  KIRQL Irql
)
{...}
```

Parameters

`Csq`

Pointer to the IO_CSQ structure for the cancel-safe IRP queue.

`Irql`

Specifies an IRQL. This is the value stored by CsqAcquireLock when the lock was acquired.

Return Value

None

Remarks

The driver specifies the *CsqReleaseLock* routine for a cancel-safe IRP queue when it initializes the queue's **IO_CSQ** structure. The driver specifies the routine as the *CsqReleaseLock* parameter of IoCsqInitialize or IoCsqInitializeEx when it initializes **IO_CSQ**. For more information, see Cancel-Safe IRP Queues.

The system calls this function to release a lock that was acquired using CsqAcquireLock.

If the driver uses a spin lock to implement locking for the queue, it must store the current IRQL when it acquires the lock, and provide the stored IRQL when it releases the lock. The *CsqAcquireLock* routine stores the current IRQL, and the system passes the stored value as the *Irql* parameter to *CsqReleaseLock*. Otherwise the driver can ignore the *Irql* parameter. For information about spin locks, see Spin Locks.

Drivers can use any locking mechanism to lock the queue, such as mutexes. For more information about mutexes, see Mutex Objects.

Examples

To define a *CsqReleaseLock* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *CsqReleaseLock* callback routine that is named `MyCsqReleaseLock`, use the IO_CSQ_RELEASE_LOCK type as shown in this code example:

```
IO_CSQ_RELEASE_LOCK MyCsqReleaseLock;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
 MyCsqReleaseLock(
    PIO_CSQ  Csq,
    KIRQL  Irql
    )
  {
      // Function body
  }
```

The IO_CSQ_RELEASE_LOCK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the IO_CSQ_RELEASE_LOCK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IO_CSQ_REMOVE_IRP callback function

1/25/2019 • 2 minutes to read • Edit Online

The *CsqRemoveIrp* routine is used by the system to remove the specified IRP from a driver-implemented, cancel-safe IRP queue.

Syntax

```
IO_CSQ_REMOVE_IRP IoCsqRemoveIrp;

void IoCsqRemoveIrp(
  PIO_CSQ Csq,
  PIRP Irp
)
{...}
```

Parameters

`Csq`

Pointer to the IO_CSQ structure for the cancel-safe IRP queue.

`Irp`

Pointer to the IRP to remove from the IRP queue.

Return Value

None

Remarks

The driver specifies the *CsqRemoveIrp* routine for a cancel-safe IRP queue when it initializes the queue's **IO_CSQ** structure. The driver specifies the routine as the *CsqRemoveIrp* parameter of IoCsqInitialize or IoCsqInitializeEx when it initializes **IO_CSQ**. For more information, see Cancel-Safe IRP Queues.

The IoCsqRemoveIrp and IoCsqRemoveNextIrp routines call the cancel-safe IRP queue's *CsqRemoveIrp* routine to remove the specified IRP from the queue. The system also uses *CsqRemoveIrp* to remove a canceled IRP from the queue.

Examples

To define a *CsqRemoveIrp* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *CsqRemoveIrp* callback routine that is named `MyCsqRemoveIrp`, use the IO_CSQ_REMOVE_IRP type as shown in this code example:

```
```

```
IO_CSQ_REMOVE_IRP MyCsqRemoveIrp;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
 MyCsqRemoveIrp(
    PIO_CSQ  Csq,
    PIRP  Irp
    )
  {
      // Function body
  }
```

The IO_CSQ_REMOVE_IRP function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the IO_CSQ_REMOVE_IRP function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

IO_DPC_ROUTINE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *DpcForIsr* routine finishes the servicing of an I/O operation, after an InterruptService routine returns.

Syntax

```
IO_DPC_ROUTINE IoDpcRoutine;

void IoDpcRoutine(
  PKDPC Dpc,
  _DEVICE_OBJECT *DeviceObject,
  _IRP *Irp,
  PVOID Context
)
{...}
```

Parameters

`Dpc`

Caller-supplied pointer to a KDPC structure, which represents the DPC object that is associated with this *DpcForIsr* routine.

`*DeviceObject`

Caller-supplied pointer to a DEVICE_OBJECT structure. This is the device object for the target device, previously created by the driver's AddDevice routine.

`*Irp`

Caller-supplied pointer to an IRP structure that describes the I/O operation.

`Context`

Caller-supplied pointer to driver-defined context information, specified in a previous call to IoRequestDpc.

Return Value

None

Remarks

To register a *DpcForIsr* routine for a specific device object, a driver must call IoInitializeDpcRequest, which causes the system to allocate and initialize one DPC object. (If you need multiple DPC routines, use CustomDpc routines.)

To queue a *DpcForIsr* routine for execution, a driver's InterruptService routine must call IoRequestDPC.

A *DpcForIsr* routine is typically responsible for at least the following tasks:

- Completing the I/O operation described by the received IRP.
- Dequeuing next IRP.

  If the driver uses the system-supplied IRP queue, the *DpcForIsr* routine should call IoStartNextPacket or

IoStartNextPacketByKey, so the driver's StartIo routine will start processing the next I/O request.

If the driver uses internal IRP queues, the *DpcForIsr* routine should dequeue the next IRP and begin processing for the next I/O request.

- Setting the I/O status block in the received IRP and calling IoCompleteRequest for the completed request.

A *DpcForIsr* routine might also retry a failed operation or set up the next transfer for a large I/O request that has been broken into smaller pieces.

For more information about *DpcForIsr* routines, see DPC Objects and DPCs.

Examples

To define a *DpcForIsr* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *DpcForIsr* callback routine that is named `MyDpcForIsr`, use the IO_DPC_ROUTINE type as shown in this code example:

```
IO_DPC_ROUTINE MyDpcForIsr;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyDpcForIsr(
    PKDPC  Dpc,
    struct _DEVICE_OBJECT  *DeviceObject,
    struct _IRP  *Irp,
    PVOID  Context
    )
  {
      // Function body
  }
```

The IO_DPC_ROUTINE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the IO_DPC_ROUTINE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IRQL	Called at DISPATCH_LEVEL.

IO_SESSION_NOTIFICATION_FUNCTION callback function

1/25/2019 • 2 minutes to read • Edit Online

The IO_SESSION_NOTIFICATION_FUNCTION function type defines a callback routine through which a driver receives notifications of changes in the state of user sessions that the driver is interested in.

Syntax

```
IO_SESSION_NOTIFICATION_FUNCTION IoSessionNotificationFunction;

NTSTATUS IoSessionNotificationFunction(
  PVOID SessionObject,
  PVOID IoObject,
  ULONG Event,
  PVOID Context,
  PVOID NotificationPayload,
  ULONG PayloadLength
)
{...}
```

Parameters

`SessionObject`

Pointer to an opaque, system object that contains information about the user session. The driver can pass this pointer value to the IoGetContainerInformation routine as the *ContainerObject* parameter value.

`IoObject`

Pointer to an I/O object owned by the driver. This parameter is the I/O object pointer that the driver supplied to the IoRegisterContainerNotification routine when the driver previously registered to receive notifications of session events. The **IoRegisterContainerNotification** routine's *NotificationInformation* parameter points to an IO_SESSION_STATE_NOTIFICATION structure whose **IoObject** member points to the I/O object.

`Event`

An IO_SESSION_EVENT enumeration constant that indicates which session event caused the notification callback.

`Context`

The context value that the driver previously supplied to the **IoRegisterContainerNotification** routine when the driver registered to receive notifications of session events. In the **IoRegisterContainerNotification** call, the driver supplied a pointer to an **IO_SESSION_STATE_NOTIFICATION** structure whose **Context** member contains the context value.

`NotificationPayload`

Pointer to a payload buffer that contains an IO_SESSION_CONNECT_INFO structure.

`PayloadLength`

The size, in bytes, of the buffer pointed to by *NotificationPayload*. The buffer size never needs exceeds the constant value IO_SESSION_MAX_PAYLOAD_SIZE, which is defined in the Wdm.h header file.

Return Value

If the routine succeeds, it must return STATUS_SUCCESS. Otherwise, it must return one of the error status values defined in the Ntstatus.h header file.

Remarks

A kernel-mode driver implements this routine. The I/O manager calls this routine to notify the driver of session events.

To receive notifications of session events, a driver calls the **IoRegisterContainerNotification** routine and sets this routine's *CallbackFunction* parameter to point to the driver's IO_SESSION_NOTIFICATION_FUNCTION routine. The I/O object that the driver passes to **IoRegisterContainerNotification** determines whether the driver will receive notifications of events in a particular user session or of events in all sessions. For more information, see IO_SESSION_STATE_NOTIFICATION.

Examples

To define an an I/O-session notification routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define an an I/O-session notification routine that is named `MyIoSessionNotification`, use the IO_SESSION_NOTIFICATION_FUNCTION type as shown in this code example:

```
IO_SESSION_NOTIFICATION_FUNCTION MyIoSessionNotification;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
NTSTATUS
  MyIoSessionNotification(
    PVOID  SessionObject,
    PVOID  IoObject,
    ULONG  Event,
    PVOID  Context,
    PVOID  NotificationPayload,
    ULONG  PayloadLength
    )
  {
      // Function body
  }
```

The IO_SESSION_NOTIFICATION_FUNCTION function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the IO_SESSION_NOTIFICATION_FUNCTION function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Supported in Windows 7 and later versions of the Windows operating system.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Fltkernel.h)

IO_TIMER_ROUTINE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *IoTimer* routine is a DPC that, if registered, is called once per second.

Syntax

```
IO_TIMER_ROUTINE IoTimerRoutine;

void IoTimerRoutine(
  _DEVICE_OBJECT *DeviceObject,
  PVOID Context
)
{...}
```

Parameters

`*DeviceObject`

Caller-supplied pointer to a DEVICE_OBJECT structure. This is the device object for the target device, previously created by the driver's AddDevice routine.

`Context`

Caller-supplied pointer to driver-defined context information, specified in a previous call to IoInitializeTimer.

Return Value

None

Remarks

A driver's *IoTimer* routine executes in a DPC context, at IRQL = DISPATCH_LEVEL.

A driver can associate an *IoTimer* routine with each device object it creates. (You can use a single *IoTimer* routine with multiple device objects, or a separate routine with each device object.) To register an *IoTimer* routine, a driver must call IoInitializeTimer, supplying the *IoTimer* routine's address and a device object pointer.

To queue an *IoTimer* routine for execution, a driver routine must call IoStartTimer. The system calls the *IoTimer* routine once per second until the driver calls IoStopTimer.

For more information about *IoTimer* routines, see IoTimer Routines.

Examples

To define an *IoTimer* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define an *IoTimer* callback routine that is named `MyIoTimer`, use the IO_TIMER_ROUTINE type as shown in this code example:

```
IO_TIMER_ROUTINE MyIoTimer;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyIoTimer(
    struct DEVICE_OBJECT  *DeviceObject,
    PVOID  Context
    )
  {
      // Function body
  }
```

The IO_TIMER_ROUTINE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the IO_TIMER_ROUTINE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at DISPATCH_LEVEL (see Remarks section).

IO_WORKITEM_ROUTINE callback function

1/25/2019 • 2 minutes to read • Edit Online

A *WorkItem* routine performs the processing for a work item that was queued by the IoQueueWorkItem routine.

Syntax

```
IO_WORKITEM_ROUTINE IoWorkitemRoutine;

void IoWorkitemRoutine(
  PDEVICE_OBJECT DeviceObject,
  PVOID Context
)
{...}
```

Parameters

`DeviceObject`

Pointer to one of the caller's device objects. This is the pointer that was passed as the *DeviceObject* parameter to IoAllocateWorkItem when the work item was allocated, or as the *IoObject* parameter to IoInitializeWorkItem when the work item was initialized.

`Context`

Specifies driver-specific context information. This is the value that was passed as the *Context* parameter to IoQueueWorkItem when the work item was queued.

Return Value

None

Remarks

The driver queues a *WorkItem* routine by calling IoQueueWorkItem, and a system worker thread subsequently executes the routine. A *WorkItem* routine must run for a limited amount of time; otherwise, the system can deadlock. For more information, see System Worker Threads.

A *WorkItem* routine runs at IRQL = PASSIVE_LEVEL and in a system thread context.

Examples

To define a *WorkItem* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *WorkItem* callback routine that is named `MyWorkItem`, use the IO_WORKITEM_ROUTINE type as shown in this code example:

```
```

```
IO_WORKITEM_ROUTINE MyWorkItem;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyWorkItem(
    PDEVICE_OBJECT  DeviceObject,
    PVOID  Context
    )
  {
      // Function body
  }
```

The IO_WORKITEM_ROUTINE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the IO_WORKITEM_ROUTINE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at PASSIVE_LEVEL.

IO_WORKITEM

IoQueueWorkItem

IO_WORKITEM_ROUTINE_EX callback function

1/25/2019 • 2 minutes to read • Edit Online

A *WorkItemEx* routine performs the processing for a work item that was queued by the IoQueueWorkItemEx or IoTryQueueWorkItem routine.

Syntax

```
IO_WORKITEM_ROUTINE_EX IoWorkitemRoutineEx;

void IoWorkitemRoutineEx(
  PVOID IoObject,
  PVOID Context,
  PIO_WORKITEM IoWorkItem
)
{...}
```

Parameters

`IoObject`

Pointer to the caller's driver object or to one of the caller's device objects. This is the pointer that was passed as the *DeviceObject* parameter to IoAllocateWorkItem when the work item was allocated, or as the *IoObject* parameter to IoInitializeWorkItem or IoTryQueueWorkItem when the work item was initialized.

`Context`

Specifies driver-specific context information. This is the value that was passed as the *Context* parameter to IoQueueWorkItemEx or IoTryQueueWorkItem when the work item was queued.

`IoWorkItem`

Pointer to the IO_WORKITEM structure for the work item. This is the pointer that was passed as the *IoWorkItem* parameter to IoQueueWorkItemEx or IoTryQueueWorkItem.

Return Value

None

Remarks

Drivers can implement *WorkItemEx* routines only on Windows Vista and later versions of Windows.

The driver queues a *WorkItemEx* routine by calling IoQueueWorkItemEx or IoTryQueueWorkItem, and a system worker thread subsequently executes the routine. For more information, see System Worker Threads.

A *WorkItemEx* routine must run for a limited amount of time; otherwise, the system can deadlock. For more information, see System Worker Threads.

A *WorkItemEx* routine runs at IRQL = PASSIVE_LEVEL and in a system thread context.

Examples

To define a *WorkItemEx* callback routine, you must first provide a function declaration that identifies the type of

callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *WorkItemEx* callback routine that is named `MyWorkItemEx`, use the IO_WORKITEM_ROUTINE_EX type as shown in this code example:

```
IO_WORKITEM_ROUTINE_EX MyWorkItemEx;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyWorkItemEx(
    PVOID  IoObject,
    PVOID  Context,
    PIO_WORKITEM  IoWorkItem
    )
  {
      // Function body
  }
```

The IO_WORKITEM_ROUTINE_EX function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the IO_WORKITEM_ROUTINE_EX function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at PASSIVE_LEVEL.

IoInitializeWorkItem

IoQueueWorkItemEx

IoTryQueueWorkItem

IoAcquireRemoveLock macro

1/25/2019 • 2 minutes to read • Edit Online

The **IoAcquireRemoveLock** routine increments the count for a remove lock, indicating that the associated device object should not be detached from the device stack or deleted.

Syntax

```
void IoAcquireRemoveLock(
   RemoveLock,
   Tag
);
```

Parameters

`RemoveLock`

Pointer to an **IO_REMOVE_LOCK** structure that the caller initialized with a previous call to IoInitializeRemoveLock.

`Tag`

Optionally points to a caller-supplied tag that identifies this instance of acquiring the remove lock. For example, a driver Dispatch routine typically sets this parameter to a pointer to the IRP the routine is processing.

If a driver specifies a *Tag* on a call to **IoAcquireRemoveLock**, the driver must supply the same *Tag* in the corresponding call to IoReleaseRemoveLock.

The *Tag* does not have to be unique, but should be something meaningful during debugging.

The I/O system uses this parameter on checked builds only.

Return Value

This macro wraps and assumes the return value of **IoAcquireRemoveLockEx**, which is NTSTATUS.

IoAcquireRemoveLock returns STATUS_SUCCESS if the call was successful. One possible error return value is the following:

STATUS_DELETE_PENDING: The driver has received an IRP_MN_REMOVE_DEVICE for the device and has called IoReleaseRemoveLockandWait. That routine is waiting for all remove locks to clear before returning control to the driver.

If the routine returns any value besides STATUS_SUCCESS, do not start any new operations on the device.

Remarks

A driver must initialize a remove lock with a call to IoInitializeRemoveLock before using the lock.

A driver must call IoReleaseRemoveLock to release the lock when it is no longer needed.

For more information, see Using Remove Locks.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoAdjustPagingPathCount macro

1/25/2019 • 2 minutes to read • Edit Online

The **IoAdjustPagingPathCount** routine increments or decrements a caller-supplied page-file counter as an atomic operation.

Syntax

```
void IoAdjustPagingPathCount(
   _count_,
   _paging_
);
```

Parameters

`_count_`

`_paging_`

[in]

Specifies whether the counter is to be incremented or decremented. A value of **TRUE** specifies an increment operation.

Return Value

None

Remarks

This routine is useful for maintaining a count of paging files on a device. The operating system notifies a driver that a paging file has been created on, or removed from, one of the driver's devices by sending an IRP. The IRP has the major code IRP_MJ_PNP and the minor code IRP_MN_DEVICE_USAGE_NOTIFICATION.

This routine can be used for other counters, such as counters for hibernation files or crash-dump files.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Any level

See Also

IRP_MJ_PNP

IRP_MN_DEVICE_USAGE_NOTIFICATION

IoAllocateDriverObjectExtension function

1/25/2019 • 2 minutes to read • Edit Online

The **IoAllocateDriverObjectExtension** routine allocates a per-driver context area, called a driver object extension, and assigns a unique identifier to it.

Syntax

```
NTSTATUS IoAllocateDriverObjectExtension(
  PDRIVER_OBJECT DriverObject,
  PVOID          ClientIdentificationAddress,
  ULONG          DriverObjectExtensionSize,
  PVOID          *DriverObjectExtension
);
```

Parameters

`DriverObject`

Pointer to a driver object to which the context area will be associated.

`ClientIdentificationAddress`

Specifies a unique identifier for the context area to be allocated.

`DriverObjectExtensionSize`

Specifies the length, in bytes, of the context area to be allocated.

`DriverObjectExtension`

Pointer to, on completion, the allocated context area.

Return Value

IoAllocateDriverObjectExtension returns one of the following NTSTATUS codes:

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	Indicates that the routine allocated an extension of the requested size.

STA TUS _IN SUF FICI ENT _RE SO URC ES	Indicates that the memory could not be allocated for the driver object extension.
STA TUS _OB JEC T_N AM E_C OLL ISIO N	Indicates that a driver object extension with the given *ClientIdentificationAddress* already exists.

Remarks

Memory allocated by the system for the driver object extension is resident storage and is accessible from any IRQL. The allocated storage is automatically freed by the I/O manager when the driver object is deleted.

Callers of this routine must provide a unique identifier for *ClientIdentificationAddress*. To retrieve a pointer to the context area, a caller passes the *ClientIdentificationAddress* to IoGetDriverObjectExtension.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

IoGetDriverObjectExtension

IoAllocateErrorLogEntry function

1/25/2019 • 2 minutes to read • Edit Online

The **IoAllocateErrorLogEntry** routine allocates an error log entry, and returns a pointer to the packet that the caller uses to supply information about an I/O error.

Syntax

```
PVOID IoAllocateErrorLogEntry(
  PVOID IoObject,
  UCHAR EntrySize
);
```

Parameters

`IoObject`

Pointer to a device object representing the device on which an I/O error occurred, or to a driver object representing the driver that found an error.

`EntrySize`

Specifies the size, in bytes, of the error log entry to be allocated. This value cannot exceed ERROR_LOG_MAXIMUM_SIZE.

> **Warning** *EntrySize* is a UCHAR value. If you specify a larger value, the compiler will silently truncate that value to a (wrong) UCHAR.

Return Value

IoAllocateErrorLogEntry returns a pointer to the error log entry, or **NULL** if a log entry could not be allocated.

Remarks

The driver must first fill in the packet with information about the error, then call IoWriteErrorLogEntry to post the entry to the error log. The error log entry buffer is automatically freed once the log entry is recorded. Entry buffers that are not going to be written to the log can be freed by using IoFreeErrorLogEntry.

An error log entry consists of a variable-length IO_ERROR_LOG_PACKET structure, possibly followed by one or more zero-counted Unicode strings. The Event Viewer inserts these strings into the error message it displays for the entry. **IO_ERROR_LOG_PACKET** contains one variable-length member, the **DumpData** member. Thus, the value for *EntrySize* must be **sizeof**(**IO_ERROR_LOG_PACKET**) + size of the **DumpData** member + combined size of any driver-supplied insertion strings.

Drivers should check that the value for *EntrySize* is less than ERROR_LOG_MAXIMUM_SIZE before calling **IoAllocateErrorLogEntry**. Since *EntrySize* is declared as a UCHAR, and the compiler will silently truncate any value too big to fit into a UCHAR, the routine itself cannot reliably detect if the passed value is too large.

Drivers must not treat **IoAllocateErrorLogEntry** returning **NULL** as a fatal error. The driver must continue to function normally, regardless of whether it can log errors.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoWriteErrorLogEntry

IoAllocateIrp function

1/25/2019 • 2 minutes to read • Edit Online

The **IoAllocateIrp** routine allocates an IRP, given the number of I/O stack locations for each driver layered under the caller, and, optionally, for the caller.

Syntax

```
PIRP IoAllocateIrp(
  CCHAR   StackSize,
  BOOLEAN ChargeQuota
);
```

Parameters

`StackSize`

Specifies the number of I/O stack locations to be allocated for the IRP. This value must be at least equal to the **StackSize** of the next-lower driver's device object, but can be one greater than this value. The calling driver need not allocate a stack location in the IRP for itself.

`ChargeQuota`

Setting this to **TRUE** causes the memory allocated for the IRP to be charged against the quota for the current process. Should be set to **FALSE** by intermediate drivers. This can be set to **TRUE** only by highest-level drivers that are called in the context of the thread that originates the I/O request for which the driver is allocating another IRP.

Return Value

IoAllocateIrp returns a pointer to an IRP, which was allocated from nonpaged system space, or **NULL** if an IRP could not be allocated.

Remarks

The **IoAllocateIrp** routine does not associate the IRP with a thread. The allocating driver must free the IRP instead of completing it back to the I/O manager.

An intermediate or highest-level driver can call **IoAllocateIrp** to create IRPs for requests it sends to lower-level drivers. Such a driver must initialize the IRP and must set its IoCompletion routine in the IRP it creates so the caller can dispose of the IRP when lower-level drivers have completed processing of the request.

IoAllocateIrp automatically initializes the IRP's members. Do not use **IoInitializeIrp** to initialize the IRP before its first use. (You can use **IoInitializeIrp** to reuse an IRP that you have already used under certain special circumstances. See Reusing IRPs for details.)

An intermediate or highest-level driver also can call IoBuildDeviceIoControlRequest, IoBuildAsynchronousFsdRequest or IoBuildSynchronousFsdRequest to set up requests it sends to lower-level drivers. Only a highest-level driver can call IoMakeAssociatedIrp.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

IoSetCompletionRoutine

IoAllocateMdl function

1/25/2019 • 2 minutes to read • Edit Online

The **IoAllocateMdl** routine allocates a memory descriptor list (MDL) large enough to map a buffer, given the buffer's starting address and length. Optionally, this routine associates the MDL with an IRP.

Syntax

```
PMDL IoAllocateMdl(
  __drv_aliasesMem PVOID VirtualAddress,
  ULONG                  Length,
  BOOLEAN                SecondaryBuffer,
  BOOLEAN                ChargeQuota,
  PIRP                   Irp
);
```

Parameters

`VirtualAddress`

Pointer to the base virtual address of the buffer the MDL is to describe.

`Length`

Specifies the length, in bytes, of the buffer that the MDL is to describe. For more information, see the following Remarks section.

`SecondaryBuffer`

Indicates whether the buffer is a primary or secondary buffer. This parameter determines how the MDL is to be linked to the IRP. All buffers except the first buffer described by an MDL in an IRP are considered secondary buffers. This field must be **FALSE** if no IRP is associated with the MDL. For more information, see the following Remarks section.

`ChargeQuota`

Reserved for system use. Drivers must set this parameter to **FALSE**.

`Irp`

Pointer to an IRP to be associated with the MDL. If the *Irp* pointer is non-**NULL**, the allocated MDL is associated with the specified IRP's MDL list, according to the value of *SecondaryBuffer*.

Return Value

IoAllocateMdl returns a pointer to an MDL, or, if the MDL cannot be allocated, it returns **NULL**.

Remarks

IoAllocateMdl can be used by a driver that needs to break a buffer into pieces, each mapped by a separate MDL, or to map a driver-allocated buffer. The driver should call MmBuildMdlForNonPagedPool with the MDL allocated by this call to set up an MDL describing a driver-allocated buffer in nonpaged pool.

The *Length* parameter specifies the size of the buffer that is to be described by the MDL. In Windows Server 2003, Windows XP, and Windows 2000, the maximum buffer size, in bytes, that this routine can allocate is PAGE_SIZE * (65535 - **sizeof**(MDL)) / **sizeof**(ULONG_PTR). In Windows Vista and Windows Server 2008, the maximum buffer size is (2 gigabytes - PAGE_SIZE). In Windows 7 and Windows Server 2008 R2, the maximum buffer size is (4 gigabytes - PAGE_SIZE).

If the *SecondaryBuffer* parameter is **FALSE**, the routine updates *Irp*->**MdlAddress** to point to the new MDL. If *SecondaryBuffer* is **TRUE**, the routine adds the MDL to the end of the MDL chain that *Irp*->**MdlAddress** points to.

For more information about MDLs, see Using MDLs.

Requirements

IoAllocateWorkItem function

1/25/2019 • 2 minutes to read • Edit Online

The **IoAllocateWorkItem** routine allocates a work item.

Syntax

```
PIO_WORKITEM IoAllocateWorkItem(
  PDEVICE_OBJECT DeviceObject
);
```

Parameters

`DeviceObject`

Pointer to the caller's driver object or to one of the caller's device objects. If the caller will later pass the work item to IoQueueWorkItem, *DeviceObject* must point to a device object.

Return Value

IoAllocateWorkItem returns a pointer to the allocated IO_WORKITEM structure. The routine returns **NULL** if sufficient resources do not exist.

Remarks

The driver must free the work item that is returned by **IoAllocateWorkItem** by calling IoFreeWorkItem.

IoAllocateWorkItem both allocates and initializes a work item. A related routine, IoInitializeWorkItem, initializes a work item in storage that the driver has previously allocated. Do not call **IoInitializeWorkItem** to initialize a work item that was allocated by **IoAllocateWorkItem**.

For more information about work items, see System Worker Threads.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of the Windows operating system, and in Windows Me. This routine is not available in Windows 98.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IoQueueWorkItemEx

IoAttachDevice function

1/25/2019 • 2 minutes to read • Edit Online

The **IoAttachDevice** routine attaches the caller's device object to a named target device object, so that I/O requests bound for the target device are routed first to the caller.

Syntax

```
NTSTATUS IoAttachDevice(
  PDEVICE_OBJECT  SourceDevice,
  PUNICODE_STRING TargetDevice,
  PDEVICE_OBJECT  *AttachedDevice
);
```

Parameters

`SourceDevice`

Pointer to the caller-created device object.

`TargetDevice`

Pointer to a buffer containing the name of the device object to which the specified *SourceDevice* is to be attached.

`AttachedDevice`

Pointer to caller-allocated storage for a pointer. On return, contains a pointer to the target device object if the attachment succeeds.

Return Value

IoAttachDevice can return one of the following NTSTATUS values:

Remarks

IoAttachDevice establishes layering between drivers so that the same IRPs can be sent to each driver in the chain.

This routine is used by intermediate drivers during initialization. It allows such a driver to attach its own device object to another device in such a way that any requests being made to the original device are given first to the intermediate driver.

The caller can be layered only at the top of an existing chain of layered drivers. **IoAttachDevice** searches for the highest device object layered over *TargetDevice* and attaches to that object (that can be the *TargetDevice*). Therefore, this routine must not be called if a driver that must be higher-level has already layered itself over the target device.

Note that for file system drivers and drivers in the storage stack, **IoAttachDevice** opens the target device with FILE_READ_ATTRIBUTES and then calls IoGetRelatedDeviceObject. This does not cause a file system to be mounted. Thus, a successful call to **IoAttachDevice** returns the device object of the storage driver, not that of the file system driver.

This routine sets the **AlignmentRequirement** in *SourceDevice* to the value in the next-lower device object and sets the **StackSize** to the value in the next-lower object plus one.

Warning *AttachedDevice* must point to a global memory location, such as the driver's device extension. **IoAttachDevice** opens the file object for the target device, updates *AttachedDevice*, performs the attach, and then closes the file object. Thus, the source device receives the IRP_MJ_CLEANUP and IRP_MJ_CLOSE requests for the file object before **IoAttachDevice** returns. The driver must forward these requests to the target device, and *AttachedDevice* must be a memory location accessible to the driver's DispatchCleanup and DispatchClose routines.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

DEVICE_OBJECT

IoAttachDeviceToDeviceStack

IoAttachDeviceToDeviceStackSafe

IoCreateDevice

IoDetachDevice

IoGetRelatedDeviceObject

IoAttachDeviceToDeviceStack function

1/25/2019 • 2 minutes to read • Edit Online

The **IoAttachDeviceToDeviceStack** routine attaches the caller's device object to the highest device object in the chain and returns a pointer to the previously highest device object.

Syntax

```
PDEVICE_OBJECT IoAttachDeviceToDeviceStack(
  PDEVICE_OBJECT SourceDevice,
  PDEVICE_OBJECT TargetDevice
);
```

Parameters

`SourceDevice`

Pointer to the caller-created device object.

`TargetDevice`

Pointer to another driver's device object, such as a pointer returned by a preceding call to IoGetDeviceObjectPointer.

Return Value

IoAttachDeviceToDeviceStack returns a pointer to the device object to which the *SourceDevice* was attached. The returned device object pointer can differ from *TargetDevice* if *TargetDevice* had additional drivers layered on top of it.

IoAttachDeviceToDeviceStack returns **NULL** if it could not attach the device object because, for example, the target device was being unloaded.

Remarks

IoAttachDeviceToDeviceStack establishes layering between drivers so that the same IRPs are sent to each driver in the chain.

An intermediate driver can use this routine during initialization to attach its own device object to another driver's device object. Subsequent I/O requests sent to *TargetDevice* are sent first to the intermediate driver.

This routine sets the **AlignmentRequirement** in *SourceDevice* to the value in the next-lower device object and sets the **StackSize** to the value in the next-lower-object plus one.

A driver writer must take care to call this routine before any drivers that must layer on top of their driver. **IoAttachDeviceToDeviceStack** attaches *SourceDevice* to the highest device object currently layered in the chain and has no way to determine whether drivers are being layered in the correct order.

A driver that acquired a pointer to the target device by calling IoGetDeviceObjectPointer should call ObDereferenceObject with the file object pointer that was returned by **IoGetDeviceObjectPointer** to release its reference to the file object before it detaches its own device object, for example, when such a higher-level driver is unloaded.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoBuildAsynchronousFsdRequest function

1/25/2019 • 4 minutes to read • Edit Online

The **IoBuildAsynchronousFsdRequest** routine allocates and sets up an IRP to be sent to lower-level drivers.

Syntax

```
__drv_aliasesMem PIRP IoBuildAsynchronousFsdRequest(
  ULONG            MajorFunction,
  PDEVICE_OBJECT   DeviceObject,
  PVOID            Buffer,
  ULONG            Length,
  PLARGE_INTEGER   StartingOffset,
  PIO_STATUS_BLOCK IoStatusBlock
);
```

Parameters

`MajorFunction`

The major function code to be set in the IRP. This code can be IRP_MJ_PNP, IRP_MJ_READ, IRP_MJ_WRITE, IRP_MJ_FLUSH_BUFFERS, or IRP_MJ_SHUTDOWN.

`DeviceObject`

A pointer to the next-lower driver's device object. This object represents the target device for the read, write, flush, or shutdown operation.

`Buffer`

A pointer to a buffer into which data is read or from which data is written. The value of this argument is **NULL** for flush and shutdown requests.

`Length`

The length, in bytes, of the buffer pointed to by *Buffer*. For devices such as disks, this value must be an integer multiple of the sector size. Starting with Windows 8, the sector size can be 4,096 or 512 bytes. In earlier versions of Windows, the sector size is always 512 bytes. This parameter is required for read and write requests, but must be zero for flush and shutdown requests.

`StartingOffset`

A pointer to the starting offset on the input/output media. The value of this argument is zero for flush and shutdown requests.

`IoStatusBlock`

A pointer to the address of an I/O status block in which the to-be-called drivers return final status about the requested operation.

Return Value

IoBuildAsynchronousFsdRequest returns a pointer to an IRP, or a **NULL** pointer if the IRP cannot be allocated.

Remarks

Intermediate or highest-level drivers can call **IoBuildAsynchronousFsdRequest** to set up IRPs for requests sent to lower-level drivers. The calling driver must supply an IoCompletion routine for the IRP, so the IRP can be deallocated with IoFreeIrp. For more information about IRP deallocation, see Examples.

The IRP that gets built contains only enough information to get the operation started and to complete the IRP. No other context information is tracked because an asynchronous request is context-independent.

Lower-level drivers might impose restrictions on parameters supplied to this routine. For example, disk drivers might require that values supplied for *Length* and *StartingOffset* be integer multiples of the device's sector size.

An intermediate or highest-level driver also can call IoBuildDeviceIoControlRequest, IoAllocateIrp, or IoBuildSynchronousFsdRequest to set up requests it sends to lower-level drivers. Only a highest-level driver can call IoMakeAssociatedIrp.

During an **IoBuildAsynchronousFsdRequest** call, the I/O manager sets the **Tail.Overlay.Thread** member of the IRP structure to point to the caller's thread object, but does not take a counted reference to the thread object on behalf of the caller. After the caller sends the IRP to the driver for the target device, this driver might use the **Tail.Overlay.Thread** member to access the thread object. For example, a storage driver might call the IoSetHardErrorOrVerifyDevice routine and supply a pointer to the IRP as an input parameter. During this call, **IoSetHardErrorOrVerifyDevice** uses the **Tail.Overlay.Thread** member to access the thread object. When the thread object is accessed in this way, the driver that called **IoBuildAsynchronousFsdRequest** to allocate the IRP is responsible for ensuring that the thread object stays valid while the IRP is being handled.

To keep the thread object valid, the driver that calls **IoBuildAsynchronousFsdRequest** can take a counted reference on the thread object before sending the IRP. For example, this driver can call the ObReferenceObjectByPointerWithTag routine and supply, as the *Object* parameter, the object pointer from the **Tail.Overlay.Thread** member of the **IRP** structure. Later, this driver's completion routine can dereference the object by calling a routine such as ObDereferenceObjectWithTag.

A driver might call **IoBuildAsynchronousFsdRequest** in one thread, and send the IRP allocated by this call in another thread. Before sending the IRP, this driver should set the **Tail.Overlay.Thread** member of the IRP to point to the thread object for the sending thread. Typically, the driver calls the PsGetCurrentThread routine to get the thread object pointer.

A driver that calls **IoBuildAsynchronousFsdRequest** to allocate an IRP does not necessarily need to take a counted reference on the thread object pointed to by the **Tail.Overlay.Thread** member of the IRP. The driver might instead use another technique to guarantee that this thread object remains valid while the IRP is being handled. For example, if the driver created the thread, the thread can wait until the IRP is completed to terminate itself.

Examples

Before calling IoFreeIrp, an additional step is required to free the buffer for an IRP built by **IoBuildAsynchronousFsdRequest** if the following are all true:

- The buffer was allocated from system memory pool.
- In the device object for the target device, the DO_DIRECT_IO flag is set in the **DeviceObject->Flags** field.
- The **Irp->MdlAddress** field is non-NULL.

Before freeing the buffer for this IRP, call the MmUnlockPages routine with **Irp->MdlAddress** as the parameter value. This call decrements the extra reference count that **IoBuildAsynchronousFsdRequest** added to the pool pages in the MDL. Otherwise, the subsequent call to IoFreeMdl will bug check because the reference count for these pool pages will be 2, not 1. The following code example shows the **MmUnlockPages**, **IoFreeMdl**, and **IoFreeIrp** calls for this case:

```
if (((DeviceObject->Flags & DO_DIRECT_IO) == DO_DIRECT_IO) &&
    (Irp->MdlAddress != NULL))
{
    MmUnlockPages(Irp->MdlAddress);
}

IoFreeMdl(Irp->MdlAddress);
IoFreeIrp(Irp);
```

Requirements

IoBuildDeviceIoControlRequest function

1/25/2019 • 3 minutes to read • Edit Online

The **IoBuildDeviceIoControlRequest** routine allocates and sets up an IRP for a synchronously processed device control request.

Syntax

```
__drv_aliasesMem PIRP IoBuildDeviceIoControlRequest(
  ULONG            IoControlCode,
  PDEVICE_OBJECT   DeviceObject,
  PVOID            InputBuffer,
  ULONG            InputBufferLength,
  PVOID            OutputBuffer,
  ULONG            OutputBufferLength,
  BOOLEAN          InternalDeviceIoControl,
  PKEVENT          Event,
  PIO_STATUS_BLOCK IoStatusBlock
);
```

Parameters

`IoControlCode`

Supplies the I/O control code (IOCTL) to be used in the request. For information about device type-specific I/O control codes, see device type-specific sections in the Windows Driver Kit (WDK).

`DeviceObject`

Supplies a pointer to the DEVICE_OBJECT structure for the next-lower driver's device object, which represents the target device.

`InputBuffer`

Supplies a pointer to an input buffer to be passed to the lower driver, or **NULL** if the request does not pass input data to lower drivers.

`InputBufferLength`

Supplies the length, in bytes, of the input buffer. If *InputBuffer* is **NULL**, *InputBufferLength* must be zero.

`OutputBuffer`

Supplies a pointer to an output buffer in which the lower driver is to return data, or **NULL** if the request does not require lower drivers to return data.

`OutputBufferLength`

Supplies the length, in bytes, of the output buffer. If *OutputBuffer* is **NULL**, *OutputBufferLength* must be zero.

`InternalDeviceIoControl`

If **TRUE**, the routine sets the IRP's major function code to IRP_MJ_INTERNAL_DEVICE_CONTROL. Otherwise, the routine sets the IRP's major function code to IRP_MJ_DEVICE_CONTROL.

`Event`

Supplies a pointer to a caller-allocated and initialized event object. The I/O manager sets the event to the Signaled state when a lower-level driver completes the requested operation. After calling IoCallDriver, the driver can wait for the event object. The *Event* parameter is optional and can be set to NULL. However, if *Event* is NULL, the caller must supply an IoCompletion routine for the IRP to notify the caller when the operation completes.

`IoStatusBlock`

Specifies an I/O status block to be set when the request is completed by lower drivers.

Return Value

If the operation succeeds, **IoBuildDeviceIoControlRequest** returns a pointer to an IRP, with the next-lower driver's I/O stack location set up from the supplied parameters. Otherwise, the routine returns **NULL**.

Remarks

A driver can call **IoBuildDeviceIoControlRequest** to set up IRPs for device control requests that it synchronously sends to lower-level drivers.

After calling **IoBuildDeviceIoControlRequest** to create a request, the driver must call IoCallDriver to send the request to the next-lower driver. If **IoCallDriver** returns STATUS_PENDING, the driver must wait for the completion of the IRP by calling KeWaitForSingleObject on the given *Event*. Most drivers do not need to set an IoCompletion routine for the IRP.

IRPs that are created by **IoBuildDeviceIoControlRequest** must be completed by a driver's call to IoCompleteRequest. A driver that calls **IoBuildDeviceIoControlRequest** must not call IoFreeIrp, because the I/O manager frees these synchronous IRPs after **IoCompleteRequest** has been called.

IoBuildDeviceIoControlRequest queues the IRPs that it creates to an IRP queue that is specific to the current thread. If the thread exits, the I/O manager cancels the IRP.

If the caller supplies an *InputBuffer* or *OutputBuffer* parameter, this parameter must point to a buffer that resides in system memory. The caller is responsible for validating any parameter values that it copies into the input buffer from a user-mode buffer. The input buffer might contain parameter values that are interpreted differently depending on whether the originator of the request is a user-mode application or a kernel-mode driver. In the IRP that **IoBuildDeviceIoControlRequest** returns, the **RequestorMode** field is always set to **KernelMode**. This value indicates that the request, and any information contained in the request, is from a trusted, kernel-mode component.

If the caller cannot validate parameter values that it copies from a user-mode buffer to the input buffer, or if these values must not be interpreted as coming from a kernel-mode component, the caller should set the **RequestorMode** field in the IRP to **UserMode**. This setting informs the driver that handles the I/O control request that the buffer contains untrusted, user-mode data.

The actual method by which the contents of the *InputBuffer* and *OutputBuffer* parameters are stored in the IRP depends on the *TransferType* value for the IOCTL. For more information about this value, see Buffer Descriptions for I/O Control Codes.

IoBuildPartialMdl function

1/25/2019 • 2 minutes to read • Edit Online

The **IoBuildPartialMdl** routine builds a new memory descriptor list (MDL) that represents part of a buffer that is described by an existing MDL.

Syntax

```
void IoBuildPartialMdl(
  PMDL  SourceMdl,
  PMDL  TargetMdl,
  PVOID VirtualAddress,
  ULONG Length
);
```

Parameters

`SourceMdl`

A pointer to an MDL that describes the original buffer, of which a subrange is to be mapped.

`TargetMdl`

A pointer to a caller-allocated MDL. This MDL must be large enough to describe the pages in the subrange that are specified by *VirtualAddress* and *Length*.

`VirtualAddress`

A pointer to the base virtual address for the subrange to be described by the *TargetMdl*.

`Length`

Specifies the length, in bytes, to be mapped by the *TargetMdl*. This value, in combination with *VirtualAddress*, must specify a buffer that is a proper subrange of the buffer that is described by *SourceMdl*. If *Length* is zero, the subrange to be mapped starts at *VirtualAddress* and includes the remaining range described by the *SourceMdl*.

Return Value

None

Remarks

This routine builds a target MDL that describes a subrange of the buffer that is described by the source MDL. This subrange is specified by the *VirtualAddress* and *Length* parameters. The *SourceMdl* and *TargetMdl* parameters point to the source MDL and target MDL.

A driver can use **IoBuildPartialMdl** to split a large transfer request into smaller transfer requests. The physical pages that the source MDL describes must be locked before the driver calls **IoBuildPartialMdl**. Typically, the source MDL describes a buffer in user address space, and the driver calls the MmProbeAndLockPages routine to lock the pages in this buffer. However, the driver can build the source MDL from nonpaged memory by calling the MmBuildMdlForNonPagedPool, MmAllocatePagesForMdlEx, or MmAllocatePagesForMdl routine.

A driver can map a partial MDL into the system address space by using the MmGetSystemAddressForMdlSafe

macro. If a partial MDL is built from a source MDL that is already mapped into the system address space, **MmGetSystemAddressForMdlSafe** uses the existing source mapping. Otherwise, **MmGetSystemAddressForMdlSafe** creates a new mapping. To prevent this new mapping from being leaked, drivers must call MmPrepareMdlForReuse before reusing a partial MDL. In addition, the IoFreeMdl routine releases the system-address-space mapping for a partial MDL, if such a mapping exists.

For more information about MDLs, see Using MDLs.

IoBuildSynchronousFsdRequest function

1/25/2019 • 2 minutes to read • Edit Online

The **IoBuildSynchronousFsdRequest** routine allocates and sets up an IRP for a synchronously processed I/O request.

Syntax

```
__drv_aliasesMem PIRP IoBuildSynchronousFsdRequest(
  ULONG            MajorFunction,
  PDEVICE_OBJECT   DeviceObject,
  PVOID            Buffer,
  ULONG            Length,
  PLARGE_INTEGER   StartingOffset,
  PKEVENT          Event,
  PIO_STATUS_BLOCK IoStatusBlock
);
```

Parameters

`MajorFunction`

The major function code for the IRP. This code can be IRP_MJ_PNP, IRP_MJ_READ, IRP_MJ_WRITE, IRP_MJ_FLUSH_BUFFERS, or IRP_MJ_SHUTDOWN.

`DeviceObject`

A pointer to the DEVICE_OBJECT structure for the next-lower driver's device object, which represents the target device.

`Buffer`

A pointer to a data buffer. If *MajorFunction* is **IRP_MJ_WRITE**, the buffer contains data to be written. If *MajorFunction* is **IRP_MJ_READ**, the buffer receives data. If *MajorFunction* is **IRP_MJ_FLUSH_BUFFERS** or **IRP_MJ_SHUTDOWN**, this parameter must be **NULL**.

`Length`

The length, in bytes, of the buffer pointed to by *Buffer*. For devices such as disks, this value must be an integer multiple of the sector size. Starting with Windows 8, the sector size can be 4,096 or 512 bytes. In earlier versions of Windows, the sector size is always 512 bytes. This parameter is required for read and write requests, but must be zero for flush and shutdown requests.

`StartingOffset`

A pointer to the offset on the disk, for read and write requests. The units and meaning of this value are driver-specific. This parameter is required for read and write requests, but must be zero for flush and shutdown requests.

`Event`

A pointer to a caller-allocated and initialized event object. The I/O manager sets the event to the Signaled state when a lower-level driver completes the requested operation. After calling IoCallDriver, the driver can wait for the event object.

`IoStatusBlock`

A pointer to a location that receives the I/O status block that is set when the IRP is completed by a lower-level driver.

Return Value

If the operation succeeds, **IoBuildSynchronousFsdRequest** returns a pointer to an initialized IRP structure, with the next-lower driver's I/O stack location set up from the supplied parameters. Otherwise, the routine returns **NULL**.

Remarks

A file system driver (FSD) or other higher-level driver can call **IoBuildSynchronousFsdRequest** to set up IRPs that it synchronously sends to lower-level drivers.

IoBuildSynchronousFsdRequest allocates and sets up an IRP that requests lower-level drivers to perform a synchronous read, write, flush, or shutdown operation. The IRP contains enough information to start the operation.

Lower-level drivers might impose restrictions on parameters supplied to this routine. For example, disk drivers might require that values supplied for *Length* and *StartingOffset* be integer multiples of the device's sector size.

After calling **IoBuildSynchronousFsdRequest** to create a request, the driver must call IoCallDriver to send the request to the next-lower driver. If **IoCallDriver** returns STATUS_PENDING, the driver must wait for the completion of the IRP by calling KeWaitForSingleObject on the given *Event*. Most drivers do not need to set an IoCompletion routine for the IRP.

IRPs that are created by **IoBuildSynchronousFsdRequest** must be completed by a driver's call to IoCompleteRequest. A driver that calls **IoBuildSynchronousFsdRequest** must not call IoFreeIrp, because the I/O manager frees these synchronous IRPs after **IoCompleteRequest** has been called.

IoBuildSynchronousFsdRequest queues the IRPs that it creates to an IRP queue that is specific to the current thread. If the thread exits, the I/O manager cancels the IRP.

Requirements

Minimum supported client	Available starting with Windows 2000.

IoCallDriver macro

1/25/2019 • 2 minutes to read • Edit Online

The **IoCallDriver** routine, wraps **IofCallDriver** that sends an IRP to the driver associated with a specified device object. For more information, see **IofCallDriver**.

> Do not call **IofCallDriver**. Call **IoCallDriver** instead.

Syntax

```
void IoCallDriver(
   a,
   b
);
```

Parameters

`a`

See **IofCallDriver**.

`b`

See **IofCallDriver**.

Return Value

See **IofCallDriver**.

Remarks

see **IofCallDriver**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

IoCancelIrp function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCancelIrp** routine sets the cancel bit in a given IRP and calls the cancel routine for the IRP if there is one.

Syntax

```
BOOLEAN IoCancelIrp(
  PIRP Irp
);
```

Parameters

`Irp`

A pointer to the IRP to be canceled.

Return Value

IoCancelIrp returns **TRUE** if the IRP had a cancel routine and this routine was called. Otherwise, it returns **FALSE**. In either case, the IRP's cancel bit is set to **TRUE**. For more information, see Remarks.

Remarks

If the IRP has a cancel routine, **IoCancelIrp** sets the cancel bit and calls the cancel routine.

If *Irp*->**CancelRoutine** is **NULL**, and therefore the IRP is not cancelable, **IoCancelIrp** sets the IRP's cancel bit and returns **FALSE**. The IRP should be canceled at a later time when it becomes cancelable.

If a driver that does not own the IRP calls **IoCancelIrp**, the results are unpredictable. The IRP might be completed with a successful status even though its cancel bit was set.

An intermediate driver should not arbitrarily call **IoCancelIrp** unless that driver created the IRP passed in the call. Otherwise, the intermediate driver might cancel an IRP that some higher-level driver is tracking for purposes of its own.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

IoSetCancelRoutine

IoCheckLinkShareAccess function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCheckLinkShareAccess** routine is called by file system drivers (FSDs) or other highest-level drivers to check whether link shared access to a file object is permitted.

Syntax

```
NTSTATUS IoCheckLinkShareAccess(
  ACCESS_MASK        DesiredAccess,
  ULONG              DesiredShareAccess,
  PFILE_OBJECT       FileObject,
  PSHARE_ACCESS      ShareAccess,
  PLINK_SHARE_ACCESS LinkShareAccess,
  ULONG              IoShareAccessFlags
);
```

Parameters

`DesiredAccess`

Specifies an ACCESS_MASK value that indicates the desired type of access to the given file object.

`DesiredShareAccess`

Specifies the desired type of shared access to the file object for the current open request. The value of this parameter is usually the same as the *ShareAccess* parameter that is passed to the file system or highest-level driver by the I/O manager when the open request was made. This value can be zero, or any combination of the following:

FILE_SHARE_READ

FILE_SHARE_WRITE

FILE_SHARE_DELETE

`FileObject`

A pointer to the file object for which to check access for the current open request.

`ShareAccess`

A pointer to the common share-access data structure that is associated with *FileObject*. Drivers should treat this structure as opaque.

`LinkShareAccess`

A pointer to the common link share-access data structure (LINK_SHARE_ACCESS) that is associated with *FileObject*. Drivers should treat this structure as opaque.

`IoShareAccessFlags`

A bitmask of these flags:

IO_SHARE_ACCESS_NO_WRITE_PERMISSION (0x80000000) specifies that the user has no write permission for the file. This flag is used to prevent opening a file for exclusive read access when the user does not have

appropriate permissions.

IO_CHECK_SHARE_ACCESS_UPDATE_SHARE_ACCESS (0x00000001) indicates whether the SHARE_ACCESS structure is updated.

Return Value

The **IoCheckLinkShareAccess** routine returns STATUS_SUCCESS if the requester's access to the file object is compatible with the way in which it is currently open. If the request is denied because of a sharing violation, then STATUS_SHARING_VIOLATION is returned.

Remarks

The *ShareAccess* parameter must be locked against other accesses from other threads while this routine is executing. Otherwise the counts can be synchronization.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Target Platform	Universal
Header	wdm.h
Library	Ntoskrnl.lib

I/O Manager Routines

IoRemoveLinkShareAccess

IoSetLinkShareAccess

IoUpdateLinkShareAccess

IoCheckShareAccess function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCheckShareAccess** routine is called by file system drivers (FSDs) or other highest-level drivers to check whether shared access to a file object is permitted.

Syntax

```
NTSTATUS IoCheckShareAccess(
  ACCESS_MASK   DesiredAccess,
  ULONG         DesiredShareAccess,
  PFILE_OBJECT  FileObject,
  PSHARE_ACCESS ShareAccess,
  BOOLEAN       Update
);
```

Parameters

`DesiredAccess`

Specifies an ACCESS_MASK value that indicates the desired type of access to the given *FileObject* for the current open request. Drivers compute the value of this parameter by taking the requested access in the IRP_MJ_CREATE request and then applying SeAccessCheck for each security descriptor to determine the actual access granted. If the granted access is more restrictive than the desired access, then that is an error, and the driver should complete the current IRP with a status of STATUS_ACCESS_DENIED. (Note that **SeAccessCheck** clears the MAXIMUM_ALLOWED bit in the granted access; be sure to not use that bit when comparing desired access to granted access.) The driver then passes the granted access as the value of *DesiredAccess*.

`DesiredShareAccess`

Specifies the desired type of shared access to *FileObject* for the current open request. The value of this parameter is usually the same as the *ShareAccess* passed to the file system or highest-level driver by the I/O manager when the open request was made. This value can be zero, or any combination of the following:

FILE_SHARE_READ

FILE_SHARE_WRITE

FILE_SHARE_DELETE

`FileObject`

Pointer to the file object for which to check access for the current open request.

`ShareAccess`

Pointer to the common share-access data structure associated with *FileObject*. Drivers should treat this structure as opaque.

`Update`

Specifies whether to update the share-access status for *FileObject*. A Boolean value of **TRUE** means this routine will update the share access information for the file object if the open request is permitted.

Return Value

IoCheckShareAccess returns STATUS_SUCCESS if the requester's access to the file object is compatible with the way in which it is currently open. If the request is denied because of a sharing violation, then STATUS_SHARING_VIOLATION is returned.

Remarks

IoCheckShareAccess checks a file object open request to determine whether the types of desired and shared accesses specified are compatible with the way in which the file object is currently being accessed by other opens.

File systems maintain state about files through structures called file control blocks (FCBs). The SHARE_ACCESS is a structure describing how the file is currently accessed by all opens. This state is contained in the FCB as part of the open state for each file object. Each file object should have only one share access structure. Other highest-level drivers might call this routine to check the access requested when a file object representing such a driver's device object is opened.

IoCheckShareAccess is not an atomic operation. Therefore, drivers calling this routine must protect the shared file object passed to **IoCheckShareAccess** by means of some kind of lock, such as a mutex or a resource lock, in order to prevent corruption of the shared access counts.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoSetShareAccess

IoUpdateShareAccess

IoCheckShareAccessEx function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCheckShareAccessEx** routine is called by file system drivers (FSDs) or other highest-level drivers to check whether shared access to a file object is permitted.

Syntax

```
NTSTATUS IoCheckShareAccessEx(
  ACCESS_MASK   DesiredAccess,
  ULONG         DesiredShareAccess,
  PFILE_OBJECT  FileObject,
  PSHARE_ACCESS ShareAccess,
  BOOLEAN       Update,
  PBOOLEAN      WritePermission
);
```

Parameters

`DesiredAccess`

Specifies an ACCESS_MASK value that indicates the desired type of access to the given file object.

`DesiredShareAccess`

Specifies the desired type of shared access to the file object for the current open request. The value of this parameter is usually the same as the *ShareAccess* parameter that is passed to the file system or highest-level driver by the I/O manager when the open request was made. This value can be zero, or any combination of the following:

FILE_SHARE_READ

FILE_SHARE_WRITE

FILE_SHARE_DELETE

`FileObject`

A pointer to the file object for which to check access for the current open request.

`ShareAccess`

A pointer to the common share-access data structure that is associated with *FileObject*. Drivers should treat this structure as opaque.

`Update`

Specifies whether to update the share-access status for *FileObject*. A Boolean value of **TRUE** means this routine will update the share access information for the file object if the open request is permitted.

`WritePermission`

Specifies whether the share access has write permission. This value is TRUE if the share has write permission; otherwise, FALSE. If the value is FALSE and the share access has write permission and the caller attempts to take exclusive read access, the write permission is downgraded to FILE_SHARE_READ. This value is NULL if a write permission check is not done on the share access.

Return Value

The **IoCheckShareAccessEx** routine returns STATUS_SUCCESS if the requester's access to the file object is compatible with the way in which it is currently open. If the request is denied because of a sharing violation, then STATUS_SHARING_VIOLATION is returned.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h
Library	Ntoskrnl.lib

I/O Manager Routines

IoCompleteRequest macro

1/25/2019 • 2 minutes to read • Edit Online

The **IoCompleteRequest** macro indicates that the caller has completed all processing for a given I/O request and is returning the given IRP to the I/O manager.

> **IoCompleteRequest** wraps **IofCompleteRequest**.

Syntax

```
void IoCompleteRequest(
   a,
   b
);
```

Parameters

`a`

Pointer to the IRP to be completed.

`b`

Specifies a system-defined CCHAR constant by which to increment the run-time priority of the original thread that requested the operation. This value is IO_NO_INCREMENT if the original thread requested an operation the driver could complete quickly (so the requesting thread is not compensated for its assumed wait for I/O to be completed) or if the IRP is completed with an error. Otherwise, the set of *PriorityBoost* constants are device-type-specific. See Ntddk.h or Wdm.h for these constants.

Return Value

None

Remarks

When a driver has finished all processing for a given IRP, it calls **IoCompleteRequest**. The I/O manager checks the IRP to determine whether any higher-level drivers have set up an IoCompletion routine for the IRP. If so, each *IoCompletion* routine is called, in turn, until every layered driver in the chain has completed the IRP.

When all drivers have completed a given IRP, the I/O manager returns status to the original requester of the operation. Note that a higher-level driver that sets up a driver-created IRP must supply an *IoCompletion* routine to release the IRP it created.

Never call **IoCompleteRequest** while holding a spin lock. Attempting to complete an IRP while holding a spin lock can cause deadlocks.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

IoSetCompletionRoutine

IoConnectInterrupt function

1/25/2019 • 2 minutes to read • Edit Online

The **IoConnectInterrupt** routine registers a device driver's InterruptService routine (ISR), so that it will be called when a device interrupts on any of a specified set of processors.

Syntax

```
NTSTATUS IoConnectInterrupt(
  PKINTERRUPT       *InterruptObject,
  PKSERVICE_ROUTINE ServiceRoutine,
  PVOID             ServiceContext,
  PKSPIN_LOCK       SpinLock,
  ULONG             Vector,
  KIRQL             Irql,
  KIRQL             SynchronizeIrql,
  KINTERRUPT_MODE   InterruptMode,
  BOOLEAN           ShareVector,
  KAFFINITY         ProcessorEnableMask,
  BOOLEAN           FloatingSave
);
```

Parameters

`InterruptObject`

Pointer to the address of driver-supplied storage for a pointer to a set of interrupt objects. This pointer must be passed in subsequent calls to KeSynchronizeExecution.

`ServiceRoutine`

Pointer to the entry point for the driver-supplied InterruptService routine.

`ServiceContext`

Pointer to the driver-determined context that will be supplied to the *InterruptService* routine when it is called. The *ServiceContext* area must be in resident memory: in the device extension of a driver-created device object, in the controller extension of a driver-created controller object, or in nonpaged pool allocated by the device driver. See Providing ISR Context Information for details.

`SpinLock`

Pointer to an initialized spin lock, for which the driver supplies the storage, that will be used to synchronize access to driver-determined data shared by other driver routines. This parameter is required if the ISR handles more than one vector or if the driver has more than one ISR. Otherwise, the driver need not allocate storage for an interrupt spin lock and the input pointer is **NULL**.

`Vector`

Specifies the interrupt vector passed in the interrupt resource at the **u.Interrupt.Vector** member of CM_PARTIAL_RESOURCE_DESCRIPTOR.

`Irql`

Specifies the DIRQL passed in the interrupt resource at the **u.Interrupt.Level** member of

CM_PARTIAL_RESOURCE_DESCRIPTOR.

`SynchronizeIrql`

Specifies the DIRQL at which the ISR will run. If the ISR handles more than one interrupt vector or the driver has more than one ISR, this value must be the highest of the *Irql* values passed at **u.Interrupt.Level** in each interrupt resource. Otherwise, the *Irql* and *SynchronizeIrql* values are identical.

`InterruptMode`

Specifies whether the device interrupt is **LevelSensitive** or **Latched**.

`ShareVector`

Specifies whether the interrupt vector is sharable.

`ProcessorEnableMask`

Specifies a **KAFFINITY** value representing the set of processors on which device interrupts can occur in this platform. This value is passed in the interrupt resource at **u.Interrupt.Affinity**.

`FloatingSave`

Specifies whether to save the floating-point stack when the driver's device interrupts. For x86-based and Itanium-based platforms, this value must be set to **FALSE**. For more information about saving floating-point and MMX state, see Using Floating Point or MMX in a WDM Driver.

Return Value

IoConnectInterrupt can return one of the following NTSTATUS values:

Remarks

New drivers should use the IoConnectInterruptEx routine, which is easier to use. Drivers for devices that support message-signaled interrupts (MSI) must use **IoConnectInterruptEx**.

A PnP driver should call **IoConnectInterrupt** as part of device start-up, before it completes the PnP IRP_MN_START_DEVICE request.

When a driver receives an **IRP_MN_START_DEVICE** request, the driver receives raw and translated hardware resources in the **Parameters.StartDevice.AllocatedResources** and **Parameters.StartDevice.AllocatedResourcesTranslated** members of the IRP's IO_STACK_LOCATION structure, respectively. To connect its interrupt, the driver uses the resources at **AllocatedResourcesTranslated.List.PartialResourceList.PartialDescriptors[]**. The driver must scan the array of partial descriptors for resources of type **CmResourceTypeInterrupt**.

If the driver supplies the storage for the *SpinLock*, it must call KeInitializeSpinLock before passing its interrupt spin lock to **IoConnectInterrupt**.

On return from a successful call to **IoConnectInterrupt**, the caller's ISR can be called if interrupts are enabled on the driver's device or if *ShareVector* was set to **TRUE**. Drivers must not enable interrupts until after **IoConnectInterrupt** returns.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

WdmlibIoConnectInterruptEx

IoCopyCurrentIrpStackLocationToNext function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCopyCurrentIrpStackLocationToNext** routine copies the IRP stack parameters from the current I/O stack location to the stack location of the next-lower driver.

Syntax

```
void IoCopyCurrentIrpStackLocationToNext(
  PIRP Irp
);
```

Parameters

`Irp`

A pointer to the IRP.

Return Value

None

Remarks

A driver calls **IoCopyCurrentIrpStackLocationToNext** to copy the IRP parameters from its stack location to the next-lower driver's stack location.

After calling this routine, a driver typically sets an I/O completion routine with IoSetCompletionRoutine before passing the IRP to the next-lower driver with IoCallDriver. Drivers that pass on their IRP parameters but do not set an I/O completion routine should call IoSkipCurrentIrpStackLocation instead of this routine.

If your driver calls **IoSkipCurrentIrpStackLocation**, be careful not to modify the IO_STACK_LOCATION structure in a way that could unintentionally affect the lower driver or the system's behavior with respect to that driver. In particular, your driver should not modify the **IO_STACK_LOCATION** structure's **Parameters** union, and should not call the IoMarkIrpPending routine.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	"<=DISPATCH_LEVEL"

See Also

IO_STACK_LOCATION

IoCallDriver

IoMarkIrpPending

IoSetCompletionRoutine

IoSkipCurrentIrpStackLocation

IoCreateDevice function

1/25/2019 • 3 minutes to read • Edit Online

The **IoCreateDevice** routine creates a device object for use by a driver.

Syntax

```
NTSTATUS IoCreateDevice(
  PDRIVER_OBJECT  DriverObject,
  ULONG           DeviceExtensionSize,
  PUNICODE_STRING DeviceName,
  DEVICE_TYPE     DeviceType,
  ULONG           DeviceCharacteristics,
  BOOLEAN         Exclusive,
  PDEVICE_OBJECT  *DeviceObject
);
```

Parameters

`DriverObject`

Pointer to the driver object for the caller. Each driver receives a pointer to its driver object in a parameter to its DriverEntry routine. WDM function and filter drivers also receive a driver object pointer in their AddDevice routines.

`DeviceExtensionSize`

Specifies the driver-determined number of bytes to be allocated for the device extension of the device object. The internal structure of the device extension is driver-defined.

`DeviceName`

Optionally points to a buffer containing a null-terminated Unicode string that names the device object. The string must be a full path name. WDM filter and function drivers do not name their device objects. For more information, see Named Device Objects.

> [!ALERT] If a device name is not supplied (that is, *DeviceName* is **NULL**), the device object created by **IoCreateDevice** will not (and cannot) have a discretionary access control list (DACL) associated with it. For additional information, see Security Descriptors.

`DeviceType`

Specifies one of the system-defined FILE_DEVICE_*XXX* constants that indicate the type of device (such as FILE_DEVICE_DISK or FILE_DEVICE_KEYBOARD) or a vendor-defined value for a new type of device. For more information, see Specifying Device Types.

`DeviceCharacteristics`

Specifies one or more system-defined constants, ORed together, that provide additional information about the driver's device. For a list of possible device characteristics, see DEVICE_OBJECT. For more information about how to specify device characteristics, see Specifying Device Characteristics. Most drivers specify FILE_DEVICE_SECURE_OPEN for this parameter.

`Exclusive`

Specifies if the device object represents an exclusive device. Most drivers set this value to **FALSE**. For more information about exclusive access, see Specifying Exclusive Access to Device Objects.

`DeviceObject`

Pointer to a variable that receives a pointer to the newly created DEVICE_OBJECT structure. The **DEVICE_OBJECT** structure is allocated from nonpaged pool.

Return Value

IoCreateDevice returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure. A partial list of the failure codes returned by this function includes:

- **STATUS_INSUFFICIENT_RESOURCES**
- **STATUS_OBJECT_NAME_COLLISION**

Remarks

IoCreateDevice creates a device object and returns a pointer to the object. The caller is responsible for deleting the object when it is no longer needed by calling IoDeleteDevice.

IoCreateDevice can only be used to create an unnamed device object, or a named device object for which a security descriptor is set by an INF file. Otherwise, drivers must use IoCreateDeviceSecure to create named device objects. For more information, see Creating a Device Object. The caller is responsible for setting certain members of the returned device object. For more information, see Initializing a Device Object and the device-type-specific documentation for your device.

Be careful to specify the *DeviceType* and *DeviceCharacteristics* values in the correct parameters. Both parameters use system-defined FILE_*XXX* constants and some driver writers specify the values in the wrong parameters by mistake.

A remote file system that creates a named device object for a network redirector, and that registers using FsRtlRegisterUncProvider, must specify FILE_REMOTE_DEVICE as one of the options in the *DeviceCharacteristics* parameter of **IoCreateDevice**.

Device objects for disks, tapes, CD-ROMs, and RAM disks are given a Volume Parameter Block (VPB) that is initialized to indicate that the volume has never been mounted on the device.

If a driver's call to **IoCreateDevice** returns an error, the driver should release any resources that it allocated for that device.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"
DDI compliance rules	AddDevice, CheckDeviceObjectFlags, IrqlIoPassive1, MiniportOnlyWdmDevice, HwStorPortProhibitedDDIs

IoDeleteDevice

IoCreateFile function

1/25/2019 • 15 minutes to read • Edit Online

The **IoCreateFile** routine either causes a new file or directory to be created, or it opens an existing file, device, directory, or volume, giving the caller a handle for the file object.

Syntax

```
NTSTATUS IoCreateFile(
  PHANDLE            FileHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  PIO_STATUS_BLOCK   IoStatusBlock,
  PLARGE_INTEGER     AllocationSize,
  ULONG              FileAttributes,
  ULONG              ShareAccess,
  ULONG              Disposition,
  ULONG              CreateOptions,
  PVOID              EaBuffer,
  ULONG              EaLength,
  CREATE_FILE_TYPE   CreateFileType,
  PVOID              InternalParameters,
  ULONG              Options
);
```

Parameters

`FileHandle`

A pointer to a variable that receives the file handle if the call is successful. The driver must close the handle with ZwClose once the handle is no longer in use.

`DesiredAccess`

Specifies the ACCESS_MASK value that represents the type of access that the caller requires to the file or directory. See ZwCreateFile for a description of the possible values for this parameter.

`ObjectAttributes`

A pointer to a structure that specifies the object's attributes, which has already been initialized with InitializeObjectAttributes. If the caller is not running in the system process context, it must set the OBJ_KERNEL_HANDLE attribute for *ObjectAttributes*.

`IoStatusBlock`

A pointer to a variable that receives the final completion status and information about the requested operation. On return from **IoCreateFile**, the **Information** member contains one of the following values:

- FILE_CREATED
- FILE_OPENED
- FILE_OVERWRITTEN
- FILE_SUPERSEDED
- FILE_EXISTS
- FILE_DOES_NOT_EXIST

`AllocationSize`

Optionally specifies the initial allocation size in bytes for the file. A nonzero value has no effect unless the file is being created, overwritten, or superseded.

`FileAttributes`

Explicitly specified attributes are applied only when the file is created, superseded, or, in some cases, overwritten. By default, this value is FILE_ATTRIBUTE_NORMAL, which can be overridden by an ORed combination of one or more FILE_ATTRIBUTE_*XXX* flags, which are defined in Wdm.h. For a list of flags that can be used with **IoCreateFile**, see CreateFile in the Microsoft Windows SDK documentation.

`ShareAccess`

Specifies the type of share access that the caller would like to the file, as zero, or as one or a combination of the following:

SHAREACCESS FLAGS	MEANING
FILE_SHARE_READ	The file can be opened for read access by other threads' calls to **IoCreateFile**.
FILE_SHARE_WRITE	The file can be opened for write access by other threads' calls to **IoCreateFile**.
FILE_SHARE_DELETE	The file can be opened for delete access by other threads' calls to **IoCreateFile**.

Device and intermediate drivers usually set *ShareAccess* to zero, which gives the caller exclusive access to the open file.

`Disposition`

Specifies what to do, depending on whether the file already exists, as one of the following:

DISPOSITION VALUES	MEANING
FILE_SUPERSEDE	If the file already exists, replace it with the given file. If it does not, create the given file.
FILE_CREATE	If the file already exists, fail the request and do not create or open the given file. If it does not, create the given file.
FILE_OPEN	If the file already exists, open it instead of creating a new file. If it does not, fail the request and do not create a new file.
FILE_OPEN_IF	If the file already exists, open it. If it does not, create the given file.
FILE_OVERWRITE	If the file already exists, open it and overwrite it. If it does not, fail the request.
FILE_OVERWRITE_IF	If the file already exists, open it and overwrite it. If it does not, create the given file.

`CreateOptions`

Specifies the options to be applied when creating or opening the file, as a compatible combination of the following

flags:

CREATEOPTIONS FLAGS	MEANING
FILE_DIRECTORY_FILE	The file being created or opened is a directory file. With this flag, the *Disposition* parameter must be set to one of FILE_CREATE, FILE_OPEN, or FILE_OPEN_IF. With this flag, other compatible *CreateOptions* flags include only the following: FILE_SYNCHRONOUS_IO_ALERT, FILE_SYNCHRONOUS_IO_NONALERT, FILE_WRITE_THROUGH, FILE_OPEN_FOR_BACKUP_INTENT, and FILE_OPEN_BY_FILE_ID.
FILE_NON_DIRECTORY_FILE	The file being opened must not be a directory file or this call will fail. The file object being opened can represent a data file, a logical, virtual, or physical device, or a volume.
FILE_WRITE_THROUGH	System services, file system drivers (FSDs), and drivers that write data to the file must actually transfer the data into the file before any requested write operation is considered complete.
FILE_SEQUENTIAL_ONLY	All accesses to the file will be sequential.
FILE_RANDOM_ACCESS	Accesses to the file can be random, so no sequential read-ahead operations should be performed on the file by FSDs or the system.
FILE_NO_INTERMEDIATE_BUFFERING	The file cannot be cached or buffered in a driver's internal buffers. This flag is incompatible with the *DesiredAccess* FILE_APPEND_DATA flag.
FILE_SYNCHRONOUS_IO_ALERT	All operations on the file are performed synchronously. Any wait on behalf of the caller is subject to premature termination from alerts. This flag also causes the I/O system to maintain the file position context. If this flag is set, the *DesiredAccess* SYNCHRONIZE flag also must be set.
FILE_SYNCHRONOUS_IO_NONALERT	All operations on the file are performed synchronously. Waits in the system to synchronize I/O queuing and completion are not subject to alerts. This flag also causes the I/O system to maintain the file position context. If this flag is set, the *DesiredAccess* SYNCHRONIZE flag also must be set.
FILE_CREATE_TREE_CONNECTION	Create a tree connection for this file in order to open it over the network. This flag is irrelevant to device and intermediate drivers.
FILE_COMPLETE_IF_OPLOCKED	Complete this operation immediately with an alternate success code if the target file is oplocked, rather than blocking the caller's thread. If the file is oplocked, another caller already has access to the file over the network. This flag is irrelevant to device and intermediate drivers.
FILE_NO_EA_KNOWLEDGE	If the extended attributes on an existing file being opened indicate that the caller must understand EAs to properly interpret the file, fail this request because the caller does not understand how to deal with EAs. Device and intermediate drivers can ignore this flag.

FILE_OPEN_REPARSE_POINT	Open a file with a reparse point and bypass normal reparse point processing for the file. For more information, see the following Remarks section.
FILE_DELETE_ON_CLOSE	Delete the file when the last handle to it is passed to **ZwClose**.
FILE_OPEN_BY_FILE_ID	The file name specified in the *ObjectAttributes* parameter includes the 8-byte file reference number for the file. This number is assigned by the file system and is file-system-specific. If the file is a reparse point, the file name also includes the name of a device. Note: The FAT file system does not support FILE_OPEN_BY_FILE_ID.
FILE_OPEN_FOR_BACKUP_INTENT	The file is being opened for backup intent, hence, the system should check for certain access rights and grant the caller the appropriate accesses to the file before checking the input *DesiredAccess* against the file's security descriptor. This flag is irrelevant to device and intermediate drivers.
FILE_OPEN_REQUIRING_OPLOCK	The file is being opened and an opportunistic lock (oplock) on the file is being requested as a single atomic operation. The file system checks for oplocks before it performs the create operation, and the create operation will fail with a return code of STATUS_CANNOT_BREAK_OPLOCK if the create operation would break an existing oplock. **Note** The FILE_OPEN_REQUIRING_OPLOCK flag is available in Windows 7, Windows Server 2008 R2, and later Windows operating systems.
FILE_RESERVE_OPFILTER	This flag allows an application to request a filter opportunistic lock (oplock) to prevent other applications from getting share violations. If there are already open handles, the create request will fail with STATUS_OPLOCK_NOT_GRANTED. For more information, see the following Remarks section.

`EaBuffer`

For device and intermediate drivers, this parameter must be a **NULL** pointer.

`EaLength`

For device and intermediate drivers, this parameter must be zero.

`CreateFileType`

Drivers must set this parameter to **CreateFileTypeNone**.

`InternalParameters`

Drivers must set this parameter to **NULL**.

`Options`

Specifies options to be used during the creation of the create request. These options can be from the following list:

OPTIONS FLAGS	MEANING

IO_NO_PARAMETER_CHECKING	Indicates that the parameters for this call should not be validated before attempting to issue the create request. Driver writers should use this flag with caution as certain invalid parameters can cause a system failure. For more information, see Remarks.
IO_FORCE_ACCESS_CHECK	Indicates that the I/O manager must check the operation against the file's security descriptor. For more information, see Remarks.
IO_STOP_ON_SYMLINK	The I/O manager or the file system will return STATUS_STOPPED_ON_SYMLINK if a symbolic link is encountered while opening or creating the file.
IO_OPEN_TARGET_DIRECTORY	Open the file's parent directory.

Return Value

IoCreateFile either returns STATUS_SUCCESS or an appropriate error status. If it returns an error status, the caller can find additional information about the cause of the failure by checking the *IoStatusBlock*.

Remarks

> **NOTE**
> The **IoCreateFileEx** routine is similar to the **IoCreateFile** routine but provides greater functionality than the **IoCreateFile** routine, including access to extra create parameters (ECPs), device objects, and transaction information.

The handle obtained by **IoCreateFile** can be used by subsequent calls to manipulate data within the file or the file object's state or attributes.

There are two alternate ways to specify the name of the file to be created or opened with **IoCreateFile**:

1. As a fully qualified pathname, supplied in the **ObjectName** member of the input *ObjectAttributes*
2. As pathname relative to the directory file represented by the handle in the **RootDirectory** member of the input *ObjectAttributes*

Certain *DesiredAccess* flags and combinations of flags have the following effects:

- For a caller to synchronize an I/O completion by waiting for the returned *FileHandle*, the SYNCHRONIZE flag must be set. Otherwise, a caller that is a device or intermediate driver must synchronize an I/O completion by using an event object.
- If only the FILE_APPEND_DATA and SYNCHRONIZE flags are set, the caller can write only to the end of the file, and any offset information about writes to the file is ignored. However, the file will automatically be extended as necessary for this type of write operation.
- Setting the FILE_WRITE_DATA flag for a file also allows writes beyond the end of the file to occur. The file is automatically extended for this type of write, as well.
- If only the FILE_EXECUTE and SYNCHRONIZE flags are set, the caller cannot directly read or write any data in the file using the returned *FileHandle*: that is, all operations on the file occur through the system pager in response to instruction and data accesses. Device and intermediate drivers should not set the FILE_EXECUTE flag in *DesiredAccess*.

The *ShareAccess* parameter determines whether separate threads can access the same file, possibly simultaneously.

Provided that both file openers have the privilege to access a file in the specified manner, the file can be successfully opened and shared. If the original caller of **IoCreateFile** does not specify FILE_SHARE_READ, FILE_SHARE_WRITE, or FILE_SHARE_DELETE, no other open operations can be performed on the file: that is, the original caller is given exclusive access to the file.

In order for a shared file to be successfully opened, the requested *DesiredAccess* to the file must be compatible with both the *DesiredAccess* and *ShareAccess* specifications of all preceding opens that have not yet been released with **ZwClose**. That is, the *DesiredAccess* specified to **IoCreateFile** for a given file must not conflict with the accesses that other openers of the file have disallowed.

The *Disposition* value FILE_SUPERSEDE requires that the caller have DELETE access to a existing file object. If so, a successful call to **IoCreateFile** with FILE_SUPERSEDE on an existing file effectively deletes that file, and then recreates it. This implies that, if the file has already been opened by another thread, it opened the file by specifying a *ShareAccess *parameter with the FILE_SHARE_DELETE flag set. Note that this type of disposition is consistent with the POSIX style of overwriting files.

The *Disposition* values FILE_OVERWRITE_IF and FILE_SUPERSEDE are similar. If **IoCreateFile** is called with a existing file and either of these *Disposition* values, the file will be replaced.

Overwriting a file is semantically equivalent to a supersede operation, except for the following:

- The caller must have write access to the file, rather than delete access. This implies that, if the file has already been opened by another thread, it opened the file with the FILE_SHARE_WRITE flag set in the input *ShareAccess*.
- The specified file attributes are logically ORed with those already on the file. This implies that, if the file has already been opened by another thread, a subsequent caller of **IoCreateFile** cannot disable existing *FileAttributes* flags but can enable additional flags for the same file.

The *CreateOptions* FILE_DIRECTORY_FILE value specifies that the file to be created or opened is a directory file. When a directory file is created, the file system creates an appropriate structure on the disk to represent an empty directory for that particular file system's on-disk structure. If this option was specified and the given file to be opened is not a directory file, or if the caller specified an inconsistent *CreateOptions* or *Disposition* value, the call to **IoCreateFile** will fail.

The *CreateOptions* FILE_NO_INTERMEDIATE_BUFFERING flag prevents the file system from performing any intermediate buffering on behalf of the caller. Specifying this value places certain restrictions on the caller's parameters to the **Zw*Xxx*File** routines, including the following:

- Any optional *ByteOffset* passed to ZwReadFile or ZwWriteFile must be an integral of the sector size.
- The *Length* passed to **ZwReadFile** or **ZwWriteFile**, must be an integral of the sector size. Note that specifying a read operation to a buffer whose length is exactly the sector size might result in a lesser number of significant bytes being transferred to that buffer if the end of the file was reached during the transfer.
- Buffers must be aligned in accordance with the alignment requirement of the underlying device. This information can be obtained by calling **IoCreateFile** to get a handle for the file object that represents the physical device, and, then, calling ZwQueryInformationFile with that handle. For a list of the system FILE_*XXX*_ALIGNMENT values, see DEVICE_OBJECT.
- Calls to ZwSetInformationFile with the *FileInformationClass* parameter set to **FilePositionInformation** must specify an offset that is an integral of the sector size.

The *CreateOptions* FILE_SYNCHRONOUS_IO_ALERT and FILE_SYNCHRONOUS_IO_NONALERT, which are mutually exclusive as their names suggest, specify that all I/O operations on the file are to be synchronous as long as they occur through the file object referred to by the returned *FileHandle*. All I/O on such a file is serialized across all threads using the returned handle. With either of these *CreateOptions*, the *DesiredAccess* SYNCHRONIZE flag must be set so that the I/O manager will use the file object as a synchronization object. With

either of these *CreateOptions* set, the I/O manager maintains the "file position context" for the file object, an internal, current file position offset. This offset can be used in calls to **ZwReadFile** and **ZwWriteFile**. Its position also can be queried or set with **ZwQueryInformationFile** and **ZwSetInformationFile**.

If the *CreateOptions* FILE_OPEN_REPARSE_POINT flag is not specified and **IoCreateFile** attempts to open a file with a reparse point, normal reparse point processing occurs for the file. If, on the other hand, the FILE_OPEN_REPARSE_POINT flag is specified, normal reparse processing does not occur and **IoCreateFile** attempts to directly open the reparse point file. In either case, if the open operation was successful, **IoCreateFile** returns STATUS_SUCCESS; otherwise, the routine returns an NTSTATUS error code. **IoCreateFile** never returns STATUS_REPARSE.

The *CreateOptions* FILE_OPEN_REQUIRING_OPLOCK flag eliminates the time between when you open the file and request an oplock that could potentially enable a third party to open the file and get a sharing violation. An application can use the FILE_OPEN_REQUIRING_OPLOCK flag on **IoCreateFile** and then request any oplock. This ensures that an oplock owner will be notified of any later open request that causes a sharing violation.

In Windows 7, if other handles exist on the file when an application uses the FILE_OPEN_REQUIRING_OPLOCK flag, the create operation will fail with STATUS_OPLOCK_NOT_GRANTED. This restriction no longer exists starting with Windows 8.

If this create operation would break an oplock that already exists on the file, then setting the FILE_OPEN_REQUIRING_OPLOCK flag will cause the create operation to fail with STATUS_CANNOT_BREAK_OPLOCK. The existing oplock will not be broken by this create operation.

An application that uses the FILE_OPEN_REQUIRING_OPLOCK flag must request an oplock after this call succeeds, or all subsequent attempts to open the file will be blocked without the benefit of normal oplock processing. Similarly, if this call succeeds but the subsequent oplock request fails, an application that uses this flag must close its handle after it detects that the oplock request has failed.

> **NOTE**
>
> The FILE_OPEN_REQUIRING_OPLOCK flag is available in Windows 7, Windows Server 2008 R2 and later versions of Windows. The Microsoft file systems that implement this flag in Windows 7 are NTFS, FAT, and exFAT.

The *CreateOptions* flag, FILE_RESERVE_OPFILTER, allows an application to request a level 1, batch, or filter oplock to prevent other applications from getting share violations. However, FILE_RESERVE_OPFILTER is only useful for filter oplocks. To use it, you must follow these steps:

1. Issue a create request with *CreateOptions* of FILE_RESERVE_OPFILTER, *DesiredAccess* of exactly FILE_READ_ATTRIBUTES, and *ShareAccess* of exactly FILE_SHARE_READ | FILE_SHARE_WRITE | FILE_SHARE_DELETE.
   - If there are already open handles, the create request fails with STATUS_OPLOCK_NOT_GRANTED, and the next requested oplock also fails.
   - If you open with more access or less sharing will also cause a failure of STATUS_OPLOCK_NOT_GRANTED.
2. If the create request succeeds, request an oplock.
3. Open another handle to the file to do I/O.

Step 3 makes this practical only for filter oplocks. The handle opened in step 3 can have a *DesiredAccess* that contains a maximum of FILE_READ_ATTRIBUTES | FILE_WRITE_ATTRIBUTES | FILE_READ_DATA | FILE_READ_EA | FILE_EXECUTE | SYNCHRONIZE | READ_CONTROL and still not break a filter oplock. However, any *DesiredAccess* greater than FILE_READ_ATTRIBUTES | FILE_WRITE_ATTRIBUTES | SYNCHRONIZE will break a level 1 or batch oplock and make the FILE_RESERVE_OPFILTER flag useless for those oplock types.

The *Options* IO_NO_PARAMETER_CHECKING flag can be useful if a driver is issuing a kernel-mode create

request on behalf of an operation initiated by a user-mode application. Because the request occurs within a user-mode context, the I/O manager, by default, probes the supplied parameter values, which can cause an access violation if the parameters are kernel-mode addresses. This flag enables the caller to override this default behavior and avoid the access violation.

For create requests originating in user mode, if the driver sets both IO_NO_PARAMETER_CHECKING and IO_FORCE_ACCESS_CHECK in the *Options* parameter of **IoCreateFile** then it should also set OBJ_FORCE_ACCESS_CHECK in the *ObjectAttributes* parameter. For info on this flag, see the **Attributes** member of OBJECT_ATTRIBUTES.

NTFS is the only Microsoft file system that implements FILE_RESERVE_OPFILTER.

Driver routines that run in a process context other than that of the system process must set the OBJ_KERNEL_HANDLE attribute for the *ObjectAttributes* parameter of **IoCreateFile**. This restricts the use of the handle returned by **IoCreateFile** to processes running only in kernel mode. Otherwise, the handle can be accessed by the process in whose context the driver is running. Drivers can call InitializeObjectAttributes to set the OBJ_KERNEL_HANDLE attribute as follows.

