCsqInsertIrpEx(
    struct _IO_CSQ  *Csq,
    PIRP  Irp,
    PVOID  InsertContext
    )
  {
      // Function body
  }
```

The IO_CSQ_INSERT_IRP_EX function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the IO_CSQ_INSERT_IRP_EX function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

IO_CSQ_PEEK_NEXT_IRP callback function

1/25/2019 • 2 minutes to read • Edit Online

The *CsqPeekNextIrp* routine is used by the system to find the next matching IRP in a driver-implemented, cancel-safe IRP queue.

Syntax

```
IO_CSQ_PEEK_NEXT_IRP IoCsqPeekNextIrp;

PIRP IoCsqPeekNextIrp(
  PIO_CSQ Csq,
  PIRP Irp,
  PVOID PeekContext
)
{...}
```

Parameters

`Csq`

Pointer to the IO_CSQ structure for the cancel-safe IRP queue.

`Irp`

Pointer to an IRP in the driver's IRP queue, or **NULL** to specify the beginning of the queue.

`PeekContext`

Pointer to driver-defined context information. The *CsqPeekNextIrp* routine returns the first IRP that follows *Irp* and matches *PeekContext*.

Return Value

CsqPeekNextIrp returns the first IRP that follows *Irp* in the queue and matches *PeekContext*, or **NULL** if there is no matching IRP. If *Irp* is **NULL**, *CsqPeekNextIrp* returns the first matching IRP in the queue, or **NULL** if there is no matching IRP.

Remarks

The driver specifies the *CsqPeekNextIrp* routine for a cancel-safe IRP queue when it initializes the queue's **IO_CSQ** structure. The driver specifies the routine as the *CsqPeekNextIrp* parameter of IoCsqInitialize or IoCsqInitializeEx when it initializes **IO_CSQ**. For more information, see Cancel-Safe IRP Queues.

The system uses *CsqPeekNextIrp* to iterate through the IRPs in the driver's IRP queue. For example, the IoCsqRemoveNextIrp routine uses this routine to find the IRP to be removed.

Examples

To define a *CsqPeekNextIrp* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *CsqPeekNextIrp* callback routine that is named `MyCsqPeekNextIrp`, use the IO_CSQ_PEEK_NEXT_IRP type as shown in this code example:

```
IO_CSQ_PEEK_NEXT_IRP MyCsqPeekNextIrp;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
PIRP
 MyCsqPeekNextIrp(
    PIO_CSQ  Csq,
    PIRP  Irp,
    PVOID  PeekContext
    )
  {
      // Function body
  }
```

The IO_CSQ_PEEK_NEXT_IRP function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the IO_CSQ_PEEK_NEXT_IRP function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IO_CSQ_RELEASE_LOCK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *CsqReleaseLock* routine is used by the system to release the lock that was acquired using CsqAcquireLock.

Syntax

```
IO_CSQ_RELEASE_LOCK IoCsqReleaseLock;

void IoCsqReleaseLock(
  PIO_CSQ Csq,