```
InitializeObjectAttributes(&amp;ObjectAttributes, NULL, OBJ_KERNEL_HANDLE, NULL, NULL);
```

ZwCreateFile

IoCreateNotificationEvent function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCreateNotificationEvent** routine creates or opens a named notification event used to notify one or more threads of execution that an event has occurred.

Syntax

```
PKEVENT IoCreateNotificationEvent(
  PUNICODE_STRING EventName,
  PHANDLE         EventHandle
);
```

Parameters

`EventName`

Pointer to a buffer containing a null-terminated Unicode string that names the event.

`EventHandle`

Pointer to a location in which to return a handle for the event object. In Windows Server 2003 and later versions of Windows, the returned handle is a kernel handle.

Return Value

IoCreateNotificationEvent returns a pointer to the created or opened event object or **NULL** if the event object could not be created or opened.

Remarks

IoCreateNotificationEvent creates and opens the event object if it does not already exist. **IoCreateNotificationEvent** sets the state of a new notification event to Signaled. If the event object already exists, **IoCreateNotificationEvent** just opens the event object.

When a notification event is set to the Signaled state it remains in that state until it is explicitly cleared.

Notification events, like synchronization events, are used to coordinate execution. Unlike a synchronization event, a notification event is not auto-resetting. Once a notification event is in the Signaled state, it remains in that state until it is explicitly reset (with a call to KeClearEvent or KeResetEvent).

To synchronize on a notification event:

1. Open the notification event with **IoCreateNotificationEvent**. Identify the event with the *EventName* string.
2. Wait for the event to be signaled by calling KeWaitForSingleObject with the PKEVENT returned by **IoCreateNotificationEvent**. More than one thread of execution can wait for a given notification event. To poll instead of stall, specify a *Timeout* of zero to **KeWaitForSingleObject**.
3. Close the handle to the notification event with ZwClose when access to the event is no longer needed.

Sharing event objects between user mode and kernel mode requires care. There are two main methods for sharing event objects:

- The user-mode application creates the event object and passes a handle to the object to the driver by sending an IOCTL to the driver. The driver must handle the IOCTL in the context of the process that created the event object and must validate the handle by calling ObReferenceObjectByHandle. This method is the recommended method for sharing event objects between user and kernel modes.
- The driver creates a named event object in the \BaseNamedObjects object directory. You can open a kernel-mode event named \BaseNamedObjects<i>Xxx in user mode under the name *Xxx*. Note that security settings can prevent an application from opening the event. For more information, see the OpenEvent Fails in a Non-Administrator Account KB article. The \BaseNamedObjects object directory is not created until the Microsoft Win32 subsystem initializes, so drivers that are loaded at boot time cannot create event objects in the \BaseNamedObjects directory in their DriverEntry routines.

For more information about events, see Event Objects.

IoCreateSymbolicLink function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCreateSymbolicLink** routine sets up a symbolic link between a device object name and a user-visible name for the device.

Syntax

```
NTSTATUS IoCreateSymbolicLink(
  PUNICODE_STRING SymbolicLinkName,
  PUNICODE_STRING DeviceName
);
```

Parameters

`SymbolicLinkName`

Pointer to a buffered Unicode string that is the user-visible name.

`DeviceName`

Pointer to a buffered Unicode string that is the name of the driver-created device object.

Return Value

IoCreateSymbolicLink returns STATUS_SUCCESS if the symbolic link object was created.

Remarks

WDM drivers do not name device objects and therefore should not use this routine. Instead, a WDM driver should call IoRegisterDeviceInterface to set up a symbolic link.

For more information about when to use **IoCreateSymbolicLink**, see Named Device Objects.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoCreateSynchronizationEvent function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCreateSynchronizationEvent** routine creates or opens a named synchronization event for use in serialization of access to hardware between two otherwise unrelated drivers.

Syntax

```
PKEVENT IoCreateSynchronizationEvent(
  PUNICODE_STRING EventName,
  PHANDLE         EventHandle
);
```

Parameters

`EventName`

Pointer to a buffer containing a null-terminated Unicode string that names the event.

`EventHandle`

Pointer to a location in which to return a handle for the event object. In Windows Server 2003 and later versions of Windows, the returned handle is a kernel handle.

Return Value

IoCreateSynchronizationEvent returns a pointer to the created or opened event object or **NULL** if the event object could not be created or opened.

Remarks

The event object is created if it does not already exist. **IoCreateSynchronizationEvent** sets the state of a new synchronization event to Signaled. If the event object already exists, it is simply opened. The pair of drivers that use a synchronization event call KeWaitForSingleObject with the PKEVENT pointer returned by this routine.

When a synchronization event is set to the Signaled state, a single thread of execution that was waiting for the event is released, and the event is automatically reset to the Not-Signaled state.

To release the event, a driver calls ZwClose with the event handle.

Sharing event objects between user mode and kernel mode requires care. There are two main methods for sharing event objects:

- The user-mode application creates the event object and passes a handle to the object to the driver by sending an IOCTL to the driver. The driver must handle the IOCTL in the context of the process that created the event object and must validate the handle by calling ObReferenceObjectByHandle. This method is the recommended method for sharing event objects between user and kernel modes.
- The driver creates a named event object in the \BaseNamedObjects object directory. You can open a kernel-mode event named \BaseNamedObjects<i>Xxx in user mode under the name *Xxx*. Note that security settings can prevent an application from opening the event. For more information, see the OpenEvent Fails in a Non-Administrator Account KB article. The \BaseNamedObjects object directory is not created until the Microsoft

Win32 subsystem initializes, so drivers that are loaded at boot time cannot create event objects in the \BaseNamedObjects directory in their DriverEntry routines

For more information about events, see Event Objects.

ZwClose

IoCreateSystemThread function

1/25/2019 • 3 minutes to read • Edit Online

The **IoCreateSystemThread** routine creates a system thread that executes in kernel mode, and supplies a handle for the thread.

Syntax

```
NTSTATUS IoCreateSystemThread(
  PVOID              IoObject,
  PHANDLE            ThreadHandle,
  ULONG              DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  HANDLE             ProcessHandle,
  PCLIENT_ID         ClientId,
  PKSTART_ROUTINE    StartRoutine,
  PVOID              StartContext
);
```

Parameters

`IoObject`

A pointer to the DEVICE_OBJECT or DRIVER_OBJECT to associate with the created thread. **IoCreateSystemThread** takes a counted reference to this object. The I/O manager later releases this reference when the thread exits. For more information, see Remarks.

`ThreadHandle`

A pointer to a variable to which the routine writes the kernel handle for the created thread. When the handle is no longer needed, the driver must close the handle by calling the ZwClose routine.

`DesiredAccess`

The ACCESS_MASK value that represents the types of access the caller requests to the created thread.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the thread object's attributes. The OBJ_PERMANENT, OBJ_EXCLUSIVE, and OBJ_OPENIF attributes are not valid attributes for a thread object. If the caller is not running in the system process context, it must set the OBJ_KERNEL_HANDLE attribute in the **OBJECT_ATTRIBUTES** structure.

`ProcessHandle`

An open handle for the process in whose address space the created thread is to run. The caller's thread must have PROCESS_CREATE_THREAD access to this process. If this parameter is **NULL**, the thread will be created in the initial system process. This parameter should be **NULL** for a driver-created thread. Use the **NtCurrentProcess** macro, defined in the Wdm.h header file, to specify the current process.

`ClientId`

A pointer to a structure to which the routine writes the client identifier for the created thread. This parameter should be **NULL** for a driver-created thread.

`StartRoutine`

A pointer to a ThreadStart routine that is the entry point for the created thread.

`StartContext`

A context pointer that is passed as the *StartContext* parameter to the ThreadStart routine when the created thread starts to run.

Return Value

IoCreateSystemThread returns STATUS_SUCCESS if the new thread was successfully created. Possible return values include the following error status codes.

RETURN CODE	DESCRIPTION
STATUS_INVALID_HANDLE	*ProcessHandle* is not a valid process handle.
STATUS_PROCESS_IS_TERMINATING	The process specified by *ProcessHandle* is terminating.
STATUS_INSUFFICIENT_RESOURCES	Insufficient system resources are available to perform the requested operation.

Remarks

Starting with Windows 8, a driver can call **IoCreateSystemThread** to create a device-dedicated thread. This routine creates a new system thread that has no thread environment block (TEB) or user-mode context, and runs only in kernel mode.

Typically, the driver calls **IoCreateSystemThread** either when it starts the device, or when the driver's *Dispatch*Xxx routines start to receive I/O requests. For example, a driver might call this routine to create a thread when a *Dispatch*Xxx routine receives an asynchronous device control request.

If the *ProcessHandle* parameter is **NULL**, the created thread is associated with the system process. Such a thread continues running until either the system is shut down or the thread exits.

Driver routines that run in a process context other than that of the system process must set the OBJ_KERNEL_HANDLE attribute for the *ObjectAttributes* parameter of **IoCreateSystemThread**. This attribute restricts the use of the handle returned by **IoCreateSystemThread** to processes running in kernel mode. Otherwise, the thread handle could be accessed by the process in whose context the driver is running. Drivers can call the InitializeObjectAttributes macro to set the OBJ_KERNEL_HANDLE attribute in the object attributes, as shown in the following code example.

```
OBJECT_ATTRIBUTES ObjectAttributes;

InitializeObjectAttributes(&ObjectAttributes, NULL, OBJ_KERNEL_HANDLE, NULL, NULL);
```

IoCreateSystemThread is similar to the PsCreateSystemThread routine, but has an additional parameter, *IoObject*, which is a pointer to the caller's driver object or device object. **IoCreateSystemThread** uses this parameter to ensure that the driver cannot unload while the created thread exists. Before scheduling *StartRoutine* to run in this thread, **IoCreateSystemThread** takes a counted reference to the *IoObject* object. The I/O manager releases this reference after the created thread exits. Thus, this object persists for the lifetime of the created thread.

In contrast to a system thread that is created by the PsCreateSystemThread routine, a thread created by **IoCreateSystemThread** does not call the PsTerminateSystemThread routine to terminate itself. Instead, the I/O manager calls **PsTerminateSystemThread** on behalf of the created thread when the thread exits.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IoCreateUnprotectedSymbolicLink function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCreateUnprotectedSymbolicLink** routine sets up an unprotected symbolic link between a device object name and a corresponding Win32-visible name.

Syntax

```
NTSTATUS IoCreateUnprotectedSymbolicLink(
  PUNICODE_STRING SymbolicLinkName,
  PUNICODE_STRING DeviceName
);
```

Parameters

`SymbolicLinkName`

Supplies the symbolic link name as a Unicode string.

`DeviceName`

Supplies the name of the device object to which the symbolic link name refers.

Return Value

IoCreateUnprotectedSymbolicLink returns the final status of the operation.

Remarks

WDM drivers do not name device objects and therefore should not use this routine. Instead, a WDM driver should call IoRegisterDeviceInterface to set up a symbolic link.

IoCreateUnprotectedSymbolicLink can be used by drivers if the user needs to be able to manipulate the symbolic link. For example, the parallel and serial drivers create unprotected symbolic links for LPTx and COMx, so that users can manipulate and reassign them by using the MODE command.

In general, drivers should call this routine instead of IoCreateSymbolicLink if a protected subsystem lets end users change what a named device references as, for example, when using LPT1 to access a network printer.

For more information about when to use **IoCreateSymbolicLink**, see Named Device Objects.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

IoCsqInitialize function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCsqInitialize** routine initializes the driver's cancel-safe IRP queue dispatch table.

Syntax

```
NTSTATUS IoCsqInitialize(
  PIO_CSQ                      Csq,
  PIO_CSQ_INSERT_IRP           CsqInsertIrp,
  PIO_CSQ_REMOVE_IRP           CsqRemoveIrp,
  PIO_CSQ_PEEK_NEXT_IRP        CsqPeekNextIrp,
  PIO_CSQ_ACQUIRE_LOCK         CsqAcquireLock,
  PIO_CSQ_RELEASE_LOCK         CsqReleaseLock,
  PIO_CSQ_COMPLETE_CANCELED_IRP CsqCompleteCanceledIrp
);
```

Parameters

`Csq`

Pointer to the IO_CSQ structure to be initialized by **IoCsqInitialize**.

`CsqInsertIrp`

Pointer to the driver-defined CsqInsertIrp function for the driver's cancel-safe IRP queue.

`CsqRemoveIrp`

Pointer to the driver-defined CsqRemoveIrp function for the driver's cancel-safe IRP queue.

`CsqPeekNextIrp`

Pointer to the driver-defined CsqPeekNextIrp function for the driver's cancel-safe IRP queue.

`CsqAcquireLock`

Pointer to the driver-defined CsqAcquireLock function for the driver's cancel-safe IRP queue.

`CsqReleaseLock`

Pointer to the driver-defined CsqReleaseLock function for the driver's cancel-safe IRP queue.

`CsqCompleteCanceledIrp`

Pointer to the driver-defined CsqCompleteCanceledIrp function for the driver's cancel-safe IRP queue.

Return Value

This routine returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure.

Remarks

The **IoCsqInitialize** routine initializes an IO_CSQ structure that describes a driver's cancel-safe IRP queue. Drivers can also use IoCsqInitializeEx to create an IRP queue with extended capabilities. For more information, see Cancel-

Safe IRP Queues.

Note that **IoCsq*Xxx*** routines use the **DriverContext**[3] member of the IRP to hold IRP context information. Drivers that use these routines to queue IRPs must leave that member unused.

Requirements

Minimum supported client	Available in Windows XP and later versions of the Windows operating system. Drivers that must also work for Windows 2000 and Windows 98/Me can instead link to Csq.lib to use the routine.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

IoCsqInitializeEx function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCsqInitializeEx** routine initializes the dispatch table for a cancel-safe IRP queue.

Syntax

```
NTSTATUS IoCsqInitializeEx(
  PIO_CSQ                      Csq,
  PIO_CSQ_INSERT_IRP_EX        CsqInsertIrp,
  PIO_CSQ_REMOVE_IRP           CsqRemoveIrp,
  PIO_CSQ_PEEK_NEXT_IRP        CsqPeekNextIrp,
  PIO_CSQ_ACQUIRE_LOCK         CsqAcquireLock,
  PIO_CSQ_RELEASE_LOCK         CsqReleaseLock,
  PIO_CSQ_COMPLETE_CANCELED_IRP CsqCompleteCanceledIrp
);
```

Parameters

`Csq`

Pointer to the IO_CSQ structure to be initialized by **IoCsqInitializeEx**.

`CsqInsertIrp`

Pointer to the driver-defined CsqInsertIrpEx function for the driver's cancel-safe IRP queue.

`CsqRemoveIrp`

Pointer to the driver-defined CsqRemoveIrp function for the driver's cancel-safe IRP queue.

`CsqPeekNextIrp`

Pointer to the driver-defined CsqPeekNextIrp function for the driver's cancel-safe IRP queue.

`CsqAcquireLock`

Pointer to the driver-defined CsqAcquireLock function for the driver's cancel-safe IRP queue.

`CsqReleaseLock`

Pointer to the driver-defined CsqReleaseLock function for the driver's cancel-safe IRP queue.

`CsqCompleteCanceledIrp`

Pointer to the driver-defined CsqCompleteCanceledIrp function for the driver's cancel-safe IRP queue.

Return Value

IoCsqInitializeEx returns STATUS_SUCCESS on success, or the appropriate error code on failure.

Remarks

The IoCsqInitialize and **IoCsqInitializeEx** routines initialize an IO_CSQ structure that describes a driver's cancel-safe IRP queue. You can use **IoCsqInitializeEx** to specify an IRP queue with extended capabilities instead of one

specified by **IoCsqInitialize**:

- The driver implements a CsqInsertIrpEx routine rather than a CsqInsertIrp routine. *CsqInsertIrpEx* takes an additional parameter, *InsertContext*. When the driver calls IoCsqInsertIrpEx to insert the IRP, it specifies the value that is passed as *InsertContext*.
- **IoCsqInsertIrpEx** returns the return value of *CsqInsertIrpEx*. Drivers can use the return value to indicate whether an insert operation succeeded or failed.

Otherwise, the effect of **IoCsqInitializeEx** is identical to that of **IoCsqInitialize**. For more information, see Cancel-Safe IRP Queues.

Note that **IoCsq*Xxx*** routines use the **DriverContext**[3] member of the IRP to hold IRP context information. Drivers that use these routines to queue IRPs must leave that member unused.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of the Windows operating system. The routine is also available in the Csq.lib library that ships with the Windows Driver Kit (WDK) and the Driver Development Kit (DDK) for Windows Server 2003. Drivers that must also work on Windows XP, Windows 2000, and Windows 98/Me can instead link to Csq.lib to use the routine.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

IoCsqInsertIrp function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCsqInsertIrp** routine inserts an IRP in the driver's cancel-safe IRP queue.

Syntax

```
void IoCsqInsertIrp(
  PIO_CSQ             Csq,
  PIRP                Irp,
  PIO_CSQ_IRP_CONTEXT Context
);
```

Parameters

`Csq`

Pointer to the IO_CSQ structure for the driver's cancel-safe IRP queue. This structure must have been initialized by IoCsqInitialize or IoCsqInitializeEx.

`Irp`

Pointer to the IRP to be queued.

`Context`

Pointer to an IO_CSQ_IRP_CONTEXT structure. **IoCsqInsertIrp** initializes this structure with context information for the inserted IRP. The driver passes this value to IoCsqRemoveIrp to delete the IRP from the queue. *Context* can be **NULL** if the driver will not use **IoCsqRemoveIrp** to remove this IRP from the queue.

Return Value

None

Remarks

IoCsqInsertIrp uses the queue's dispatch routines to insert the IRP. The **IoCsqInsertIrp** routine:

1. Calls the queue's CsqAcquireLock routine to lock the queue.
2. Calls the queue's CsqInsertIrp routine to insert the IRP.
3. Marks the IRP as pending.
4. Calls the queue's CsqReleaseLock routine to unlock the queue.

If the IRP to be inserted has already been canceled, **IoCsqInsertIrp** does not attempt to insert the IRP into the queue.

Drivers can also use IoCsqInsertIrpEx to insert an IRP into the queue. For a queue that is specified by IoCsqInitializeEx, **IoCsqInsertIrpEx** provides additional capabilities. For more information, see Cancel-Safe IRP Queues.

Note that the **IoCsq*Xxx*** routines use the **DriverContext**[3] member of the IRP to hold IRP context information. Drivers that use these routines to queue IRPs must leave that member unused.

Callers of **IoCsqInsertIrp** must be running at an IRQL <= DISPATCH_LEVEL. The driver's callback routines must work correctly at that IRQL.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows. Drivers that must also work in Windows 2000 and Windows 98/Me can instead link to Csq.lib to use the routine.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

IoCsqInsertIrpEx function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCsqInsertIrpEx** routine inserts an IRP into the driver's cancel-safe IRP queue.

Syntax

```
NTSTATUS IoCsqInsertIrpEx(
  PIO_CSQ             Csq,
  PIRP                Irp,
  PIO_CSQ_IRP_CONTEXT Context,
  PVOID               InsertContext
);
```

Parameters

`Csq`

Pointer to the IO_CSQ structure for the driver's cancel-safe IRP queue. This structure must have been initialized by IoCsqInitialize or IoCsqInitializeEx.

`Irp`

Pointer to the IRP to be queued.

`Context`

Pointer to an IO_CSQ_IRP_CONTEXT structure. **IoCsqInsertIrpEx** initializes this structure with context information for the inserted IRP. The driver passes this value to IoCsqRemoveIrp to delete the IRP from the queue. *Context* can be **NULL** if the driver will not use **IoCsqRemoveIrp** to remove this IRP from the queue.

`InsertContext`

Pointer to a driver-defined context value. This parameter is passed to the driver's CsqInsertIrpEx routine, if it has one. Otherwise, this parameter is ignored.

Return Value

If the *Csq* parameter was initialized with IoCsqInitialize, **IoCsqInsertIrpEx** always returns STATUS_SUCCESS. If *Csq* was initialized with **IoCsqInitializeEx**, **IoCsqInsertIrpEx** returns the value that was returned by the driver's CsqInsertIrpEx routine.

Remarks

IoCsqInsertIrpEx uses the queue's dispatch routines to insert the IRP. The **IoCsqInsertIrpEx** routine:

1. Calls the queue's CsqAcquireLock routine to lock the queue.
2. If the queue's IO_CSQ structure was initialized by IoCsqInitialize, **IoCsqInsertIrpEx** calls the queue's CsqInsertIrp routine to insert the IRP. If the queue's **IO_CSQ** structure was initialized by IoCsqInitializeEx, **IoCsqInsertIrpEx** calls the queue's CsqInsertIrpEx routine to insert the IRP, and passes the *InsertContext* parameter as the *InsertContext* parameter of *CsqInsertIrpEx*.

3. Calls the queue's CsqReleaseLock routine to unlock the queue.

If the IRP to be inserted has already been canceled, **IoCsqInsertIrpEx** does not attempt to insert the IRP into the queue.

For more information, see Cancel-Safe IRP Queues.

Note that **IoCsq*Xxx*** routines use the **DriverContext**[3] member of the IRP to hold IRP context information. Drivers that use these routines to queue IRPs must leave that member unused.

Callers of **IoCsqInsertIrpEx** must be running at an IRQL <= DISPATCH_LEVEL. The driver's callback routines must work correctly at this IRQL.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of the Windows operating system. The routine is also available in the Csq.lib library that ships with the Windows Driver Kit (WDK) and the Driver Development Kit (DDK) for Windows Server 2003. Drivers that must also work for on Windows XP, Windows 2000, and Windows 98/Me can instead link to Csq.lib to use the routine.

IoCsqRemoveIrp function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCsqRemoveIrp** routine removes a particular IRP from the queue.

Syntax

```
PIRP IoCsqRemoveIrp(
  PIO_CSQ            Csq,
  PIO_CSQ_IRP_CONTEXT Context
);
```

Parameters

`Csq`

Pointer to the IO_CSQ structure for the driver's cancel-safe IRP queue. This structure must have been initialized by IoCsqInitialize or IoCsqInitializeEx.

`Context`

Pointer to the IO_CSQ_IRP_CONTEXT structure that identifies the IRP to remove. The **IO_CSQ_IRP_CONTEXT** structure is initialized by IoCsqInsertIrp or IoCsqInsertIrpEx when the IRP is first inserted in the queue.

Return Value

This routine returns a pointer to the IRP that was removed from the queue, or **NULL** if that IRP has been canceled.

Remarks

IoCsqRemoveIrp uses the queue's dispatch routines to remove the IRP. The **IoCsqRemoveIrp** routine:

1. Calls the queue's CsqAcquireLock routine to lock the queue.
2. Uses the *IrpContext* parameter to determine which IRP to remove, and calls the queue's CsqRemoveIrp routine to remove that IRP.
3. Calls the queue's CsqReleaseLock routine to unlock the queue.

Drivers can use the IoCsqRemoveNextIrp routine to remove an IRP that matches a specific criterion. For more information, see Cancel-Safe IRP Queues.

Note that **IoCsq*Xxx*** routines use the **DriverContext[**3**]** member of the IRP to hold IRP context information. Drivers that use these routines to queue IRPs must leave that member unused.

Callers of **IoCsqRemoveIrp** must be running at an IRQL <= DISPATCH_LEVEL. The driver's callback routines must work correctly at that IRQL.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows. Drivers that must also work in Windows 2000 and Windows 98/Me can instead link to Csq.lib to use the routine.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IoCsqRemoveNextIrp function

1/25/2019 • 2 minutes to read • Edit Online

The **IoCsqRemoveNextIrp** routine removes the next matching IRP in the queue.

Syntax

```
PIRP IoCsqRemoveNextIrp(
  PIO_CSQ Csq,
  PVOID   PeekContext
);
```

Parameters

`Csq`

Pointer to the driver's dispatch table for cancel-safe IRP queues. The dispatch table must be initialized by IoCsqInitialize.

`PeekContext`

A pointer to a driver-defined context value. **IoCsqRemoveNextIrp** passes this parameter to the driver's CsqPeekNextIrp routine. For more information, see the following Remarks section.

Return Value

This routine returns a pointer to the next matching IRP in the queue, or **NULL** if no more IRPs are available. The routine only returns IRPs that have not yet been canceled.

Remarks

IoCsqRemoveNextIrp uses the queue's dispatch routines to remove the IRP. The **IoCsqRemoveNextIrp** routine:

1. Calls the queue's CsqAcquireLock routine to lock the queue.
2. Calls the queue's CsqPeekNextIrp routine to find the next matching IRP in the queue. **IoCsqRemoveNextIrp** passes the value of the *PeekContext* parameter as the *PeekContext* parameter of *CsqPeekNextIrp*. *CsqPeekNextIrp* returns a pointer to the next matching IRP, or **NULL** if there is no matching IRP.
3. If the return value of *CsqPeekNextIrp* is non-**NULL**, **IoCsqRemoveNextIrp** calls the queue's CsqRemoveIrp routine to remove the IRP.
4. Calls the queue's CsqReleaseLock routine to unlock the queue.

For more information, see Cancel-Safe IRP Queues.

Note that **IoCsq*Xxx*** routines use the **DriverContext**[3] member of the IRP to hold IRP context information. Drivers that use these routines to queue IRPs must leave that member unused.

Callers of **IoCsqRemoveNextIrp** must be running at an IRQL <= DISPATCH_LEVEL. The driver's callback routines must work correctly at that IRQL.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows. Drivers that must also work on Windows 2000 and Windows 98/Me can instead link to Csq.lib to use the routine.
Target Platform	Universal

IoDeleteDevice function

1/25/2019 • 2 minutes to read • Edit Online

The **IoDeleteDevice** routine removes a device object from the system, for example, when the underlying device is removed from the system.

Syntax

```
void IoDeleteDevice(
  PDEVICE_OBJECT DeviceObject
);
```

Parameters

`DeviceObject`

Pointer to the device object to be deleted.

Return Value

None

Remarks

When handling a PnP IRP_MN_REMOVE_DEVICE request, a PnP driver calls **IoDeleteDevice** to delete any associated device objects. See Handling an IRP_MN_REMOVE_DEVICE Request for details.

A legacy driver should call this routine when it is being unloaded or when its DriverEntry routine encounters a fatal initialization error, such as being unable to properly initialize a physical device. This routine also is called when a driver reconfigures its devices dynamically. For example, a disk driver called to repartition a disk would call **IoDeleteDevice** to tear down the device objects representing partitions to be replaced.

A driver must release certain resources for which the driver supplied storage in its device extension before it calls **IoDeleteDevice**. For example, if the driver stores the pointer to its interrupt object(s) in the device extension, it must call IoDisconnectInterrupt before calling **IoDeleteDevice**.

A driver can call **IoDeleteDevice** only once for a given device object.

When a driver calls **IoDeleteDevice**, the I/O manager deletes the target device object if there are no outstanding references to it. However, if any outstanding references remain, the I/O manager marks the device object as "delete pending" and deletes the device object when the references are released.

Requirements

Minimum supported client	Available starting with Windows 2000.

IoCreateDevice

IoDisconnectInterrupt

IoDeleteSymbolicLink function

1/25/2019 • 2 minutes to read • Edit Online

The **IoDeleteSymbolicLink** routine removes a symbolic link from the system.

Syntax

```
NTSTATUS IoDeleteSymbolicLink(
  PUNICODE_STRING SymbolicLinkName
);
```

Parameters

`SymbolicLinkName`

Pointer to a buffered Unicode string that is the user-visible name for the symbolic link.

Return Value

IoDeleteSymbolicLink returns STATUS_SUCCESS if the symbolic link object is deleted.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoCreateSymbolicLink

IoCreateUnprotectedSymbolicLink

IoDeassignArcName

IoDetachDevice function

1/25/2019 • 2 minutes to read • Edit Online

The **IoDetachDevice** routine releases an attachment between the caller's device object and a lower driver's device object.

Syntax

```
void IoDetachDevice(
  PDEVICE_OBJECT TargetDevice
);
```

Parameters

`TargetDevice`

Pointer to the lower driver's device object. The caller previously called IoAttachDevice or IoAttachDeviceToDeviceStack successfully to get this pointer.

Return Value

None

Remarks

IoDetachDevice decrements the reference count of the *TargetDevice* object. If the reference count goes to zero and the lower driver has been marked for an unload operation, the lower driver is unloaded.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoAttachDevice

IoAttachDeviceToDeviceStack

IoDisconnectInterrupt function

1/25/2019 • 2 minutes to read • Edit Online

The **IoDisconnectInterrupt** routine releases a device driver's set of interrupt object(s) when the device is paused or removed, or when the driver is being unloaded.

Syntax

```
void IoDisconnectInterrupt(
  PKINTERRUPT InterruptObject
);
```

Parameters

`InterruptObject`

A pointer to a KINTERRUPT structure. The caller obtained this pointer from the IoConnectInterrupt call that previously connected the interrupt or interrupts.

Return Value

None.

Remarks

The driver should configure the device to issue interrupts only when these interrupts are connected. Failure to prevent a device from issuing interrupts when the interrupts are disconnected might cause system instability. For example, if a device shares a level-triggered interrupt line with other devices, and the device issues an interrupt request when the device's interrupts are disconnected, the other devices on the line will not acknowledge the interrupt and the interrupt will continue to fire. Before calling **IoDisconnectInterrupt**, the driver should configure the device to stop issuing interrupts. After calling IoConnectInterrupt, the driver should configure the device to start issuing interrupts.

If the driver stored the pointer to its interrupt object(s) in the device extension of its device object or in the controller extension of its controller object, it must call **IoDisconnectInterrupt** before it calls IoDeleteDevice or IoDeleteController.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	IrqlIoPassive4, PowerIrpDDis, HwStorPortProhibitedDDIs

KINTERRUPT

IoDisconnectInterruptEx function

1/25/2019 • 2 minutes to read • Edit Online

For more information, see the WdmlibIoDisconnectInterruptEx function.

```
#define IoDisconnectInterruptEx WdmlibIoDisconnectInterruptEx
```

Syntax

```
void IoDisconnectInterruptEx(
  PIO_DISCONNECT_INTERRUPT_PARAMETERS Parameters
);
```

Parameters

`Parameters`

For more information, see the WdmlibIoDisconnectInterruptEx function.

Return Value

For more information, see the WdmlibIoDisconnectInterruptEx function.

Requirements

Minimum supported client	Available starting with Windows Vista. Drivers that must also work Microsoft Windows 2000, Windows XP, or Windows Server 2003 can instead link to Iointex.lib to use the routine.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib; Iointex.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

See Also

WdmlibIoDisconnectInterruptEx

IoForwardIrpSynchronously function

1/25/2019 • 2 minutes to read • Edit Online

The **IoForwardIrpSynchronously** routine sends an IRP to a specified driver and waits for that driver to complete the IRP.

Syntax

```
BOOLEAN IoForwardIrpSynchronously(
  PDEVICE_OBJECT DeviceObject,
  PIRP           Irp
);
```

Parameters

`DeviceObject`

Specifies the device object of the driver to which the IRP is sent.

`Irp`

Specifies the IRP to send.

Return Value

IoForwardIrpSynchronously returns **TRUE** if the IRP is sent successfully. Otherwise, it returns **FALSE**.

Remarks

Use the **IoForwardIrpSynchronously** routine to synchronously forward the current IRP to the next driver in the stack. (To asynchronously forward the IRP, use the IoCopyCurrentIrpStackLocationToNext, IoCallDriver, and IoSetCompletionRoutine routines.)

The **IoForwardIrpSynchronously** routine copies the current stack location to the next stack location. That stack location is then used as the current stack location by the driver specified in *DeviceObject*. If no next stack location is available, the routine returns **FALSE**. If the routine returns **TRUE**, then the IRP has been sent to the specified driver, and that driver has completed its processing of this IRP.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"
DDI compliance rules	PnpIrpCompletion

IoCopyCurrentIrpStackLocationToNext

IoSetCompletionRoutine

IoFreeErrorLogEntry function

1/25/2019 • 2 minutes to read • Edit Online

The **IoFreeErrorLogEntry** routine frees an unused error log entry.

Syntax

```
void IoFreeErrorLogEntry(
  PVOID ElEntry
);
```

Parameters

`ElEntry`

Pointer to an error log packet allocated by IoAllocateErrorLogEntry.

Return Value

None

Remarks

Drivers use **IoFreeErrorLogEntry** to free an error log entry allocated by IoAllocateErrorLogEntry. IoWriteErrorLogEntry also frees any error log entries passed to it, so drivers must not call both on the same log entry.

Requirements

Minimum supported client	Available in Windows XP and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

See Also

IO_ERROR_LOG_PACKET

IoAllocateErrorLogEntry

IoWriteErrorLogEntry

IoFreeIrp function

1/25/2019 • 2 minutes to read • Edit Online

The **IoFreeIrp** routine releases a caller-allocated IRP from the caller's IoCompletion routine.

Syntax

```
void IoFreeIrp(
  PIRP Irp
);
```

Parameters

`Irp`

Pointer to the IRP that is to be released.

Return Value

None

Remarks

This routine is the reciprocal to IoAllocateIrp or IoBuildAsynchronousFsdRequest. The released IRP must have been allocated by the caller.

This routine also releases an IRP allocated with IoMakeAssociatedIrp in which the caller set up its IoCompletion routine that returns STATUS_MORE_PROCESSING_REQUIRED for the associated IRP.

IoFreeIrp does not free any MDLs that might be attached to the IRP. The driver that frees the IRP must explicitly free these MDLs. In addition, if the physical pages that are described by an MDL are locked, the driver must unlock the pages before it frees the MDL. However, the driver does not need to explicitly unmap these pages. Instead, IoFreeMdl automatically unmaps the pages when it frees the MDL. For a code example that shows how to free an MDL chain, see Using MDLs.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IRQL	"<= DISPATCH_LEVEL"
DDI compliance rules	IoAllocateFree, IoBuildDeviceControlNoFree, IoBuildFsdFree, IoBuildSynchronousFsdRequestNoFree, HwStorPortProhibitedDDIs, IoFreeIrp

IoBuildAsynchronousFsdRequest

IoCompletion

IoMakeAssociatedIrp

IoSetCompletionRoutine

IoFreeMdl function

1/25/2019 • 2 minutes to read • Edit Online

The **IoFreeMdl** routine releases a caller-allocated memory descriptor list (MDL).

Syntax

```
void IoFreeMdl(
  PMDL Mdl
);
```

Parameters

`Mdl`

Pointer to the MDL to be released.

Return Value

None

Remarks

If a driver allocates an MDL to describe a buffer, it must explicitly release the MDL when operations on the buffer are done.

If the MDL is a partial MDL, **IoFreeMdl** unmaps any pages that have been mapped to the MDL.

If the physical pages that are described by the MDL are locked, the driver must unlock the pages before it frees the MDL.

This routine frees only the specified MDL. Any MDLs that are chained to this MDL must be explicitly freed through additional calls to this routine. For a code example that shows how to free an MDL chain, see Using MDLs.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

See Also

IoAllocateMdl

IoBuildPartialMdl

IoFreeWorkItem function

1/25/2019 • 2 minutes to read • Edit Online

The **IoFreeWorkItem** routine frees a work item that was allocated by IoAllocateWorkItem.

Syntax

```
void IoFreeWorkItem(
  PIO_WORKITEM IoWorkItem
);
```

Parameters

`IoWorkItem`

Pointer to an IO_WORKITEM structure that was returned by a previous call to IoAllocateWorkItem.

Return Value

None

Remarks

Only free a work item that is not currently queued. The system dequeues a work item before it runs the work item's callback routine, so **IoFreeWorkItem** can be called from within the WorkItem or WorkItemEx routine for the work item.

For more information about work items, see System Worker Threads.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

IoGetAffinityInterrupt function

1/25/2019 • 2 minutes to read • Edit Online

For more information, see the WdmlibIoGetAffinityInterrupt function.

```
#define IoGetAffinityInterrupt WdmlibIoGetAffinityInterrupt
```

Syntax

```
NTSTATUS IoGetAffinityInterrupt(
  PKINTERRUPT     InterruptObject,
  PGROUP_AFFINITY GroupAffinity
);
```

Parameters

`InterruptObject`

For more information, see the WdmlibIoGetAffinityInterrupt function.

`GroupAffinity`

For more information, see the WdmlibIoGetAffinityInterrupt function.

Return Value

For more information, see the WdmlibIoGetAffinityInterrupt function.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

WdmlibIoGetAffinityInterrupt

IoGetAttachedDeviceReference function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetAttachedDeviceReference** routine returns a pointer to the highest level device object in a driver stack and increments the reference count on that object.

Syntax

```
PDEVICE_OBJECT IoGetAttachedDeviceReference(
  PDEVICE_OBJECT DeviceObject
);
```

Parameters

`DeviceObject`

Pointer to the device object for which the topmost attached device object is retrieved.

Return Value

IoGetAttachedDeviceReference returns a pointer to the highest level device object in a stack of attached device objects after incrementing the reference count on the object.

Remarks

If the device object at *DeviceObject* has no device objects attached to it, *DeviceObject* and the returned pointer are equal.

Device driver writers must ensure that when they have completed all operations that required them to make this call, that they call ObDereferenceObject with the device object pointer returned by this routine. Failure to do so will prevent the system from freeing or deleting the device object because of an outstanding reference count.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"
DDI compliance rules	DanglingDeviceObjectReference, HwStorPortProhibitedDDIs

ObDereferenceObject

IoGetBootDiskInformation function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetBootDiskInformation** routine returns information describing the boot and system disks.

Syntax

```
NTSTATUS IoGetBootDiskInformation(
  PBOOTDISK_INFORMATION BootDiskInformation,
  ULONG                 Size
);
```

Parameters

`BootDiskInformation`

Pointer to a caller-allocated buffer that the routine uses to return information about the boot and system disks. The routine fills this buffer in with either a BOOTDISK_INFORMATION or a BOOTDISK_INFORMATION_EX structure.

`Size`

Specifies the size, in bytes, of the buffer specified by *BootDiskInformation*. Should be either **sizeof**(**BOOTDISK_INFORMATION**) or **sizeof**(**BOOTDISK_INFORMATION_EX**).

Return Value

IoGetBootDiskInformation returns one of the following status values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The routine successfully returned the requested information in the buffer specified by *BootDiskInformation*.
STATUS_INVALID_PARAMETER	The value of *Size* is less than the size, in bytes, of a **BOOTDISK_INFORMATION** structure.

STATUS_TOO_LATE	The driver called the routine after the system has already booted. Only boot and system drivers can call **IoGetBootDiskInformation**, and then only in their DriverEntry or AddDevice routines.

Remarks

IoGetBootDiskInformation can be called only by a boot driver. This driver should call **IoGetBootDiskInformation** in a Reinitialize callback routine that the driver registers by calling the IoRegisterBootDriverReinitialization routine.

On Windows XP and later versions of Windows, if the *Size* parameter is **sizeof**(**BOOTDISK_INFORMATION_EX**) or larger, the routine returns a BOOTDISK_INFORMATION_EX structure in the *BootDiskInformation* buffer. Otherwise, if *Size* is at least **sizeof**(**BOOTDISK_INFORMATION**), the routine returns a BOOTDISK_INFORMATION structure.

On Windows 2000, the routine returns only the **BOOTDISK_INFORMATION** structure.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

BOOTDISK_INFORMATION_EX

IoRegisterBootDriverReinitialization

Reinitialize

IoGetContainerInformation function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetContainerInformation** routine provides information about the current state of a user session.

Syntax

```
NTSTATUS IoGetContainerInformation(
  IO_CONTAINER_INFORMATION_CLASS InformationClass,
  PVOID                          ContainerObject,
  PVOID                          Buffer,
  ULONG                          BufferLength
);
```

Parameters

`InformationClass`

Specifies the class of events for which the caller (driver) requests information. Set this parameter to the following IO_CONTAINER_INFORMATION_CLASS enumeration value:

- **IoSessionStateInformation**

For more information, see the following Remarks section.

`ContainerObject`

A pointer to an opaque, system object supplied by the I/O manager. For *InformationClass* = **IoSessionStateInformation**, set this parameter to the *SessionObject* parameter value that is provided by the I/O manager during the call to the driver's IO_SESSION_NOTIFICATION_FUNCTION function.

`Buffer`

A pointer to a caller-allocated buffer into which this routine writes the state information for the event class specified by *InformationClass*. For *InformationClass* = **IoSessionStateInformation**, the routine writes an IO_SESSION_STATE_INFORMATION structure to the buffer. The buffer must be large enough to contain this structure.

`BufferLength`

The size, in bytes, of the buffer pointed to by *Buffer*. For *InformationClass* = IoSessionStateInformation, *BufferLength* must be at least **sizeof**(**IO_SESSION_STATE_INFORMATION**).

Return Value

IoGetContainerInformation returns STATUS_SUCCESS if the call is successful. Possible error return values include the following:

RETURN CODE	DESCRIPTION

STA TUS _IN VAL ID_ PAR AM ETE R_1	Parameter *InformationClass* is not a valid IO_CONTAINER_INFORMATION_CLASS enumeration constant.
STA TUS _IN VAL ID_ PAR AM ETE R_2	Parameter *ContainerObject* is **NULL**.
STA TUS _IN VAL ID_ PAR AM ETE R_4	Parameter *BufferLength* is too small for the information class specified by *InformationClass*.

Remarks

This routine can potentially support queries for a variety of information classes. In Windows 7, this routine supports only queries for **IoSessionStateInformation** information, which is status information about user sessions.

Requirements

Minimum supported client	Available in Windows 7 and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Fltkernel.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

IO_CONTAINER_INFORMATION_CLASS

IO_CONTAINER_NOTIFICATION_CLASS

IO_SESSION_STATE_INFORMATION

IoGetCurrentIrpStackLocation function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetCurrentIrpStackLocation** routine returns a pointer to the caller's I/O stack location in the specified IRP.

Syntax

```
__drv_aliasesMem PIO_STACK_LOCATION IoGetCurrentIrpStackLocation(
  PIRP Irp
);
```

Parameters

`Irp`

A pointer to the IRP.

Return Value

IoGetCurrentIrpStackLocation returns a pointer to an IO_STACK_LOCATION structure that contains the I/O stack location for the driver.

Remarks

Every driver must call **IoGetCurrentIrpStackLocation** with each IRP it is sent in order to get any parameters for the current request. Unless a driver supplies a dispatch routine for each **IRP_MJ_*XXX*** code that the driver handles, the driver also must check its I/O stack location in the IRP to determine what operation is being requested.

If a driver is passing the same parameters that it received to the next-lower driver, it should call IoCopyCurrentIrpStackLocationToNext or IoSkipCurrentIrpStackLocation instead of getting a pointer to the next-lower stack location and copying the parameters manually.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Any level

See Also

IO_STACK_LOCATION

IoGetNextIrpStackLocation

IoSetNextIrpStackLocation

IoGetCurrentProcess function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetCurrentProcess** routine returns a pointer to the current process. Call **PsGetCurrentProcess** instead of **IoGetCurrentProcess**.

Syntax

```
PEPROCESS IoGetCurrentProcess(

);
```

Parameters

This function has no parameters.

Return Value

IoGetCurrentProcess returns a pointer to the current process.

Remarks

This routine is identical to **PsGetCurrentProcess**.

```
#define PsGetCurrentProcess IoGetCurrentProcess
```

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

PsGetCurrentThread

IoGetDeviceInterfaceAlias function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetDeviceInterfaceAlias** routine returns the alias device interface of the specified device interface instance, if the alias exists.

Syntax

```
NTSTATUS IoGetDeviceInterfaceAlias(
  PUNICODE_STRING SymbolicLinkName,
  const GUID      *AliasInterfaceClassGuid,
  PUNICODE_STRING AliasSymbolicLinkName
);
```

Parameters

`SymbolicLinkName`

Pointer to the name of the device interface instance for which to retrieve an alias. The caller typically received this string from a call to IoGetDeviceInterfaces or in a PnP notification structure.

`AliasInterfaceClassGuid`

Pointer to a GUID specifying the interface class of the alias to retrieve.

`AliasSymbolicLinkName`

Specifies a pointer to a **NULL** Unicode string. On successful return, *AliasSymbolicLinkName*.**Buffer** points to a string containing the name of the alias. The caller must free the Unicode string with RtlFreeUnicodeString when it is no longer needed.

Return Value

IoGetDeviceInterfaceAlias returns STATUS_SUCCESS if the call was successful. Possible error return values are described following.

RETURN CODE	DESCRIPTION
STATUS_OBJECT_NAME_NOT_FOUND	Possibly indicates that there is no alias of the specified interface class.

STA TUS _OB JEC T_P AT H_N OT_ FOU ND	Possibly indicates that there is no alias of the specified interface class.
STA TUS _IN VAL ID_ HA NDL E	Possibly indicates an invalid *SymbolicLinkName* or an invalid *AliasClassGuid*.

Remarks

Device interfaces are considered aliases if they are exposed by the same underlying device and have identical interface reference strings, but are of different interface classes.

The *SymbolicLinkName* parameter specifies a device interface instance for a particular device, belonging to a particular interface class, with a particular reference string. **IoGetDeviceInterfaceAlias** returns another device interface instance for the same device and reference string, but of a different interface class, if it exists.

For example, the function driver for a fault-tolerant volume could register and set two device interfaces, one of the fault-tolerant-volume interface class and one of the volume interface class. Another driver could call **IoGetDeviceInterfaceAlias** with the symbolic link for one of the interfaces and ask whether the other interface exists by specifying its interface class.

Two device interfaces with **NULL** reference strings are aliases if they are exposed by the same underlying device and have different interface class GUIDs.

Callers of **IoGetDeviceInterfaceAlias** must be running at IRQL = PASSIVE_LEVEL in the context of a system thread.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoRegisterDeviceInterface

RtlFreeUnicodeString

IoGetDeviceInterfacePropertyData function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetDeviceInterfacePropertyData** routine retrieves the current value of a device interface property.

Syntax

```
NTSTATUS IoGetDeviceInterfacePropertyData(
  PUNICODE_STRING  SymbolicLinkName,
  const DEVPROPKEY *PropertyKey,
  LCID             Lcid,
  ULONG            Flags,
  ULONG            Size,
  PVOID            Data,
  PULONG           RequiredSize,
  PDEVPROPTYPE     Type
);
```

Parameters

`SymbolicLinkName`

A pointer to a string that identifies the device interface instance. This string was obtained from a previous call to the IoGetDeviceInterfaces, IoGetDeviceInterfaceAlias, or IoRegisterDeviceInterface routine.

`PropertyKey`

A pointer to a DEVPROPKEY structure that contains the device interface property key.

`Lcid`

Specifies a locale identifier. Set this parameter either to a language-specific LCID value or to **LOCALE_NEUTRAL**. The **LOCALE_NEUTRAL** LCID specifies that the property is language-neutral (that is, not specific to any language). Do not set this parameter to **LOCALE_SYSTEM_DEFAULT** or **LOCALE_USER_DEFAULT**. For more information about language-specific LCID values, see LCID Structure.

`Flags`

Reserved for system use. Drivers should set this value to zero.

`Size`

Specifies the size, in bytes, of the buffer that *Data* points to.

`Data`

A pointer to a caller-allocated buffer into which the routine writes the device interface property data.

`RequiredSize`

A pointer to a ULONG variable into which **IoGetDeviceInterfacePropertyData** writes the required size of the property data. If the routine succeeds, the required size value is the number of bytes that the routine writes to the output buffer that *Data* points to. If the routine returns STATUS_BUFFER_TOO_SMALL, the required size value is the size of the buffer that the caller should allocate for this property value.

Type

A pointer to a DEVPROPTYPE variable. If **IoGetDeviceInterfacePropertyData** successfully retrieves the property data, the routine writes the property type value to this variable. This value indicates the type of property data that is in the *Data* buffer.

Return Value

IoGetDeviceInterfacePropertyData returns STATUS_SUCCESS if it is successful. Possible error return values include the following status codes.

RETURN CODE	DESCRIPTION
STATUS_BUFFER_TOO_SMALL	The buffer that *Data* points to is too small to contain the property data. **RequiredSize* contains the required buffer length.
STATUS_UNSUCCESSFUL	The specified LCID value is not valid.
STATUS_NOT_IMPLEMENTED	The specified property is not supported.

Remarks

Kernel-mode drivers use the **IoGetDeviceInterfacePropertyData** routine to retrieve device interface properties that are defined as part of the unified device property model. For more information about device interface properties, see Device Properties.

Drivers can use the IoSetDeviceInterfacePropertyData routine to modify a device interface property.

Callers of **IoGetDeviceInterfacePropertyData** must be running at IRQL = PASSIVE_LEVEL in the context of a system thread.

Requirements

Minimum supported client	Available in Windows 8 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

DEVPROPTYPE

IoSetDeviceInterfacePropertyData

IoGetDeviceInterfaces function

1/25/2019 • 3 minutes to read • Edit Online

The **IoGetDeviceInterfaces** routine returns a list of device interface instances of a particular device interface class (such as all devices on the system that support a HID interface).

Syntax

```
NTSTATUS IoGetDeviceInterfaces(
  const GUID     *InterfaceClassGuid,
  PDEVICE_OBJECT PhysicalDeviceObject,
  ULONG          Flags,
  PZZWSTR        *SymbolicLinkList
);
```

Parameters

`InterfaceClassGuid`

Pointer to a class GUID specifying the device interface class. The GUIDs for a class should be in a device-specific header file.

`PhysicalDeviceObject`

Pointer to an optional PDO that narrows the search to only the device interface instances of the device represented by the PDO.

`Flags`

Specifies flags that modify the search for device interfaces. Only one flag is currently defined, and is described in the following table.

FLAG	MEANING
DEVICE_INTERFACE_INCLUDE_NONACTIVE	Return disabled device interface instances in addition to enabled interface instances.

When searching for a device that supports a particular interface class, the caller requires an enabled interface instance and thus does not set the DEVICE_INTERFACE_INCLUDE_NONACTIVE flag.

A driver typically sets the DEVICE_INTERFACE_INCLUDE_NONACTIVE flag to locate disabled interface instances that the driver must enable. For example, the class installer for the device might have been directed by the INF file to register one or more interface instances for the device. The interface instances would be registered but are not usable until they are enabled by the driver (using IoSetDeviceInterfaceState). To narrow the list of interface instances returned to only those exposed by a given device, a driver can specify a *PhysicalDeviceObject*.

`SymbolicLinkList`

A pointer to a wide character pointer to which the routine, if successful, writes the base address of a buffer that contains a list of Unicode strings. These strings are symbolic link names that identify the device interface instances that match the search criteria. Each Unicode string in the list is null-terminated; the end of the whole list is marked by an additional null character. The routine allocates the buffer for these strings from paged system memory. The caller is responsible for freeing the buffer (by calling the ExFreePool routine) when it is no longer needed.

If no device interface instances match the search criteria, this routine returns STATUS_SUCCESS and the string contains a single NULL character.

Return Value

IoGetDeviceInterfaces returns STATUS_SUCCESS if the call was successful. Possible error return values include the following.

RETURN CODE	DESCRIPTION
STATUS_INVALID_DEVICE_REQUEST	Possibly indicates that *PhysicalDeviceObject* was not a valid PDO pointer.

Remarks

IoGetDeviceInterfaces returns a list of device interface instances that match the search criteria. A kernel-mode component typically calls this routine to get a list of all enabled device interface instances of a particular device interface class. Such a component can get a pointer to the file object and/or the device object for an interface by calling the IoGetDeviceObjectPointer or ZwCreateFile routine. The device object pointer returned by **IoGetDeviceObjectPointer** points to the top of the device stack for the device and can be used in calls to the IoCallDriver routine.

If there is a default interface for the requested device interface class, it is listed first in *SymbolicLinkList*. Default interfaces can be set by user mode, but not by kernel mode.

The format of a symbolic link name is opaque; the caller should not attempt to parse a symbolic link name.

Symbolic links for device interface instances can be used across system boots.

To be notified when additional device interface instances of a particular class are enabled on the system, register for notification of a device class change by calling the IoRegisterPlugPlayNotification routine.

Callers of **IoGetDeviceInterfaces** must be running at IRQL = PASSIVE_LEVEL in the context of a system thread.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoGetDeviceNumaNode function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetDeviceNumaNode** routine gets the node number of a device.

Syntax

```
NTSTATUS IoGetDeviceNumaNode(
  PDEVICE_OBJECT Pdo,
  PUSHORT        NodeNumber
);
```

Parameters

`Pdo`

A pointer to a physical device object (PDO). This parameter points to a DEVICE_OBJECT structure that represents a physical device.

`NodeNumber`

A pointer to a location into which the routine writes the node number, if the node number is known.

Return Value

IoGetDeviceNumaNode returns STATUS_SUCCESS if the call is successful. Possible error return values include the following:

RETURN CODE	DESCRIPTION
STATUS_NO_FOUND	The node number of this device is unknown.
STATUS_INVALID_PARAMETER	The *Pdo* parameter is **NULL** or does not point to a valid device object.

Remarks

In a non-uniform memory access (NUMA) multiprocessor architecture, a node is a collection of processors that

share fast access to a region of memory. Memory access is non-uniform because a processor can access the memory in its node faster than it can access the memory in other nodes.

A device (for example, a network controller or storage controller) that is connected to a particular node can access the memory in this node faster than it can access the memory in other nodes. The *Pdo* parameter points to a PDO that represents the bus connection between the device and the node.

If a NUMA multiprocessor system contains *n* nodes, the nodes are numbered from 0 to *n*-1. To obtain the highest node number, call the KeQueryHighestNodeNumber routine.

After the system is initialized, the node count remains fixed while the system continues to run. This count might include memory-only nodes, which are nodes that contain memory but no active logical processors. A node in which all the logical processors are inactive is effectively a memory-only node until the first processor in the node starts to run. Do not assume that the node that a device is connected to contains active processors.

If a system does not have a NUMA architecture, the routine writes zero to the location that the *NodeNumber* parameter points to. An example of non-NUMA architecture is a symmetric multiprocessor system (SMP).

Requirements

Minimum supported client	Available in Windows 7 and later versions of the Windows operating systems.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoGetDeviceObjectPointer function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetDeviceObjectPointer** routine returns a pointer to the top object in the named device object's stack and a pointer to the corresponding file object, if the requested access to the objects can be granted.

Syntax

```
NTSTATUS IoGetDeviceObjectPointer(
  PUNICODE_STRING ObjectName,
  ACCESS_MASK     DesiredAccess,
  PFILE_OBJECT    *FileObject,
  PDEVICE_OBJECT  *DeviceObject
);
```

Parameters

`ObjectName`

Pointer to a buffer that contains a Unicode string that is the name of the device object.

`DesiredAccess`

Specifies the ACCESS_MASK value that represents the desired access. Usually *DesiredAccess* is FILE_READ_DATA. Infrequently, the FILE_WRITE_DATA, or FILE_ALL_ACCESS access rights are specified.

`FileObject`

Pointer to the file object that represents the corresponding device object to user-mode code if the call is successful.

`DeviceObject`

Pointer to the device object that represents the named logical, virtual, or physical device if the call is successful.

Return Value

IoGetDeviceObjectPointer returns STATUS_SUCCESS if it is successful. Possible error return values include the following status codes:

STATUS_OBJECT_TYPE_MISMATCH

STATUS_INVALID_PARAMETER

STATUS_PRIVILEGE_NOT_HELD

STATUS_INSUFFICIENT_RESOURCES

STATUS_OBJECT_NAME_INVALID

Remarks

IoGetDeviceObjectPointer establishes a "connection" between the caller and the next-lower-level driver. A successful caller can use the returned device object pointer to initialize its own device objects. It can also be used as an argument to IoAttachDeviceToDeviceStack, IoCallDriver, and any routine that creates IRPs for lower drivers.

The returned pointer is a required argument to **IoCallDriver**.

This routine also returns a pointer to the corresponding file object. When unloading, a driver can dereference the file object as a means of indirectly dereferencing the device object. To do so, the driver calls ObDereferenceObject from its Unload routine, passing the file object pointer returned by **IoGetDeviceObjectPointer**. Failure to dereference the device object in a driver's Unload routine prevents the next-lower driver from being unloaded. However, drivers that close the file object before the unload process must take out an extra reference on the device object before dereferencing the file object. Otherwise, dereferencing the file object can lead to a premature deletion of the device object.

To get a pointer to the highest-level driver in the file system driver stack, a driver must ensure that the file system is mounted; if it is not, this routine traverses the storage device stack. To ensure that the file system is mounted on the storage device, the driver must specify an appropriate access mask, such as FILE_READ_DATA or FILE_WRITE_ATTRIBUTES, in the *DesiredAccess* parameter. Specifying FILE_READ_ATTRIBUTES does not cause the file system to be mounted.

After any higher-level driver has chained itself over another driver by successfully calling this routine, the higher-level driver must set the **StackSize** field in its device object to that of the next-lower-level driver's device object plus one.

Callers of **IoGetDeviceObjectPointer** must be running at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IoGetDeviceProperty function

1/25/2019 • 4 minutes to read • Edit Online

The **IoGetDeviceProperty** routine retrieves information about a device such as configuration information and the name of its PDO.

Syntax

```
NTSTATUS IoGetDeviceProperty(
  PDEVICE_OBJECT           DeviceObject,
  DEVICE_REGISTRY_PROPERTY DeviceProperty,
  ULONG                    BufferLength,
  PVOID                    PropertyBuffer,
  PULONG                   ResultLength
);
```

Parameters

`DeviceObject`

Pointer to the physical device object (PDO) for the device being queried.

`DeviceProperty`

Specifies the device property being requested. Must be one of the following DEVICE_REGISTRY_PROPERTY enumeration values:

DevicePropertyAddress

Requests the address of the device on the bus. *PropertyBuffer* points to a ULONG.

The interpretation of this address is bus-specific. The caller of this routine should call the routine again to request the **DevicePropertyBusTypeGuid**, or possibly the **DevicePropertyLegacyBusType**, so it can interpret the address. An address value of 0xFFFFFFFF indicates that the underlying bus driver did not supply a bus address for the device.

DevicePropertyBootConfiguration

Requests the hardware resources assigned to the device by the firmware, in raw form. *PropertyBuffer* points to a CM_RESOURCE_LIST structure.

DevicePropertyBootConfigurationTranslated

The hardware resources assigned to the device by the firmware, in translated form. *PropertyBuffer* points to a **CM_RESOURCE_LIST** structure.

DevicePropertyBusNumber

Requests the legacy bus number of the bus the device is connected to. *PropertyBuffer* points to a ULONG.

DevicePropertyBusTypeGuid

Requests the GUID for the bus that the device is connected to. The system-defined bus type GUIDs are listed in the Wdmguid.h header file. *PropertyBuffer* points to a GUID, which is a 16-byte structure that contains the GUID in binary form.

DevicePropertyClassGuid

Requests the GUID for the device's setup class.*PropertyBuffer* points to a NULL-terminated array of WCHAR. This routine returns the GUID in a string format as follows, where each "c" represents a hexadecimal character:

{cccccccc-cccc-cccc-cccc-cccccccccccc}

DevicePropertyClassName

Requests the name of the device's setup class, in text format. *PropertyBuffer* points to a NULL-terminated WCHAR string.

DevicePropertyCompatibleIDs

Requests the compatible IDs reported by the device. *PropertyBuffer* points to a REG_MULTI_SZ value.

DevicePropertyDeviceDescription

Requests a string describing the device, such as "Microsoft PS/2 Port Mouse", typically defined by the manufacturer. *PropertyBuffer* points to a NULL-terminated WCHAR string.

DevicePropertyDriverKeyName

Requests the name of the driver-specific registry key. *PropertyBuffer* points to a NULL-terminated WCHAR string.

DevicePropertyEnumeratorName

Requests the name of the enumerator for the device, such as "PCI" or "root". *PropertyBuffer* points to a NULL-terminated WCHAR string.

DevicePropertyFriendlyName

Requests a string that can be used to distinguish between two similar devices, typically defined by the class installer. *PropertyBuffer* points to a NULL-terminated WCHAR string.

DevicePropertyHardwareID

Requests the hardware IDs provided by the device that identify the device. *PropertyBuffer* points to a REG_MULTI_SZ value.

DevicePropertyInstallState

Requests the device's installation state. The installation state is returned as a DEVICE_INSTALL_STATE enumeration value.

DevicePropertyLegacyBusType

Requests the bus type, such as PCIBus or PCMCIABus. *PropertyBuffer* points to an INTERFACE_TYPE enumeration value.

DevicePropertyLocationInformation

Requests information about the device's location on the bus; the interpretation of this information is bus-specific. *PropertyBuffer* points to a NULL-terminated WCHAR string.

DevicePropertyManufacturer

Requests a string identifying the manufacturer of the device. *PropertyBuffer* points to a NULL-terminated WCHAR string.

DevicePropertyPhysicalDeviceObjectName

Requests the name of the PDO for this device. *PropertyBuffer* points to a NULL-terminated WCHAR string.

DevicePropertyRemovalPolicy

Requests the device's current removal policy. The operating system uses this value as a hint to determine how the device is normally removed. The *PropertyBuffer* parameter points to a DEVICE_REMOVAL_POLICY enumeration value.

DevicePropertyUINumber

Requests a number associated with the device that can be displayed in the user interface. *PropertyBuffer* points to a ULONG value.

This number is typically a user-perceived slot number, such as a number printed next to the slot on the board, or some other number that makes locating the physical device easier for the user. If the device is on a bus that has no UI number convention, or if the bus driver for the device cannot determine the UI number, this value is 0xFFFFFFFF.

`BufferLength`

Specifies the size, in bytes, of the caller-supplied *PropertyBuffer*.

`PropertyBuffer`

Pointer to a caller-supplied buffer to receive the property information. The buffer can be allocated from pageable memory. The type of the buffer is determined by the *DeviceProperty* (see above).

`ResultLength`

Pointer to a ULONG to receive the size of the property information returned at *PropertyBuffer*. If **IoGetDeviceProperty** returns STATUS_BUFFER_TOO_SMALL, it sets this parameter to the required buffer length.

Return Value

IoGetDeviceProperty returns STATUS_SUCCESS if the call was successful. Possible error return values include the following.

RETURN CODE	DESCRIPTION
STATUS_BUFFER_TOO_SMALL	The buffer at *PropertyBuffer* was too small. *ResultLength* points to the required buffer length.
STATUS_INVALID_PARAMETER_2	The given *DeviceProperty* is not one of the properties handled by this routine.
STATUS_INVALID_DEVICE_REQUEST	Possibly indicates that the given *DeviceObject* was not a valid PDO pointer.

Remarks

IoGetDeviceProperty retrieves device setup information from the registry. Use this routine, rather than accessing the registry directly, to insulate a driver from differences across platforms and from possible changes in the registry structure.

For many *DeviceProperty* requests, it can take two or more calls to **IoGetDeviceProperty** to determine the required *BufferLength*. The first call should use a best-guess value. If the return status is STATUS_BUFFER_TOO_SMALL, the driver should free its current buffer, allocate a buffer of the size returned in *ResultLength*, and call **IoGetDeviceProperty** again. Because some of the setup properties are dynamic, the data size can change between the time the required size is returned and driver calls this routine again. Therefore, drivers should call **IoGetDeviceProperty** inside a loop that runs until the return status is not STATUS_BUFFER_TOO_SMALL.

Function drivers that support devices on a legacy bus and a PnP bus can use the **DevicePropertyBusNumber**, **DevicePropertyBusTypeGuid**, and **DevicePropertyLegacyBusType** properties to distinguish between the buses.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoGetDevicePropertyData function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetDevicePropertyData** routine retrieves the current setting for a device property.

Syntax

```
NTSTATUS IoGetDevicePropertyData(
  PDEVICE_OBJECT   Pdo,
  const DEVPROPKEY *PropertyKey,
  LCID             Lcid,
  ULONG            Flags,
  ULONG            Size,
  PVOID            Data,
  PULONG           RequiredSize,
  PDEVPROPTYPE     Type
);
```

Parameters

`Pdo`

A pointer to the physical device object (PDO) for the device that is being queried.

`PropertyKey`

A pointer to a DEVPROPKEY structure that specifies the device property key.

`Lcid`

A locale identifier. Set this parameter either to a language-specific LCID value or to **LOCALE_NEUTRAL**. The **LOCALE_NEUTRAL** LCID specifies that the property is language-neutral (that is, not specific to any language). Do not set this parameter to **LOCALE_SYSTEM_DEFAULT** or **LOCALE_USER_DEFAULT**. For more information about language-specific LCID values, see LCID Structure.

`Flags`

Reserved for system use. Drivers should set this value to 0.

`Size`

The size, in bytes, of the buffer that *Data* points to.

`Data`

A pointer to the device property data.

`RequiredSize`

A pointer to a ULONG to receive the size of the property information that is returned at *Data*. If **IoGetDevicePropertyData** returns STATUS_BUFFER_TOO_SMALL, the caller can use this value to allocate a buffer of the correct size.

`Type`

A pointer to a DEVPROPTYPE value. If **IoGetDevicePropertyData** completes successfully, the routine uses *Type*

to supply the type of data that is returned in the *Data* buffer.

Return Value

IoGetDevicePropertyData returns an NTSTATUS value. This routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The operation succeeded. The *Data* buffer contains the retrieved data. **Type* contains the type of the retrieved data.
STATUS_BUFFER_TOO_SMALL	The *Data* buffer is too small. **RequiredSize* contains the required buffer length.
STATUS_OBJECT_NAME_NOT_FOUND	The specified device property was not found.

Remarks

Kernel-mode drivers use the **IoGetDevicePropertyData** routine to retrieve device properties that are defined as part of the unified device property model. For more information about device properties, see Device Properties.

Drivers can use the IoSetDevicePropertyData routine to modify a device property.

Callers of **IoGetDevicePropertyData** must be running at IRQL <= APC_LEVEL in the context of a system thread.

Requirements

Minimum supported client	Available starting with Windows Vista.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

DEVPROPTYPE

IoSetDevicePropertyData

IoGetDmaAdapter function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetDmaAdapter** routine returns a pointer to the DMA adapter structure for a physical device object.

Syntax

```
_DMA_ADAPTER * IoGetDmaAdapter(
  PDEVICE_OBJECT      PhysicalDeviceObject,
  _DEVICE_DESCRIPTION *DeviceDescription,
  PULONG              NumberOfMapRegisters
);
```

Parameters

`PhysicalDeviceObject`

Pointer to the physical device object for the device requesting the DMA adapter structure.

`DeviceDescription`

Pointer to a DEVICE_DESCRIPTION structure, which describes the attributes of the physical device.

`NumberOfMapRegisters`

A pointer to, on output, the maximum number of map registers that the driver can allocate for any DMA transfer operation.

Return Value

IoGetDmaAdapter returns a pointer to a DMA_ADAPTER structure, which contains pointers to functions that support system-defined DMA operations. If the structure cannot be allocated, the routine returns **NULL**.

Remarks

Before calling this routine, a driver must zero-initialize the DEVICE_DESCRIPTION structure pointed to by *DeviceDescription* and then add the relevant information for its device to this structure.

On success, the **DmaOperations** member of the routine's return value points to a **DMA_ADAPTER** structure. This structure contains a pointer to a DMA_OPERATIONS structure, which is a table of pointers to functions that the driver can subsequently use to perform DMA operations. The version of this structure that the routine returns is determined as follows:

- If the driver sets the **Version** member of the **DEVICE_DESCRIPTION** structure to DEVICE_DESCRIPTION_VERSION or DEVICE_DESCRIPTION_VERSION1, the returned **DMA_ADAPTER** structure points to version 1 of the **DMA_OPERATIONS** structure.
- If the driver sets **Version** = DEVICE_DESCRIPTION_VERSION2, the returned **DMA_ADAPTER** structure points to version 2 of the **DMA_OPERATIONS** structure if version 2 is supported; otherwise, the routine returns **NULL**. Drivers must check to see if version 2 is supported before attempting to use any version 2 function.
- If the driver sets **Version** = DEVICE_DESCRIPTION_VERSION3, the returned **DMA_ADAPTER** structure points to version 3 of the **DMA_OPERATIONS** structure if version 3 is supported; otherwise, the routine

returns **NULL**. Drivers must check to see if version 3 is supported before attempting to use any version 3 function. Version 3 is supported starting with Windows 8.

A PnP driver calls **IoGetDmaAdapter** when its AddDevice routine is called or when it handles a PnP IRP_MN_START_DEVICE request for a device. This IRP includes information about the device's hardware resources that the driver must supply in the *DeviceDescription* structure.

The caller uses the **MaximumLength** member in the *DeviceDescription* structure to indicate the optimal number of map registers it can use. The I/O manager will attempt to allocate enough map registers to accommodate a DMA transfer operation of this maximum size. On output, the I/O manager returns, in the *NumberOfMapRegisters* parameter, the number of map registers that it allocates. Drivers should check the returned value; there is no guarantee a driver will receive the same number of map registers it requested.

To free the adapter object, the driver should call PutDmaAdapter through the pointer returned in the **DMA_ADAPTER** structure.

> **Note** As previously described, **IoGetDmaAdapter** returns **NULL** if it does not support the version of the **DMA_ADAPTER** structure that is specified by *DeviceDescription*->**Version**. Callers should rely on this behavior to determine whether the routine returns a pointer to the requested version of the **DMA_ADAPTER** structure. When **IoGetDmaAdapter** returns a pointer to version 1 or version 2 of the **DMA_ADAPTER** structure, the **Version** member of this structure is always set to 1. Thus, the caller cannot use the **Version** member of the returned **DMA_ADAPTER** structure to distinguish between versions 1 and 2 of this structure.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IoGetDriverObjectExtension function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetDriverObjectExtension** routine retrieves a previously allocated per-driver context area.

Syntax

```
__drv_aliasesMem PVOID IoGetDriverObjectExtension(
  PDRIVER_OBJECT DriverObject,
  PVOID          ClientIdentificationAddress
);
```

Parameters

`DriverObject`

Specifies the driver object with which the context area is associated.

`ClientIdentificationAddress`

Specifies the unique identifier, provided when it was allocated, of the context area to be retrieved.

Return Value

IoGetDriverObjectExtension returns a pointer to the context area, if any or returns **NULL**.

Remarks

Drivers call **IoGetDriverObjectExtension** to retrieve a pointer to a previously allocated extension area.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

IoGetFunctionCodeFromCtlCode macro

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetFunctionCodeFromCtlCode** macro returns the value of the function code contained in an I/O control code.

Syntax

```
void IoGetFunctionCodeFromCtlCode(
   ControlCode
);
```

Parameters

`ControlCode`

The IOCTL_*XXX* (or FSCTL_*XXX*) value, which can be obtained from the driver's I/O stack location of the IRP at **Parameters.DeviceIoControl.IoControlCode**.

Return Value

IoGetFunctionCodeFromCtlCode returns the value of the Function part of the given IOCTL_XXX code.

Remarks

For information about the layout of IOCTL codes, see Using I/O Control Codes.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Any level

IoBuildDeviceIoControlRequest

IoGetInitialStack function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetInitialStack** routine returns the base address of the current thread's stack.

Syntax

```
PVOID IoGetInitialStack(

);
```

Parameters

This function has no parameters.

Return Value

IoGetInitialStack returns the initial base address of the current thread's stack.

Remarks

Highest-level drivers can call this routine, particularly file systems attempting to determine whether they've been passed a pointer to a location on the current thread's stack.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoGetIoPriorityHint function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetIoPriorityHint** routine gets the priority hint value from an IRP.

Syntax

```
IO_PRIORITY_HINT IoGetIoPriorityHint(
  PIRP Irp
);
```

Parameters

`Irp`

Specifies the IRP to obtain the priority hint from.

Return Value

IoGetIoPriorityHint returns the IO_PRIORITY_HINT value that indicates the current priority hint.

Remarks

For more information about priority hints, see Using IRP Priority Hints.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

IO_PRIORITY_HINT

IoSetIoPriorityHint

IoGetNextIrpStackLocation function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetNextIrpStackLocation** routine gives a higher level driver access to the next-lower driver's I/O stack location in an IRP so the caller can set it up for the lower driver.

Syntax

```
__drv_aliasesMem PIO_STACK_LOCATION IoGetNextIrpStackLocation(
  PIRP Irp
);
```

Parameters

`Irp`

A pointer to the IRP.

Return Value

IoGetNextIrpStackLocation returns a pointer to the next-lower-level driver's I/O stack location in the given IRP.

Remarks

Each driver that passes IRPs on to lower drivers must set up the stack location for the next lower driver. A driver calls **IoGetNextIrpStackLocation** to get a pointer to the next-lower driver's I/O stack location.

If a driver is passing the same parameters that it received to the next-lower driver, it should call IoCopyCurrentIrpStackLocationToNext or IoSkipCurrentIrpStackLocation instead of getting a pointer to the next-lower stack location and copying the parameters manually.

The return value is a pointer to an IO_STACK_LOCATION structure. For more information, see I/O Stack Locations.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Any level

IoGetRelatedDeviceObject function

1/25/2019 • 2 minutes to read • Edit Online

Given a file object, the **IoGetRelatedDeviceObject** routine returns a pointer to the corresponding device object.

Syntax

```
PDEVICE_OBJECT IoGetRelatedDeviceObject(
  PFILE_OBJECT FileObject
);
```

Parameters

`FileObject`

Pointer to the file object.

Return Value

IoGetRelatedDeviceObject returns a pointer to the device object.

Remarks

When called on a file object that represents the underlying storage device, **IoGetRelatedDeviceObject** returns the highest-level device object in the storage device stack. To obtain the highest-level device object in the file system driver stack, drivers must call **IoGetRelatedDeviceObject** on a file object that represents the file system's driver stack, and the file system must currently be mounted. (Otherwise, the storage device stack is traversed instead of the file system stack.)

To ensure that the file system is mounted on the storage device, the driver must have specified an appropriate access mask, such as FILE_READ_DATA or FILE_WRITE_ATTRIBUTES, when opening the file or device represented by the file object. Specifying FILE_READ_ATTRIBUTES does not cause the file system to be mounted.

The caller must be running at IRQL <= DISPATCH_LEVEL. Usually, callers of this routine are running at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IRQL	"<= DISPATCH_LEVEL (see Remarks section)"

IoGetDeviceObjectPointer

IoGetRemainingStackSize function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetRemainingStackSize** routine returns the current amount of available kernel-mode stack space.

Syntax

```
ULONG_PTR IoGetRemainingStackSize(

);
```

Parameters

This function has no parameters.

Return Value

IoGetRemainingStackSize returns the number of bytes of stack space in the current thread context.

Remarks

Highest-level drivers, such as file systems, can call this routine, particularly drivers that use recursive code paths. Such a driver would call **IoGetRemainingStackSize** before launching a recursion to determine whether it should continue processing on an alternate code path.

For Windows Server 2003 Service Pack 1 (SP1) and later versions of Windows, callers of **IoGetRemainingStackSize** can be running at any IRQL. For earlier versions of Windows, the caller must be running at IRQL <= APC_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	See Remarks section.

IoGetInitialStack

IoGetStackLimits

IoGetStackLimits function

1/25/2019 • 2 minutes to read • Edit Online

The **IoGetStackLimits** routine returns the boundaries of the current thread's stack frame.

Syntax

```
void IoGetStackLimits(
  PULONG_PTR LowLimit,
  PULONG_PTR HighLimit
);
```

Parameters

`LowLimit`

Pointer to a caller-supplied variable in which this routine returns the lower offset of the current thread's stack frame.

`HighLimit`

Pointer to a caller-supplied variable in which this routine returns the higher offset of the current thread's stack frame.

Return Value

None

Remarks

Highest-level drivers can call this routine, particularly file systems that have been passed a pointer to a location on the current thread's stack.

In Windows Server 2003 Service Pack 1 (SP1) and later versions of Windows, callers of **IoGetStackLimits** can be running at any IRQL. For earlier operating systems, the caller must be running at IRQL <= APC_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoInitializeDpcRequest function

1/25/2019 • 2 minutes to read • Edit Online

The **IoInitializeDpcRequest** routine registers a driver-supplied DpcForIsr routine.

Syntax

```
void IoInitializeDpcRequest(
  PDEVICE_OBJECT  DeviceObject,
  PIO_DPC_ROUTINE DpcRoutine
);
```

Parameters

`DeviceObject`

Supplies a pointer to the DEVICE_OBJECT structure representing the physical device that generates interrupts.

`DpcRoutine`

Supplies a pointer to the driver-supplied *DpcForIsr* routine.

Return Value

None

Remarks

IoInitializeDpcRequest associates a driver-supplied DpcForIsr routine with a given device object. The driver's InterruptService routine (ISR) can call IoRequestDpc to queue the *DpcForIsr* routine. The *DpcForIsr* routine completes interrupt-driven I/O operations at a lower IRQL than that of the ISR.

PnP drivers call **IoInitializeDpcRequest** from the AddDevice routine.

For more information, see DPC Objects and DPCs.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KeInitializeDpc

IoInitializeIrp function

1/25/2019 • 2 minutes to read • Edit Online

The **IoInitializeIrp** routine initializes a given IRP that was allocated by the caller.

Syntax

```
void IoInitializeIrp(
  PIRP   Irp,
  USHORT PacketSize,
  CCHAR  StackSize
);
```

Parameters

`Irp`

Pointer to the IRP to be initialized.

`PacketSize`

Specifies the size in bytes of the IRP.

`StackSize`

Specifies the number of stack locations in the IRP.

Return Value

None

Remarks

Drivers use **IoInitializeIrp** to initialize IRPs the driver allocated as raw memory. Do not use **IoInitializeIrp** to initialize an IRP allocated by **IoAllocateIrp**. **IoAllocateIrp** automatically initializes the members of the IRP.

Drivers can use **IoInitializeIrp** to reinitialize an IRP for reuse only under certain circumstances. See Reusing IRPs for details.

If the driver associates an MDL with the IRP it allocated, the driver is responsible for releasing the MDL when the IRP is completed.

An intermediate or highest-level driver also can call **IoBuildDeviceIoControlRequest**, **IoBuildAsynchronousFsdRequest**, or **IoBuildSynchronousFsdRequest** to set up requests it sends to lower-level drivers. Only a highest-level driver can call **IoMakeAssociatedIrp**.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoInitializeRemoveLock macro

1/25/2019 • 2 minutes to read • Edit Online

The **IoInitializeRemoveLock** routine initializes a remove lock for a device object.

Syntax

```
void IoInitializeRemoveLock(
   Lock,
   Tag,
   Maxmin,
   HighWater
);
```

Parameters

`Lock`

Pointer to a caller-supplied **IO_REMOVE_LOCK** structure that this routine initializes with information about the lock, including a counter and a synchronization event. A driver writer must allocate this structure as part of the device object's device extension.

`Tag`

Specifies a tag to identify the creator of the lock. Driver writers typically use a 4-character string, specified in reverse order, like the tags used for ExAllocatePoolWithTag.

The I/O system uses this parameter if Driver Verifier is enabled, and on checked builds regardless of whether Driver Verifier is enabled. The caller should always supply a nonzero tag value for this parameter, for both free and checked builds.

`Maxmin`

`HighWater`

Return Value

None

Remarks

A driver can use a remove lock to track outstanding I/O operations on a device and to determine when the driver can delete its device object in response to an IRP_MN_REMOVE_DEVICE request.

Before calling **IoInitializeRemoveLock**, a driver should allocate an **IO_REMOVE_LOCK** structure in its device extension. A driver typically calls **IoInitializeRemoveLock** in its AddDevice routine, when the driver initializes the rest of the device extension for a device object.

After the **IoReleaseRemoveLockAndWait** routine returns, the driver should consider the device to be in a state in which it is ready to be removed and cannot perform I/O operations. Therefore, the driver must not call **IoInitializeRemoveLock** to re-initialize the remove lock. Violation of this rule while the driver is being verified by Driver Verifier will result in a bug check.

Because the driver stores the **IO_REMOVE_LOCK** structure in the device extension of a device object, the remove lock is deleted when the driver deletes the device extension as part of processing an IRP_MN_REMOVE_DEVICE request.

For more information, see Using Remove Locks.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoReleaseRemoveLockAndWait

IoInitializeTimer function

1/25/2019 • 2 minutes to read • Edit Online

The **IoInitializeTimer** routine sets up a driver-supplied IoTimer routine associated with a given device object.

Syntax

```
NTSTATUS IoInitializeTimer(
  PDEVICE_OBJECT         DeviceObject,
  PIO_TIMER_ROUTINE      TimerRoutine,
  __drv_aliasesMem PVOID Context
);
```

Parameters

`DeviceObject`

Pointer to a device object representing a device on which I/O operations can time out.

`TimerRoutine`

Pointer to the driver-supplied *IoTimer* routine.

`Context`

Pointer to the driver-determined context with which its *IoTimer* routine will be called.

Return Value

IoInitializeTimer returns STATUS_SUCCESS if the *IoTimer* routine is set up.

Remarks

IoInitializeTimer should be called only once per device object.

A driver's IoTimer routine is called once per second after the driver enables the timer by calling IoStartTimer. The driver can disable the timer by calling IoStopTimer and can reenable it again with **IoStartTimer**.

The driver's *IoTimer* routine is called at IRQL = DISPATCH_LEVEL and therefore must not contain pageable code.

When the timer is running, the I/O manager calls the driver-supplied *IoTimer* routine once per second. Drivers whose time-out routines should be called at variable intervals or at intervals of finer granularity can set up a CustomTimerDpc routine and use the **Ke*Xxx*Timer** routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KeSetTimer

IoInitializeWorkItem function

1/25/2019 • 2 minutes to read • Edit Online

The **IoInitializeWorkItem** routine initializes a work item that the caller has already allocated.

Syntax

```
void IoInitializeWorkItem(
  PVOID        IoObject,
  PIO_WORKITEM IoWorkItem
);
```

Parameters

`IoObject`

Pointer to the caller's driver object or to one of the caller's device objects. If the caller will later pass the work item to IoQueueWorkItem, *IoObject* must point to a device object.

`IoWorkItem`

Pointer to the IO_WORKITEM structure to initialize.

Return Value

None

Remarks

The driver allocates its own storage for an IO_WORKITEM structure, and then calls **IoInitializeWorkItem** to initialize it. Memory must be allocated from nonpaged pool. To determine the number of bytes that is necessary to hold an **IO_WORKITEM** structure, call IoSizeofWorkItem.

An **IO_WORKITEM** structure that is initialized by **IoInitializeWorkItem**must be uninitialized by IoUninitializeWorkItem before it is freed.

A related routine, IoAllocateWorkItem, both allocates and initializes a work item. By combining allocation and initialization into a single call, **IoAllocateWorkItem** might be more convenient for some drivers to use than **IoInitializeWorkItem**, which does initialization only. However, **IoInitializeWorkItem** is required by drivers that must initialize work items in previously allocated storage.

For example, a driver might allocate a block of storage for a pool of work items. The driver can call **IoInitializeWorkItem** to initialize a work item when the work item is allocated from the pool. The driver can call **IoUninitializeWorkItem** to uninitialize the work item when it is returned to the pool. During the initial storage allocation for the pool, the driver can call **IoSizeofWorkitem** to determine how much storage to allocate for each work item.

For more information about work items, see System Worker Threads.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoInvalidateDeviceRelations function

1/25/2019 • 2 minutes to read • Edit Online

The **IoInvalidateDeviceRelations** routine notifies the PnP manager that the relations for a device (such as bus relations, ejection relations, removal relations, and the target device relation) have changed.

Syntax

```
void IoInvalidateDeviceRelations(
  PDEVICE_OBJECT       DeviceObject,
  DEVICE_RELATION_TYPE Type
);
```

Parameters

`DeviceObject`

Pointer to the PDO for the device.

`Type`

Specifies a **DEVICE_RELATION_TYPE** enumeration value that describes the type of relations that have changed. Possible values include **BusRelations**, **EjectionRelations**, **RemovalRelations**, and **TargetDeviceRelation**. Starting with Windows 7, the **PowerRelations** value is also supported.

Return Value

None

Remarks

For some relation types, such as **BusRelations**, this routine causes the PnP manager or power manager to gather updated relations information by sending an IRP_MN_QUERY_DEVICE_RELATIONS request to the drivers for the device. For other relation types, such as **EjectionRelations**, the PnP manager does not need to gather new relation information immediately; the PnP manager queries drivers for ejection relations only when it is preparing to eject a device.

After a bus driver calls **IoInvalidateDeviceRelations** to inform the PnP manager that a device has disappeared, the bus driver must continue to handle PnP IRPs for that device until it receives an IRP_MN_REMOVE_DEVICE request. In response to this IRP, the bus driver returns STATUS_NO_SUCH_DEVICE. Until the bus driver successfully completes the **IRP_MN_REMOVE_DEVICE** request, the bus driver can access the device extension to check its flags for the device.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IRP_MN_QUERY_DEVICE_RELATIONS

IRP_MN_REMOVE_DEVICE

IoInvalidateDeviceState function

1/25/2019 • 2 minutes to read • Edit Online

The **IoInvalidateDeviceState** routine notifies the PnP manager that some aspect of the PnP state of a device has changed.

Syntax

```
void IoInvalidateDeviceState(
  PDEVICE_OBJECT PhysicalDeviceObject
);
```

Parameters

`PhysicalDeviceObject`

Pointer to the PDO for the device.

Return Value

None

Remarks

Drivers call this routine to indicate that something has changed with respect to one of the following aspects of a device's PnP state:

PNP_DEVICE_DISABLED

PNP_DEVICE_DONT_DISPLAY_IN_UI

PNP_DEVICE_FAILED

PNP_DEVICE_NOT_DISABLEABLE

PNP_DEVICE_REMOVED

PNP_DEVICE_RESOURCE_REQUIREMENTS_CHANGED

For descriptions of the preceding constants, see PNP_DEVICE_STATE.

In response to this routine, the PnP manager sends an IRP_MN_QUERY_PNP_DEVICE_STATE request to the device stack, to determine the current PnP state of the device.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

IRP_MN_QUERY_PNP_DEVICE_STATE

PNP_DEVICE_STATE

IoIs32bitProcess function

1/25/2019 • 2 minutes to read • Edit Online

The **IoIs32bitProcess** routine checks whether the originator of the current I/O request is a 32-bit user-mode application.

Syntax

```
BOOLEAN IoIs32bitProcess(
  PIRP Irp
);
```

Parameters

`Irp`

Optional pointer to the IRP containing the current I/O request. Note that this must be the original IRP that was issued by the I/O manager. If the caller is a fast I/O dispatch routine (and thus there is no IRP), the caller should set this parameter to **NULL**.

Return Value

IoIs32bitProcess returns **TRUE** if the originator of the current I/O request is a 32-bit user-mode process. Otherwise, it returns **FALSE**.

Remarks

Drivers call **IoIs32bitProcess** to determine whether an I/O request is likely to contain data elements that need to be converted, or "thunked," before they can be used in a 64-bit driver.

If the *Irp* parameter is **NULL**, and the caller is running in the context of a user-mode process, **IoIs32bitProcess** returns **TRUE** if this process is a 32-bit process.

If the *Irp* parameter is not **NULL**, it must point to an IRP that was issued by the I/O manager on behalf of a user-mode process. **IoIs32bitProcess** cannot be used to check driver-allocated IRPs. Driver-allocated IRPs, as well as kernel-mode drivers, are assumed to be 64-bit-ready.

For more information, see Programming Issues for 64-Bit Drivers.

Requirements

Minimum supported client	Available in 64-bit versions of Microsoft Windows XP and later 64-bit versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

IoIsErrorUserInduced macro

1/25/2019 • 2 minutes to read • Edit Online

The **IoIsErrorUserInduced** routine determines whether an I/O error encountered while processing a request to a removable-media device was caused by the user.

Syntax

```
void IoIsErrorUserInduced(
   Status
);
```

Parameters

`Status`

Specifies the current NTSTATUS value, usually within the driver's DpcForIsr routine.

Return Value

IoIsErrorUserInduced returns TRUE if an I/O request failed because of a user-induced error.

Remarks

This routine indicates whether an I/O request failed for one of the following user-correctable conditions:

STATUS_DEVICE_NOT_READY

STATUS_IO_TIMEOUT

STATUS_MEDIA_WRITE_PROTECTED

STATUS_NO_MEDIA_IN_DEVICE

STATUS_UNRECOGNIZED_MEDIA

STATUS_VERIFY_REQUIRED

STATUS_WRONG_VOLUME

If **IoIsErrorUserInduced** returns **TRUE**, the removable-media driver must call IoSetHardErrorOrVerifyDevice before completing the IRP.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IRQL	Any level

IoAllocateErrorLogEntry

IoSetHardErrorOrVerifyDevice

IoWriteErrorLogEntry

IoIsWdmVersionAvailable function

1/25/2019 • 2 minutes to read • Edit Online

The **IoIsWdmVersionAvailable** routine checks whether a given WDM version is supported by the operating system.

Syntax

```
BOOLEAN IoIsWdmVersionAvailable(
  UCHAR MajorVersion,
  UCHAR MinorVersion
);
```

Parameters

`MajorVersion`

Specifies the major version number of WDM that is requested.

`MinorVersion`

Specifies the minor version number of WDM that is requested.

Return Value

IoIsWdmVersionAvailable returns **TRUE** if the version of WDM that the operating system provides is greater than or equal to the version number of WDM being requested. Otherwise, it returns **FALSE**.

Remarks

Drivers should use the RtlIsNtDdiVersionAvailable routine instead of the **IoIsWdmVersionAvailable** routine.

Cross-platform drivers should use this routine to check the WDM version before performing any operations that vary by platform or are not supported in all versions of WDM.

The WDM_MAJORVERSION and WDM_MINORVERSION constants, which are defined in the Wdm.h header file, specify the WDM major and minor version numbers for the current version of Windows. The following lists the WDM version provided with each operating system.

OPERATING SYSTEM	WDM MAJOR VERSION	WDM MINOR VERSION
Windows 7	6	0x00
Windows Server 2008 R2	6	0x00
Windows Server 2008	6	0x00
Windows Vista	6	0x00
Windows Server 2003	1	0x30

Windows XP	1	0x20
Windows 2000	1	0x10
Windows Me	1	0x05
Windows 98	1	0x00

Note that the minor version number is defined as a hexadecimal value.

Later versions of WDM support all the features available in earlier versions of WDM; that is, each version of WDM is a superset of the previous WDM version.

The following call returns **TRUE** on any of the listed operating systems, because all these systems support all the features of WDM 1.0:

```
bVersion = IoIsWdmVersionAvailable(1,0);
```

The following example shows how a driver can dynamically detect the current operating system:

```
if (IoIsWdmVersionAvailable(1, 0x10)) {
    //
    //If WDM 1.10 is supported, this is Windows 2000
    //or better.
    //
} else if (IoIsWdmVersionAvailable(1, 5)) {
    //
    //If WDM 1.05 is supported, this is Windows ME
    //or better.
    //
} else {
    //
    //WDM 1.0 is always supported, so this is Windows 98,
    //Windows 98 SE, or better.
    //
}
```

As the example shows, calling **IoIsWdmVersionAvailable**(1, 5) returns **TRUE** on Windows Me, Windows 2000, and any succeeding operating systems, but **FALSE** on Windows 98 and Windows 98 SE.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RtlIsNtDdiVersionAvailable

IoMarkIrpPending function

1/25/2019 • 2 minutes to read • Edit Online

The **IoMarkIrpPending** routine marks the specified IRP, indicating that a driver's dispatch routine subsequently returned STATUS_PENDING because further processing is required by other driver routines.

Syntax

```
void IoMarkIrpPending(
  PIRP Irp
);
```

Parameters

`Irp`

Pointer to the IRP to be marked as pending.

Return Value

None

Remarks

Unless the driver's dispatch routine completes the IRP (by calling IoCompleteRequest) or passes the IRP on to lower drivers, it must call **IoMarkIrpPending** with the IRP. Otherwise, the I/O manager attempts to complete the IRP as soon as the dispatch routine returns control.

After calling **IoMarkIrpPending**, the dispatch routine must return STATUS_PENDING, even if some routine completes the IRP (by calling IoCompleteRequest) before the dispatch routine that called **IoMarkIrpPending** returns.

If a driver queues incoming IRPs, it should call **IoMarkIrpPending** before it queues each IRP. Otherwise, an IRP could be dequeued, completed by another driver routine, and freed by the system before the call to **IoMarkIrpPending** occurs, thereby causing a crash.

If a driver sets an IoCompletion routine for an IRP and then passes the IRP down to a lower driver, the *IoCompletion* routine should check the **IRP->PendingReturned** flag. If the flag is set, the *IoCompletion* routine must call **IoMarkIrpPending** with the IRP. (*IoCompletion* routines do not return STATUS_PENDING, however. For more information, see Implementing an IoCompletion Routine.)

> **Note** Drivers that create the IRP and send it to another stack must not call **IoMarkIrpPending** in their completion routine. This call will corrupt the pool header of the next allocation because there is no stack location for those drivers.

A driver that passes down the IRP and then waits on an event should not mark the IRP pending. Instead, its *IoCompletion* routine should signal the event and return STATUS_MORE_PROCESSING_REQUIRED.

If your driver calls IoSkipCurrentIrpStackLocation, be careful not to modify the IO_STACK_LOCATION structure in a way that could unintentionally affect the lower driver or the system's behavior with respect to that driver. In particular, your driver should not modify the **IO_STACK_LOCATION** structure's **Parameters** union, and should

not call **IoMarkIrpPending**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Any level

IoOpenDeviceInterfaceRegistryKey function

1/25/2019 • 2 minutes to read • Edit Online

The **IoOpenDeviceInterfaceRegistryKey** routine returns a handle to a registry key for storing information about a particular device interface instance.

Syntax

```
NTSTATUS IoOpenDeviceInterfaceRegistryKey(
  PUNICODE_STRING SymbolicLinkName,
  ACCESS_MASK     DesiredAccess,
  PHANDLE         DeviceInterfaceRegKey
);
```

Parameters

`SymbolicLinkName`

Pointer to a string identifying the device interface instance. This string was obtained from a previous call to IoGetDeviceInterfaces, IoGetDeviceInterfaceAlias, or IoRegisterDeviceInterface.

`DesiredAccess`

Specifies the ACCESS_MASK value that represents the access the caller requires to the key, such as KEY_READ, KEY_WRITE, or KEY_ALL_ACCESS. See ZwCreateKey for a description of each KEY_*XXX* access right.

`DeviceInterfaceRegKey`

Pointer to a returned handle to the requested registry key if the call is successful.

Return Value

IoOpenDeviceInterfaceRegistryKey returns STATUS_SUCCESS if the call was successful. Possible error return values include the following.

RETURN CODE	DESCRIPTION
STATUS_OBJECT_NAME_NOT_FOUND	The routine was not able to locate a registry key for the device interface instance, probably due to an error in the *SymbolicLinkName*.

STA TUS _OB JEC T_P AT H_N OT_ FOU ND	The routine was not able to locate a registry key for the device interface instance, probably due to an error in the *SymbolicLinkName*.
STA TUS _IN VAL ID_ PAR AM ETE R	Possibly indicates an error in the *SymbolicLinkName*.

Remarks

IoOpenDeviceInterfaceRegistryKey opens a nonvolatile subkey of the registry key for the device interface instance specified by *SymbolicLinkName*. Drivers can store information in this subkey that is specific to this instance of the device interface, such as the default resolution for a camera. User-mode applications can access this subkey using **SetupDi*Xxx*** routines.

The driver must call ZwClose to close the handle returned from this routine when access is no longer required.

Callers of **IoOpenDeviceInterfaceRegistryKey** must be running at IRQL = PASSIVE_LEVEL in the context of a system thread.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwClose

IoOpenDeviceRegistryKey function

1/25/2019 • 2 minutes to read • Edit Online

The **IoOpenDeviceRegistryKey** routine returns a handle to a device-specific or a driver-specific registry key for a particular device instance.

Syntax

```
NTSTATUS IoOpenDeviceRegistryKey(
  PDEVICE_OBJECT DeviceObject,
  ULONG          DevInstKeyType,
  ACCESS_MASK    DesiredAccess,
  PHANDLE        DeviceRegKey
);
```

Parameters

`DeviceObject`

Pointer to the PDO of the device instance for which the registry key is to be opened.

`DevInstKeyType`

Specifies flags indicating whether to open a device-specific hardware key or a driver-specific software key. The flags also indicate whether the key is relative to the current hardware profile. For more information about hardware and software keys, see Registry Keys for Drivers and Introduction to Registry Keys for Drivers.

The flags are defined as follows:

PLUGPLAY_REGKEY_DEVICE

Open the **Device Parameters** subkey under the device's hardware key (see HKLM\SYSTEM\CurrentControlSet\Enum Registry Tree), a device-specific registry subkey that contains information about the device. The key is located under the key for the device instance specified by *DeviceObject*. This flag cannot be specified with PLUGPLAY_REGKEY_DRIVER.

PLUGPLAY_REGKEY_DRIVER

Open a *software key* for storing driver-specific information. This flag cannot be specified with PLUGPLAY_REGKEY_DEVICE.

A driver's software key is also called its *driver key* because the registry contains a software key for each driver. The registry contains a list of all of the device classes, and each driver's software key resides under its device class entry. The system stores information about each driver under its software key. For more information about software keys, see The HKLM\SYSTEM\CurrentControlSet\Control Tree.

PLUGPLAY_REGKEY_CURRENT_HWPROFILE

Open a key relative to the current hardware profile for device or driver information. This allows the driver to access configuration information that is hardware-profile-specific. The caller must specify either PLUGPLAY_REGKEY_DEVICE or PLUGPLAY_REGKEY_DRIVER with this flag. For more information, see HKLM\SYSTEM\CurrentControlSet\HardwareProfiles Registry Tree.

`DesiredAccess`

Specifies the ACCESS_MASK value that represents the access the caller needs to the key. See the ZwCreateKey

routine for a description of each KEY_*XXX* access right.

`DeviceRegKey`

Pointer to a caller-allocated buffer that, on successful return, contains a handle to the requested registry key.

Return Value

IoOpenDeviceRegistryKey returns STATUS_SUCCESS if the call was successful. Possible error return values include the following.

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	Possibly indicates that the caller specified an illegal set of *DevInstKeyType* flags.
STATUS_INVALID_DEVICE_REQUEST	Possibly indicates that the *DeviceObject* is not a valid PDO.

Remarks

The driver must call ZwClose to close the handle returned from this routine when access is no longer required.

The registry keys opened by this routine are nonvolatile.

User-mode setup applications can access these registry keys by using device installation functions such as SetupDiOpenDevRegKey. An example of a user-mode setup applications would be a class installer, a Win32 DLL that performs installation operations for devices in a particular Device Setup Class.

To create registry keys, use INF AddReg directives in an INF file or use SetupDiCreateDevRegKey in a setup application.

Callers of **IoOpenDeviceRegistryKey** must be running at IRQL = PASSIVE_LEVEL in the context of a system thread.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoQueueWorkItem function

1/25/2019 • 2 minutes to read • Edit Online

The **IoQueueWorkItem** routine associates a WorkItem routine with a work item, and it inserts the work item into a queue for later processing by a system worker thread.

Syntax

```
void IoQueueWorkItem(
  __drv_aliasesMem PIO_WORKITEM IoWorkItem,
  PIO_WORKITEM_ROUTINE          WorkerRoutine,
  WORK_QUEUE_TYPE               QueueType,
  __drv_aliasesMem PVOID        Context
);
```

Parameters

`IoWorkItem`

Pointer to an IO_WORKITEM structure that was allocated by IoAllocateWorkItem or initialized by IoInitializeWorkItem.

`WorkerRoutine`

Pointer to a WorkItem routine.

`QueueType`

Specifies a WORK_QUEUE_TYPE value that stipulates the type of system worker thread to handle the work item. Drivers must specify **DelayedWorkQueue**.

`Context`

Specifies driver-specific information for the work item. The system passes this value as the *Context* parameter to WorkItem.

Return Value

None.

Remarks

For more information about work items, see System Worker Threads.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

WorkItem

IoQueueWorkItemEx function

1/25/2019 • 2 minutes to read • Edit Online

The **IoQueueWorkItemEx** routine associates a WorkItemEx routine with a work item, and it inserts the work item into a queue for later processing by a system worker thread.

Syntax

```
void IoQueueWorkItemEx(
  __drv_aliasesMem PIO_WORKITEM IoWorkItem,
  PIO_WORKITEM_ROUTINE_EX       WorkerRoutine,
  WORK_QUEUE_TYPE               QueueType,
  __drv_aliasesMem PVOID        Context
);
```

Parameters

`IoWorkItem`

Pointer to an IO_WORKITEM structure that was allocated by IoAllocateWorkItem or initialized by IoInitializeWorkItem.

`WorkerRoutine`

Pointer to a WorkItemEx routine.

`QueueType`

Specifies a WORK_QUEUE_TYPE value that stipulates the type of system worker thread to handle the work item. Drivers must specify **DelayedWorkQueue**.

`Context`

Specifies driver-specific information for the work item. The system passes this value as the *Context* parameter to WorkItemEx.

Return Value

None

Remarks

For more information about work items, see System Worker Threads.

Requirements

IoRegisterContainerNotification function

1/25/2019 • 2 minutes to read • Edit Online

The **IoRegisterContainerNotification** routine registers a kernel-mode driver to receive notifications about a specified class of events.

Syntax

```
NTSTATUS IoRegisterContainerNotification(
  IO_CONTAINER_NOTIFICATION_CLASS     NotificationClass,
  PIO_CONTAINER_NOTIFICATION_FUNCTION CallbackFunction,
  PVOID                               NotificationInformation,
  ULONG                               NotificationInformationLength,
  PVOID                               CallbackRegistration
);
```

Parameters

`NotificationClass`

Specifies the class of events for which the caller (driver) requests notifications. Set this parameter to the following IO_CONTAINER_NOTIFICATION_CLASS enumeration value:

- **IoSessionStateNotification**

For more information, see the following Remarks section.

`CallbackFunction`

A pointer to a callback function that is implemented by the caller (driver). The I/O manager calls this function to notify the caller when an event of the class indicated by *NotificationClass* occurs. For *NotificationClass* = **IoSessionStateNotification**, this parameter is a pointer to a caller-supplied IO_SESSION_NOTIFICATION_FUNCTION function. However, the caller should cast this function pointer to type PIO_CONTAINER_NOTIFICATION_FUNCTION to match the parameter type. For more information, see the following Remarks section.

`NotificationInformation`

A pointer to a caller-allocated buffer that contains the notification information structure for an event of the class specified by *NotificationClass*. For *NotificationClass* = **IoSessionStateNotification**, *NotificationInformation* points to an IO_SESSION_STATE_NOTIFICATION structure. The caller must fill out this structure before it calls **IoRegisterContainerNotification**. During this call, **IoRegisterContainerNotification** copies the data from this structure, and the I/O manager does not access the driver's copy of the structure after the call returns.

`NotificationInformationLength`

The size, in bytes, of the notification information structure contained in the buffer that is pointed to by *NotificationInformation*. For *NotificationClass* = **IoSessionStateNotification**, set this parameter to **sizeof**(**IO_SESSION_STATE_NOTIFICATION**).

`CallbackRegistration`

A pointer to a location into which this routine writes the address of a container notification registration object. This

object is an opaque, system object in which the I/O manager stores information about the caller's container notification registration. When notifications are no longer required, the caller cancels the registration by passing this object pointer to the IoUnregisterContainerNotification routine.

Return Value

IoRegisterContainerNotification returns STATUS_SUCCESS if the call is successful. Possible error return values include the following:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER_1	Parameter *NotificationClass* is not a valid **IO_CONTAINER_NOTIFICATION_CLASS** enumeration constant.
STATUS_INVALID_PARAMETER_3	The information in the structure that is pointed to by *NotificationInformation* is incorrect.
STATUS_INVALID_PARAMETER_4	Parameter *NotificationInformationLength* does not equal the size of the notification information structure that is required for use with the specified *NotificationClass* parameter value.
STATUS_ALREADY_COMMITTED	The driver is already registered to receive *NotificationClass* notifications of events that are associated with the specified I/O object.

STA TUS _IN SUF FICI ENT _RE SO URC ES	The operating system has insufficient resources to create the requested registration.

Remarks

This routine can potentially support notifications of events in a variety of event classes. In Windows 7, this routine supports only **IoSessionStateNotification** notifications, which notify a kernel-mode driver of changes in the status of user sessions that the driver is interested in. For user-mode applications, the WTSRegisterSessionNotification function fills a similar role.

The function pointer type for the *CallbackFunction* parameter is defined as follows:

```
typedef NTSTATUS
  (*PIO_CONTAINER_NOTIFICATION_FUNCTION)(
    );
```

The caller should cast the callback function pointer to this type to match the *CallbackFunction* parameter type. **IoRegisterContainerNotification** determines the actual type of the callback function pointer from the *NotificationClass* parameter. For *NotificationClass* = **IoSessionStateNotification**, *CallbackFunction* points to an IO_SESSION_NOTIFICATION_FUNCTION function.

Requirements

Minimum supported client	Available in Windows 7 and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Fltkernel.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

IoRegisterDeviceInterface function

1/25/2019 • 3 minutes to read • Edit Online

The **IoRegisterDeviceInterface** routine registers a device interface class, if it has not been previously registered, and creates a new instance of the interface class, which a driver can subsequently enable for use by applications or other system components.

Syntax

```
NTSTATUS IoRegisterDeviceInterface(
  PDEVICE_OBJECT  PhysicalDeviceObject,
  const GUID      *InterfaceClassGuid,
  PUNICODE_STRING ReferenceString,
  PUNICODE_STRING SymbolicLinkName
);
```

Parameters

`PhysicalDeviceObject`

A pointer to the PDO for the device.

`InterfaceClassGuid`

A pointer to the class GUID that identifies the functionality (the device interface class) being registered.

`ReferenceString`

Optionally points to a UNICODE_STRING. The string must not contain any path separator characters ("/" or "\"). Function drivers typically specify **NULL** for this parameter. Filter drivers must specify **NULL**.

Reference strings are only used by a few bus drivers, such as *swenum*, which is a bus driver that uses device interface instances as placeholders for software devices created on demand. When an instance of an interface is opened, the I/O manager passes the instance's reference string to the driver. The string becomes part of the interface instance's name (as an appended path component). The driver can then use the reference string to differentiate between two interface instances of the same class for a single device.

On Microsoft Windows 98/Me systems, the *ReferenceString* value can be no longer than MAX_PATH characters. There is no length limit on Windows 2000 and later versions of Windows.

`SymbolicLinkName`

A pointer to a Unicode string structure allocated by the caller. If this routine is successful, it initializes the Unicode string and allocates the string buffer containing the kernel-mode path to the symbolic link for an instance of the specified device interface class.

The caller must treat *SymbolicLinkName* as opaque and must not disassemble it.

The caller is responsible for freeing *SymbolicLinkName* with RtlFreeUnicodeString when it is no longer needed.

Return Value

IoRegisterDeviceInterface returns STATUS_SUCCESS if the call was successful. Possible error return values include the following.

RETURN CODE	DESCRIPTION
STA TUS _IN VAL ID_ DEV ICE_ REQ UES T	The parameters are invalid. Possibilities include that *PhysicalDeviceObject* does not point to a valid PDO, or that the *ReferenceString* string contains an invalid character.

Remarks

IoRegisterDeviceInterface registers a device interface class, if it has not been previously registered, and creates a new instance of the interface class. A driver can call this routine several times for a given device to register several interface classes and create instances of the classes. A function or filter driver typically registers device interfaces in its AddDevice routine. For example, a fault-tolerant volume driver might register an instance of a fault-tolerant-volume interface and an instance of a volume interface for a particular volume.

If the device interface class has not been registered previously, the I/O manager creates a registry key for it, along with instance-specific persistent storage under the key. Drivers can access this persistent storage using IoOpenDeviceInterfaceRegistryKey.

A driver registers an interface instance once and then calls IoSetDeviceInterfaceState to enable and disable the interface.

Registered interfaces persist across operating system reboots. If the specified interface is already registered, the I/O manager passes its name in *SymbolicLinkName*and returns the informational success status STATUS_OBJECT_NAME_EXISTS.

Most drivers use a **NULL** reference string for a device interface instance. If a driver uses a non-**NULL** reference string, it must do additional work, including possibly managing its own namespace and security. A filter driver that exposes a device interface must use a **NULL** *ReferenceString* to avoid conflicts with other drivers in the device stack.

Callers of this routine are not required to remove the registration for a device interface when it is no longer needed. Device interface registrations can be removed from user mode, if necessary.

Callers of **IoRegisterDeviceInterface** must be running at IRQL = PASSIVE_LEVEL in the context of a system thread.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL (see Remarks section)

RtlFreeUnicodeString

IoRegisterLastChanceShutdownNotification function

1/25/2019 • 2 minutes to read • Edit Online

The **IoRegisterLastChanceShutdownNotification** routine registers a driver to receive an IRP_MJ_SHUTDOWN IRP when the system is shut down, after all file systems have been flushed.

Syntax

```
NTSTATUS IoRegisterLastChanceShutdownNotification(
  PDEVICE_OBJECT DeviceObject
);
```

Parameters

`DeviceObject`

Pointer to the device object of the device for which the driver requests shutdown notification. The system passes this pointer to the driver's DispatchShutdown routine.

Return Value

IoRegisterLastChanceShutdownNotification returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure.

Remarks

The **IoRegisterLastChanceShutdownNotification** routine registers the driver to receive an IRP_MJ_SHUTDOWN IRP for the specified device when the system shuts down. The driver receives one such IRP for each device it registers to receive notification for. Drivers handle **IRP_MJ_SHUTDOWN** IRPs within their DispatchShutdown routines.

For any device that is registered with this routine, the system sends the **IRP_MJ_SHUTDOWN** IRP after all file systems are flushed. Only one driver in a device stack should register to receive shutdown notification, by calling either IoRegisterShutdownNotification or **IoRegisterLastChanceShutdownNotification**.

If the driver ceases to require shutdown notification for that device, use IoUnregisterShutdownNotification to remove the driver from the shutdown notification queue.

A driver that calls **IoRegisterLastChanceShutdownNotification** must satisfy the following restrictions in its *DispatchShutdown* routine:

- The *DispatchShutdown* routine must not call any pageable routines.
- The *DispatchShutdown* routine must not access pageable memory.
- The *DispatchShutdown* routine must not perform any file I/O operations.

Most drivers that require shutdown notification should call the IoRegisterShutdownNotification routine, which does not impose these limitations on the *DispatchShutdown* routine, and which causes the *DispatchShutdown* routine to be called before the file systems are flushed. Only drivers that must do some cleanup after the file systems are flushed, such as a driver for a mass storage device, should use **IoRegisterLastChanceShutdownNotification**.

The registered *DispatchShutdown* routine is called before the power manager sends an IRP_MN_SET_POWER request for **PowerSystemShutdown**. The *DispatchShutdown* routine is not called for transitions to any other power states.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows. Not available in Microsoft Windows 98/Me.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

DispatchShutdown

IoRegisterShutdownNotification

IoUnregisterShutdownNotification

IoRegisterPlugPlayNotification function

1/25/2019 • 5 minutes to read • Edit Online

The **IoRegisterPlugPlayNotification** routine registers a Plug and Play (PnP) notification callback routine to be called when a PnP event of the specified category occurs.

Syntax

```
NTSTATUS IoRegisterPlugPlayNotification(
  IO_NOTIFICATION_EVENT_CATEGORY        EventCategory,
  ULONG                                 EventCategoryFlags,
  PVOID                                 EventCategoryData,
  PDRIVER_OBJECT                        DriverObject,
  PDRIVER_NOTIFICATION_CALLBACK_ROUTINE CallbackRoutine,
  __drv_aliasesMem PVOID                Context,
  PVOID                                 *NotificationEntry
);
```

Parameters

`EventCategory`

The category of PnP event for which the callback routine is being registered. *EventCategory* must be one of the following:

EventCategoryDeviceInterfaceChange

PnP events in this category include the arrival (enabling) of a new instance of a device interface class (GUID_DEVICE_INTERFACE_ARRIVAL), or the removal (disabling) of an existing device interface instance (GUID_DEVICE_INTERFACE_REMOVAL).

EventCategoryHardwareProfileChange

PnP events in this category include query-change (GUID_HWPROFILE_QUERY_CHANGE), change-complete (GUID_HWPROFILE_CHANGE_COMPLETE), and change-cancel (GUID_HWPROFILE_CHANGE_CANCELLED) of a hardware profile.

EventCategoryTargetDeviceChange

PnP events in this category include events related to removing a device: the device's drivers received a query-remove IRP (GUID_TARGET_DEVICE_QUERY_REMOVE), the drivers completed a remove IRP (GUID_TARGET_DEVICE_REMOVE_COMPLETE), or the drivers received a cancel-remove IRP (GUID_TARGET_DEVICE_REMOVE_CANCELLED). This category is also used for custom notification events.

`EventCategoryFlags`

Flag bits that modify the registration operation. Possible values include:

PNPNOTIFY_DEVICE_INTERFACE_INCLUDE_EXISTING_INTERFACES

Only valid with an *EventCategory* of **EventCategoryDeviceInterfaceChange**. If set, the PnP manager calls the driver callback routine for each device interface instance that is currently registered and active and registers the callback routine for future arrivals or removals of device interface instances.

`EventCategoryData`

A pointer to further information about the events for which *CallbackRoutine* is being registered. The information varies for different *EventCategory* values:

- When *EventCategory* is **EventCategoryDeviceInterfaceChange**, *EventCategoryData* must point to a GUID specifying a device interface class. *CallbackRoutine* will be called when an interface of that class is enabled or removed.
- When *EventCategory* is **EventCategoryHardwareProfileChange**, *EventCategoryData* must be **NULL**.
- When *EventCategory* is **EventCategoryTargetDeviceChange**, *EventCategoryData* must point to the file object for which PnP notification is requested.

`DriverObject`

A pointer to the caller's driver object.

To ensure that the driver remains loaded while it is registered for PnP notification, this call increments the reference count on *DriverObject*. The PnP manager decrements the reference count when this registration is removed.

`CallbackRoutine`

A pointer to the PnP notification callback routine to be called when the specified PnP event occurs.

The function prototype for this callback routine is defined as follows:

```
typedef NTSTATUS
  DRIVER_NOTIFICATION_CALLBACK_ROUTINE(
    _In_ PVOID NotificationStructure,
    _Inout_opt_ PVOID Context
    );</pre>
```

The callback routine's *NotificationStructure* is specific to the *EventCategory* value, as shown in the following table.

EVENT CATEGORY	NOTIFICATION STRUCTURE
EventCategoryDeviceInterfaceChange	DEVICE_INTERFACE_CHANGE_NOTIFICATION
EventCategoryHardwareProfileChange	HWPROFILE_CHANGE_NOTIFICATION
EventCategoryTargetDeviceChange	TARGET_DEVICE_REMOVAL_NOTIFICATION

The callback routine's *Context* parameter contains the context data the driver supplied during registration.

For information about including a function declaration for the callback routine that meets the requirements of Static Driver Verifier (SDV), see Examples.

The PnP manager calls driver callback routines at IRQL = PASSIVE_LEVEL.

`Context`

A pointer to a caller-allocated buffer containing context that the PnP manager passes to the callback routine.

`NotificationEntry`

A pointer to an opaque value returned by this call that identifies the registration. Pass this value to the IoUnregisterPlugPlayNotificationEx routine to remove the registration.

Return Value

IoRegisterPlugPlayNotification returns STATUS_SUCCESS or an appropriate error status.

Remarks

A driver registers for an event category. Each category includes one or more types of PnP events.

A driver can register different callback routines for different event categories or can register a single callback routine. A single callback routine can cast the *NotificationStructure* to a PLUGPLAY_NOTIFICATION_HEADER and use the **Event** field to determine the exact type of the notification structure.

> **NOTE**
> If the caller specifies PNPNOTIFY_DEVICE_INTERFACE_INCLUDE_EXISTING_INTERFACES, the operating system might call the PnP notification callback routine twice for a single **EventCategoryDeviceInterfaceChange** event for an existing interface. You can safely ignore the second call to the callback. The operating system will not call the callback more than twice for a single event.

PnP notification callback routines should complete their tasks as quickly as possible and return control to the PnP manager, to prevent delays in notifying other drivers and applications that have registered for the event.

The PnP manager does not take out a reference on the file object when a driver registers for notification of an **EventCategoryTargetDeviceChange** event. If the driver's PnP notification callback routine requires access to the file object, the driver should take out an extra reference on the file object before calling **IoRegisterPlugPlayNotification**.

Typically, Kernel-Mode Driver Framework (KMDF) drivers should call **IoRegisterPlugPlayNotification** from their EvtDeviceSelfManagedIoInit callback function, and should call **IoUnregisterPlugPlayNotification** from their EvtDeviceSelfManagedIoCleanup callback function. These drivers should **not** call **IoRegisterPlugPlayNotification** from their EvtDriverDeviceAdd callback function; otherwise, the PnP notification callback routine might be called before the driver stack is started by PnP, in which case the driver will not be prepared to handle the notification.

For more information, see Using PnP Notification.

Examples

To define a PnP notification callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a PnP notification callback routine that is named `MyCallbackRoutine`, use the DRIVER_NOTIFICATION_CALLBACK_ROUTINE type as shown in this code example:

```
DRIVER_NOTIFICATION_CALLBACK_ROUTINE MyCallbackRoutine;</pre>
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
NTSTATUS
  MyCallbackRoutine(
    PVOID NotificationStructure,
    PVOID Context
    )
  {
      // Function body
  }
```

The **DRIVER_NOTIFICATION_CALLBACK_ROUTINE** function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are

applied to the DRIVER_NOTIFICATION_CALLBACK_ROUTINE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about `_Use_decl_annotations_`, see Annotating Function Behavior.

Requirements

IoRegisterShutdownNotification function

1/25/2019 • 2 minutes to read • Edit Online

The **IoRegisterShutdownNotification** routine registers the driver to receive an IRP_MJ_SHUTDOWN IRP when the system is shut down.

Syntax

```
NTSTATUS IoRegisterShutdownNotification(
  PDEVICE_OBJECT DeviceObject
);
```

Parameters

`DeviceObject`

Pointer to the device object of the device for which the driver requests shutdown notification. The system passes this pointer to the driver's DispatchShutdown routine.

Return Value

IoRegisterShutdownNotification returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure.

Remarks

The **IoRegisterShutdownNotification** routine registers the driver to receive an IRP_MJ_SHUTDOWN IRP for the specified device when the system shuts down. The driver receives one such IRP for each device it registers to receive notification for. Drivers handle **IRP_MJ_SHUTDOWN** IRPs within their DispatchShutdown routines.

If the driver ceases to require shutdown notification for the device, use IoUnregisterShutdownNotification to remove the driver from the shutdown notification queue.

Only one driver in a device stack should register to receive shutdown notification.

The system sends the driver the **IRP_MJ_SHUTDOWN** request before it flushes the file systems. Some drivers, such as drivers for mass storage devices, can require shutdown notification after the system flushes the file systems. To receive shutdown notification for a device after the file systems are flushed, use the IoRegisterLastChanceShutdownNotification routine instead.

The registered *DispatchShutdown* routine is called before the power manager sends an IRP_MN_SET_POWER request for **PowerSystemShutdown**. The *DispatchShutdown* routine is not called for transitions to any other power states.

A driver writer can make no assumptions about the order in which the driver's *DispatchShutdown* routine will be called in relation to other such routines or to other shutdown activities.

A PnP driver might register a shutdown routine to perform certain tasks before system shutdown starts, such as locking down code.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows. Not available in Microsoft Windows 98/Me.
Target Platform	Universal

IoRegisterLastChanceShutdownNotification

IoUnregisterShutdownNotification

IoReleaseRemoveLock macro

1/25/2019 • 2 minutes to read • Edit Online

The **IoReleaseRemoveLock** routine releases a remove lock acquired with a previous call to IoAcquireRemoveLock.

Syntax

```
void IoReleaseRemoveLock(
   RemoveLock,
   Tag
);
```

Parameters

`RemoveLock`

Pointer to an **IO_REMOVE_LOCK** structure that the caller passed to a previous call to **IoAcquireRemoveLock**.

`Tag`

Pointer to a caller-supplied tag that was passed to a previous call to **IoAcquireRemoveLock**.

If a driver specified a *Tag* when it acquired the lock, the driver must specify the same *Tag* when releasing the lock. If the tags do not match, this routine asserts on a checked build.

If the call to **IoAcquireRemoveLock** did not specify a *Tag*, then this parameter is **NULL**.

The I/O system only uses this parameter on checked builds.

Return Value

None

Remarks

A driver calls **IoReleaseRemoveLock** when it has completed the I/O operation for which it called IoAcquireRemoveLock.

- For I/O operations (including power and PnP IRPs) that set an IoCompletion routine, a driver should call **IoReleaseRemoveLock** in the *IoCompletion* routine, after calling IoCompleteRequest.
- For I/O operations that do not set an *IoCompletion* routine, a driver should call **IoReleaseRemoveLock** after passing the current IRP to the next-lower driver, but before exiting the dispatch routine.

Each call to IoAcquireRemoveLock must have a corresponding call to **IoReleaseRemoveLock**.

IoReleaseRemoveLock decrements the count of outstanding acquisitions of the remove lock. If the count goes to zero and the driver has received an IRP_MN_REMOVE_DEVICE request, **IoReleaseRemoveLock** sets an internal event. When a driver is ready to delete a device object, it calls a similar routine, IoReleaseRemoveLockAndWait. The driver makes this call only in its dispatch code for an **IRP_MN_REMOVE_DEVICE** request. The **IoReleaseRemoveLockAndWait** routine does not return until **IoReleaseRemoveLock** sets the event that indicates the acquisition count is zero. After **IoReleaseRemoveLockAndWait** returns, the driver can safely detach

and delete the device object.

For more information, see Using Remove Locks.

Requirements

IoAcquireRemoveLock

IoInitializeRemoveLock

IoReleaseRemoveLockAndWait

IoReleaseRemoveLockAndWait macro

1/25/2019 • 2 minutes to read • Edit Online

The **IoReleaseRemoveLockAndWait** routine releases a remove lock that the driver acquired in a previous call to IoAcquireRemoveLock, and waits until all acquisitions of the lock have been released.

Syntax

```
void IoReleaseRemoveLockAndWait(
   RemoveLock,
   Tag
);
```

Parameters

`RemoveLock`

Pointer to an **IO_REMOVE_LOCK** structure that the caller passed in a previous call to **IoAcquireRemoveLock**.

`Tag`

Pointer to a caller-supplied tag that was passed in a previous call to **IoAcquireRemoveLock**.

If a driver specified a *Tag* when it acquired the lock, the driver must specify the same *Tag* when releasing the lock. If the tags do not match, this routine asserts on a checked build.

If the call to **IoAcquireRemoveLock** did not specify a *Tag*, then this parameter is **NULL**.

The I/O system only uses this parameter on checked builds.

Return Value

None

Remarks

A driver typically calls this routine in its dispatch code for an IRP_MN_REMOVE_DEVICE request. To allow queued I/O requests to complete, each driver should call **IoReleaseRemoveLockAndWait** *after* it passes the remove IRP to the next-lower driver, and *before* it releases memory, calls IoDetachDevice, or calls IoDeleteDevice. The **IoReleaseRemoveLockAndWait** routine waits for the bus driver to cancel any IRPs that might be outstanding (for example, an IRP_MN_WAIT_WAKE IRP).

A driver must acquire the remove lock before calling **IoReleaseRemoveLockAndWait**. Typically, a driver calls IoAcquireRemoveLock early in its DispatchPnp routine, before the switch statement. As a result, the lock is acquired for each PnP operation, including the acquisition that is required before calling **IoReleaseRemoveLockAndWait** in the code that handles **IRP_MN_REMOVE_DEVICE**.

To release a lock from code other than the **IRP_MN_REMOVE_DEVICE** dispatch code, use IoReleaseRemoveLock.

After **IoReleaseRemoveLockAndWait** has been called for a particular remove lock, subsequent calls to **IoAcquireRemoveLock** for the same remove lock will fail. **IoReleaseRemoveLockAndWait** does not return

until all outstanding acquisitions of the remove lock have been released.

After **IoReleaseRemoveLockAndWait** returns, the driver should consider the device to be in a state in which it is ready to be removed and cannot perform I/O operations. Therefore, the driver must not call the IoInitializeRemoveLock routine to re-initialize the remove lock. Violation of this rule while the driver is being verified by Driver Verifier will result in a bug check.

For more information, see Using Remove Locks.

IoRemoveLinkShareAccess function

1/25/2019 • 2 minutes to read • Edit Online

The **IoRemoveLinkShareAccess** routine removes the access and link share-access information for a given open instance of a file object.

Syntax

```
void IoRemoveLinkShareAccess(
  PFILE_OBJECT       FileObject,
  PSHARE_ACCESS      ShareAccess,
  PLINK_SHARE_ACCESS LinkShareAccess
);
```

Parameters

`FileObject`

Pointer to the file object, which usually is being closed by the current thread.

`ShareAccess`

Pointer to the share-access structure that describes how the open file object is currently being accessed.

`LinkShareAccess`

Pointer to the share-access structure that describes how the open file object is currently being accessed.

Return Value

None

Remarks

This routine is a reciprocal to IoUpdateLinkShareAccess.

IoRemoveLinkShareAccess is not an atomic operation. Therefore, drivers calling this routine must protect the shared file object passed to **IoRemoveLinkShareAccess** by means of some kind of lock, such as a mutex or a resource lock, in order to prevent corruption of the shared access counts.

Callers of **IoRemoveLinkShareAccess** must be running at IRQL = PASSIVE_LEVEL and in the context of the thread that requested that the *FileObject* be closed.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016

Target Platform	Universal
Header	wdm.h
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoReportInterruptActive function

1/25/2019 • 2 minutes to read • Edit Online

The **IoReportInterruptActive** routine informs the operating system that a registered interrupt service routine (ISR) is active and ready to handle interrupt requests.

Syntax

```
void IoReportInterruptActive(
  PIO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS Parameters
);
```

Parameters

`Parameters`

A pointer to an IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS structure that contains the connection context associated with the interrupt. The caller received this context from the IoConnectInterruptEx call that registered the ISR.

Return Value

None.

Remarks

The IoConnectInterruptEx routine registers an ISR and connects the ISR to an interrupt or interrupts. After the ISR is registered, the driver can make the ISR active or inactive by calling the **IoReportInterruptActive** or IoReportInterruptInactive routine. By default, the ISR is active after the **IoConnectInterruptEx** call.

An ISR that is in the active state can be disconnected or made inactive. To disconnect the ISR and delete its registration, call the IoDisconnectInterruptEx routine. To make the ISR inactive without changing its registration, call **IoReportInterruptInactive**.

The **IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS** structure must contain a valid connection contect obtained from an **IoConnectInterruptEx** call. Otherwise, the **IoReportInterruptActive** routine bug checks in a checked build.

For more information about **IoReportInterruptActive**, see Making an ISR Active or Inactive.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	wdm.h (include Wdm.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

IoReportInterruptInactive

IoReportInterruptInactive function

1/25/2019 • 2 minutes to read • Edit Online

The **IoReportInterruptInactive** routine informs the operating system that a registered interrupt service routine (ISR) is inactive and is not expecting interrupt requests.

Syntax

```
void IoReportInterruptInactive(
  PIO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS Parameters
);
```

Parameters

`Parameters`

A pointer to an IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS structure that contains the connection context associated with the interrupt. The caller received this context from the IoConnectInterruptEx call that registered the ISR.

Return Value

None.

Remarks

The IoConnectInterruptEx routine registers an ISR and connects the ISR to an interrupt or interrupts. After the ISR is registered, the driver can make the ISR active or inactive by calling the IoReportInterruptActive or **IoReportInterruptInactive** routine. By default, the ISR is active after the **IoConnectInterruptEx** call.

An ISR that is in the inactive state can be disconnected or made active. To disconnect the ISR and delete its registration, call the IoDisconnectInterruptEx routine. To make the ISR active without changing its registration, call **IoReportInterruptActive**.

The **IO_REPORT_INTERRUPT_ACTIVE_STATE_PARAMETERS** structure must contain a valid connection contect obtained from an **IoConnectInterruptEx** call. Otherwise, the **IoReportInterruptInactive** routine bug checks in a checked build.

For more information about **IoReportInterruptInactive**, see Making an ISR Active or Inactive.

IoConnectInterruptEx

IoDisconnectInterruptEx

IoReportInterruptActive

IoReportTargetDeviceChange function

1/25/2019 • 2 minutes to read • Edit Online

The **IoReportTargetDeviceChange** routine notifies the PnP manager that a custom event has occurred on a device.

Syntax

```
NTSTATUS IoReportTargetDeviceChange(
  PDEVICE_OBJECT PhysicalDeviceObject,
  PVOID          NotificationStructure
);
```

Parameters

`PhysicalDeviceObject`

Pointer to the PDO of the device being reported.

`NotificationStructure`

Pointer to a caller-supplied TARGET_DEVICE_CUSTOM_NOTIFICATION structure describing the custom event. The PnP manager sends this structure to drivers that registered for notification of the event.

NotificationStructure.**FileObject** must be **NULL**. *NotificationStructure*.**Event** must contain the custom GUID for the event. The other fields of the *NotificationStructure* must be filled in as appropriate for the custom event.

The PnP manager fills in the *NotificationStructure*.**FileObject** field when it sends notifications to registrants.

Return Value

IoReportTargetDeviceChange returns STATUS_SUCCESS or an appropriate error status. Possible error status values include the following.

RETURN CODE	DESCRIPTION
STATUS_INVALID_DEVICE_REQUEST	The caller specified a system PnP event, such as GUID_TARGET_DEVICE_QUERY_REMOVE. This routine is only for custom events.

Remarks

After **IoReportTargetDeviceChange** notifies the PnP manager that a custom event has occurred on a device, the PnP manager sends notification of the event to drivers that registered for notification on the device. Do not use this

routine to report system PnP events, such as GUID_TARGET_DEVICE_REMOVE_COMPLETE.

A driver that defines a custom device event calls **IoReportTargetDeviceChange** to inform the PnP manager that the custom event has occurred. Custom notification can be used for events like a volume label change.

A driver should call the asynchronous form of this routine, IoReportTargetDeviceChangeAsynchronous, instead of this routine, to prevent deadlocks.

Certain kernel-mode components can call this synchronous routine. For example, a file system can call **IoReportTargetDeviceChange** to report a "get off the volume" custom event when a component tries to open the volume for exclusive access. Clients that register for notification on file system volumes are careful to not request an exclusive open in a PnP notification callback routine.

The custom notification structure contains a driver-defined event with its own GUID. Driver writers can generate GUIDs with Uuidgen.exe or Guidgen.exe (which are included in the Microsoft Windows SDK).

Callers of **IoReportTargetDeviceChange** must be running at IRQL = PASSIVE_LEVEL in the context of a system thread. To report a target device change from IRQL > PASSIVE_LEVEL, call **IoReportTargetDeviceChangeAsynchronous**.

IoReportTargetDeviceChange is not supported on Windows 98/Me; it returns STATUS_NOT_IMPLEMENTED.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL (see Remarks section)
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

IoReportTargetDeviceChangeAsynchronous

TARGET_DEVICE_CUSTOM_NOTIFICATION

IoReportTargetDeviceChangeAsynchronous function

1/25/2019 • 2 minutes to read • Edit Online

The **IoReportTargetDeviceChangeAsynchronous** routine notifies the PnP manager that a custom event has occurred on a device.

Syntax

```
NTSTATUS IoReportTargetDeviceChangeAsynchronous(
  PDEVICE_OBJECT                  PhysicalDeviceObject,
  PVOID                           NotificationStructure,
  PDEVICE_CHANGE_COMPLETE_CALLBACK Callback,
  PVOID                           Context
);
```

Parameters

`PhysicalDeviceObject`

Pointer to the PDO of the device being reported.

`NotificationStructure`

Pointer to a caller-supplied TARGET_DEVICE_CUSTOM_NOTIFICATION structure describing the custom event. The PnP manager sends this structure to drivers that registered for notification of the event.

NotificationStructure.**FileObject** must be **NULL**. *NotificationStructure*.**Event** must contain the custom GUID for the event. The other fields of the *NotificationStructure* must be filled in as appropriate for the custom event.

The PnP manager fills in the *NotificationStructure*.**FileObject** field when it sends notifications to registrants.

`Callback`

Optionally points to a caller-supplied routine that the PnP manager calls after it finishes notifying drivers that registered for this custom event.

The callback routine has the following type:

```
typedef
VOID
(*PDEVICE_CHANGE_COMPLETE_CALLBACK)(
    IN PVOID Context
    );
```

A device-change-complete callback routine should not block and must not call synchronous routines that generate PnP events.

The PnP manager calls device-change-complete callback routines at IRQL = PASSIVE_LEVEL.

`Context`

Optionally points to a caller-supplied context structure that the PnP manager passes to the *Callback* routine. The caller must allocate this structure from nonpaged memory.

Return Value

IoReportTargetDeviceChangeAsynchronous returns STATUS_SUCCESS or an appropriate error status. Possible error status values include the following.

RETURN CODE	DESCRIPTION
STA TUS _IN VAL ID_ DEV ICE_ REQ UES T	The caller specified a system PnP event, such as GUID_TARGET_DEVICE_QUERY_REMOVE. This routine is only for custom events.

Remarks

After the **IoReportTargetDeviceChangeAsynchronous** routine notifies the PnP manager that a custom event has occurred on a device, the routine returns immediately; it does not wait while the PnP manager sends notification of the event to drivers that registered for notification on the device. Do not use this routine to report system PnP events, such as GUID_TARGET_DEVICE_REMOVE_COMPLETE.

A driver that defines a custom device event calls **IoReportTargetDeviceChangeAsynchronous** to inform the PnP manager that the custom event has occurred. Custom notification can be used for events like a volume label change.

The custom notification structure contains a driver-defined event with its own GUID. Driver writers can generate GUIDs with Uuidgen.exe or Guidgen.exe (which are included in the Microsoft Windows SDK).

When a driver calls this routine while handling an event, an IRP_MN_REMOVE_DEVICE, or an IRP_MN_SURPRISE_REMOVAL, the PnP manager calls the driver's *Callback* routine after the driver returns and the stack unwinds.

Callers of **IoReportTargetDeviceChangeAsynchronous** must be running at IRQL <= DISPATCH_LEVEL. If a driver writer calls this routine at IRQL = DISPATCH_LEVEL, the *NotificationStructure* must be allocated from nonpaged memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL (see Remarks section)"
DDI compliance rules	HwStorPortProhibitedDDIs

IoReportTargetDeviceChange

TARGET_DEVICE_CUSTOM_NOTIFICATION

IoRequestDeviceEject function

1/25/2019 • 3 minutes to read • Edit Online

The **IoRequestDeviceEject** routine notifies the PnP manager that the device eject button was pressed.

Syntax

```
void IoRequestDeviceEject(
  PDEVICE_OBJECT PhysicalDeviceObject
);
```

Parameters

`PhysicalDeviceObject`

Pointer to the PDO for the device.

Return Value

None

Remarks

Note that this routine reports a request for device eject, not media eject.

Typically, a PnP bus driver calls **IoRequestDeviceEject** to notify the PnP manager that a user pressed the device eject button on one of its child devices.

A driver calls this routine, rather than sending an IRP_MN_EJECT request, because this routine allows the PnP manager to coordinate additional actions for the eject besides sending the IRP. For example, the PnP manager notifies user-mode and kernel-mode components that registered for notification of changes on the device.

The PnP manager directs an orderly shutdown of the device. The PnP manager:

1. Creates a list of other devices that are affected by this device being ejected.

   The PnP manager queries for the device's removal relations, ejection relations, and bus relations (child devices).

2. Determines whether the device and its related devices can be software-removed.

   The PnP manager sends IRP_MN_QUERY_REMOVE_DEVICE IRPs to the drivers for the device and its related devices. The PnP manager also sends notifications to any user-mode and kernel-mode components that registered for device-change notification on the device or any of its related devices. If any of the drivers or user-mode components fail the query-remove, the PnP manager pops up a dialog box to notify the user that the eject failed.

3. Software-removes the device and its related devices.

   If the previous steps are successful, the PnP manager notifies registered drivers and applications that the device and its related devices are being software-removed. Then the PnP manager sends IRP_MN_REMOVE_DEVICE IRPs to the drivers for the device and its related devices. Function and filter drivers detach from the device stack and delete their device objects for the device(s). The bus drivers retain

the PDO(s) for the device(s), unless a device is physically gone and the bus driver omitted the device in its most recent response to IRP_MN_QUERY_DEVICE_RELATIONS/**BusRelations** for the device's parent bus.

4. Directs the bus driver to eject the device (if possible).

   The PnP manager takes different steps, depending on the eject capabilities of the device:

   - Hot eject is supported.

     If the **EjectSupported** capability is set for the device, the device can be ejected when the system is running (is in the **PowerSystemWorking** state). The PnP manager sends an IRP_MN_EJECT request to the bus driver for the device. Any function and filter drivers detached previously from the stack in response to the remove IRP, so the bus driver handles the eject IRP. When the bus driver completes the IRP, the PnP manager expects the device to be physically absent from the system.

   - Hot eject is not supported.

     In this case, the device is **Removable** but does not support eject. The PnP manager marks the device as not-present/not-working-properly. The PnP manager will not restart the device until a user physically removes it and reinserts it. In this case, the PnP manager does not send an **IRP_MN_EJECT**.

   A device's parent bus driver sets the capabilities for a device, including its eject capabilities, in response to an IRP_MN_QUERY_CAPABILITIES request. A function or filter driver can optionally specify capabilities.

When a device is ejected, its child devices are physically removed from the system along with it.

A user-mode application can initiate a device eject. In that case, no driver calls this routine but the operating system calls the PnP manager to initiate the steps listed above.

Callers of **IoRequestDeviceEject** must be running at IRQL <= DISPATCH_LEVEL. The PnP manager performs most of its device-eject tasks listed above at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL (see Remarks section)"

IoRequestDpc function

1/25/2019 • 2 minutes to read • Edit Online

The **IoRequestDpc** routine queues a driver-supplied DpcForIsr routine to complete interrupt-driven I/O processing at a lower IRQL.

Syntax

```
void IoRequestDpc(
  PDEVICE_OBJECT         DeviceObject,
  PIRP                   Irp,
  __drv_aliasesMem PVOID Context
);
```

Parameters

`DeviceObject`

Pointer to the device object for which the request that caused the interrupt is being processed.

`Irp`

Pointer to the current IRP for the specified device.

`Context`

Pointer to a driver-determined context to be passed to the DPC routine.

Return Value

None

Remarks

Callers of **IoRequestDpc** must be running at DIRQL.

Drivers call **IoRequestDpc** from an InterruptService routine. Because of this, **IoRequestDpc** runs at the DIRQL value that was specified by *SynchronizeIrql* when the driver called IoConnectInterrupt. However, it is also possible to queue a DPC at any IRQL >= DISPATCH_LEVEL by using the **Ke*Xxx*Dpc** routines. For more information, see Which Type of DPC Should You Use?

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IRQL	DIRQL

KeInsertQueueDpc

IoReuseIrp function

1/25/2019 • 2 minutes to read • Edit Online

The **IoReuseIrp** routine reinitializes an IRP so that it can be reused.

Syntax

```
void IoReuseIrp(
  PIRP     Irp,
  NTSTATUS Iostatus
);
```

Parameters

`Irp`

Pointer to the IRP to be reinitialized for reuse.

`Iostatus`

Return Value

None

Remarks

Drivers for Windows 2000 and later versions of Windows use **IoReuseIrp** to reuse an IRP.

A driver should use **IoReuseIrp** only on IRPs it previously allocated either as raw memory or with IoAllocateIrp. In particular, drivers should not use this routine for IRPs created with IoMakeAssociatedIrp, IoBuildSynchronousFsdRequest, IoBuildAsynchronousFsdRequest, or IoBuildDeviceIoControlRequest.

See Reusing IRPs for more details on how to reuse IRPs.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=DISPATCH_LEVEL"

IoSetCancelRoutine function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetCancelRoutine** routine sets up a driver-supplied Cancel routine to be called if a given IRP is canceled.

Syntax

```
PDRIVER_CANCEL IoSetCancelRoutine(
  PIRP           Irp,
  PDRIVER_CANCEL CancelRoutine
);
```

Parameters

`Irp`

Pointer to the IRP being put into or removed from a cancelable state.

`CancelRoutine`

Specifies the entry point of the caller-supplied Cancel routine to be called if the specified IRP is canceled or is **NULL** if the given IRP is being removed from the cancelable state. This routine is declared as follows:

```
VOID
(*PDRIVER_CANCEL)(
    IN PDEVICE_OBJECT DeviceObject,
    IN PIRP Irp
    );
```

Return Value

IoSetCancelRoutine returns the previous value of *Irp*->**CancelRoutine**. If no *Cancel* routine was previously set, or if IRP cancellation is already in progress, **IoSetCancelRoutine** returns **NULL**.

Remarks

This routine can disable the *Cancel* routine currently set in an IRP.

A driver must hold the system cancel spin lock when calling this routine if the driver uses the I/O manager-supplied device queue in the device object. The driver runs at IRQL = DISPATCH_LEVEL after calling IoAcquireCancelSpinLock until it releases the cancel spin lock with IoReleaseCancelSpinLock.

If the driver manages its own queues of IRPs, then the driver need not hold the cancel spin lock when calling this routine. **IoSetCancelRoutine** uses an interlocked exchange intrinsic to set the address of the *Cancel* routine as an atomic operation. Reduced usage of the cancel spin lock can improve driver performance and overall system performance.

Driver *Cancel* routines are called at IRQL = DISPATCH_LEVEL with the cancel spin lock held. The *Cancel* routine must release the cancel spin lock before it returns control.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoAcquireCancelSpinLock

IoReleaseCancelSpinLock

IoSetCompletionRoutine function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetCompletionRoutine** routine registers an IoCompletion routine, which will be called when the next-lower-level driver has completed the requested operation for the given IRP.

Syntax

```
void IoSetCompletionRoutine(
  PIRP                    Irp,
  PIO_COMPLETION_ROUTINE CompletionRoutine,
  __drv_aliasesMem PVOID Context,
  BOOLEAN                 InvokeOnSuccess,
  BOOLEAN                 InvokeOnError,
  BOOLEAN                 InvokeOnCancel
);
```

Parameters

`Irp`

Pointer to the IRP that the driver is processing.

`CompletionRoutine`

Specifies the entry point for the driver-supplied IoCompletion routine, which is called when the next-lower driver completes the packet.

`Context`

Pointer to a driver-determined context to pass to the IoCompletion routine. Context information must be stored in nonpaged memory, because the *IoCompletion* routine is called at IRQL <= DISPATCH_LEVEL.

`InvokeOnSuccess`

Specifies whether the completion routine is called if the IRP is completed with a success status value in the IRP's IO_STATUS_BLOCK structure, based on results of the **NT_SUCCESS** macro (see Using NTSTATUS values).

`InvokeOnError`

Specifies whether the completion routine is called if the IRP is completed with a nonsuccess status value in the IRP's **IO_STATUS_BLOCK** structure.

`InvokeOnCancel`

Specifies whether the completion routine is called if a driver or the kernel has called IoCancelIrp to cancel the IRP.

Return Value

None

Remarks

Note Only a driver that can guarantee it will not be unloaded before its completion routine finishes can use **IoSetCompletionRoutine**. Otherwise, the driver must use IoSetCompletionRoutineEx, which prevents the driver from unloading until its completion routine executes.

This routine sets the transfer address of the IoCompletion routine in the given IRP. The lowest-level driver in a chain of layered drivers cannot call this routine.

IoSetCompletionRoutine registers the specified routine to be called when the next-lower-level driver has completed the requested operation in any or all of the following ways:

- With a success status value
- With a nonsuccess status value
- By canceling the IRP

Usually, the I/O status block is set by the underlying device driver. It is read but not altered by any higher-level drivers' *IoCompletion* routines.

Higher-level drivers that allocate IRP's with IoAllocateIrp or IoBuildAsynchronousFsdRequest must call this routine with all *InvokeOn*Xxx parameters set to **TRUE** before passing the driver-allocated IRP to IoCallDriver. When the *IoCompletion* routine is called with such an IRP, it must free the driver-allocated IRP and any other resources that the driver set up for the request, such as MDLs with IoBuildPartialMdl. Such a driver should return STATUS_MORE_PROCESSING_REQUIRED when it calls IoFreeIrp to forestall the I/O manager's completion processing for the driver-allocated IRP.

Non-PnP drivers that might be unloaded before their *IoCompletion* routines run should use IoSetCompletionRoutineEx instead.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IoBuildPartialMdl

IoFreeIrp

IoSetCompletionRoutineEx

IoSetCompletionRoutineEx function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetCompletionRoutineEx** routine registers an IoCompletion routine, which is called when the next-lower-level driver has completed the requested operation for the given IRP.

Syntax

```
NTSTATUS IoSetCompletionRoutineEx(
  PDEVICE_OBJECT         DeviceObject,
  PIRP                   Irp,
  PIO_COMPLETION_ROUTINE CompletionRoutine,
  PVOID                  Context,
  BOOLEAN                InvokeOnSuccess,
  BOOLEAN                InvokeOnError,
  BOOLEAN                InvokeOnCancel
);
```

Parameters

`DeviceObject`

Pointer to the driver's device object.

`Irp`

Pointer to the IRP that the driver is processing.

`CompletionRoutine`

Specifies the entry point for the driver-supplied IoCompletion routine, which is called when the next-lower driver completes the packet.

`Context`

Pointer to a driver-determined context to pass to the *IoCompletion* routine. Context information must be stored in nonpaged memory, because the *IoCompletion* routine is called at IRQL <= DISPATCH_LEVEL.

`InvokeOnSuccess`

Specifies whether the completion routine is called if the IRP is completed with a success status value in the IRP's IO_STATUS_BLOCK structure, based on results of the NT_SUCCESS macro (see Using NTSTATUS values).

`InvokeOnError`

Specifies whether the completion routine is called if the IRP is completed with a nonsuccess status value in the IRP's **IO_STATUS_BLOCK** structure.

`InvokeOnCancel`

Specifies whether the completion routine is called if a driver or the kernel has called IoCancelIrp to cancel the IRP.

Return Value

This routine returns STATUS_SUCCESS on success, or STATUS_INSUFFICIENT_RESOURCES if insufficient

memory is available for the operation.

Remarks

> **Note** Unlike IoSetCompletionRoutine, the **IoSetCompletionRoutineEx** routine returns an NTSTATUS value. The driver must check this value to determine if the IoCompletion routine was successfully registered. If the *IoCompletion* routine is successfully registered, **IoSetCompletionRoutineEx** allocates memory that remains allocated until the *IoCompletion* routine executes. Drivers must ensure that their *IoCompletion* routine executes by calling IoCallDriver; otherwise, the kernel will leak memory.

The *IoCompletion* routine must belong to the driver that owns the device object pointed to by *DeviceObject*. This requirement prevents the *IoCompletion* routine from being unloaded before it returns.

The behavior of **IoSetCompletionRoutineEx** is the same as the IoSetCompletionRoutine routine, except that:

- **IoSetCompletionRoutineEx** guarantees that a non-Plug and Play driver is not unloaded before the *IoCompletion* routine runs.
- **IoSetCompletionRoutineEx** is a routine that returns an NTSTATUS value.

IoSetCompletionRoutine

IoSetDeviceInterfacePropertyData function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetDeviceInterfacePropertyData** routine modifies the current value of a device interface property.

Syntax

```
NTSTATUS IoSetDeviceInterfacePropertyData(
  PUNICODE_STRING  SymbolicLinkName,
  const DEVPROPKEY *PropertyKey,
  LCID             Lcid,
  ULONG            Flags,
  DEVPROPTYPE      Type,
  ULONG            Size,
  PVOID            Data
);
```

Parameters

`SymbolicLinkName`

A pointer to a string that identifies the device interface instance. This string was obtained from a previous call to the IoGetDeviceInterfaces, IoGetDeviceInterfaceAlias, or IoRegisterDeviceInterface routine.

`PropertyKey`

A pointer to a DEVPROPKEY structure that contains the device interface property key.

`Lcid`

Specifies a locale identifier. Set this parameter either to a language-specific LCID value or to **LOCALE_NEUTRAL**. The **LOCALE_NEUTRAL** LCID specifies that the property is language-neutral (that is, not specific to any language). Do not set this parameter to **LOCALE_SYSTEM_DEFAULT** or **LOCALE_USER_DEFAULT**. For more information about language-specific LCID values, see LCID Structure.

`Flags`

Set this parameter to **PLUGPLAY_PROPERTY_PERSISTENT** if the property value set by this routine should persist across computer restarts. Otherwise, set *Flags* to zero.

`Type`

Set this parameter to the DEVPROPTYPE value that specifies the type of the data that is supplied in the *Data* buffer.

`Size`

Specifies the size, in bytes, of the buffer that *Data* points to.

`Data`

A pointer to the device interface property data. Set this parameter to **NULL** to delete the specified property. If *Data* is non-**NULL**, the routine stores an internal copy of the property value. The buffer pointed to by *Data* does not need to remain valid after the call returns.

Return Value

IoSetDeviceInterfacePropertyData returns STATUS_SUCCESS if the call was successful. Possible error return values include the following status codes.

RETURN CODE	DESCRIPTION
STA TUS _UN SUC CES SFU L	The specified LCID value is not valid.
STA TUS _NO T_I MP LEM ENT ED	The specified property is not supported.

Remarks

Kernel-mode drivers use the **IoSetDeviceInterfacePropertyData** routine to modify device interface properties that are defined as part of the unified device property model. For more information about device interface properties, see Device Properties.

Drivers can use the IoGetDeviceInterfacePropertyData routine to obtain the current value for a device interface property.

Callers of **IoSetDeviceInterfacePropertyData** must be running at IRQL <= APC_LEVEL in the context of a system thread.

Requirements

Minimum supported client	Available for Windows 8 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

IoGetDeviceInterfacePropertyData

IoSetDeviceInterfaceState function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetDeviceInterfaceState** routine enables or disables an instance of a previously registered device interface class.

Syntax

```
NTSTATUS IoSetDeviceInterfaceState(
  PUNICODE_STRING SymbolicLinkName,
  BOOLEAN         Enable
);
```

Parameters

`SymbolicLinkName`

Pointer to a string that identifies the device interface instance that is being enabled or disabled. This string was obtained from a previous call to IoRegisterDeviceInterface or IoGetDeviceInterfaces.

`Enable`

TRUE indicates that the device interface is being enabled. **FALSE** indicates that the device interface is being disabled.

Return Value

IoSetDeviceInterfaceState returns STATUS_SUCCESS if the call was successful. This routine returns an informational status of STATUS_OBJECT_NAME_EXISTS if the caller requested to enable a device interface that was already enabled. Possible error return values are described following.

RETURN CODE	DESCRIPTION
STATUS_OBJECT_NAME_NOT_FOUND	The caller tried to disable a device interface that was not enabled.

Remarks

IoSetDeviceInterfaceState enables an instance of a registered device interface for use by applications and other system components. The interface class must have been previously registered with IoRegisterDeviceInterface or from user mode.

Applications and other system components can open only interfaces that are enabled.

A function or a filter driver typically calls this routine with *Enable* set to **TRUE** after it successfully starts a device in response to an IRP_MN_START_DEVICE IRP. Such a driver should disable the device interface instance (that is, call **IoSetDeviceInterfaceState** and set *Enable* to **FALSE**) when it removes the device in response to an IRP_MN_REMOVE_DEVICE IRP or an IRP_MN_SURPRISE_REMOVAL IRP. If a driver does not disable a device interface when it processes these removal IRPs, the driver should not subsequently attempt to do so because the PnP manager will disable the interface when the PnP manager removes the device.

If a device is removed suddenly (for example, by a surprise removal) but still has a valid device interface instance, a problem will occur if the device is reattached. This problem occurs when the PnP manager enumerates the newly attached device and enables a device interface instance, which will exist at the same registry path as the existing device interface instance.

Note that if the driver calls **IoSetDeviceInterfaceState** to disable a device interface instance in response to an **IRP_MN_SURPRISE_REMOVAL** IRP, the driver must not attempt to disable the same device interface instance in response to an **IRP_MN_REMOVE_DEVICE** IRP.

If a call to **IoSetDeviceInterfaceState** successfully exposes a device interface instance, the system notifies any components that registered for PnP notification of a device class change. Similarly, if a call to this routine disables an existing device interface instance, the system sends appropriate notifications.

The PnP manager does not send notification of interface instance arrivals until the **IRP_MN_START_DEVICE** IRP completes, indicating that all the drivers for the device have completed their start operations. In addition, the PnP manager fails create requests for the device until the **IRP_MN_START_DEVICE** IRP completes.

Callers of **IoSetDeviceInterfaceState** must be running at IRQL = PASSIVE_LEVEL in the context of a system thread.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL (see Remarks section)

IoSetDevicePropertyData function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetDevicePropertyData** routine modifies the current setting for a device property.

Syntax

```
NTSTATUS IoSetDevicePropertyData(
  PDEVICE_OBJECT   Pdo,
  const DEVPROPKEY *PropertyKey,
  LCID             Lcid,
  ULONG            Flags,
  DEVPROPTYPE      Type,
  ULONG            Size,
  PVOID            Data
);
```

Parameters

`Pdo`

A pointer to the physical device object (PDO) for the device that is being queried.

`PropertyKey`

A pointer to a DEVPROPKEY structure that specifies the device property key.

`Lcid`

A locale identifier. Set this parameter either to a language-specific LCID value or to **LOCALE_NEUTRAL**.

The **LOCALE_NEUTRAL** LCID specifies that the property is language-neutral (that is, not specific to any language).

Do not set this parameter to **LOCALE_SYSTEM_DEFAULT** or **LOCALE_USER_DEFAULT**.

For more information about language-specific LCID values, see LCID Structure.

`Flags`

Set this parameter to **PLUGPLAY_PROPERTY_PERSISTENT** if the property value set by this routine should persist across computer restarts. Otherwise, set *Flags* to zero.

Windows 8 and Windows Server 2012 and later operating systems treat **Flags** as if **PLUGPLAY_PROPERTY_PERSISTENT** is always passed.

`Type`

A DEVPROPTYPE value that specifies the type of the data that is provided in the *Data* buffer.

`Size`

The size, in bytes, of the buffer that *Data* points to.

`Data`

A pointer to the device property data. Set this parameter to **NULL** to delete the specified property. If *Data* is non-**NULL**, the routine stores an internal copy of the property value. The buffer pointed to by *Data* does not need to remain valid after the call returns.

Return Value

IoSetDevicePropertyData returns STATUS_SUCCESS if the call was successful, or the appropriate NTSTATUS code on failure.

Remarks

Kernel-mode drivers use the **IoSetDevicePropertyData** routine to modify device properties that are defined as part of the unified device property model. For more information about device properties, see Device Properties.

To delete a property for a specific locale, pass a language-specific LCID value in *Lcid* and **NULL** in *Data*.

To delete a property for all locales, pass **LOCALE_NEUTRAL** in *Lcid* and **NULL** in *Data*.

To modify a property for a specific locale, pass a language-specific LCID value in *Lcid* and non-**NULL** in *Data*.

To modify a property for all locales, pass **LOCALE_NEUTRAL** in *Lcid* and non-**NULL** in *Data*.

Beginning with Windows 8 and Windows Server 2012 passing **LOCALE_NEUTRAL** in *Lcid* is treated like any other locale.

Drivers can use the IoGetDevicePropertyData routine to obtain the current value for a device property.

Callers of **IoSetDeviceProperty** must be running at IRQL <= APC_LEVEL in the context of a system thread.

Requirements

Minimum supported client	Available starting with Windows Vista.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoGetDevicePropertyData

IoSetIoPriorityHint function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetIoPriorityHint** routine sets the priority hint value for an IRP.

Syntax

```
NTSTATUS IoSetIoPriorityHint(
  PIRP             Irp,
  IO_PRIORITY_HINT PriorityHint
);
```

Parameters

`Irp`

Specifies the IRP to set the priority hint value for.

`PriorityHint`

Specifies the IO_PRIORITY_HINT value that indicates the new priority hint.

Return Value

IoSetIoPriorityHint returns STATUS_SUCCESS if the operation succeeds and the appropriate NTSTATUS value if the operation fails.

Remarks

For more information about priority hints, see Using IRP Priority Hints.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

IO_PRIORITY_HINT

IoSetLinkShareAccess function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetLinkShareAccess** routine sets the access rights for link sharing the specified file object.

Syntax

```
void IoSetLinkShareAccess(
  ACCESS_MASK        DesiredAccess,
  ULONG              DesiredShareAccess,
  PFILE_OBJECT       FileObject,
  PSHARE_ACCESS      ShareAccess,
  PLINK_SHARE_ACCESS LinkShareAccess,
  ULONG              IoShareAccessFlags
);
```

Parameters

`DesiredAccess`

Specifies an ACCESS_MASK value that indicates the desired type of access to the given file object.

`DesiredShareAccess`

Specifies the desired type of shared access to the file object for the current open request. The value of this parameter is usually the same as the *ShareAccess* parameter that is passed to the file system or highest-level driver by the I/O manager when the open request was made. This value can be zero, or any combination of the following:

FILE_SHARE_READ

FILE_SHARE_WRITE

FILE_SHARE_DELETE

`FileObject`

A pointer to the file object for which to check access for the current open request.

`ShareAccess`

A pointer to the common share-access data structure that is associated with *FileObject*. Drivers should treat this structure as opaque.

`LinkShareAccess`

A pointer to the common link share-access data structure (LINK_SHARE_ACCESS) that is associated with *FileObject*. Drivers should treat this structure as opaque.

`IoShareAccessFlags`

A bitmask of these flags:

IO_SHARE_ACCESS_NO_WRITE_PERMISSION (0x80000000) specifies that the user has no write permission for the file. This flag is used to prevent opening a file for exclusive read access when the user does not have appropriate permissions.

IO_CHECK_SHARE_ACCESS_UPDATE_SHARE_ACCESS (0x00000001) indicates whether the SHARE_ACCESS structure is updated.

Return Value

This function does not return a value.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Target Platform	Universal
Header	wdm.h
Library	Ntoskrnl.lib

See Also

IoCheckLinkShareAccess

IoRemoveLinkShareAccess

IoUpdateLinkShareAccess

IoSetNextIrpStackLocation function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetNextIrpStackLocation** routine sets the IRP stack location in a driver-allocated IRP to that of the caller.

Syntax

```
void IoSetNextIrpStackLocation(
  PIRP Irp
);
```

Parameters

`Irp`

Pointer to the IRP whose stack location is to be set.

Return Value

None

Remarks

In general, this routine is seldom used by drivers. It is primarily used by drivers that require their own stack location in an IRP that they have allocated, on their own, to send to another driver.

IoSetNextIrpStackLocation is generally not needed because either:

- The driver received the IRP it is passing from another, higher-level driver, and so it already owns a stack location,
- Or, the driver allocated the IRP but does not need its own stack location because it can keep everything that it needs in a context block whose address can be passed to its *IoCompletion* routine.

Care should be taken if this routine is called, especially when allocating the IRP with **IoAllocateIrp** or **IoMakeAssociatedIrp**. The writer of the allocating driver must remember that a caller-specific stack location is not included in the number of stack locations required by the lower-level drivers to which it sends IRPs with **IoCallDriver**. A driver must explicitly specify a stack location for itself in its call to **IoAllocateIrp** or **IoMakeAssociatedIrp** if it calls **IoSetNextIrpStackLocation** with the IRP returned by either routine.

A driver cannot call **IoSetNextIrpStackLocation** with any IRP it allocates by calling **IoBuildAsynchronousFsdRequest**, **IoBuildDeviceIoControlRequest**, or **IoBuildSynchronousFsdRequest**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Any level

IoSetCompletionRoutine

IoSetShareAccess function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetShareAccess** routine sets the access rights for sharing the given file object.

Syntax

```
void IoSetShareAccess(
  ACCESS_MASK   DesiredAccess,
  ULONG         DesiredShareAccess,
  PFILE_OBJECT  FileObject,
  PSHARE_ACCESS ShareAccess
);
```

Parameters

`DesiredAccess`

Specifies an ACCESS_MASK value that represents the type of access requested for the *FileObject*. See IoCreateFile for a complete list of system-defined *DesiredAccess*flags.

`DesiredShareAccess`

Specifies the type of share access to be set for the file object. This value can be zero, or any combination of the following:

FILE_SHARE_READ

FILE_SHARE_WRITE

FILE_SHARE_DELETE

`FileObject`

Pointer to the file object whose share access is being set or reset.

`ShareAccess`

Pointer to the SHARE_ACCESS structure associated with *FileObject*. Drivers should treat this structure as opaque.

Return Value

None

Remarks

Only highest-level kernel-mode drivers should call this routine. The call must occur in the context of the first thread that attempts to open the *FileObject*.

This routine sets the access and share access information when the *FileObject* is first opened. It returns a pointer to the common share-access data structure associated with *FileObject*. Callers should save this pointer for later use when updating the access or closing the file.

Generally, file system drivers (FSDs) are most likely to call this routine. However, other highest-level drivers can

call **IoSetShareAccess** to control the kind of access allowed to a driver-created device object associated with the given *FileObject*.

IoSetShareAccess is not an atomic operation. Therefore, drivers calling this routine must protect the shared file object passed to **IoSetShareAccess** by means of some kind of lock, such as a mutex or a resource lock, in order to prevent corruption of the shared access counts.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoRemoveShareAccess

IoUpdateShareAccess

IoSetShareAccessEx function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetShareAccessEx** routine sets the access rights for sharing the specified file object.

Syntax

```
void IoSetShareAccessEx(
  ACCESS_MASK   DesiredAccess,
  ULONG         DesiredShareAccess,
  PFILE_OBJECT  FileObject,
  PSHARE_ACCESS ShareAccess,
  PBOOLEAN      WritePermission
);
```

Parameters

`DesiredAccess`

Specifies an ACCESS_MASK value that represents the type of access requested for the file object. See IoCreateFile for a complete list of system-defined *DesiredAccess* flags.

`DesiredShareAccess`

Specifies the type of share access to be set for the file object. This value can be zero, or any combination of the following flags:

FILE_SHARE_READ

FILE_SHARE_WRITE

FILE_SHARE_DELETE

`FileObject`

A pointer to the file object whose share access is being set or reset.

`ShareAccess`

A pointer to the **SHARE_ACCESS** structure that is associated with *FileObject*. Drivers should treat this structure as opaque.

`WritePermission`

A pointer to the value that specifies whether the file object has write permission. This value is **TRUE** if the share has write permission; otherwise, it is **FALSE**. If the value is **FALSE** and the caller attempts to take exclusive read access, the write permission is downgraded to FILE_SHARE_READ.

Return Value

None.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h
Library	Ntoskrnl.lib

IoCreateFile

IoSetStartIoAttributes function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSetStartIoAttributes** routine sets attributes for the driver's StartIo routine.

Syntax

```
void IoSetStartIoAttributes(
  PDEVICE_OBJECT DeviceObject,
  BOOLEAN        DeferredStartIo,
  BOOLEAN        NonCancelable
);
```

Parameters

`DeviceObject`

Pointer to the device object for the driver's device.

`DeferredStartIo`

If **TRUE**, the I/O manager will defer any call to the driver's StartIo routine while the driver is already inside the routine. In particular, if the *StartIo* routine calls IoStartNextPacket, the *StartIo* routine will not be called again until the current invocation completes. The default is **FALSE**.

`NonCancelable`

If **TRUE**, the IRP cannot be canceled once it has been dequeued by a call to **IoStartNextPacket**. The default is **FALSE**. Drivers that set this member to **FALSE** must synchronize their IRP handling with the cancel spin lock.

Return Value

None

Requirements

Minimum supported client	Available for Microsoft Windows XP and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

IoSizeOfIrp macro

1/25/2019 • 2 minutes to read • Edit Online

The **IoSizeOfIrp** routine determines the size in bytes for an IRP, given the number of stack locations in the IRP.

Syntax

```
void IoSizeOfIrp(
   StackSize
);
```

Parameters

`StackSize`

Specifies the number of stack locations for the IRP.

Return Value

IoSizeOfIrp returns the size, in bytes, of the IRP.

Remarks

The input *StackSize* value is either that of the next-lower driver's device object or one more than that value.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Any level

See Also

IoAllocateIrp

IoMakeAssociatedIrp

IoSizeofWorkItem function

1/25/2019 • 2 minutes to read • Edit Online

The **IoSizeofWorkItem** routine returns the size, in bytes, of an IO_WORKITEM structure.

Syntax

```
ULONG IoSizeofWorkItem(

);
```

Parameters

This function has no parameters.

Return Value

IoSizeofWorkItem returns the number of bytes necessary to hold an IO_WORKITEM structure.

Remarks

For more information about work items, see System Worker Threads.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IO_WORKITEM

IoInitializeWorkItem

IoStartNextPacket function

1/25/2019 • 2 minutes to read • Edit Online

The **IoStartNextPacket** routine dequeues the next IRP, if any, from the given device object's associated device queue and calls the driver's StartIo routine.

Syntax

```
void IoStartNextPacket(
  PDEVICE_OBJECT DeviceObject,
  BOOLEAN        Cancelable
);
```

Parameters

`DeviceObject`

Pointer to the device object for which the IRP is to be dequeued.

`Cancelable`

Specifies whether IRPs in the device queue can be canceled.

Return Value

None

Remarks

If there are no IRPs currently in the device queue for the target *DeviceObject*, this routine simply returns control to the caller.

If the driver passed a pointer to a cancel routine when it called **IoStartPacket**, it should pass **TRUE** in the *Cancelable* parameter. If *Cancelable* is **TRUE**, the I/O manager will use the cancel spin lock to protect the device queue and the current IRP.

Drivers that do not have a *StartIo* routine cannot call **IoStartNextPacket**.

Drivers that call **IoStartNextPacket** from their *StartIo* routine should be aware of recursion issues. If a driver can call **IoStartNextPacket** on a large number of requests in succession from its *StartIo* routine (for example, when a device error occurs and the driver is clearing out it device queue), you should set the *DeferredStartIo* attribute for the device by using IoSetStartIoAttributes routine. This attribute ensures that the next packet will not be issued until the previous *StartIo* call returns.

Callers of **IoStartNextPacket** must be running at IRQL = DISPATCH_LEVEL. Usually, this routine is called from a device driver's DpcForIsr or CustomDpc routine, both of which are run at IRQL = DISPATCH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	DISPATCH_LEVEL (see Remarks section)
DDI compliance rules	IrqlDispatch, SpinLockSafe, StartIoRecursion, HwStorPortProhibitedDDIs, IrqlDispatch(storport), SpinLockSafe(storport)

IoStartNextPacketByKey

IoStartPacket

IoStartNextPacketByKey function

1/25/2019 • 2 minutes to read • Edit Online

The **IoStartNextPacketByKey** routine dequeues the next I/O request packet from the specified device object's associated device queue according to a specified sort-key value and calls the driver's StartIo routine with that IRP.

Syntax

```
void IoStartNextPacketByKey(
  PDEVICE_OBJECT DeviceObject,
  BOOLEAN        Cancelable,
  ULONG          Key
);
```

Parameters

`DeviceObject`

Pointer to the device object for which the IRP is to be dequeued.

`Cancelable`

Specifies whether IRPs in the device queue can be canceled.

`Key`

Specifies the sort key that determines which entry to remove from the queue.

Return Value

None

Remarks

If there are no IRPs currently in the device queue for the target device object, this routine simply returns control to the caller.

If the driver passed a pointer to a cancel routine when it called **IoStartPacket**, it should pass **TRUE** in the *Cancelable* parameter. If *Cancelable* is **TRUE**, the I/O manager will use the cancel spin lock to protect the device queue and the current IRP.

Drivers that do not have a *StartIo* routine cannot call **IoStartNextPacketByKey**.

Callers of **IoStartNextPacketByKey** must be running at IRQL <= DISPATCH_LEVEL. Usually, this routine is called from a device driver's DpcForIsr or CustomDpc routine, both of which are run at IRQL = DISPATCH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

DEVICE_OBJECT

IoStartNextPacket

IoStartPacket

IoStartPacket function

1/25/2019 • 2 minutes to read • Edit Online

The **IoStartPacket** routine calls the driver's StartIo routine with the given IRP or inserts the IRP into the device queue associated with the given device object if the device is already busy.

Syntax

```
void IoStartPacket(
  PDEVICE_OBJECT DeviceObject,
  PIRP           Irp,
  PULONG         Key,
  PDRIVER_CANCEL CancelFunction
);
```

Parameters

`DeviceObject`

Pointer to the target device object for the IRP.

`Irp`

Pointer to the IRP to be processed.

`Key`

Pointer to a value that determines where to insert the packet into the device queue. If this is zero, the packet is inserted at the tail of the device queue.

`CancelFunction`

Specifies the entry point for a driver-supplied Cancel routine.

Return Value

None

Remarks

If the driver is already busy processing a request for the target device object, then the packet is queued in the device queue. Otherwise, this routine calls the driver's *StartIo* routine with the specified IRP.

If a non-NULL *CancelFunction* pointer is supplied, it is set in the IRP so the driver's *Cancel* routine is called if the IRP is canceled before its completion.

Drivers that do not have a *StartIo* routine cannot call **IoStartPacket**.

Callers of **IoStartPacket** must be running at IRQL <= DISPATCH_LEVEL. Usually, this routine is called from a device driver's Dispatch routine at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoRegisterContainerNotification

IoUnregisterPlugPlayNotification function

1/25/2019 • 2 minutes to read • Edit Online

This routine is obsolete in Windows 7 and later versions of Windows. For more information, see the following Remarks section.

The **IoUnregisterPlugPlayNotification** routine removes the registration of a driver's callback routine for a PnP event.

Syntax

```
NTSTATUS IoUnregisterPlugPlayNotification(
  PVOID NotificationEntry
);
```

Parameters

`NotificationEntry`

Pointer to an opaque value representing the registration to be removed. The value was returned by a previous call to IoRegisterPlugPlayNotification.

Return Value

IoUnregisterPlugPlayNotification always returns STATUS_SUCCESS if *NotificationEntry*is valid.

Remarks

In Windows 7 and later versions of Windows, this function is obsolete and is provided only to support existing drivers. Use the IoUnregisterPlugPlayNotificationEx routine instead.

> **Note** The system does not synchronize between the execution of the notification routine and **IoUnregisterPlugPlayNotification**. Therefore, the routine can be called after the **IoUnregisterPlugPlayNotification** method has returned. If necessary, a driver should implement its own mechanism to ignore any notifications after **IoUnregisterPlugPlayNotification** has been called.

IoUnregisterPlugPlayNotification removes one PnP notification registration; that is, the registration of one driver callback routine for one PnP event category.

Drivers should unregister a notification first, then free any related context buffer.

A driver cannot be unloaded until it removes all of its PnP notification registrations because there is a reference on its driver object for each active registration.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

IoRegisterPlugPlayNotification

IoUnregisterPlugPlayNotificationEx

IoUnregisterPlugPlayNotificationEx function

1/25/2019 • 2 minutes to read • Edit Online

The **IoUnregisterPlugPlayNotificationEx** routine cancels the registration of a driver's callback routine for notifications of Plug and Play (PnP) events.

Syntax

```
NTSTATUS IoUnregisterPlugPlayNotificationEx(
  PVOID NotificationEntry
);
```

Parameters

`NotificationEntry`

A pointer to an opaque value that represents the registration to cancel. The caller previously obtained this value by calling the IoRegisterPlugPlayNotification routine.

Return Value

IoUnregisterPlugPlayNotificationEx returns STATUS_SUCCESS if the *NotificationEntry* parameter is valid.

Remarks

A kernel-mode driver calls this routine to remove a registration to receive PnP notifications. That is, an **IoUnregisterPlugPlayNotificationEx** call cancels the registration of a driver callback routine for one PnP event category. The driver previously obtained this registration by calling the **IoRegisterPlugPlayNotification** routine.

After an **IoUnregisterPlugPlayNotificationEx** call returns, the specified registration is canceled and no further callbacks can occur.

The IoUnregisterPlugPlayNotification routine is similar to **IoUnregisterPlugPlayNotificationEx**, except that it cannot guarantee that no further callbacks can occur after a **IoUnregisterPlugPlayNotification** call returns.

Frequently, a driver calls **IoUnregisterPlugPlayNotificationEx** from a notification callback routine. In most cases, the driver can safely delete the registration of the notification callback routine in this way. However, it is unsafe for a notification callback routine to call **IoUnregisterPlugPlayNotificationEx** to unregister itself if the following are both true:

- The driver sets the PNPNOTIFY_DEVICE_INTERFACE_INCLUDE_EXISTING_INTERFACES flag in the *EventCategoryFlags* parameter value supplied to the IoRegisterPlugPlayNotification call that registers the notification callback routine.
- The **IoRegisterPlugPlayNotification** call that registers the notification callback routine has not yet returned.

The callback routine must not call any routine that might block the execution of the thread on which the callback routine is running. For example, if a poorly designed callback routine places a work item that calls **IoUnregisterPlugPlayNotificationEx** in the work item queue, and then waits for a worker thread to complete the work item, it would result in a deadlock of the operating system.

Drivers should cancel the registration of a notification callback routine first, and then free any context buffer that is

associated with the routine.

A driver cannot be unloaded until it removes all of its PnP notification registrations because each active registration holds a counted reference to the driver object that represents the loaded image of the driver.

For more information, see Using PnP Notification.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoRegisterPlugPlayNotification

IoUnregisterPlugPlayNotification

IoUnregisterShutdownNotification function

1/25/2019 • 2 minutes to read • Edit Online

The **IoUnregisterShutdownNotification** routine removes a registered driver from the shutdown notification queue.

Syntax

```
void IoUnregisterShutdownNotification(
  PDEVICE_OBJECT DeviceObject
);
```

Parameters

`DeviceObject`

Pointer to the driver's device object.

Return Value

None

Remarks

IoUnregisterShutdownNotification can be called by a driver only if that driver previously called IoRegisterShutdownNotification or IoRegisterLastChanceShutdownNotification with the given *DeviceObject*. This routine is usually called from a driver's Unload routine.

Calling **IoUnregisterShutdownNotification** cancels all shutdown notifications that have been registered for the given *DeviceObject*.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoUpdateLinkShareAccess function

1/25/2019 • 2 minutes to read • Edit Online

The **IoUpdateLinkShareAccess** routine updates the share access for the given file object, usually when the file is being opened.

Syntax

```
void IoUpdateLinkShareAccess(
  PFILE_OBJECT       FileObject,
  PSHARE_ACCESS      ShareAccess,
  PLINK_SHARE_ACCESS LinkShareAccess
);
```

Parameters

`FileObject`

Pointer to the file object, which usually is being closed by the current thread.

`ShareAccess`

Pointer to the share-access structure that describes how the open file object is currently being accessed.

`LinkShareAccess`

Pointer to the share-access structure that describes how the open file object is currently being accessed.

Return Value

None

Remarks

IoUpdateLinkShareAccess is not an atomic operation. Therefore, drivers calling this routine must protect the shared file object passed to **IoUpdateLinkShareAccess** by means of some kind of lock, such as a mutex or a resource lock, in order to prevent corruption of the shared access counts.

Before calling **IoUpdateLinkShareAccess**, the caller must successfully call IoCheckLinkShareAccess with *Update* set to False. Such a call to **IoCheckLinkShareAccess** determines whether the requested shared access is compatible with the way the file object is currently being accessed by other opens, but it does not update the **SHARE_ACCESS** structure. **IoUpdateLinkShareAccess** actually updates the **SHARE_ACCESS** structure associated with the file object.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016

Target Platform	Universal
Header	wdm.h
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

1/25/2019 • 2 minutes to read • Edit Online

The **IoUpdateShareAccess** routine updates the share access for the given file object, usually when the file is being opened.

Syntax

```
void IoUpdateShareAccess(
  PFILE_OBJECT  FileObject,
  PSHARE_ACCESS ShareAccess
);
```

Parameters

`FileObject`

Pointer to a referenced file object representing the file or associated device object for which to update the share access.

`ShareAccess`

Pointer to the common **SHARE_ACCESS** structure associated with the *FileObject*. Drivers should treat this structure as opaque.

Return Value

None

Remarks

IoUpdateShareAccess is not an atomic operation. Therefore, drivers calling this routine must protect the shared file object passed to **IoUpdateShareAccess** by means of some kind of lock, such as a mutex or a resource lock, in order to prevent corruption of the shared access counts.

Before calling **IoUpdateShareAccess**, the caller must successfully call **IoCheckShareAccess** with *Update* set to False. Such a call to **IoCheckShareAccess** determines whether the requested shared access is compatible with the way the file object is currently being accessed by other opens, but it does not update the **SHARE_ACCESS** structure. **IoUpdateShareAccess** actually updates the **SHARE_ACCESS** structure associated with the file object.

IoValidateDeviceIoControlAccess function

1/25/2019 • 2 minutes to read • Edit Online

For more information, see the WdmlibIoValidateDeviceIoControlAccess function.

Syntax

```
NTSTATUS IoValidateDeviceIoControlAccess(
  PIRP  Irp,
  ULONG RequiredAccess
);
```

Parameters

`Irp`

For more information, see the WdmlibIoValidateDeviceIoControlAccess function.

`RequiredAccess`

For more information, see the WdmlibIoValidateDeviceIoControlAccess function.

Return Value

For more information, see the WdmlibIoValidateDeviceIoControlAccess function.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of Windows. Drivers that must also work for Windows 2000 and Windows XP can instead link to Wdmsec.lib to use this routine. (The Wdmsec.lib library first shipped with the Windows XP Service Pack 1 [SP1] and Windows Server 2003 editions of the Driver Development Kit [DDK] and now ships with the Windows Driver Kit [WDK].)

IoWithinStackLimits function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWithinStackLimits** routine determines whether a region of memory is within the stack limit of the current thread.

Syntax

```
LOGICAL IoWithinStackLimits(
  ULONG_PTR RegionStart,
  SIZE_T    RegionSize
);
```

Parameters

`RegionStart`

A pointer to the start of the region.

`RegionSize`

The size of the region.

Return Value

IoWithinStackLimits returns **TRUE** is the current thread's stack contains the region completely and **FALSE** otherwise.

Remarks

The **IoWithinStackLimits** routine considers all possible stack segments and the DPC stack, if necessary.

> **Note** For drivers that use KeExpandKernelStackAndCallout, **IoWithinStackLimits** considers only the current thread.

Requirements

Minimum supported client	Available on Windows Vista and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoGetStackLimits

IoWMIAllocateInstanceIds function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMIAllocateInstanceIds** routine allocates one or more instance IDs that are unique to the GUID.

Syntax

```
NTSTATUS IoWMIAllocateInstanceIds(
  LPCGUID Guid,
  ULONG   InstanceCount,
  ULONG   *FirstInstanceId
);
```

Parameters

`Guid`

Pointer to the GUID for which to generate instance identifiers.

`InstanceCount`

Specifies how many instance identifiers should be provided.

`FirstInstanceId`

Pointer to the first instance identifier that the driver should use.

Return Value

IoWMIAllocateInstanceIds returns a status code from the following list:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	Indicates that WMI successfully provided unique instance identifiers for the GUID specified.
STATUS_UNSUCCESSFUL	Indicates that the WMI services are not available.

STA **TUS** **_IN** **SUF** **FICI** **ENT** **_RE** **SO** **URC** **ES**	Indicates that insufficient resources were available to provide the caller with instance IDs.

Remarks

If greater than one instance was requested in *InstanceCount* and the routine completed successfully, *FirstInstanceId* points to the first instance that the caller should use. For each instance requested beyond one, the caller should increment the value returned in **FirstInstanceId*. For example, if the caller requested six instances and one was returned as the value of *FirstInstanceId*, the caller should use the values 1-6 as his unique instance identifiers.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoWmiSuggestInstanceName

IoWMIDeviceObjectToInstanceName function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMIDeviceObjectToInstanceName** routine determines the instance name for the WMI class instance implemented by the driver that is specified by a device object.

Syntax

```
NTSTATUS IoWMIDeviceObjectToInstanceName(
  PVOID           DataBlockObject,
  PDEVICE_OBJECT  DeviceObject,
  PUNICODE_STRING InstanceName
);
```

Parameters

`DataBlockObject`

Pointer to a WMI data block object. The caller opens the data block object for the WMI class with IoWMIOpenBlock.

`DeviceObject`

Specifies a device object. The routine returns the instance name for the driver corresponding to the device object.

`InstanceName`

Pointer to the UNICODE_STRING structure that the routine uses to return the instance name. The caller frees the returned buffer within **UNICODE_STRING**.

Return Value

The routine returns an NTSTATUS code. Possible return values include:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The operation succeeded. The routine stores the instance name in the **UNICODE_STRING** specified by the *InstanceName* parameter.

STA **TUS** **_W** **MI_I** **NST** **AN** **CE_** **NO** **T_F** **OU** **ND**	The driver does not implement any instances of the WMI class specified by *DataBlockObject*.

Requirements

Minimum supported client	Available in Windows XP and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IoWMIHandleToInstanceName

IoWMIOpenBlock

IoWMIDeviceObjectToProviderId function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMIDeviceObjectToProviderId** routine translates the specified device object into the corresponding WMI Provider ID.

Syntax

```
ULONG IoWMIDeviceObjectToProviderId(
  PDEVICE_OBJECT DeviceObject
);
```

Parameters

`DeviceObject`

Pointer to a device object.

Return Value

IoWMIDeviceObjectToProviderId returns the WMI Provider ID associated with the specified device object.

Remarks

IoWMIDeviceObjectToProviderId should be used when filling in the **ProviderId** member of the WNODE_HEADER structure in those cases when the **WNODEHEADER** structure is being initialized as part of a WNODE_EVENT_ITEM or WNODE_EVENT_REFERENCE structure. (If the **WNODE_HEADER** is being used for other purposes, *ProviderId* is reserved.)

When running on a 32-bit operating system, the provider ID and the device object are identical. When running on a 64-bit operating system, **IoWMIDeviceObjectToProviderId** will convert the 64-bit device object to a 32-bit provider ID.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

IoWMIExecuteMethod function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMIExecuteMethod** routine runs a WMI class method on the specified WMI data block instance.

Syntax

```
NTSTATUS IoWMIExecuteMethod(
  PVOID           DataBlockObject,
  PUNICODE_STRING InstanceName,
  ULONG           MethodId,
  ULONG           InBufferSize,
  PULONG          OutBufferSize,
  PUCHAR          InOutBuffer
);
```

Parameters

`DataBlockObject`

Pointer to a WMI data block object. The caller opens the data block object for the WMI class with IoWMIOpenBlock. The object must be opened with the WMIGUID_EXECUTE access right.

`InstanceName`

Specifies the name of the instance of the data block. This value corresponds to the value of the **InstanceName** property for the block.

`MethodId`

Specifies the method item ID for the method to be set. The value of this parameter corresponds to the value declared in the **WmiMethodId** qualifier for the method.

`InBufferSize`

Specifies the size, in bytes, of input data for the method. The actual input data is passed in the buffer pointed to by the *InOutBuffer* parameter.

`OutBufferSize`

Pointer to a ULONG that specifies the expected size, bytes, of the data output by the method. The actual output data is returned in the buffer pointed to by the *InOutBuffer* parameter. If the routine succeeds, it updates the memory location to specify the number of bytes actually stored in *InOutBuffer*. If the routine fails with STATUS_BUFFER_TOO_SMALL, it returns the number of bytes required to return the data.

`InOutBuffer`

Pointer to the buffer where the caller passes the WMI method's input data, and receives the WMI method's output data.

Return Value

The routine returns an NTSTATUS code. Possible return values include:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The operation succeeded. The routine returns the WMI data in the buffer pointed to by the *InOutBuffer* parameter. The routine also returns the size, in bytes, of the returned data in the memory location pointed to by the *OutBufferSize* parameter.
STATUS_WMI_GUID_NOT_FOUND	No drivers implement the WMI class.
STATUS_WMI_INSTANCE_NOT_FOUND	No driver implements an instance of the WMI class with **InstanceName** property equal to the value specified in the *InstanceName* parameter.
STATUS_WMI_ITEMID_NOT_FOUND	The WMI class does not contain a method with method ID equal to the value of *MethodId*.
STATUS_BUFFER_TOO_SMALL	The buffer passed by the caller in the *OutBuffer* parameter is too small. The routine returns the required buffer size in the memory location pointed to by the *InOutBufferSize* parameter.

STA **TUS** **_W** **MI_** **GUI** **D_D** **ISC** **ON** **NEC** **TED**	The WMI GUID is no longer available or was never available.

Remarks

IoWMIExecuteMethod determines which drivers might support the specified WMI class and instance name. It issues an IRP_MN_EXECUTE_METHOD request to each such driver. The driver that exports the data block instance with matching **InstanceName** property then runs the specified WMI method.

Requirements

Minimum supported client	Available in Windows XP and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

IoWMIOpenBlock

IoWMIHandleToInstanceName function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMIHandleToInstanceName** routine determines the instance name for the WMI class instance implemented by the driver that is specified by a file handle.

Syntax

```
NTSTATUS IoWMIHandleToInstanceName(
  PVOID           DataBlockObject,
  HANDLE          FileHandle,
  PUNICODE_STRING InstanceName
);
```

Parameters

`DataBlockObject`

Pointer to a WMI data block object. The caller opens the data block object for the WMI class with the IoWMIOpenBlock routine.

`FileHandle`

Specifies a file handle. The routine returns the instance name corresponding to the driver that is represented by the file handle.

`InstanceName`

Pointer to the UNICODE_STRING structure that the routine uses to return the instance name. The caller frees the returned buffer within **UNICODE_STRING**.

Return Value

The routine returns an NTSTATUS code. Possible return values include:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The operation succeeded. The routine fills the **UNICODE_STRING** structure pointed to by the *InstanceName* parameter with the instance name.

STA **TUS** **_W** **MI_I** **NST** **AN** **CE_** **NO** **T_F** **OU** **ND**	The driver does not implement any instances of the WMI class specified by *DataBlockObject*.

Requirements

Minimum supported client	Available in Windows XP and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IoWMIDeviceObjectToInstanceName

IoWMIOpenBlock

IoWMIOpenBlock function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMIOpenBlock** routine opens the WMI data block object for the specified WMI class.

Syntax

```
NTSTATUS IoWMIOpenBlock(
  LPCGUID Guid,
  ULONG   DesiredAccess,
  PVOID   *DataBlockObject
);
```

Parameters

`Guid`

`DesiredAccess`

Specifies the desired access rights to the data block object. The caller must have particular access rights to perform certain operations.

The following is a description of each access right bit and the operations it allows:

WMIGUID_EXECUTE

The data block object can be used to run WMI class methods. This flag must be set to use IoWMIExecuteMethod on the data block object.

WMIGUID_NOTIFICATION

The data block object can be used to register event notification callbacks. This flag must be set to use IoWMISetNotificationCallback, and can only be used for WMI event blocks. Callers that specify this flag must also specify the SYNCHRONIZE flag.

WMIGUID_QUERY

The data block object can be used to query WMI class properties. This flag must be set to use any of the **IoWMIQuery*Xxx*** routines on the data block object.

WMIGUID_SET

The data block object can be used to set WMI class properties. This flag must be set to use any of the **IoWMISet*Xxx*** routines on the data block object.

`DataBlockObject`

Pointer to a memory location where the routine returns a pointer to the data block object.

Return Value

Returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure.

Remarks

The caller uses **IoWMIOpenBlock** to create a data block object for the specified WMI class GUID. Subsequently, the caller can use the data block object to read or write WMI class properties, run WMI class methods, and register

callbacks for WMI events.

Use the **IoWMIQuery*Xxx*** and **IoWMISet*Xxx*** routines to read and write WMI class properties. Use IoWMIExecuteMethod to run WMI class methods, and use IoWMISetNotificationCallback to register a WMI event notification callback.

Use ObDereferenceObject to close the data block object once it is no longer needed.

Requirements

Minimum supported client	Available in Windows XP and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Ntddk.h, Ntifs.h. The WMIGUID_XXX values are declared in Wmistr.h. To use them, include Wmistr.h.)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

IoWMIQueryAllData function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMIQueryAllData** routine returns all WMI data blocks that implement a given WMI class.

Syntax

```
NTSTATUS IoWMIQueryAllData(
  PVOID  DataBlockObject,
  PULONG InOutBufferSize,
  PVOID  OutBuffer
);
```

Parameters

`DataBlockObject`

Pointer to a WMI data block object. The caller opens the data block object for the WMI class with the IoWMIOpenBlock routine. The object must be opened with the WMIGUID_QUERY access right.

`InOutBufferSize`

Pointer to a memory location that specifies the size of the buffer passed in the *OutBuffer* parameter. If the routine succeeds, it updates the memory location to specify the number of bytes actually stored in *OutBuffer*. If the routine fails with status code of STATUS_BUFFER_TOO_SMALL, it returns the number of bytes required to return the data.

`OutBuffer`

Pointer to the buffer where the routine returns the WMI data. The routine returns a sequence of variable-sized WNODE_ALL_DATA structures, one for each set of returned data blocks. The **WnodeHeader.Linkage** member of each **WNODE_ALL_DATA** structure contains the offset from the beginning of the current **WNODE_ALL_DATA** to the beginning of the next **WNODE_ALL_DATA**. The final block in the chain has **WnodeHeader.Linkage** set to zero. *OutBuffer* must point to a buffer allocated from nonpaged pool.

Return Value

The routine returns an NTSTATUS code. Possible return values include:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The operation succeeded. The routine returns the WMI data in the buffer pointed to by the *OutBuffer* parameter. The routine also returns the size, in bytes, of the returned data in the memory location pointed to by the *InOutBufferSize* parameter.

STA **TUS** **_W** **MI_** **GUI** **D_N** **OT_** **FOU** **ND**	No drivers implement the specified WMI class.
STA **TUS** **_BU** **FFE** **R_T** **OO_** **SM** **ALL**	The buffer passed by the caller in the *OutBuffer* parameter is too small. The routine returns the required buffer size in the memory location pointed to by the *InOutBufferSize* parameter.

Remarks

IoWMIQueryAllData determines which drivers support the specified WMI class, and issues an **IRP_MN_QUERY_ALL_DATA** request to every such driver.

To query for multiple WMI classes, use IoWMIQueryAllDataMultiple.

Requirements

Minimum supported client	Available in Microsoft Windows XP and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

IoWMIOpenBlock

IoWMIQueryAllDataMultiple

IoWMIQueryAllDataMultiple function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMIQueryAllDataMultiple** routine returns all WMI data blocks that implement one of a set of WMI classes.

Syntax

```
NTSTATUS IoWMIQueryAllDataMultiple(
  PVOID  *DataBlockObjectList,
  ULONG  ObjectCount,
  PULONG InOutBufferSize,
  PVOID  OutBuffer
);
```

Parameters

`DataBlockObjectList`

Pointer to an array of pointers to WMI data block objects. The caller opens a data block object for each WMI class with the IoWMIOpenBlock routine. Each object must be opened with the WMIGUID_QUERY access right.

`ObjectCount`

Specifies the number of entries in the array passed in the *DataBlockObjectList* parameter.

`InOutBufferSize`

Pointer to a memory location that specifies the size of the buffer passed in the *OutBuffer* parameter. If the routine succeeds, it updates the memory location to specify the number of bytes actually stored in *OutBuffer*. If the routine fails with status code of STATUS_BUFFER_TOO_SMALL, it returns the number of bytes required to return the data.

`OutBuffer`

Pointer to the buffer where the routine returns the WMI data. The routine returns a sequence of variable-sized WNODE_ALL_DATA structures, one for each set of returned data blocks. The **WnodeHeader.Linkage** member of each **WNODE_ALL_DATA** structure contains the offset from the beginning of the current **WNODE_ALL_DATA** to the beginning of the next **WNODE_ALL_DATA**. The final block in the chain has **WnodeHeader.Linkage** set to zero. *OutBuffer* must point to a buffer allocated from nonpaged pool.

Return Value

The routine returns an NTSTATUS code. Possible return values include:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The operation succeeded. The routine returns the WMI data in the buffer pointed to by the *OutBuffer* parameter. The routine also returns the size, in bytes, of the returned data in the memory location pointed to by the *InOutBufferSize* parameter.

STA **TUS** **_BU** **FFE** **R_T** **OO_** **SM** **ALL**	The buffer passed by the caller in the *OutBuffer* parameter is too small. The routine returns the required buffer size in the memory location pointed to by the *InOutBufferSize* parameter.

Remarks

IoWMIQueryAllDataMultiple determines which drivers support the specified WMI classes, and issues an IRP_MN_QUERY_ALL_DATA request to every such driver.

If no drivers implement any of the specified WMI classes, the routine returns STATUS_SUCCESS It also returns a value of zero in the memory location pointed to by the *InOutBufferSize* parameter.

To query a single WMI class, use IoWMIQueryAllData.

Requirements

Minimum supported client	Available in Windows XP and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

See Also

IoWMIOpenBlock

IoWMIQueryAllData

IoWMIQuerySingleInstance function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMIQuerySingleInstance** routine returns the specified instance of a WMI data block.

Syntax

```
NTSTATUS IoWMIQuerySingleInstance(
  PVOID           DataBlockObject,
  PUNICODE_STRING InstanceName,
  PULONG          InOutBufferSize,
  PVOID           OutBuffer
);
```

Parameters

`DataBlockObject`

Pointer to a WMI data block object. The caller opens the data block object for the WMI class with the IoWMIOpenBlock routine. The object must be opened with the WMIGUID_QUERY access right.

`InstanceName`

Specifies the name of the instance of the data block. This value corresponds to the value of the **InstanceName** property for the block.

`InOutBufferSize`

Pointer to a memory location that specifies the size of the buffer passed in the *OutBuffer* parameter. If the routine succeeds, it updates the memory location to specify the number of bytes actually stored in *OutBuffer*. If the routine fails with status code of STATUS_BUFFER_TOO_SMALL, it returns the number of bytes required to return the data.

`OutBuffer`

Pointer to the buffer where the routine returns the WMI data. The routine returns a variable-sized WNODE_SINGLE_INSTANCE structure. *OutBuffer* must point to a buffer allocated from nonpaged pool.

Return Value

The routine returns an NTSTATUS code. Possible return values include:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The operation succeeded. The routine returns the WMI data in the buffer pointed to by the *OutBuffer* parameter. The routine also returns the size, in bytes, of the returned data in the memory location pointed to by the *InOutBufferSize* parameter.

STA TUS _W MI_ GUI D_N OT_ FOU ND	No drivers implement the specified WMI class.
STA TUS _W MI_I NST AN CE_ NO T_F OU ND	No driver implements an instance of the WMI class with **InstanceName** property equal to the value specified in the *InstanceName* parameter.
STA TUS _BU FFE R_T OO_ SM ALL	The buffer passed by the caller in the *OutBuffer* parameter is too small. The routine returns the required buffer size in the memory location pointed to by the *InOutBufferSize* parameter.

Remarks

IoWMIQuerySingleInstance determines which drivers might support the specified WMI class with the specified instance name, and issues an IRP_MN_QUERY_SINGLE_INSTANCE request to each such driver. The driver that exports the data block instance with matching **InstanceName** property returns the appropriate data.

To query for multiple WMI classes and instance names, use the IoWMIQuerySingleInstanceMultiple routine. Drivers can use the IoWMISetSingleInstance routine to update the class instance.

Requirements

Minimum supported client	Available in Windows XP and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

IRP_MN_QUERY_SINGLE_INSTANCE

IoWMIOpenBlock

IoWMIQuerySingleInstanceMultiple

IoWMISetSingleInstance

IoWMIQuerySingleInstanceMultiple function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMIQuerySingleInstanceMultiple** routine returns all WMI data block instances that implement the specified WMI classes with the specified instance names.

Syntax

```
NTSTATUS IoWMIQuerySingleInstanceMultiple(
  PVOID           *DataBlockObjectList,
  PUNICODE_STRING InstanceNames,
  ULONG           ObjectCount,
  PULONG          InOutBufferSize,
  PVOID           OutBuffer
);
```

Parameters

`DataBlockObjectList`

Pointer to an array of pointers of WMI data block objects. The caller opens a data block object for each WMI class with the IoWMIOpenBlock routine. Each object must be opened with the WMIGUID_QUERY access right.

`InstanceNames`

Pointer to an array of UNICODE_STRING structures containing instance names. The *n*th instance name in the array corresponds to the value of the **InstanceName** property for the *n*th WMI class specified in the array pointed to by the *DataBlockObjectList* parameter.

`ObjectCount`

Specifies the number of entries in the arrays passed in the *DataBlockObjectList* and *InstanceNames* parameters.

`InOutBufferSize`

Pointer to a memory location that specifies the size of the buffer passed in the *OutBuffer* parameter. If the routine succeeds, it updates the memory location to specify the number of bytes actually stored in *OutBuffer*. If the routine fails with STATUS_BUFFER_TOO_SMALL, it returns the number of bytes required to return the data.

`OutBuffer`

Pointer to the buffer where the routine returns the WMI data. The routine returns a sequence of variable-sized WNODE_SINGLE_INSTANCE structures, one for each data block instance. The **WnodeHeader.Linkage** member of each **WNODE_SINGLE_INSTANCE** structure contains the offset from the beginning of the current **WNODE_SINGLE_INSTANCE** to the beginning of the next **WNODE_SINGLE_INSTANCE**. The final block in the chain has **WnodeHeader.Linkage** set to zero. Each distinct data block instance corresponds to a single matching WMI class and instance name. *OutBuffer* must point to a buffer allocated from nonpaged pool.

Return Value

The routine returns an NTSTATUS code. Possible return values include:

RETURN CODE	DESCRIPTION

STA TUS _SU CCE SS	The operation succeeded. The routine returns the WMI data in the buffer pointed to by the *OutBuffer* parameter. The routine also returns the size, in bytes, of the returned data in the memory location pointed to by the *InOutBufferSize* parameter.
STA TUS _BU FFE R_T OO_ SM ALL	The buffer passed by the caller in the *OutBuffer* parameter is too small. The routine returns the required buffer size in the memory location pointed to by the *InOutBufferSize* parameter.

Remarks

IoWMIQuerySingleInstanceMultiple determines which drivers might support the specified WMI classes and instance names, and issues an IRP_MN_QUERY_SINGLE_INSTANCE request to each such driver. Each driver that exports the data block instance with matching **InstanceName** property returns the appropriate data.

If no drivers implement any of the specified WMI classes and instance names, the routine returns STATUS_SUCCESS. It also returns a value of zero in the memory location pointed to by the *InOutBufferSize* parameter.

To query for a single WMI class and instance name, use the IoWMIQuerySingleInstance routine. Drivers can use the IoWMISetSingleInstance routine to update a class instance.

Requirements

Minimum supported client	Available in Windows XP and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoWMIQuerySingleInstance

IoWMISetSingleInstance

UNICODE_STRING

IoWMIRegistrationControl function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMIRegistrationControl** routine registers or unregisters the caller as a WMI data provider for a specified device object.

Syntax

```
NTSTATUS IoWMIRegistrationControl(
  PDEVICE_OBJECT DeviceObject,
  ULONG          Action
);
```

Parameters

`DeviceObject`

A pointer to a device object. This object is a DEVICE_OBJECT system structure.

`Action`

The action that WMI should take. The requested action is indicated by one of the following values.

ACTION VALUE	MEANING
WMIREG_ACTION_REGISTER	Specifies that WMI should register the caller as a WMI provider for *DeviceObject*. This will result in WMI sending an IRP_MN_REGINFO or IRP_MN_REGINFO_EX request to the driver.
WMIREG_ACTION_DEREGISTER	Specifies that WMI should remove the caller from its list of WMI providers for *DeviceObject*.
WMIREG_ACTION_REREGISTER	Specifies that WMI should unregister the driver and then register (reregister) the driver. Reregistering the driver results in WMI sending an **IRP_MN_REGINFO** or **IRP_MN_REGINFO_EX** request to the driver.
WMIREG_ACTION_UPDATE_GUIDS	Specifies that WMI should re-query the driver for a new list of GUID identifiers that it provides data for. This will result in WMI sending an **IRP_MN_REGINFO** or **IRP_MN_REGINFO_EX** request to the driver.

Return Value

IoWMIRegistrationControl returns a status code from the following list:

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	Indicates that WMI completed the action requested without error.
STATUS_INVALID_PARAMETER	Indicates that the action, specified in *Action*, was invalid.
STATUS_*XXX*	Indicates that the request failed for the reason specified by the NTSTATUS value. See Ntstatus.h for detailed information for the actual status return code.

Remarks

After a driver calls **IoWMIRegistrationControl**, WMI sends the driver an IRP_MN_REGINFO or IRP_MN_REGINFO_EX request so the driver can provide information to WMI. For more information, see Registering as a WMI Data Provider.

If the caller specifies WMIREG_ACTION_DEREGISTER for *Action*, **IoWMIRegistrationControl** causes the calling thread to block until all **IRP_MJ_SYSTEM_CONTROL** requests that were previously sent to the specified device object have completed. In such a case, if a driver calls **IoWMIRegistrationControl** within a dispatch routine for an **IRP_MJ_SYSTEM_CONTROL** request, the calling thread will deadlock.

If a device is removed suddenly (for example, in a surprise removal), causing the PnP manager to send an IRP_MN_SURPRISE_REMOVAL IRP, the driver must call **IoWMIRegistrationControl** and specify WMIREG_ACTION_DEREGISTER in *Action* in the call. Note that if the driver calls **IoWMIRegistrationControl** with *Action* set to WMIREG_ACTION_DEREGISTER in response to an **IRP_MN_SURPRISE_REMOVAL** IRP, the driver must not make the same call to **IoWMIRegistrationControl** in response to an IRP_MN_REMOVE_DEVICE IRP.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe

IoWMISetNotificationCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMISetNotificationCallback** routine registers a notification callback for a WMI event.

Syntax

```
NTSTATUS IoWMISetNotificationCallback(
  PVOID                    Object,
  WMI_NOTIFICATION_CALLBACK Callback,
  PVOID                    Context
);
```

Parameters

`Object`

Pointer to a WMI data block object. The caller opens the data block object for the WMI event with the IoWMIOpenBlock routine. The object must be opened with the WMIGUID_NOTIFICATION access right.

`Callback`

Pointer to a function of the form:

```
XxxWmiNotificationCallback(PVOID Wnode, PVOID Context);
```

WMI calls this function to notify the caller that the specified event has occurred. The *Wnode* parameter of the callback routine points to the WNODE_EVENT_ITEM structure returned by the driver triggering the event. The *Context* parameter of the callback routine points to the value specified in the *Context* parameter of the **IoWMISetNotificationCallback** routine.

`Context`

Specifies the value that WMI passes to the callback routine when the event occurs.

Return Value

This routine returns STATUS_SUCCESS on success, and the appropriate NTSTATUS error code on failure.

Requirements

Minimum supported client	Available in Windows XP and later versions of the Windows operating system.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

IoWMIOpenBlock

WNODE_EVENT_ITEM

IoWMISetSingleInstance function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMISetSingleInstance** routine sets the values for properties within the data block instance that matches the specified WMI class and instance name.

Syntax

```
NTSTATUS IoWMISetSingleInstance(
  PVOID           DataBlockObject,
  PUNICODE_STRING InstanceName,
  ULONG           Version,
  ULONG           ValueBufferSize,
  PVOID           ValueBuffer
);
```

Parameters

`DataBlockObject`

Pointer to a WMI data block object. The caller opens the data block object for the WMI class with the IoWMIOpenBlock routine. The object must be opened with the WMIGUID_SET access right.

`InstanceName`

Specifies the name of the instance of the data block. This value corresponds to the value of the **InstanceName** property for the block.

`Version`

Reserved for future use. Callers must set this parameter to zero.

`ValueBufferSize`

Specifies the size, in bytes, of the buffer passed in the *ValueBuffer* parameter.

`ValueBuffer`

Pointer to the buffer that contains the new values for the properties within the data block.

Return Value

The routine returns an NTSTATUS code. Possible return values include:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The operation succeeded. The values of the WMI data block instance properties are updated to the contents of the buffer pointed to by the *ValueBuffer* parameter.

STATUS_WMI_GUID_NOT_FOUND	No drivers implement the WMI class.
STATUS_WMI_INSTANCE_NOT_FOUND	No driver implements an instance of the WMI class with **InstanceName** property equal to the value specified in the *InstanceName* parameter.
STATUS_WMI_READ_ONLY	All properties of the WMI class are read-only.
STATUS_WMI_SET_FAILURE	The driver that implements the WMI data block instance is unable to update the instance.

Remarks

IoWMISetSingleInstance determines which drivers might support the specified WMI class and instance name, and issues an IRP_MN_CHANGE_SINGLE_INSTANCE request to each such driver. The driver that exports the data block instance with matching **InstanceName** property updates its data block instance. Note that a data block might have both read-only and read/write properties. In this case, only the read/write properties will be updated and STATUS_SUCCESS is returned.

Drivers can also use the IoWMISetSingleItem routine to update a single property within the class instance.

Requirements

Minimum supported client	Available in Windows XP and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

See Also

IRP_MN_CHANGE_SINGLE_INSTANCE

IoWMIOpenBlock

IoWMIQuerySingleInstance

IoWMISetSingleItem

IoWMISetSingleItem function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMISetSingleItem** routine sets a single property in the data block instance that matches the specified WMI class and instance name.

Syntax

```
NTSTATUS IoWMISetSingleItem(
  PVOID           DataBlockObject,
  PUNICODE_STRING InstanceName,
  ULONG           DataItemId,
  ULONG           Version,
  ULONG           ValueBufferSize,
  PVOID           ValueBuffer
);
```

Parameters

`DataBlockObject`

Pointer to a WMI data block object. The caller opens the data block object for the WMI class with the IoWMIOpenBlock routine. The object must be opened with the WMIGUID_SET access right.

`InstanceName`

Specifies the name of the instance of the data block. This value corresponds to the value of the **InstanceName** property for the block.

`DataItemId`

Specifies the data item ID for the property to be set. The value of this parameter corresponds to the value declared in the **WmiDataId** qualifier for the property.

`Version`

Reserved for future use. Callers must set this parameter to zero.

`ValueBufferSize`

Specifies the size, in bytes, of the buffer passed in the *ValueBuffer* parameter.

`ValueBuffer`

Pointer to the buffer that contains the new value for the property specified by the *DataItemId* parameter.

Return Value

The routine returns an NTSTATUS code. Possible return values include:

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	The operation succeeded. The value of the property within WMI data block instance is updated to the contents of the buffer pointed to by the *ValueBuffer* parameter.
STATUS_WMI_GUID_NOT_FOUND	No drivers implement the WMI class.
STATUS_WMI_INSTANCE_NOT_FOUND	No driver implements an instance of the WMI data block with **InstanceName** property equal to the value specified in the *InstanceName* parameter.
STATUS_WMI_ITEMID_NOT_FOUND	The WMI class does not contain a property with data item ID equal to the value of *DataItemId*.
STATUS_WMI_READ_ONLY	The data item ID in the data block is read-only.

STATUS_WMI_SET_FAILURE	The driver that implements the WMI data block instance is unable to update the property specified by *DataItemId*.

Remarks

IoWMISetSingleItem determines which drivers might support the specified WMI class and instance name. It issues an IRP_MN_CHANGE_SINGLE_ITEM request to each such driver. The driver that exports the data block instance with matching **InstanceName** property updates the specified property in the data block instance.

Drivers can also use IoWMISetSingleInstance to update every property of the WMI class instance simultaneously.

Requirements

Minimum supported client	Available in Windows XP and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

IRP_MN_CHANGE_SINGLE_ITEM

IoWMIOpenBlock

IoWMIQuerySingleInstance

IoWMISetSingleInstance

IoWMISuggestInstanceName function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMISuggestInstanceName** routine is used to request that WMI suggest a base name which a driver can use to build WMI instance names for the device.

Syntax

```
NTSTATUS IoWMISuggestInstanceName(
  PDEVICE_OBJECT  PhysicalDeviceObject,
  PUNICODE_STRING SymbolicLinkName,
  BOOLEAN         CombineNames,
  PUNICODE_STRING SuggestedInstanceName
);
```

Parameters

`PhysicalDeviceObject`

If supplied, points to the driver's physical device object.

`SymbolicLinkName`

If supplied, points to the symbolic link name returned from IoRegisterDeviceInterface.

`CombineNames`

If **TRUE** then the suggested names returned will combine the *PhysicalDeviceObject* and *SymbolicLinkName* information.

`SuggestedInstanceName`

A pointer to a buffer which upon successful completion will contain a UNICODE_STRING which contains the suggested instance name. The caller is responsible for freeing this buffer when it is no longer needed.

Return Value

IoWMISuggestInstanceName returns a status code from the following list:

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	Indicates that WMI was able to successfully complete this function.

STATUS_UNSUCCESSFUL	Indicates that the WMI services are not available.
STATUS_INSUFFICIENT_RESOURCES	Indicates that insufficient resources were available to provide the caller with a buffer containing the Unicode string.
STATUS_NO_MEMORY	Indicates that insufficient resources were available to provide the caller with a buffer containing the Unicode string.

Remarks

If the *CombineNames* parameter is **TRUE** then both *PhysicalDeviceObject* and *SymbolicLinkName* must be specified. Otherwise, only one of them should be specified.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

See Also

IoWMIAllocateInstanceIds

IoWMIWriteEvent function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWMIWriteEvent** routine delivers a given event to the user-mode WMI components for notification.

Syntax

```
NTSTATUS IoWMIWriteEvent(
  PVOID WnodeEventItem
);
```

Parameters

`WnodeEventItem`

Pointer to a WNODE_EVENT_ITEM structure to be delivered to the user-mode WMI components that requested notification of the event.

Return Value

IoWMIWriteEvent returns a status code from the following list:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	Indicates that WMI has successfully queued the event for delivery to the user-mode WMI components.
STATUS_UNSUCCESSFUL	Indicates that WMI services are unavailable.
STATUS_BUFFER_OVERFLOW	Indicates that the event item specified exceeds the maximum allowed size.

STA TUS _IN SUF FICI ENT _RE SO URC ES	Indicates that insufficient resources were available for WMI to queue the event for delivery.

Remarks

The WNODE_EVENT_ITEM structure that is allocated by the caller and passed in *WnodeEventItem* must be allocated from nonpaged pool. If **IoWMIWriteEvent** returns STATUS_SUCCESS, the memory for the event item will automatically be freed by the system. If **IoWMIWriteEvent** returns anything other than STATUS_SUCCESS, it is the caller's responsibility to free the buffer.

Drivers should only call **IoWMIWriteEvent** for events that have been enabled for WMI. This ensures that there is an event consumer waiting for indication on that event.

Callers of this routine must be running at IRQL <= APC_LEVEL, with one exception. When the **Flags** member of the WNODE_HEADER structure contains WNODE_FLAG_TRACED_GUID, **IoWMIWriteEvent** can be called at any IRQL. (The **WNODE_HEADER** structure is a member of the WNODE_EVENT_ITEM structure that the *WnodeEventItem* parameter points to.)

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL (see Remarks section)"

WNODE_EVENT_ITEM

IoWriteErrorLogEntry function

1/25/2019 • 2 minutes to read • Edit Online

The **IoWriteErrorLogEntry** routine queues a given error log packet to the system error logging thread.

Syntax

```
void IoWriteErrorLogEntry(
  PVOID ElEntry
);
```

Parameters

`ElEntry`

Pointer to the error log packet the driver has allocated with IoAllocateErrorLogEntry and filled in by the caller.

Return Value

None

Remarks

IoWriteErrorLogEntry frees the error log entry. Drivers must not call **IoFreeErrorLogEntry** on a log entry that they have already passed to **IoWriteErrorLogEntry**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"
DDI compliance rules	IrqlDispatch

IoFreeErrorLogEntry

IsListEmpty function

1/25/2019 • 2 minutes to read • Edit Online

The **IsListEmpty** routine indicates whether a doubly linked list of LIST_ENTRY structures is empty.

Syntax

```
BOOLEAN IsListEmpty(
  const LIST_ENTRY *ListHead
);
```

Parameters

`ListHead`

Pointer to a LIST_ENTRY structure that represents the head of the list.

Return Value

IsListEmpty returns **TRUE** if there are currently no entries in the list and **FALSE** otherwise.

Remarks

IsListEmpty returns **TRUE** if *ListHead*->**Flink** refers back to *ListHead*.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

Callers of **IsListEmpty** can be running at any IRQL. If **IsListEmpty** is called at IRQL >= DISPATCH_LEVEL, the storage for *ListHead* must be resident.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
IRQL	Any level (see Remarks section)

KBUGCHECK_CALLBACK_ROUTINE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *BugCheckCallback* routine is executed whenever the system issues a bug check.

Syntax

```
KBUGCHECK_CALLBACK_ROUTINE KbugcheckCallbackRoutine;

void KbugcheckCallbackRoutine(
  IN PVOID Buffer,
  IN ULONG Length
)
{...}
```

Parameters

`Buffer`

A pointer to the buffer that was specified when the callback was registered.

`Length`

Specifies the length, in bytes, of the buffer that is pointed to by the *Buffer* parameter.

Return Value

None

Remarks

Drivers can supply a *BugCheckCallback* that resets the device to a known state if the system issues a bug check.

Use KeRegisterBugCheckCallback to register a *BugCheckCallback* routine. A driver can subsequently remove the callback by using the KeDeregisterBugCheckCallback routine. If the driver can be unloaded, it must remove any registered callbacks in its Unload routine.

A *BugCheckCallback* routine is strongly restricted in the actions it can take. For more information, see Writing a Bug Check Callback Routine. The routine can safely use the **READ_PORT_*XXX***, **READ_REGISTER_*XXX***, **WRITE_PORT_*XXX***, and **WRITE_REGISTER_*XXX*** routines to interact with the device.

Drivers that require more sophisticated interaction with the system as it issues a bug check can instead implement BugCheckDumpIoCallback or BugCheckSecondaryDumpDataCallback routines.

Note that beginning with the Windows XP SP1 and Windows Server 2003 operating systems, *BugCheckCallback* routines execute after the system crash dump file has already been written. (On earlier versions of Windows, the routines execute before the crash dump file is written.) Thus, any data that is stored in the buffer specified by the *Buffer* parameter will not appear in the crash dump file. Drivers that are required to write data to the crash dump file instead implement a BugCheckSecondaryDumpDataCallback routine. (On earlier versions of Windows, the data written to *Buffer* does appear in the crash dump file.)

Examples

To define a *BugCheckCallback* callback routine, you must first provide a function declaration that identifies the type

of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *BugCheckCallback* callback routine that is named `MyBugCheckCallback`, use the KBUGCHECK_CALLBACK_ROUTINE type as shown in this code example:

```
KBUGCHECK_CALLBACK_ROUTINE MyBugCheckCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyBugCheckCallback(
    PVOID  Buffer,
    ULONG  Length
    )
  {
      // Function body
  }
```

The KBUGCHECK_CALLBACK_ROUTINE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the KBUGCHECK_CALLBACK_ROUTINE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at HIGH_LEVEL.

KBUGCHECK_REASON_CALLBACK_ROUTINE callback function

1/25/2019 • 9 minutes to read • Edit Online

Driver-implemented callback functions that the system executes when it issues a bug check.

The *BugCheckAddPagesCallback* routine adds one or more pages of data to the crash dump file when the operating system issues a bug check.

The *BugCheckDumpIoCallback* routine is executed each time the system writes data to a crash dump file.

The *BugCheckSecondaryDumpDataCallback* routine provides data to the system to append to the crash dump file when the system issues a bug check.

Syntax

```
KBUGCHECK_REASON_CALLBACK_ROUTINE KbugcheckReasonCallbackRoutine;

void KbugcheckReasonCallbackRoutine(
  KBUGCHECK_CALLBACK_REASON Reason,
  _KBUGCHECK_REASON_CALLBACK_RECORD *Record,
  PVOID ReasonSpecificData,
  ULONG ReasonSpecificDataLength
)
{...}
```

Parameters

`Reason`

Specifies the reason for the call to the callback routine. This value can be one of the following as defined in KBUGCHECK_CALLBACK_REASON

- **KbCallbackAddPages**: The purpose of the callback function is to enable the driver to add pages of data to the crash dump file.
- **KbCallbackDumpIo**: This callback function is executed each time the system writes data to a crash dump file.
- **KbCallbackSecondaryDumpData**: This callback function provides data to the system to append to the crash dump file when the system issues a bug check.

`Record`

A pointer to the KBUGCHECK_REASON_CALLBACK_RECORD structure that the driver supplied when it registered this callback. For more information, see the description of the *CallbackRecord* parameter in KeRegisterBugCheckCallback.

`ReasonSpecificData`

A pointer to a KBUGCHECK_ADD_PAGES structure. This pointer is cast to type PVOID. Certain members of this structure are filled in by the operating system before it calls the callback routine, and other members must be filled in by the callback routine. For more information, see the following Remarks section.

`ReasonSpecificDataLength`

Specifies the size, in bytes, of the buffer that the *ReasonSpecificData* parameter points to.

- **KbCallbackAddPages**: **sizeof**(**KBUGCHECK_ADD_PAGES**).
- **KbCallbackDumpIo**: **sizeof**(**KBUGCHECK_DUMP_IO**).
- **KbCallbackSecondaryDumpData**: **sizeof**(**KBUGCHECK_SECONDARY_DUMP_DATA**).

Return Value

None.

Remarks

About implementing *BugCheckAddPagesCallback*: A kernel-mode driver can implement a *BugCheckAddPagesCallback* callback routine to add one or more pages of data to a crash dump file when a bug check occurs. To register this routine with the operating system, the driver calls the KeRegisterBugCheckReasonCallback routine. Before the driver unloads, it must call the KeDeregisterBugCheckReasonCallback routine to remove the registration.

Starting with Windows 8, a registered *BugCheckAddPagesCallback* routine is called during a kernel memory dump or a complete memory dump. In earlier versions of Windows, a registered *BugCheckAddPagesCallback* routine is called during a kernel memory dump, but not during a complete memory dump. By default, a kernel memory dump includes only the physical pages that are being used by the Windows kernel at the time that the bug check occurs, whereas a complete memory dump includes all of the physical memory that is used by Windows. A complete memory dump does not, by default, include physical memory that is used by the platform firmware.

Your *BugCheckAddPagesCallback* routine can supply driver-specific data to add to the dump file. For example, for a kernel memory dump, this additional data can include physical pages that are not mapped to the system address range in virtual memory but that contain information that can help you to debug your driver. The *BugCheckAddPagesCallback* routine might add to the dump file any driver-owned physical pages that are unmapped or that are mapped to user-mode addresses in virtual memory.

When a bug check occurs, the operating system calls all the registered *BugCheckAddPagesCallback* routines to poll drivers for data to add to the crash dump file. Each call adds one or more pages of contiguous data to the crash dump file. A *BugCheckAddPagesCallback* routine can supply either a virtual address or a physical address for the starting page. If more than one page is supplied during a call, the pages are contiguous in either virtual or physical memory, depending on whether the starting address is virtual or physical. To supply noncontiguous pages, the *BugCheckAddPagesCallback* routine can set a flag in the **KBUGCHECK_ADD_PAGES** structure to indicate that it has additional data and has to be called again. For more information, see KBUGCHECK_ADD_PAGES.

Unlike a BugCheckSecondaryDumpDataCallback routine, which appends data to the secondary crash dump region, a *BugCheckAddPagesCallback* routine adds pages of data to the primary crash dump region. During debugging, primary crash dump data is easier to access than secondary crash dump data.

Before the operating system calls a *BugCheckAddPagesCallback* routine, it fills in the **BugCheckCode** member of the **KBUGCHECK_ADD_PAGES** structure that *ReasonSpecificData* points to. During the call, the *BugCheckAddPagesCallback* routine must set the values of the **Flags**, **Address**, and **Count** members of this structure. If the *BugCheckAddPagesCallback* routine is called more than one time, the operating system preserves the value that the callback routine wrote to the **Context** member in the previous call. Before the first call, the operating system initializes **Context** to **NULL**.

A *BugCheckAddPagesCallback* routine is very restricted in the actions it can take. For more information, see Writing a Bug Check Callback Routine.

About implementing *BugCheckDumpIoCallback*: The driver's *BugCheckDumpIoCallback* routine is called each time data is written to the crash dump file. The system passes, in the *ReasonSpecificData* parameter, a description of the data being written. The **Buffer** member points to the current data, and the **BufferLength** member specifies

its length. The **Type** member indicates the type of data currently being written, such as dump file header information, memory state, or data provided by a driver. For a description of the possible types of information, see KBUGCHECK_DUMP_IO_TYPE.

The system can write the crash dump file either sequentially, or out of order. If the system is writing the crash dump file sequentially, then the **Offset** member of *ReasonSpecificData* is -1; otherwise, **Offset** is set to the current offset, in bytes, in the crash dump file.

When the system writes the file sequentially, it calls each *BugCheckDumpIoCallback* routine one or more times when writing the header information (**Type** = **KbDumpIoHeader**), one or more times when writing the main body of the crash dump file (**Type** = **KbDumpIoBody**), and one or more times when writing the secondary dump data (**Type** = **KbDumpIoSecondaryDumpData**). Once the system has completed writing the crash dump file, it calls the callback with **Buffer** = **NULL**, **BufferLength** = 0, and **Type** = **KbDumpIoComplete**.

The main purpose of a *BugCheckDumpIoCallback* routine is to allow system crash dump data to be written to devices other than the disk. For example, a device that monitors system state can use the callback to report that the system has issued a bug check, and to provide a crash dump for analysis.

Use KeRegisterBugCheckReasonCallback to register a *BugCheckDumpIoCallback* routine. A driver can subsequently remove the callback by using the KeDeregisterBugCheckReasonCallback routine. If the driver can be unloaded, it must remove any registered callbacks in its Unload routine.

A *BugCheckDumpIoCallback* routine is strongly restricted in the actions it can take. For more information, see Writing a Bug Check Callback Routine.

About implementing *BugCheckSecondaryDumpDataCallback*: The system uses *BugCheckSecondaryDumpDataCallback* routines to poll drivers for crash dump data.

The system sets the **InBuffer**, **InBufferLength**, **OutBuffer**, and **MaximumAllowed** members of the KBUGCHECK_SECONDARY_DUMP_DATA structure that *ReasonSpecificData* points to. The **MaximumAllowed** member specifies the maximum amount of dump data the routine can provide.

The value of the **OutBuffer** member determines whether the system is requesting the size of the driver's dump data, or the data itself, as follows:

- If the **OutBuffer** member of KBUGCHECK_SECONDARY_DUMP_DATA is **NULL**, the system is only requesting size information. The *BugCheckSecondaryDumpDataCallback* routine fills in the **OutBuffer** and **OutBufferLength** members.
- If the **OutBuffer** member of KBUGCHECK_SECONDARY_DUMP_DATA equals the **InBuffer** member, the system is requesting the driver's secondary dump data. The *BugCheckSecondaryDumpDataCallback* routine fills in the **OutBuffer** and **OutBufferLength** members, and writes the data to the buffer specified by **OutBuffer**.

The **InBuffer** member of KBUGCHECK_SECONDARY_DUMP_DATA points to a small buffer for the routine's use. The **InBufferLength** member specifies the size of the buffer. If the amount of data to be written is less than **InBufferLength**, the callback routine can use this buffer to supply the crash dump data to the system. The callback routine then sets **OutBuffer** to **InBuffer** and **OutBufferLength** to the actual amount of data written to the buffer.

A driver that must write an amount of data that is larger than **InBufferLength** can use its own buffer to provide the data. This buffer must have been allocated before the callback routine is executed, and must reside in resident memory (such as nonpaged pool). The callback routine then sets **OutBuffer** to point to the driver's buffer, and **OutBufferLength** to the amount of data in the buffer to be written to the crash dump file.

In Windows XP and Windows Server 2003, if **OutBuffer** is set to point to a driver-allocated buffer, the buffer must begin on a page-aligned boundary in memory. Otherwise, no data is written to the secondary data area of the crash dump file. In Windows Vista and later versions of Windows, there is no such alignment requirement.

Each block of data to be written to the crash dump file is tagged with the value of the **Guid** member of KBUGCHECK_SECONDARY_DUMP_DATA. The GUID used must be unique to the driver. To display the secondary dump data corresponding to this GUID, you can use the **.enumtag** command or the **IDebugDataSpaces3::ReadTagged** method in a debugger extension. For information about debuggers and debugger extensions, see Windows Debugging.

A driver can write multiple blocks with the same GUID to the crash dump file, but this is very poor practice, because only the first block will be accessible to the debugger. Drivers that register multiple *BugCheckSecondaryDumpDataCallback* routines should allocate a unique GUID for each callback.

Use KeRegisterBugCheckReasonCallback to register a *BugCheckSecondaryDumpDataCallback* routine. A driver can subsequently remove the callback routine by using the KeDeregisterBugCheckReasonCallback routine. If the driver can be unloaded, then it must remove any registered callback routines in its Unload routine.

A *BugCheckSecondaryDumpDataCallback* is very restricted in the actions it can take. For more information, see Writing a Bug Check Callback Routine.

Examples

To define the callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *BugCheckAddPagesCallback* callback routine that is named `MyBugCheckAddPagesCallback`, use the KBUGCHECK_REASON_CALLBACK_ROUTINE type as shown in this code example:

```
KBUGCHECK_REASON_CALLBACK_ROUTINE MyBugCheckAddPagesCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyBugCheckAddPagesCallback(
    KBUGCHECK_CALLBACK_REASON  Reason,
    struct _KBUGCHECK_REASON_CALLBACK_RECORD  *Record,
    PVOID  ReasonSpecificData,
    ULONG  ReasonSpecificDataLength
    )
  {
      // Function body
  }
```

The KBUGCHECK_REASON_CALLBACK_ROUTINE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the KBUGCHECK_REASON_CALLBACK_ROUTINE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Supported starting with Windows Server 2008.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at HIGH_LEVEL.

KDEFERRED_ROUTINE callback function

1/25/2019 • 3 minutes to read • Edit Online

The callback routine performs actions, after an InterruptService returns, of a threaded DPC,

The *CustomDpc* routine finishes the servicing of an I/O operation, after an InterruptService routine returns.

The *CustomThreadedDpc* routine performs the action of a threaded DPC. The system executes this routine when the threaded DPC runs.

The *CustomTimerDpc* routine executes after a timer object's time interval expires.

Syntax

```
KDEFERRED_ROUTINE KdeferredRoutine;

void KdeferredRoutine(
  _KDPC *Dpc,
  PVOID DeferredContext,
  PVOID SystemArgument1,
  PVOID SystemArgument2
)
{...}
```

Parameters

`*Dpc`

Caller-supplied pointer to a KDPC structure, which represents the DPC object that is associated with this callback routine.

`DeferredContext`

For *CustomDpc*, a caller-supplied pointer to driver-defined context information that was specified in a previous call to KeInitializeDpc.

For *CustomThreadedDpc*, specifies driver-defined context information. When it initialized the DPC object, the driver supplied this value as the *DeferredContext* parameter to KeInitializeThreadedDpc.

Caller-supplied pointer to a KDPC structure, which represents the DPC object associated with this *CustomTimerDpc* routine.

`SystemArgument1`

Caller-supplied pointer to driver-supplied information that was specified in a previous call to KeInsertQueueDpc. When it added the DPC to the DPC queue, the driver supplied this value as the *SystemArgument1* parameter to **KeInsertQueueDpc**.

For *CustomTimerDpc*, this value is not used.

`SystemArgument2`

Specifies driver-defined context information. When it added the DPC to the DPC queue, the driver supplied this value as the *SystemArgument2* parameter to **KeInsertQueueDpc**.

For *CustomTimerDpc*, this value is not used.

Return Value

None

Remarks

About implementing *CustomDpc*: To create a DPC object and register a *CustomDpc* routine for that object, a driver must call KeInitializeDpc. (If you need only one DPC routine, you can use a DpcForIsr routine and the system-allocated DPC object.)

To queue a *CustomDpc* routine for execution, a driver's InterruptService routine must call **KeInsertQueueDpc**.

One or more *CustomDpc* routines can be used instead of, or in conjunction with, a *DpcForIsr* routine. A driver that maintains several internal IRP queues typically supplies a *CustomDpc* routine for each queue. Each *CustomDpc* routine is typically responsible for at least the following tasks:

- Completing the I/O operation that is described by the current IRP.
- Dequeuing the next IRP from one of the driver's IRP queues. (Drivers that use the system-supplied IRP queue together with a StartIo routine call IoStartNextPacket.)
- Setting the I/O status block in the current IRP and calling IoCompleteRequest for the completed request.

A *CustomDpc* routine might also retry a failed operation or set up the next transfer for a large I/O request that has been broken into smaller pieces.

For more information about *CustomDpc* routines, see DPC Objects and DPCs.

About implementing *CustomThreadedDpc*: A driver registers a *CustomThreadedDpc* for a DPC object by calling KeInitializeThreadedDpc. To actually add the DPC to the DPC queue so that the *CustomThreadedDpc* routine will be executed, call KeInsertQueueDpc.

For more information about using *CustomThreadedDpc* routines, see Threaded DPCs.

A *CustomThreadedDpc* routine can run at IRQL = DISPATCH_LEVEL, or it can run at IRQL = PASSIVE_LEVEL in a real-time thread.

About implementing *CustomTimerDpc*: To create a DPC object and register a *CustomTimerDpc* routine for that object, a driver must call KeInitializeDpc.

To queue a *CustomTimerDpc* routine for execution, a driver routine must call KeSetTimer or KeSetTimerEx, supplying a DPC object pointer returned by **KeInitializeDpc**. The system calls the *CustomTimerDpc* routine when the timer interval expires.

For more information about *CustomTimerDpc* routines, see Timer Objects and DPCs.

Examples

To define a callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *CustomDpc* callback routine that is named `MyCustomDpc`, use the KDEFERRED_ROUTINE type as shown in this code example:

```
```

```
KDEFERRED_ROUTINE MyCustomDpc;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyCustomDpc(
    struct _KDPC  *Dpc,
    PVOID  DeferredContext,
    PVOID  SystemArgument1,
    PVOID  SystemArgument2
    )
  {
      // Function body
  }
```

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at DISPATCH_LEVEL.

KeAcquireSpinLock macro

1/25/2019 • 2 minutes to read • Edit Online

The **KeAcquireSpinLock** routine acquires a spin lock so the caller can synchronize access to shared data in a multiprocessor-safe way by raising IRQL.

Syntax

```
void KeAcquireSpinLock(
   a,
   b
);
```

Parameters

`a`

Pointer to an initialized KSPIN_LOCK spin lock for which the caller provides the storage.

`b`

Pointer to a KIRQL variable that is set to the current IRQL when this call occurs.

Return Value

None

Remarks

KeAcquireSpinLock first resets the IRQL to DISPATCH_LEVEL and then acquires the lock. The previous IRQL is written to *OldIrql* after the lock is acquired.

The *OldIrql* value must be specified when the spin lock is released with KeReleaseSpinLock.

Most drivers use a local variable to store the old IRQL value. A driver can also use a shared memory location, such as a global variable, but the driver must not use the same location for two different locks. Otherwise, a race condition can occur.

Spin locks can cause serious problems if not used judiciously. In particular, no deadlock protection is performed and dispatching is disabled while the spin lock is held. Therefore:

- The code within a critical region guarded by an spin lock must neither be pageable nor make any references to pageable data.
- The code within a critical region guarded by a spin lock can neither call any external function that might access pageable data or raise an exception, nor can it generate any exceptions.
- The caller should release the spin lock with **KeReleaseSpinLock** as quickly as possible.

Attempting to acquire a spin lock recursively is guaranteed to cause a deadlock. For more information about spin locks, see Spin Locks.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Hal.lib
IRQL	"<= DISPATCH_LEVEL"
DDI compliance rules	IrqlKeDispatchLte, MarkingQueuedIrps, SpinLock, SpinLockDpc, SpinlockRelease, SpinLockSafe, ReqSendWhileSpinlock, Spinlock(kmdf), SpinlockDpc(kmdf), SpinlockRelease(kmdf), HwStorPortProhibitedDDIs, SpinLock(storport), SpinLockDpc(storport), SpinLockRelease(storport), SpinLockSafe(storport)

KeReleaseSpinLock

KeAcquireSpinLockAtDpcLevel macro

1/25/2019 • 2 minutes to read • Edit Online

The **KeAcquireSpinLockAtDpcLevel** routine acquires a spin lock when the caller is already running at IRQL >= DISPATCH_LEVEL.

Syntax

```
void KeAcquireSpinLockAtDpcLevel(
   a
);
```

Parameters

`a`

Pointer to an initialized KSPIN_LOCK spin lock for which the caller must provide the storage.

Return Value

None

Remarks

Drivers call **KeAcquireSpinLockAtDpcLevel** instead of KeAcquireSpinLock for better driver performance if and only if they are already running at an IRQL of DISPATCH_LEVEL or above.

If a driver is running at IRQL <= APC_LEVEL, it should call **KeAcquireSpinLock** to have IRQL raised by that routine. **KeAcquireSpinLockAtDpcLevel** assumes the caller is already running at IRQL >= DISPATCH_LEVEL, so no raise is necessary.

The caller should release the spin lock with KeReleaseSpinLockFromDpcLevel as quickly as possible.

For more information about spin locks, see Spin Locks.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	See Remarks section.

KeAreAllApcsDisabled function

1/25/2019 • 2 minutes to read • Edit Online

The **KeAreAllApcsDisabled** routine indicates whether the calling thread is inside a guarded region or running at IRQL >= APC_LEVEL, which disables all APC delivery.

Syntax

```
BOOLEAN KeAreAllApcsDisabled(

);
```

Parameters

This function has no parameters.

Return Value

KeAreAllApcsDisabled returns **TRUE** if the calling thread is inside a guarded region or running at IRQL >= APC_LEVEL, and **FALSE** otherwise.

Remarks

A thread inside a guarded region or running at IRQL >= APC_LEVEL has all APCs disabled, including special kernel APCs.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"
DDI compliance rules	HwStorPortProhibitedDDIs

KeAreApcsDisabled

KeAreApcsDisabled function

1/25/2019 • 2 minutes to read • Edit Online

The **KeAreApcsDisabled** routine returns whether the calling thread is within a critical region or a guarded region, which disables normal kernel APC delivery.

Syntax

```
BOOLEAN KeAreApcsDisabled(

);
```

Parameters

This function has no parameters.

Return Value

KeAreApcsDisabled returns **TRUE** if the thread is within a critical region or a guarded region, and **FALSE** otherwise.

Remarks

A thread running at IRQL = PASSIVE_LEVEL can use **KeAreApcsDisabled** to determine if normal kernel APCs are disabled. A thread that is inside a critical region has both user APCs and normal kernel APCs disabled, but not special kernel APCs. A thread that is inside a guarded region has all APCs disabled, including special kernel APCs.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeLeaveCriticalRegion

KeBugCheckEx function

1/25/2019 • 2 minutes to read • Edit Online

The **KeBugCheckEx** routine brings down the system in a controlled manner when the caller discovers an unrecoverable inconsistency that would corrupt the system if the caller continued to run.

Syntax

```
void KeBugCheckEx(
  ULONG     BugCheckCode,
  ULONG_PTR BugCheckParameter1,
  ULONG_PTR BugCheckParameter2,
  ULONG_PTR BugCheckParameter3,
  ULONG_PTR BugCheckParameter4
);
```

Parameters

`BugCheckCode`

Specifies a value that indicates the reason for the bug check.

`BugCheckParameter1`

`BugCheckParameter2`

`BugCheckParameter3`

`BugCheckParameter4`

The four *BugCheckParameterX* values supply additional information, such as the address and data where a memory-corruption error occurred, depending on the value of *BugCheckCode*.

Return Value

None

Remarks

A bug check is a system-detected error that causes an immediate, controlled shutdown of the system. Various kernel-mode components perform run-time consistency checking. When such a component discovers an unrecoverable inconsistency, it causes a bug check to be generated.

Whenever possible, all kernel-mode components should log an error and continue to run, rather than calling **KeBugCheckEx**. For example, if a driver is unable to allocate required resources, it should log an error so that the system continues to run; it must not generate a bug check.

A driver or other kernel-mode component should call this routine only in cases of a fatal, unrecoverable error that could corrupt the system itself.

KeBugCheckEx can be useful in the early stages of developing a driver, or while it is undergoing testing. In these circumstances, the *BugCheckCode* passed to this routine should be distinct from those codes already in use by Windows or its drivers. For a list of these codes, see Bug Check Codes.

However, even during driver development, this routine is of only limited utility, since it results in a complete system shutdown. A more effective debugging method is to attach a kernel debugger to the system and then use routines that send messages to the debugger or break into the debugger. For further information, see Using Debugging Code in a Driver.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.

KeRegisterBugCheckReasonCallback

KeCancelTimer function

1/25/2019 • 2 minutes to read • Edit Online

The **KeCancelTimer** routine dequeues a timer object before the timer interval, if any was set, expires.

Syntax

```
BOOLEAN KeCancelTimer(
  PKTIMER Arg1
);
```

Parameters

`Arg1`

Pointer to an initialized timer object, for which the caller provides the storage.

Return Value

If the specified timer object is in the system timer queue, **KeCancelTimer** returns **TRUE**.

Remarks

If the timer object is currently in the system timer queue, it is removed from the queue. If a DPC object is associated with the timer, it too is canceled. Otherwise, no operation is performed.

The routine returns **TRUE** if the timer is still in the timer queue. A nonperiodic timer is removed from the system queue as soon as it expires. Thus, for nonperiodic timers, **KeCancelTimer** returns **FALSE** if the timer DPC has been queued. Periodic timers are always in the timer queue, so **KeCancelTimer** always returns **TRUE** for periodic timers.

Note that a DPC that is already running runs to completion. The driver must ensure that the DPC has completed before freeing any resources used by the DPC. For a nonperiodic timer, you can use synchronization primitives, such as event objects, to synchronize between the driver and the DPC. The driver can check the return code of **KeCancelTimer** to determine if the DPC is running. If so, the DPC can signal the event before exiting, and the driver can wait for that event to be reset to the not-signaled state.

Since for periodic timers **KeCancelTimer** always returns **TRUE**, drivers must use a different technique to wait until the DPC has completed. Use the KeFlushQueuedDpcs routine to block until the DPC executes.

Drivers do not need to synchronize for data stored in global variables or driver object extensions. The system automatically calls **KeFlushQueuedDpcs** before deallocating either of these regions.

For more information about timer objects, see Timer Objects and DPCs.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeClearEvent function

1/25/2019 • 2 minutes to read • Edit Online

The **KeClearEvent** routine sets an event to a not-signaled state.

Syntax

```
void KeClearEvent(
  PRKEVENT Event
);
```

Parameters

`Event`

Pointer to an initialized dispatcher object of type event for which the caller supplies the storage.

Return Value

None

Remarks

Event is set to a not-signaled state, meaning its value is set to zero.

For better performance, use **KeClearEvent** unless the caller uses the value returned by KeResetEvent to determine what to do next.

For more information about event objects, see Event Objects.

Requirements

Minimum supported client	Available starting with Windows 2000.

KeConvertAuxiliaryCounterToPerformanceCounter function

1/25/2019 • 2 minutes to read • Edit Online

The **KeConvertAuxiliaryCounterToPerformanceCounter** routine converts the specified auxiliary counter value into a performance counter value.

Syntax

```
NTSTATUS KeConvertAuxiliaryCounterToPerformanceCounter(
  ULONG64  AuxiliaryCounterValue,
  PULONG64 PerformanceCounterValue,
  PULONG64 ConversionError
);
```

Parameters

`AuxiliaryCounterValue`

The auxiliary counter value to convert.

`PerformanceCounterValue`

A pointer to the variable that contains the converted performance counter value.

`ConversionError`

A pointer to a variable that contains the estimated conversion error in units of nanosecond.

Return Value

KeConvertAuxiliaryCounterToPerformanceCounter can return one of the following:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The conversion succeeded.
STATUS_NOT_SUPPORTED	Auxiliary counter is not supported.

STATUS_INVALID_PARAMETER	The *AuxiliaryCounterValue* value is not valid. For example, the value is earlier than the last system boot/recovery, or is out of the +/- 10s range compared to the current auxiliary counter value.
STATUS_UNSUCCESSFUL	The routine cannot convert the specified value with acceptable accuracy.

Remarks

Make sure that the specified auxiliary counter value is within +/- 10s compared to the current value.

Requirements

Minimum supported client	Available starting with Windows 10.

  ULONG64  PerformanceCounterValue,
  PULONG64 AuxiliaryCounterValue,
  PULONG64 ConversionError
);
```

Parameters

`PerformanceCounterValue`

The performance counter value to convert.

`AuxiliaryCounterValue`

A pointer to the variable that contains the converted auxiliary counter value.

`ConversionError`

A pointer to a variable that contains the estimated conversion error in units of nanosecond.

Return Value

KeConvertPerformanceCounterToAuxiliaryCounter can return one of the following:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The conversion succeeded.
STATUS_NOT_SUPPORTED	Auxiliary counter is not supported.

STATUS_INVALID_PARAMETER	The *PerformanceCounterValue* value is not valid. For example, the value is earlier than the last system boot/recovery, or is out of the +/- 10s range compared to the current performance counter value.
STATUS_UNSUCCESSFUL	The routine cannot convert the specified value with acceptable accuracy.

Remarks

Make sure that the specified performance counter value is:

- Within +/- 10s compared to the current performance counter read value.
- Not earlier than the recorded performance counter value at the last system boot or recovery from S3/S4 state.

The *ConversionError* value is the difference, in nanoseconds, between the expected calculated value and the actual calculated value for the auxiliary counter. If the *ConversionError* value is greater than the expected value (determined by you), then call the routine again.

Requirements

Minimum supported client	Available starting with Windows 10.
Target Platform	Universal
Header	wdm.h
Library	Ntoskrnl.lib
DLL	Hal.dll
IRQL	Any level

KeConvertAuxiliaryCounterToPerformanceCounter

KeDelayExecutionThread function

1/25/2019 • 2 minutes to read • Edit Online

The **KeDelayExecutionThread** routine puts the current thread into an alertable or nonalertable wait state for a specified interval.

Syntax

```
NTSTATUS KeDelayExecutionThread(
  KPROCESSOR_MODE WaitMode,
  BOOLEAN         Alertable,
  PLARGE_INTEGER  Interval
);
```

Parameters

`WaitMode`

Specifies the processor mode in which the caller is waiting, which can be either **KernelMode** or **UserMode**. Lower-level drivers should specify **KernelMode**.

`Alertable`

Specifies **TRUE** if the wait is alertable. Lower-level drivers should specify **FALSE**.

`Interval`

Specifies the absolute or relative time, in units of 100 nanoseconds, for which the wait is to occur. A negative value indicates relative time. Absolute expiration times track any changes in system time; relative expiration times are not affected by system time changes.

Return Value

KeDelayExecutionThread returns one of the following values that describes how the delay was completed:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The delay completed because the specified interval elapsed.
STATUS_ALERTED	The delay completed because the thread was alerted.

STA TUS _US ER_ APC	A user-mode APC was delivered before the specified *Interval* expired.

Note that the NT_SUCCESS macro recognizes all of these status values as "success" values.

Remarks

The expiration time is computed and the current thread is put in a wait state. When the specified interval has passed, the thread exits the wait state and is put in the ready state, becoming eligible for execution.

The *Alertable* parameter determines when the thread can be alerted and its wait state consequently aborted. For additional information, see Waits and APCs.

If the *WaitMode* parameter is **UserMode**, the kernel stack can be swapped out during the wait. Consequently, a caller must never attempt to pass parameters on the stack when calling **KeDelayExecutionThread** using the **UserMode** argument.

It is especially important to check the return value of **KeDelayExecutionThread** when the *WaitMode* parameter is **UserMode** or *Alertable* is **TRUE**, because **KeDelayExecutionThread** might return early with a status of STATUS_USER_APC or STATUS_ALERTED.

All long term waits that can be aborted by a user should be **UserMode** waits and *Alertable* should be set to **FALSE**.

Where possible, *Alertable* should be set to **FALSE** and *WaitMode* should be set to **KernelMode**, in order to reduce driver complexity. The principal exception to this guideline is when the wait is a long-term wait.

The expiration time of the delay is expressed as either an absolute time at which the delay is to expire, or a time relative to the current system time. If the *Interval* parameter value is positive, the expiration time is an absolute time. If this value is negative, the expiration time is a relative time.

Expiration times are measured relative to the system clock, and the accuracy with which the operating system can detect when a timer expires is limited by the granularity of the system clock. For more information, see Timer Accuracy.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

KeDeregisterBoundCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **KeDeregisterBoundCallback** routine deregisters a user-mode bound exception callback registered by KeRegisterBoundCallback.

Syntax

```
NTSTATUS KeDeregisterBoundCallback(
  PVOID Handle
);
```

Parameters

`Handle`

Specifies the value returned by KeRegisterBoundCallback when the callback was registered.

Return Value

The **KeDeregisterBoundCallback** routine returns STATUS_SUCCESS if the callback is successfully removed. It returns STATUS_INVALID_HANDLE if no callback matching the provided *Handle* value is found.

Requirements

Minimum supported client	Available starting with Windows 10.
Target Platform	Universal
Header	wdm.h
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeRegisterBoundCallback

KeDeregisterBugCheckCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **KeDeregisterBugCheckCallback** routine removes a callback routine that was registered by KeRegisterBugCheckCallback.

Syntax

```
BOOLEAN KeDeregisterBugCheckCallback(
  PKBUGCHECK_CALLBACK_RECORD CallbackRecord
);
```

Parameters

`CallbackRecord`

Pointer to a KBUGCHECK_CALLBACK_RECORD structure. *CallbackRecord* must be the same value that was passed to KeRegisterBugCheckCallback when the callback was registered.

Return Value

KeDeregisterBugCheckCallback returns **TRUE** if the specified callback is successfully removed. It returns **FALSE** if the specified callback is not registered.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeDeregisterBugCheckReasonCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **KeDeregisterBugCheckReasonCallback** routine removes a callback routine that was registered by KeRegisterBugCheckReasonCallback.

Syntax

```
BOOLEAN KeDeregisterBugCheckReasonCallback(
  PKBUGCHECK_REASON_CALLBACK_RECORD CallbackRecord
);
```

Parameters

`CallbackRecord`

Pointer to a KBUGCHECK_REASON_CALLBACK_RECORD structure. *CallbackRecord* must be the same value that was passed to KeRegisterBugCheckReasonCallback when the callback was registered.

Return Value

KeDeregisterBugCheckReasonCallback returns **TRUE** if the callback is successfully removed. It returns **FALSE** if the specified callback is not registered.

Requirements

Minimum supported client	Available in Windows XP Service Pack 1 (SP1), Windows Server 2003, and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KeDeregisterNmiCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **KeDeregisterNmiCallback** routine deregisters a nonmaskable interrupt (NMI) callback registered by KeRegisterNmiCallback.

Syntax

```
NTSTATUS KeDeregisterNmiCallback(
  PVOID Handle
);
```

Parameters

`Handle`

Specifies the value returned by KeRegisterNmiCallback when the NMI callback was registered.

Return Value

The **KeDeregisterNmiCallback** routine returns STATUS_SUCCESS if the callback is successfully removed. It returns STATUS_INVALID_HANDLE if no callback matching the provided *Handle* value is found.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeRegisterNmiCallback

KeDeregisterProcessorChangeCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **KeDeregisterProcessorChangeCallback** routine unregisters a callback function that was previously registered with the operating system by calling the KeRegisterProcessorChangeCallback routine.

Syntax

```
void KeDeregisterProcessorChangeCallback(
  PVOID CallbackHandle
);
```

Parameters

`CallbackHandle`

The callback registration handle that was returned by the KeRegisterProcessorChangeCallback routine when the callback function was registered with the operating system.

Return Value

None

Remarks

A device driver calls the KeRegisterProcessorChangeCallback routine to register a callback function with the operating system so that the operating system will notify the driver when a new processor is added to the hardware partition. When the device driver no longer needs to receive notification when new processors are added to the hardware paritition, it calls the **KeDeregisterProcessorChangeCallback** routine to unregister the callback function. A callback function that has been registered for notification of processor changes must be unregistered before the device driver is unloaded from the operating system.

Requirements

Minimum supported client	Available in Windows Server 2008 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

KeRegisterProcessorChangeCallback

KeEnterCriticalRegion function

1/25/2019 • 2 minutes to read • Edit Online

The **KeEnterCriticalRegion** routine temporarily disables the execution of normal kernel APCs, but does not prevent special kernel APCs from running.

Syntax

```
void KeEnterCriticalRegion(

);
```

Parameters

This function has no parameters.

Return Value

None

Remarks

A driver calls this routine to enter a critical region in which the execution of normal kernel APCs is deferred until this driver exits the critical region by calling the KeLeaveCriticalRegion routine. Any caller of **KeEnterCriticalRegion** should call **KeLeaveCriticalRegion** as quickly as possible after entering a critical region.

Highest-level drivers can call **KeEnterCriticalRegion** while running in the context of the thread that requested the current I/O operation.

A thread that is inside a critical region has both user APCs and normal kernel APCs disabled, but not special kernel APCs. For more information about these APC types, see Types of APCs.

Critical regions can be entered recursively and each call to **KeEnterCriticalRegion** must have a matching call to **KeLeaveCriticalRegion**.

A driver can use a critical region to acquire and release exclusive access to a shared resource. In this case, the ExEnterCriticalRegionAndAcquireResourceExclusive and ExReleaseResourceAndLeaveCriticalRegion routines can be used instead of the **KeEnterCriticalRegion** and **KeLeaveCriticalRegion** routines. For more information, see the code example in ExEnterCriticalRegionAndAcquireResourceExclusive.

For more information about APCs, see Asynchronous Procedure Calls.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

KeLeaveCriticalRegion

KeEnterGuardedRegion function

1/25/2019 • 2 minutes to read • Edit Online

The **KeEnterGuardedRegion** routine enters a guarded region, which disables all kernel-mode APC delivery to the current thread.

Syntax

```
void KeEnterGuardedRegion(

);
```

Parameters

This function has no parameters.

Return Value

None

Remarks

To exit a guarded region entered with **KeEnterGuardedRegion**, call the **KeLeaveGuardedRegion** routine. Guarded regions can be nested. APCs are not reenabled until the thread exits the outermost guarded region.

For more information about guarded regions, see Critical Regions and Guarded Regions.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

KeLeaveGuardedRegion

KeFlushIoBuffers function

1/25/2019 • 2 minutes to read • Edit Online

The **KeFlushIoBuffers** routine flushes the memory region described by an MDL from caches of all processors.

Syntax

```
void KeFlushIoBuffers(
  PMDL    Mdl,
  BOOLEAN ReadOperation,
  BOOLEAN DmaOperation
);
```

Parameters

`Mdl`

A pointer to an MDL that describes the range for the I/O buffer.

`ReadOperation`

Specifies **TRUE** if the flush is being performed for a read operation, and **FALSE** for a write operation. For more information, see the following Remarks section.

`DmaOperation`

Specifies **TRUE** for a DMA transfer, **FALSE** for PIO.

Return Value

None

Remarks

Drivers call **KeFlushIoBuffers** to maintain data integrity during DMA or PIO device transfer operations. Calling this routine affects all processors in the machine.

If *ReadOperation* is **TRUE**, the driver is reading information from the device to system memory, so valid data still might be in the processor instruction and data caches. **KeFlushIoBuffers** flushes data from all processors' caches to system memory, including the processor on which the caller is running.

If *ReadOperation* is **FALSE**, the driver is writing data from system memory to a device, so valid data might be in the processor's data cache but not yet transferred to the device. **KeFlushIoBuffers** flushes all processors' data caches, including that of the processor on which the caller is running.

As a general rule, drivers should call **KeFlushIoBuffers** just before beginning a DMA transfer operation or immediately following any PIO read operation.

KeFlushIoBuffers flushes only the memory region that is described by the MDL that the *Mdl* parameter points to. To flush all the memory regions that are described by an MDL chain requires a separate **KeFlushIoBuffers** call for each MDL in the chain.

For more information, see the following topics:

Flushing Cached Data during DMA Operations Flushing Cached Data during PIO Operations

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

KeFlushQueuedDpcs function

1/25/2019 • 2 minutes to read • Edit Online

The **KeFlushQueuedDpcs** routine returns after all queued DPCs on all processors have executed.

Syntax

```
void KeFlushQueuedDpcs(

);
```

Parameters

This function has no parameters.

Return Value

None

Remarks

Drivers can use this routine to wait until all currently-queued DPCs are run. Note that **KeFlushQueuedDpcs** can take a long time to return, so drivers should not use it along any critical code paths.

Requirements

Minimum supported client	Available starting with Windows XP with SP2 and Windows Server 2003.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

KefReleaseSpinLockFromDpcLevel function

1/25/2019 • 2 minutes to read • Edit Online

The **KeReleaseSpinLockFromDpcLevel** routine releases an executive spin lock without changing the IRQL.

Syntax

```
void KefReleaseSpinLockFromDpcLevel(
  PKSPIN_LOCK SpinLock
);
```

Parameters

`SpinLock`

Pointer to an executive spin lock for which the caller provides the storage.

Return Value

None

Remarks

Drivers call **KeReleaseSpinLockFromDpcLevel** to release a spin lock acquired by calling KeAcquireSpinLockAtDpcLevel.

It is an error to call **KeReleaseSpinLockFromDpcLevel** if the specified spin lock was acquired by calling KeAcquireSpinLock because the caller's original IRQL is not restored, which can cause deadlocks or fatal page faults.

For more information about spin locks, see Spin Locks.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeGetCurrentNodeNumber function

1/25/2019 • 2 minutes to read • Edit Online

The **KeGetCurrentNodeNumber** routine gets the NUMA node number for the logical processor that the caller is running on.

Syntax

```
USHORT KeGetCurrentNodeNumber(

);
```

Parameters

This function has no parameters.

Return Value

KeGetCurrentNodeNumber returns the node number.

Remarks

In a non-uniform memory access (NUMA) multiprocessor architecture, a node is a collection of processors that share fast access to a region of memory. Memory access is non-uniform because a processor can access the memory in its node faster than it can access the memory in other nodes.

In a NUMA multiprocessor system that contains *n* nodes, the nodes are numbered from 0 to *n*-1. To get the highest node number (*n*-1) in the system, call the KeQueryHighestNodeNumber routine.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Ntddk.h, Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeQueryHighestNodeNumber

KeGetCurrentProcessorNumberEx function

1/25/2019 • 2 minutes to read • Edit Online

The **KeGetCurrentProcessorNumberEx** routine gets the processor number of the logical processor that the caller is running on.

Syntax

```
ULONG KeGetCurrentProcessorNumberEx(
  PPROCESSOR_NUMBER ProcNumber
);
```

Parameters

`ProcNumber`

A pointer to a caller-allocated buffer into which the routine writes a PROCESSOR_NUMBER structure that identifies the current logical processor. This structure contains the group number and the group-relative processor number. You can set this parameter to **NULL** if you do not need this information.

Return Value

KeGetCurrentProcessorNumberEx returns the systemwide processor index of the logical processor that the caller is running on.

Remarks

If *ProcNumber* is non-**NULL**, the buffer that is pointed to by *ProcNumber* must be large enough to contain a PROCESSOR_NUMBER structure. In contrast to this structure, which contains a group number and a group-relative processor number, the return value is a processor index that identifies the processor across the entire multiprocessor system.

For example, if a multiprocessor system contains two groups, and each group contains 64 logical processors, the processor numbers in each group range from 0 to 63, but the systemwide processor indexes range from 0 to 127.

A related routine, KeGetCurrentProcessorNumber, returns the current processor number, but this routine, unlike **KeGetCurrentProcessorNumberEx**, does not provide a group number for the processor. In Windows 7 and later versions of the Windows operating system, **KeGetCurrentProcessorNumber** returns the group-relative processor number if the caller is running on a processor in group 0, which is compatible with the behavior of this routine in earlier versions of Windows that do not support groups. However, if the caller is running on a processor in any group other than group 0, this routine returns a number that is less than the number of processors in group 0. This behavior ensures that the return value is less than the return value of the KeQueryActiveProcessorCount routine. Existing drivers that call **KeGetCurrentProcessorNumber** and that use no group-oriented features run correctly in multiprocessor systems that have two or more groups. However, drivers that use any group-oriented features in Windows 7 and later versions of the Windows operating system should call **KeGetCurrentProcessorNumberEx** instead of **KeGetCurrentProcessorNumber**.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Ntddk.h, Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

PROCESSOR_NUMBER

KeGetCurrentThread function

1/25/2019 • 2 minutes to read • Edit Online

The **KeGetCurrentThread** routine identifies the current thread.

Syntax

```
PKTHREAD KeGetCurrentThread(

);
```

Parameters

This function has no parameters.

Return Value

KeGetCurrentThread returns a pointer to an opaque thread object.

Remarks

This routine is identical to PsGetCurrentThread.

A caller of **KeGetCurrentThread** can use the returned pointer as an input parameter to KeQueryPriorityThread, KeSetBasePriorityThread, or KeSetPriorityThread. However, the memory containing the thread object is opaque; that is, it is reserved for exclusive use by the operating system.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

PsGetCurrentThread

KeGetProcessorIndexFromNumber function

1/25/2019 • 2 minutes to read • Edit Online

The **KeGetProcessorIndexFromNumber** routine converts a group number and a group-relative processor number to a systemwide processor index.

Syntax

```
ULONG KeGetProcessorIndexFromNumber(
  PPROCESSOR_NUMBER ProcNumber
);
```

Parameters

`ProcNumber`

A pointer to a caller-allocated PROCESSOR_NUMBER structure that contains a group number and a group-relative processor number.

Return Value

KeGetProcessorIndexFromNumber returns a systemwide processor index if the call is successful. If *ProcNumber* points to an invalid **PROCESSOR_NUMBER** value, the routine returns INVALID_PROCESSOR_INDEX, which is defined in the Wdm.h header file.

Remarks

This routine accepts as input a **PROCESSOR_NUMBER** structure that identifies a processor by its group number and its processor number within the group. The return value is a processor index that identifies the processor across the entire multiprocessor system.

For example, if a multiprocessor system contains two groups, and each group contains 64 logical processors, the processor numbers in each group range from 0 to 63, but the systemwide processor indexes range from 0 to 127.

To obtain the total number of active logical processors in the system, call the KeQueryActiveProcessorCountEx routine and set this routine's *GroupNumber* parameter to ALL_PROCESSOR_GROUPS.

The KeGetProcessorNumberFromIndex routine converts a systemwide processor index to a group number and a group-relative processor number.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeGetProcessorNumberFromIndex

KeQueryActiveProcessorCountEx

PROCESSOR_NUMBER

KeGetProcessorNumberFromIndex function

1/25/2019 • 2 minutes to read • Edit Online

The **KeGetProcessorNumberFromIndex** routine converts a systemwide processor index to a group number and a group-relative processor number.

Syntax

```
NTSTATUS KeGetProcessorNumberFromIndex(
  ULONG             ProcIndex,
  PPROCESSOR_NUMBER ProcNumber
);
```

Parameters

`ProcIndex`

A systemwide processor index. If a multiprocessor system contains a total of *n* logical processors, valid processor indexes range from 0 to *n*-1.

`ProcNumber`

A pointer to a caller-allocated PROCESSOR_NUMBER structure into which the routine writes the group number and group-relative processor number of the processor that is identified by *ProcIndex*.

Return Value

KeGetProcessorNumberFromIndex returns STATUS_SUCCESS if the call is successful. Possible error return values include the following:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The *ProcIndex* parameter value is not a valid processor index.

Remarks

This routine accepts as input a processor index that identifies the processor across the entire multiprocessor system. The output value is a **PROCESSOR_NUMBER** structure that identifies a processor by its group number and its processor number within the group.

For example, if a multiprocessor system contains two groups, and each group contains 64 logical processors, the processor numbers in each group range from 0 to 63, but the systemwide processor indexes range from 0 to 127.

To obtain the total number of active logical processors in the system, call the KeQueryActiveProcessorCountEx routine.

The KeGetProcessorIndexFromNumber routine converts a group number and a group-relative processor number to a systemwide processor index.

Examples

The following code example uses the **KeQueryActiveProcessorCountEx** and **KeGetProcessorNumberFromIndex** routines to enumerate all active logical processors in the system:

```
ULONG Count;
ULONG ProcIndex;
PROCESSOR_NUMBER ProcNumber;

Count = KeQueryActiveProcessorCountEx(ALL_PROCESSOR_GROUPS);
for (ProcIndex = 0; ProcIndex < Count; ProcIndex += 1)
{
    KeGetProcessorNumberFromIndex(ProcIndex, &ProcNumber);

    // Do something with the contents of ProcNumber.
    ...
}
```

The constant value ALL_PROCESSOR_GROUPS is defined in Winnt.h and Ntdef.h.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Ntddk.h, Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeGetRecommendedSharedDataAlignment function

1/25/2019 • 2 minutes to read • Edit Online

The **KeGetRecommendedSharedDataAlignment** routine returns the preferred alignment for memory structures that can be accessed by more than one processor.

Syntax

```
ULONG KeGetRecommendedSharedDataAlignment(

);
```

Parameters

This function has no parameters.

Return Value

KeGetRecommendedSharedDataAlignment returns the preferred alignment, in bytes, for memory structures that can be shared by more than one processor.

Remarks

Use **KeGetRecommendedSharedDataAlignment** to determine the best alignment for data structures that will be shared between processors. The value returned minimizes cache effects that negatively impact performance on multiprocessor systems.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeInitializeCrashDumpHeader function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInitializeCrashDumpHeader** routine supplies the header information the system requires for a crash dump file.

Syntax

```
NTSTATUS KeInitializeCrashDumpHeader(
  ULONG  DumpType,
  ULONG  Flags,
  PVOID  Buffer,
  ULONG  BufferSize,
  PULONG BufferNeeded
);
```

Parameters

`DumpType`

Specifies the type of dump file. The only valid value is DUMP_TYPE_FULL.

`Flags`

Specifies flags for the dump file. The only valid value is 0.

`Buffer`

Pointer to the buffer that receives the header information.

`BufferSize`

Specifies the size in bytes of the buffer pointed to by *Buffer*.

`BufferNeeded`

Optionally, a pointer to a variable that receives the size necessary to hold the complete header information.

Return Value

KeInitializeCrashDumpHeader returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure.

Remarks

Drivers can use this routine to manually create a crash dump file. The file can be created at any time, and used by a debugger to examine the state of the system.

To create a crash-dump file, call **KeInitializeCrashDumpHeader** to create the header, then append the contents of memory to the header. Note that the driver is not required to record the contents of memory immediately after calling the routine: the header can normally be created at any time before the crash-dump file is written.

Because the routine is designed to be called well before the memory contents are recorded, it has the following limitations:

- The routine does not record any information about active exception records.
- If the size of system RAM changes, the header must be recreated.

The routine does not record any secondary dump data.

Starting with Windows 8, **KeInitializeCrashDumpHeader** always writes the base address of the system process page directory to the crash-dump header, regardless of the process context from which **KeInitializeCrashDumpHeader** is called. The debugger can use this directory to access the crash-dump file in the context of the system process.

In earlier versions of Windows, **KeInitializeCrashDumpHeader** writes the base address of the page directory of the caller's current process context to the crash-dump header. Thus, **KeInitializeCrashDumpHeader** must be called from the system process. Otherwise, the debugger will be unable to access the crash-dump file in the process context in which the file was saved.

Starting with Windows 8, **KeInitializeCrashDumpHeader** is declared in the Wdm.h header file in the Windows Driver Kit (WDK). To use this routine with earlier versions of the WDK, include the following function declaration in your driver code:

C++

```
NTSTATUS
  KeInitializeCrashDumpHeader(
    __in ULONG  DumpType,
    __in ULONG  Flags,
    __out PVOID  Buffer,
    __in ULONG  BufferSize,
    __out_opt PULONG  BufferNeeded
    );
```

Requirements

Minimum supported client	Available starting with Windows Server 2003 with SP1.
Target Platform	Universal

KeInitializeDeviceQueue function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInitializeDeviceQueue** routine initializes a device queue object to a not-busy state.

Syntax

```
void KeInitializeDeviceQueue(
  PKDEVICE_QUEUE DeviceQueue
);
```

Parameters

`DeviceQueue`

Pointer to a device queue object for which the caller provides the storage.

Return Value

None

Remarks

KeInitializeDeviceQueue initializes the specified device queue and sets its state to not-busy.

A driver should call **KeInitializeDeviceQueue** from its *AddDevice* routine after creating the device object for the associated device. Storage for the device queue object must be resident: in the device extension of a driver-created device object, in the controller extension of a driver-created controller object, or in nonpaged pool allocated by the caller.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"
DDI compliance rules	IrqlKeDispatchLte, HwStorPortProhibitedDDIs

KeInitializeDpc function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInitializeDpc** routine initializes a DPC object, and registers a CustomDpc routine for that object.

Syntax

```
void KeInitializeDpc(
  __drv_aliasesMem PRKDPC Dpc,
  PKDEFERRED_ROUTINE      DeferredRoutine,
  __drv_aliasesMem PVOID  DeferredContext
);
```

Parameters

`Dpc`

Pointer to a KDPC structure that represents the DPC object to initialize. The caller must allocate storage for the structure from resident memory.

`DeferredRoutine`

Pointer to the CustomDpc routine to associate with the DPC.

`DeferredContext`

Specifies the value to pass as the *DeferredContext* parameter to CustomDpc.

Return Value

None

Remarks

The caller can queue an initialized DPC with KeInsertQueueDpc. The caller also can set up a timer object associated with the initialized DPC object and queue the DPC with KeSetTimer.

Storage for the DPC object must be resident: in the device extension of a driver-created device object, in the controller extension of a driver-created controller object, or in nonpaged pool allocated by the caller.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	Any level

KeInitializeEvent function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInitializeEvent** routine initializes an event object as a synchronization (single waiter) or notification type event and sets it to a signaled or not-signaled state.

Syntax

```
void KeInitializeEvent(
  PRKEVENT   Event,
  EVENT_TYPE Type,
  BOOLEAN    State
);
```

Parameters

`Event`

Pointer to an event object, for which the caller provides the storage.

`Type`

Specifies the event type, either **NotificationEvent** or **SynchronizationEvent**.

`State`

Specifies the initial state of the event. **TRUE** indicates a signaled state.

Return Value

None

Remarks

Storage for an event object must be resident: in the device extension of a driver-created device object, in the controller extension of a driver-created controller object, or in nonpaged pool allocated by the caller. If you allocate the event on the stack, you must specify a **KernelMode** wait when calling KeWaitForSingleObject, KeWaitForMutexObject, or KeWaitForMultipleObjects. During a **KernelMode** wait, the stack containing the event will not be paged out.

Drivers typically use a **NotificationEvent** to wait for an I/O operation to complete. When a notification event is set to the signaled state, all threads that were waiting for the event to be set to the signaled state become eligible for execution. The event remains in the signaled state until a thread calls KeResetEvent or KeClearEvent to set the event in the not-signaled state.

A **SynchronizationEvent** is also called an *autoreset* or *autoclearing* event. When such an event is set, a single waiting thread becomes eligible for execution. The kernel automatically resets the event to the not-signaled state each time a wait is satisfied. A driver might use a synchronization event to protect a shared resource that is used in synchronizing the operations of several threads. Synchronization events are rarely used in a typical driver.

For more information about event objects, see Event Objects.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KeInitializeGuardedMutex function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInitializeGuardedMutex** routine initializes a guarded mutex.

Syntax

```
void KeInitializeGuardedMutex(
  PKGUARDED_MUTEX Mutex
);
```

Parameters

`Mutex`

Pointer to the KGUARDED_MUTEX structure to initialize. The storage must be 4-byte aligned on 32-bit platforms, and 8-byte aligned on 64-bit platforms.

Return Value

None

Remarks

Guarded mutexes must be allocated from nonpaged pool.

For more information about guarded mutexes, see Fast Mutexes and Guarded Mutexes.

Requirements

Minimum supported client	Available in Windows Server 2003 with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

KGUARDED_MUTEX

KeAcquireGuardedMutex

KeInitializeMutex function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInitializeMutex** routine initializes a mutex object, setting it to a signaled state.

Syntax

```
void KeInitializeMutex(
  PRKMUTEX Mutex,
  ULONG    Level
);
```

Parameters

`Mutex`

Pointer to a mutex object, for which the caller provides the storage. The storage must be 4-byte aligned on 32-bit platforms, and 8-byte aligned on 64-bit platforms.

`Level`

Reserved. Drivers set this to zero.

Return Value

None

Remarks

For better performance, use fast mutexes or guarded mutexes. For more information, see Alternatives to Mutex Objects.

The mutex object is initialized with an initial state of signaled.

Storage for a mutex object must be resident: in the device extension of a driver-created device object, in the controller extension of a driver-created controller object, or in nonpaged pool allocated by the caller.

For more information about mutex objects, see Mutex Objects.

KeInitializeSemaphore function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInitializeSemaphore** routine initializes a semaphore object with a specified count and specifies an upper limit that the count can attain.

Syntax

```
void KeInitializeSemaphore(
  PRKSEMAPHORE Semaphore,
  LONG         Count,
  LONG         Limit
);
```

Parameters

`Semaphore`

Pointer to a dispatcher object of type semaphore, for which the caller provides the storage.

`Count`

Specifies the initial count value to be assigned to the semaphore. This value must be positive. A nonzero value sets the initial state of the semaphore to signaled.

`Limit`

Specifies the maximum count value that the semaphore can attain. This value must be positive. It determines how many waiting threads become eligible for execution when the semaphore is set to the signaled state and can therefore access the resource that the semaphore protects.

Return Value

None

Remarks

The semaphore object is initialized with the specified initial count and limit.

Storage for a semaphore object must be resident: in the device extension of a driver-created device object, in the controller extension of a driver-created controller object, or in nonpaged pool allocated by the caller.

For more information about semaphore objects, see Semaphore Objects.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

KeInitializeSpinLock function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInitializeSpinLock** routine initializes a variable of type KSPIN_LOCK.

Syntax

```
void KeInitializeSpinLock(
  PKSPIN_LOCK SpinLock
);
```

Parameters

`SpinLock`

Pointer to a spin lock, for which the caller must provide the storage.

Return Value

None

Remarks

This routine must be called before an initial call to KeAcquireSpinLock, to KeAcquireInStackQueuedSpinLock, or to any other support routine that requires a spin lock as an argument.

Storage for a spin lock object must be resident: in the device extension of a driver-created device object, in the controller extension of a driver-created controller object, or in nonpaged pool allocated by the caller.

For more information about spin locks, see Spin Locks.

Callers of this routine can be running at any IRQL. Usually, a caller is running at IRQL = PASSIVE_LEVEL in an AddDevice routine.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeInitializeThreadedDpc function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInitializeThreadedDpc** routine initializes a threaded DPC object, and registers a CustomThreadedDpc routine for that object.

Syntax

```
void KeInitializeThreadedDpc(
  PRKDPC             Dpc,
  PKDEFERRED_ROUTINE DeferredRoutine,
  PVOID              DeferredContext
);
```

Parameters

`Dpc`

Pointer to a KDPC structure that represents the DPC object to initialize. The caller must allocate storage for the structure from resident memory.

`DeferredRoutine`

Pointer to the CustomThreadedDpc routine to associate with the DPC.

`DeferredContext`

Specifies the value to pass as the *DeferredContext* parameter to CustomThreadedDpc.

Return Value

None

Remarks

For more information about threaded DPCs, see Threaded DPCs.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeInitializeTimer function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInitializeTimer** routine initializes a timer object.

Syntax

```
void KeInitializeTimer(
  PKTIMER Timer
);
```

Parameters

`Timer`

Pointer to a timer object, for which the caller provides the storage.

Return Value

None

Remarks

The timer object is initialized to a not-signaled state.

Storage for a timer object must be resident: in the device extension of a driver-created device object, in the controller extension of a driver-created controller object, or in nonpaged pool allocated by the caller.

KeInitializeTimer can only initialize a notification timer. Use KeInitializeTimerEx to initialize a notification timer or a synchronization timer.

Use KeSetTimer or KeSetTimerEx to define when the timer will expire.

For more information about timer objects, see Timer Objects and DPCs.

Callers of **KeInitializeTimer** should be running at IRQL = DISPATCH_LEVEL or lower. It is best to initialize timers at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe

KeInitializeTimerEx function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInitializeTimerEx** routine initializes an extended kernel timer object.

Syntax

```
void KeInitializeTimerEx(
  PKTIMER    Timer,
  TIMER_TYPE Type
);
```

Parameters

`Timer`

Pointer to a timer object, for which the caller provides the storage.

`Type`

Specifies the type of the timer object, either **NotificationTimer** or **SynchronizationTimer**.

Return Value

None

Remarks

The timer object is initialized to a not-signaled state.

Storage for a timer object must be resident: in the device extension of a driver-created device object, in the controller extension of a driver-created controller object, or in nonpaged pool allocated by the caller.

When a notification timer expires, all waiting threads are released and the timer remains in the signaled state until it is explicitly reset. When a synchronization timer expires, it is set to a signaled state until a single waiting thread is released and then the timer is reset to a not-signaled state.

Callers of **KeInitializeTimerEx** should be running at IRQL = DISPATCH_LEVEL or lower. It is best to initialize timers at IRQL = PASSIVE_LEVEL.

For more information about timer objects, see Timer Objects and DPCs.

Use KeSetTimer or KeSetTimerEx to define when the timer will expire.

KeInsertByKeyDeviceQueue function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInsertByKeyDeviceQueue** routine acquires the spin lock for the specified *DeviceQueue* and queues an entry according to the specified sort-key value if the device queue is set to a busy state.

Syntax

```
BOOLEAN KeInsertByKeyDeviceQueue(
  PKDEVICE_QUEUE       DeviceQueue,
  PKDEVICE_QUEUE_ENTRY DeviceQueueEntry,
  ULONG                SortKey
);
```

Parameters

`DeviceQueue`

Pointer to a control object of the device queue type for which the caller provides the storage.

`DeviceQueueEntry`

Pointer to the device queue entry to be inserted into the device queue according to the specific key value.

`SortKey`

Specifies the sort-key value that determines the position in the device queue in which to insert the entry.

Return Value

If the device queue is empty, **FALSE** is returned, meaning the *DeviceQueueEntry* is not inserted in the device queue.

Remarks

The specified device queue spin lock is acquired and the state of the device queue is checked. If the device queue is set to a busy state, the IRP specified by the *DeviceQueueEntry* is inserted into the device queue according to its sort key value and the device queue spin lock is released.

The new entry is positioned in the device queue after any entries in the queue with sort key values less than or equal to its sort key value and preceding any entries with sort key values that are greater.

If **KeInsertByKeyDeviceQueue** returns **FALSE**, the caller must begin processing the IRP. A call to KeInsertDeviceQueue or **KeInsertByKeyDeviceQueue** when the queue is empty causes the device queue to transition from a not-busy state to a busy state.

This routine is for code that queues an I/O request to a device driver.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeRemoveEntryDeviceQueue

KeInsertDeviceQueue function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInsertDeviceQueue** routine acquires the spin lock for the specified device queue object and, if the device queue is set to a busy state, queues the specified entry.

Syntax

```
BOOLEAN KeInsertDeviceQueue(
  PKDEVICE_QUEUE       DeviceQueue,
  PKDEVICE_QUEUE_ENTRY DeviceQueueEntry
);
```

Parameters

`DeviceQueue`

Pointer to a control object of type device queue for which the caller provides the storage.

`DeviceQueueEntry`

Pointer to the device queue entry that is to be inserted.

Return Value

If the device queue is empty, **FALSE** is returned and the *DeviceQueueEntry* is not inserted in the device queue.

Remarks

If the device queue is set to a busy state, the specified *DeviceQueueEntry* is inserted at the tail of the device queue and the device queue spin lock is released.

If **KeInsertDeviceQueue** returns **FALSE**, the entry was not queued and the caller must begin processing the IRP. A call to **KeInsertDeviceQueue** or KeInsertByKeyDeviceQueue when the queue is empty causes the device queue to change from a not-busy state to a busy state.

This routine is for code that queues an I/O request to a device driver.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

KeInsertQueueDpc function

1/25/2019 • 2 minutes to read • Edit Online

The **KeInsertQueueDpc** routine queues a DPC for execution.

Syntax

```
BOOLEAN KeInsertQueueDpc(
  PRKDPC                 Dpc,
  PVOID                  SystemArgument1,
  __drv_aliasesMem PVOID SystemArgument2
);
```

Parameters

`Dpc`

Pointer to the KDPC structure for the DPC object. This structure must have been initialized by either KeInitializeDpc or KeInitializeThreadedDpc.

`SystemArgument1`

Specifies driver-determined context data. This value is passed as the *SystemArgument1* parameter to the DPC object's CustomDpc or CustomThreadedDpc routine.

`SystemArgument2`

Specifies driver-determined context data. This value is passed as the *SystemArgument2* parameter to the DPC object's CustomDpc or CustomThreadedDpc routine.

Return Value

If the specified DPC object is not currently in a DPC queue, **KeInsertQueueDpc** queues the DPC and returns **TRUE**.

Remarks

If the specified DPC object has already been queued, no operation is performed except to return **FALSE**. Otherwise, the DPC object is inserted in a DPC queue. For more information about DPC queues, see Organization of DPC Queues.

Note that a particular DPC object and the function that it represents can each be queued for execution only once at any particular time.

Requirements

Minimum supported client	Available starting with Windows 2000.

KeIpiGenericCall function

1/25/2019 • 2 minutes to read • Edit Online

The **KeIpiGenericCall** routine causes the specified routine to run on all processors simultaneously.

Syntax

```
ULONG_PTR KeIpiGenericCall(
  PKIPI_BROADCAST_WORKER BroadcastFunction,
  ULONG_PTR              Context
);
```

Parameters

`BroadcastFunction`

Pointer to an IpiGenericCall routine. This routine is run on every processor simultaneously.

`Context`

Specifies the value to pass to *IpiGenericCall* when it is called.

Return Value

KeIpiGenericCall returns the value that IpiGenericCall returns on the source processor (the processor that called **KeIpiGenericCall**).

Remarks

When a driver calls **KeIpiGenericCall**, the system interrupts every processor and raises the IRQL to IPI_LEVEL (interprocessor interrupt level). Each processor spins on a barrier until all processors have reached the barrier; then, all processors begin calling IpiGenericCall. **KeIpiGenericCall** waits for all calls to *IpiGenericCall* to complete before returning.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

KeLowerIrql function

1/25/2019 • 2 minutes to read • Edit Online

The **KeLowerIrql** routine restores the IRQL on the current processor to its original value. For information about IRQLs, see Managing Hardware Priorities.

Syntax

```
void KeLowerIrql(
  KIRQL NewIrql
);
```

Parameters

`NewIrql`

[in] Specifies the IRQL that was returned from KeRaiseIrql or KeRaiseIrqlToDpcLevel.

Return Value

None

Remarks

It is a fatal error to call **KeLowerIrql** using an input *NewIrql* that was not returned by the immediately preceding call to **KeRaiseIrql** or KeRaiseIrqlToDpcLevel.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

KeMemoryBarrier function

1/25/2019 • 2 minutes to read • Edit Online

The **KeMemoryBarrier** routine creates a barrier at its position in the code—across which the compiler and the processor cannot move any operations.

Syntax

```
void KeMemoryBarrier(

);
```

Parameters

This function has no parameters.

Return Value

None

Remarks

The **KeMemoryBarrier** routine inserts a memory barrier into your code. This barrier guarantees that every operation that appears in the source code before the call to **KeMemoryBarrier** will complete before any operation that appears after the call.

The implementation of the **KeMemoryBarrier** routine depends on the processor architecture. For example, for an x86 processor, the Wdm.h header file defines **KeMemoryBarrier** to be the following inline function:

```
FORCEINLINE
VOID
KeMemoryBarrier (
    VOID
    )
{
    LONG Barrier;

    __asm {
        xchg Barrier, eax
    }
}
```

In this definition, the braces that follow the **__asm** keyword contain inline assembly code. The compiler optimizer cannot move an instruction from a position before the inline assembly code to a position after the inline assembly code, and vice versa. In addition, the **xchg** instruction implicitly includes the **lock** prefix, which forces the processor hardware to complete the memory operations for all instructions that precede the **xchg** instruction before it initiates memory operations for instructions that follow the **xchg** instruction.

KeMemoryBarrier prevents both the compiler and the processor from moving operations across the barrier. To

prevent only the compiler from moving operations, call KeMemoryBarrierWithoutFence.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Any level

See Also

KeMemoryBarrierWithoutFence

KeQueryActiveGroupCount function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryActiveGroupCount** routine returns the number of active processor groups in a multiprocessor system.

Syntax

```
USHORT KeQueryActiveGroupCount(

);
```

Parameters

This function has no parameters.

Return Value

KeQueryActiveGroupCount returns a count of the active groups.

Remarks

A processor group is active if it contains one or more active logical processors.

An active logical processor is a logical processor that Windows has started up and added to a multiprocessor system. The term *active processor* applies to a processor that is available to perform processing work, regardless of whether the processor is currently performing processing work or is idle. In some systems, the number of active processors might remain unchanged from system startup to shutdown. In other systems, Windows might dynamically add active processors while the system is running. Windows never removes active processors from a system.

Thus, the number of active processors in a multiprocessor system can increase between system startup and shutdown, but this number never decreases. Similarly, the number of active groups in the system can increase if a processor is dynamically added to an inactive group while the system is running. The number of active groups never decreases.

In contrast, the value that is returned by KeQueryMaximumGroupCount remains constant during runtime. This value is the maximum number of groups that the system can have.

Call the KeQueryActiveProcessorCountEx routine to determine the number of active logical processors in a particular group.

Windows 7 is the first version of Windows to support processor groups. In Windows 7, only 64-bit versions of Windows support multiple groups; 32-bit versions of Windows support only one group. If a multiprocessor system is running a 64-bit version of Windows and contains no more than 64 logical processors, Windows assigns all processors to group 0. A multiprocessor system that is running a 32-bit version of Windows can contain no more than 32 processors.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal

KeQueryActiveProcessorCountEx

KeQueryMaximumGroupCount

KeQueryActiveProcessorCount function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryActiveProcessorCount** routine returns the number of currently active processors.

Syntax

```
ULONG KeQueryActiveProcessorCount(
  PKAFFINITY ActiveProcessors
);
```

Parameters

`ActiveProcessors`

A pointer to a **KAFFINITY**-typed variable into which the routine writes a bitmask that represents the set of currently active processors. In a hot-add environment, this mask may change during runtime. This parameter is optional and can be specified as **NULL** if the caller does not require the mask of active processors.

Return Value

KeQueryActiveProcessorCount returns the number of currently active processors.

Remarks

A device driver calls the **KeQueryActiveProcessorCount** routine to retrieve the number of currently active processors. Device drivers that are built for Windows Vista and later versions of the Windows operating system should not use the **KeNumberProcessors** kernel variable for this purpose.

Callers cannot assume that the **KeQueryActiveProcessorCount** routine maps processors to bits in the returned **KAFFINITY** value consecutively, or that the routine will return the same bitmask each time it is called.

Callers must also be aware that the value returned by **KeQueryActiveProcessorCount** can change at runtime on versions of Windows that support hot-add CPU functionality.

If necessary, register for notification of changes to the number of processors by calling the KeRegisterProcessorChangeCallback routine.

To query just the affinity mask without getting the number of active processors, use KeQueryActiveProcessors.

Windows 7 and later versions of Windows support processor groups. Drivers that are designed to handle information about processor groups should use the KeQueryActiveProcessorCountEx routine, which specifies a processor group, instead of **KeQueryActiveProcessorCount**, which does not. However, the implementation of **KeQueryActiveProcessorCount** in Windows 7 and later versions of Windows provides compatibility for drivers that were written for earlier versions of Windows, which do not support processor groups. In this implementation, **KeQueryActiveProcessorCount** returns the number of active logical processors in group 0, and writes an affinity mask to **ActiveProcessors* that specifies the set of active logical processors in group 0.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeQueryActiveProcessorCountEx

KeQueryActiveProcessors

KeRegisterProcessorChangeCallback

KeQueryActiveProcessorCountEx function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryActiveProcessorCountEx** routine returns the number of active logical processors in a specified group in a multiprocessor system or in the entire system.

Syntax

```
ULONG KeQueryActiveProcessorCountEx(
  USHORT GroupNumber
);
```

Parameters

`GroupNumber`

The group number. If a multiprocessor system contains *n* groups, valid group numbers range from 0 to *n*-1. To count all active processors in all groups in the system, set this parameter to ALL_PROCESSOR_GROUPS, which is defined in header files Winnt.h and Ntdef.h.

Return Value

KeQueryActiveProcessorCountEx returns the number of active logical processors in the group. If *GroupNumber* is not a valid group number and is not ALL_PROCESSOR_GROUPS, it returns zero.

Remarks

An active logical processor is a logical processor that Windows has started up and added to a multiprocessor system. The term active processor applies to a processor that is available to perform processing work, regardless of whether the processor is currently performing processing work or is idle. In some systems, the number of active processors might remain unchanged from system startup to shutdown. In other systems, Windows might dynamically add active processors while the system is running. Windows never removes active processors from a system. Thus, the number of active processors in a multiprocessor system can increase between system startup and shutdown, but this number never decreases.

A related routine, KeQueryActiveProcessorCount, returns an active processor count, but this routine, unlike **KeQueryActiveProcessorCountEx**, does not accept a group number as an input parameter. In Windows 7 and later versions of the Windows operating system, **KeQueryActiveProcessorCount** returns the active processor count in group 0, which is compatible with the behavior of this routine in earlier versions of Windows that do not support groups. This behavior ensures that existing drivers that call **KeQueryActiveProcessorCount** and that use no group-oriented features will run correctly in multiprocessor systems that have two or more groups. However, drivers that use any group-oriented features in Windows 7 and later versions of the Windows operating system should call **KeQueryActiveProcessorCountEx** instead of **KeQueryActiveProcessorCount**.

For a code example that uses **KeQueryActiveProcessorCountEx**, see KeGetProcessorNumberFromIndex.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Ntddk.h, Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeGetProcessorNumberFromIndex

KeQueryActiveProcessorCount

KeQueryActiveProcessors function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryActiveProcessors** routine returns a bitmask of the currently active processors.

Syntax

```
KAFFINITY KeQueryActiveProcessors(

);
```

Parameters

This function has no parameters.

Return Value

KeQueryActiveProcessors returns a **KAFFINITY** value that represents the set of currently active processors.

Remarks

Callers cannot assume that **KeQueryActiveProcessors** maps processors to bits consecutively, or that the routine consistently uses the same mapping each time it is called. The only valid use for the return value is to determine the number of active processors by counting the number of bits that are set.

Callers must also be aware that the value returned by **KeQueryActiveProcessors** can change during runtime on versions of Windows that support hot-add CPU functionality.

Windows 7 and later versions of Windows support processor groups. Drivers that are designed to handle information about processor groups should use the KeQueryGroupAffinity routine, which specifies a processor group, instead of **KeQueryActiveProcessors**, which does not. However, the implementation of **KeQueryActiveProcessors** in Windows 7 and later versions of Windows provides compatibility for drivers that were written for earlier versions of Windows, which do not support processor groups. In this implementation, **KeQueryActiveProcessors** returns an affinity mask that specifies the set of active logical processors in group 0.

In Windows Vista and later versions of Windows, this routine can be called at any IRQL. However, in Windows Server 2003 and earlier versions of Windows, this routine must be called at IRQL <= APC_LEVEL.

The **KeNumberProcessors** kernel variable is obsolete in Windows Vista with Service Pack 1 (SP1), Windows Server 2008, and later versions of Windows. **KeNumberProcessors** does not appear in WDK headers for WDK releases starting with Windows Vista SP1; however, the variable is still exported from the kernel, so drivers built for earlier platforms will not break

Windows Server 2008 includes support for Dynamic Hardware Partitioning (DHP) in the Windows Datacenter and Enterprise Edition SKUs. As part of DHP, Windows Server 2008 supports hot adding CPUs at runtime. In a hot-add CPU environment, the number of processors may not remain constant during runtime.

Accordingly, in Windows Server 2008, code that can determine the number of processors must use **KeQueryActiveProcessors** instead of direct references to the kernel variable, **KeNumberProcessors**.

Review any code that currently references **KeNumberProcessors** to make sure that it accommodates changes to

CPU count in hot-add CPU environments.

You can use the PNPCPU tool to simulate hot adding a CPU for testing purposes.

C++

```
#if (NTDDI_VERSION >= NTDDI_VISTA)
extern NTSYSAPI volatile CCHAR KeNumberProcessors;
#else
#if (NTDDI_VERSION >= NTDDI_WINXP)
extern NTSYSAPI CCHAR KeNumberProcessors;
#else
extern PCCHAR KeNumberProcessors;
#endif
#endif
```

Starting with Windows XP, **KeNumberProcessors** is an 8-bit integer value that indicates the number of processors in the platform. In earlier versions of Windows, **KeNumberProcessors** is a pointer to an 8-bit integer value that indicates the number of processors in the platform.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	See Remarks section.

KeQueryAuxiliaryCounterFrequency function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryAuxiliaryCounterFrequency** routine returns frequency of the auxiliary counter in units of Hz.

Syntax

```
NTSTATUS KeQueryAuxiliaryCounterFrequency(
  PULONG64 AuxiliaryCounterFrequency
);
```

Parameters

`AuxiliaryCounterFrequency`

A pointer to a variable to which **KeQueryAuxiliaryCounterFrequency** writes the auxiliary counter frequency, in ticks per second. This parameter can be NULL.

Return Value

KeQueryAuxiliaryCounterFrequency can return one of the following:

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	The query succeeded.
STA TUS _NO T_S UPP ORT ED	Auxiliary counter is not supported.

Remarks

Call this routine to programmatically determine whether auxiliary counter is supported. In that call, if you do not need the frequency of the counter, pass NULL. If not supported, the routine returns STATUS_NOT_SUPPORTED.

Requirements

Minimum supported client	Available starting with Windows 10.

Target Platform	Universal
Header	wdm.h
Library	Ntoskrnl.lib
DLL	Hal.dll
IRQL	Any level

KeConvertAuxiliaryCounterToPerformanceCounter

KeConvertPerformanceCounterToAuxiliaryCounter

KeQueryDpcWatchdogInformation function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryDpcWatchdogInformation** routine returns the deferred procedure call (DPC) watchdog timer values for the current processor.

Syntax

```
NTSTATUS KeQueryDpcWatchdogInformation(
  PKDPC_WATCHDOG_INFORMATION WatchdogInformation
);
```

Parameters

`WatchdogInformation`

A pointer to a caller-supplied KDPC_WATCHDOG_INFORMATION structure. The routine writes the current DPC watchdog timer values to this structure.

Return Value

KeQueryDpcWatchdogInformation returns an NTSTATUS value. Possible return values include the following status codes.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	**KeQueryDpcWatchdogInformation** was called while a DPC was running on the current processor.
STATUS_UNSUCCESSFUL	The current processor was not running a DPC when **KeQueryDpcWatchdogInformation** was called.

Remarks

The **KeQueryDpcWatchdogInformation** routine can be called from a DPC routine or at an IRQL=DISPATCH_LEVEL to determine the amount of time that remains before a DPC time-out occurs. The operating system implements a DPC watchdog timer to detect when a single DPC routine runs for too long, or when a series of queued DPC routines runs back-to-back for too long. If DPC time-out errors are enabled, and if either a DPC routine exceeds the time limit for a single routine, or a series of DPC routines exceeds the aggregate time limit, a DPC_WATCHDOG_VIOLATION (0x133) bug check occurs.

KeQueryDpcWatchdogInformation must be called while a DPC is running or invoked at an IRQL = DISPATCH_LEVEL or higher on the current processor. Otherwise, the call fails and returns STATUS_UNSUCCESSFUL.

DPC routines should run only for brief periods, and should delegate as much processing as possible to worker threads. To avoid degrading system responsiveness, a typical DPC routine should run for no more than 100 microseconds each time it is called. For more information, see Guidelines for Writing DPC Routines.

Requirements

Minimum supported client	Available starting with Windows Vista.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	DISPATCH_LEVEL

See Also

KDPC_WATCHDOG_INFORMATION

KeQueryGroupAffinity function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryGroupAffinity** routine returns an affinity mask that identifies the active logical processors in a specified group in a multiprocessor system.

Syntax

```
KAFFINITY KeQueryGroupAffinity(
  USHORT GroupNumber
);
```

Parameters

`GroupNumber`

The group number. If a multiprocessor system contains *n* groups, the groups are numbered from 0 to *n*-1. To obtain the number of active groups in the system, call the KeQueryActiveGroupCount routine.

Return Value

KeQueryGroupAffinity returns a **KAFFINITY** value that identifies the active logical processors in the specified group. If the *GroupNumber* parameter value is not a valid group number, the routine returns zero.

Remarks

A related routine, KeQueryActiveProcessors, returns an affinity mask that represents a set of active processors, but this routine, unlike **KeQueryGroupAffinity**, does not accept a group number as an input parameter. In Windows 7 and later versions of the Windows operating system, **KeQueryActiveProcessors** returns an affinity mask for the active processors in group 0, which is compatible with the behavior of this routine in earlier versions of Windows that do not support groups. This behavior ensures that existing drivers that call **KeQueryActiveProcessors** and that use no group-oriented features will run correctly in multiprocessor systems that have two or more groups. However, drivers that use any group-oriented features in Windows 7 and later versions of the Windows operating system should call **KeQueryGroupAffinity** instead of **KeQueryActiveProcessors**.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IRQL	Any level

KAFFINITY

KeQueryActiveProcessors

KeQueryHighestNodeNumber function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryHighestNodeNumber** routine returns the highest node number in a multiprocessor system that has a non-uniform memory access (NUMA) architecture.

Syntax

```
USHORT KeQueryHighestNodeNumber(

);
```

Parameters

This function has no parameters.

Return Value

KeQueryHighestNodeNumber returns the highest node number.

Remarks

In a non-uniform memory access (NUMA) multiprocessor architecture, a node is a collection of processors that share fast access to a region of memory. Memory access is non-uniform because a processor can access the memory in its node faster than it can access the memory in other nodes.

If a NUMA multiprocessor system contains *n* nodes, the nodes are numbered from 0 to *n*-1, and **KeQueryHighestNodeNumber** returns *n*-1. If a system contains one node, **KeQueryHighestNodeNumber** returns zero.

If a system does not have a NUMA architecture, **KeQueryHighestNodeNumber** returns zero. An example of non-NUMA architecture is a symmetric multiprocessor system (SMP).

When Windows initializes a NUMA multiprocessor system, it assigns logical processors to nodes and counts the number of resulting nodes. Windows defines the capacity of a node as the number of processors that are present when the system starts in addition to any other logical processors that can be added to the node while the system is running. If, during initialization, Windows encounters a NUMA hardware node that contains more logical processors than will fit into a group, Windows splits the node into smaller, logical nodes. Each of these nodes does not exceed the maximum group size. The value that is returned by **KeQueryHighestNodeNumber** indicates the number of logical nodes in the system.

After the system has been initialized, the node count remains fixed while the system continues to run. This count might include memory-only nodes, which are nodes that contain memory but no active logical processors.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

KeQueryInterruptTime function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryInterruptTime** routine returns the current value of the system interrupt time count, with accuracy to within system clock tick.

Syntax

```
ULONGLONG KeQueryInterruptTime(

);
```

Parameters

This function has no parameters.

Return Value

KeQueryInterruptTime returns the current interrupt-time count in 100-nanosecond units. The update to this return value generally occurs at least once per system clock tick.

Remarks

This routine returns the system interrupt time, which is the amount of time since the operating system was last started. The interrupt-time count begins at zero when the operating system starts and is incremented at each clock interrupt by the length of a clock tick. For various reasons, such as hardware differences, the length of a system clock tick can vary between computers. Call the KeQueryTimeIncrement routine to determine the size of a system clock tick.

> **Note** The preceding remarks describe the behavior of **KeQueryInterruptTime** in free (or retail) builds of Windows. In checked (or debug) builds, this behavior is modified to help developers to identify bugs that might not occur until the operating system has been running for many days without being restarted. Specifically, the interrupt-time count and tick count in checked builds are advanced by approximately 49 days. For more information about checked and free builds, see Checked and Free Build Differences.

KeQueryInterruptTime can be used for performance tuning. This routine returns a finer grained measurement than the KeQueryTickCount routine. A call to **KeQueryInterruptTime** has considerably less overhead than a call to the KeQueryPerformanceCounter routine, as well.

Consequently, interrupt time can be used to measure very fine-grained durations while the system is running because operations that set or reset the system time have no effect on the system interrupt time count.

However, power-management state changes do affect the system interrupt time count. Maintenance of the interrupt time count is suspended during system sleep states. When a subsequent wake state transition occurs, the system adds a "bias" value to the interrupt time count to compensate for the estimated duration of such a sleep state. The interrupt time count that is returned by **KeQueryInterruptTime** includes this bias value. To obtain an unbiased interrupt time count, use the KeQueryUnbiasedInterruptTime routine instead of **KeQueryInterruptTime**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeQueryInterruptTimePrecise

KeQueryPerformanceCounter

KeQueryTickCount

KeQueryTimeIncrement

KeQueryUnbiasedInterruptTime

KeQueryInterruptTimePrecise function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryInterruptTimePrecise** routine returns the current value of the system interrupt time count, with accuracy to within a microsecond.

Syntax

```
ULONG64 KeQueryInterruptTimePrecise(
  PULONG64 QpcTimeStamp
);
```

Parameters

`QpcTimeStamp`

A pointer to a ULONG64 variable into which the routine writes the performance counter value used to interpolate the return value.

Return Value

The current interrupt-time count in 100-nanosecond units.

Remarks

KeQueryInterruptTimePrecise returns the system's current interrupt time, which is the amount of time since the operating system was last started. **KeQueryInterruptTimePrecise** is similar to the KeQueryInterruptTime routine, but is more precise.

The interrupt time reported by KeQueryInterruptTime is based on the latest tick of the system clock timer. The clock timer is the hardware timer that periodically generates interrupts for the system clock. The uniform period between clock timer interrupts is referred to as a system clock tick, and is typically in the range of 500 microseconds to 15.625 milliseconds, depending on the hardware platform. The interrupt time value retrieved by **KeQueryInterruptTime** is accurate within a system clock tick.

To provide an interrupt time value that is more precise than that of KeQueryInterruptTime, **KeQueryInterruptTimePrecise** uses the system performance counter to measure the time elapsed since the last clock timer interrupt, and adds this time to the interrupt time associated with the latest clock time. The interrupt time reported by **KeQueryInterruptTimePrecise** is accurate to within a microsecond.

On some hardware platforms, a **KeQueryInterruptTimePrecise** call might be slower than a KeQueryInterruptTime call. The reason is that **KeQueryInterruptTimePrecise** reads the performance counter, which can introduce an additional delay. For more information, see KeQueryPerformanceCounter.

Call the KeQueryTimeIncrement routine to determine the size of a system clock tick.

> **Note** The preceding remarks describe the behavior of **KeQueryInterruptTime** in free (or retail) builds of Windows. In checked (or debug) builds, this behavior is modified to help developers to identify bugs that might not occur until the operating system has been running for many days without being restarted. Specifically, the interrupt-time count and tick count in checked builds are advanced by approximately 49 days. For more information about checked and free builds, see Checked and Free Build Differences.

Precise interrupt time can be used to measure very fine-grained durations while the system is running because operations that set or reset the system time have no effect on the system interrupt time count.

However, power-management state changes do affect the system interrupt time count. Maintenance of the interrupt time count is suspended during system sleep states. When a subsequent wake state transition occurs, the system adds a "bias" value to the interrupt time count to compensate for the estimated duration of such a sleep state. The interrupt time count that is returned by **KeQueryInterruptTimePrecise** includes this bias value. To obtain an unbiased interrupt time count, use the KeQueryUnbiasedInterruptTime. A precise version of the unbiased interrupt time count is not currently available.

Requirements

Minimum supported client	Available starting with Windows 8.1.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KeQueryInterruptTime

KeQueryTimeIncrement

KeQueryUnbiasedInterruptTime

KeQueryLogicalProcessorRelationship function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryLogicalProcessorRelationship** routine gets information about the relationships of one or more processors to the other processors in a multiprocessor system.

Syntax

```
NTSTATUS KeQueryLogicalProcessorRelationship(
  PPROCESSOR_NUMBER                       ProcessorNumber,
  LOGICAL_PROCESSOR_RELATIONSHIP          RelationshipType,
  PSYSTEM_LOGICAL_PROCESSOR_INFORMATION_EX Information,
  PULONG                                  Length
);
```

Parameters

`ProcessorNumber`

A pointer to a PROCESSOR_NUMBER structure that identifies the logical processor for which the caller requests relationship information. To request information about all logical processors in the system, set this parameter to **NULL**.

`RelationshipType`

Specifies the type of relationship information that is requested by the caller. Set this parameter to one of the following LOGICAL_PROCESSOR_RELATIONSHIP enumeration values:

- **RelationProcessorCore**
- **RelationNumaNode**
- **RelationCache**
- **RelationProcessorPackage**
- **RelationGroup**
- **RelationAll**

`Information`

A pointer to a caller-allocated buffer into which the routine writes an array of one or more SYSTEM_LOGICAL_PROCESSOR_INFORMATION_EX structures that contain the information requested by the caller. If the function fails, the contents of this buffer are undefined. Set *Information* = **NULL** to obtain the required buffer length before you allocate the buffer. For more information, see the following Remarks section.

`Length`

A pointer to a location that contains the size, in bytes, of the buffer that is pointed to by *Information*. On entry, * *Length* contains the size of the caller-allocated buffer that is pointed to by *Information*. During the call, the routine overwrites the value that is pointed to by *Length* with the buffer size that is required to contain the requested relationship information.

Return Value

KeQueryLogicalProcessorRelationship returns STATUS_SUCCESS if the call is successful. Possible error return

values include the following:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The *ProcessorNumber* parameter points to a PROCESSOR_NUMBER structure that contains invalid information.
STATUS_INFO_LENGTH_MISMATCH	The caller-allocated buffer that is pointed to by the *Information* parameter is not large enough to contain the requested relationship information.

Remarks

To determine the buffer size to allocate, initially call **KeQueryLogicalProcessorRelationship** with *Information* = **NULL** and **Length* = 0. In response, the routine writes the required buffer size to **Length* and returns STATUS_INFO_LENGTH_MISMATCH. Next, allocate a buffer of the required size and call **KeQueryLogicalProcessorRelationship** a second time. In this second call, set *Information* to the buffer address and **Length* to the buffer size. If the second call succeeds, the routine writes the requested relationship information to the buffer and returns STATUS_SUCCESS.

Examples

The following code example gets processor relationship information for all the logical processors in a multiprocessor system:

```
//
// Get required buffer size.
//
NTSTATUS Status;
PSYSTEM_LOGICAL_PROCESSOR_INFORMATION_EX Info = NULL;
ULONG BufferSize = 0;
Status = KeQueryLogicalProcessorRelationship(NULL, RelationAll, NULL, &BufferSize);

NT_ASSERT(Status == STATUS_INFO_LENGTH_MISMATCH && BufferSize > 0);

//
// Allocate buffer (assume IRQL <= APC_LEVEL).
//
Info = ExAllocatePoolWithTag(PagedPool, BufferSize, ' gaT');
if (Info == NULL)
{
    Status = STATUS_INSUFFICIENT_RESOURCES;
}

//
// Get processor relationship information.
//
if (NT_SUCCESS(Status))
{
    Status = KeQueryLogicalProcessorRelationship(NULL, RelationAll, Info, &BufferSize);
}
```

The NT_ASSERT macro is defined in the Wdm.h header file. The NT_SUCCESS macro is defined in the Ntdef.h header file.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Ntddk.h, Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

PROCESSOR_NUMBER

SYSTEM_LOGICAL_PROCESSOR_INFORMATION_EX

KeQueryMaximumGroupCount function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryMaximumGroupCount** routine returns the maximum number of groups in a multiprocessor system.

Syntax

```
USHORT KeQueryMaximumGroupCount(

);
```

Parameters

This function has no parameters.

Return Value

KeQueryMaximumGroupCount returns the maximum number of groups.

Remarks

The value that is returned by **KeQueryMaximumGroupCount** remains constant during runtime. This value depends on the hardware configuration of the multiprocessor system, but it can never exceed a fixed limit that is set by the Windows operating system.

In Windows 7, the maximum number of groups in a multiprocessor system is four, but this value might change in future versions of Windows. The safest way to determine the maximum number of groups in Windows 7 or a later versions of the Windows operating system is to call **KeQueryMaximumGroupCount**. Kernel-mode drivers that call **KeQueryMaximumGroupCount** will not require code changes if the formula that is used to calculate the maximum number of groups changes in a future version of Windows.

To obtain the number of active groups in a multiprocessor system, call the KeQueryActiveGroupCount routine.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeQueryActiveGroupCount

KeQueryMaximumProcessorCount function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryMaximumProcessorCount** routine returns the maximum number of processors.

Syntax

```
ULONG KeQueryMaximumProcessorCount(

);
```

Parameters

This function has no parameters.

Return Value

KeQueryMaximumProcessorCount returns the maximum number of processors as a ULONG value.

Remarks

The value returned by the **KeQueryMaximumProcessorCount** routine does not change at runtime.

If your code uses an array of buffers, one buffer for each processor, you must decide whether to have a statically sized array based on **KeQueryMaximumProcessorCount** or a dynamically sized array based on KeQueryActiveProcessorCount.

To optimize based on the number of processors, you need a resizable structure for Windows Server 2008. In this case, use **KeQueryActiveProcessorCount**.

If you are not optimizing and if the data structures that result from using maximum processor count are relatively small, a resizable structure is not necessary. In this case, use **KeQueryMaximumProcessorCount** to determine size for a static array.

Windows 7 and later versions of Windows support processor groups. Drivers that are designed to handle information about processor groups should use the KeQueryMaximumProcessorCountEx routine, which specifies a processor group, instead of **KeQueryMaximumProcessorCount**, which does not. However, the implementation of **KeQueryMaximumProcessorCount** in Windows 7 and later versions of Windows provides compatibility for drivers that were written for earlier versions of Windows, which do not support processor groups. In this implementation, **KeQueryMaximumProcessorCount** returns the maximum number of logical processors that can be in group 0.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeQueryActiveProcessorCount

KeQueryMaximumProcessorCountEx

KeQueryMaximumProcessorCountEx function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryMaximumProcessorCountEx** routine returns the maximum number of logical processors in a specified group in a multiprocessor system.

Syntax

```
ULONG KeQueryMaximumProcessorCountEx(
  USHORT GroupNumber
);
```

Parameters

`GroupNumber`

Specifies a group number. If a multiprocessor system contains *n* groups, the groups are numbered from 0 to *n*-1. To obtain the maximum number of processors in the system, set this parameter to ALL_PROCESSOR_GROUPS, which is defined in the Winnt.h and Ntdef.h header files.

Return Value

KeQueryMaximumProcessorCountEx returns the maximum number of logical processors in the specified group or in the system, as indicated by the value of the *GroupNumber* parameter.

Remarks

The value that is returned by **KeQueryMaximumProcessorCountEx** remains constant during runtime. This value depends on the hardware configuration of the multiprocessor system, but it can never exceed a fixed limit that is set by the Windows operating system. This limit is 32 logical processors for 32-bit versions of Windows and 64 logical processors for 64-bit versions of Windows.

In contrast, the value that is returned by the KeQueryActiveProcessorCountEx routine can change during runtime as processors are dynamically added to the system.

A related routine, KeQueryMaximumProcessorCount, returns a maximum processor count, but this routine, unlike **KeQueryMaximumProcessorCountEx**, does not accept a group number as an input parameter. In Windows 7 and later versions of the Windows operating system, **KeQueryMaximumProcessorCount** returns the maximum number of logical processors in group 0, which is compatible with the behavior of this routine in earlier versions of Windows that do not support groups. This behavior ensures that existing drivers that call **KeQueryMaximumProcessorCount** and that use no group-oriented features will run correctly in multiprocessor systems that have two or more groups. However, drivers that use any group-oriented features in Windows 7 and later versions of the Windows operating system should call **KeQueryMaximumProcessorCountEx** instead of **KeQueryMaximumProcessorCount**.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeQueryActiveProcessorCountEx

KeQueryMaximumProcessorCount

KeQueryNodeActiveAffinity function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryNodeActiveAffinity** routine gets the current processor affinity of a specified node in a multiprocessor system that has a non-uniform memory access (NUMA) architecture.

Syntax

```
void KeQueryNodeActiveAffinity(
  USHORT          NodeNumber,
  PGROUP_AFFINITY Affinity,
  PUSHORT         Count
);
```

Parameters

`NodeNumber`

The node number. If a multiprocessor system contains *n* nodes, the nodes are numbered from 0 to *n*-1. To obtain the highest node number (*n*-1) in the system, call the KeQueryHighestNodeNumber routine.

`Affinity`

A pointer to a caller-allocated buffer into which the routine writes a GROUP_AFFINITY structure. This structure contains the group number of the group that contains the node that is identified by *NodeNumber*, and an affinity mask that indicates which logical processors in the node are active. You can set this parameter to **NULL** if you do not need this information.

`Count`

A pointer to a location into which the routine writes the number of active processors that are represented in the node affinity mask that is pointed to by *Affinity*. You can set this parameter to **NULL** if you do not need this information.

Return Value

None

Remarks

The caller-allocated buffer that is pointed to by the *Affinity* parameter must be large enough to contain a **GROUP_AFFINITY** structure. The **Mask** member of this structure contains an affinity mask that indicates which processors are active. If a processor is active, the corresponding bit in the mask is one. All other bits are zero.

In a NUMA multiprocessor architecture, a node is a collection of processors that share fast access to a region of memory. Memory access is non-uniform because a processor can access the memory in its node faster than it can access the memory in other nodes.

The number of processors in a node cannot exceed the number of bits in the affinity mask in the structure that is pointed to by *Affinity*. The affinity mask also determines the maximum number of processors in a group.

If, during system initialization, Windows encounters a NUMA hardware node that contains more logical processors

than will fit into a group, Windows splits the node into smaller, logical nodes. Each of these nodes does not exceed the maximum group size. The *NodeNumber* parameter identifies a logical node. To obtain the maximum number of processors per group, call the KeQueryMaximumProcessorCountEx routine.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

GROUP_AFFINITY

KeQueryHighestNodeNumber

KeQueryMaximumProcessorCountEx

KeQueryNodeMaximumProcessorCount function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryNodeMaximumProcessorCount** routine returns the maximum number of logical processors that a specified node in a non-uniform memory access (NUMA) multiprocessor system can contain.

Syntax

```
USHORT KeQueryNodeMaximumProcessorCount(
  USHORT NodeNumber
);
```

Parameters

`NodeNumber`

The node number. If a NUMA multiprocessor system contains *n* nodes, valid node numbers are in the range 0 to *n*-1. To get the highest node number (*n*-1) in the system, call the KeQueryHighestNodeNumber routine.

Return Value

KeQueryNodeMaximumProcessorCount returns the maximum number of logical processors.

Remarks

In a multiprocessor system with a NUMA architecture, a node is a collection of processors that share fast access to a region of memory. Memory access is non-uniform because a processor can access the memory in its node faster than it can access the memory in other nodes.

The count returned by this routine includes any logical processors that can be dynamically added to the node while the multiprocessor system is running.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeQueryHighestNodeNumber

KeQueryPerformanceCounter function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryPerformanceCounter** routine retrieves the current value and frequency of the performance counter.

Use **KeQueryPerformanceCounter** to acquire high resolution (<1us) time stamps for time interval measurements.

Syntax

```
NTHALAPI LARGE_INTEGER KeQueryPerformanceCounter(
  PLARGE_INTEGER PerformanceFrequency
);
```

Parameters

`PerformanceFrequency`

A pointer to a variable to which **KeQueryPerformanceCounter** writes the performance counter frequency, in ticks per second. This parameter is optional and can be NULL if the caller does not need the counter frequency value.

Return Value

KeQueryPerformanceCounter returns the performance counter value in units of ticks.

Remarks

KeQueryPerformanceCounter returns a 64-bit integer that represents the current value of a high-resolution monotonically nondecreasing counter.

To obtain the frequency of the performance counter, specify a non-**NULL** pointer value for the *PerformanceFrequency* parameter. The frequency of the performance counter is fixed at system boot and is consistent across all processors. Therefore, a driver can cache the frequency of the performance counter during initialization.

For more info about this function and its usage, see Acquiring high-resolution time stamps.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Hal.lib
DLL	Hal.dll

KeQueryPriorityThread function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryPriorityThread** routine returns the current priority of a particular thread.

Syntax

```
KPRIORITY KeQueryPriorityThread(
  PKTHREAD Thread
);
```

Parameters

`Thread`

Pointer to a dispatcher object of type KTHREAD.

Return Value

KeQueryPriorityThread returns the current priority of the specified thread.

Remarks

Thread priorities range from 0 to 31, where 0 is the lowest priority and 31 is the highest.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

KeQueryRuntimeThread function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryRuntimeThread** routine reports the accumulated kernel-mode and user-mode run time of a thread, in clock ticks.

Syntax

```
ULONG KeQueryRuntimeThread(
  PKTHREAD Thread,
  PULONG   UserTime
);
```

Parameters

`Thread`

Pointer to a dispatcher object of type KTHREAD.

`UserTime`

Pointer to the memory location where **KeQueryRuntimeThread** returns the accumulated user-mode run time of the current thread, in clock ticks.

Return Value

KeQueryRuntimeThread returns the accumulated kernel-mode run time of the current thread, in clock ticks.

Requirements

Minimum supported client	Available starting with Windows XP.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeQueryTimeIncrement

KeQuerySystemTime function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQuerySystemTime** routine obtains the current system time.

Syntax

```
void KeQuerySystemTime(
  PLARGE_INTEGER CurrentTime
);
```

Parameters

`CurrentTime`

Return Value

None

Remarks

System time is a count of 100-nanosecond intervals since January 1, 1601. System time is typically updated approximately every ten milliseconds. This value is computed for the GMT time zone. To adjust this value for the local time zone use ExSystemTimeToLocalTime.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

ExSystemTimeToLocalTime

KeQueryPerformanceCounter

KeQueryTickCount

KeQueryTimeIncrement

KeQuerySystemTimePrecise function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQuerySystemTimePrecise** routine retrieves the current system time, and is more precise than the KeQuerySystemTime routine.

Syntax

```
void KeQuerySystemTimePrecise(
  PLARGE_INTEGER CurrentTime
);
```

Parameters

`CurrentTime`

A pointer to a LARGE_INTEGER variable into which the routine writes the current system time.

Return Value

None

Remarks

System time is a count of 100-nanosecond intervals since January 1, 1601. This value is computed for the GMT time zone. To adjust this value for the local time zone, call the ExSystemTimeToLocalTime routine.

KeQuerySystemTimePrecise is similar to the **KeQuerySystemTime** routine, but is more precise. The system time reported by **KeQuerySystemTime** is based on the latest tick of the system clock timer. The clock timer is the hardware timer that periodically generates interrupts for the system clock. The uniform period between clock timer interrupts is referred to as a system clock tick, and is typically in the range of 500 microseconds to 15.625 milliseconds, depending on the hardware platform. The system time value retrieved by **KeQuerySystemTime** is accurate within a system clock tick.

To provide a system time value that is more accurate than that of **KeQuerySystemTime**, **KeQuerySystemTimePrecise** uses the system performance counter to measure the time elapsed since the last clock timer interrupt, and adds this time to the system clock time that it calculates from the clock timer count. The system time reported by **KeQuerySystemTimePrecise** is accurate to within a microsecond.

On some hardware platforms, a **KeQuerySystemTimePrecise** call might be slower than a **KeQuerySystemTime** call. The reason is that **KeQuerySystemTimePrecise** reads the performance counter, which can introduce an additional delay. For more information, see KeQueryPerformanceCounter.

Call the KeQueryTimeIncrement routine to determine the duration of a system clock tick.

Requirements

Minimum supported client	Available starting with Windows 8.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeQueryTimeIncrement

KeQueryTickCount macro

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryTickCount** routine maintains a count of the interval timer interrupts that have occurred since the system was booted.

Syntax

```
void KeQueryTickCount(
   CurrentCount
);
```

Parameters

`CurrentCount`

Pointer to the LARGE_INTEGER tick count value on return from **KeQueryTickCount**.

Return Value

None

Remarks

The *TickCount* value increases by one at each interval timer interrupt while the system is running.

The preferred method of determining elapsed time is by using *TickCount* for relative timing and time stamps.

To determine the absolute elapsed time multiply the returned *TickCount* by the KeQueryTimeIncrement return value using compiler support for 64-bit integer operations.

You should not make any assumptions about the length of a tick, because it might vary depending on hardware and other considerations.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeQueryInterruptTime

KeQueryPerformanceCounter

KeQueryTimeIncrement

KeQueryTimeIncrement function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryTimeIncrement** routine returns the number of 100-nanosecond units that are added to the system time each time the interval clock interrupts.

Syntax

```
ULONG KeQueryTimeIncrement(

);
```

Parameters

This function has no parameters.

Return Value

KeQueryTimeIncrement returns a ULONG value indicating the number of 100-nanosecond units that are added to the system time each time the interval clock interrupts.

Remarks

At startup time, the operating system determines the time increment to use for the system time. This time increment remains constant until the computer restarts. During this time, calls to **KeQueryTimeIncrement** always return the same time increment value. The time increment does not change while the computer is running, and it does not change as the result of a suspend-resume cycle.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeQueryTotalCycleTimeThread function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryTotalCycleTimeThread** routine returns the accumulated cycle time for the specified thread.

Syntax

```
ULONG64 KeQueryTotalCycleTimeThread(
  PKTHREAD Thread,
  PULONG64 CycleTimeStamp
);
```

Parameters

`Thread`

A pointer to a dispatcher object of type KTHREAD.

`CycleTimeStamp`

A pointer to the cycle counter value at the time of the query.

Return Value

The accumulated cycle time for the thread.

Requirements

Minimum supported client	Available in Windows 8 and later versions of Windows.
Target Platform	Universal
Header	wdm.h

KeQueryUnbiasedInterruptTime function

1/25/2019 • 2 minutes to read • Edit Online

The **KeQueryUnbiasedInterruptTime** routine returns the current value of the system interrupt time count.

Syntax

```
ULONGLONG KeQueryUnbiasedInterruptTime(

);
```

Parameters

This function has no parameters.

Return Value

KeQueryUnbiasedInterruptTime returns the current interrupt time count in 100-nanosecond units. The count begins at zero when the computer starts. Updates to this count are suspended when the computer enters a sleep state and are resumed when the computer awakens.

Remarks

Kernel-mode drivers can call this routine to measure relatively fine-grained durations.

This routine returns the system interrupt time, which is the amount of time since the operating system was last started. The interrupt-time count begins at zero when the operating system starts and is incremented at each clock interrupt by the length of a clock tick. For various reasons, such as hardware differences, the length of a system clock tick can vary between computers. Call the KeQueryTimeIncrement routine to determine the size of a system clock tick.

> **Note** The preceding remarks describe the behavior of **KeQueryUnbiasedInterruptTime** in free (or retail) builds of Windows. In checked (or debug) builds, this behavior is modified to help developers to identify bugs that might not occur until the operating system has been running for many days without being restarted. Specifically, the interrupt-time count and tick count in checked builds are advanced by approximately 49 days. For more information about checked and free builds, see Checked and Free Build Differences.

The **KeQueryUnbiasedInterruptTime** and KeQueryInterruptTime routines are similar, but they differ in the way in which they account for periods in which the operating system suspends updates of the interrupt time count. For example, these updates are suspended while the computer is in a system sleep state. To compensate for periods in which updates of the count are suspended, **KeQueryInterruptTime** returns a biased count value that it calculates by adding a bias count to the raw interrupt time count. The bias count is the estimated sum of all of the updates to the interrupt time count that the operating system missed while counting was suspended. In contrast, **KeQueryUnbiasedInterruptTime** returns the raw, unbiased count.

Unlike the KeQuerySystemTime routine, **KeQueryUnbiasedInterruptTime** returns a count value that is not affected by operations that set or reset the system time. In addition, the system time that is reported by **KeQuerySystemTime** is typically updated approximately every ten milliseconds. In contrast, the count that is returned by **KeQueryUnbiasedInterruptTime** is updated at least once per system clock tick.

In Windows 2000 and later versions of the Windows operating system, the KeQueryPerformanceCounter routine provides the finest grained running count that is available from the operating system.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KeRaiseIrql macro

1/25/2019 • 2 minutes to read • Edit Online

The **KeRaiseIrql** routine raises the hardware priority to the specified IRQL value, thereby masking off interrupts of equivalent or lower IRQL on the current processor. For information about IRQLs, see Managing Hardware Priorities.

Syntax

```
void KeRaiseIrql(
   a,
   b
);
```

Parameters

`a`

Specifies the new KIRQL value to which the hardware priority is to be raised.

`b`

Pointer to the storage for the original (unraised) KIRQL value to be used in a subsequent call to KeLowerIrql.

Return Value

None

Remarks

If the new IRQL is less than the current IRQL, a bug check occurs. Otherwise, the current IRQL is set to the specified value.

Callers of this routine can be running at any IRQL. Any caller should restore the original IRQL with KeLowerIrql as soon as possible.

A call to **KeLowerIrql** is valid if it specifies *NewIrql* <= *CurrentIrql*. A call to **KeRaiseIrql** is valid if the caller specifies *NewIrql* >= *CurrentIrql*.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Hal.lib

KeLowerIrql

KeRaiseIrqlToDpcLevel function

1/25/2019 • 2 minutes to read • Edit Online

The **KeRaiseIrqlToDpcLevel** routine raises the hardware priority to IRQL = DISPATCH_LEVEL, thereby masking off interrupts of equivalent or lower IRQL on the current processor.

Syntax

```
_DECL_HAL_KE_IMPORT KIRQL KeRaiseIrqlToDpcLevel(

);
```

Parameters

This function has no parameters.

Return Value

KeRaiseIrqlToDpcLevel returns the IRQL at which the call occurred.

Remarks

Any caller of **KeRaiseIrqlToDpcLevel** should save the returned IRQL value. Every such caller must restore the original IRQL as quickly as possible by passing this returned IRQL in a subsequent call to KeLowerIrql.

Callers of **KeRaiseIrqlToDpcLevel** must be running at IRQL <= DISPATCH_LEVEL. Otherwise, a call to this routine causes a bug check.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h)
Library	Hal.lib
IRQL	"<= DISPATCH_LEVEL (see Remarks section)"

KeReadStateEvent function

1/25/2019 • 2 minutes to read • Edit Online

The **KeReadStateEvent** routine returns the current state, signaled or not-signaled, of an event object.

Syntax

```
LONG KeReadStateEvent(
  PRKEVENT Event
);
```

Parameters

`Event`

A pointer to an initialized event object for which the caller provides the storage.

Return Value

If the event object is currently set to a signaled state, a nonzero value is returned. Otherwise, zero is returned.

Remarks

This routine provides an efficient way to poll the signal state of an event. **KeReadStateEvent** reads the state of the event without synchronizing its access to the event. Do not assume that accesses of an event state by **KeReadStateEvent** are mutually exclusive of accesses by routines, such as KeSetEvent and KeWaitForSingleObject, that do synchronize their access to the event state.

It is also possible to read the state of an event from a driver's interrupt service routine at DIRQL, if the following conditions are met: the driver's event object is resident (probably in its device extension), and any other function that accesses the event synchronizes its access with the ISR.

For more information about event objects, see Event Objects.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeReadStateMutex function

1/25/2019 • 2 minutes to read • Edit Online

The **KeReadStateMutex** routine returns the current state, signaled or not-signaled, of the specified mutex object.

Syntax

```
LONG KeReadStateMutex(
  PRKMUTEX Mutex
);
```

Parameters

`Mutex`

Pointer to an initialized mutex object for which the caller provides the storage.

Return Value

If the return value is 1, the state of the mutex object is signaled.

Remarks

This routine provides an efficient way to poll the signal state of a mutex. **KeReadStateMutex** reads the state of the mutex without synchronizing its access to the mutex. Do not assume that accesses of a mutex state by **KeReadStateMutex** are mutually exclusive of accesses by routines, such as KeReleaseMutex and KeWaitForSingleObject, that do synchronize their access to the mutex state.

For more information about mutex objects, see Mutex Objects.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeReadStateSemaphore function

1/25/2019 • 2 minutes to read • Edit Online

The **KeReadStateSemaphore** routine returns the current state, signaled or not-signaled, of the specified semaphore object.

Syntax

```
LONG KeReadStateSemaphore(
  PRKSEMAPHORE Semaphore
);
```

Parameters

`Semaphore`

Pointer to an initialized semaphore object for which the caller provides the storage.

Return Value

If the return value is zero, the semaphore object is set to a not-signaled state.

Remarks

This routine provides an efficient way to poll the signal state of a semaphore. **KeReadStateSemaphore** reads the state of the semaphore without synchronizing its access to the semaphore. Do not assume that accesses of a semaphore state by **KeReadStateSemaphore** are mutually exclusive of accesses by routines, such as KeReleaseSemaphore and KeWaitForSingleObject, that do synchronize their access to the semaphore state.

For more information about semaphore objects, see Semaphore Objects.

Requirements

KeReadStateTimer function

1/25/2019 • 2 minutes to read • Edit Online

The **KeReadStateTimer** routine reads the current state of a timer object.

Syntax

```
BOOLEAN KeReadStateTimer(
  PKTIMER Timer
);
```

Parameters

`Timer`

A pointer to an initialized timer object, for which the caller provides the storage.

Return Value

KeReadStateTimer returns **TRUE** if the current state of the timer object is signaled; otherwise, it returns **FALSE**.

Remarks

This routine provides an efficient way to poll the signal state of a timer. **KeReadStateTimer** reads the state of the timer without synchronizing its access to the timer. Do not assume that accesses of a timer state by **KeReadStateTimer** are mutually exclusive of accesses by routines, such as KeSetTimer and KeWaitForSingleObject, that do synchronize their access to the timer state.

For more information about timer objects, see Timer Objects and DPCs.

KeRegisterBoundCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **KeRegisterBoundCallback** routine registers a routine to be called whenever a user-mode bound exception occurs.

Syntax

```
PVOID KeRegisterBoundCallback(
  PBOUND_CALLBACK CallbackRoutine
);
```

Parameters

`CallbackRoutine`

Pointer to a BoundCallback function.

Return Value

On success, **KeRegisterBoundCallback** returns an opaque pointer that the caller passes to KeDeregisterBoundCallback to deregister the callback. The routine returns **NULL** if it is unable to register the callback.

Remarks

The **KeRegisterBoundCallback** routine provides the opportunity for a kernel-mode driver to intercept and handle user-mode bound exceptions. When a bounds exception for a user-mode thread occurs, the system calls the registered BoundCallback function to manage the bounds trap. The return value of the *BoundCallback* function indicates the action that the system should then perform, such as propagating the bounds exception or terminating the user-mode process.

Requirements

Minimum supported client	Available starting with Windows 10.
Target Platform	Universal
Header	wdm.h
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeDeregisterBoundCallback

KeRegisterBugCheckCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **KeRegisterBugCheckCallback** routine registers a BugCheckCallback routine, which executes when the operating system issues a bug check.

Syntax

```
BOOLEAN KeRegisterBugCheckCallback(
  PKBUGCHECK_CALLBACK_RECORD  CallbackRecord,
  PKBUGCHECK_CALLBACK_ROUTINE CallbackRoutine,
  PVOID                       Buffer,
  ULONG                       Length,
  PUCHAR                      Component
);
```

Parameters

`CallbackRecord`

Pointer to a callback record that was previously initialized by KeInitializeCallbackRecord, for which the caller provides nonpaged storage.

`CallbackRoutine`

Pointer to the driver-supplied BugCheckCallback routine.

`Buffer`

Pointer to a caller-supplied buffer, which must be in resident memory, such as nonpaged pool.

`Length`

Specifies the size in bytes of the caller-allocated buffer.

`Component`

Pointer to a null-terminated ANSI string that identifies the caller. This string usually contains the name of the device driver, or possibly of its device.

Return Value

KeRegisterBugCheckCallback returns **TRUE** if the caller-supplied routine is successfully added to the set of registered bug-check callbacks; otherwise, it returns **FALSE**.

Remarks

The **KeRegisterBugCheckCallback** routine registers a BugCheckCallback routine, the simplest kind of bug-check callback routine. To register other kinds of bug-check callbacks, such as BugCheckDumpIoCallback and BugCheckAddPagesCallback routines, use the KeRegisterBugCheckReasonCallback routine instead.

The *BugCheckCallback* routine is executed when the system issues a bug check. A driver can use the routine to reset the device to a known state. For more information, see *BugCheckCallback*.

Drivers can use the **KeDeregisterBugCheckCallback** routine to remove the callback. Any driver that can be unloaded must remove all of its callbacks in its Unload routine.

The *Component* string is used to identify the driver during crash-dump debugging. To display the crash dump data corresponding to any specified *Component* string, you can use the **!bugdump** debugger extension. It is also possible to debug the bug check callback routine itself. For information about debuggers and debugger extensions, see Windows Debugging.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

The **KeRegisterBugCheckReasonCallback** routine registers a BugCheckDumpIoCallback, BugCheckSecondaryDumpDataCallback, or BugCheckAddPagesCallback routine, which executes when the operating system issues a bug check.

Syntax

```
BOOLEAN KeRegisterBugCheckReasonCallback(
  PKBUGCHECK_REASON_CALLBACK_RECORD  CallbackRecord,
  PKBUGCHECK_REASON_CALLBACK_ROUTINE CallbackRoutine,
  KBUGCHECK_CALLBACK_REASON          Reason,
  PUCHAR                             Component
);
```

Parameters

`CallbackRecord`

A pointer to a KBUGCHECK_REASON_CALLBACK_RECORD structure that was initialized by a call to the KeInitializeCallbackRecord routine.

`CallbackRoutine`

A pointer to the callback routine to register. This parameter points to one of the following types of driver-implemented routine:

BugCheckDumpIoCallback

BugCheckSecondaryDumpDataCallback

BugCheckAddPagesCallback

`Reason`

Specifies the type of callback routine that *CallbackRoutine* points to. Set *Reason* to one of the KBUGCHECK_CALLBACK_REASON enumeration values in the following table.

VALUE	CALLBACK ROUTINE
KbCallbackDumpIo	*BugCheckDumpIoCallback*
KbCallbackSecondaryDumpData	*BugCheckSecondaryDumpDataCallback*
KbCallbackAddPages	*BugCheckAddPagesCallback*

`Component`

A pointer to a null-terminated ANSI string that identifies the caller. For example, you can select a string that describes the device driver, or that contains the device name. You can use the !bugdump debugger extension to display the crash dump data that is associated with this string.

Return Value

KeRegisterBugCheckReasonCallback returns **TRUE** if the callback routine is successfully registered; otherwise, it returns **FALSE**.

Remarks

Drivers can use **KeRegisterBugCheckReasonCallback** to register routines that execute during a system bug check.

BugCheckDumpIoCallback routines are called each time data is written to the crash dump file. Drivers for devices that monitor the system state can register a *BugCheckDumpIoCallback* routine to copy the crash dump data to the monitoring device.

BugCheckSecondaryDumpDataCallback routines are called to poll drivers for any device-specific information that should be added to the secondary data area of a crash dump file.

BugCheckAddPagesCallback routines are called to enable drivers to add pages of driver-specific data to the primary data area of a crash dump file. *BugCheckAddPagesCallback* routines are supported in Windows Server 2008 and later versions of Windows.

Drivers can use the KeDeregisterBugCheckReasonCallback routine to remove the *BugCheckXxxCallback* registration. Any driver that can be unloaded must remove the registrations of all of its callbacks in its Unload routine.

To display secondary dump data, you can use the .enumtag command or the IDebugDataSpaces3::ReadTagged method in a debugger extension. Another option is to debug the bug check callback routine itself. For more information about debuggers and debugger extensions, see Windows Debugging.

Requirements

Minimum supported client	Available in Windows XP Service Pack 1 (SP1), Windows Server 2003, and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

KeRegisterBugCheckCallback

KeRegisterNmiCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **KeRegisterNmiCallback** routine registers a routine to be called whenever a nonmaskable interrupt (NMI) occurs.

Syntax

```
PVOID KeRegisterNmiCallback(
  PNMI_CALLBACK CallbackRoutine,
  PVOID         Context
);
```

Parameters

`CallbackRoutine`

Pointer to a function of the form:

```
BOOLEAN
 XxxNmiCallback(
 IN PVOID Context,
  IN BOOLEAN Handled
 );
```

`Context`

Specifies the value to be passed as the *Context* parameter of *XxxNmiCallback* when it is called.

Return Value

On success, **KeRegisterNmiCallback** returns an opaque pointer that the caller passes to KeDeregisterNmiCallback to deregister the callback. The routine returns **NULL** if it is unable to register the callback.

Remarks

When a nonmaskable interrupt occurs, the system calls each registered callback in reverse order from the order in which they were registered. For the first callback, the system passes **FALSE** as the *Handled* parameter. For each subsequent callback, if any previous callback returned **TRUE**, the system passes **TRUE** as the *Handled* parameter, otherwise it passes **FALSE**. If any callback returns a value of **TRUE**, the system considers the interrupt to have been handled. Otherwise, the system calls the HAL's default handler for the interrupt, which normally causes the system to bug check.

The callback routine must be able to be run at IRQL = HIGH_LEVEL.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeDeregisterNmiCallback

KeRegisterProcessorChangeCallback function

1/25/2019 • 6 minutes to read • Edit Online

The **KeRegisterProcessorChangeCallback** routine registers a callback function with the operating system so that the operating system will notify the driver when a new processor is added to the hardware partition.

Syntax

```
PVOID KeRegisterProcessorChangeCallback(
  PPROCESSOR_CALLBACK_FUNCTION CallbackFunction,
  PVOID                        CallbackContext,
  ULONG                        Flags
);
```

Parameters

`CallbackFunction`

A pointer to a driver-supplied processor change callback function that is to be called by the operating system whenever a new processor is added to the hardware partition. A processor change callback function is defined as follows:

```
VOID
  ProcessorCallback(
    __in PVOID CallbackContext,
    __in PKE_PROCESSOR_CHANGE_NOTIFY_CONTEXT ChangeContext,
    __inout PNTSTATUS OperationStatus
    );
```

CallbackContext

The context that was supplied in the *CallbackContext* parameter to the **KeRegisterProcessorChangeCallback** routine when the callback function was registered with the operating system.

ChangeContext

A pointer to a KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT structure that describes the processor change notification event.

OperationStatus

A pointer to a variable that contains an NTSTATUS code. A device driver must not change the value of this variable except if an error occurs during the processing of the callback function when the **State** member of the KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT structure that is pointed to by the *ChangeContext* parameter contains **KeProcessorAddStartNotify**.

The processor change callback function is called at IRQL = PASSIVE_LEVEL.

`CallbackContext`

A driver-supplied context that is passed to the callback function. This parameter can be **NULL**.

`Flags`

Optional flags that modify the behavior of the **KeRegisterProcessorChangeCallback** routine. The following is one possible flag:

KE_PROCESSOR_CHANGE_ADD_EXISTING

If this flag is set, the registered callback function is immediately called for each active processor that currently exists in the hardware partition, in addition to being called whenever a new processor is added to the hardware partition. If this flag is not set, the registered callback function is only called whenever a new processor is added to the system.

Return Value

KeRegisterProcessorChangeCallback returns a non-**NULL** callback registration handle if the callback function is successfully registered with the operating system. Otherwise, **KeRegisterProcessorChangeCallback** returns **NULL**. For more information about this handle, see the following Remarks section.

Remarks

A device driver calls the **KeRegisterProcessorChangeCallback** routine to register a callback function that is to be called by the operating system whenever a new processor is added to the hardware partition. When a user hot-plugs a new processor into the partition, the operating system calls the registered callback functions to rebalance the system resources that are allocated among the processors in the partition.

The registered callback function is called two times whenever a new processor is added to the hardware partition. The first time that the callback function is called, the **State** member of the KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT structure that is pointed to by the *ChangeContext* parameter contains **KeProcessorAddStartNotify**. It is during this callback that the device driver should allocate any per-processor resources and perform any other tasks in preparation for the new processor to become active in the hardware partition. If an error occurs while the device driver processes this callback that could cause a bugcheck to occur if the operating system continues to add the new processor to the hardware partition, the callback function sets the variable that is pointed to by the *OperationStatus* parameter to an NTSTATUS code that describes the error condition. For example, if the device driver experiences a memory allocation failure for a per-processor data structure for a new processor, the callback function sets this variable to STATUS_INSUFFICIENT_RESOURCES. If the callback is processed successfully, the contents of the variable that is pointed to by the *OperationStatus* parameter should not be changed.

The second time that the callback function is called, the **State** member of the KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT structure that is pointed to by the *ChangeContext* parameter contains either **KeProcessorAddCompleteNotify**, which indicates that the operating system has added the new processor to the hardware partition successfully, or **KeProcessorAddFailureNotify**, which indicates that the operating system did not add the new processor to the hardware partition. If the operating system successfully adds the new processor to the hardware partition, the callback function is not called the second time until after the new processor has been started and is available for thread scheduling. If the operating system did not add the new processor to the hardware partition, the device driver should free any per-processor resources during the second callback that it allocated during the first callback.

If the device driver specifies the KE_PROCESSOR_CHANGE_ADD_EXISTING flag in the *Flags* parameter when it calls the **KeRegisterProcessorChangeCallback** routine, the callback function is immediately called one time for each active processor that currently exists in the hardware partition. For these callbacks, the **State** member of the KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT structure that is pointed to by the *ChangeContext* parameter contains **KeProcessorAddStartNotify**. It is during these callbacks that the device driver should allocate any per-processor resources and perform any other tasks to prepare to use the existing processors in the hardware partition. If the device driver successfully processes this callback for all active processors that currently exist in the hardware partition, the callback function is immediately called again for each active processor that currently exists in the hardware partition. For these callbacks, the **State** member of the

KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT structure that is pointed to by the *ChangeContext* parameter contains **KeProcessorAddCompleteNotify**. **KeRegisterProcessorChangeCallback** returns after these callbacks complete.

If an error occurs while the device driver processes the first callback for one of the existing active processors in the hardware partition that could cause a bugcheck to occur if the driver were to continue to load, the callback function sets the variable pointed to by the *OperationStatus* parameter to an NTSTATUS code that describes the error condition. For example, if the device driver experiences a memory allocation failure for a per-processor data structure for an existing active processor, the callback function sets this variable to STATUS_INSUFFICIENT_RESOURCES. If the callback is processed successfully, the contents of the variable that is pointed to by the *OperationStatus* parameter should not be changed.

If the device driver indicates an error when the first callback for one of the existing active processors in the hardware partition is processed, the callback function is not called for any more of the existing active processors. Instead, the callback function is immediately called a second time for each active processor for which the callback was called the first time, excluding the active processor for which the callback indicated the error. For these callbacks, the **State** member of the KE_PROCESSOR_CHANGE_NOTIFY_CONTEXT structure that is pointed to by the *ChangeContext* parameter contains **KeProcessorAddFailureNotify**.

A device driver typically calls the **KeRegisterProcessorChangeCallback** routine from within its DriverEntry routine. If the call to the **KeRegisterProcessorChangeCallback** routine returns **NULL**, the device driver's **DriverEntry** routine should return an NTSTATUS code that describes the error condition.

> **Note** A device driver can use the context that is passed in the *CallbackContext* parameter to the **KeRegisterProcessorChangeCallback** routine as a place where the callback function can store the NTSTATUS code that describes the error condition. This NTSTATUS code can then be used as the return value for the device driver's **DriverEntry** routine.

> **Note** The status value returned by **KeRegisterProcessorChangeCallback** indicates only whether the registration of the callback function succeeds or fails. It does not indicate the success or failure of any calls to callback functions that might occur before **KeRegisterProcessorChangeCallback** returns.

A callback function that has been registered for notification of processor changes must be unregistered before the device driver is unloaded from the operating system. To unregister the callback function, the device driver calls the KeDeregisterProcessorChangeCallback routine, and passes, as an input parameter to this routine, the registration handle that was returned by the call to the **KeRegisterProcessorChangeCallback** routine.

Requirements

KeReleaseGuardedMutex function

1/25/2019 • 2 minutes to read • Edit Online

The **KeReleaseGuardedMutex** routine releases a guarded mutex acquired with KeAcquireGuardedMutex or KeTryToAcquireGuardedMutex.

Syntax

```
void KeReleaseGuardedMutex(
  PKGUARDED_MUTEX Mutex
);
```

Parameters

`Mutex`

Pointer to the KGUARDED_MUTEX structure for the guarded mutex.

Return Value

None

Remarks

KeReleaseGuardedMutex implicitly exits the guarded region entered by **KeAcquireGuardedMutex** and **KeTryToAcquireGuardedMutex**.

For more information about guarded mutexes, see Fast Mutexes and Guarded Mutexes.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeAcquireGuardedMutex

KeReleaseGuardedMutexUnsafe function

1/25/2019 • 2 minutes to read • Edit Online

The **KeReleaseGuardedMutexUnsafe** routine releases a guarded mutex acquired by KeAcquireGuardedMutexUnsafe.

Syntax

```
void KeReleaseGuardedMutexUnsafe(
  PKGUARDED_MUTEX FastMutex
);
```

Parameters

`FastMutex`

Pointer to the KGUARDED_MUTEX structure for the guarded mutex.

Return Value

None

Remarks

For more information about guarded mutexes, see Fast Mutexes and Guarded Mutexes.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KeReleaseInStackQueuedSpinLock function

1/25/2019 • 2 minutes to read • Edit Online

The **KeReleaseInStackQueuedSpinLock** routine releases a queued spin lock acquired by KeAcquireInStackQueuedSpinLock.

Syntax

```
void KeReleaseInStackQueuedSpinLock(
  PKLOCK_QUEUE_HANDLE LockHandle
);
```

Parameters

`LockHandle`

Specifies the queued spin lock handle initialized by the call to KeAcquireInStackQueuedSpinLock that acquired the lock.

Return Value

None

Remarks

This routine restores the original IRQL that the operating system saved at the beginning of the **KeAcquireInStackQueuedSpinLock** call.

For more information about queued spin locks, see Queued Spin Locks.

Use Hal.lib on 32-bit versions of Windows and Ntoskrnl.lib on 64-bit versions of Windows.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.

KeAcquireInStackQueuedSpinLock

KeReleaseInStackQueuedSpinLockForDpc function

1/25/2019 • 2 minutes to read • Edit Online

The **KeReleaseInStackQueuedSpinLockForDpc** routine releases a queued spin lock that was acquired by calling KeAcquireInStackQueuedSpinLockForDpc.

Syntax

```
void KeReleaseInStackQueuedSpinLockForDpc(
  PKLOCK_QUEUE_HANDLE LockHandle
);
```

Parameters

`LockHandle`

Pointer to the KLOCK_QUEUE_HANDLE structure that KeAcquireInStackQueuedSpinLockForDpc initialized when the queued spin lock was acquired.

Return Value

None

Remarks

For more information about queued spin locks, see Queued Spin Locks.

If the current IRQL was PASSIVE_LEVEL when the queued spin lock was acquired, **KeReleaseSpinLockForDpc** lowers the current IRQL to PASSIVE_LEVEL. If the current IRQL was DISPATCH_LEVEL when the queued spin lock was acquired, **KeReleaseSpinLockForDpc** does not change the current IRQL.

Requirements

KeAcquireInterruptSpinLock

KeSynchronizeExecution

KeReleaseMutex function

1/25/2019 • 2 minutes to read • Edit Online

The **KeReleaseMutex** routine releases a mutex object, and specifies whether the caller is to call one of the **KeWait *Xxx*** routines as soon as **KeReleaseMutex** returns control.

Syntax

```
LONG KeReleaseMutex(
  PRKMUTEX Mutex,
  BOOLEAN  Wait
);
```

Parameters

`Mutex`

A pointer to an initialized mutex object for which the caller provides the storage.

`Wait`

Specifies whether the call to **KeReleaseMutex** is to be immediately followed by a call to one of the **KeWait*Xxx*** routines. If **TRUE**, the **KeReleaseMutex** call must be followed by a call to KeWaitForMultipleObjects, KeWaitForMutexObject, or KeWaitForSingleObject. For more information, see the following Remarks section.

Return Value

If the return value is zero, the mutex object was released and attained a state of *signaled*.

Remarks

For better performance, use fast mutexes or guarded mutexes. For more information, see Alternatives to Mutex Objects.

If the mutex object attains a signaled state, an attempt is made to satisfy a wait for the mutex object.

A mutex object can be released only by the thread that currently holds the mutex. If an attempt is made to release a mutex that the thread does not hold or if a mutex was acquired at IRQL = DISPATCH_LEVEL and the thread is not running at DISPATCH_LEVEL (and vice versa), the routine raises a STATUS_ABANDONED or STATUS_MUTEX_NOT_OWNED exception.

When a mutex object attains a signaled state, it is removed from the list of the mutexes that are held by that thread. If this list contains no more entries, the original priority for the thread is restored.

The **KeReleaseMutex** routine might temporarily raise the IRQL. If the *Wait* parameter is **FALSE**, the routine, before it returns, restores the IRQL to the original value that it had at the start of the call.

If *Wait* = **TRUE**, the routine returns without lowering the IRQL. In this case, the **KeReleaseMutex** call must be immediately followed by a **KeWait*Xxx*** call. By setting *Wait* = **TRUE**, the caller can prevent an unnecessary context switch from occurring between the **KeReleaseMutex** call and the **KeWait*Xxx*** call. The **KeWait*Xxx*** routine, before it returns, restores the IRQL to its original value at the start of the **KeReleaseMutex** call. Although the IRQL disables context switches between the two calls, these calls cannot reliably be used as the start and end of an

atomic operation. For example, between these two calls, a thread that is running at the same time on another processor might change the state of the event object or of the target of the wait.

If the caller is executing at IRQL = DISPATCH_LEVEL or in an arbitrary thread context, the *Timeout* parameter to **KeWait*Xxx*** must be zero.

If a mutex is acquired recursively, the holding thread must call **KeReleaseMutex** as many times as it acquired the mutex to set it to the signaled state.

For more information about mutex objects, see Mutex Objects.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeReadStateMutex

KeWaitForMultipleObjects

KeWaitForMutexObject

KeWaitForSingleObject

KeReleaseSemaphore function

1/25/2019 • 2 minutes to read • Edit Online

The **KeReleaseSemaphore** routine releases the specified semaphore object.

Syntax

```
LONG KeReleaseSemaphore(
  PRKSEMAPHORE Semaphore,
  KPRIORITY    Increment,
  LONG         Adjustment,
  BOOLEAN      Wait
);
```

Parameters

`Semaphore`

A pointer to an initialized semaphore object for which the caller provides the storage.

`Increment`

Specifies the priority increment to be applied if releasing the semaphore causes a wait to be satisfied.

`Adjustment`

Specifies a value to be added to the current semaphore count. This value must be positive.

`Wait`

Specifies whether the call to **KeReleaseSemaphore** is to be followed immediately by a call to one of the **KeWait*Xxx*** routines. If **TRUE**, the **KeReleaseSemaphore** call must be followed by a call to KeWaitForMultipleObjects, KeWaitForMutexObject, or KeWaitForSingleObject. For more information, see the following Remarks section.

Return Value

If the return value is zero, the previous state of the semaphore object is not-signaled.

Remarks

KeReleaseSemaphore supplies a run-time priority boost for waiting threads. If this call sets the semaphore to the signaled state, the semaphore count is augmented by the specified value. The caller can also specify whether it will call one of the **KeWait*Xxx*** routines as soon as **KeReleaseSemaphore** returns control.

Releasing a semaphore object causes the semaphore count to be augmented by the value of the *Adjustment* parameter. If the resulting value is greater than the limit of the semaphore object, the count is not adjusted and an exception, STATUS_SEMAPHORE_LIMIT_EXCEEDED, is raised.

Augmenting the semaphore object count causes the semaphore to attain a signaled state, and an attempt is made to satisfy as many waits as possible on the semaphore object.

The **KeReleaseSemaphore** routine might temporarily raise the IRQL. If the *Wait* parameter is **FALSE**, the routine, before it returns, restores the IRQL to the original value that it had at the start of the call.

If *Wait* = **TRUE**, the routine returns without lowering the IRQL. In this case, the **KeReleaseSemaphore** call must be immediately followed by a **KeWait*Xxx*** call. By setting *Wait* = **TRUE**, the caller can prevent an unnecessary context switch from occurring between the **KeReleaseSemaphore** call and the **KeWait*Xxx*** call. The **KeWait*Xxx*** routine, before it returns, restores the IRQL to its original value at the start of the **KeReleaseSemaphore** call. Although the IRQL disables context switches between the two calls, these calls cannot reliably be used as the start and end of an atomic operation. For example, between these two calls, a thread that is running at the same time on another processor might change the state of the semaphore object or of the target of the wait.

If the caller is executing at IRQL = DISPATCH_LEVEL or in an arbitrary thread context, the *Timeout* parameter to **KeWait*Xxx*** must be zero.

For more information about semaphore objects, see Semaphore Objects.

Callers of **KeReleaseSemaphore** must be running at IRQL <= DISPATCH_LEVEL provided that *Wait* is set to **FALSE**. Otherwise, the caller must be running at IRQL = PASSIVE_LEVEL.

Requirements

KeReleaseSpinLock macro

1/25/2019 • 2 minutes to read • Edit Online

The **KeReleaseSpinLock** routine releases a spin lock and restores the original IRQL at which the caller was running.

Syntax

```
void KeReleaseSpinLock(
   a,
   b
);
```

Parameters

`a`

Pointer to a KSPIN_LOCK spin lock for which the caller provides the storage.

`b`

Specifies the KIRQL value saved from the preceding call to KeAcquireSpinLock.

Return Value

None

Remarks

This call is a reciprocal to KeAcquireSpinLock. The input *NewIrql* value must be the *OldIrql* returned by **KeAcquireSpinLock**.

For more information about spin locks, see Spin Locks.

Callers of this routine are running at IRQL = DISPATCH_LEVEL. On return from **KeReleaseSpinLock**, IRQL is restored to the *NewIrql* value.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Hal.lib
IRQL	DISPATCH_LEVEL (see Remarks section)

KeReleaseSpinLockForDpc function

1/25/2019 • 2 minutes to read • Edit Online

The **KeReleaseSpinLockForDpc** routine releases a spin lock that was acquired by calling KeAcquireSpinLockForDpc.

Syntax

```
void KeReleaseSpinLockForDpc(
  PKSPIN_LOCK SpinLock,
  KIRQL       OldIrql
);
```

Parameters

`SpinLock`

Pointer to the spin lock that **KeAcquireSpinLockForDpc** acquired.

`OldIrql`

Specifies the IRQL that was current when the spin lock was acquired. Specify the value returned by **KeAcquireSpinLockForDpc**.

Return Value

None

Remarks

For more information about spin locks, see Spin Locks.

If *OldIrql* = PASSIVE_LEVEL, **KeReleaseSpinLockForDpc** lowers the current IRQL to PASSIVE_LEVEL. If *OldIrql* = DISPATCH_LEVEL, **KeReleaseSpinLockForDpc** does not change the current IRQL.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KeAcquireSpinLockForDpc

KeReleaseSpinLockFromDpcLevel macro

1/25/2019 • 2 minutes to read • Edit Online

The **KeReleaseSpinLockFromDpcLevel** routine releases an executive spin lock without changing the IRQL.

Syntax

```
void KeReleaseSpinLockFromDpcLevel(
   a
);
```

Parameters

`a`

Pointer to an executive KSPIN_LOCK spin lock for which the caller provides the storage.

Return Value

None

Remarks

Drivers call **KeReleaseSpinLockFromDpcLevel** to release a spin lock acquired by calling KeAcquireSpinLockAtDpcLevel.

It is an error to call **KeReleaseSpinLockFromDpcLevel** if the specified spin lock was acquired by calling KeAcquireSpinLock because the caller's original IRQL is not restored, which can cause deadlocks or fatal page faults.

For more information about spin locks, see Spin Locks.

Requirements

KeRemoveByKeyDeviceQueue function

1/25/2019 • 2 minutes to read • Edit Online

The **KeRemoveByKeyDeviceQueue** routine removes an entry, selected according to a sort key value, from the specified device queue.

Syntax

```
PKDEVICE_QUEUE_ENTRY KeRemoveByKeyDeviceQueue(
  PKDEVICE_QUEUE DeviceQueue,
  ULONG          SortKey
);
```

Parameters

`DeviceQueue`

Pointer to an initialized device queue object for which the caller provides the storage.

`SortKey`

Specifies the key to be used when searching the *DeviceQueue*.

Return Value

KeRemoveByKeyDeviceQueue returns the device queue entry that was removed; returns **NULL** if the queue was empty.

Remarks

This routine searches for the first entry in the device queue that has a value greater than or equal to the *SortKey*. After this entry is found, this routine removes the entry from the device queue and returns it. If no such entry is found, then the first entry in the queue is returned. If the device queue is empty, then the device is set to a not-busy state and a **NULL** pointer is returned.

It is an error to call **KeRemoveByKeyDeviceQueue** when the device queue object is set to a not-busy state.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IRQL	DISPATCH_LEVEL

KeRemoveEntryDeviceQueue

KeRemoveDeviceQueue function

1/25/2019 • 2 minutes to read • Edit Online

The **KeRemoveDeviceQueue** routine removes an entry from the head of a specified device queue.

Syntax

```
PKDEVICE_QUEUE_ENTRY KeRemoveDeviceQueue(
  PKDEVICE_QUEUE DeviceQueue
);
```

Parameters

`DeviceQueue`

Pointer to an initialized device queue object for which the caller provides the storage.

Return Value

If the device queue is empty but is set to a busy state, **KeRemoveDeviceQueue** returns **NULL**.

Remarks

The specified device queue spin lock is acquired and the state of the device queue is checked. If the device queue is set to a busy state and an IRP is queued, this routine dequeues the entry and returns a pointer to the IRP. A call to **KeRemoveDeviceQueue** when the device queue object is set to a busy state but no IRPs are queued causes a state change to not-busy. The specified device queue's spin lock is released.

It is an error to call **KeRemoveDeviceQueue** when the device queue object is set to a not-busy state.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeRemoveByKeyDeviceQueue

KeRemoveEntryDeviceQueue

KeRemoveEntryDeviceQueue function

1/25/2019 • 2 minutes to read • Edit Online

The **KeRemoveEntryDeviceQueue** routine returns whether the specified entry is in the device queue and removes it, if it was queued, from the device queue.

Syntax

```
BOOLEAN KeRemoveEntryDeviceQueue(
  PKDEVICE_QUEUE       DeviceQueue,
  PKDEVICE_QUEUE_ENTRY DeviceQueueEntry
);
```

Parameters

`DeviceQueue`

Pointer to an initialized device queue object for which the caller provides the storage.

`DeviceQueueEntry`

Pointer to the entry to be removed from the specified *DeviceQueue*.

Return Value

If the *DeviceQueueEntry* is queued, it is removed and **KeRemoveEntryDeviceQueue** returns **TRUE**.

Remarks

The IRQL is set to DISPATCH_LEVEL and the *DeviceQueue* spin lock is acquired.

If the specified *DeviceQueueEntry* is not in the queue, the IRP either is already being processed, or the IRP has been canceled. In this case, **KeRemoveEntryDeviceQueue** simply returns **FALSE**.

The specified *DeviceQueue* spin lock is released and IRQL is restored to its previous value.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeRemoveDeviceQueue

KeRemoveQueueDpc function

1/25/2019 • 2 minutes to read • Edit Online

The **KeRemoveQueueDpc** routine removes the specified DPC object from the system DPC queue.

Syntax

```
BOOLEAN KeRemoveQueueDpc(
  PRKDPC Dpc
);
```

Parameters

`Dpc`

A pointer to an initialized DPC object that was queued by a previous call to the KeInsertQueueDpc routine.

Return Value

KeRemoveQueueDpc returns **TRUE** if the DPC object is in the DPC queue. If the specified DPC object is not currently in the DPC queue, no operation is performed and **FALSE** is returned.

Remarks

If the specified DPC object is currently queued, it is removed from the queue, canceling a call to the associated DPC routine.

Starting with Windows Vista with Service Pack 1 (SP1) and Windows Server 2008, a return value of **TRUE** always means that **KeRemoveQueueDpc** successfully removed the DPC object from the DPC queue before the DPC routine started to run. In earlier versions of Windows, the DPC routine might occasionally run even if **KeRemoveQueueDpc** returns **TRUE**. In these earlier versions of Windows, drivers that cannot tolerate ambiguity in the **TRUE** return value should treat return values of **TRUE** and **FALSE** identically.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeResetEvent function

1/25/2019 • 2 minutes to read • Edit Online

The **KeResetEvent** routine resets a specified event object to a not-signaled state and returns the previous state of that event object.

Syntax

```
LONG KeResetEvent(
  PRKEVENT Event
);
```

Parameters

`Event`

A pointer to an initialized dispatcher object of type event for which the caller provides the storage.

Return Value

KeResetEvent returns a value that indicates the previous state of the specified *Event*, which is nonzero for a signaled state.

Remarks

Event is reset to a not-signaled state, meaning that its value is set to zero.

Unless the caller requires the value that is returned by **KeResetEvent**, using the KeClearEvent routine is a faster way to set an event object to a not-signaled state.

For more information about event objects, see Event Objects.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

KeRestoreExtendedProcessorState function

1/25/2019 • 2 minutes to read • Edit Online

The **KeRestoreExtendedProcessorState** routine restores extended processor state information that was previously saved.

Syntax

```
void KeRestoreExtendedProcessorState(
  PXSTATE_SAVE XStateSave
);
```

Parameters

`XStateSave`

A pointer to an XSTATE_SAVE structure that contains the extended processor state information to restore. The contents of this structure must have been previously saved by the KeSaveExtendedProcessorState routine.

Return Value

None

Remarks

Kernel-mode driver code must ensure that calls to **KeSaveExtendedProcessorState** and **KeRestoreExtendedProcessorState** are properly nested. This is required so that, at each nesting level, the state that was restored by the **KeRestoreExtendedProcessorState** call is the same state that was saved by the corresponding **KeSaveExtendedProcessorState** call. To ensure proper nesting, kernel-mode driver code must follow these rules:

- A **KeRestoreExtendedProcessorState** call that restores a saved state must be running at the same IRQL as the **KeSaveExtendedProcessorState** call that saved the state.
- If a pair of **KeSaveExtendedProcessorState** and **KeRestoreExtendedProcessorState** calls is nested within a pair of surrounding **KeSaveExtendedProcessorState** and **KeRestoreExtendedProcessorState** calls, the IRQL for the nested calls must not be lower than the IRQL for the surrounding calls.
- Typically, the caller-allocated **XSTATE_SAVE** structure that contains the state that was saved by **KeSaveExtendedProcessorState** resides on the stack. The stack naturally preserves the nesting of saved state information. If driver code stores the state in a location other than the stack, the driver writer must take special care to preserve the nesting of the **KeSaveExtendedProcessorState** and **KeRestoreExtendedProcessorState** calls.
- The **KeRestoreExtendedProcessorState** call that restores a saved state must be running in the same thread as the **KeSaveExtendedProcessorState** call that saved the state.

A similar set of rules apply to the KeSaveFloatingPointState and KeRestoreFloatingPointState routines.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeSaveFloatingPointState

XSTATE_SAVE

KeRestoreFloatingPointState function

1/25/2019 • 2 minutes to read • Edit Online

The **KeRestoreFloatingPointState** routine restores the nonvolatile floating-point context saved by the preceding call to KeSaveFloatingPointState.

Syntax

```
NTSTATUS KeRestoreFloatingPointState(
  PKFLOATING_SAVE FloatSave
);
```

Parameters

`FloatSave`

A pointer to the KFLOATING_SAVE structure that was passed in the preceding call to KeSaveFloatingPointState.

Return Value

KeRestoreFloatingPointState returns STATUS_SUCCESS.

Remarks

KeRestoreFloatingPointState is the reciprocal of **KeSaveFloatingPointState**.

Any routine that calls **KeSaveFloatingPointState***must* call **KeRestoreFloatingPointState** before that routine returns control, and it must be running at the same IRQL as that from which the preceding call to **KeSaveFloatingPointState** occurred. Failure to meet either of these conditions causes a system bug check.

Kernel-mode driver code must ensure that calls to **KeSaveFloatingPointState** and **KeRestoreFloatingPointState** are properly nested. This is required so that, at each nesting level, the state that was restored by the **KeRestoreFloatingPointState** call is the same state that was saved by the corresponding **KeSaveFloatingPointState** call. To ensure proper nesting, kernel-mode driver code must follow these rules:

- A **KeRestoreFloatingPointState** call that restores a saved state must be running at the same IRQL as the **KeSaveFloatingPointState** call that saved the state.
- If a pair of **KeSaveFloatingPointState** and **KeRestoreFloatingPointState** calls is nested within a pair of surrounding **KeSaveFloatingPointState** and **KeRestoreFloatingPointState** calls, the IRQL for the nested calls must not be lower than the IRQL for the surrounding calls.
- Typically, the caller-allocated **KFLOATING_SAVE** structure that contains the state that was saved by **KeSaveFloatingPointState** resides on the stack. The stack naturally preserves the nesting of saved state information. If driver code stores the state in a location other than the stack, the driver writer must take special care to preserve the nesting of the **KeSaveFloatingPointState** and **KeRestoreFloatingPointState** calls.
- The **KeRestoreFloatingPointState** call that restores a saved state must be running in the same thread as the **KeSaveFloatingPointState** call that saved the state.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL (see Remarks section)"

KFLOATING_SAVE

KeSaveFloatingPointState

KeRevertToUserAffinityThreadEx function

1/25/2019 • 2 minutes to read • Edit Online

The **KeRevertToUserAffinityThreadEx** routine restores the previous affinity of the current thread.

Syntax

```
void KeRevertToUserAffinityThreadEx(
  KAFFINITY Affinity
);
```

Parameters

`Affinity`

A **KAFFINITY**-typed variable that specifies the new system affinity of the current thread. Set this parameter to the value that was returned by a previous call to the KeSetSystemAffinityThreadEx routine.

Return Value

None

Remarks

KeRevertToUserAffinityThreadEx changes the affinity of the current thread. The affinity value is a mask that identifies a set of processors on which the thread can run. If successful, the routine schedules the thread to run on a processor in this set.

If the *Affinity* value is nonzero, **KeRevertToUserAffinityThreadEx** sets the affinity mask of the thread to the *Affinity* value. If the *Affinity* value is zero, **KeRevertToUserAffinityThreadEx** restores the original user affinity mask of the thread. This original user affinity mask was saved in the thread object by a previous call to KeSetSystemAffinityThreadEx. A call to **KeRevertToUserAffinityThreadEx** has no effect unless it is preceded by a call to **KeSetSystemAffinityThreadEx**.

If the *Affinity* value is nonzero, the routine changes the affinity mask of the current thread to the *Affinity* value only if both of the following are true:

- The *Affinity* value is valid (that is, only mask bits that correspond to logical processors are set).
- At least one of the processors that is specified in the *Affinity* value is active.

If either of these conditions is not met, the call to **KeRevertToUserAffinityThreadEx** has no effect.

Windows 7 and later versions of Windows support processor groups. Drivers that are designed to handle information about processor groups should use the KeRevertToUserGroupAffinityThread routine, which specifies a processor group, instead of **KeRevertToUserAffinityThreadEx**, which does not. However, the implementation of **KeRevertToUserAffinityThreadEx** in Windows 7 and later versions of Windows provides compatibility for drivers that were written for earlier versions of Windows, which do not support processor groups. In this implementation, a nonzero *Affinity* value is an affinity mask that specifies a set of logical processors in group 0 on which the thread can run. If *Affinity* is zero, the thread reverts to its original user-mode group number and affinity mask.

If **KeRevertToUserAffinityThreadEx** is called at IRQL <= APC_LEVEL and the call is successful, the new (reverted) affinity mask takes effect immediately. When the call returns, the calling thread is already running on a processor that is specified in the new affinity mask. If **KeRevertToUserAffinityThreadEx** is called at IRQL = DISPATCH_LEVEL and the call is successful, the pending processor change is deferred until the caller lowers the IRQL below DISPATCH_LEVEL.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL (see Remarks section)."

KAFFINITY

KeRevertToUserGroupAffinityThread

KeSetSystemAffinityThreadEx

KeRevertToUserGroupAffinityThread function

1/25/2019 • 3 minutes to read • Edit Online

The **KeRevertToUserGroupAffinityThread** routine restores the group affinity of the calling thread to its original value at the time that the thread was created.

Syntax

```
void KeRevertToUserGroupAffinityThread(
  PGROUP_AFFINITY PreviousAffinity
);
```

Parameters

`PreviousAffinity`

A pointer to the group affinity to restore. This parameter points to a GROUP_AFFINITY structure that contains a group number and an affinity mask. The affinity mask specifies the set of logical processors that the user thread can run on.

Return Value

None

Remarks

This routine changes the group number and group-relative affinity mask of the calling thread. The group number and affinity mask identify a set of processors on which the thread can run. If successful, the routine schedules the thread to run on a processor in this set.

The *PreviousAffinity* parameter points to a **GROUP_AFFINITY** structure that specifies the new group number (**Group** member) and affinity mask (**Mask** member) for the thread. If *PreviousAffinity*->**Mask** is nonzero, **KeRevertToUserGroupAffinityThread** sets the group number and affinity mask of the calling thread to the values in the structure. If *PreviousAffinity*->**Mask** is zero, the routine restores the group number and affinity mask to their original values at the time that the thread was initialized.

A process can have affinity for more than one group at a time. However, a thread can be assigned to only one group at any time, and that group is always in the affinity of the thread's process.

A thread can change the group to which it is assigned by calling the KeSetSystemGroupAffinityThread routine. Following one or more calls to **KeSetSystemGroupAffinityThread**, the thread can restore the original group affinity that it had when the thread was created by calling **KeRevertToUserGroupAffinityThread**.

After the thread is created, a call to **KeRevertToUserGroupAffinityThread** has no effect (that is, the group number and affinity mask of the thread remain unchanged) unless the thread first calls **KeSetSystemGroupAffinityThread**. Following a call to **KeRevertToUserGroupAffinityThread**, a second call to **KeRevertToUserGroupAffinityThread** has no effect unless the thread first calls **KeSetSystemGroupAffinityThread**.

The routine changes the group number and affinity mask to the values that are specified in **PreviousAffinity* only if the following are true:

- The group number is valid.
- The affinity mask is valid (that is, only mask bits that correspond to logical processors in the group are set).
- At least one of the processors that is specified in the affinity mask is active.

If any of these conditions is not met, the call to **KeRevertToUserGroupAffinityThread** has no effect.

A related routine, KeRevertToUserAffinityThreadEx, changes the affinity mask of the calling thread, but this routine, unlike **KeRevertToUserGroupAffinityThread**, does not accept a group number as an input parameter. In Windows 7 and later versions of the Windows operating system, **KeRevertToUserAffinityThreadEx** assumes that the affinity mask refers to processors in group 0, which is compatible with the behavior of this routine in earlier versions of Windows that do not support groups. This behavior ensures that existing drivers that call **KeRevertToUserAffinityThreadEx** and that use no group-oriented features will run correctly in multiprocessor systems that have two or more groups. However, drivers that use any group-oriented features in Windows 7 and later versions of the Windows operating system should call **KeRevertToUserGroupAffinityThread** instead of **KeRevertToUserAffinityThreadEx**.

If **KeRevertToUserGroupAffinityThread** is called at IRQL <= APC_LEVEL and the call is successful, the new (reverted) group affinity takes effect immediately. When the call returns, the calling thread is already running on a processor that is specified in the new group affinity. If **KeRevertToUserGroupAffinityThread** is called at IRQL = DISPATCH_LEVEL and the call is successful, the pending processor change is deferred until the caller lowers the IRQL below DISPATCH_LEVEL.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Ntddk.h, Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL (see Remarks section)."

GROUP_AFFINITY

KeRevertToUserAffinityThreadEx

KeSetSystemGroupAffinityThread

KeSaveExtendedProcessorState function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSaveExtendedProcessorState** routine saves extended processor state information.

Syntax

```
NTSTATUS KeSaveExtendedProcessorState(
  ULONG64      Mask,
  PXSTATE_SAVE XStateSave
);
```

Parameters

`Mask`

A 64-bit feature mask. The bits in this mask identify the extended processor feature states to save. If a mask bit is one, the routine saves the state of the feature that is identified by this bit. If a mask bit is zero, the state for the corresponding feature is not saved. This mask must not identify extended processor features that the operating system has not enabled. To obtain a mask of the enabled features, call the RtlGetEnabledExtendedFeatures routine.

A caller can set this parameter to the bitwise OR of one or more of the following **XSTATE_MASK_*XXX*** flag bits:

VALUE	MEANING
XSTATE_MASK_LEGACY_FLOATING_POINT	The floating-point extension (x87/MMX).
XSTATE_MASK_LEGACY_SSE	The streaming SIMD extension (SSE).

XST ATE _M ASK _LE GA CY	Both the x87/MMX and SSE extensions.
XST ATE _M ASK _GS SE	The Intel Sandy Bridge (formerly Gesher) SSE extension.

`XStateSave`

A pointer to a caller-allocated buffer into which the routine writes an XSTATE_SAVE structure. This structure contains the saved state information for the extended processor features indicated by the *Mask* parameter. The buffer must be large enough to contain this structure.

Return Value

KeSaveExtendedProcessorState returns STATUS_SUCCESS if the call is successful. Possible error return values include the following:

RETURN CODE	DESCRIPTION
STA TUS _IN SUF FICI ENT _RE SO URC ES	A memory allocation operation failed.

Remarks

On x86-based processors that support the XSAVE and XRSTOR instructions, these instructions provide a flexible mechanism to save and restore extended processor state information. **KeSaveExtendedProcessorState** uses these instructions if they are available.

To restore the extended processor state that was saved by **KeSaveExtendedProcessorState**, call the KeRestoreExtendedProcessorState routine.

The *Mask* parameter specifies the extended processor features whose state is to be saved. A **KeRestoreExtendedProcessorState** call restores only the extended processor state that was saved by the **KeSaveExtendedProcessorState** call that saved the state.

Kernel-mode code must save the state of an extended processor feature before it uses that feature, and it must restore the state before it exits.

Interrupt service routines (ISRs) run under severe time constraints that typically prevent them from using extended processor features. However, an ISR can schedule a deferred procedure call (DPC) that uses one or more extended processor features. The DPC routine must save and restore the state of the extended features to preserve the context of the interrupted program in whose process address space the routine runs.

The KeSaveFloatingPointState and KeRestoreFloatingPointState routines save and restore just the floating-point state (the x87/MMX registers) and the SSE state.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Ntoskrnl.lib
DLL	Ntoskrnl.exe
IRQL	"<= DISPATCH_LEVEL"

KeRestoreExtendedProcessorState

KeRestoreFloatingPointState

KeSaveFloatingPointState

RtlGetEnabledExtendedFeatures

XSTATE_SAVE

KeSaveFloatingPointState function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSaveFloatingPointState** routine saves the nonvolatile floating-point context so the caller can carry out floating-point operations.

Syntax

```
NTSTATUS KeSaveFloatingPointState(
  PKFLOATING_SAVE FloatSave
);
```

Parameters

`FloatSave`

Pointer to a caller-allocated resident buffer, which must be at least **sizeof**(KFLOATING_SAVE).

Return Value

KeSaveFloatingPointState returns STATUS_SUCCESS if it saved the current thread's floating-point context and set up a fresh floating-point context for the caller. Otherwise, it returns one of the following error status codes.

RETURN CODE	DESCRIPTION
STATUS_ILLEGAL_FLOAT_CONTEXT	The system is configured to use floating-point emulation, rather than doing floating-point operations in the processors.
STATUS_INSUFFICIENT_RESOURCES	**KeSaveFloatingPointState** could not allocate sufficient memory to save the current thread's floating-point context.

Remarks

A successful call to **KeSaveFloatingPointState** allows the caller to carry out floating-point operations of its own,

but such a caller must restore the previous nonvolatile floating-point context as soon as its floating-point operations are done. Any routine that calls **KeSaveFloatingPointState** must call KeRestoreFloatingPointState before that routine returns control.

If the call to **KeSaveFloatingPointState** is successful, the data at *FloatSave* is opaque to the caller. The caller should not release the memory that it allocated for this data until after the call to KeRestoreFloatingPointState.

In Windows Vista and earlier versions of Windows, a **KeSaveFloatingPointState** call and the corresponding **KeRestoreFloatingPointState** call must occur in a guarded region. That is, the KeEnterGuardedRegion routine must be called before **KeSaveFloatingPointState** is called, and the KeLeaveGuardedRegion routine must be called after **KeRestoreFloatingPointState** is called. No such requirement exists in Windows 7 and later versions of Windows.

For performance reasons, drivers should avoid doing any floating-point operations unless absolutely necessary. The overhead of saving and restoring the current thread's nonvolatile floating-point state degrades the performance of any driver that does floating-point operations.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

PsCreateSystemThread

KeSetCoalescableTimer function

1/25/2019 • 5 minutes to read • Edit Online

The **KeSetCoalescableTimer** routine sets the initial expiration time and period of a timer object and specifies how much delay can be tolerated in the expiration times.

Syntax

```
BOOLEAN KeSetCoalescableTimer(
  PKTIMER       Timer,
  LARGE_INTEGER DueTime,
  ULONG         Period,
  ULONG         TolerableDelay,
  PKDPC         Dpc
);
```

Parameters

`Timer`

A pointer to a timer object. This parameter points to a KTIMER structure, which is an opaque, system structure that represents the timer object. This object must have been previously initialized by the KeInitializeTimerEx or KeInitializeTimer routine.

`DueTime`

Specifies an absolute or relative time at which the timer is to expire. If the value of the *DueTime* parameter is negative, the expiration time is relative to the current system time. Otherwise, the expiration time is absolute. The expiration time is expressed in system time units, which are 100-nanosecond intervals. Absolute expiration times track any changes that are made to the system clock. Relative expiration times are not affected by system clock changes.

`Period`

Specifies the interval between periodic timer expirations in milliseconds. The value of this parameter must not exceed MAXLONG. This parameter is optional and can be set to zero to indicate that the timer is nonperiodic.

`TolerableDelay`

Specifies a tolerance, in milliseconds, for the timer period that *Period* specifies and for the initial time interval that *DueTime* specifies. For a periodic timer, the time interval between two successive timer expirations will be in the range from (*Period* - *TolerableDelay*) to (*Period* + *TolerableDelay*). The initial expiration time will be in the range from *DueTime* to (*DueTime* + *TolerableDelay*). The *TolerableDelay* value cannot be negative.

`Dpc`

A pointer to a DPC object. This parameter points to a KDPC structure, which is an opaque, system structure that represents the DPC object. This object must have been previously initialized by the KeInitializeDpc routine. This parameter is optional and can be specified as **NULL** if the caller does not require a DPC.

Return Value

KeSetCoalescableTimer returns **TRUE** if the timer object was already in the system timer queue. Otherwise, it

returns **FALSE**.

Remarks

This routine does the following:

- Sets the timer to a nonsignaled state.
- Associates the timer with the DPC, if a DPC is specified.
- Cancels the timer if it is already active.
- Makes the timer active and sets the due time and period of the timer to the specified values. The timer can expire immediately if the specified due time has already passed.

The KeSetTimerEx routine is similar to **KeSetCoalescableTimer** but does not accept a *TolerableDelay* parameter. The *TolerableDelay* parameter of **KeSetCoalescableTimer** enables the caller to specify a tolerance for the timer period. A call to **KeSetCoalescableTimer** with *TolerableDelay* = 0 is the same as a call to **KeSetTimerEx**. In many instances, developers can easily modify existing drivers by replacing calls to **KeSetTimerEx** with calls to **KeSetCoalescableTimer**.

If two **KeSetCoalescableTimer** calls specify the same timer object, and the second call occurs before the *DueTime* that is specified for the first call expires, the second call implicitly cancels the timer from the first call. However, if a timer expiration from the first call has already enabled a DPC to run, the DPC might run after the timer is canceled. The second call replaces the pending expiration time from the first call with a new expiration time, and activates the timer again.

If the *Period* parameter is nonzero, the timer is periodic. For a periodic timer, the first timer expiration occurs at the time indicated by the *DueTime* parameter. Later expirations are separated by the interval that is specified by *Period*. If *Period* = 0, the timer is nonperiodic and expires at the time that is indicated by *DueTime*.

If the *Dpc* parameter is non-**NULL**, the routine creates an association between the specified DPC object and the timer object. After the timer expires, the timer service removes the timer object from the system timer queue and sets this object to a signaled state. If a DPC object is associated with the timer object, the timer service inserts the DPC object into the system DPC queue to run as soon as conditions allow.

Only one instance of a particular DPC object can be in the system DPC queue at a time. To avoid potential race conditions, avoid passing the same DPC object to both the **KeSetCoalescableTimer** and KeInsertQueueDpc routines.

Avoid changing the importance or the target processor of a DPC that is associated with an active timer. Either cancel the timer or make sure that the timer has expired before you call a routine such as KeSetImportanceDpc or KeSetTargetProcessorDpcEx to change the DPC settings. For example, if a driver updates the target processor of a DPC while a timer enables the DPC to run, the DPC might run on an arbitrary processor.

A periodic timer automatically restarts as soon as it expires. Therefore, in a multiprocessor system, the DPC for a periodic timer might be running on two or more processors at the same time.

Drivers must cancel any active timers in their Unload routines. Call the KeCancelTimer routine to cancel a timer. If a DPC is associated with a timer that is periodic or that might recently have expired, a driver must wait (for example, by calling the KeFlushQueuedDpcs routine) to free the DPC and its associated data until all pending DPC executions on all processors finish.

KeSetCoalescableTimer uses the *TolerableDelay* parameter to perform timer coalescing. That is, the routine adjusts the expiration times for the timer to coincide with the expiration times of other software timers. Timer coalescing helps increase the length of idle periods so that the operating system can reduce power consumption and improve energy efficiency.

To use timer coalescing effectively, a caller should specify a *TolerableDelay* value of at least 32 milliseconds. This value equals two default system clock intervals of 15.6 milliseconds. If you can, use a larger *TolerableDelay* value, such as 100 milliseconds.

Try to specify the *Period* and *TolerableDelay* values in multiples of 50 milliseconds. Typical *Period* values are 50, 100, 250, 500, and 1000 milliseconds. Typical *TolerableDelay* values are 50, 100, 150, and 250 milliseconds.

Typically, a timer with a large *Period* value can use a proportionally large *TolerableDelay* value. For example, a timer with *Period* = 500 milliseconds might use *TolerableDelay* = 50 milliseconds, but a timer with *Period* = 10 seconds might use *TolerableDelay* = 1 second.

Expiration times are measured relative to the system clock, and the accuracy with which the operating system can detect when a timer expires is limited by the granularity of the system clock. For more information, see Timer Accuracy.

For more information about timer objects, see Timer Objects and DPCs. For more information about timer coalescing, see the Windows Timer Coalescing white paper on the WHDC website.

KeSetEvent function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSetEvent** routine sets an event object to a signaled state if the event was not already signaled, and returns the previous state of the event object.

Syntax

```
LONG KeSetEvent(
  PRKEVENT  Event,
  KPRIORITY Increment,
  BOOLEAN   Wait
);
```

Parameters

`Event`

A pointer to an initialized event object for which the caller provides the storage.

`Increment`

Specifies the priority increment to be applied if setting the event causes a wait to be satisfied.

`Wait`

Specifies whether the call to **KeSetEvent** is to be followed immediately by a call to one of the **KeWait*Xxx*** routines. If **TRUE**, the **KeSetEvent** call must be followed by a call to KeWaitForMultipleObjects, KeWaitForMutexObject, or KeWaitForSingleObject. For more information, see the following Remarks section.

Return Value

If the previous state of the event object was signaled, a nonzero value is returned.

Remarks

Calling **KeSetEvent** causes the event to attain a signaled state. If the event is a notification event, the system attempts to satisfy as many waits as possible on the event object. The event remains signaled until a call to KeClearEvent or KeResetEvent clears it. If the event is a synchronization event, one wait is satisfied before the system automatically clears the event.

The **KeSetEvent** routine might temporarily raise the IRQL. If the *Wait* parameter is **FALSE**, the routine, before it returns, restores the IRQL to the original value that it had at the start of the call.

If *Wait* = **TRUE**, the routine returns without lowering the IRQL. In this case, the **KeSetEvent** call must be immediately followed by a **KeWait*Xxx*** call. By setting *Wait* = **TRUE**, the caller can prevent an unnecessary context switch from occurring between the **KeSetEvent** call and the **KeWait*Xxx*** call. The **KeWait*Xxx*** routine, before it returns, restores the IRQL to its original value at the start of the **KeSetEvent** call. Although the IRQL disables context switches between the two calls, these calls cannot reliably be used as the start and end of an atomic operation. For example, between these two calls, a thread that is running at the same time on another processor might change the state of the event object or of the target of the wait.

A pageable thread or pageable driver routine that runs at IRQL = PASSIVE_LEVEL should never call **KeSetEvent** with the *Wait* parameter set to TRUE. Such a call causes a fatal page fault if the caller happens to be paged out between the calls to **KeSetEvent** and **KeWait*Xxx***.

For more information about event objects, see Event Objects.

If *Wait* is set to **FALSE**, the caller can be running at IRQL <= DISPATCH_LEVEL. Otherwise, callers of **KeSetEvent** must be running at IRQL <= APC_LEVEL and in a nonarbitrary thread context.

Requirements

KeSetImportanceDpc function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSetImportanceDpc** routine specifies how soon the DPC routine is run.

Syntax

```
void KeSetImportanceDpc(
  PRKDPC          Dpc,
  KDPC_IMPORTANCE Importance
);
```

Parameters

`Dpc`

Pointer to the caller's DPC object, which KeInitializeDpc already initialized.

`Importance`

Specifies one of the following system-defined values to determine the behavior of KeInsertQueueDpc and IoRequestDpc when either routine is used to queue the DPC.

LowImportance

Place the DPC at the end of the DPC queue, and do not begin processing of the queue.

MediumImportance

Place the DPC at the end of the DPC queue. If the DPC is assigned to the current processor's DPC queue, begin processing the queue immediately. **MediumImportance** is the default value for *Importance*.

MediumHighImportance

Place the DPC at the end of the DPC queue, and begin processing the queue immediately. MediumHighImportance is available only on Windows Vista and later versions of Windows.

HighImportance

Place the DPC at the beginning of the DPC queue, and begin processing the queue immediately.

Return Value

None

Remarks

The **KeSetImportanceDpc** routine influences how soon a DPC is run after it is queued by determining:

- The location of the DPC within the DPC queue. Typically, the **KeInsertQueueDpc** and **IoRequestDpc** routines place a DPC at the end of the queue. If a driver first calls **KeSetImportanceDpc** with *Importance* = **HighImportance**, **KeInsertQueueDpc** and **IoRequestDpc** will place the DPC at the beginning of the queue.
- When the system begins processing the DPC queue. Typically, **KeInsertQueueDpc** and **IoRequestDpc** immediately begin processing the DPC queue for the current processor. Drivers can specify different values for *Importance* to change this behavior.

By default, DPCs are assigned to the DPC queue for the current processor, so specifying **MediumImportance** or **MediumHighImportance** for *Importance* has the same effect. However, drivers can use KeSetTargetProcessorDpc to change the processor that the DPC will be assigned to.

For Windows Vista and later versions of the Windows operating system, you can use **KeSetImportanceDpc** for threaded DPCs. If the caller sets *Importance* to **HighImportance**, the DPC is placed at the beginning of the queue; otherwise, it is placed at the end. The routine does not affect when the threaded DPC queue is processed. Threaded DPCs are always processed by a dedicated thread at IRQL = PASSIVE_LEVEL. For more information about threaded DPCs, see Threaded DPCs.

Note that a driver must call **KeSetImportanceDpc** before it calls **KeInsertQueueDpc** and **IoRequestDpc** to have any effect.

For more information about how the system processes the DPC queue, see Organization of DPC Queues.

KeSetPriorityThread function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSetPriorityThread** routine sets the run-time priority of a driver-created thread.

Syntax

```
KPRIORITY KeSetPriorityThread(
  PKTHREAD  Thread,
  KPRIORITY Priority
);
```

Parameters

`Thread`

Pointer to the driver-created thread.

`Priority`

Specifies the priority of the driver-created thread, usually to the real-time priority value, LOW_REALTIME_PRIORITY. The value LOW_PRIORITY is reserved for system use.

Return Value

KeSetPriorityThread returns the old priority of the thread.

Remarks

If a call to **KeSetPriorityThread** resets the thread's priority to a lower value, execution of the thread can be rescheduled even if it is currently running or is about to be dispatched for execution.

Requirements

Minimum supported client	Available starting with Windows 2000.

KeGetCurrentThread

KeQueryPriorityThread

KeSetBasePriorityThread

KeSetSystemAffinityThread function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSetSystemAffinityThread** routine sets the system affinity of the current thread.

Syntax

```
void KeSetSystemAffinityThread(
  KAFFINITY Affinity
);
```

Parameters

`Affinity`

A **KAFFINITY**-typed variable that specifies the new system affinity of the current thread.

Return Value

None

Remarks

The implementation of **KeSetSystemAffinityThread** in Windows 7 and later versions of Windows provides compatibility for drivers that were written for earlier versions of Windows, which do not support processor groups. In this implementation, **KeSetSystemAffinityThread** assigns the thread to group 0, and uses the affinity mask to specify a set of logical processors in this group on which the thread can run.

If **KeSetSystemAffinityThread** is called at IRQL <= APC_LEVEL and the call is successful, the new affinity mask takes effect immediately. When the call returns, the calling thread is already running on a processor that is specified in the new affinity mask. If **KeSetSystemAffinityThread** is called at IRQL = DISPATCH_LEVEL and the call is successful, the pending processor change is deferred until the caller lowers the IRQL below DISPATCH_LEVEL.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows. Use KeSetSystemAffinityThread only on systems before Windows Vista. In Windows Vista and later versions of the Windows operating system, use KeSetSystemAffinityThreadEx instead.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IRQL	"<= DISPATCH_LEVEL (see Remarks section)."

KAFFINITY

KeSetSystemAffinityThreadEx

KeSetSystemAffinityThreadEx function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSetSystemAffinityThreadEx** routine sets the system affinity of the current thread.

Syntax

```
KAFFINITY KeSetSystemAffinityThreadEx(
  KAFFINITY Affinity
);
```

Parameters

`Affinity`

A **KAFFINITY**-typed variable that specifies the new system affinity of the current thread.

Return Value

KeSetSystemAffinityThreadEx returns either the previous system affinity of the current thread, or zero to indicate that there was no previous system affinity.

Remarks

KeSetSystemAffinityThreadEx changes the affinity mask of the current thread. The affinity mask identifies a set of processors on which the thread can run. If successful, the routine schedules the thread to run on a processor in this set.

Callers of **KeSetSystemAffinityThreadEx** should save the return value and later pass this value to the **KeRevertToUserAffinityThreadEx** routine to restore the previous affinity mask.

In a multiprocessor system, a kernel-mode driver routine that runs in the context of a user-mode thread might need to call **KeSetSystemAffinityThreadEx** to temporarily change the affinity mask of the thread. Before the routine exits, it should call **KeRevertToUserAffinityThreadEx** to restore the affinity mask of the thread to its original value.

The term *user affinity* refers to the original affinity of the user-mode thread. The affinity that is set by the kernel-mode driver is referred to as the *system affinity*. If a call to **KeSetSystemAffinityThreadEx** replaces the user affinity of a thread with a system affinity, the call returns zero. Later, the driver restores the user affinity by calling **KeRevertToUserAffinityThreadEx** and passing this return value (zero) as the *Affinity* value.

Additionally, a kernel-mode driver routine that requires a particular affinity mask might call another kernel-mode routine that requires a different affinity mask. Each routine can call **KeSetSystemAffinityThreadEx** to set a new affinity mask and then call **KeRevertToUserAffinityThreadEx** to restore the previous affinity mask before returning.

The **KeSetSystemAffinityThreadEx** routine changes the affinity mask of the current thread to the *Affinity* value only if both of the following are true:

- The *Affinity* value is valid (that is, only mask bits that correspond to logical processors are set).
- At least one of the processors that is specified in the *Affinity* value is active.

If either of these conditions is not met, the call to **KeSetSystemAffinityThreadEx** has no effect.

Windows 7 and later versions of Windows support processor groups. Drivers that are designed to handle information about processor groups should use the KeSetSystemGroupAffinityThread routine, which specifies a processor group, instead of **KeSetSystemAffinityThreadEx**, which does not. However, the implementation of **KeSetSystemAffinityThreadEx** in Windows 7 and later versions of Windows provides compatibility for drivers that were written for earlier versions of Windows, which do not support processor groups. In this implementation, **KeSetSystemAffinityThreadEx** assigns the thread to group 0, and uses the affinity mask to specify a set of logical processors in this group on which the thread can run. The routine returns the previous group-relative affinity mask, but not the previous group.

If **KeSetSystemAffinityThreadEx** is called at IRQL <= APC_LEVEL and the call is successful, the new affinity mask takes effect immediately. When the call returns, the calling thread is already running on a processor that is specified in the new affinity mask. If **KeSetSystemAffinityThreadEx** is called at IRQL = DISPATCH_LEVEL and the call is successful, the pending processor change is deferred until the caller lowers the IRQL below DISPATCH_LEVEL.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL (see Remarks section)."

KAFFINITY

KeRevertToUserAffinityThreadEx

KeSetSystemAffinityThread

KeSetSystemGroupAffinityThread

KeSetSystemGroupAffinityThread function

1/25/2019 • 5 minutes to read • Edit Online

The **KeSetSystemGroupAffinityThread** routine changes the group number and affinity mask of the calling thread.

Syntax

```
void KeSetSystemGroupAffinityThread(
  PGROUP_AFFINITY Affinity,
  PGROUP_AFFINITY PreviousAffinity
);
```

Parameters

`Affinity`

A pointer to a GROUP_AFFINITY structure that specifies the new group number and group-relative affinity mask for the calling thread.

`PreviousAffinity`

A pointer to a caller-allocated **GROUP_AFFINITY** structure into which the routine writes information about the previous group affinity of the calling thread. The caller can later use this pointer as an input parameter to the KeRevertToUserGroupAffinityThread routine to restore the previous thread affinity. Frequently, **KeSetSystemGroupAffinityThread** writes values to this structure that are not valid group affinities but that have special meaning to **KeRevertToUserGroupAffinityThread**. Do not supply pointers to these special values as *Affinity* parameters in subsequent **KeSetSystemGroupAffinityThread** calls.

If necessary, the caller can change the thread affinity more than once by calling **KeSetSystemGroupAffinityThread** multiple times. During the first of these calls, the caller should specify a non-**NULL** value for *PreviousAffinity* so that the original thread affinity can be captured and later restored. However, the later calls to **KeSetSystemGroupAffinityThread** can, as an option, set *PreviousAffinity* = **NULL**. For more information, see Remarks.

Return Value

None

Remarks

This routine changes the group number and group-relative affinity mask of the calling thread. The *Affinity* parameter points to a GROUP_AFFINITY structure. The group number and affinity mask in this structure identify a set of processors on which the thread can run. If successful, the routine schedules the thread to run on a processor in this set.

If the *PreviousAffinity* parameter is non-**NULL**, the routine saves information about the previous group affinity, which were in effect at the start of the call, in the **GROUP_AFFINITY** structure that *PreviousAffinity* points to. To restore the previous thread affinity, the caller can supply the pointer to this structure as an input parameter to the KeRevertToUserGroupAffinityThread routine.

In a multiprocessor system, a kernel-mode driver routine that runs in the context of a user-mode thread might need to call **KeSetSystemGroupAffinityThread** to temporarily change the group affinity of the thread. Before the routine exits, it should call **KeRevertToUserGroupAffinityThread** to restore the affinity mask of the thread to its original value.

A process can have affinity for more than one group at a time. However, a thread can be assigned to only one group at any time. That group is always in the affinity of the thread's process. A thread can change the group to which it is assigned by calling **KeSetSystemGroupAffinityThread**.

KeSetSystemGroupAffinityThread changes the group number and affinity mask to the values that are specified in **Affinity* only if the following are true:

- The group number is valid.
- The affinity mask is valid (that is, only mask bits that correspond to logical processors in the group are set).
- At least one of the processors that is specified in the affinity mask is active.

If any of these conditions is not met, the group number and affinity mask of the thread remain unchanged. If *PreviousAffinity* is non-**NULL**, the routine writes zero to both the group number and the affinity mask in **PreviousAffinity*.

Additionally, **KeSetSystemGroupAffinityThread** writes zero to both the group number and the affinity mask in **PreviousAffinity* if the previous group affinity was assigned to the thread in user mode. In response to a **GROUP_AFFINITY** structure in which the group number and affinity mask are both zero, **KeRevertToUserGroupAffinityThread** restores the current user-mode thread affinity. If the user-mode thread affinity changes between the **KeSetSystemGroupAffinityThread** and **KeRevertToUserGroupAffinityThread** calls, the most recent user-mode affinity is assigned to the thread. (An application can call a function such as SetThreadGroupAffinity to change the user-mode group affinity of a thread.)

Before the new affinity mask in **Affinity* takes effect, **KeSetSystemGroupAffinityThread** removes (sets to zero) any affinity mask bits that correspond to processors that are not currently active. In a subsequent **KeSetSystemGroupAffinityThread** call, the value that the routine writes to **PreviousAffinity* might contain an affinity mask that has been modified in this way.

A related routine, KeSetSystemAffinityThreadEx, changes the affinity mask of the calling thread, but this routine, unlike **KeSetSystemGroupAffinityThread**, does not accept a group number as an input parameter. Starting with Windows 7, **KeSetSystemAffinityThreadEx** assumes that the affinity mask refers to processors in group 0, which is compatible with the behavior of this routine in earlier versions of Windows that do not support groups. This behavior ensures that existing drivers that call **KeSetSystemAffinityThreadEx** and that use no group-oriented features will run correctly in multiprocessor systems that have two or more groups. However, drivers that use any group-oriented features in Windows 7 and later versions of the Windows operating system should call **KeSetSystemGroupAffinityThread** instead of **KeSetSystemAffinityThreadEx**.

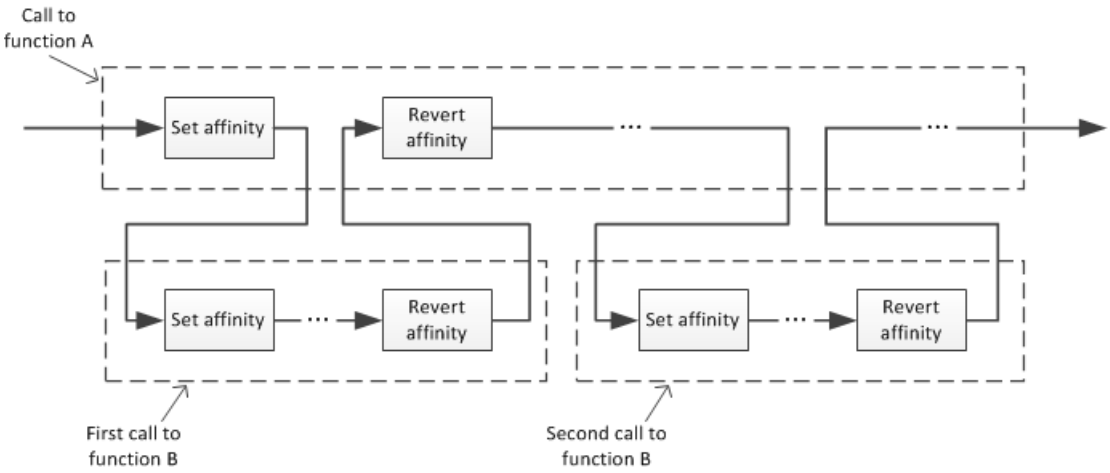
KeSetSystemGroupAffinityThread and **KeRevertToUserGroupAffinityThread** support a variety of calling patterns. Two examples are shown in the following diagrams.

The following diagram represents a driver thread that calls **KeSetSystemGroupAffinityThread** three times to change the thread affinity, and then calls **KeRevertToUserGroupAffinityThread** to restore the original thread affinity.

In the preceding diagram, the three boxes labeled "Set affinity" are calls to **KeSetSystemGroupAffinityThread**, and the box labeled "Revert affinity" is a call to **KeRevertToUserGroupAffinityThread**. The first

KeSetSystemGroupAffinityThread call uses the *PreviousAffinity* output pointer to save the original thread affinity. In the next two calls to **KeSetSystemGroupAffinityThread** (marked with asterisks), the caller sets *PreviousAffinity* to **NULL**. Before the thread exits, it calls **KeRevertToUserGroupAffinityThread** to restore the thread affinity that was saved by the first **KeSetSystemGroupAffinityThread** call.

The following diagram shows a somewhat different calling pattern in which pairs of **KeSetSystemGroupAffinityThread** and **KeRevertToUserGroupAffinityThread** calls are nested. In this diagram, each call to **KeSetSystemGroupAffinityThread** in the driver thread uses the *PreviousAffinity* output parameter to save the previous thread affinity, and each of these calls is paired with a call to **KeRevertToUserGroupAffinityThread** that restores the saved thread affinity.



In the preceding diagram, function A in the driver thread calls function B twice. Assume that on entry to function A, the thread still has the affinity assigned to it by the user-mode application. Thus, the **KeSetSystemGroupAffinityThread** call in function A saves the original, user-mode thread affinity. During the first call to function B, the **KeSetSystemGroupAffinityThread** saves the thread affinity assigned by the driver in function A, and the corresponding call to **KeRevertToUserGroupAffinityThread** restores this affinity. After B returns, the **KeRevertToUserGroupAffinityThread** in A restores the original, user-mode thread affinity. During the second call to B, the **KeSetSystemGroupAffinityThread** call saves the original, user-mode thread affinity, and the corresponding call to **KeRevertToUserGroupAffinityThread** restores this affinity. The point of this example is that function B does not need to know whether the caller (function A) changed the thread affinity to a driver-defined value before calling B.

If **KeSetSystemGroupAffinityThread** is called at IRQL <= APC_LEVEL and the call is successful, the new group affinity takes effect immediately. When the call returns, the calling thread is already running on a processor that is specified in the new group affinity. If **KeSetSystemGroupAffinityThread** is called at IRQL = DISPATCH_LEVEL and the call is successful, the pending processor change is deferred until the caller lowers the IRQL below DISPATCH_LEVEL.

Requirements

GROUP_AFFINITY

KeRevertToUserGroupAffinityThread

KeSetSystemAffinityThreadEx

KeSetTargetProcessorDpc function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSetTargetProcessorDpc** routine specifies the processor that a DPC routine will be run on.

Syntax

```
void KeSetTargetProcessorDpc(
  PRKDPC Dpc,
  CCHAR  Number
);
```

Parameters

`Dpc`

Pointer to the caller's DPC object, which KeInitializeDpc already initialized.

`Number`

Specifies the zero-based number of the target processor on which the DPC should be queued and executed.

Return Value

None

Remarks

On multiprocessor systems, each processor has its own DPC queue. The **KeSetTargetProcessorDpc** routine specifies which processor's queue the system should use when the driver calls KeInsertQueueDpc or IoRequestDpc to queue a DPC to be run later.

Starting with Windows Vista, you can also use **KeSetTargetProcessorDpc** to specify the target processor for threaded DPCs.

A call to **KeSetTargetProcessorDpcEx** that occurs after a DPC object has been queued has no effect on the selection of a processor for the DPC routine to run on. To control the selection of the target processor, a **KeSetTargetProcessorDpc** call must occur before the call to **KeInsertQueueDpc** or **IoRequestDpc** that queues the DPC object.

For more information about DPC queues, see Organization of DPC Queues.

Windows 7 and later versions of Windows support processor groups. Drivers that are designed to handle information about processor groups should use the KeSetTargetProcessorDpcEx routine, which specifies a processor group, instead of **KeSetTargetProcessorDpc**, which does not. However, the implementation of **KeSetTargetProcessorDpc** in Windows 7 and later versions of Windows provides compatibility for drivers that were written for earlier versions of Windows, which do not support processor groups. In this implementation, if *Number* is less than the number of active logical processors in group 0, **KeSetTargetProcessorDpc** sets the target for the DPC to the processor in group 0 that is specified by *Number*. Otherwise, the DPC target does not change.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

IoRequestDpc

KeGetCurrentProcessorNumber

KeInitializeDpc

KeInsertQueueDpc

KeSetImportanceDpc

KeSetTargetProcessorDpcEx

KeSetTargetProcessorDpcEx function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSetTargetProcessorDpcEx** routine specifies the processor that a DPC routine will run on.

Syntax

```
NTSTATUS KeSetTargetProcessorDpcEx(
  PKDPC             Dpc,
  PPROCESSOR_NUMBER ProcNumber
);
```

Parameters

`Dpc`

A pointer to the caller's DPC object. This parameter points to a KDPC structure, which is an opaque, system structure that represents the DPC object. This object must previously have been initialized by the KeInitializeDpc routine.

`ProcNumber`

A pointer to a caller-allocated PROCESSOR_NUMBER structure that identifies the target processor on which the DPC will be queued and executed. This structure specifies a group and a processor within this group.

Return Value

KeSetTargetProcessorDpcEx returns STATUS_SUCCESS if the call is successful. Otherwise, it returns the following:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The *ProcNumber* parameter points to an invalid processor number.

Remarks

Each processor in a multiprocessor system has its own DPC queue. **KeSetTargetProcessorDpcEx** specifies which processor's queue the system should use when the driver calls the KeInsertQueueDpc or IoRequestDpc routine to queue a DPC to be run later.

KeSetTargetProcessorDpcEx can specify the target processor for both ordinary DPCs and threaded DPCs. An ordinary DPC cannot be preempted by even a high-priority thread, but a threaded DPC can be preempted by time-critical threads that have sufficiently high priorities.

A related routine, KeSetTargetProcessorDpc, specifies a target processor for a DPC, but this routine, unlike **KeSetTargetProcessorDpcEx**, does not specify a group for the target processor. Starting with Windows 7, **KeSetTargetProcessorDpc** assumes that the target processor belongs to group 0. This behavior ensures that existing drivers that call **KeSetTargetProcessorDpc** and that use no group-oriented features will run correctly in multiprocessor systems that have two or more groups. However, drivers that use any group-oriented features in Windows 7 and later versions of the Windows operating system should call **KeSetTargetProcessorDpcEx** instead of **KeSetTargetProcessorDpc**.

A call to **KeSetTargetProcessorDpcEx** that occurs after a DPC object has been queued has no effect on the selection of a processor for the DPC routine to run on. To control the selection of the target processor, a **KeSetTargetProcessorDpcEx** call must occur before the call to **KeInsertQueueDpc** or **IoRequestDpc** that queues the DPC object.

For more information about DPC queues, see Organization of DPC Queues.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KeSetTargetProcessorDpc

PROCESSOR_NUMBER

KeSetTimer function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSetTimer** routine sets the absolute or relative interval at which a timer object is to be set to a signaled state and, optionally, supplies a CustomTimerDpc routine to be executed when that interval expires.

Syntax

```
BOOLEAN KeSetTimer(
  PKTIMER       Timer,
  LARGE_INTEGER DueTime,
  PKDPC         Dpc
);
```

Parameters

`Timer`

Pointer to a timer object that was initialized with KeInitializeTimer or KeInitializeTimerEx.

`DueTime`

Specifies the absolute or relative time at which the timer is to expire. If the value of the *DueTime* parameter is negative, the expiration time is relative to the current system time. Otherwise, the expiration time is absolute. The expiration time is expressed in system time units (100-nanosecond intervals). Absolute expiration times track any changes in the system time; relative expiration times are not affected by system time changes.

`Dpc`

Pointer to a DPC object that was initialized by KeInitializeDpc. This parameter is optional.

Return Value

If the timer object was already in the system timer queue, **KeSetTimer** returns **TRUE**.

Remarks

The **KeSetTimer** routine does the following:

- Computes the expiration time.
- Sets the timer to a not-signaled state.
- Inserts the timer object in the system timer queue.

If the timer object was already in the timer queue, it is implicitly canceled before being set to the new expiration time. A call to **KeSetTimer** before the previously specified *DueTime* has expired cancels both the timer and the call to the *Dpc*, if any, associated with the previous call.

If the *Dpc* parameter is specified, a DPC object is associated with the timer object. When the timer expires, the timer object is removed from the system timer queue and its state is set to signaled. If a DPC object was associated with the timer when it was set, the DPC object is inserted in the system DPC queue to be executed as soon as conditions permit after the timer interval expires.

Expiration times are measured relative to the system clock, and the accuracy with which the operating system can detect when a timer expires is limited by the granularity of the system clock. For more information, see Timer Accuracy.

Only one instantiation of a given DPC object can be queued at any given moment. To avoid potential race conditions, the DPC passed to **KeSetTimer** should not be passed to KeInsertQueueDpc.

Drivers must cancel any active timers in their Unload routines. Use KeCancelTimer to cancel any timers.

Callers of **KeSetTimer** can specify one expiration time for a timer. To set a recurring timer use KeSetTimerEx.

For more information about timer objects, see Timer Objects and DPCs.

Requirements

Minimum supported client	Available starting with Windows 2000.

KeWaitForSingleObject

KeSetTimerEx function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSetTimerEx** routine sets the absolute or relative interval at which a timer object is to be set to a signaled state, optionally supplies a CustomTimerDpc routine to be executed when that interval expires, and optionally supplies a recurring interval for the timer.

Syntax

```
BOOLEAN KeSetTimerEx(
  PKTIMER       Timer,
  LARGE_INTEGER DueTime,
  LONG          Period,
  PKDPC         Dpc
);
```

Parameters

`Timer`

Pointer to a timer object that was initialized with KeInitializeTimer or KeInitializeTimerEx.

`DueTime`

Specifies the absolute or relative time at which the timer is to expire. If the value of the *DueTime* parameter is negative, the expiration time is relative to the current system time. Otherwise, the expiration time is absolute. The expiration time is expressed in system time units (100-nanosecond intervals). Absolute expiration times track any changes in the system time; relative expiration times are not affected by system time changes.

`Period`

Specifies an optional recurring interval for the timer in milliseconds. Must be a value that is greater than or equal to zero. If the value of this parameter is zero, the timer is a nonperiodic timer that does not automatically re-queue itself.

`Dpc`

Pointer to a DPC object that was initialized by KeInitializeDpc. This parameter is optional.

Return Value

If the timer object was already in the system timer queue, **KeSetTimerEx** returns **TRUE**.

Remarks

The **KeSetTimerEx** routine does the following:

- Computes the expiration time.
- Sets the timer to a not-signaled state.
- Sets the recurring interval for the timer, if one was specified.
- Inserts the timer object in the system timer queue.

If the timer object was already in the timer queue, it is implicitly canceled before being set to the new expiration time. A call to **KeSetTimerEx** before the previously specified *DueTime* has expired cancels both the timer and the call to the *Dpc*, if any, associated with the previous call.

Expiration times are measured relative to the system clock, and the accuracy with which the operating system can detect when a timer expires is limited by the granularity of the system clock. For more information, see Timer Accuracy.

If the *Dpc* parameter is specified, a DPC object is associated with the timer object. When the timer expires, the timer object is removed from the system timer queue and it is set to a signaled state. If a DPC object was associated with the timer when it was set, the DPC object is inserted in the system DPC queue to be executed as soon as conditions permit after the timer interval expires.

A DPC routine cannot deallocate a periodic timer. A DPC routine can deallocate a nonperiodic timer.

Note that a periodic timer is automatically restarted as soon as it expires. Thus, on a multiprocessor machine, the DPC for a periodic timer can be running on two processors simultaneously.

Only one instantiation of a given DPC object can be queued at any given moment. To avoid potential race conditions, the DPC passed to **KeSetTimerEx** should not be passed to KeInsertQueueDpc.

Drivers must cancel any active timers in their Unload routines. Use KeCancelTimer to cancel any timers.

For more information about timer objects, see Timer Objects and DPCs.

KeWaitForMultipleObjects

KeWaitForSingleObject

KeStallExecutionProcessor function

1/25/2019 • 2 minutes to read • Edit Online

The **KeStallExecutionProcessor** routine stalls the caller on the current processor for a specified time interval.

Syntax

```
NTHALAPI VOID KeStallExecutionProcessor(
  ULONG MicroSeconds
);
```

Parameters

`MicroSeconds`

Specifies the number of microseconds to stall.

Return Value

None

Remarks

KeStallExecutionProcessor is a processor-dependent routine that busy-waits for at least the specified number of microseconds, but not significantly longer.

This routine is for use by device drivers and other software that must wait for an interval of less than a clock tick but more than for a few instructions. If you use this routine you must minimize the stall interval, typically to less than 50 microseconds. If a driver must wait for a longer interval, you should use a different synchronization technique.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Hal.lib
DLL	Hal.dll

KeDelayExecutionThread

KeWaitForMultipleObjects

KeWaitForSingleObject

KeSynchronizeExecution function

1/25/2019 • 2 minutes to read • Edit Online

The **KeSynchronizeExecution** routine synchronizes the execution of the specified routine with the interrupt service routine (ISR) that is assigned to a set of one or more interrupt objects.

Syntax

```
BOOLEAN KeSynchronizeExecution(
  PKINTERRUPT            Interrupt,
  PKSYNCHRONIZE_ROUTINE  SynchronizeRoutine,
  __drv_aliasesMem PVOID SynchronizeContext
);
```

Parameters

`Interrupt`

A pointer to a set of interrupt objects. The caller obtained this pointer from the IoConnectInterrupt or IoConnectInterruptEx routine.

`SynchronizeRoutine`

Specifies a caller-supplied SynchCritSection routine whose execution is to be synchronized with the execution of the ISR assigned to the interrupt objects.

`SynchronizeContext`

A pointer to a caller-supplied context value to be passed to the SynchCritSection routine when it is called.

Return Value

KeSynchronizeExecution returns **TRUE** if the operation succeeds. Otherwise, it returns **FALSE**.

Remarks

When this routine is called, the following occurs:

1. The IRQL is raised to the *SynchronizeIrql* value specified in the call to IoConnectInterrupt or IoConnectInterruptEx.
2. Access to *SynchronizeContext* is synchronized with the assigned ISR by acquiring the associated interrupt object spin lock (or system event object, in the case of an ISR that runs at PASSIVE_LEVEL).
3. The specified SynchCritSection routine is called with the *SynchronizeContext* value as its parameter.

If the ISR runs at DIRQL >= DISPATCH_LEVEL, the *SynchCritSection* routine runs at the same DIRQL and must therefore run for as brief a time as possible to avoid delaying other high-priority tasks.

Callers of **KeSynchronizeExecution** must be running at IRQL <= DIRQL; that is, at an IRQL that is less than or equal to the value of the **SynchronizeIrql** value that the caller specified when it registered its ISR with **IoConnectInterrupt** or **IoConnectInterruptEx**.

Starting with Windows 8, a driver can call **KeSynchronizeExecution** to synchronize execution of a *SynchCritSection* routine with an ISR that runs at IRQL = PASSIVE_LEVEL. In earlier versions of Windows, **KeSynchronizeExecution** can synchronize execution only with an ISR that runs at IRQL >= DISPATCH_LEVEL. For more information, see Using Passive-Level Interrupt Service Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IoConnectInterruptEx

KeTestSpinLock function

1/25/2019 • 2 minutes to read • Edit Online

The **KeTestSpinLock** routine tests for the availability of a spin lock.

Syntax

```
BOOLEAN KeTestSpinLock(
  PKSPIN_LOCK SpinLock
);
```

Parameters

`SpinLock`

A pointer to a spin lock. The spin lock must have been initialized by calling KeInitializeSpinLock.

Return Value

KeTestSpinLock returns **FALSE** if the spin lock is currently being held. Otherwise, it returns **TRUE**.

Remarks

This routine enables the caller that is running at a low IRQL to test the spin lock. If **KeTestSpinLock** returns **TRUE**, the caller can try to acquire the spin lock with a high probability of immediate success.

This routine neither raises nor lowers the IRQL, and it never acquires the spin lock.

For more information about spin locks, see Spin Locks.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	See Remarks section.

KeAcquireSpinLock

KeInitializeSpinLock

KeReleaseSpinLock

KeTryToAcquireSpinLockAtDpcLevel function

1/25/2019 • 2 minutes to read • Edit Online

The **KeTryToAcquireSpinLockAtDpcLevel** routine attempts to acquire a spin lock at DISPATCH_LEVEL.

Syntax

```
BOOLEAN KeTryToAcquireSpinLockAtDpcLevel(
  PKSPIN_LOCK SpinLock
);
```

Parameters

`SpinLock`

Specifies the spin lock to acquire. The spin lock must have already been initialized by KeInitializeSpinLock.

Return Value

KeTryToAcquireSpinLockAtDpcLevel returns **TRUE** if the spin lock has been acquired, and **FALSE** if the spin lock is already being held and cannot be acquired.

Remarks

If the specified spin lock is not busy, the **KeTryToAcquireSpinLockAtDpcLevel** routine acquires the spin lock (see KeAcquireSpinLock for details) and returns **TRUE**. If the spin lock has already been acquired, the routine immediately returns **FALSE**.

If the spin lock is acquired, the caller can release it by using the KeReleaseSpinLock routine.

If you want the driver to block when it is unable to acquire the spin lock, use KeAcquireSpinLockAtDpcLevel instead.

For more information about spin locks, see Spin Locks.

Requirements

Minimum supported client	Available in Windows Server 2003 with Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

KeWaitForMultipleObjects function

1/25/2019 • 6 minutes to read • Edit Online

The **KeWaitForMultipleObjects** routine puts the current thread into an alertable or nonalertable wait state until any or all of a number of dispatcher objects are set to a signaled state or (optionally) until the wait times out.

Syntax

```
NTSTATUS KeWaitForMultipleObjects(
  ULONG                                                                  Count,
  PVOID []                                                               Object,
  WAIT_TYPE                                                              WaitType,
  KWAIT_REASON                                                           WaitReason,
  __drv_strictType(KPROCESSOR_MODE / enum _MODE,__drv_typeConst)KPROCESSOR_MODE WaitMode,
  BOOLEAN                                                                Alertable,
  PLARGE_INTEGER                                                         Timeout,
  PKWAIT_BLOCK                                                           WaitBlockArray
);
```

Parameters

`Count`

The number of objects to be waited on. This parameter specifies the number of elements in the array pointed to by the *Object* parameter.

`Object`

A pointer to an array of pointers to dispatcher objects (events, mutexes, semaphores, threads, and timers) for which the caller supplies the storage. Both the pointer array and the dispatcher objects must reside in nonpaged system memory. For more information, see Remarks.

`WaitType`

The type of wait operation to perform. Specify either **WaitAll**, indicating that all of the specified objects must attain a signaled state before the wait is satisfied; or **WaitAny**, indicating that any one of the objects must attain a signaled state before the wait is satisfied.

`WaitReason`

The reason for the wait. Drivers should set this value to **Executive** or, if the driver is doing work on behalf of a user and is running in the context of a user thread, to **UserRequest**.

`WaitMode`

Whether the caller waits in **KernelMode** or **UserMode**. Intermediate and lowest-level drivers should specify **KernelMode**. If the set of objects waited on includes a mutex, the caller must specify **KernelMode**.

`Alertable`

A Boolean value that indicates whether the thread can be alerted while it is in the waiting state.

`Timeout`

A pointer to a time-out value that specifies the absolute or relative time, in 100-nanosecond units, at which the wait

is to be completed.

A positive value specifies an absolute time, relative to January 1, 1601. A negative value specifies an interval relative to the current time. Absolute expiration times track any changes in the system time; relative expiration times are not affected by system time changes.

If **Timeout* = 0, the routine returns without waiting. If the caller supplies a **NULL** pointer, the routine waits indefinitely until any or all of the dispatcher objects are set to the signaled state. For more information, see the following Remarks section.

`WaitBlockArray`

A pointer to a caller-allocated **KWAIT_BLOCK** array. If *Count* <= THREAD_WAIT_OBJECTS, then *WaitBlockArray* can be **NULL**. Otherwise, this parameter must point to a memory buffer of **sizeof**(**KWAIT_BLOCK**) * *Count* bytes. The routine uses this buffer for record-keeping while performing the wait operation. The *WaitBlockArray* buffer must reside in nonpaged system memory. For more information, see Remarks.

Return Value

KeWaitForMultipleObjects can return one of the following:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The caller specified **WaitAll** for the *WaitType* parameter and all dispatcher objects in the *Object* array have been set to the signaled state.
STATUS_ALERTED	The wait was interrupted to deliver an alert to the calling thread.
STATUS_USER_APC	The wait was interrupted to deliver a user asynchronous procedure call (APC) to the calling thread.
STATUS_TIMEOUT	A time-out occurred before the specified set of wait conditions was met. This value can be returned when an explicit time-out value of zero is specified, but the specified set of wait conditions cannot be met immediately.

Note that the NT_SUCCESS macro recognizes all of these status values as "success" values.

Remarks

Each thread object has a built-in array of wait blocks that can be used to wait for several objects to be set concurrently. Whenever possible, the built-in array of wait blocks should be used in a wait-multiple operation

because no additional wait block storage needs to be allocated and later deallocated. However, if the number of objects that must be waited on concurrently is greater than the number of built-in wait blocks, use the *WaitBlockArray* parameter to specify an alternate set of wait blocks to be used in the wait operation. Drivers only need to allocate a sufficiently large memory buffer for *WaitBlockArray*. The buffer does not need to be initialized; however, it must be allocated from nonpaged system memory. If the *WaitMode* parameter is **UserMode**, the *WaitBlockArray* buffer must not be allocated on the local stack because the stack might be swapped out of memory. Drivers can treat this buffer as an opaque structure and can free it after the routine returns. If either *Count* > MAXIMUM_WAIT_OBJECTS or if *WaitBlockArray* is **NULL** and *Count* > THREAD_WAIT_OBJECTS, the system issues Bug Check 0xC (MAXIMUM_WAIT_OBJECTS_EXCEEDED).

The current state for each of the specified objects is examined to determine whether the wait can be satisfied immediately. If the necessary side effects are performed on the objects, an appropriate value is returned.

If the wait cannot be satisfied immediately and either no time-out value or a nonzero time-out value has been specified, the current thread is put in a waiting state and a new thread is selected for execution on the current processor. If no *Timeout* is supplied, the calling thread will remain in a wait state until the conditions specified by *Object* and *WaitType* are satisfied.

If *Timeout* is specified, the wait will be automatically satisfied if none of the specified wait conditions is met when the given interval expires.

A time-out value of zero allows the testing of a set of wait conditions, conditionally performing any side effects if the wait can be immediately satisfied, as in the acquisition of a mutex.

Time-out intervals are measured relative to the system clock, and the accuracy with which the operating system can detect the end of a time-out interval is limited by the granularity of the system clock. For more information, see Timer Accuracy.

The *Alertable* parameter determines when the thread can be alerted and its wait state consequently aborted. For additional information, see Waits and APCs.

The array pointed to by the *Objects* parameter must reside in nonpaged system memory. Typically, a driver allocates the storage for the *Objects* array on the local stack. The *Objects* array can be allocated on the local stack regardless of the value of the *WaitMode* parameter.

The dispatcher objects pointed to by the elements in the *Objects* array must reside in nonpaged system memory. If the *WaitMode* parameter is **UserMode**, the kernel stack can be swapped out during the wait. Consequently, a caller must never attempt to pass parameters on the stack when calling **KeWaitForMultipleObjects** with the **UserMode** argument. If you allocate the event on the stack, you must set the *WaitMode* parameter to **KernelMode**.

A special consideration applies when the *Object* parameter passed to **KeWaitForMultipleObjects** is a mutex. If the dispatcher object waited on is a mutex, APC delivery is the same as for all other dispatcher objects during the wait. However, after **KeWaitForMultipleObjects** returns with STATUS_SUCCESS and the thread actually holds the mutex, only special kernel-mode APCs are delivered. Delivery of all other APCs, both kernel-mode and user-mode, is disabled. This restriction on the delivery of APCs persists until the mutex is released.

It is especially important to check the return value of **KeWaitForMultipleObjects** when the *WaitMode* parameter is **UserMode** or *Alertable* is **TRUE**, because **KeWaitForMultipleObjects** might return early with a status of STATUS_USER_APC or STATUS_ALERTED.

All long term waits that can be aborted by a user should be **UserMode** waits and *Alertable* should be set to **FALSE**.

Where possible, *Alertable* should be set to **FALSE** and *WaitMode* should be set to **KernelMode**, in order to reduce driver complexity. The principal exception to this is when the wait is a long-term wait.

A mutex can be recursively acquired only MINLONG times. If this limit is exceeded, the routine raises a

STATUS_MUTANT_LIMIT_EXCEEDED exception.

Callers of **KeWaitForMultipleObjects** can be running at IRQL <= DISPATCH_LEVEL. However, if *Timeout* = **NULL** or **Timeout* != 0, the caller must be running at IRQL <= APC_LEVEL and in a nonarbitrary thread context. (If *Timeout* != **NULL** and **Timeout* = 0, the caller must be running at IRQL <= DISPATCH_LEVEL.)

Requirements

KeWaitForSingleObject

KeWaitForSingleObject function

1/25/2019 • 5 minutes to read • Edit Online

The **KeWaitForSingleObject** routine puts the current thread into a wait state until the given dispatcher object is set to a signaled state or (optionally) until the wait times out.

Syntax

```
NTSTATUS KeWaitForSingleObject(
  PVOID                                                                Object,
  KWAIT_REASON                                                         WaitReason,
  __drv_strictType(KPROCESSOR_MODE / enum _MODE,__drv_typeConst)KPROCESSOR_MODE WaitMode,
  BOOLEAN                                                              Alertable,
  PLARGE_INTEGER                                                       Timeout
);
```

Parameters

`Object`

Pointer to an initialized dispatcher object (event, mutex, semaphore, thread, or timer) for which the caller supplies the storage.

`WaitReason`

Specifies the reason for the wait. A driver should set this value to **Executive**, unless it is doing work on behalf of a user and is running in the context of a user thread, in which case it should set this value to **UserRequest**.

`WaitMode`

Specifies whether the caller waits in **KernelMode** or **UserMode**. Lowest-level and intermediate drivers should specify **KernelMode**. If the given *Object* is a mutex, the caller must specify **KernelMode**.

`Alertable`

Specifies a Boolean value that is **TRUE** if the wait is alertable and **FALSE** otherwise.

`Timeout`

Pointer to a time-out value that specifies the absolute or relative time, in 100-nanosecond units, at which the wait is to be completed.

A positive value specifies an absolute time, relative to January 1, 1601. A negative value specifies an interval relative to the current time. Absolute expiration times track any changes in the system time; relative expiration times are not affected by system time changes.

If **Timeout* = 0, the routine returns without waiting. If the caller supplies a **NULL** pointer, the routine waits indefinitely until the dispatcher object is set to the signaled state. For more information, see the following Remarks section.

Return Value

KeWaitForSingleObject can return one of the following:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The dispatcher object specified by the *Object* parameter satisfied the wait.
STATUS_ALERTED	The wait was interrupted to deliver an alert to the calling thread.
STATUS_USER_APC	The wait was interrupted to deliver a user asynchronous procedure call (APC) to the calling thread.
STATUS_TIMEOUT	A time-out occurred before the object was set to a signaled state. This value can be returned when the specified set of wait conditions cannot be immediately met and *Timeout* is set to zero.

Note that the NT_SUCCESS macro recognizes all of these status values as "success" values.

Remarks

The current state of the specified *Object* is examined to determine whether the wait can be satisfied immediately. If so, the necessary side effects are performed on the object. Otherwise, the current thread is put in a waiting state and a new thread is selected for execution on the current processor.

The *Alertable* parameter determines when the thread can be alerted and its wait state consequently aborted. For additional information, see Waits and APCs.

A special consideration applies when the *Object* parameter passed to **KeWaitForSingleObject** is a mutex. If the dispatcher object waited on is a mutex, APC delivery is the same as for all other dispatcher objects during the wait. However, after **KeWaitForSingleObject** returns with STATUS_SUCCESS and the thread actually holds the mutex, only special kernel-mode APCs are delivered. Delivery of all other APCs, both kernel-mode and user-mode, is disabled. This restriction on the delivery of APCs persists until the mutex is released.

If the *WaitMode* parameter is **UserMode**, the kernel stack can be swapped out during the wait. Consequently, a caller must never attempt to pass parameters on the stack when calling **KeWaitForSingleObject** using the **UserMode** argument. If you allocate the event on the stack, you must set the *WaitMode* parameter to **KernelMode**.

It is especially important to check the return value of **KeWaitForSingleObject** when the *WaitMode* parameter is **UserMode** or *Alertable* is **TRUE**, because **KeWaitForSingleObject** might return early with a status of STATUS_USER_APC or STATUS_ALERTED.

All long-term waits that can be aborted by a user should be **UserMode** waits and *Alertable* should be set to **FALSE**.

Where possible, *Alertable* should be set to **FALSE** and *WaitMode* should be set to **KernelMode**, in order to reduce driver complexity. The principal exception to this is when the wait is a long-term wait.

If a **NULL** pointer is supplied for *Timeout*, the calling thread remains in a wait state until the *Object* is signaled.

A time-out value of zero allows the testing of a set of wait conditions and for the conditional performance of any side effects if the wait can be immediately satisfied, as in the acquisition of a mutex.

Time-out intervals are measured relative to the system clock, and the accuracy with which the operating system can detect the end of a time-out interval is limited by the granularity of the system clock. For more information, see Timer Accuracy.

A mutex can be recursively acquired only MINLONG times. If this limit is exceeded, the routine raises a STATUS_MUTANT_LIMIT_EXCEEDED exception.

Callers of **KeWaitForSingleObject** must be running at IRQL <= DISPATCH_LEVEL. However, if *Timeout* = **NULL** or **Timeout* != 0, the caller must be running at IRQL <= APC_LEVEL and in a nonarbitrary thread context. (If *Timeout* != **NULL** and **Timeout* = 0, the caller must be running at IRQL <= DISPATCH_LEVEL.)

KeWaitForMutexObject is a macro that converts to **KeWaitForSingleObject**, which can be used instead.

For better performance, use fast mutexes or guarded mutexes. For more information, see Alternatives to Mutex Objects.

For more information about mutex objects, see Mutex Objects.

A mutex can be recursively acquired only MINLONG times. If this limit is exceeded, the routine raises a STATUS_MUTANT_LIMIT_EXCEEDED exception.

Callers of **KeWaitForMutexObject** must be running at IRQL <= DISPATCH_LEVEL. However, if *Timeout* = **NULL** or **Timeout* != 0, the caller must be running at IRQL <= APC_LEVEL and in a nonarbitrary thread context. KIPI_BROADCAST_WORKER callback function

1/25/2019 • 2 minutes to read • Edit Online

The *IpiGenericCall* routine runs simultaneously on all processors.

Syntax

```
KIPI_BROADCAST_WORKER KipiBroadcastWorker;

ULONG_PTR KipiBroadcastWorker(
  ULONG_PTR Argument
)
{...}
```

Parameters

`Argument`

Supplies the value that was passed to the KeIpiGenericCall routine that called *IpiGenericCall*.

Return Value

IpiGenericCall returns a driver-defined value. If *IpiGenericCall* ran on the same processor that called **KeIpiGenericCall**, **KeIpiGenericCall** returns the driver-defined value that *IpiGenericCall* returns. Otherwise, the value is ignored.

Remarks

IpiGenericCall routines run at IRQL = IPI_LEVEL, which is greater than DIRQL for every device. *IpiGenericCall* routines must satisfy the same restrictions as bug check callback routines. For more information about these restrictions, see Writing a Bug Check Callback Routine.

Examples

To define an *IpiGenericCall* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define an *IpiGenericCall* callback routine that is named `MyIpiGenericCall`, use the KIPI_BROADCAST_WORKER type as shown in this code example:

```
KIPI_BROADCAST_WORKER MyIpiGenericCall;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
ULONG_PTR
  MyIpiGenericCall(
    ULONG_PTR  Argument
    )
  {
      // Function body
  }
```

The KIPI_BROADCAST_WORKER function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the KIPI_BROADCAST_WORKER function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at IPI_LEVEL.

KMESSAGE_SERVICE_ROUTINE callback function

1/25/2019 • 2 minutes to read • Edit Online

An *InterruptMessageService* routine services a message-signaled interrupt.

Syntax

```
KMESSAGE_SERVICE_ROUTINE KmessageServiceRoutine;

BOOLEAN KmessageServiceRoutine(
  _KINTERRUPT *Interrupt,
  PVOID ServiceContext,
  ULONG MessageID
)
{...}
```

Parameters

`Interrupt`

A pointer to the KINTERRUPT structure for the interrupt. The driver received this pointer in the call to the IoConnectInterruptEx routine that registered the driver's *InterruptMessageService* routine.

`ServiceContext`

The *ServiceContext* value that the driver passed to IoConnectInterruptEx when the *InterruptMessageService* routine was registered.

`MessageID`

Return Value

The *InterruptMessageService* routine returns **TRUE** if the interrupt is one handled by the *InterruptMessageService* routine. Otherwise, it returns **FALSE**.

Remarks

Drivers use IoConnectInterruptEx to register an *InterruptMessageService* routine to handle their message-signaled interrupts. A driver can subsequently unregister the routine by calling IoDisconnectInterruptEx. Message-signaled interrupts are supported starting with Windows Vista.

The system can call an *InterruptMessageService* routine even when the routine's interrupt has not occurred. For example, if a message-signaled interrupt is shared, *InterruptMessageService* can be called for interrupts belonging to other devices. The routine must check whether the value for the *ServiceContext* parameter matches the value passed to **IoConnectInterruptEx**. If the value does match, *InterruptMessageService* handles the interrupt and returns **TRUE**. Otherwise, *InterruptMessageService* does not handle the interrupt and returns **FALSE**.

Note that if the system receives multiple identical interrupts over a short time interval, it can combine these into a single call to *InterruptMessageService*. The routine must be written to handle multiple identical interrupts within a single call.

Message-signaled interrupts are similar in behavior to edge-triggered interrupts. The device sends an interrupt

request but does not receive any hardware acknowledgment that the request was received.

An *InterruptMessageService* executes at an IRQL greater than or equal to the maximum device IRQL (DIRQL) for every interrupt the routine handles.

Examples

To define an *InterruptMessageService* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define an *InterruptMessageService* callback routine that is named `MyInterruptMessageService`, use the KMESSAGE_SERVICE_ROUTINE type as shown in this code example:

```
KMESSAGE_SERVICE_ROUTINE MyInterruptMessageService;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
BOOLEAN
  MyInterruptMessageService(
    struct _KINTERRUPT  *Interrupt,
    PVOID  ServiceContext,
    ULONG  MessageId
    )
  {
      // Function body
  }
```

The KMESSAGE_SERVICE_ROUTINE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the KMESSAGE_SERVICE_ROUTINE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	See Remarks section.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

IO_INTERRUPT_MESSAGE_INFO

IoConnectInterruptEx

IoDisconnectInterruptEx

KSERVICE_ROUTINE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *InterruptService* routine (ISR) quickly services a device interrupt and schedules post-interrupt processing of received data, if necessary.

Syntax

```
KSERVICE_ROUTINE KserviceRoutine;

BOOLEAN KserviceRoutine(
  _KINTERRUPT *Interrupt,
  PVOID ServiceContext
)
{...}
```

Parameters

`Interrupt`

Caller-supplied pointer to the KINTERRUPT structure for the interrupt.

`ServiceContext`

Caller-supplied pointer to context information, specified in a previous call to IoConnectInterrupt or IoConnectInterruptEx.

Return Value

If the routine determines that the interrupt did not come from one of the driver's devices, it must return **FALSE**. Otherwise, the routine must service the interrupt and return **TRUE**.

Remarks

To register an ISR for a specific interrupt vector and processor affinity, a driver must call IoConnectInterrupt or IoConnectInterruptEx.

A driver's *InterruptService* routine (ISR) executes in an interrupt context, at some system-assigned DIRQL, as specified by the *SynchronizeIrql* parameter to **IoConnectInterrupt**. (Other devices, with higher DIRQL values, can interrupt the ISR.)

Before the system calls an ISR, it acquires the interrupt's spin lock (the *SpinLock* parameter to **IoConnectInterrupt**), so the ISR cannot simultaneously execute on another processor. After the ISR returns, the system releases the spin lock.

An ISR must first determine if the interrupt came from one of the driver's devices, by examining context information supplied by *Context*. If the interrupt is not from one of the driver's devices, the routine must immediately return **FALSE** so the I/O manager can call other drivers that have registered ISRs for the same processor and interrupt vector.

For more information about implementing ISRs, see Interrupt Service Routines.

Examples

To define an *InterruptService* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define an *InterruptService* callback routine that is named `MyInterruptService`, use the KSERVICE_ROUTINE type as shown in this code example:

```
KSERVICE_ROUTINE MyInterruptService;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
BOOLEAN
  MyInterruptService(
    struct _KINTERRUPT  *Interrupt,
    PVOID  ServiceContext
    )
  {
      // Function body
  }
```

The KSERVICE_ROUTINE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the KSERVICE_ROUTINE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at DIRQL (see Remarks section).

KSTART_ROUTINE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *ThreadStart* routine provides an entry point for a driver-created system thread.

Syntax

```
KSTART_ROUTINE KstartRoutine;

void KstartRoutine(
  PVOID StartContext
)
{...}
```

Parameters

`StartContext`

A caller-supplied pointer to driver-defined context information that is specified in the *StartContext* parameter a previous call to PsCreateSystemThread.

Return Value

None

Requirements

Minimum supported client	Supported starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at PASSIVE_LEVEL.

PsCreateSystemThread

KSYNCHRONIZE_ROUTINE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *SynchCritSection* routine is used to access hardware resources or driver data that are shared with a driver's InterruptService routine.

Syntax

```
KSYNCHRONIZE_ROUTINE KsynchronizeRoutine;

BOOLEAN KsynchronizeRoutine(
  PVOID SynchronizeContext
)
{...}
```

Parameters

`SynchronizeContext`

Caller-supplied context information, specified by the driver's call to KeSynchronizeExecution.

Return Value

If the routine's operation succeeds, the routine should return **TRUE**; otherwise, it should return **FALSE**. (Success and failure of this routine are driver-defined.) The specified return value becomes the return value for **KeSynchronizeExecution**.

Remarks

Drivers must use *SynchCritSection* routines to access hardware resources or driver data that can also be accessed by an *InterruptService* routine (ISR).

The system calls a driver's *SynchCritSection* routine when the driver calls KeSynchronizeExecution. When a driver calls **KeSynchronizeExecution**, it specifies the address of a *SynchCritSection* routine, context information for the routine, and an interrupt object pointer. The **KeSynchronizeExecution** routine acquires the interrupt object's spin lock, then calls the *SynchCritSection* routine.

A driver's *SynchCritSection* routine executes at the same IRQL as the ISR with which it is associated. Specifically, it executes at some system-assigned DIRQL, as specified by the *SynchronizeIrql* parameter to IoConnectInterrupt. (Other devices, with higher DIRQL values, can interrupt a *SynchCritSection* routine.)

Examples

To define a *SynchCritSection* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *SynchCritSection* callback routine that is named `MySynchCritSection`, use the KSYNCHRONIZE_ROUTINE type as shown in this code example:

```
KSYNCHRONIZE_ROUTINE MySynchCritSection;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
BOOLEAN
  MySynchCritSection(
    PVOID  SynchronizeContext
    )
  {
      // Function body
  }
```

The KSYNCHRONIZE_ROUTINE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the KSYNCHRONIZE_ROUTINE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at DIRQL (see Remarks section).

MM_MDL_ROUTINE callback function

1/25/2019 • 2 minutes to read • Edit Online

A driver-supplied callback routine that is invoked after a memory descriptor list (MDL) is mapped by calling the MmMapMdl function.

Syntax

```
MM_MDL_ROUTINE MmMdlRoutine;

void MmMdlRoutine(
  PVOID DriverContext,
  PVOID MappedVa
)
{...}
```

Parameters

`DriverContext`

A pointer to a driver-defined context. The driver's callback function can store any status information in the driver context and then examine the value, when the callback is invoked.

`MappedVa`

A pointer to a buffer that contains the system virtual address of the mapping.

Return Value

This callback function does not return a value.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	wdm.h
IRQL	"<=DISPATCH_LEVEL"

See Also

MmMapMdl

MmAdvanceMdl function

1/25/2019 • 2 minutes to read • Edit Online

The **MmAdvanceMdl** routine advances the beginning of an MDL's virtual memory range by the specified number of bytes.

Syntax

```
NTSTATUS MmAdvanceMdl(
  PMDL  Mdl,
  ULONG NumberOfBytes
);
```

Parameters

`Mdl`

Specifies the MDL to advance.

`NumberOfBytes`

Specifies the number of bytes to advance the beginning of the MDL.

Return Value

MmAdvanceMdl returns an NTSTATUS code. The possible return values include:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The routine successfully advanced the beginning of the MDL.
STATUS_INVALID_PARAMETER_2	The caller attempted to advance the beginning of the MDL past the end.

Remarks

MmAdvanceMdl advances only the beginning of the virtual memory address range. The ending address remains the same, and the length of the range is shrunk accordingly.

A higher-level driver can use **MmAdvanceMdl** under low-memory conditions when a lower-level driver can only partially complete a read/write request. The higher-level driver can use **MmAdvanceMdl** to advance past the part of the buffer that has already been read or written, and then reissue the IRP to complete the request. (The driver can, of course, repeat this process as many times as necessary.)

If **MmAdvanceMdl** advances past the initial page, any pages that **MmAdvanceMdl** passed are immediately unlocked, and the system virtual address that maps the MDL and the user address are also adjusted.

Use of **MmAdvanceMdl** can slow system performance. It must be used only when all of the following conditions hold:

- The higher-level driver, in its own I/O handling, can only complete certain I/O requests after transferring a fixed amount of data, but the lower-level driver only transfers data in smaller amounts. (An example is a network transport driver for the SPX or NBT protocols. Each protocol supports reliable message passing for messages that are bigger than one Ethernet frame. The transport driver can only complete a read request for such a message once it has reassembled the message from multiple Ethernet frames.)
- The higher-level driver already tried and failed to allocate a new MDL to transfer a data fragment from an incomplete I/O request. (If the driver succeeds in allocating a new MDL, it must use that MDL and IoBuildPartialMdl to perform the I/O request instead of **MmAdvanceMdl**.)
- The higher-level driver must continue to make progress, even under low-memory conditions.

Drivers that do not satisfy these conditions must instead use the **IoBuildPartialMdl** routine to complete any partially-successful I/O operations.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=DISPATCH_LEVEL"

IoBuildPartialMdl

MmAllocateContiguousMemory function

1/25/2019 • 2 minutes to read • Edit Online

The **MmAllocateContiguousMemory** routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.

Syntax

```
PVOID MmAllocateContiguousMemory(
  SIZE_T           NumberOfBytes,
  PHYSICAL_ADDRESS HighestAcceptableAddress
);
```

Parameters

`NumberOfBytes`

The size, in bytes, of the block of contiguous memory to allocate. For more information, see Remarks.

`HighestAcceptableAddress`

The highest valid physical address the caller can use. For example, if a device can address only locations in the first 16 megabytes of the processor's physical memory address range, the driver for this device should set *HighestAcceptableAddress* to 0x0000000000FFFFFF. If you do not have specific requirements for memory allocation, set to MAXULONG64.

Return Value

MmAllocateContiguousMemory returns the base virtual address for the allocated memory. If the request cannot be satisfied, the routine returns **NULL**.

Remarks

MmAllocateContiguousMemory allocates a block of nonpaged memory that is contiguous in physical address space. The routine maps this block to a contiguous block of virtual memory in the system address space and returns the virtual address of the base of this block. The routine aligns the starting address of a contiguous memory allocation to a memory page boundary.

Drivers must not access memory beyond the requested allocation size. For example, developers should not assume that their drivers can safely use memory between the end of their requested allocation and the next page boundary.

Because contiguous physical memory is usually in short supply, it should be used sparingly and only when necessary. A driver that must use contiguous memory should allocate this memory during driver initialization because physical memory is likely to become fragmented over time as the operating system allocates and frees memory. Typically, a driver calls **MmAllocateContiguousMemory** from its DriverEntry routine to allocate an internal buffer for long-term use, and frees the buffer just before the driver is unloaded.

Memory allocated by **MmAllocateContiguousMemory** must be freed when the memory is no longer needed. Call the MmFreeContiguousMemory routine to free memory that is allocated by **MmAllocateContiguousMemory**.

Note When physical memory is fragmented on a computer that has a large amount of RAM, calls to **MmAllocateContiguousMemory**, which require the operating system to search for contiguous blocks of memory, can severely degrade performance. This degradation is greatly reduced starting with Windows Vista SP1 and Windows Server 2008, but contiguous memory can still be expensive to allocate. For this reason, drivers should avoid repeated calls to **MmAllocateContiguousMemory**. Instead, drivers should allocate all required contiguous buffers in their **DriverEntry** routines and reuse these buffers.

Memory that **MmAllocateContiguousMemory** allocates is uninitialized. A kernel-mode driver must first set this memory to zero if it is going to make it visible to user-mode software (to avoid leaking potentially privileged contents).

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

MmAllocateContiguousMemorySpecifyCache

MmAllocateNonCachedMemory

MmFreeContiguousMemory

MmAllocateContiguousMemorySpecifyCache function

1/25/2019 • 3 minutes to read • Edit Online

The **MmAllocateContiguousMemorySpecifyCache** routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.

Syntax

```
PVOID MmAllocateContiguousMemorySpecifyCache(
  SIZE_T              NumberOfBytes,
  PHYSICAL_ADDRESS    LowestAcceptableAddress,
  PHYSICAL_ADDRESS    HighestAcceptableAddress,
  PHYSICAL_ADDRESS    BoundaryAddressMultiple,
  MEMORY_CACHING_TYPE CacheType
);
```

Parameters

`NumberOfBytes`

The size, in bytes, of the block of contiguous memory to allocate. For more information, see Remarks.

`LowestAcceptableAddress`

The lowest valid physical address the caller can use. For example, if a device can address only locations above the first 8 megabytes of the processor's physical memory address range, the driver for this device should set *LowestAcceptableAddress* to 0x0000000000800000.

`HighestAcceptableAddress`

The highest valid physical address the caller can use. For example, if a device can address only locations in the first 16 megabytes of the processor's physical memory address range, the driver for this device should set *HighestAcceptableAddress* to 0x0000000000FFFFFF.

`BoundaryAddressMultiple`

The physical address multiple that the allocated buffer must not cross. A physical address multiple must always be a power of two. This parameter is optional and can be specified as zero to indicate that the device has no special memory boundary restrictions. For more information, see Remarks.

`CacheType`

Specifies a MEMORY_CACHING_TYPE value, which indicates the type of caching allowed for the requested memory.

Return Value

MmAllocateContiguousMemorySpecifyCache returns the base virtual address for the allocated memory. If the system is unable to allocate the requested buffer, the routine returns **NULL**.

Remarks

MmAllocateContiguousMemorySpecifyCache allocates a block of nonpaged memory that is contiguous in physical address space. The routine maps this block to a contiguous block of virtual memory in the system address space and returns the virtual address of the base of this block. The routine aligns the starting address of a contiguous memory allocation to a memory page boundary.

Drivers must not access memory beyond the requested allocation size. For example, developers should not assume that their drivers can safely use memory between the end of their requested allocation and the next page boundary.

Because contiguous physical memory is usually in short supply, it should be used sparingly and only when necessary. A driver that must use contiguous memory should allocate this memory during driver initialization because physical memory is likely to become fragmented over time as the operating system allocates and frees memory. Typically, a driver calls **MmAllocateContiguousMemorySpecifyCache** from its DriverEntry routine to allocate an internal buffer for long-term use, and frees the buffer just before the driver is unloaded.

Memory allocated by **MmAllocateContiguousMemorySpecifyCache** must be freed when the memory is no longer needed. Call the MmFreeContiguousMemory routine to free memory that is allocated by **MmAllocateContiguousMemorySpecifyCache**.

If you specify a nonzero value for the *BoundaryAddressMultiple* parameter, the physical address range of the allocated memory block will not cross an address boundary that is an integer multiple of this value. A driver should set this parameter to zero unless a nonzero value is required to work around a hardware limitation. For example, if a device cannot transfer data across 16-megabyte physical boundaries, the driver should specify a value of 0x1000000 for this parameter to ensure that the addresses that the device sees do not wrap around at a 16-megabyte boundary.

> **Note** If you use the **MmAllocateContiguousMemorySpecifyCache** routine on computers with large amounts of memory, the operating system's performance might severely degrade when the system tries to create a contiguous chunk of memory. This degradation is greatly reduced starting with Windows Vista SP1 and Windows Server 2008, but contiguous memory can still be expensive to allocate. For this reason, drivers should avoid repeated calls to **MmAllocateContiguousMemorySpecifyCache**. Instead, drivers should allocate all required contiguous buffers in their **DriverEntry** routines and reuse these buffers.

> **Note** Memory that **MmAllocateContiguousMemorySpecifyCache** allocates is uninitialized. A kernel-mode driver must first zero this memory if it is going to make it visible to user-mode software (to avoid leaking potentially privileged contents).

Requirements

Minimum supported client	Available starting with Windows 2000.

MmAllocateContiguousMemory

MmFreeContiguousMemory

MmAllocateContiguousMemorySpecifyCacheNode function

1/25/2019 • 3 minutes to read • Edit Online

The **MmAllocateContiguousMemorySpecifyCacheNode** routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.

Syntax

```
PVOID MmAllocateContiguousMemorySpecifyCacheNode(
  SIZE_T              NumberOfBytes,
  PHYSICAL_ADDRESS    LowestAcceptableAddress,
  PHYSICAL_ADDRESS    HighestAcceptableAddress,
  PHYSICAL_ADDRESS    BoundaryAddressMultiple,
  MEMORY_CACHING_TYPE CacheType,
  NODE_REQUIREMENT    PreferredNode
);
```

Parameters

`NumberOfBytes`

The size, in bytes, of the block of contiguous memory to allocate. For more information, see Remarks.

`LowestAcceptableAddress`

The lowest valid physical address the caller can use. For example, if a device can address only locations above the first 8 megabytes of the processor's physical memory address range, the driver for this device should set *LowestAcceptableAddress* to 0x0000000000800000.

`HighestAcceptableAddress`

The highest valid physical address the caller can use. For example, if a device can address only locations in the first 16 megabytes of the processor's physical memory address range, the driver for this device should set *HighestAcceptableAddress* to 0x0000000000FFFFFF.

`BoundaryAddressMultiple`

The physical address multiple that the allocated buffer must not cross. A physical address multiple must always be a power of two. This parameter is optional and can be specified as zero to indicate that the device has no special memory boundary restrictions. For more information, see Remarks.

`CacheType`

Specifies a MEMORY_CACHING_TYPE value, which indicates the type of caching requested for the contiguous physical memory.

`PreferredNode`

The preferred node number. If a multiprocessor system contains N nodes, the nodes are numbered 0 to N-1. If MM_ANY_NODE_OK is specified or the machine only has one node, then the allocation is satisfied from any node. Otherwise, the allocation is made from the preferred node or if a satisfactory range cannot be found from the preferred node, then **NULL** is returned.

Return Value

MmAllocateContiguousMemorySpecifyCacheNode returns the base virtual address for the allocated memory. If the request cannot be satisfied, the routine returns **NULL**.

Remarks

A kernel-mode device driver calls this routine to allocate a contiguous block of physical memory. In a non-uniform memory access (NUMA) multiprocessor system, the caller can specify a preferred node from which to allocate the memory. A node is a collection of processors that share fast access to a region of memory. In a non-NUMA multiprocessor or a single-processor system, **MmAllocateContiguousMemorySpecifyCacheNode** treats all memory as belonging to a single node and allocates memory from this node.

MmAllocateContiguousMemorySpecifyCacheNode allocates a block of nonpaged memory that is contiguous in physical address space. The routine maps this block to a contiguous block of virtual memory in the system address space and returns the virtual address of the base of this block. The routine aligns the starting address of a contiguous memory allocation to a memory page boundary.

Drivers must not access memory beyond the requested allocation size. For example, developers should not assume that their drivers can safely use memory between the end of their requested allocation and the next page boundary.

Because contiguous physical memory is usually in short supply, it should be used sparingly and only when necessary. A driver that must use contiguous memory should allocate this memory during driver initialization because physical memory is likely to become fragmented over time as the operating system allocates and frees memory. Typically, a driver calls **MmAllocateContiguousMemorySpecifyCacheNode** from its DriverEntry routine to allocate an internal buffer for long-term use, and frees the buffer just before the driver is unloaded.

Memory allocated by **MmAllocateContiguousMemorySpecifyCacheNode** must be freed when the memory is no longer needed. Call the MmFreeContiguousMemory routine to free memory that is allocated by **MmAllocateContiguousMemorySpecifyCacheNode**.

If you specify a nonzero value for the *BoundaryAddressMultiple* parameter, the physical address range of the allocated memory block will not cross an address boundary that is an integer multiple of this value. A driver should set this parameter to zero unless a nonzero value is required to work around a hardware limitation. For example, if a device cannot transfer data across 16-megabyte physical boundaries, the driver should specify a value of 0x1000000 for this parameter to ensure that the addresses that the device sees do not wrap around at a 16-megabyte boundary.

> **Note** If you use the **MmAllocateContiguousMemorySpecifyCacheNode** routine on computers with large amounts of memory, the operating system's performance might severely degrade when the system tries to create a contiguous chunk of memory. This degradation is greatly reduced starting with Windows Vista SP1 and Windows Server 2008, but contiguous memory can still be expensive to allocate. For this reason, drivers should avoid repeated calls to **MmAllocateContiguousMemorySpecifyCacheNode**. Instead, drivers should allocate all required contiguous buffers in their **DriverEntry** routines and reuse these buffers.

> **Note** Memory that **MmAllocateContiguousMemorySpecifyCacheNode** allocates is uninitialized. A kernel-mode driver must first zero this memory if it is going to make it visible to user-mode software (to avoid leaking potentially privileged contents).

MEMORY_CACHING_TYPE

MmFreeContiguousMemory

MmAllocateContiguousNodeMemory function

1/25/2019 • 4 minutes to read • Edit Online

The **MmAllocateContiguousNodeMemory** routine allocates a range of contiguous, nonpaged physical memory and maps it to the system address space.

Syntax

```
PVOID MmAllocateContiguousNodeMemory(
  SIZE_T           NumberOfBytes,
  PHYSICAL_ADDRESS LowestAcceptableAddress,
  PHYSICAL_ADDRESS HighestAcceptableAddress,
  PHYSICAL_ADDRESS BoundaryAddressMultiple,
  ULONG            Protect,
  NODE_REQUIREMENT PreferredNode
);
```

Parameters

`NumberOfBytes`

The size, in bytes, of the block of contiguous memory to allocate. For more information, see Remarks.

`LowestAcceptableAddress`

The lowest valid physical address the caller can use. For example, if a device can address only locations above the first 8 megabytes of the processor's physical memory address range, the driver for this device should set *LowestAcceptableAddress* to 0x0000000000800000.

`HighestAcceptableAddress`

The highest valid physical address the caller can use. For example, if a device can address only locations in the first 16 megabytes of the processor's physical memory address range, the driver for this device should set *HighestAcceptableAddress* to 0x0000000000FFFFFF.

`BoundaryAddressMultiple`

The physical address multiple that the allocated buffer must not cross. A physical address multiple must always be a power of two. This parameter is optional and can be specified as zero to indicate that the device has no special memory boundary restrictions. For more information, see Remarks.

`Protect`

Flag bits that specify the protection to use for the allocated memory. The caller must set one (but not both) of the following flag bits in the *Protect* parameter.

FLAG BIT	MEANING
PAGE_READWRITE	Allocate read/write, no-execute (NX) memory. Most callers should set this flag bit. For more information, see Remarks.

PAGE_EXECUTE_READWRITE	Allocate read/write memory that is executable. This flag bit should be set only if the caller requires the ability to execute instructions in the allocated memory.

In addition, the caller can set one (but not both) of the following optional flag bits in the *Protect* parameter.

FLAG BIT	MEANING
PAGE_NOCACHE	Allocate non-cached memory. This flag bit is similar in effect to calling MmAllocateContiguousMemorySpecifyCache with *CacheType* set to **MmNonCached**.
PAGE_WRITECOMBINE	Allocate write-combined memory. This flag bit is similar in effect to calling **MmAllocateContiguousMemorySpecifyCache** with *CacheType* set to **MmWriteCombined**.

If neither PAGE_NOCACHE nor PAGE_WRITECOMBINE is specified, the allocated memory is fully cached. In this case, the effect is similar to calling **MmAllocateContiguousMemorySpecifyCache** with *CacheType* set to **MmCached**.

`PreferredNode`

The preferred node number. If a multiprocessor system contains N nodes, the nodes are numbered from 0 to N-1. If the caller sets *PreferredNode* to MM_ANY_NODE_OK, the routine chooses which node to allocate memory from. Otherwise, if memory in the specified address range cannot be allocated from the preferred node, the routine returns **NULL**.

Return Value

MmAllocateContiguousNodeMemory returns the base virtual address for the allocated memory. If the request cannot be satisfied, the routine returns **NULL**.

Remarks

A kernel-mode device driver calls this routine to allocate a contiguous block of physical memory. The calling driver can specify whether to use no-execute (NX) memory for the allocation. In a non-uniform memory access (NUMA) multiprocessor system, the caller can specify a preferred node from which to allocate the memory. A node is a collection of processors that share fast access to a region of memory. In a non-NUMA multiprocessor or a single-processor system, **MmAllocateContiguousNodeMemory** treats all memory as belonging to a single node and allocates memory from this node.

MmAllocateContiguousNodeMemory allocates a block of nonpaged memory that is contiguous in physical address space. The routine maps this block to a contiguous block of virtual memory in the system address space and returns the virtual address of the base of this block. The routine aligns the starting address of a contiguous memory allocation to a memory page boundary.

Drivers must not access memory beyond the requested allocation size. For example, developers should not assume that their drivers can safely use memory between the end of their requested allocation and the next page boundary.

Because contiguous physical memory is usually in short supply, it should be used sparingly and only when necessary. A driver that must use contiguous memory should allocate this memory during driver initialization because physical memory is likely to become fragmented over time as the operating system allocates and frees memory. Typically, a driver calls **MmAllocateContiguousNodeMemory** from its DriverEntry routine to allocate an internal buffer for long-term use, and frees the buffer just before the driver is unloaded.

Memory allocated by **MmAllocateContiguousNodeMemory** must be freed when the memory is no longer needed. Call the MmFreeContiguousMemory routine to free memory that is allocated by **MmAllocateContiguousNodeMemory**.

MmAllocateContiguousNodeMemory is similar to the MmAllocateContiguousMemorySpecifyCacheNode routine. Unlike **MmAllocateContiguousMemorySpecifyCacheNode**, **MmAllocateContiguousNodeMemory** can be used to allocate no-execute (NX) memory. As a best practice, a driver should allocate NX memory unless the driver explicitly requires the ability to execute instructions in the allocated memory. By allocating NX memory, a driver improves security by preventing malicious software from executing instructions in this memory. Memory allocated by the MmAllocateContiguousMemory, MmAllocateContiguousMemorySpecifyCache, and **MmAllocateContiguousMemorySpecifyCacheNode** routines is always executable.

If you specify a nonzero value for the *BoundaryAddressMultiple* parameter, the physical address range of the allocated memory block will not cross an address boundary that is an integer multiple of this value. A driver should set this parameter to zero unless a nonzero value is required to work around a hardware limitation. For example, if a device cannot transfer data across 16-megabyte physical boundaries, the driver should specify a value of 0x1000000 for this parameter to ensure that the addresses that the device sees do not wrap around at a 16-megabyte boundary.

> **Note** Memory that **MmAllocateContiguousNodeMemory** allocates is uninitialized. A kernel-mode driver must first zero this memory if it is going to make it visible to user-mode software (to avoid leaking potentially privileged contents).

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

MmAllocateMappingAddress function

1/25/2019 • 2 minutes to read • Edit Online

The **MmAllocateMappingAddress** routine reserves a range of system virtual address space of the specified size.

Syntax

```
PVOID MmAllocateMappingAddress(
  SIZE_T NumberOfBytes,
  ULONG  PoolTag
);
```

Parameters

`NumberOfBytes`

Specifies the number of bytes to reserve.

`PoolTag`

Specifies a four-character tag used to identify the buffer. Use a distinct *PoolTag* tag for each allocation code path. For a description of pool tags, see ExAllocatePoolWithTag.

Return Value

MmAllocateMappingAddress returns a pointer to the beginning of the reserved memory buffer.

Remarks

MmAllocateMappingAddress reserves a system virtual address range for the caller to use. No physical memory is allocated for the virtual address range and the virtual memory cannot be accessed until it is mapped by the MmMapLockedPagesWithReservedMapping routine. The caller unmaps the reserved memory range by calling the MmUnmapReservedMapping routine. Finally, the caller can free the reserved range by calling MmFreeMappingAddress.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IRQL	"<=APC_LEVEL"

MmFreeMappingAddress

MmMapLockedPagesWithReservedMapping

MmUnmapReservedMapping

MmAllocateMdlForIoSpace function

1/25/2019 • 3 minutes to read • Edit Online

The **MmAllocateMdlForIoSpace** routine allocates an MDL and initializes this MDL to describe a set of physical address ranges in I/O address space.

Syntax

```
NTSTATUS MmAllocateMdlForIoSpace(
  PMM_PHYSICAL_ADDRESS_LIST PhysicalAddressList,
  SIZE_T                    NumberOfEntries,
  PMDL                      *NewMdl
);
```

Parameters

`PhysicalAddressList`

A pointer to an array of MM_PHYSICAL_ADDRESS_LIST structures that describe the physical address ranges to include in the allocated MDL.

`NumberOfEntries`

The number of elements in the **MM_PHYSICAL_ADDRESS_LIST** array pointed to by *PhysicalAddressList*.

`NewMdl`

A pointer to a location to which the routine writes a pointer to the newly allocated MDL.

Return Value

MmAllocateMdlForIoSpace returns STATUS_SUCCESS if it is successful. Possible error return values include the following status codes.

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER_1	A physical address is not aligned to a page boundary; or a physical address range is not a multiple of the page size; or a physical address range is used by the operating system for RAM and is not available for use as I/O space.

STA TUS _IN SUF FICI ENT _RE SO URC ES	Insufficient system resources are available to perform the requested operation.

Do not assume that the preceding list of error return codes is exhaustive. The routine might return error codes that do not appear in the list.

Remarks

This routine accepts, as an input parameter, an array of **MM_PHYSICAL_ADDRESS_LIST** structures that describe a set of physical address ranges in I/O address space, and allocates an MDL that describes these ranges. Consecutive physical address ranges in the array are not required to be contiguous.

The physical address ranges in the *PhysicalAddressList* array must satisfy the following conditions:

- The base physical address for each range must be aligned to a PAGE_SIZE boundary in memory.
- The size, in bytes, of each range must be an integer multiple of PAGE_SIZE.
- All physical address ranges must be in memory that is available for use as I/O address space. They cannot be in memory space that is used by the operating system for RAM.
- The total size of all the ranges must be less than 4 gigabytes. Specifically, the total size must not exceed 2^{32}-1 bytes.

The caller is responsible for freeing the allocated MDL when it is no longer needed. To free the MDL, call the IoFreeMdl routine. For more information about MDLs, see Using MDLs.

The MDL that is created by **MmAllocateMdlForIoSpace** is not mapped to virtual memory, but can be supplied to a routine such as MapTransferEx to initiate a DMA transfer to or from the physical memory ranges described by the MDL. To map this MDL to a contiguous range of virtual addresses so that it can be accessed by the processor, call the MmMapLockedPagesSpecifyCache routine.

Only ranges of the physical address space that are not reserved by the operating system for use as memory are available to drivers for use as I/O address space. Drivers use I/O address space to access memory-mapped hardware resources such as device registers. When a driver starts, it might receive one or more physical address ranges as translated hardware resources. For more information, see Mapping Bus-Relative Addresses to Virtual Addresses.

In some processor architectures, such as the x86, devices can be either memory-mapped or mapped to port addresses in a special I/O address space that is dedicated to devices and is separate from the memory address space. Drivers can use **MmAllocateMdlForIoSpace** to allocate MDLs only for memory-mapped devices.

Examples

The following code example shows how to construct an array of MM_PHYSICAL_ADDRESS_LIST structures that describe the physical address ranges to include in the allocated MDL.

```
extern ULONG64 BasePhysicalAddress;
extern SIZE_T ChunkSize;
extern SIZE_T Stride;

#define ARRAYSIZE(x)  (sizeof(x)/sizeof((x)[0]))

NTSTATUS Status;
PMDL Mdl;
MM_PHYSICAL_ADDRESS_LIST AddressList[3];

AddressList[0].PhysicalAddress.QuadPart = BasePhysicalAddress;
AddressList[0].NumberOfBytes = ChunkSize;

BasePhysicalAddress += Stride;

AddressList[1].PhysicalAddress.QuadPart = BasePhysicalAddress;
AddressList[1].NumberOfBytes = ChunkSize;

BasePhysicalAddress += Stride;

AddressList[2].PhysicalAddress.QuadPart = BasePhysicalAddress;
AddressList[2].NumberOfBytes = ChunkSize;

Status = MmAllocateMdlForIoSpace (AddressList, ARRAYSIZE(AddressList), &Mdl);
```

In this example, the starting physical address is specified by the `BasePhysicalAddress` variable. The number of bytes in each physical address range is specified by the `ChunkSize` variable. The byte offset from the start of one physical range to the start of the next is specified by the `Stride` variable. `BasePhysicalAddress` must be aligned to a page boundary in memory, and `ChunkSize` and `Stride` must be multiples of the page size.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	wdm.h (include Wdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

MapTransferEx

MmMapLockedPagesSpecifyCache

MmAllocateNodePagesForMdlEx function

1/25/2019 • 4 minutes to read • Edit Online

The **MmAllocateNodePagesForMdlEx** routine allocates nonpaged physical memory from an ideal node, and allocates an MDL structure to describe this memory.

Syntax

```
PMDL MmAllocateNodePagesForMdlEx(
  PHYSICAL_ADDRESS    LowAddress,
  PHYSICAL_ADDRESS    HighAddress,
  PHYSICAL_ADDRESS    SkipBytes,
  SIZE_T              TotalBytes,
  MEMORY_CACHING_TYPE CacheType,
  ULONG               IdealNode,
  ULONG               Flags
);
```

Parameters

`LowAddress`

The physical address of the start of the first address range from which the allocated pages can come. If **MmAllocateNodePagesForMdlEx** cannot allocate the requested number of bytes in the first address range, the routine iterates through additional address ranges to get more pages. At each iteration, **MmAllocateNodePagesForMdlEx** adds the value of *SkipBytes* to the previous start address to calculate the start of the next address range.

`HighAddress`

The physical address of the end of the first address range that the allocated pages can come from.

`SkipBytes`

The number of bytes to skip from the start of the previous address range that the allocated pages can come from. *SkipBytes* must be an integer multiple of the virtual memory page size, in bytes.

`TotalBytes`

The total number of bytes to allocate for the MDL.

`CacheType`

A MEMORY_CACHING_TYPE value, which indicates the type of caching that is allowed for the requested memory.

`IdealNode`

The ideal node number. If a multiprocessor system contains N nodes, valid node numbers are in the range 0 to N-1. Your driver can call the KeQueryHighestNodeNumber routine to get the highest node number. A single-processor or non-NUMA multiprocessor system has only one node, node 0, from which to allocate memory. For a NUMA multiprocessor system, the allocation is made from the ideal node, if possible. If insufficient memory is available in the ideal node to satisfy the allocation request, and the caller does not set the MM_ALLOCATE_FROM_LOCAL_NODE_ONLY flag, **MmAllocateNodePagesForMdlEx** will try to allocate memory from other nodes.

`Flags`

Flags for this operation. Set this parameter to zero or to the bitwise-OR of one or more of the following flag bits:

- MM_DONT_ZERO_ALLOCATION
- MM_ALLOCATE_FROM_LOCAL_NODE_ONLY
- MM_ALLOCATE_FULLY_REQUIRED
- MM_ALLOCATE_NO_WAIT
- MM_ALLOCATE_PREFER_CONTIGUOUS
- MM_ALLOCATE_REQUIRE_CONTIGUOUS_CHUNKS

The MM_ALLOCATE_PREFER_CONTIGUOUS and MM_ALLOCATE_REQUIRE_CONTIGUOUS_CHUNKS flag bits are mutually exclusive. For more information about these flags, see MM_ALLOCATE_XXX.

Return Value

MmAllocateNodePagesForMdlEx returns a pointer to an MDL structure if it is successful. Otherwise, if the routine fails to allocate any memory, the routine returns **NULL**.

A return value of **NULL** indicates that no physical memory pages are available in the specified address ranges, or that there is not enough memory pool available to allocate the MDL structure.

If the routine successfully allocates some, but not all, of the requested memory, the MDL describes as much physical memory as the routine was able to allocate.

Remarks

In a non-uniform memory access (NUMA) multiprocessor system, the caller can specify an ideal node from which to allocate the memory. A node is a collection of processors that share fast access to a region of memory. In a non-NUMA multiprocessor or a single-processor system, **MmAllocateNodePagesForMdlEx** treats all memory as belonging to a single node and allocates memory from this node.

By default, the physical memory pages that **MmAllocateNodePagesForMdlEx** returns are not contiguous pages. Callers can override the default behavior of this routine by setting the MM_ALLOCATE_PREFER_CONTIGUOUS or MM_ALLOCATE_REQUIRE_CONTIGUOUS_CHUNKS flag bit in the *Flags* parameter.

MmAllocateNodePagesForMdlEx does not map the allocated physical memory into virtual memory. If necessary, the caller can call a routine such as MmMapLockedPagesSpecifyCache to map the physical memory pages described by the MDL.

MmAllocateNodePagesForMdlEx is designed for kernel-mode drivers that do not need corresponding virtual addresses (that is, they need physical pages and do not need them to be physically contiguous), and for kernel-mode drivers that can achieve substantial performance gains if physical memory for a device is allocated in a specific physical address range (for example, an AGP graphics card).

Depending on how much physical memory is currently available in the requested ranges, **MmAllocateNodePagesForMdlEx** might return an MDL that describes less memory than was requested. The routine also might return **NULL** if no memory was allocated. The caller should check the amount of memory that is actually allocated, as described by the MDL.

The caller must use MmFreePagesFromMdl to release the memory pages that are described by an MDL that was created by **MmAllocateNodePagesForMdlEx**. After calling **MmFreePagesFromMdl**, the caller must also call ExFreePool to release the memory allocated for the MDL structure.

By default, **MmAllocateNodePagesForMdlEx** fills the pages that it allocates with zeros. The caller can specify the MM_DONT_ZERO_ALLOCATION flag to override this default and to possibly improve performance.

> **Note** Memory that **MmAllocateNodePagesForMdlEx** allocates is uninitialized if you specify the MM_DONT_ZERO_ALLOCATION flag. A kernel-mode driver must first zero this memory if the driver is going to make the memory visible to user-mode software (to avoid leaking potentially privileged contents). For more information about this flag, see MM_ALLOCATE_XXX.

The maximum amount of memory that **MmAllocateNodePagesForMdlEx** can allocate in a single call is (4 gigabytes - PAGE_SIZE). The routine can satisfy an allocation request for this amount only if enough pages are available.

MmAllocateNodePagesForMdlEx runs at IRQL <= APC_LEVEL. If necessary, your driver can call **MmAllocateNodePagesForMdlEx** at DISPATCH_LEVEL. However, you can improve driver performance by calling at APC_LEVEL or below.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL (See Remarks section.)"

MEMORY_CACHING_TYPE

MM_ALLOCATE_XXX

MmFreePagesFromMdl

MmMapLockedPagesSpecifyCache

MmAllocatePagesForMdl function

1/25/2019 • 3 minutes to read • Edit Online

The **MmAllocatePagesForMdl** routine allocates zero-filled, nonpaged, physical memory pages to an MDL.

Syntax

```
PMDL MmAllocatePagesForMdl(
  PHYSICAL_ADDRESS LowAddress,
  PHYSICAL_ADDRESS HighAddress,
  PHYSICAL_ADDRESS SkipBytes,
  SIZE_T           TotalBytes
);
```

Parameters

`LowAddress`

Specifies the physical address of the start of the first address range from which the allocated pages can come. If **MmAllocatePagesForMdl** cannot allocate the requested number of bytes in the first address range, it iterates through additional address ranges to get more pages. At each iteration, **MmAllocatePagesForMdl** adds the value of *SkipBytes* to the previous start address to obtain the start of the next address range.

`HighAddress`

Specifies the physical address of the end of the first address range from which the allocated pages can come.

`SkipBytes`

Specifies the number of bytes to skip from the start of the previous address range from which the allocated pages can come. *SkipBytes* must be an integer multiple of the virtual memory page size, in bytes.

`TotalBytes`

Specifies the total number of bytes to allocate for the MDL.

Return Value

MmAllocatePagesForMdl returns one of the following:

RETURN CODE	DESCRIPTION
MDL pointer	The MDL pointer describes a set of physical pages in the specified address range. If the requested number of bytes is not available, the MDL describes as much physical memory as is available.
NULL	There are no physical memory pages in the specified address ranges, or there is not enough memory pool for the MDL itself.

Remarks

Drivers that are running in Windows Server 2003 Service Pack 1 (SP1) and later versions of Windows should use the MmAllocatePagesForMdlEx routine instead of **MmAllocatePagesForMdl**. **MmAllocatePagesForMdlEx** provides better performance than **MmAllocatePagesForMdl** by avoiding unnecessary flushes of the TLB and cache memory.

The physical memory pages that are returned by **MmAllocatePagesForMdl** are typically not contiguous pages. **MmAllocatePagesForMdl** always fills the allocated pages in the returned MDL with zeros.

MmAllocatePagesForMdl is designed to be used by kernel-mode drivers that do not need corresponding virtual addresses (that is, they need physical pages and do not need the pages to be physically contiguous) or by kernel-mode drivers that can achieve substantial performance gains if physical memory for a device is allocated in a specific physical address range. A driver for an AGP graphics card is an example of such a driver.

Depending on how much physical memory is currently available in the requested ranges, **MmAllocatePagesForMdl** might return an MDL that describes less memory than was requested. The routine returns **NULL** if no memory was allocated. The caller should check the amount of memory that is actually allocated to the MDL.

The caller must use MmFreePagesFromMdl to release the memory pages that are described by an MDL that was created by **MmAllocatePagesForMdl**. After calling **MmFreePagesFromMdl**, the caller must also call ExFreePool to release the memory that is allocated for the MDL structure itself.

In Windows 2000 and later versions of Windows, the maximum amount of memory that **MmAllocatePagesForMdl** can allocate in a single call is (4 gigabytes - PAGE_SIZE). The routine can satisfy an allocation request for this amount only if enough pages are available.

MmAllocatePagesForMdl runs at IRQL <= APC_LEVEL. Windows Server 2008 and later versions of the Windows operating system enable **MmAllocatePagesForMdl** callers to call at DISPATCH_LEVEL. However, you can improve driver performance by calling at APC_LEVEL or below.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows; however, MmAllocatePagesForMdlEx should be used instead of MmAllocatePagesForMdl in Windows Server 2003 Service Pack 1 (SP1) and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

MmAllocatePagesForMdlEx

MmFreePagesFromMdl

MmMapLockedPages

MmAllocatePagesForMdlEx function

1/25/2019 • 6 minutes to read • Edit Online

The **MmAllocatePagesForMdlEx** routine allocates nonpaged, physical memory pages to an MDL.

Syntax

```
PMDL MmAllocatePagesForMdlEx(
  PHYSICAL_ADDRESS    LowAddress,
  PHYSICAL_ADDRESS    HighAddress,
  PHYSICAL_ADDRESS    SkipBytes,
  SIZE_T              TotalBytes,
  MEMORY_CACHING_TYPE CacheType,
  ULONG               Flags
);
```

Parameters

`LowAddress`

Specifies the physical address of the start of the first address range from which the allocated pages can come. If **MmAllocatePagesForMdlEx** cannot allocate the requested number of bytes in the first address range, it iterates through additional address ranges to get more pages. At each iteration, **MmAllocatePagesForMdlEx** adds the value of *SkipBytes* to the previous start address to obtain the start of the next address range.

`HighAddress`

Specifies the physical address of the end of the first address range that the allocated pages can come from.

`SkipBytes`

Specifies the number of bytes to skip from the start of the previous address range that the allocated pages can come from. *SkipBytes* must be an integer multiple of the virtual memory page size, in bytes.

`TotalBytes`

Specifies the total number of bytes to allocate for the MDL.

`CacheType`

Specifies a MEMORY_CACHING_TYPE value, which indicates the type of caching that is allowed for the requested memory.

`Flags`

Specifies flags for this operation. Set this parameter to zero or to the bitwise OR of one or more of the following **MM_ALLOCATE_*XXX*** flag bits:

The last four items in the preceding list are supported only in Windows 7 and later versions of Windows.

VALUE	MEANING

VALUE	MEANING
MM_DONT_ZERO_ALLOCATION 0x00000001	Do not fill the allocated pages with zeros. By default, MmAllocatePagesForMdlEx zeros the pages that it allocates. By skipping this operation, you can potentially improve the performance of the MmAllocatePagesForMdlEx call. However, you must not use this flag unless either you never expose the allocated pages to user-mode programs, or you always overwrite the original contents of the pages before you expose the allocated pages to user-mode programs.
MM_ALLOCATE_FROM_LOCAL_NODE_ONLY 0x00000002	Allocate pages only from the ideal node. This flag applies only to multiprocessor systems that have non-uniform memory access (NUMA) architectures. Starting with Windows Vista, this flag indicates that all pages must be allocated from the ideal node of the current thread. No pages are to be allocated from other nodes. In versions of Windows earlier than Windows Vista, this flag indicates that all pages must be allocated from the local node; that is, from the node that the current processor belongs to. For more information about NUMA multiprocessor systems, see NUMA Support .
MM_ALLOCATE_FULLY_REQUIRED 0x00000004	A full allocation is required. Starting with Windows 7, this flag requires MmAllocatePagesForMdlEx to return NULL if it cannot allocate all the requested pages. The routine returns a non-NULL value only if it successfully obtains the entire requested allocation. This flag enables the memory manager to perform the allocation more efficiently in cases in which the caller requires a full allocation.
MM_ALLOCATE_NO_WAIT 0x00000008	Do not wait. Starting with Windows 7, this flag indicates that the MmAllocatePagesForMdlEx call must not block the calling thread. Typically, the caller is a kernel-mode driver that is running at IRQL < DISPATCH_LEVEL but cannot allow its execution to be blocked. For example, the driver might be assisting with paging or power-management operations. Regardless of whether this flag is set, MmAllocatePagesForMdlEx never blocks callers that are running at IRQL = DISPATCH_LEVEL.
MM_ALLOCATE_PREFER_CONTIGUOUS 0x00000010	Allocation is performed in a way that minimizes system memory fragmentation. Starting with Windows 7, this flag indicates that the caller wants to avoid fragmenting physical memory to make more contiguous memory available to other callers. The allocated pages are not guaranteed to be (and usually are not) physically contiguous, even if plenty of contiguous memory is available. Callers that require contiguous memory should specify MM_ALLOCATE_REQUIRE_CONTIGUOUS_CHUNKS instead of MM_ALLOCATE_PREFER_CONTIGUOUS.

VALUE	MEANING
MM_ALLOCATE_REQUIRE_CONTIGUOUS_CHUNKS 0x00000020	Contiguous memory is required. Starting with Windows 7, this flag indicates that the requested pages must be allocated as contiguous blocks of physical memory. If the SkipBytes parameter is zero, MmAllocatePagesForMdlEx either succeeds and returns a single, contiguous block, or it fails and returns NULL. It never returns a partial allocation. For SkipBytes = 0, the allocated pages satisfy the address range requirements that are specified by the LowAddress and HighAddress parameters, but the pages are subject to no special alignment restrictions. If SkipBytes is nonzero, SkipBytes must be a power of two and must be greater than or equal to PAGE_SIZE, and the TotalBytes parameter value must be a multiple of SkipBytes. In this case, the returned MDL can contain multiple blocks of contiguous pages. That is, each block is internally contiguous but the blocks are not necessarily contiguous with each other. Each block of contiguous pages is guaranteed to be exactly SkipBytes long and to be aligned on a SkipBytes boundary. Partial allocations can occur if SkipBytes is nonzero, but each contiguous block in a partial allocation is guaranteed to be SkipBytes long.
MM_ALLOCATE_FAST_LARGE_PAGES 0x00000040	Starting with Windows 8, this flag specifies that the allocation must be satisfied from the operating system's large page cache. If the cache is empty, allocation fails. If MM_ALLOCATE_FAST_LARGE_PAGES is not specified, **MmAllocatePagesForMdlEx** uses cached large pages if they are available. If the cache is exhausted, **MmAllocatePagesForMdlEx** attempts to construct additional large pages, which may take a long time. MM_ALLOCATE_FAST_LARGE_PAGES must be used with the MM_ALLOCATE_REQUIRE_CONTIGUOUS_CHUNKS flag. The *SkipBytes* parameter must be set to a multiple of large page size.

Return Value

MmAllocatePagesForMdlEx returns one of the following:

RETURN CODE	DESCRIPTION
MDL pointer	A non-**NULL** return value is a pointer to an MDL that describes a set of physical pages in the specified address range. If the requested number of bytes is not available, the MDL describes as much physical memory as is available.
NULL	Indicates that no physical memory pages are available in the specified address ranges, or that there is not enough memory pool for the MDL itself.

Remarks

By default, the physical memory pages that **MmAllocatePagesForMdlEx** returns are not contiguous pages. Starting with Windows 7, callers can override the default behavior of this routine by setting the MM_ALLOCATE_PREFER_CONTIGUOUS or MM_ALLOCATE_REQUIRE_CONTIGUOUS_CHUNKS flag bit in the *Flags* parameter.

MmAllocatePagesForMdlEx is designed for kernel-mode drivers that do not need corresponding virtual addresses (that is, they need physical pages and do not need them to be physically contiguous), and for kernel-mode drivers that can achieve substantial performance gains if physical memory for a device is allocated in a specific physical address range (for example, an AGP graphics card).

Depending on how much physical memory is currently available in the requested ranges, **MmAllocatePagesForMdlEx** might return an MDL that describes less memory than was requested. The routine also might return **NULL** if no memory was allocated. The caller should check the amount of memory that is actually allocated to the MDL.

The caller must use MmFreePagesFromMdl to release the memory pages that are described by an MDL that was created by **MmAllocatePagesForMdlEx**. After calling **MmFreePagesFromMdl**, the caller must also call ExFreePool to release the memory that is allocated for the MDL structure.

By default, **MmAllocatePagesForMdlEx** fills the pages that it allocates with zeros. The caller can specify the MM_DONT_ZERO_ALLOCATION flag to override this default and to possibly improve performance.

> **Note** Memory that **MmAllocatePagesForMdlEx** allocates is uninitialized if you specify the MM_DONT_ZERO_ALLOCATION flag. A kernel-mode driver must first zero this memory if the driver is going to make the memory visible to user-mode software (to avoid leaking potentially privileged contents). For more information about this flag, see MM_ALLOCATE_XXX.

The maximum amount of memory that **MmAllocatePagesForMdlEx** can allocate in a single call is (4 gigabytes - PAGE_SIZE). The routine can satisfy an allocation request for this amount only if enough pages are available.

MmAllocatePagesForMdlEx runs at IRQL <= APC_LEVEL. In Windows Server 2008 and later versions of Windows, callers of **MmAllocatePagesForMdlEx** are allowed to be at DISPATCH_LEVEL. However, you can improve driver performance by calling at APC_LEVEL or below.

Requirements

Minimum supported client	Available in Windows Server 2003 with Service Pack 1 (SP1) and later versions of Windows. You should use this routine instead of MmAllocatePagesForMdl on these operating systems.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	See Remarks section.

MEMORY_CACHING_TYPE

MmAllocatePagesForMdl

MmFreePagesFromMdl

MmMapLockedPages

MmBuildMdlForNonPagedPool function

1/25/2019 • 2 minutes to read • Edit Online

The **MmBuildMdlForNonPagedPool** routine receives an MDL that specifies a nonpaged virtual memory buffer, and updates it to describe the underlying physical pages.

Syntax

```
void MmBuildMdlForNonPagedPool(
  PMDL MemoryDescriptorList
);
```

Parameters

`MemoryDescriptorList`

A pointer to an MDL that specifies a virtual memory buffer in nonpaged memory. The caller used the IoAllocateMdl routine to create the MDL for this buffer.

Return Value

None

Remarks

At entry, the specified MDL must describe a buffer in nonpaged system memory or in memory that is locked down (the physical pages cannot be traded), such as memory that is allocated by the ExAllocatePoolWithTag routine with *PoolType* = **NonPagedPool** or by the MmAllocateContiguousMemorySpecifyCache routine. **MmBuildMdlForNonPagedPool** updates the MDL to describe the underlying physical pages.

MmBuildMdlForNonPagedPool may not be used with MDLs describing buffers allocated on a kernel stack. To build an MDL describing a kernel stack buffer, drivers must call MmProbeAndLockPages. This is because kernel stack pages can be traded unless they are probe-and-locked. This rule applies even if the driver guarantees that the kernel stack cannot be paged out.

Because the pages described by the MDL are already nonpageable and are already mapped to the system address space, drivers must not try to lock them by using the MmProbeAndLockPages routine, or to create additional system-address-space mappings by using the MmMapLockedPagesSpecifyCache routine. Similarly, drivers must not try to unlock the pages by using the MmUnlockPages routine, or to release the existing system-address-space mapping by using the MmUnmapLockedPages routine. If a driver performs any of these illegal operations on an MDL that is built by **MmBuildMdlForNonPagedPool,** the resulting behavior is undefined.

Passing an MDL built by **MmBuildMdlForNonPagedPool** to the MmGetSystemAddressForMdlSafe routine is allowed. The **MmGetSystemAddressForMdlSafe** call, in this case, simply returns the starting virtual address of the buffer that is described by the MDL.

A driver can use the **MmMapLockedPagesSpecifyCache** routine to map an MDL that is built by **MmBuildMdlForNonPagedPool** into user virtual address space. However, the driver must perform this operation in a way that avoids certain security issues. For more information, see MmMapLockedPagesSpecifyCache.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

MmFreeContiguousMemory function

1/25/2019 • 2 minutes to read • Edit Online

The **MmFreeContiguousMemory** routine releases a range of physically contiguous memory that was allocated by an **MmAllocateContiguousMemory*Xxx*** routine.

Syntax

```
void MmFreeContiguousMemory(
  PVOID BaseAddress
);
```

Parameters

`BaseAddress`

Pointer to the virtual address of the memory to be freed.

Return Value

None

Remarks

The **MmFreeContiguousMemory** routine frees a block of physically contiguous memory that was allocated by a previous call to the MmAllocateContiguousMemory, MmAllocateContiguousMemorySpecifyCache, or MmAllocateContiguousMemorySpecifyCacheNode routine. The *BaseAddress* parameter must be the base address that was obtained from the previous call to the **MmAllocateContiguousMemory*Xxx*** routine.

A device driver that must use contiguous memory should allocate only what it needs during driver initialization because physical memory is likely to become fragmented as the system runs. Such a driver must deallocate the memory when the driver is done using the memory.

Callers of **MmFreeContiguousMemory** must be running at IRQL = APC_LEVEL. For Windows Server 2008 and later versions of the Windows operating system, you can also call **MmFreeContiguousMemory** with IRQL <= DISPATCH_LEVEL. However, you can improve driver performance by calling at APC_LEVEL or below.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe

MmAllocateContiguousMemorySpecifyCacheNode

MmFreeContiguousMemorySpecifyCache function

1/25/2019 • 2 minutes to read • Edit Online

The **MmFreeContiguousMemorySpecifyCache** routine frees a buffer that was allocated by an **MmAllocateContiguousMemorySpecifyCache*Xxx*** routine.

Syntax

```
void MmFreeContiguousMemorySpecifyCache(
  PVOID               BaseAddress,
  SIZE_T              NumberOfBytes,
  MEMORY_CACHING_TYPE CacheType
);
```

Parameters

`BaseAddress`

Specifies the base address of the buffer to be freed. Must match the address returned by the **MmAllocateContiguousMemorySpecifyCache*Xxx*** call that allocated the buffer.

`NumberOfBytes`

Specifies the size in bytes of the buffer to be freed. Must match the size requested when the buffer was allocated by the **MmAllocateContiguousMemorySpecifyCache*Xxx*** routine.

`CacheType`

Specifies the cache type of the buffer to be freed. Must match the cache type requested when the buffer was allocated by the **MmAllocateContiguousMemorySpecifyCache*Xxx*** routine.

Return Value

None

Remarks

The **MmFreeContiguousMemorySpecifyCache** routine frees a block of physically contiguous memory that was allocated by a previous call to the MmAllocateContiguousMemorySpecifyCache or MmAllocateContiguousMemorySpecifyCacheNode routine. However, MmFreeContiguousMemory is the preferred routine to use to free memory that was allocated by an **MmAllocateContiguousMemorySpecifyCache*Xxx*** routine. **MmFreeContiguousMemory** is faster than **MmFreeContiguousMemorySpecifyCache** and requires fewer parameters.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

MmFreeMappingAddress function

1/25/2019 • 2 minutes to read • Edit Online

The **MmFreeMappingAddress** routine frees a range of virtual memory reserved by the MmAllocateMappingAddress routine.

Syntax

```
void MmFreeMappingAddress(
  PVOID BaseAddress,
  ULONG PoolTag
);
```

Parameters

`BaseAddress`

Pointer to the beginning of the reserved memory buffer to free. This must be an address previously returned by MmAllocateMappingAddress.

`PoolTag`

Specifies the pool tag for the reserved memory buffer. This must be identical to the value specified in the *PoolTag* parameter of the call to MmAllocateMappingAddress that reserved the buffer.

Return Value

None

Remarks

MmFreeMappingAddress frees a range of memory reserved by MmAllocateMappingAddress. If the memory range has already been mapped by MmMapLockedPagesWithReservedMapping, it must first be unmapped with MmUnmapReservedMapping before the memory range can be freed.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

MmFreePagesFromMdl function

1/25/2019 • 2 minutes to read • Edit Online

The **MmFreePagesFromMdl** routine frees all the physical pages that are described by an MDL that was created by the MmAllocatePagesForMdl routine.

Syntax

```
void MmFreePagesFromMdl(
  PMDL MemoryDescriptorList
);
```

Parameters

`MemoryDescriptorList`

Pointer to an MDL that was created by **MmAllocatePagesForMdl**.

Return Value

None

Remarks

MmFreePagesFromMdl can only be used to free the memory pages that are described by an MDL that was created by **MmAllocatePagesForMdl**.

After calling **MmFreePagesFromMdl**, the caller must also call ExFreePool to release the memory that was allocated for the MDL structure.

MmFreePagesFromMdl runs at IRQL <= APC_LEVEL. For Windows Server 2008 and later versions of the Windows operating system, you can also call this routine at DISPATCH_LEVEL. However, you can improve driver performance by calling at IRQL <= APC_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.

MmAllocatePagesForMdl

MmGetSystemAddressForMdl macro

1/25/2019 • 2 minutes to read • Edit Online

The **MmGetSystemAddressForMdl** routine is obsolete for Windows 2000 and later versions of Windows, and for Windows Me. It is supported only for WDM drivers that must run on Windows 98. Otherwise, use MmGetSystemAddressForMdlSafe.

MmGetSystemAddressForMdl is a macro that returns a nonpaged system-space virtual address for the buffer described by the MDL. It maps the physical pages described by a given MDL into system space, if they are not already mapped to system space.

Syntax

```
void MmGetSystemAddressForMdl(
   MDL
);
```

Parameters

`MDL`

Pointer to a buffer whose corresponding base virtual address is to be mapped.

Return Value

MmGetSystemAddressForMdl returns the base system-space virtual address that maps the physical pages described by the given MDL.

Remarks

Drivers of PIO devices call this routine to translate a virtual address range, described by the MDL at **Irp->MdlAddress**, for a user buffer to a system-space address range.

The MDL must describe nonpageable memory. In other words, the input MDL must describe an already locked-down user-space buffer returned by MmProbeAndLockPages, a locked-down buffer returned by MmBuildMdlForNonPagedPool, or system-space memory allocated from nonpaged pool, contiguous memory, or noncached memory.

The returned base address has the same offset as the virtual address in the MDL.

Windows 2000 issues a bug check if the attempt to map to system space fails. (Therefore, you should use MmGetSystemAddressForMdlSafe instead). In Windows 98, this routine returns **NULL** in case of failure.

Requirements

Minimum supported client	Obsolete for Windows 2000 and later versions of Windows, and for Windows Me. This routine is supported only for WDM drivers that must run on Windows 98. Otherwise, use MmGetSystemAddressForMdlSafe.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

MmGetSystemRoutineAddress function

1/25/2019 • 2 minutes to read • Edit Online

The **MmGetSystemRoutineAddress** routine returns a pointer to a function specified by *SystemRoutineName*.

Syntax

```
PVOID MmGetSystemRoutineAddress(
  PUNICODE_STRING SystemRoutineName
);
```

Parameters

`SystemRoutineName`

Specifies the name of the system routine to resolve.

Return Value

If the function name can be resolved, the routine returns a pointer to the function. Otherwise, the routine returns **NULL**.

Remarks

Drivers can use this routine to determine if a routine is available on a specific version of Windows. It can only be used for routines exported by the kernel or HAL, not for any driver-defined routine.

Requirements

Minimum supported client	Available starting with Windows 2000.

MmIsDriverSuspectForVerifier function

1/25/2019 • 2 minutes to read • Edit Online

The **MmIsDriverSuspectForVerifier** routine indicates whether the driver represented by the specified driver object is in the list of drivers that are selected to be verified by Driver Verifier.

Syntax

```
LOGICAL MmIsDriverSuspectForVerifier(
  _DRIVER_OBJECT *DriverObject
);
```

Parameters

`DriverObject`

A pointer to the driver object. This object is a DRIVER_OBJECT structure that represents a loaded driver image. The driver receives this pointer as an input parameter to its DriverEntry routine.

Return Value

MmIsDriverSuspectForVerifier returns **TRUE** if the driver is selected for verification. Otherwise, the routine returns **FALSE**.

Remarks

A kernel-mode driver can call this routine to determine whether it is being monitored by Driver Verifier. Driver Verifier monitors kernel-mode drivers to detect illegal function calls or actions that might corrupt the system. To select drivers to be verified, you can use the Verifier Command Line or Driver Verifier Manager. For more information about adding drivers to the driver verification list, see Selecting Drivers to be Verified.

A related routine, MmIsDriverVerifying, returns **TRUE** if the specified driver either is in the driver verification list or imports calls to entry points in a driver that is in the driver verification list. Otherwise, **MmIsDriverVerifying** returns **FALSE**.

For example, if driver A has an import table through which it calls one or more entry points in driver B, and driver B is in the driver verification list, then `MmIsDriverVerifying(A)` returns **TRUE** and `MmIsDriverSuspectForVerifier(B)` returns **TRUE**. If driver A is not in the driver verification list, `MmIsDriverSuspectForVerifier(A)` returns **FALSE**. Even if driver B does not call entry points in any drivers that are in the driver verification list, `MmIsDriverVerifying(B)` returns **TRUE** because driver B is in the driver verification list. If a driver C is not in the driver verification list and does not call entry points in any drivers that are in the driver verification list, `MmIsDriverVerifying(C)` and `MmIsDriverSuspectForVerifier(C)` both return **FALSE**.

Another related routine, MmIsDriverVerifyingByAddress, indicates whether a driver identified by a driver image address is being verified or calls a driver that is being verified. **MmIsDriverVerifyingByAddress** is available starting with Windows Vista.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	wdm.h (include Ntddk.h, Ntifs.h)

MmIsDriverVerifying function

1/25/2019 • 2 minutes to read • Edit Online

The **MmIsDriverVerifying** routine indicates whether the kernel-mode driver that is identified by the specified driver object is being verified or calls a driver that is being verified by Driver Verifier.

Syntax

```
LOGICAL MmIsDriverVerifying(
  _DRIVER_OBJECT *DriverObject
);
```

Parameters

`DriverObject`

A pointer to a DRIVER_OBJECT structure that represents a driver object. The driver receives this pointer as an input parameter to its DriverEntry routine.

Return Value

MmIsDriverVerifying returns **TRUE** if the specified driver either is in the driver verification list or imports calls to entry points in a driver that is in the driver verification list. Otherwise, this routine returns **FALSE**.

Remarks

A kernel-mode driver can call this routine to determine whether it is being monitored by Driver Verifier. Driver Verifier monitors kernel-mode drivers to detect illegal function calls or actions that might corrupt the system. To select drivers to be verified, you can use the Verifier Command Line or Driver Verifier Manager. For more information about adding drivers to the driver verification list, see Selecting Drivers to be Verified.

A similar routine, MmIsDriverVerifyingByAddress, indicates whether a driver identified by a driver image address is being verified or calls a driver that is being verified. **MmIsDriverVerifyingByAddress** is available starting with Windows Vista.

Another related routine, MmIsDriverSuspectForVerifier, indicates whether a driver represented by a driver object is in the list of drivers that are selected to be verified. **MmIsDriverSuspectForVerifier** is available starting with Windows 8.

For example, if driver A has an import table through which it calls one or more entry points in driver B, and driver B is in the driver verification list, then `MmIsDriverVerifying(A)` returns **TRUE** and `MmIsDriverSuspectForVerifier(B)` returns **TRUE**. If driver A is not in the driver verification list, `MmIsDriverSuspectForVerifier(A)` returns **FALSE**. Even if driver B does not call entry points in any drivers that are in the driver verification list, `MmIsDriverVerifying(B)` returns **TRUE** because driver B is in the driver verification list. If a driver C is not in the driver verification list and does not call entry points in any drivers that are in the driver verification list, `MmIsDriverVerifying(C)` and `MmIsDriverSuspectForVerifier(C)` both return **FALSE**.

MmIsDriverVerifyingByAddress

MmIsDriverVerifyingByAddress function

1/25/2019 • 2 minutes to read • Edit Online

The **MmIsDriverVerifyingByAddress** routine checks whether the kernel-mode driver that is identified by the specified image address is being verified or calls a driver that is being verified by Driver Verifier.

Syntax

```
LOGICAL MmIsDriverVerifyingByAddress(
  PVOID AddressWithinSection
);
```

Parameters

`AddressWithinSection`

A pointer to the virtual address within the driver image. **MmIsDriverVerifyingByAddress** uses this address to determine which driver to check.

Return Value

MmIsDriverVerifyingByAddress returns **TRUE** if the specified driver either is in the driver verification list or imports calls to entry points in a driver that is in the driver verification list. Otherwise, this routine returns **FALSE**.

Remarks

A kernel-mode driver can call this routine to determine whether it or another driver is being monitored by Driver Verifier. Driver Verifier monitors kernel-mode drivers to detect illegal function calls or actions that might corrupt the system. To select drivers to be verified, you can use the Verifier Command Line or Driver Verifier Manager. For more information about adding drivers to the driver verification list, see Selecting Drivers to be Verified.

A similar routine, MmIsDriverVerifying, indicates whether a driver identified by a driver object is being verified or calls a driver that is being verified.

Another related routine, MmIsDriverSuspectForVerifier, indicates whether a driver represented by a driver object is in the list of drivers that are selected to be verified.

For example, if driver A has an import table through which it calls one or more entry points in driver B, and driver B is in the driver verification list, then `MmIsDriverVerifyingByAddress(Aobj)` returns **TRUE** and `MmIsDriverSuspectForVerifier(Badr)` returns **TRUE**, where `Aobj` is a pointer to the driver object for A and `Badr` is an address in driver B. If driver A is not in the driver verification list, `MmIsDriverSuspectForVerifier(Aobj)` returns **FALSE**. Even if driver B does not call entry points in any drivers that are in the driver verification list, `MmIsDriverVerifyingByAddress(Badr)` returns **TRUE** because driver B is in the driver verification list. If a driver C is not in the driver verification list and does not call entry points in any drivers that are in the driver verification list, `MmIsDriverVerifyingByAddress(Cadr)` and `MmIsDriverSuspectForVerifier(Cobj)` both return **FALSE**.

MmIsDriverVerifying

MmLockPagableCodeSection macro

1/25/2019 • 5 minutes to read • Edit Online

The **MmLockPagableCodeSection** routine locks a section of driver code, containing a set of driver routines marked with a special compiler directive, into system space.

Syntax

```
void MmLockPagableCodeSection(
   Address
);
```

Parameters

`Address`

Specifies a symbolic address. This address is typically the name of a driver function within a section of driver code that has been marked with something like **#pragma alloc_text (PAGExxxx, driverfunction)**. All functions in the **PAGExxxx** section are then guaranteed to be locked down when this function returns.

Return Value

MmLockPagableCodeSection returns an opaque value that the operating system uses to identify this section of the driver code. This opaque value can be passed subsequently to **MmLockPagableSectionByHandle** (if the driver unlocks and then later relocks the section) or to **MmUnlockPagableImageSection**.

Remarks

The **MmLockPagableCodeSection** routine and **MmUnlockPagableImageSection** (the routine that performs the opposite action) support drivers that can do the following:

- Defer loading a subset of driver routines into resident memory until incoming I/O requests for the driver's devices make it necessary for these routines to process IRPs.
- Make the same subset of driver routines available for paging out when they have completed the processing of I/O requests and no additional requests for the driver's devices are currently expected.

MmLockPagableCodeSection, **MmLockPagableSectionByHandle** and **MmUnlockPagableImageSection** are intended for use by device and intermediate drivers that have the following characteristics:

- The driver has code paths that might not be needed while the system is running, but, if they are needed, the driver's code must be resident because it runs in an arbitrary thread context or at IRQL >= DISPATCH_LEVEL.
- The driver can determine exactly when the pageable routines should be loaded and when they can be paged out again.

For example, the system-supplied fault-tolerant disk driver supports the creation of mirror sets, stripe sets, and volume sets. Yet, a particular machine can be configured only with a mirror set, only with a stripe set, only with a volume set, or with any combination of these three possible options. In these circumstances, the system ftdisk driver reduces the size of its loaded image by marking routines that explicitly support mirror, stripe, and volume sets as belonging to pageable code sections. During driver initialization, pageable code sections are made resident only if the user has configured the

disks to have mirror, stripe, or volume sets. If the user repartitions the disks dynamically, the ftdisk driver locks down any additional pageable code sections necessary to support any mirror, stripe, or volume sets that the user requests.

As other examples, the system-supplied serial and parallel drivers have *DispatchCreate* and *DispatchClose* routines that are called when a particular port is opened for exclusive I/O and when the handle for an opened port is released, respectively. Yet, serial and parallel I/O requests are sporadic, determined by which applications the end user is currently running and which application options the end user is currently exercising. In these circumstances, the system serial and parallel drivers reduce the sizes of their loaded images by marking many routines as belonging to a pageable code section that the *DispatchCreate* routine makes resident only when the first port is opened for I/O.

Note that each of the preceding system drivers satisfies both criteria for having pageable sections: the driver has code paths that might not be needed while the system is running, and the driver can determine exactly when its pageable section should be loaded and can be paged out again.

Because it is an expensive operation to lock down a section, if a driver locks down a pageable code section in more than one place, use **MmLockPagableCodeSection** for the first request. Make subsequent lock requests by calling **MmLockPagableSectionByHandle** passing the handle returned by **MmLockPagableCodeSection**. Locking by handle significantly improves driver performance because the memory manager uses the opaque return value to quickly locate the relevant section rather than searching a loaded module list. A locked down section is unlocked by calling **MmUnlockPagableImageSection**.

Each driver routine within a pageable code section must be marked with the following compiler directive:

```
#pragma alloc_text(PAGExxxx, DriverRoutine)
```

where *xxxx* is an optional four-character, unique identifier for the caller's pageable section and*DriverRoutine* is an entry point to be included within the pageable code section. The keyword **PAGE** and the driver-determined suffix, which can be up to four characters, are case-sensitive; that is, **PAGE** must be capitalized.

A single call to **MmLockPagableCodeSection** in, for example, a driver's *DispatchCreate* routine, causes the entire section, containing every driver routine marked with the same **PAGE***xxxx* identifier, to be locked in system space.

Certain types of driver routines cannot be made part of any driver's pageable section, including the following:

- Never make an ISR pageable. It is possible for a device driver to receive a spurious interrupt even if its device is not in use, particularly if the interrupt vector could be shared. In general, even if a driver can explicitly disable interrupts on its device, an ISR should not be made pageable.
- Never make a DPC routine pageable if the driver cannot control when the DPC is queued, such as any *DpcForIsr* or *CustomDpc* routine that might be queued from an ISR. In general, driver routines that run at IRQL >= DISPATCH_LEVEL and that can be called in an arbitrary thread context or in response to a random external event should not be made pageable.
- Never make the *DispatchRead* or *DispatchWrite* routine pageable in any driver that might be part of the system paging I/O path. The driver of a disk that might contain the system page file must have *DispatchRead* and *DispatchWrite* routines that are resident while the system is running, as must all drivers layered above such a disk driver.

Note that routines in a pageable section marked with the compiler directive **#pragma alloc_text(PAGExxxx, ...)** differ from routines marked with the compiler directive **#pragma alloc_text(INIT, ...)**. The routines in the **INIT** section are not pageable and are discarded as soon as the driver returns from its **DriverEntry** or its *Reinitialize* routine, if it has one.

The memory manager maintains an internal lock count on any driver's pageable section. Calls to **MmLockPagableCodeSection** increment this count and the reciprocal **MmUnlockPagableImageSection** decrements the count. A driver's pageable section is not available to be paged out unless this count is zero.

For more information about creating pageable code sections, see Making Drivers Pageable.

MmResetDriverPaging

MmUnlockPagableImageSection

MmLockPagableDataSection function

1/25/2019 • 2 minutes to read • Edit Online

The **MmLockPagableDataSection** routine locks an entire section of driver data into system space.

Syntax

```
PVOID MmLockPagableDataSection(
  PVOID AddressWithinSection
);
```

Parameters

`AddressWithinSection`

Specifies the symbolic address of one item of data within the pageable section.

Return Value

MmLockPagableDataSection returns an opaque value that identifies the section. This value must be passed subsequently to **MmLockPagableSectionByHandle** or to **MmUnlockPagableImageSection**.

Remarks

Drivers can use this routine, **MmLockPagableSectionByHandle**, and **MmUnlockPagableImageSection** to make their private data that is typically pageable locked into memory.

Data can be locked down if:

- The data is typically accessed at <= APC_LEVEL, but it might need to be accessed at higher IRQL levels for short periods.
- The driver uses the data infrequently and predictably.

For example, drivers for mixer devices use pageable-data sections. Because the driver uses sufficient data to make creating a pageable-data section worthwhile and the driver knows when the data is needed, such a driver uses **MmLockPagableDataSection**, **MmLockPagableSectionByHandle** and **MmUnlockPagableImageSection** to bring a data section into system space when needed and make it available to be paged out when not needed.

A single call to **MmLockPagableDataSection** causes the entire section, containing the referenced data, to be locked into system space.

It is an expensive operation to lock down a section. If a pageable-data section is locked down in more than one place by a driver, use **MmLockPagableDataSection** for the first request. Make subsequent lock requests by calling **MmLockPagableSectionByHandle**, passing the handle returned by **MmLockPagableDataSection**. Locking by handle significantly improves driver performance. A locked down section is unlocked by calling **MmUnlockPagableImageSection**.

The memory manager maintains a reference count on the section. A pageable-data section is only available to be paged out when the reference count is zero. Every lock request increments the count; every unlock request decrements the count. A driver must unlock a section as many times as it locks a section to ensure that such a section will be available to be paged out when the section is not needed. A handle is always valid, no matter what

the count. If the count on a handle is zero and a call is made to **MmLockPagableSectionByHandle**, the count is set to one, and if the section has been paged out, it will be paged in.

Data in a pageable-data section is marked by a compiler directive. To create a pageable data section, use **#pragma data_seg ("PAGE")**, at the beginning of the data module, and **#pragma data_seg ()** at the end of the module. The keyword **PAGE** is case-sensitive, that is, **PAGE** must be capitalized.

Note that there is also a **#pragma data_seg("INIT")** that is used to make data discardable after system initialization. Except for the use of **INIT** rather than **PAGE**, the syntax is the same. However the result is not; use of the **PAGE** directive makes the data section pageable. When the **INIT** directive is used, the data in the section is discarded as soon as the driver returns from its driver entry routine or its reinitialization routine if the driver has one.

For more information about paging data, see Making Drivers Pageable.

MmMapIoSpace function

1/25/2019 • 2 minutes to read • Edit Online

The **MmMapIoSpace** routine maps the given physical address range to nonpaged system space.

Syntax

```
PVOID MmMapIoSpace(
  PHYSICAL_ADDRESS    PhysicalAddress,
  SIZE_T              NumberOfBytes,
  MEMORY_CACHING_TYPE CacheType
);
```

Parameters

`PhysicalAddress`

Specifies the starting physical address of the I/O range to be mapped.

`NumberOfBytes`

Specifies a value greater than zero, indicating the number of bytes to be mapped.

`CacheType`

Specifies a MEMORY_CACHING_TYPE value, which indicates the cache attribute to use to map the physical address range.

Return Value

MmMapIoSpace returns the base virtual address that maps the base physical address for the range. If space for mapping the range is insufficient, it returns **NULL**.

Remarks

A driver must call this routine during device start-up if it receives translated resources of type **CmResourceTypeMemory** in a CM_PARTIAL_RESOURCE_DESCRIPTOR structure. **MmMapIoSpace** maps the physical address returned in the resource list to a logical address through which the driver can access device registers.

For example, drivers of PIO devices that allocate long-term I/O buffers can call this routine to make such buffers accessible or to make device memory accessible.

For more information about using this routine, see Mapping Bus-Relative Addresses to Virtual Addresses.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=DISPATCH_LEVEL"

MmMapIoSpaceEx function

1/25/2019 • 2 minutes to read • Edit Online

The **MmMapIoSpaceEx** routine maps the given physical address range to non-paged system space using the specified page protection.

Syntax

```
PVOID MmMapIoSpaceEx(
  PHYSICAL_ADDRESS PhysicalAddress,
  SIZE_T           NumberOfBytes,
  ULONG            Protect
);
```

Parameters

`PhysicalAddress`

Specifies the starting physical address of the I/O range to be mapped.

`NumberOfBytes`

Specifies a value greater than zero, indicating the number of bytes to be mapped.

`Protect`

Flag bits that specify the protection to use for the mapped range. The caller must set one of the following flag bits in the *Protect* parameter.

FLAG BIT	MEANING
PAGE_READONLY	The mapped range can only be read, not written.
PAGE_READWRITE	The mapped range can be read or written.
PAGE_EXECUTE	The mapped range can be executed, but not read or written.
PAGE_EXECUTE_READ	The mapped range can be executed or read, but not written.
PAGE_EXECUTE_READWRITE	The mapped range can be executed, read, or written.

In addition, the caller can set one (but not both) of the following optional flag bits in the *Protect* parameter.

FLAG BIT	MEANING
PAGE_NOCACHE	Specifies non-cached memory.
PAGE_WRITECOMBINE	Specifies write-combined memory (the memory should not be cached by the processor, but writes to the memory can be combined by the processor).

Return Value

MmMapIoSpaceEx returns the base virtual address that maps the base physical address for the range. If space for mapping the range is insufficient, it returns **NULL**.

Remarks

A driver must call this routine during device start-up if it receives translated resources of type **CmResourceTypeMemory** in a CM_PARTIAL_RESOURCE_DESCRIPTOR structure. **MmMapIoSpaceEx** maps the physical address returned in the resource list to a logical address through which the driver can access device registers.

For example, drivers of PIO devices that allocate long-term I/O buffers can call this routine to make such buffers accessible or to make device memory accessible.

For more information about using this routine, see Mapping Bus-Relative Addresses to Virtual Addresses.

Requirements

Minimum supported client	Available starting with Windows 10.

MmAllocateContiguousMemory

MmAllocateNonCachedMemory

MmMapLockedPages

MmUnmapIoSpace

MmMapLockedPages function

1/25/2019 • 2 minutes to read • Edit Online

The **MmMapLockedPages** routine is obsolete for Windows 2000 and later versions of Windows, and for Windows Me. It is supported only for WDM drivers that must run on Windows 98. Otherwise, use MmMapLockedPagesSpecifyCache.

The **MmMapLockedPages** routine maps the physical pages that are described by a given MDL.

Syntax

```
PVOID MmMapLockedPages(
  PMDL                                                                    MemoryDescriptorList,
  __drv_strictType(KPROCESSOR_MODE / enum _MODE,__drv_typeConst)KPROCESSOR_MODE AccessMode
);
```

Parameters

`MemoryDescriptorList`

Pointer to an MDL that was updated by MmProbeAndLockPages.

`AccessMode`

Specifies the access mode in which to map the MDL, either **KernelMode** or **UserMode**. Almost all drivers should use **KernelMode**.

Return Value

MmMapLockedPages returns the starting address of the mapped pages. (For NT-based operating systems prior to Windows NT 4.0 Service Pack 4 (SP4), **MmMapLockedPages** returns the beginning address of the first page of the mapped pages.)

Remarks

Use MmUnmapLockedPages to unmap the physical pages that were mapped by **MmMapLockedPages**.

If *AccessMode* is KernelMode and **MmMapLockedPages** cannot map the specified pages, the system issues a bug check. (For this reason, drivers should use MmMapLockedPagesSpecifyCache when available; that routine returns **NULL** on failure, rather than causing a bug check.) If *AccessMode* is **UserMode** and the specified pages cannot be mapped, the routine raises an exception. Callers that specify **UserMode** must wrap the call to **MmMapLockedPages** in a **try/except** block. For more information, see Handling Exceptions.

Callers of **MmMapLockedPages** must be running at IRQL <= DISPATCH_LEVEL if *AccessMode* is **KernelMode**. Otherwise, the caller must be running at IRQL <= APC_LEVEL.

Requirements

Minimum supported client	Obsolete for Windows 2000 and later versions of Windows, and for Windows Me. This routine is supported only for WDM drivers that must run on Windows 98. Otherwise, use MmMapLockedPagesSpecifyCache.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	See Remarks section.

MmMapLockedPagesSpecifyCache

MmProbeAndLockPages

MmUnmapLockedPages

MmMapLockedPagesSpecifyCache function

1/25/2019 • 4 minutes to read • Edit Online

The **MmMapLockedPagesSpecifyCache** routine maps the physical pages that are described by an MDL to a virtual address, and enables the caller to specify the cache attribute that is used to create the mapping.

Syntax

```
PVOID MmMapLockedPagesSpecifyCache(
  PMDL                                                                  MemoryDescriptorList,
  __drv_strictType(KPROCESSOR_MODE / enum _MODE,__drv_typeConst)KPROCESSOR_MODE AccessMode,
  __drv_strictTypeMatch(__drv_typeCond)MEMORY_CACHING_TYPE              CacheType,
  PVOID                                                                 RequestedAddress,
  ULONG                                                                 BugCheckOnFailure,
  ULONG                                                                 Priority
);
```

Parameters

`MemoryDescriptorList`

A pointer to the MDL that is to be mapped. This MDL must describe physical pages that are locked down. A locked-down MDL can be built by the MmProbeAndLockPages or MmAllocatePagesForMdlEx routine. For mappings to user space, MDLs that are built by the MmBuildMdlForNonPagedPool routine can be used.

`AccessMode`

Specifies the access mode in which to map the MDL: **KernelMode** or **UserMode**. Almost all drivers should use **KernelMode**.

`CacheType`

Specifies a MEMORY_CACHING_TYPE value, which indicates the cache attribute to use to map the MDL. For more information, see the following Remarks section.

`RequestedAddress`

[in, optional]

If *AccessMode* = **UserMode**, this parameter specifies the starting user virtual address to map the MDL to, or set to **NULL** to allow the system to choose the starting address. The system might round down the requested address to fit address boundary requirements, so callers must check the return value.

`BugCheckOnFailure`

Specifies the behavior of the routine for *AccessMode* = **KernelMode** if the MDL cannot be mapped because of low system resources. If **TRUE**, the system issues a bug check. If **FALSE**, the routine returns **NULL**. Drivers must set this parameter to **FALSE**.

`Priority`

An **MM_PAGE_PRIORITY** value that indicates the importance of success when page table entries (PTEs) are scarce. Starting with Windows 8, the specified priority value can be bitwise-ORed with the **MdlMappingNoWrite** or **MdlMappingNoExecute** flags to specify memory in which writes or instruction execution are disabled. For

more information about the possible values for *Priority*, see MmGetSystemAddressForMdlSafe.

Return Value

MmMapLockedPagesSpecifyCache returns the starting address of the mapped pages. If the pages cannot be mapped and *BugCheckOnFailure* is **FALSE**, the routine returns **NULL**.

Remarks

Use MmUnmapLockedPages to unmap the physical pages that were mapped by **MmMapLockedPagesSpecifyCache**.

If *AccessMode* is **KernelMode**, and if **MmMapLockedPagesSpecifyCache** cannot map the specified pages, the routine returns **NULL** (if *BugCheckOnFailure* = **FALSE**), or the operating system issues a bug check (if *BugCheckOnFailure* = **TRUE**).

If *AccessMode* is **UserMode**, be aware of the following details:

- If the specified pages cannot be mapped, the routine raises an exception. Callers that specify **UserMode** must wrap the call to **MmMapLockedPagesSpecifyCache** in a **try/except** block. For more information, see Handling Exceptions.
- The routine returns a user address that is valid in the context of the process in which the driver is running. For example, if a 64-bit driver is running in the context of a 32-bit application, the buffer is mapped to an address in the 32-bit address range of the application.
- A non-executable mapping is always created when *AccessMode* is **UserMode**. Therefore, using the **MdlMappingNoExecute** flag with the *Priority* parameter is unnecessary in this scenario. However, the **MdlMappingNoWrite** flag can still be used with the *Priority* parameter in this scenario to request a read-only mapping.
- The non-executable protection of the mapping and any write protection of the mapping specified by using the **MdlMappingNoWrite** flag with the *Priority* parameter cannot be changed by code that is running in user mode. For example, if a driver maps some pages into a user process and specifies the **MdlMappingNoWrite** flag, the system guarantees that the process cannot modify the pages.

The routine uses the *CacheType* parameter only if the pages that are described by the MDL do not already have a cache type associated with them. However, in nearly all cases, the pages already have an associated cache type, and this cache type is used by the new mapping. An exception to this rule is for pages that are allocated by MmAllocatePagesForMdl, which do not have a specific cache type associated with them. For such pages, the *CacheType* parameter determines the cache type of the mapping.

A driver must not try to create more than one system-address-space mapping for an MDL. Additionally, because an MDL that is built by the MmBuildMdlForNonPagedPool routine is already mapped to the system address space, a driver must not try to map this MDL into the system address space again by using the **MmMapLockedPagesSpecifyCache** routine (although creating user-address-space mappings is allowed). If it is not known whether a locked-down MDL already has a system-address-space mapping, a driver can use the MmGetSystemAddressForMdlSafe macro instead of **MmMapLockedPagesSpecifyCache**. If the MDL is already mapped into the system address space, **MmGetSystemAddressForMdlSafe** will return the existing system-address-space mapping instead of creating a new mapping.

Warning A driver that maps kernel memory into user address space must avoid exposing potentially sensitive kernel data to untrusted processes. Uninitialized buffers, such as buffers that are allocated from pool, must be explicitly filled with zeros before they are mapped. In addition, the size of a user-mode buffer that is allocated from pool must be a multiple of the virtual memory page size to prevent any part of the pages in the buffer from being used for other allocations. Finally, buffers must not be freed back to the pool while they are still mapped to user address space.

If *AccessMode* is **UserMode**, the caller must be running at IRQL <= APC_LEVEL. If *AccessMode* is **KernelMode**, the caller must be running at IRQL <= DISPATCH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

MmMapLockedPagesWithReservedMapping function

1/25/2019 • 2 minutes to read • Edit Online

The **MmMapLockedPagesWithReservedMapping** routine maps all or part of an address range that was previously reserved by the MmAllocateMappingAddress routine.

Syntax

```
PVOID MmMapLockedPagesWithReservedMapping(
  PVOID                                                MappingAddress,
  ULONG                                                PoolTag,
  PMDL                                                 MemoryDescriptorList,
  __drv_strictTypeMatch(__drv_typeCond)MEMORY_CACHING_TYPE CacheType
);
```

Parameters

`MappingAddress`

Pointer to the beginning of the reserved virtual memory range. This must be an address previously returned by MmAllocateMappingAddress.

`PoolTag`

Specifies the pool tag for the reserved memory buffer. This must be identical to the value specified in the *PoolTag* parameter of the call to MmAllocateMappingAddress that reserved the buffer.

`MemoryDescriptorList`

A pointer to the MDL that is to be mapped. This MDL must describe physical pages that are locked down. A locked-down MDL can be built by the MmProbeAndLockPages or MmAllocatePagesForMdlEx routine.

`CacheType`

Specifies the MEMORY_CACHING_TYPE value to use to create the mapping.

Return Value

MmMapLockedPagesWithReservedMapping returns a pointer to the beginning of the mapped memory, or **NULL** if the system could not map the memory. This routine returns **NULL** only if there is an error in the function parameters (for example, the driver's mapping address is not large enough to span the supplied MDL). This function is intended to enable drivers to make forward progress even in low-resource scenarios.

Remarks

The caller can use **MmMapLockedPagesWithReservedMapping** to map a subrange of the virtual memory range reserved by MmAllocateMappingAddress as follows:

1. Use IoAllocateMdl to allocate an MDL. The returned MDL is built using the specified starting address and size of the subrange of the virtual memory range to map.
2. Use MmProbeAndLockPages to lock down the physical pages described by the MDL obtained in step 1.

3. Use **MmMapLockedPagesWithReservedMapping** to actually map the virtual memory to the physical memory that was locked down in step 2. Note that the virtual address returned by this function does include the byte offset that the MDL specifies. However, the **MappedSystemVa** field of the MDL that is set by this function does not include the byte offset.

Once the caller does not need to access the memory, it unmaps the memory with MmUnmapReservedMapping. The caller can map and unmap the memory buffer as needed, and must unmap it prior to freeing the mapping range with MmFreeMappingAddress.

Note that the *MappingAddress* parameter specifies the beginning of the range of memory previously reserved by the caller, not the beginning of the memory subrange to be mapped. The caller specifies the starting address and length of the buffer when it allocates the MDL with IoAllocateMdl. The buffer must fit inside the reserved memory range, but it can be a strict subset.

The routine uses the *CacheType* parameter only if the pages that are described by the MDL do not already have a cache type associated with them. However, in nearly all cases, the pages already have an associated cache type, and this cache type is used by the new mapping. An exception to this rule is for pages that are allocated by MmAllocatePagesForMdl, which do not have a specific cache type associated with them. For such pages, the *CacheType* parameter determines the cache type of the mapping.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

MmMapMdl function

1/25/2019 • 2 minutes to read • Edit Online

This function maps physical pages described by a memory descriptor list (MDL) into the system virtual address space.

Syntax

```
NTSTATUS MmMapMdl(
  PMDL            MemoryDescriptorList,
  ULONG           Protection,
  PMM_MDL_ROUTINE DriverRoutine,
  PVOID           DriverContext
);
```

Parameters

`MemoryDescriptorList`

A pointer to a valid MDL.

`Protection`

A bitwise of flags that indicates the protection to set for the pages. Possible values are PAGE_Xxx constants defined in Wdm.h.

`DriverRoutine`

A pointer to a driver-supplied callback routine (MM_MDL_ROUTINE) that is invoked after the MDL is mapped.

`DriverContext`

A pointer to a driver-defined context. The driver's callback function can store any status information in the driver context and then examine the value, when the callback is invoked.

Return Value

If the callback function pointed to by *DriverRoutine* was invoked, this function returns STATUS_SUCCESS. The function returns an appropriate NTSTATUS value if the MDL could not be mapped or the callback function could not be invoked.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Target Platform	Windows

Header	wdm.h
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode)
IRQL	"<=DISPATCH_LEVEL"

MM_MDL_ROUTINE

MmPageEntireDriver function

1/25/2019 • 2 minutes to read • Edit Online

The **MmPageEntireDriver** routine causes all of a driver's code and data to be made pageable, overriding the attributes of the various sections that make up the driver's image.

Syntax

```
PVOID MmPageEntireDriver(
  PVOID AddressWithinSection
);
```

Parameters

`AddressWithinSection`

Pointer to a virtual address within the driver (for example, the address of the DriverEntry routine).

Return Value

MmPageEntireDriver returns a pointer to the beginning of the driver image in memory.

Remarks

Use this routine to force a driver to be completely pageable. Drivers that call **MmPageEntireDriver** must not have an InterruptService routine (ISR) registered for any interrupts. If the interrupt occurs while the driver is paged out, the system issues a bug check.

The effect of a call to **MmPageEntireDriver** can be undone by calling MmResetDriverPaging.

If the driver is already completely pageable, calling **MmPageEntireDriver** has no effect. For more information about paging an entire driver, see Making Drivers Pageable.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

DDI compliance rules	IrqlMmApcLte, HwStorPortProhibitedDDIs

MmProbeAndLockPages function

1/25/2019 • 2 minutes to read • Edit Online

The **MmProbeAndLockPages** routine probes the specified virtual memory pages, makes them resident, and locks them in memory.

Syntax

```
void MmProbeAndLockPages(
  PMDL            MemoryDescriptorList,
  KPROCESSOR_MODE AccessMode,
  LOCK_OPERATION  Operation
);
```

Parameters

`MemoryDescriptorList`

A pointer to an MDL that specifies a virtual memory buffer. If the routine successfully locks the pages in memory, the MDL is updated to describe the underlying physical pages.

`AccessMode`

The access mode in which to probe the arguments, either **KernelMode** or **UserMode**.

`Operation`

The type of operation for which the caller wants the access rights probed and the pages locked. Set this parameter to **IoReadAccess**, **IoWriteAccess**, or **IoModifyAccess**. **IoReadAccess** indicates that the driver can examine the contents of the buffer but cannot change the contents. **IoWriteAccess** and **IoModifyAccess**, which are equivalent, indicate that the driver has both read and write access to the buffer.

Return Value

None

Remarks

The highest-level driver in a chain of layered drivers that use direct I/O calls this routine. Drivers that use buffered I/O never call **MmProbeAndLockPages**.

MmProbeAndLockPages performs the following operations:

1. If the specified memory range is paged to a backing store (disk, network, and so on), **MmProbeAndLockPages** makes it resident.
2. The routine then confirms that the pages permit the operation specified by the *Operation* parameter.
3. If the memory range permits the specified operation, the routine locks the pages in memory so that they cannot be paged out. Use the MmUnlockPages routine to unlock the pages.
4. Finally, the routine updates the page frame number (PFN) array in the MDL to describe the locked physical pages.

A successful call to **MmProbeAndLockPages** locks the pages in an MDL and sets the MDL structure to the locked state. Every such call must be matched by a corresponding call to **MmUnlockPages** that unlocks the pages and sets the MDL to the unlocked state. After an **MmProbeAndLockPages** call sets an MDL to the locked state, a second call to MmProbeAndLockPages to lock the same MDL is not allowed until **MmUnlockPages** is first called to unlock the MDL.

If two or more MDLs describe the same physical page, the page can be locked multiple times—once for each MDL. The page is unlocked when the last MDL is set to the unlocked state.

A routine such as MmBuildMdlForNonPagedPool or IoBuildPartialMdl updates an MDL to describe pages that are either nonpageable or already locked. A call to **MmProbeAndLockPages** or **MmUnlockPages** to lock or unlock such an MDL is not allowed.

Calls to **MmProbeAndLockPages** must be enclosed in a **try/except** block. If the pages do not support the specified operation, the routine raises the STATUS_ACCESS_VIOLATION or other exceptions. For more information, see Handling Exceptions.

Callers of **MmProbeAndLockPages** must be running at IRQL <= APC_LEVEL for pageable addresses, or at IRQL <= DISPATCH_LEVEL for nonpageable addresses.

This routine does not provide any guarantees about the virtual address that describes these pages (that is, the virtual address might be unmapped, reused, and so on). However, the physical pages are guaranteed to be locked on successful return.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	See Remarks section.
DDI compliance rules	HwStorPortProhibitedDDIs

MmUnlockPages

MmProbeAndLockSelectedPages function

1/25/2019 • 2 minutes to read • Edit Online

The **MmProbeAndLockSelectedPages** routine probes the selected virtual memory pages, makes them resident, and locks them in memory.

Syntax

```
void MmProbeAndLockSelectedPages(
  PMDL                 MemoryDescriptorList,
  PFILE_SEGMENT_ELEMENT SegmentArray,
  KPROCESSOR_MODE      AccessMode,
  LOCK_OPERATION       Operation
);
```

Parameters

`MemoryDescriptorList`

A pointer to a memory descriptor list (MDL) that specifies a virtual memory buffer. If the routine successfully locks the pages in memory, the MDL is updated to describe the underlying physical pages.

`SegmentArray`

A pointer to an array of buffer segments that contain the virtual memory pages.

`AccessMode`

Specifies the access mode in which to probe the arguments, either KernelMode or UserMode.

`Operation`

Specifies the type of operation for which the caller wants the access rights probed and the pages locked. Set this parameter to IoReadAccess, IoWriteAccess, or IoModifyAccess. IoReadAccess indicates that the driver can examine the contents of the buffer but cannot change the contents. IoWriteAccess and IoModifyAccess, which are equivalent, indicate that the driver has both read and write access to the buffer.

Return Value

None

Remarks

Calls to **MmProbeAndLockSelectedPages** must be enclosed in a **try/except** block. If the pages do not support the specified operation, the routine raises the STATUS_ACCESS_VIOLATION or other exceptions. For more information, see Handling Exceptions.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h
IRQL	"<= APC_LEVEL"

MmProbeAndLockPages

MmProtectMdlSystemAddress function

1/25/2019 • 2 minutes to read • Edit Online

The **MmProtectMdlSystemAddress** routine sets the protection type for a memory address range.

Syntax

```
NTSTATUS MmProtectMdlSystemAddress(
  PMDL  MemoryDescriptorList,
  ULONG NewProtect
);
```

Parameters

`MemoryDescriptorList`

Specifies the memory address range to set the protection type for.

`NewProtect`

Specifies the new protection setting for the memory pages. Drivers should specify one of the following values:

PAGE_NOACCESS

The underlying memory pages cannot be read or written.

PAGE_READONLY

The underlying memory pages can only be read, not written.

PAGE_READWRITE

The underlying memory pages can be read or written.

PAGE_EXECUTE

The underlying memory pages can be executed, but not read or written.

PAGE_EXECUTE_READ

The underlying memory pages can be executed or read, but not written.

PAGE_EXECUTE_READWRITE

The underlying memory pages can be executed, read, or written.

Return Value

MmProtectMdlSystemAddress returns an NTSTATUS code. The possible return values include:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The routine successfully changed the protection type for the memory address range.

STA TUS _IN VAL ID_ PA GE_ PR OTE CTI ON	The value specified for *NewProtect* is not a valid one for this routine.
STA TUS _NO T_M APP ED_ VIE W	The MDL has not yet been mapped. **MmProtectMdlSystemAddress** can only be used on MDLs that have already been mapped.

Remarks

The **MmProtectMdlSystemAddress** routine can only be called on an MDL that has already been mapped. For example, the routine can be called on an MDL mapped by MmMapLockedPagesSpecifyCache.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=DISPATCH_LEVEL"

MmIsThisAnNtAsSystem

MmResetDriverPaging function

1/25/2019 • 2 minutes to read • Edit Online

The **MmResetDriverPaging** routine resets the pageable status of a driver's sections to that specified when the driver was compiled.

Syntax

```
void MmResetDriverPaging(
  PVOID AddressWithinSection
);
```

Parameters

`AddressWithinSection`

A pointer to a virtual address in the driver (for example, the address of the DriverEntry routine).

Return Value

None

Remarks

MmResetDriverPaging causes those routines that would not normally be pageable, to be locked into memory. Hence, image sections such as .text and .data will be locked in memory if this routine is called.

A driver that calls this routine must do so before enabling interrupts on its device.

A call to MmPageEntireDriver is not a prerequisite to calling this routine. However, calls to **MmResetDriverPaging** do nothing if the driver's image-section attributes have never been overridden by a call to **MmPageEntireDriver**.

For more information about paging an entire driver, see Making Drivers Pageable.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

MmSizeOfMdl function

1/25/2019 • 2 minutes to read • Edit Online

The **MmSizeOfMdl** routine returns the number of bytes to allocate for an MDL describing a given address range.

Syntax

```
SIZE_T MmSizeOfMdl(
  PVOID  Base,
  SIZE_T Length
);
```

Parameters

`Base`

Pointer to the base virtual address for the range.

`Length`

Supplies the size, in bytes, of the range.

Return Value

MmSizeOfMdl returns the number of bytes required to contain the MDL.

Remarks

Memory for the MDL itself must be allocated from nonpaged pool.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

MmCreateMdl

MmUnlockPagableImageSection function

1/25/2019 • 2 minutes to read • Edit Online

The **MmUnlockPagableImageSection** routine releases a section of driver code or driver data, previously locked into system space with **MmLockPagableCodeSection**, **MmLockPagableDataSection** or **MmLockPagableSectionByHandle**, so the section can be paged out again.

Syntax

```
void MmUnlockPagableImageSection(
  PVOID ImageSectionHandle
);
```

Parameters

`ImageSectionHandle`

Specifies the handle returned by a call to MmLockPagableCodeSection or MmLockPagableDataSection.

Return Value

None

Remarks

The handle for a driver's pageable section must not be released if the driver has any outstanding IRPs in its device queue(s) or internal queue(s). A call to **MmUnlockPagableImageSection** restores the pageability of that entire section when there are no more references to the handle for that section.

The memory manager maintains the reference count on the handle to a section. A pageable section is only available to be paged out when the reference count is zero. Every lock request increments the count; every unlock request decrements the count. A driver must unlock a section as many times as it locks a section to make the section available to be paged out.

A handle is always valid, no matter what the count. If the count on a handle is zero and a call is made to **MmLockPagableSectionByHandle**, the count is set to one, and if the section has been paged out, it will be paged in.

In most cases, **MmUnlockPagableImageSection** is called before a driver's *Unload* routine. That is, a driver with a pageable section is likely to have its *DispatchClose* and/or *DispatchShutdown* routine call **MmUnlockPagableImageSection** before its *Unload* routine is called. However, care should be taken in unloadable drivers to release any pageable section before the driver itself is unloaded from the system.

For more information about paging code and data, see Making Drivers Pageable.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=APC_LEVEL"
DDI compliance rules	IrqlMmApcLte, HwStorPortProhibitedDDIs

MmUnlockPages function

1/25/2019 • 2 minutes to read • Edit Online

The **MmUnlockPages** routine unlocks the physical pages that are described by the specified memory descriptor list (MDL).

Syntax

```
void MmUnlockPages(
  PMDL MemoryDescriptorList
);
```

Parameters

`MemoryDescriptorList`

A pointer to an MDL.

Return Value

None

Remarks

The memory described by the specified MDL must have been locked previously by a call to MmProbeAndLockPages. If the specified MDL is mapped to system address space, **MmUnlockPages** releases this mapping before it unlocks the pages.

For more information, see Using MDLs.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=DISPATCH_LEVEL"
DDI compliance rules	HwStorPortProhibitedDDIs

MmProbeAndLockPages

MmUnmapIoSpace function

1/25/2019 • 2 minutes to read • Edit Online

The **MmUnmapIoSpace** routine unmaps a specified range of physical addresses previously mapped by **MmMapIoSpace**.

Syntax

```
void MmUnmapIoSpace(
  PVOID  BaseAddress,
  SIZE_T NumberOfBytes
);
```

Parameters

`BaseAddress`

Pointer to the base virtual address to which the physical pages were mapped.

`NumberOfBytes`

Specifies the number of bytes that were mapped.

Return Value

None

Remarks

If a driver calls **MmMapIoSpace** during device start-up, it must call **MmUnmapIoSpace** when it receives a PnP stop-device or remove-device IRP for the same device object.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=DISPATCH_LEVEL"

MmMapIoSpace

MmUnmapLockedPages function

1/25/2019 • 2 minutes to read • Edit Online

The **MmUnmapLockedPages** routine releases a mapping that was set up by a preceding call to the MmMapLockedPages or MmMapLockedPagesSpecifyCache routine.

Syntax

```
void MmUnmapLockedPages(
  PVOID BaseAddress,
  PMDL  MemoryDescriptorList
);
```

Parameters

`BaseAddress`

Pointer to the base virtual address to which the physical pages were mapped.

`MemoryDescriptorList`

Pointer to an MDL.

Return Value

None

Remarks

Callers of **MmUnmapLockedPages** must be running at IRQL <= DISPATCH_LEVEL if the pages were mapped to system space. Otherwise, the caller must be running at IRQL <= APC_LEVEL.

Note that if the call to **MmMapLockedPages** or **MmMapLockedPagesSpecifyCache** specified user mode, the caller must be in the context of the original process before calling **MmUnmapLockedPages**. This is because the unmapping operation occurs in the context of the calling process, and, if the context is incorrect, the unmapping operation could delete the address range of a random process.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

MmUnmapReservedMapping function

1/25/2019 • 2 minutes to read • Edit Online

The **MmUnmapReservedMapping** routine unmaps a memory buffer that was mapped by the MmMapLockedPagesWithReservedMapping routine.

Syntax

```
void MmUnmapReservedMapping(
  PVOID BaseAddress,
  ULONG PoolTag,
  PMDL  MemoryDescriptorList
);
```

Parameters

`BaseAddress`

Pointer to the beginning of the reserved virtual memory range. This must be an address returned by MmMapLockedPagesWithReservedMapping.

`PoolTag`

Specifies the pool tag for the reserved memory buffer. This must be identical to the value specified in the *PoolTag* parameter of the call to MmAllocateMappingAddress that initially reserved the buffer.

`MemoryDescriptorList`

Pointer to the MDL that describes the physical memory mapping.

Return Value

None

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=DISPATCH_LEVEL"

MmFreeMappingAddress

MmMapLockedPagesWithReservedMapping

NtCommitComplete function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwCommitComplete** routine notifies KTM that the calling resource manager has finished committing a transaction's data.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtCommitComplete(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SUBORDINATE_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwCommitComplete returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.
STA TUS _TR AN SAC TIO N_N OT_ REQ UES TED	The transaction or its enlistment is not in the correct state.

The routine might return other NTSTATUS values.

Remarks

A resource manager must call **ZwCommitComplete** after it has finished servicing a TRANSACTION_NOTIFY_COMMIT notification.

For more information about **ZwCommitComplete**, see Handling Commit Operations.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

TmCommitComplete

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwOpenEnlistment

NtCommitEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwCommitEnlistment** routine initiates the commit operation for a specified enlistment's transaction.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtCommitEnlistment(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The object must represent a superior enlistment and the handle must have ENLISTMENT_SUPERIOR_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwCommitEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STATUS_ACCESS_DENIED	The caller does not have appropriate access to the enlistment object.
STATUS_ENLISTMENT_NOT_SUPERIOR	The caller is not a superior transaction manager for the enlistment.
STATUS_TRANSACTION_RESPONSE_NOT_ENLISTED	The caller did not register to receive TRANSACTION_NOTIFY_COMMIT_COMPLETE notifications.
STATUS_TRANSACTION_REQUEST_NOT_VALID	The enlistment's transaction is not in a state that allows it to be committed.

STA TUS _TR AN SAC TIO N_N OT_ ACT IVE	The commit operation for this transaction has already been started.
STA TUS _TR AN SAC TIO N_A LRE AD Y_A BO RTE D	The transaction cannot be committed because it has been rolled back.

The routine might return other NTSTATUS values.

Remarks

Only superior transaction managers can call **ZwCommitEnlistment**.

Callers of **ZwCommitEnlistment** must register to receive TRANSACTION_NOTIFY_COMMIT_COMPLETE notifications.

The **ZwCommitEnlistment** routine causes KTM to send TRANSACTION_NOTIFY_COMMIT notifications to all resource managers that have enlisted in the transaction.

For more information about **ZwCommitEnlistment**, see Creating a Superior Transaction Manager and Handling Commit Operations.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)

Library	NtosKrnl.lib

TmCommitEnlistment

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwOpenEnlistment

NtCommitTransaction function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwCommitTransaction** routine initiates a commit operation for a specified transaction.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtCommitTransaction(
  HANDLE  TransactionHandle,
  BOOLEAN Wait
);
```

Parameters

`TransactionHandle`

A handle to a transaction object. Your component receives this handle from ZwCreateTransaction or ZwOpenTransaction. The handle must have TRANSACTION_COMMIT access to the object.

`Wait`

A Boolean value that the caller sets to **TRUE** for synchronous operation or **FALSE** for asynchronous operation. If this parameter is **TRUE**, the call returns after the commit operation is complete.

Return Value

ZwCommitTransaction returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The handle that was specified for the *TransactionHandle* parameter is not a handle to a transaction object.
STATUS_INVALID_HANDLE	The specified transaction object handle is invalid.

STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the transaction object.
STA TUS _TR AN SAC TIO N_S UPE RIO R_E XIS TS	The caller cannot commit the transaction because a superior transaction manager exists.
STA TUS _TR AN SAC TIO N_A LRE AD Y_A BO RTE D	The transaction cannot be committed because it has been rolled back.
STA TUS _TR AN SAC TIO N_A LRE AD Y_C OM MIT TED	The transaction is already committed.

STA TUS _TR AN SAC TIO N_R EQU EST _NO T_V ALI D	The commit operation for this transaction has already been started.
STA TUS _PE NDI NG	Commit notifications have been queued to resource managers, and the caller specified **FALSE** for the *Wait* parameter.

The routine might return other NTSTATUS values.

Remarks

For more information about how transaction clients should use the **ZwCommitTransaction** routine, see Creating a Transactional Client.

For more information about commit operations, see Handling Commit Operations.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

TmCommitTransaction

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateTransaction

ZwOpenTransaction

NtCreateEnlistment function

1/25/2019 • 4 minutes to read • Edit Online

The **ZwCreateEnlistment** routine creates a new enlistment object for a transaction.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtCreateEnlistment(
  PHANDLE            EnlistmentHandle,
  ACCESS_MASK        DesiredAccess,
  HANDLE             ResourceManagerHandle,
  HANDLE             TransactionHandle,
  POBJECT_ATTRIBUTES ObjectAttributes,
  ULONG              CreateOptions,
  NOTIFICATION_MASK  NotificationMask,
  PVOID              EnlistmentKey
);
```

Parameters

`EnlistmentHandle`

A pointer to a caller-allocated variable that receives a handle to the new enlistment object if the call to **ZwCreateEnlistment** succeeds.

`DesiredAccess`

An ACCESS_MASK value that specifies the caller's requested access to the enlistment object. In addition to the access rights that are defined for all kinds of objects (see ACCESS_MASK), the caller can specify any of the following access right flags for enlistment objects:

ACCESS_MASK FLAG	ALLOWS THE CALLER TO
ENLISTMENT_QUERY_INFORMATION	Query information about the enlistment (see ZwQueryInformationEnlistment).
ENLISTMENT_SET_INFORMATION	Set information for the enlistment (see ZwSetInformationEnlistment).
ENLISTMENT_RECOVER	Recover the enlistment (see ZwRecoverEnlistment).
ENLISTMENT_SUBORDINATE_RIGHTS	Perform operations that a resource manager that is not superior performs (see ZwRollbackEnlistment, ZwPrePrepareComplete, ZwPrepareComplete, ZwCommitComplete, ZwRollbackComplete, ZwSinglePhaseReject, ZwReadOnlyEnlistment).
ENLISTMENT_SUPERIOR_RIGHTS	Perform operations that a superior transaction manager must perform (see ZwPrepareEnlistment, ZwPrePrepareEnlistment, ZwCommitEnlistment).

Alternatively, you can specify one or more of the following ACCESS_MASK bitmaps. These bitmaps combine the flags from the previous table with the STANDARD_RIGHTS_*XXX* flags that are described on the ACCESS_MASK

reference page. You can also combine these bitmaps together with additional flags from the previous table. The following table shows how the bitmaps correspond to specific access rights.

GENERIC ACCESS RIGHT	SET OF SPECIFIC ACCESS RIGHTS
ENLISTMENT_GENERIC_READ	STANDARD_RIGHTS_READ and ENLISTMENT_QUERY_INFORMATION
ENLISTMENT_GENERIC_WRITE	STANDARD_RIGHTS_WRITE, ENLISTMENT_SET_INFORMATION, ENLISTMENT_RECOVER, ENLISTMENT_REFERENCE, ENLISTMENT_SUBORDINATE_RIGHTS, and ENLISTMENT_SUPERIOR_RIGHTS
ENLISTMENT_GENERIC_EXECUTE	STANDARD_RIGHTS_EXECUTE, ENLISTMENT_RECOVER, ENLISTMENT_SUBORDINATE_RIGHTS, and ENLISTMENT_SUPERIOR_RIGHTS
ENLISTMENT_ALL_ACCESS	STANDARD_RIGHTS_REQUIRED, ENLISTMENT_GENERIC_READ, ENLISTMENT_GENERIC_WRITE, and ENLISTMENT_GENERIC_EXECUTE

`ResourceManagerHandle`

A handle to the caller's resource manager object that was obtained by a previous call to ZwCreateResourceManager or ZwOpenResourceManager.

`TransactionHandle`

A handle to a transaction object that was obtained by a previous call to ZwCreateTransaction or ZwOpenTransaction. KTM adds this transaction to the list of transactions that the calling resource manager is handling.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use the InitializeObjectAttributes routine to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**. This parameter is optional and can be **NULL**.

`CreateOptions`

Enlistment option flags. The following table contains the only available flag.

CREATEOPTIONS FLAG	MEANING
ENLISTMENT_SUPERIOR	The caller is enlisting as a superior transaction manager for the specified transaction.

This parameter is optional and can be zero.

`NotificationMask`

A bitwise OR of TRANSACTION_NOTIFY_*XXX* values that are defined in Ktmtypes.h. This mask specifies the types of transaction notifications that KTM sends to the caller.

`EnlistmentKey`

A pointer to caller-defined information that uniquely identifies the enlistment. The resource manager receives this pointer when it calls ZwGetNotificationResourceManager or when KTM calls the ResourceManagerNotification

callback routine. The resource manager can maintain a reference count for this key by calling TmReferenceEnlistmentKey and TmDereferenceEnlistmentKey. This parameter is optional and can be **NULL**.

Return Value

ZwCreateEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_INVALID_PARAMETER	The *CreateOptions* or *NotificationMask* parameter's value is invalid, or KTM could not find the transaction that the *TransactionHandle* parameter specifies.
STATUS_INSUFFICIENT_RESOURCES	A memory allocation failed.
STATUS_TRANSACTION_MANAGER_NOT_ONLINE	The enlistment failed because KTM or the resource manager is not in an operational state.

STATUS_TRANSACTION_NOT_ACTIVE	The enlistment failed because the transaction that the *TransactionHandle* parameter specifies is not active.
STATUS_TRANSACTION_SUPERIOR_EXISTS	The caller tried to register as a superior transaction manager but a superior transaction manager already exists.
STATUS_TM_VOLATILE	The caller is trying to register as a superior transaction manager, but the caller's resource manager object is volatile while the associated transaction manager object is not volatile.
STATUS_ACCESS_DENIED	The value of the *DesiredAccess* parameter is invalid.

The routine might return other NTSTATUS values.

Remarks

A resource manager calls **ZwCreateEnlistment** to enlist in a transaction.

Resource managers that are not superior must include the ENLISTMENT_SUBORDINATE_RIGHTS flag in their access mask.

Superior transaction managers must include the ENLISTMENT_SUPERIOR_RIGHTS flag in their access masks. Typically, a superior transaction manager includes code that calls ZwRollbackEnlistment, so it must also include the ENLISTMENT_SUBORDINATE_RIGHTS flag.

A resource manager that calls **ZwCreateEnlistment** must eventually call ZwClose to close the object handle.

Your resource manager can use the *EnlistmentKey* parameter to assign a unique value to each enlistment, such as a

pointer to a data structure that contains information about the enlistment. For example, if the resource manager stores the enlistment object's handle in the structure, the resource manager can do the following:

1. Call ZwGetNotificationResourceManager to obtain a notification.
2. Obtain the enlistment key value from the TRANSACTION_NOTIFICATION structure.
3. Use the enlistment key to find the stored enlistment object handle.
4. Call routines that require the enlistment handle as input, such as ZwCommitComplete or ZwRollbackComplete.

For more information about **ZwCreateEnlistment**, see Creating a Resource Manager and Creating a Superior Transaction Manager.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

NtCreateResourceManager function

1/25/2019 • 3 minutes to read • Edit Online

The **ZwCreateResourceManager** routine creates a resource manager object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtCreateResourceManager(
  PHANDLE            ResourceManagerHandle,
  ACCESS_MASK        DesiredAccess,
  HANDLE             TmHandle,
  LPGUID             RmGuid,
  POBJECT_ATTRIBUTES ObjectAttributes,
  ULONG              CreateOptions,
  PUNICODE_STRING    Description
);
```

Parameters

`ResourceManagerHandle`

A pointer to a caller-allocated variable that receives a handle to the new resource manager object if the call to **ZwCreateResourceManager** is successful.

`DesiredAccess`

An ACCESS_MASK value that specifies the caller's requested access to the resource manager object. In addition to the access rights that are defined for all kinds of objects (see **ACCESS_MASK**), the caller can specify any of the following access right flags for resource manager objects:

ACCESS_MASK FLAG	ALLOWS THE CALLER TO
RESOURCEMANAGER_ENLIST	Enlist in transactions (see ZwCreateEnlistment).
RESOURCEMANAGER_GET_NOTIFICATION	Receive notifications about the transactions that are associated with this resource manager (see ZwGetNotificationResourceManager).
RESOURCEMANAGER_REGISTER_PROTOCOL	Not used.
RESOURCEMANAGER_QUERY_INFORMATION	Query information about the resource manager (see ZwQueryInformationResourceManager).
RESOURCEMANAGER_SET_INFORMATION	Not used.
RESOURCEMANAGER_RECOVER	Recover the resource manager (see ZwRecoverResourceManager).
RESOURCEMANAGER_COMPLETE_PROPAGATION	Not used.

Alternatively, you can specify one or more of the following generic ACCESS_MASK flags. (The STANDARD_RIGHTS_*Xxx* flags are predefined system values that are used to enforce security on system objects.)

You can also combine these generic flags with additional flags from the preceding table. The following table shows how generic access rights correspond to specific access rights.

GENERIC ACCESS RIGHT	SET OF SPECIFIC ACCESS RIGHTS
RESOURCEMANAGER_GENERIC_READ	STANDARD_RIGHTS_READ, RESOURCEMANAGER_QUERY_INFORMATION, and SYNCHRONIZE
RESOURCEMANAGER_GENERIC_WRITE	STANDARD_RIGHTS_WRITE, RESOURCEMANAGER_SET_INFORMATION, RESOURCEMANAGER_RECOVER, RESOURCEMANAGER_ENLIST, RESOURCEMANAGER_GET_NOTIFICATION, RESOURCEMANAGER_REGISTER_PROTOCOL, RESOURCEMANAGER_COMPLETE_PROPAGATION, and SYNCHRONIZE
RESOURCEMANAGER_GENERIC_EXECUTE	STANDARD_RIGHTS_EXECUTE, RESOURCEMANAGER_RECOVER, RESOURCEMANAGER_ENLIST, RESOURCEMANAGER_GET_NOTIFICATION, RESOURCEMANAGER_COMPLETE_PROPAGATION, and SYNCHRONIZE
RESOURCEMANAGER_ALL_ACCESS	STANDARD_RIGHTS_REQUIRED, RESOURCEMANAGER_GENERIC_READ, RESOURCEMANAGER_GENERIC_WRITE, and RESOURCEMANAGER_GENERIC_EXECUTE

`TmHandle`

A handle to a transaction manager object that was obtained by a previous all to ZwCreateTransactionManager or ZwOpenTransactionManager.

`RmGuid`

A pointer to a GUID that KTM will use to identify the resource manager. If this pointer is **NULL**, KTM generates a GUID.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use the InitializeObjectAttributes routine to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**. This parameter is optional and can be **NULL**.

`CreateOptions`

Optional object creation flags. The following table contains the available flags, which are defined in Ktmtypes.h.

***CREATEOPTIONS* FLAG**	**MEANING**
RESOURCE_MANAGER_COMMUNICATION	For internal use only.
RESOURCE_MANAGER_VOLATILE	The caller will manage volatile resources. It will be non-persistent and will not perform recovery.

This parameter is optional and can be zero.

`Description`

A pointer to a caller-supplied UNICODE_STRING structure that contains a NULL-terminated string. The string provides a description of the resource manager. KTM stores a copy of the string and includes the string in messages that it writes to the log stream. The maximum string length is MAX_RESOURCEMANAGER_DESCRIPTION_LENGTH. This parameter is optional and can be **NULL**.

Return Value

ZwCreateResourceManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The handle that *TmHandle* specifies is not a handle to a transaction object.
STATUS_INVALID_HANDLE	The handle that *TmHandle* specifies is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the specified transaction manager object.
STATUS_TRANSACTION_OBJECT_EXPIRED	The handle that *TmHandle* specifies is closed.

STATUS_INVALID_PARAMETER	The *CreateOptions*parameter's value is invalid or the *Description* parameter's string is too long.
STATUS_TM_VOLATILE	The *CreateOptions*parameter does not specify RESOURCE_MANAGER_VOLATILE but the transaction manager that *TmHandle* specifies is volatile.
STATUS_OBJECT_NAME_COLLISION	The GUID that *ResourceManagerGuid*specifies already exists.
STATUS_ACCESS_DENIED	The value of the *DesiredAccess* parameter is invalid.

The routine might return other NTSTATUS values.

Remarks

A resource manager that calls **ZwCreateResourceManager** must eventually call ZwClose to close the object handle.

For more information about **ZwCreateResourceManager**, see Creating a Resource Manager.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

1/25/2019 • 4 minutes to read • Edit Online

The **ZwCreateTransaction** routine creates a transaction object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtCreateTransaction(
  PHANDLE            TransactionHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  LPGUID             Uow,
  HANDLE             TmHandle,
  ULONG              CreateOptions,
  ULONG              IsolationLevel,
  ULONG              IsolationFlags,
  PLARGE_INTEGER     Timeout,
  PUNICODE_STRING    Description
);
```

Parameters

`TransactionHandle`

A pointer to a caller-allocated variable that receives a handle to the new transaction object, if the call to **ZwCreateTransaction** succeeds.

`DesiredAccess`

An ACCESS_MASK value that specifies the caller's requested access to the transaction object. In addition to the access rights that are defined for all kinds of objects (see ACCESS_MASK), the caller can specify any of the following flags for transaction objects.

ACCESS MASK	ALLOWS THE CALLER TO
TRANSACTION_COMMIT	Commit the transaction (see ZwCommitTransaction).
TRANSACTION_ENLIST	Create an enlistment for the transaction (see ZwCreateEnlistment).
TRANSACTION_PROPAGATE	Do not use.
TRANSACTION_QUERY_INFORMATION	Obtain information about the transaction (see ZwQueryInformationTransaction).
TRANSACTION_ROLLBACK	Roll back the transaction (see ZwRollbackTransaction).
TRANSACTION_SET_INFORMATION	Set information for the transaction (see ZwSetInformationTransaction).

Alternatively, you can specify one or more of the following ACCESS_MASK bitmaps. These bitmaps combine the flags from the previous table with the STANDARD_RIGHTS_*XXX* flags that are described on the ACCESS_MASK reference page. You can also combine these bitmaps with additional flags from the preceding table. The following

table shows how the bitmaps correspond to specific access rights.

RIGHTS BITMAP	SET OF SPECIFIC ACCESS RIGHTS
TRANSACTION_GENERIC_READ	STANDARD_RIGHTS_READ, TRANSACTION_QUERY_INFORMATION, and SYNCHRONIZE
TRANSACTION_GENERIC_WRITE	STANDARD_RIGHTS_WRITE, TRANSACTION_SET_INFORMATION, TRANSACTION_COMMIT, TRANSACTION_ENLIST, TRANSACTION_ROLLBACK, TRANSACTION_PROPAGATE, TRANSACTION_SAVEPOINT, and SYNCHRONIZE
TRANSACTION_GENERIC_EXECUTE	STANDARD_RIGHTS_EXECUTE, TRANSACTION_COMMIT, TRANSACTION_ROLLBACK, and SYNCHRONIZE
TRANSACTION_ALL_ACCESS	STANDARD_RIGHTS_REQUIRED, TRANSACTION_GENERIC_READ, TRANSACTION_GENERIC_WRITE, and TRANSACTION_GENERIC_EXECUTE
TRANSACTION_RESOURCE_MANAGER_RIGHTS	STANDARD_RIGHTS_WRITE, TRANSACTION_GENERIC_READ, TRANSACTION_SET_INFORMATION, TRANSACTION_ENLIST, TRANSACTION_ROLLBACK, TRANSACTION_PROPAGATE, and SYNCHRONIZE

Typically, a resource manager specifies TRANSACTION_RESOURCE_MANAGER_RIGHTS.

The *DesiredAccess* value cannot be zero.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use the InitializeObjectAttributes routine to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**. This parameter is optional and can be **NULL**.

`Uow`

A pointer to a GUID that KTM uses as the new transaction object's unit of work (UOW) identifier. This parameter is optional and can be **NULL**. If this parameter is **NULL**, KTM generates a GUID and assigns it to the transaction object. For more information, see the following Remarks section.

`TmHandle`

A handle to a transaction manager object that was obtained by a previous call to ZwCreateTransactionManager or ZwOpenTransactionManager. KTM assigns the new transaction object to the specified transaction manager object. If this parameter is **NULL**, KTM assigns the new transaction object to a transaction manager later, when a resource manager creates an enlistment for the transaction.

`CreateOptions`

Optional object creation flags. The following table contains the available flags, which are defined in Ktmtypes.h.

OPTION FLAG	MEANING
TRANSACTION_DO_NOT_PROMOTE	Reserved for future use.

`IsolationLevel`

Reserved for future use. Callers must set this parameter to zero.

`IsolationFlags`

Reserved for future use. Callers should set this parameter to zero.

`Timeout`

A pointer to a time-out value. If the transaction has not been committed by the time specified by this parameter, KTM rolls back the transaction. The time-out value is expressed in system time units (100-nanosecond intervals), and can specify either an absolute time or a relative time. If the value pointed to by *Timeout* is negative, the expiration time is relative to the current system time. Otherwise, the expiration time is absolute. This pointer is optional and can be **NULL** if you do not want the transaction to have a time-out value. If *Timeout* = **NULL** or * *Timeout* = 0, the transaction never times out. (You can also use ZwSetInformationTransaction to set a time-out value.)

`Description`

A pointer to a caller-supplied UNICODE_STRING structure that contains a NULL-terminated string. The string provides a description of the transaction. KTM stores a copy of the string and includes the string in messages that it writes to the log stream. The maximum string length is MAX_TRANSACTION_DESCRIPTION_LENGTH. This parameter is optional and can be **NULL**.

Return Value

ZwCreateTransaction returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The *CreateOptions* parameter contains an invalid flag, the *DesiredAccess* parameter is zero, or the *Description* parameter's string is too long.
STATUS_INSUFFICIENT_RESOURCES	KTM could not allocate system resources (typically memory).

STA TUS _IN VAL ID_ ACL	A security descriptor contains an invalid access control list (ACL).
STA TUS _IN VAL ID_S ID	A security descriptor contains an invalid security identifier (SID).
STA TUS _OB JEC T_N AM E_E XIS TS	The object name that the *ObjectAttributes* parameter specifies already exists.
STA TUS _OB JEC T_N AM E_IN VAL ID	The object name that the *ObjectAttributes* parameter specifies is invalid.
STA TUS _AC CES S_D ENI ED	The value of the *DesiredAccess* parameter is invalid.

The routine might return other NTSTATUS values.

Remarks

The caller can use the *Uow* parameter to specify a UOW identifier for the transaction object. If the caller does not specify a UOW identifier, KTM generates a GUID and assigns it to the transaction object. The caller can later obtain this GUID by calling ZwQueryInformationTransaction.

Typically, you should let KTM generate a GUID for the transaction object, unless your component communicates with another TPS component that has already generated a UOW identifier for the transaction.

To close the transaction handle, the component that called **ZwCreateTransaction** must call ZwClose. If the last transaction handle closes before any component calls ZwCommitTransaction for the transaction, KTM rolls back the transaction.

For more information about how transaction clients should use **ZwCreateTransaction**, see Creating a Transactional Client.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwSetInformationTransaction

NtCreateTransactionManager function

1/25/2019 • 3 minutes to read • Edit Online

The **ZwCreateTransactionManager** routine creates a new transaction manager object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtCreateTransactionManager(
  PHANDLE            TmHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  PUNICODE_STRING    LogFileName,
  ULONG              CreateOptions,
  ULONG              CommitStrength
);
```

Parameters

`TmHandle`

A pointer to a caller-allocated variable that receives a handle to the new transaction manager object.

`DesiredAccess`

An ACCESS_MASK value that specifies the caller's requested access to the transaction manager object. In addition to the access rights that are defined for all kinds of objects (see ACCESS_MASK), the caller can specify any of the following access right flags for transaction manager objects.

ACCESS_MASK FLAG	ALLOWS THE CALLER TO
TRANSACTIONMANAGER_CREATE_RM	Create a resource manager (see ZwCreateResourceManager).
TRANSACTIONMANAGER_QUERY_INFORMATION	Obtain information about the transaction manager (see ZwQueryInformationTransactionManager and ZwEnumerateTransactionObject). Also required for ZwOpenResourceManager, ZwCreateTransaction, and ZwOpenTransaction.)
TRANSACTIONMANAGER_RECOVER	Recover the transaction manager (see ZwRecoverTransactionManager and ZwRollforwardTransactionManager).
TRANSACTIONMANAGER_RENAME	Not used.
TRANSACTIONMANAGER_SET_INFORMATION	Not used.

Alternatively, you can specify one or more of the following ACCESS_MASK bitmaps. These bitmaps combine the flags from the previous table with the STANDARD_RIGHTS_*XXX* flags that are described on the **ACCESS_MASK** reference page. You can also combine these bitmaps with additional flags from the preceding table. The following table shows how the bitmaps correspond to specific access rights.

RIGHTS BITMAP	SET OF SPECIFIC ACCESS RIGHTS

TRANSACTIONMANAGER_GENERIC_READ	STANDARD_RIGHTS_READ and TRANSACTIONMANAGER_QUERY_INFORMATION
TRANSACTIONMANAGER_GENERIC_WRITE	STANDARD_RIGHTS_WRITE, TRANSACTIONMANAGER_SET_INFORMATION, TRANSACTIONMANAGER_RECOVER, TRANSACTIONMANAGER_RENAME, and TRANSACTIONMANAGER_CREATE_RM
TRANSACTIONMANAGER_GENERIC_EXECUTE	STANDARD_RIGHTS_EXECUTE
TRANSACTIONMANAGER_ALL_ACCESS	STANDARD_RIGHTS_REQUIRED, TRANSACTIONMANAGER_GENERIC_READ, TRANSACTIONMANAGER_GENERIC_WRITE, and TRANSACTIONMANAGER_GENERIC_EXECUTE

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use the InitializeObjectAttributes routine to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**. This parameter is optional and can be **NULL**.

`LogFileName`

A pointer to a UNICODE_STRING structure that contains the path and file name of a CLFS log file stream to be associated with the transaction manager object. This parameter must be **NULL** if the *CreateOptions* parameter is TRANSACTION_MANAGER_VOLATILE. Otherwise, this parameter must be non-**NULL**. For more information, see the following Remarks section.

`CreateOptions`

Optional object creation flags. The following table contains the available flags, which are defined in Ktmtypes.h.

OPTION FLAG	MEANING
TRANSACTION_MANAGER_VOLATILE	The transaction manager object will be volatile. Therefore, it will not use a log file.
TRANSACTION_MANAGER_COMMIT_DEFAULT	For internal use only.
TRANSACTION_MANAGER_COMMIT_SYSTEM_VOLUME	For internal use only.
TRANSACTION_MANAGER_COMMIT_SYSTEM_HIVES	For internal use only.
TRANSACTION_MANAGER_COMMIT_LOWEST	For internal use only.
TRANSACTION_MANAGER_CORRUPT_FOR_RECOVERY	For internal use only.
TRANSACTION_MANAGER_CORRUPT_FOR_PROGRESS	For internal use only.

`CommitStrength`

Reserved for future use. This parameter must be zero.

Return Value

ZwCreateTransactionManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The value of an input parameter is invalid.
STATUS_INSUFFICIENT_RESOURCES	KTM could not allocate system resources (typically memory).
STATUS_LOG_CORRUPTION_DETECTED	KTM encountered an error while creating or opening the log file.
STATUS_INVALID_ACL	A security descriptor contains an invalid access control list (ACL).
STATUS_INVALID_SID	A security descriptor contains an invalid security identifier (SID).

STATUS_OBJECT_NAME_EXISTS	The object name that the *ObjectAttributes* parameter specifies already exists.
STATUS_OBJECT_NAME_COLLISION	The operating system detected a duplicate object name. The error might indicate that the log stream is already being used.
STATUS_OBJECT_NAME_INVALID	The object name that the *ObjectAttributes* parameter specifies is invalid.
STATUS_ACCESS_DENIED	The value of the *DesiredAccess* parameter is invalid.

The routine might return other NTSTATUS values.

Remarks

If the log file stream that the *LogFileName* parameter specifies does not exist, KTM calls CLFS to create the stream. If the stream already exists, KTM calls CLFS to open the stream.

Your TPS component must call ZwRecoverTransactionManager after it has called **ZwCreateTransactionManager**

If your TPS component specifies the TRANSACTION_MANAGER_VOLATILE flag in the *CreateOptions* parameter, all resource managers that are associated with the transaction manager object must specify the RESOURCE_MANAGER_VOLATILE flag when they call ZwCreateResourceManager.

A TPS component that calls **ZwCreateTransactionManager** must eventually call ZwClose to close the object handle.

For more information about how use **ZwCreateTransactionManager**, see Creating a Resource Manager.

NtCreateTransactionManager and **ZwCreateTransactionManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal

NtEnumerateTransactionObject function

1/25/2019 • 3 minutes to read • Edit Online

The **ZwEnumerateTransactionObject** routine enumerates the KTM objects on a computer.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtEnumerateTransactionObject(
  HANDLE            RootObjectHandle,
  KTMOBJECT_TYPE    QueryType,
  PKTMOBJECT_CURSOR ObjectCursor,
  ULONG             ObjectCursorLength,
  PULONG            ReturnLength
);
```

Parameters

`RootObjectHandle`

A handle to a KTM object. The routine enumerates the child objects of the specified object. This parameter is optional and can be **NULL**. For more information about valid values for this parameter, see the table in the following Remarks section.

`QueryType`

A KTMOBJECT_TYPE-typed value that identifies the object type to enumerate. For more information about valid values for this parameter, see the table in the following Remarks section.

`ObjectCursor`

A pointer to a caller-allocated buffer that begins with a KTMOBJECT_CURSOR structure. **ZwEnumerateTransactionObject** uses the buffer to store the GUIDs of objects that it finds.

`ObjectCursorLength`

The length, in bytes, of the buffer that *ObjectCursor* points to.

`ReturnLength`

A pointer to a caller-allocated location that receives the number of bytes that **ZwEnumerateTransactionObject** returns in the *ObjectCursor* buffer, including the length of the **KTMOBJECT_CURSOR** structure and the length of all returned GUIDs.

Return Value

ZwEnumerateTransactionObject returns STATUS_SUCCESS if the operation succeeds but the routine has not enumerated all the objects. If there are no more objects to enumerate, the routine returns STATUS_NO_MORE_ENTRIES. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION

STATUS_INVALID_PARAMETER	The *QueryType* or *ObjectCursorLength* parameter's value is invalid.
STATUS_OBJECT_TYPE_MISMATCH	The handle that the *RootObjectHandle* parameter specifies is not a handle to a valid KTM object.
STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the objects that are being enumerated.

The routine might return other NTSTATUS values.

Remarks

The following table contains the valid values for the *RootObjectHandle* and *QueryType* parameters.

***QUERYTYPE* PARAMETER**	***ROOTOBJECTHANDLE* PARAMETER**	**OBJECTS ENUMERATED**
KTMOBJECT_TRANSACTION_MANAGER	**NULL**	All transaction manager objects
KTMOBJECT_RESOURCE_MANAGER	A handle to a transaction manager object. The handle must have TRANSACTIONMANAGER_QUERY_INFORMATION access to the object.	All resource manager objects that belong to the specified transaction manager object

KTMOBJECT_ENLISTMENT	A handle to a resource manager object. The handle must have RESOURCEMANAGER_QUERY_INFORMATION access to the object.	All enlistment objects that belong to the specified resource manager object
KTMOBJECT_TRANSACTION	A handle to a transaction manager object. The handle must have TRANSACTIONMANAGER_QUERY_INFORMATION access to the object.	All transaction objects that belong to the specified transaction manager object
KTMOBJECT_TRANSACTION	**NULL**	All transaction objects that belong to all transaction manager objects

Most TPS components do not have to call **ZwEnumerateTransactionObject**, but the routine might be useful if you have to write a debugging utility.

Before your component calls **ZwEnumerateTransactionObject**, it must allocate and zero the buffer that *ObjectCursor* points to. The buffer's GUID array can be large enough to receive one or more elements.

To enumerate all of the KTM objects of the specified type, your component must call **ZwEnumerateTransactionObject** repeatedly until it returns STATUS_NO_MORE_ENTRIES.

Every time that the routine is called, it fills the buffer's GUID array with as many object GUIDs that will fit. After each call, your component can use the KTMOBJECT_CURSOR structure's **ObjectIdCount** member to determine the number of object GUIDs that the routine stored in the array.

NtEnumerateTransactionObject and **ZwEnumerateTransactionObject** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Examples

The following code example shows how to enumerate all of the transaction objects on a computer. In this example, the **KTMOBJECT_CURSOR** structure's GUID array contains only one element, so each call to **ZwEnumerateTransactionObject** returns one GUID. The routine creates a Unicode string from the GUID and displays the string.

```
NTSTATUS Status;
UNICODE_STRING GuidString;
KTMOBJECT_CURSOR Cursor;
ULONG ReturnedBytes;

RtlZeroMemory(&Cursor, sizeof(Cursor));

do {
    Status = ZwEnumerateTransactionObject(
                                          NULL,
                                          KTMOBJECT_TRANSACTION,
                                          &Cursor,
                                          sizeof(Cursor),
                                          &ReturnedBytes
                                          );

    if (Status != STATUS_NO_MORE_ENTRIES) {
        RtlStringFromGUID(
                          &Cursor.ObjectIds[0],
                          &GuidString
                          );
        OutputMessage(GuidString.Buffer);
        OutputMessage(L"\r\n");
        RtlFreeUnicodeString(&GuidString);
    }
} while (Status == STATUS_SUCCESS);
if (Status == STATUS_NO_MORE_ENTRIES) {
    Status = STATUS_SUCCESS;
}
```

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

KTMOBJECT_CURSOR

KTMOBJECT_TYPE

Using Nt and Zw Versions of the Native System Services Routines

NtGetNotificationResourceManager function

1/25/2019 • 3 minutes to read • Edit Online

The **ZwGetNotificationResourceManager** routine retrieves the next transaction notification from a specified resource manager's notification queue.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtGetNotificationResourceManager(
  HANDLE                    ResourceManagerHandle,
  PTRANSACTION_NOTIFICATION TransactionNotification,
  ULONG                     NotificationLength,
  PLARGE_INTEGER            Timeout,
  PULONG                    ReturnLength,
  ULONG                     Asynchronous,
  ULONG_PTR                 AsynchronousContext
);
```

Parameters

`ResourceManagerHandle`

A handle to a resource manager object that was obtained by a previous call to ZwCreateResourceManager or ZwOpenResourceManager. The handle must have RESOURCEMANAGER_GET_NOTIFICATION access to the object.

`TransactionNotification`

A pointer to a caller-allocated buffer that receives information about the retrieved notification. The buffer must be large enough to contain a TRANSACTION_NOTIFICATION structure plus additional notification-specific arguments.

`NotificationLength`

The length, in bytes, of the buffer that the *TransactionNotification*parameter points to.

`Timeout`

A pointer to a value that specifies a relative or absolute time, in units of 100 nanoseconds. This pointer is optional and can be **NULL**.

If the pointer is **NULL**, **ZwGetNotificationResourceManager** does not return until a transaction notification is available. If a time value is specified, **ZwGetNotificationResourceManager** returns when a notification is available or after the specified time elapses, whichever comes first.

A negative value specifies a time that is relative to the current system time. For example, a relative time value of five seconds causes **ZwGetNotificationResourceManager** to time out five seconds after it is called.

A positive value specifies an absolute time, which is actually relative to 00:00, January 1, 1601. If an absolute time value is specified, the operating system adds the absolute time value to the time value that represents 00:00, January 1, 1601.

If the caller specifies a zero value (instead of a **NULL** pointer), **ZwGetNotificationResourceManager** returns immediately, whether a notification is available or not.

`ReturnLength`

An optional pointer to a variable. If this pointer is not **NULL**, and if the *NotificationLength* parameter's value is too small, **ZwGetNotificationResourceManager** supplies the required length in the variable and returns STATUS_BUFFER_TOO_SMALL.

`Asynchronous`

A ULONG value that must be zero. **ZwGetNotificationResourceManager** does not support asynchronous notifications. Use TmEnableCallbacks to enable asynchronous notifications.

`AsynchronousContext`

A pointer to a ULONG value. This pointer must be **NULL**.

Return Value

ZwGetNotificationResourceManager returns STATUS_SUCCESS if the operation succeeds and a notification is available. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_TIMEOUT	The time-out interval that *Timeout* specifies elapsed before a notification became available.
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to a resource manager object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the resource manager object.
STA TUS _BU FFE R_T OO_ SM ALL	The *NotificationLength* parameter's value is too small.

The routine might return other NTSTATUS values.

Remarks

Use the **ZwGetNotificationResourceManager** routine to obtain notifications synchronously. Use the TmEnableCallbacks routine to enable asynchronous notifications.

The received TRANSACTION_NOTIFICATION structure contains the enlistment key that the resource manager specified when it called ZwCreateEnlistment. You can use the enlistment key to identify the enlistment that the notification applies to.

For more information about the **ZwGetNotificationResourceManager** routine, see Creating a Resource Manager.

NtGetNotificationResourceManager and **ZwGetNotificationResourceManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

IRQL	"= PASSIVE_LEVEL"

TmEnableCallbacks

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwCreateResourceManager

ZwOpenResourceManager

NtOpenEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenEnlistment** routine obtains a handle to an existing enlistment object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtOpenEnlistment(
  PHANDLE            EnlistmentHandle,
  ACCESS_MASK        DesiredAccess,
  HANDLE             ResourceManagerHandle,
  LPGUID             EnlistmentGuid,
  POBJECT_ATTRIBUTES ObjectAttributes
);
```

Parameters

`EnlistmentHandle`

A pointer to a caller-allocated variable that receives a handle to an enlistment object if the call to **ZwOpenEnlistment** succeeds.

`DesiredAccess`

An ACCESS_MASK-typed value that specifies the requested access to the enlistment object. For more information about how to specify this parameter, see the *DesiredAccess* parameter of ZwCreateEnlistment. This parameter cannot be zero.

`ResourceManagerHandle`

A handle to a resource manager object that was obtained by a previous call to ZwCreateResourceManager or ZwOpenResourceManager.

`EnlistmentGuid`

A pointer to a GUID that identifies the enlistment. For more information, see the following Remarks section.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object's attributes. Use the InitializeObjectAttributes routine to initialize this structure, but specify only that routine's *InitializedAttributes* and *Attributes* parameters. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE flag in the *Attributes* parameter. This parameter is optional and can be **NULL**.

Return Value

ZwOpenEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION

STATUS_INVALID_HANDLE	The object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the enlistment object.
STATUS_INVALID_PARAMETER	The *DesiredAccess* parameter's value is zero, or the *EnlistmentGuid* parameter's value is **NULL**.
STATUS_ENLISTMENT_NOT_FOUND	The enlistment that the *EnlistmentGuid* parameter specifies does not exist for the resource manager that the *RmHandle* parameter specifies.
STATUS_ACCESS_DENIED	The value of the *DesiredAccess* parameter is invalid.

The routine might return other NTSTATUS values.

Remarks

Typically, a TPS component calls **ZwOpenEnlistment** after it receives an enlistment GUID from another TPS component that had previously called ZwCreateEnlistment. Most TPS designs do not require calling **ZwOpenEnlistment**.

A resource manager that calls **ZwOpenEnlistment** must eventually call ZwClose to close the object handle.

For more information about **ZwOpenEnlistment**, see Enlistment Objects.

NtOpenEnlistment and **ZwOpenEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

ZwOpenResourceManager

ZwQueryInformationEnlistment

ZwSetInformationEnlistment

NtOpenResourceManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenResourceManager** routine returns a handle to an existing resource manager object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtOpenResourceManager(
  PHANDLE            ResourceManagerHandle,
  ACCESS_MASK        DesiredAccess,
  HANDLE             TmHandle,
  LPGUID             ResourceManagerGuid,
  POBJECT_ATTRIBUTES ObjectAttributes
);
```

Parameters

`ResourceManagerHandle`

A pointer to a caller-allocated variable that receives the resource manager handle if the call to **ZwOpenResourceManager** succeeds.

`DesiredAccess`

An ACCESS_MASK value that specifies the caller's requested access to the resource manager object. For more information about how to specify this parameter, see the *DesiredAccess* parameter of ZwCreateResourceManager. This parameter cannot be zero.

`TmHandle`

A handle to a transaction manager object that was obtained by a previous call to ZwCreateTransactionManager or ZwOpenTransactionManager.

`ResourceManagerGuid`

A pointer to the GUID that identifies the resource manager to open.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object's attributes. Use the InitializeObjectAttributes routine to initialize this structure, but specify only that routine's *InitializedAttributes* and *Attributes* parameters. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE flag in the *Attributes* parameter. This parameter is optional and can be **NULL**.

Return Value

ZwOpenResourceManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION

STATUS_OBJECT_TYPE_MISMATCH	The handle that *TmHandle* specifies is not a handle to a transaction object.
STATUS_INVALID_HANDLE	The handle that *TmHandle* specifies is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the specified transaction manager object.
STATUS_INVALID_PARAMETER	The *DesiredAccess* parameter is zero or the *ResourceManagerGuid* parameter is invalid.
STATUS_RESOURCEMANAGER_NOT_FOUND	The specified resource manager could not be found.

STA TUS _TR AN SAC TIO NM AN AGE R_N OT_ ON LIN E	The specified transaction manager is not online.

The routine might return other NTSTATUS values.

Remarks

Typically, a TPS component calls **ZwOpenResourceManager** after it receives an enlistment GUID from another TPS component that had previously called ZwCreateResourceManager. Most TPS designs do not require calling **ZwOpenResourceManager**.

A resource manager that calls **ZwOpenResourceManager** must eventually call ZwClose to close the object handle.

For more information about **ZwOpenResourceManager**, see KTM Objects.

NtOpenResourceManager and **ZwOpenResourceManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

InitializeObjectAttributes

OBJECT_ATTRIBUTES

Using Nt and Zw Versions of the Native System Services Routines

ZwClose

ZwCreateResourceManager

ZwCreateTransactionManager

ZwOpenTransactionManager

NtOpenTransaction function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenTransaction** routine obtains a handle to an existing transaction object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtOpenTransaction(
  PHANDLE            TransactionHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  LPGUID             Uow,
  HANDLE             TmHandle
);
```

Parameters

`TransactionHandle`

A pointer to a caller-allocated variable that receives a handle to the transaction object if **ZwOpenTransaction** returns STATUS_SUCCESS.

`DesiredAccess`

An ACCESS_MASK value that specifies the caller's requested access to the transaction object. For information about how to specify this parameter, see the *DesiredAccess* parameter of ZwCreateTransaction.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object's attributes. Use the InitializeObjectAttributes routine to initialize this structure, but specify only that routine's *InitializedAttributes* and *Attributes* parameters. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE flag in the *Attributes* parameter. The *ObjectAttributes* parameter is optional and can be **NULL**.

`Uow`

A pointer to a GUID that is a transaction object's unit of work (UOW) identifier. This GUID identifies the transaction object to open.

`TmHandle`

A handle to a transaction manager object. If this parameter is not **NULL**, KTM searches only for transaction objects that belong to the specified transaction manager object. If this parameter is **NULL**, KTM searches all transaction objects.

Return Value

ZwCreateTransaction returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION

STATUS_INVALID_PARAMETER	The *DesiredAccess* or *Uow* parameter was zero.
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to a transaction object.
STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_TRANSACTION_NOT_FOUND	KTM could not find the transaction object.
STATUS_ACCESS_DENIED	The value of the *DesiredAccess* parameter is invalid.

The routine might return other NTSTATUS values.

Remarks

Typically, a resource manager calls **ZwOpenTransaction** after it receives a transaction UOW from a transactional

client that had previously called ZwCreateTransaction.

For more information about **ZwOpenTransaction**, see Creating a Resource Manager.

NtOpenTransaction and **ZwOpenTransaction** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

Using Nt and Zw Versions of the Native System Services Routines

ZwCommitTransaction

ZwCreateTransaction

ZwQueryInformationTransaction

ZwRollbackTransaction

NtOpenTransactionManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenTransactionManager** routine obtains a handle to an existing transaction manager object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtOpenTransactionManager(
  PHANDLE            TmHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  PUNICODE_STRING    LogFileName,
  LPGUID             TmIdentity,
  ULONG              OpenOptions
);
```

Parameters

`TmHandle`

A pointer to a caller-allocated variable that receives a handle to the transaction manager object if **ZwOpenTransactionManager** returns STATUS_SUCCESS.

`DesiredAccess`

An ACCESS_MASK value that specifies the caller's requested access to the transaction manager object. For information about how to specify this parameter, see the *DesiredAccess* parameter of ZwCreateTransactionManager.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use the InitializeObjectAttributes routine to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**. This parameter is optional and can be **NULL**.

`LogFileName`

A pointer to a UNICODE_STRING structure that contains the path and file name of the log file stream that was created when the transaction manager object was created. For more information, see the *LogFileName* parameter of **ZwCreateTransactionManager**. This parameter is optional and can be **NULL**.

`TmIdentity`

A pointer to a GUID that identifies the transaction manager object. This parameter is optional and can be **NULL**.

`OpenOptions`

This parameter is not used and must be zero.

Return Value

ZwOpenTransactionManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The value of an input parameter is invalid.
STATUS_INSUFFICIENT_RESOURCES	KTM could not allocate system resources (typically memory).
STATUS_OBJECT_NAME_INVALID	The object name that the *ObjectAttributes* parameter specifies is invalid.
STATUS_LOG_CORRUPTION_DETECTED	KTM encountered an error while creating or opening the log file.
STATUS_ACCESS_DENIED	The value of the *DesiredAccess* parameter is invalid.

The routine might return other NTSTATUS values.

Remarks

The caller can identify which transaction manager object to open by using one of the following three techniques:

- Use the *LogFileName* parameter to specify the path and file name of a log file stream that was created when the transaction manager object was created.
- Use the *TmIdentity* parameter to specify the GUID that identifies the transaction manager object.
- Use the *ObjectAttributes* parameter to supply an OBJECT_ATTRIBUTES structure that contains the object name that the caller previously specified to the ZwCreateTransactionManager routine.

You must specify only one of the above-listed parameters (an object name, a log file name, or a GUID) and set the other two parameters to **NULL**.

Your TPS component must call ZwRecoverTransactionManager after it has called **ZwOpenTransactionManager**.

A TPS component that calls **ZwOpenTransactionManager** must eventually call ZwClose to close the object handle.

For more information about how to use **ZwOpenTransactionManager**, see Transaction Manager Objects and Creating a Resource Manager.

NtOpenTransactionManager and **ZwOpenTransactionManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

UNICODE_STRING

Using Nt and Zw Versions of the Native System Services Routines

ZwClose

ZwCreateTransactionManager

ZwQueryInformationTransactionManager

NtPowerInformation function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwPowerInformation** routine sets or retrieves system power information.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtPowerInformation(
  POWER_INFORMATION_LEVEL InformationLevel,
  PVOID                   InputBuffer,
  ULONG                   InputBufferLength,
  PVOID                   OutputBuffer,
  ULONG                   OutputBufferLength
);
```

Parameters

`InformationLevel`

Specifies the requested information level, which indicates the specific power information to be set or retrieved. Currently, the only supported *POWER_INFORMATION_LEVEL* value is **PlatformInformation**.

VALUE	MEANING
PlatformInformation	Information represents the currently supported power capabilities of the system. Information may change as drivers are installed. For example, the installation of legacy device drivers that do not support power management might modify the capabilities of the system.

`InputBuffer`

Pointer to a caller-allocated input buffer. This parameter must be **NULL**, otherwise **ERROR_INVALID_PARAMETER** is returned.

`InputBufferLength`

Size, in bytes, of the buffer at *InputBuffer*. The parameter must be set to zero.

`OutputBuffer`

A pointer to an output buffer. The data type of this buffer depends on the information level requested in the *InformationLevel* parameter. For the **PlatformInformation** level, the only currently supported value, the *OutputBuffer* parameter is required and should be of the POWER_PLATFORM_INFORMATION type.

`OutputBufferLength`

Size, in bytes, of the output buffer. Depending on the information level requested, the buffer may be variably sized. *PlatformInformation*, the only currently supported value, requires a buffer that is the size of a POWER_PLATFORM_INFORMATION structure.

Return Value

Returns STATUS_SUCCESS if the call is successful. If the call fails, possible error codes include the following:

RETURN CODE	DESCRIPTION
STATUS_BUFFER_TOO_SMALL	The output buffer is of insufficient size to contain the data being returned.
STATUS_INVALID_PARAMETER	The **PlatformInformation** information level, which is the only currently supported value, requires no input buffer and must contain an output buffer. The caller either supplied an input buffer or no output buffer.
STATUS_ACCESS_DENIED	The caller had insufficient access rights to perform the requested action.

Remarks

NtPowerInformation and **ZwPowerInformation** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Examples

This example illustrates a valid function call.

C++

```
POWER_PLATFORM_INFORMATION PlatformInfo = {0};
NTSTATUS Result = NtPowerInformation(PlatformInformation, NULL, 0, &PlatformInfo, sizeof(PlatformInfo));
```

Requirements

Minimum supported client	Windows 8
Minimum supported server	Windows Server 2012
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntpoapi.h)
Library	Ntoskrnl.lib
DLL	Ntoskrnl.lib
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

POWER_PLATFORM_INFORMATION

Using Nt and Zw Versions of the Native System Services Routines

NtPrepareComplete function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwPrepareComplete** routine notifies KTM that the calling resource manager has finished preparing a transaction's data.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtPrepareComplete(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SUBORDINATE_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwPrepareComplete returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _TR AN SAC TIO N_N OT_ REQ UES TED	The transaction or its enlistment is not in the correct state.
STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

A resource manager must call **ZwPrepareComplete** after it has finished servicing a TRANSACTION_NOTIFY_PREPARE notification.

After a resource manager has called **ZwPrepareComplete**, it cannot roll back the transaction.

For more information about **ZwPrepareComplete**, see Handling Commit Operations.

NtPrepareComplete and **ZwPrepareComplete** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwOpenEnlistment

ZwPrePrepareComplete

NtPrepareEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwPrepareEnlistment** routine initiates the prepare operation for a specified enlistment's transaction.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtPrepareEnlistment(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The object must represent a superior enlistment and the handle must have ENLISTMENT_SUPERIOR_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwPrepareEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_ENLISTMENT_NOT_SUPERIOR	The caller is not a superior transaction manager for the enlistment.

STATUS_TRANSACTION_RESPONSE_NOT_ENLISTED	The caller did not register to receive TRANSACTION_NOTIFY_PREPARE_COMPLETE notifications.
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the enlistment object.

STA TUS _TR AN SAC TIO N_R EQU EST _NO T_V ALI D	The enlistment's transaction is not in a state that allows it to enter the prepare phase.

The routine might return other NTSTATUS values.

Remarks

Only superior transaction managers can call **ZwPrepareEnlistment**.

The **ZwPrepareEnlistment** routine causes KTM to send TRANSACTION_NOTIFY_PREPARE notifications to all resource managers that have enlisted in the transaction.

Callers of **ZwPrepareEnlistment** must register to receive TRANSACTION_NOTIFY_PREPARE_COMPLETE notifications.

For more information about **ZwPrepareEnlistment**, see Creating a Superior Transaction Manager and Handling Commit Operations.

NtPrePrepareEnlistment and **ZwPrePrepareEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

ZwOpenEnlistment

NtPrePrepareComplete function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwPrePrepareComplete** routine notifies KTM that the calling resource manager has finished preliminary preparation of a transaction's data.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtPrePrepareComplete(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SUBORDINATE_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwPrePrepareComplete returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _TR AN SAC TIO N_N OT_ REQ UES TED	The transaction or its enlistment is not in the correct state.
STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

A resource manager must call **ZwPrePrepareComplete** after it has finished servicing a TRANSACTION_NOTIFY_PREPREPARE notification.

For more information about **ZwPrePrepareComplete**, see Handling Commit Operations.

NtPrePrepareComplete and **ZwPrePrepareComplete** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. ZwPrepareComplete

NtPrePrepareEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwPrePrepareEnlistment** routine initiates the pre-prepare operation for a specified enlistment's transaction.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtPrePrepareEnlistment(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The object must represent a superior enlistment and the handle must have ENLISTMENT_SUPERIOR_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwPrePrepareEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_ENLISTMENT_NOT_SUPERIOR	The caller is not a superior transaction manager for the enlistment.

STATUS_TRANSACTION_RESPONSE_NOT_ENLISTED	The caller did not register to receive TRANSACTION_NOTIFY_PREPREPARE_COMPLETE notifications.
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the enlistment object.

STA TUS _TR AN SAC TIO N_R EQU EST _NO T_V ALI D	The enlistment's transaction is not in a state that allows it to enter the prepare phase.

The routine might return other NTSTATUS values.

Remarks

Only superior transaction managers can call **ZwPrePrepareEnlistment**.

Callers of **ZwPrePrepareEnlistment** must register to receive TRANSACTION_NOTIFY_PREPREPARE_COMPLETE notifications.

The **ZwPrePrepareEnlistment** routine causes KTM to send TRANSACTION_NOTIFY_PREPREPARE notifications to all resource managers that have enlisted in the transaction.

For more information about **ZwPrePrepareEnlistment**, see Creating a Superior Transaction Manager and Handling Commit Operations.

NtPrepareEnlistment and **ZwPrepareEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwOpenEnlistment

NtQueryInformationEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwQueryInformationEnlistment** routine retrieves information about a specified enlistment object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtQueryInformationEnlistment(
  HANDLE                      EnlistmentHandle,
  ENLISTMENT_INFORMATION_CLASS EnlistmentInformationClass,
  PVOID                       EnlistmentInformation,
  ULONG                       EnlistmentInformationLength,
  PULONG                      ReturnLength
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_QUERY_INFORMATION access to the object.

`EnlistmentInformationClass`

An ENLISTMENT_INFORMATION_CLASS-typed enumeration value that specifies the information to be obtained. This value must be one of the following values:

- **EnlistmentBasicInformation**
- **EnlistmentRecoveryInformation**

The enumeration's **EnlistmentFullInformation** value is not used with **ZwQueryInformationEnlistment**.

`EnlistmentInformation`

A pointer to a caller-allocated buffer that receives the information that the *EnlistmentInformationClass*parameter specifies. If the *EnlistmentInformationClass* parameter's value is **EnlistmentBasicInformation**, this buffer's structure type must be ENLISTMENT_BASIC_INFORMATION. If the *EnlistmentInformationClass* parameter's value is **EnlistmentRecoveryInformation**, this buffer's type must match the caller-defined type that the caller used when it called ZwSetInformationEnlistment.

`EnlistmentInformationLength`

The length, in bytes, of the buffer that the *EnlistmentInformation* parameter points to.

`ReturnLength`

A pointer to a caller-allocated variable that receives the length, in bytes, of the information that KTM writes to the *EnlistmentInformation*buffer. This parameter is optional and can be **NULL**.

Return Value

ZwQueryInformationEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.
STATUS_INVALID_INFO_CLASS	The *EnlistmentInformationClass* parameter's value is invalid.
STATUS_INFO_LENGTH_MISMATCH	The *EnlistmentInformationLength* parameter's value is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

A resource manager can call ZwSetInformationEnlistment to set enlistment-specific recovery information for an enlistment object and then call **ZwQueryInformationEnlistment** to retrieve the recovery information.

For more information about **ZwQueryInformationEnlistment**, see Handling Recovery Operations.

Callers of **ZwQueryInformationEnlistment** must be running at IRQL = PASSIVE_LEVEL.

NtQueryInformationEnlistment and **ZwQueryInformationEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal

NtQueryInformationResourceManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwQueryInformationResourceManager** routine retrieves information about a specified resource manager object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtQueryInformationResourceManager(
  HANDLE                          ResourceManagerHandle,
  RESOURCEMANAGER_INFORMATION_CLASS ResourceManagerInformationClass,
  PVOID                           ResourceManagerInformation,
  ULONG                           ResourceManagerInformationLength,
  PULONG                          ReturnLength
);
```

Parameters

`ResourceManagerHandle`

A handle to a resource manager object that was obtained by a previous call to ZwCreateResourceManager or ZwOpenResourceManager. The handle must have RESOURCEMANAGER_QUERY_INFORMATION access to the object.

`ResourceManagerInformationClass`

A RESOURCEMANAGER_INFORMATION_CLASS-typed value that specifies the information to retrieve. This value must be **ResourceManagerBasicInformation**.

`ResourceManagerInformation`

A pointer to a caller-allocated RESOURCEMANAGER_BASIC_INFORMATION structure that receives information from **ZwQueryInformationResourceManager**.

`ResourceManagerInformationLength`

The length, in bytes, of the buffer that the *ResourceManagerInformation* parameter points to.

`ReturnLength`

A pointer to a caller-allocated variable that receives the length, in bytes, of the information that KTM writes to the *ResourceManagerInformation* buffer. This parameter is optional and can be **NULL**.

Return Value

ZwQueryInformationResourceManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION

STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to a resource manager object.
STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_INVALID_INFO_CLASS	The *ResourceManagerInformationClass* parameter's value is invalid.
STATUS_BUFFER_TOO_SMALL	The buffer size that the *ResourceManagerInformationLength* parameter specifies is smaller than the RESOURCEMANAGER_BASIC_INFORMATION structure.
STATUS_BUFFER_OVERFLOW	The buffer size that the *ResourceManagerInformationLength* parameter specifies is too small to receive all the variable-length information that is available.

STA **TUS** **_AC** **CES** **S_D** **ENI** **ED**	The caller does not have appropriate access to the resource manager object.

The routine might return other NTSTATUS values.

Remarks

For more information about the **ZwQueryInformationResourceManager** routine, see Creating a Resource Manager.

NtQueryInformationResourceManager and **ZwQueryInformationResourceManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

ZwCreateResourceManager

ZwOpenResourceManager

ZwRecoverResourceManager

ZwSetInformationResourceManager

NtQueryInformationTransaction function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwQueryInformationTransaction** routine retrieves information about a specified transaction.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtQueryInformationTransaction(
  HANDLE                      TransactionHandle,
  TRANSACTION_INFORMATION_CLASS TransactionInformationClass,
  PVOID                       TransactionInformation,
  ULONG                       TransactionInformationLength,
  PULONG                      ReturnLength
);
```

Parameters

`TransactionHandle`

A handle to a transaction object that was obtained by a previous call to ZwCreateTransaction or ZwOpenTransaction. The handle must have TRANSACTION_QUERY_INFORMATION access to the object.

`TransactionInformationClass`

A TRANSACTION_INFORMATION_CLASS-typed value that specifies the information to obtain. The value must be one of the following values:

- **TransactionBasicInformation**
- **TransactionPropertiesInformation**
- **TransactionEnlistmentInformation**

The **TransactionFullInformation** value is not used with **ZwQueryInformationTransaction**.

`TransactionInformation`

A pointer to a caller-allocated buffer that receives the information that the *TransactionInformationClass* parameter specifies. The buffer's structure type must be TRANSACTION_BASIC_INFORMATION, TRANSACTION_PROPERTIES_INFORMATION, or TRANSACTION_ENLISTMENTS_INFORMATION.

`TransactionInformationLength`

The length, in bytes, of the buffer that the *TransactionInformation* parameter points to, including the length of any additional array elements that the caller has allocated to receive information.

`ReturnLength`

A pointer to a caller-allocated variable that receives the length, in bytes, of the information that KTM writes to the *TransactionInformation* buffer. This parameter is optional and can be **NULL**.

Return Value

ZwQueryInformationTransaction returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_INFO_CLASS	The *TransactionInformationClass* parameter's value is invalid.
STATUS_INFO_LENGTH_MISMATCH	The length of the buffer that is specified by the *TransactionInformationLength* parameter is incorrect.
STATUS_OBJECT_TYPE_MISMATCH	The handle that the *TransactionHandle*parameter specifies is not a handle to a transaction object.
STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the transaction object.

STA **TUS** **_BU** **FFE** **R_O** **VER** **FLO** **W**	The buffer that the *TransactionInformation*parameter specifies is too small.

The routine might return other NTSTATUS values.

Remarks

For more information about how to use **ZwQueryInformationTransaction**, see Creating a Transactional Client.

NtQueryInformationTransaction and **ZwQueryInformationTransaction** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

ZwSetInformationTransaction

NtQueryInformationTransactionManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwQueryInformationTransactionManager** routine retrieves information about a specified transaction manager object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtQueryInformationTransactionManager(
  HANDLE                              TransactionManagerHandle,
  TRANSACTIONMANAGER_INFORMATION_CLASS TransactionManagerInformationClass,
  PVOID                               TransactionManagerInformation,
  ULONG                               TransactionManagerInformationLength,
  PULONG                              ReturnLength
);
```

Parameters

`TransactionManagerHandle`

A handle to a transaction manager object that was obtained by a previous call to ZwCreateTransactionManager or ZwOpenTransactionManager. The handle must have TRANSACTIONMANAGER_QUERY_INFORMATION access to the object.

`TransactionManagerInformationClass`

A TRANSACTIONMANAGER_INFORMATION_CLASS-typed enumeration value that specifies the information to be obtained. This value must be one of the following:

- **TransactionManagerBasicInformation**
- **TransactionManagerLogInformation**
- **TransactionManagerLogPathInformation**

The enumeration's **TransactionManagerOnlineProbeInformation** value is not used with **ZwQueryInformationTransactionManager**.

`TransactionManagerInformation`

A pointer to a caller-allocated buffer that receives the information that the *TransactionManagerInformationClass* parameter specifies. The buffer's structure type must be TRANSACTIONMANAGER_BASIC_INFORMATION, TRANSACTIONMANAGER_LOG_INFORMATION, TRANSACTIONMANAGER_LOGPATH_INFORMATION, or TRANSACTIONMANAGER_RECOVERY_INFORMATION.

`TransactionManagerInformationLength`

The length, in bytes, of the buffer that the *TransactionManagerInformation* parameter points to, including the length of any additional array elements that the caller has allocated to receive information.

`ReturnLength`

A pointer to a caller-allocated variable that receives the length, in bytes, of the information that KTM writes to the *TransactionManagerInformation* buffer. This parameter is optional and can be **NULL**.

Return Value

ZwQueryInformationTransactionManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_INFO_CLASS	The *TransactionManagerInformationClass* parameter's value is invalid.
STATUS_INFO_LENGTH_MISMATCH	The length of the buffer that is specified by the *TransactionManagerInformationLength*parameter is incorrect.
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to a transaction manager object.
STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the transaction manager object.

STA **TUS** **_BU** **FFE** **R_T** **OO_** **SM** **ALL**	The buffer that is specified by the *TransactionManagerInformation*parameter is too small.

The routine might return other NTSTATUS values.

Remarks

For more information about how to use **ZwQueryInformationTransactionManager**, see Using Log Streams with KTM.

NtQueryInformationTransactionManager and **ZwQueryInformationTransactionManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

ZwCreateTransactionManager

ZwOpenTransactionManager

ZwRecoverTransactionManager

ZwRollforwardTransactionManager

NtReadOnlyEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwReadOnlyEnlistment** routine sets a specified enlistment to be read-only.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtReadOnlyEnlistment(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SUBORDINATE_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwReadOnlyEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _TR AN SAC TIO N_N OT_ REQ UES TED	The transaction or its enlistment is not in the correct state. For example, an enlistment cannot be read-only if the ENLISTMENT_SUPERIOR flag was specified to ZwCreateEnlistment.
STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

Your component cannot call **ZwReadOnlyEnlistment** for a superior enlistment.

For more information about **ZwReadOnlyEnlistment**, see Creating a Read-Only Enlistment.

NtReadOnlyEnlistment and **ZwReadOnlyEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwOpenEnlistment

NtRecoverEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwRecoverEnlistment** routine initiates a recovery operation for the transaction that is associated with a specified enlistment.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtRecoverEnlistment(
  HANDLE EnlistmentHandle,
  PVOID  EnlistmentKey
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_RECOVER access to the object.

`EnlistmentKey`

A pointer to the enlistment key value that the resource manager previously specified as the *EnlistmentKey* parameter to ZwCreateEnlistment. This parameter is optional and can be **NULL** if the resource manager did not provide an enlistment key when it called **ZwCreateEnlistment**.

Return Value

ZwRecoverEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.

STATUS_INVALID_HANDLE	The object handle is invalid.
STATUS_TRANSACTION_NOT_EQUEST_NOT_VALID	The transaction or its enlistment is not in the correct state.
STATUS_PENDING	KTM has added a commit, rollback, or in-doubt notification to the resource manager's notification queue, and the resource manager is not using a ResourceManagerNotification callback routine.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

After a resource manager calls **ZwRecoverEnlistment**, KTM delivers either a TRANSACTION_NOTIFY_COMMIT, TRANSACTION_NOTIFY_ROLLBACK, or TRANSACTION_NOTIFY_INDOUBT notification for the enlistment. Therefore, unless the resource manager is using a ResourceManagerNotification callback routine, it must immediately call ZwGetNotificationResourceManager if **ZwRecoverEnlistment** returns STATUS_SUCCESS or STATUS_PENDING.

For more information about **ZwRecoverEnlistment**, see Handling Recovery Operations.

NtRecoverEnlistment and **ZwRecoverEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine

can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

TmRecoverEnlistment

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwGetNotificationResourceManager

ZwOpenEnlistment

NtRecoverResourceManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwRecoverResourceManager** routine tries to recover the transaction that is associated with each enlistment of a specified resource manager object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtRecoverResourceManager(
  HANDLE ResourceManagerHandle
);
```

Parameters

`ResourceManagerHandle`

A handle to a resource manager object that was obtained by a previous call to ZwCreateResourceManager or ZwOpenResourceManager. The handle must have RESOURCEMANAGER_RECOVER access to the object.

Return Value

ZwRecoverResourceManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to a resource manager object.
STATUS_INVALID_HANDLE	An object handle is invalid.

STATUS_TRANSACTION_NOT_ENLISTED	The transaction manager that is associated with the specified resource manager is not available.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the resource manager object.

The routine might return other NTSTATUS values.

Remarks

When a resource manager calls **ZwRecoverResourceManager**, KTM sends a TRANSACTION_NOTIFY_RECOVER notification to the resource manager for each of the resource manager's enlistments. (If the enlistment is a superior enlistment, KTM sends TRANSACTION_NOTIFY_RECOVER_QUERY instead of TRANSACTION_NOTIFY_RECOVER.)

The final notification that KTM sends to the resource manager is TRANSACTION_NOTIFY_LAST_RECOVER.

For more information about **ZwRecoverResourceManager**, see Handling Recovery Operations.

NtRecoverResourceManager and **ZwRecoverResourceManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwCreateResourceManager

ZwOpenResourceManager

ZwQueryInformationResourceManager

ZwSetInformationResourceManager

NtRecoverTransactionManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwRecoverTransactionManager** routine reconstructs the state of the transaction manager object (including all transactions, enlistments, and resource managers) from the recovery information that is in the log stream.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtRecoverTransactionManager(
  HANDLE TransactionManagerHandle
);
```

Parameters

`TransactionManagerHandle`

A handle to a transaction manager object that was obtained by a previous call to ZwCreateTransactionManager or ZwOpenTransactionManager. The handle must have TRANSACTIONMANAGER_RECOVER access to the object.

Return Value

ZwRecoverTransactionManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to a transaction manager object.
STATUS_INVALID_HANDLE	An object handle is invalid.

STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the transaction manager object.
STA TUS _TM _VO LAT ILE	The transaction manager object is volatile and, therefore, its transactions cannot be recovered.
STA TUS _UN SUC CES SFU L	The transaction manager object is not in a state that allows recovery.

The routine might return other NTSTATUS values.

Remarks

The **ZwRecoverTransactionManager** routine tries to reconstruct the state of the transaction manager object, including all transactions, enlistments, and resource managers, from the recovery information that is in the object's log stream, beginning at the last restart area that KTM created and ending at the stream's end.

To recover up to a specific virtual time, use the ZwRollforwardTransactionManager routine instead of **ZwRecoverTransactionManager**.

Your TPS component must call **ZwRecoverTransactionManager** after it has called ZwCreateTransactionManager or ZwOpenTransactionManager.

For more information about recovery operations, see Handling Recovery Operations.

NtRecoverTransactionManager and **ZwRecoverTransactionManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

TmRenameTransactionManager

NtRollbackComplete function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwRollbackComplete** routine notifies KTM that the calling resource manager has finished rolling back a transaction's data.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtRollbackComplete(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SUBORDINATE_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwRollbackComplete returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _TR AN SAC TIO N_N OT_ REQ UES TED	The transaction or its enlistment is not in the correct state.
STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

A resource manager must call **ZwRollbackComplete** after it has finished servicing a TRANSACTION_NOTIFY_ROLLBACK notification.

For more information about **ZwRollbackComplete**, see Handling Rollback Operations.

NtRollbackComplete and **ZwRollbackComplete** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

ZwOpenEnlistment

NtRollbackEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwRollbackEnlistment** routine rolls back the transaction that is associated with a specified enlistment.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtRollbackEnlistment(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SUBORDINATE_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwRollbackEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _TR AN SAC TIO N_R EQU EST _NO T_V ALI D	The enlistment cannot be rolled back.
STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

A resource manager can call **ZwRollbackEnlistment** to roll back a transaction at any time before it calls ZwPrepareComplete.

For more information about **ZwRollbackEnlistment**, see Handling Rollback Operations.

NtRollbackEnlistment and **ZwRollbackEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwOpenEnlistment

ZwPrepareComplete

NtRollbackTransaction function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwRollbackTransaction** routine initiates a rollback operation for a specified transaction.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtRollbackTransaction(
  HANDLE  TransactionHandle,
  BOOLEAN Wait
);
```

Parameters

`TransactionHandle`

A handle to a transaction object that was obtained by a previous call to ZwCreateTransaction or ZwOpenTransaction. The handle must have TRANSACTION_ROLLBACK access to the object.

`Wait`

A Boolean value that the caller sets to **TRUE** for synchronous operation or **FALSE** for asynchronous operation. If this parameter is set to **TRUE**, the call does not return until the rollback operation is complete.

Return Value

ZwRollbackTransaction returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The handle that the *TransactionHandle* parameter specifies is not a handle to a transaction object.
STATUS_INVALID_HANDLE	An object handle is invalid.

STATUS_ACCESS_DENIED	The caller does not have appropriate access to the transaction object.
STATUS_TRANSACTION_ALREADY_COMMITTED	The transaction cannot be rolled back because it has already been committed.
STATUS_TRANSACTION_NOT_ROLLBACK	The transaction has not been committed but its current state does not permit rollback.
STATUS_PENDING	Rollback notifications have been queued to resource managers, and the caller specified **FALSE** for the *Wait* parameter.

The routine might return other NTSTATUS values.

Remarks

For more information about **ZwRollbackTransaction**, see Handling Rollback Operations.

NtRollbackEnlistment and **ZwRollbackEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

ZwCommitTransaction

ZwCreateTransaction

ZwOpenTransaction

ZwQueryInformationTransaction

NtRollforwardTransactionManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwRollforwardTransactionManager** routine initiates recovery operations for all of the in-progress transactions that are assigned to a specified transaction manager.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtRollforwardTransactionManager(
  HANDLE         TransactionManagerHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`TransactionManagerHandle`

A handle to a transaction manager object that was obtained by a previous call to ZwCreateTransactionManager or ZwOpenTransactionManager. The handle must have TRANSACTIONMANAGER_RECOVER access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**. For more information about this parameter, see the following Remarks section.

Return Value

ZwRollforwardTransactionManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to a transaction manager object.

STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the transaction manager object.
STATUS_TM_VOLATILE	The specified transaction manager object does not have a log file, so recovery is not available.
STATUS_UNSUCCESSFUL	The specified transaction manager object is in an unexpected state.

The routine might return other NTSTATUS values.

Remarks

The **ZwRollforwardTransactionManager** routine recovers all logged activity that KTM finds in the transaction manager's log file, up to and including the virtual clock value that the *TmVirtualClock* parameter supplies.

Your component can traverse the log file incrementally by calling **ZwRollforwardTransactionManager** repetitively and setting the *VirtualClock* parameter to a higher value before each call.

If the *TmVirtualClock* parameter is **NULL**, calling **ZwRollforwardTransactionManager** is equivalent to calling ZwRecoverTransactionManager.

For more information about recovery operations, see Handling Recovery Operations.

NtRollforwardTransactionManager and **ZwRollforwardTransactionManager** are two versions of the same Windows Native System Services routine. The **NtRollforwardTransactionManager** routine in the Windows kernel is not directly accessible to kernel-mode drivers. However, kernel-mode drivers can access this routine indirectly by calling the **ZwRollforwardTransactionManager** routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the

relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwCreateTransactionManager

ZwOpenTransactionManager

ZwRecoverTransactionManager

NtSetInformationEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwSetInformationEnlistment** routine sets information for a specified enlistment object.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtSetInformationEnlistment(
  HANDLE                      EnlistmentHandle,
  ENLISTMENT_INFORMATION_CLASS EnlistmentInformationClass,
  PVOID                       EnlistmentInformation,
  ULONG                       EnlistmentInformationLength
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SET_INFORMATION access to the object.

`EnlistmentInformationClass`

A ENLISTMENT_INFORMATION_CLASS-typed enumeration value that specifies the type of information to be set. This value must be **EnlistmentRecoveryInformation**.

The enumeration's **EnlistmentBasicInformation** and **EnlistmentFullInformation** values are not used with **ZwSetInformationEnlistment**.

`EnlistmentInformation`

A pointer to a caller-allocated buffer that contains caller-defined recovery information for the enlistment.

`EnlistmentInformationLength`

The length, in bytes, of the buffer that the *EnlistmentInformation* parameter points to.

Return Value

ZwSetInformationEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION

STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.
STATUS_INVALID_INFO_CLASS	The *EnlistmentInformationClass* parameter's value is invalid.
STATUS_INFO_LENGTH_MISMATCH	The *EnlistmentInformationLength* parameter's value is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

A resource manager can use the **ZwSetInformationEnlistment** routine to set recovery information for an enlistment. KTM writes the recovery information to the log stream, and the resource manager can call

ZwQueryInformationEnlistment to read this information from the log stream at any time.

Each subsequent call to **ZwSetInformationEnlistment** deletes the recovery information that the previous call specified before it stores the new recovery information.

For more information about how to use **ZwSetInformationEnlistment**, see Using Log Streams with KTM.

NtSetInformationEnlistment and **ZwSetInformationEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

NtSetInformationResourceManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwSetInformationResourceManager** routine is not used.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtSetInformationResourceManager(
  HANDLE                          ResourceManagerHandle,
  RESOURCEMANAGER_INFORMATION_CLASS ResourceManagerInformationClass,
  PVOID                           ResourceManagerInformation,
  ULONG                           ResourceManagerInformationLength
);
```

Parameters

`ResourceManagerHandle`

Not used.

`ResourceManagerInformationClass`

Not used.

`ResourceManagerInformation`

Not used.

`ResourceManagerInformationLength`

Not used.

Return Value

This function does not return a value.

Remarks

NtSetInformationResourceManager and **ZwSetInformationResourceManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Target Platform	Windows

Header	wdm.h

NtSetInformationTransaction function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwSetInformationTransaction** routine sets information for a specified transaction.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtSetInformationTransaction(
  HANDLE                      TransactionHandle,
  TRANSACTION_INFORMATION_CLASS TransactionInformationClass,
  PVOID                       TransactionInformation,
  ULONG                       TransactionInformationLength
);
```

Parameters

`TransactionHandle`

A handle to a transaction object that was obtained by a previous call to ZwCreateTransaction or ZwOpenTransaction. The handle must have TRANSACTION_SET_INFORMATION access to the object.

`TransactionInformationClass`

A TRANSACTION_INFORMATION_CLASS-typed value that specifies the type of information to set. The value must be **TransactionPropertiesInformation**.

`TransactionInformation`

A pointer to a caller-allocated buffer that contains the information to set. The buffer's structure type must be TRANSACTION_PROPERTIES_INFORMATION.

`TransactionInformationLength`

The length, in bytes, of the buffer that the *TransactionInformation* parameter points to.

Return Value

ZwSetInformationTransaction returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_INFO_CLASS	The *TransactionInformationClass* parameter's value is invalid.

STATUS_OBJECT_TYPE_MISMATCH	The handle that the *TransactionHandle* parameter specifies is not a handle to a transaction object.
STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the transaction object.
STATUS_INFO_LENGTH_MISMATCH	The *TransactionInformationLength*parameter's value is invalid.
STATUS_INVALID_PARAMETER	The contents of the buffer that the *TransactionInformation* buffer specifies is invalid.

The routine might return other NTSTATUS values.

Remarks

For more information about **ZwSetInformationTransaction**, see Creating a Transactional Client.

NtSetInformationTransaction and **ZwSetInformationTransaction** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

NtSetInformationTransactionManager function

1/25/2019 • 2 minutes to read • Edit Online

Do not call this routine from kernel-mode code.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtSetInformationTransactionManager(
  HANDLE                              TmHandle,
  TRANSACTIONMANAGER_INFORMATION_CLASS TransactionManagerInformationClass,
  PVOID                               TransactionManagerInformation,
  ULONG                               TransactionManagerInformationLength
);
```

Parameters

`TmHandle`

`TransactionManagerInformationClass`

`TransactionManagerInformation`

`TransactionManagerInformationLength`

Return Value

See the **Zw*Xxx*** equivalent.

Do not call this routine from kernel-mode code; instead, call the **Zw*Xxx*** equivalent. User-mode code can call this routine or the **Zw*Xxx*** equivalent. For further comments, if any, see the ZwXxx equivalent

The driver must check the return value of the function.

Requirements

Target Platform	Windows
Header	wdm.h
IRQL	"<=APC_LEVEL"

See Also

See the **Zw*Xxx*** equivalent.

NtSinglePhaseReject function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwSinglePhaseReject** routine informs KTM that the calling resource manager will not support single-phase commit operations for a specified enlistment.

Syntax

```
__kernel_entry NTSYSCALLAPI NTSTATUS NtSinglePhaseReject(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SUBORDINATE_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwSinglePhaseReject returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _TR AN SAC TIO N_N OT_ REQ UES TED	The transaction or its enlistment is not in the correct state.
STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

A resource manager can call **ZwSinglePhaseReject** when it receives a TRANSACTION_NOTIFY_SINGLE_PHASE_COMMIT notification.

For more information about **ZwSinglePhaseReject**, see Handling Commit Operations.

NtSinglePhaseReject and **ZwSinglePhaseReject** are two versions of the same Windows Native System Services routine. The **NtSinglePhaseReject** routine in the Windows kernel is not directly accessible to kernel-mode drivers. However, kernel-mode drivers can access this routine indirectly by calling the **ZwSinglePhaseReject** routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwOpenEnlistment

ObCloseHandle function

1/25/2019 • 3 minutes to read • Edit Online

The **ObCloseHandle** routine closes an object handle.

Syntax

```
NTSTATUS ObCloseHandle(
  HANDLE          Handle,
  KPROCESSOR_MODE PreviousMode
);
```

Parameters

`Handle`

A handle to a system-supplied object of any type.

`PreviousMode`

Specifies the previous processor mode of the thread that opened the handle. To close a kernel handle, set this parameter to **KernelMode**. To close a *user handle*, set this parameter to **UserMode**. For more information about these two handle types, see Remarks.

Return Value

ObCloseHandle returns STATUS_SUCCESS if the call is successful. Possible error return values include the following NTSTATUS codes.

RETURN CODE	DESCRIPTION
STATUS_INVALID_HANDLE	*Handle* is not a valid handle.
STATUS_HANDLE_NOT_CLOSABLE	The calling thread does not have permission to close the handle.

Remarks

A kernel-mode driver calls **ObCloseHandle** to close a handle to any type of object that is created by the Windows kernel. A driver must close every handle that it opens as soon as the handle is no longer required.

After **ObCloseHandle** closes an object's handle, the caller must treat the handle as invalid and avoid using the handle to access the object. However, other handles might remain open on the same object. During an **ObCloseHandle** call, the system decrements the handle count for the object and checks whether the object can be deleted. The system does not delete the object until all of the object's handles are closed and all reference-counted pointers to the object are released.

The *PreviousMode* parameter specifies whether the handle to be closed is a kernel handle or a user handle. To close a kernel handle, set *PreviousMode* to **KernelMode**. To close a user handle, set *PreviousMode* to **UserMode**.

A kernel handle is a handle that is opened by a system thread, or by a kernel-mode driver that assigns the OBJ_KERNEL_HANDLE attribute to the handle. (For example, see the description of OBJ_KERNEL_HANDLE in ZwCreateFile.) If a kernel-mode driver opens a handle for its private use, and this driver runs in the context of a user-mode thread, the driver must open the handle with the OBJ_KERNEL_HANDLE attribute. This attribute ensures that the handle is inaccessible to user-mode applications.

A user handle is a handle that is opened by a user-mode application, or by a kernel-mode driver that runs in the context of a user-mode thread but that does not open the handle with the OBJ_KERNEL_HANDLE attribute. If a driver creates a user handle to be used by a user-mode application, but an error occurs that requires the driver to close the handle on behalf of the application, the driver can call **ObCloseHandle** to close the handle.

The **ZwClose** routine is similar to **ObCloseHandle** but can close only kernel handles. The call **ZwClose**(*hObject*), which closes kernel handle *hObject*, has the same effect as the call **ObCloseHandle**(*hObject*, **KernelMode**). For more information about closing a kernel handle, see ZwClose.

To determine whether a handle is a kernel handle or a user handle, a driver that receives a handle can call the ExGetPreviousMode routine. Or, the driver can read the **RequestorMode** field from the IRP structure that describes the I/O request. The I/O manager sets the **RequestorMode** field to the previous processor mode of the thread that requested the I/O operation.

Callers of **ObCloseHandle** should not assume that this routine automatically waits for all pending I/O operations to complete before it returns.

For more information, see Object Handles.

ObCloseHandle is not declared in a header file prior to Windows 7. To use this routine in your driver, include the following function declaration in your driver code:

```
#if (NTDDI_VERSION < NTDDI_WIN7)
NTKERNELAPI
NTSTATUS
  ObCloseHandle(
    __in HANDLE Handle,
    __in KPROCESSOR_MODE PreviousMode
    );
#endif
```

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h
Library	Ntoskrnl.lib

ZwCreateFile

ObDereferenceObject macro

1/25/2019 • 2 minutes to read • Edit Online

The **ObDereferenceObject** routine decrements the given object's reference count and performs retention checks.

Syntax

```
void ObDereferenceObject(
   a
);
```

Parameters

`a`

Pointer to the object's body.

Return Value

ObDereferenceObject returns a value that is reserved for system use. Drivers must treat this value as VOID.

Remarks

ObDereferenceObject decreases the reference count of an object by one. If the object was created as temporary (the OBJ_PERMANENT flag was not specified on creation), and the reference count reaches zero, the object can be deleted by the system.

A driver can delete a temporary object it created by decreasing its reference count to zero. A driver must never attempt to delete an object it did not create.

An object is permanent if it was created with the OBJ_PERMANENT object attribute flag specified. (For more information about object attributes, see InitializeObjectAttributes.) A permanent object is created with a reference count of one, so it is not deleted when the driver dereferences it. A driver can only delete a permanent object it created by using the ZwMakeTemporaryObject routine to make it temporary. Use the following steps to delete a permanent object that you created:

1. Call **ObDereferenceObject**.
2. Call the appropriate **ZwOpen*Xxx*** or **ZwCreate*Xxx*** routine to get a handle for the object, if necessary.
3. Call ZwMakeTemporaryObject with the handle obtained in step 2.
4. Call ZwClose with the handle obtained in step 2.

> **Important**
> Use ObDereferenceObjectDeferDelete instead of **ObDereferenceObject** for any object, particularly Kernel Transaction Manager (KTM) objects, when the immediate deletion by the current thread of the object (by using **ObDereferenceObject**) might result in a deadlock.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Fltkernel.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

InitializeObjectAttributes

IoGetDeviceObjectPointer

ObDereferenceObjectDeferDelete

ZwClose

ZwMakeTemporaryObject

ObDereferenceObjectDeferDelete function

1/25/2019 • 2 minutes to read • Edit Online

The **ObDereferenceObjectDeferDelete** routine decrements the reference count for the given object, checks for object retention, and avoids deadlocks.

Syntax

```
void ObDereferenceObjectDeferDelete(
  PVOID Object
);
```

Parameters

`Object`

A pointer to the body of the object.

Return Value

None

Remarks

ObDereferenceObjectDeferDelete is similar to ObDereferenceObject except that, when the reference count of the object reaches zero, the object manager passes the object deletion request to a worker thread. Therefore, the deletion later occurs at IRQL = PASSIVE_LEVEL.

Use **ObDereferenceObjectDeferDelete** for any object when the immediate deletion by the current thread of the object (by using **ObDereferenceObject**) might result in a deadlock.

For example, such a deadlock can occur if **ObDereferenceObject** is used to dereference a Kernel Transaction Manager (KTM) object when a higher level driver on the driver stack is holding a lock.

To avoid such deadlocks, use **ObDereferenceObjectDeferDelete** instead of **ObDereferenceObject** to dereference KTM objects.

> **Note** For information about object permanence and attributes, see ObDereferenceObject.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows operating systems.
Target Platform	Universal
Header	wdm.h (include Fltkernel.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

See Also

ObDereferenceObject

ObReferenceObject

ObDereferenceObjectDeferDeleteWithTag function

1/25/2019 • 2 minutes to read • Edit Online

The **ObDereferenceObjectDeferDeleteWithTag** routine decrements the reference count for the specified object, defers deletion of the object to avoid deadlocks, and writes a four-byte tag value to the object to support object reference tracing.

Syntax

```
void ObDereferenceObjectDeferDeleteWithTag(
  PVOID Object,
  ULONG Tag
);
```

Parameters

`Object`

A pointer to the object. The caller obtains this pointer either when it creates the object, or from a previous call to the ObReferenceObjectByHandleWithTag routine after it opens the object.

`Tag`

Specifies a four-byte, custom tag value. For more information, see the following Remarks section.

Return Value

None

Remarks

ObDereferenceObjectDeferDeleteWithTag is similar to ObDereferenceObjectWithTag except that, when the reference count of the object reaches zero, **ObDereferenceObjectDeferDeleteWithTag** passes the object deletion request to a worker thread. The worker thread, which runs at IRQL = PASSIVE_LEVEL, later deletes the object.

If the immediate deletion of an object by the current thread might cause a deadlock, do not call **ObDereferenceObjectWithTag** to dereference the object. Instead, call **ObDereferenceObjectDeferDeleteWithTag** to dereference the object.

For example, such a deadlock can occur if **ObDereferenceObjectWithTag** is used to dereference a Kernel Transaction Manager (KTM) object when a higher-level driver on the driver stack is holding a lock.

For more information about object permanence and object attributes, see ObDereferenceObjectWithTag. For more information about object references, see Life Cycle of an Object.

The ObDereferenceObjectDeferDelete routine is similar to **ObDereferenceObjectDeferDeleteWithTag**, except that it does not enable the caller to write a custom tag to an object. In Windows 7 and later versions of Windows, **ObDereferenceObjectDeferDelete** always writes a default tag value ('tIfD') to the object. A call to **ObDereferenceObjectDeferDelete** has the same effect as a call to **ObDereferenceObjectDeferDeleteWithTag** that specifies *Tag* = 'tIfD'.

To view an object reference trace in the Windows debugging tools, use the !obtrace kernel-mode debugger extension. In Windows 7, the !obtrace extension is enhanced to display object reference tags, if object reference tracing is enabled. By default, object reference tracing is turned off. Use the Global Flags Editor (Gflags) to enable object reference tracing. For more information, see Object Reference Tracing with Tags.

Requirements

Minimum supported client	Available in Windows 7 and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Fltkernel.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

ObDereferenceObjectDeferDelete

ObDereferenceObjectWithTag

ObReferenceObjectByHandleWithTag

ObDereferenceObjectWithTag macro

1/25/2019 • 2 minutes to read • Edit Online

The **ObDereferenceObjectWithTag** routine decrements the reference count of the specified object, and writes a four-byte tag value to the object to support object reference tracing.

Syntax

```
void ObDereferenceObjectWithTag(
   a,
   t
);
```

Parameters

`a`

A pointer to the object. The caller obtains this pointer either when it creates the object, or from a previous call to the ObReferenceObjectByHandleWithTag routine after it opens the object.

`t`

Specifies a four-byte, custom tag value. For more information, see the following Remarks section.

Return Value

ObDereferenceObjectWithTag returns a value that is reserved for system use. Drivers must treat this value as VOID.

Remarks

A kernel-mode driver calls this routine to decrement the reference count of an object by one. If the object was created as *temporary* (that is, the OBJ_PERMANENT flag was not specified when the object was created), and the reference count reaches zero, the object manager deletes the object.

When the reference count for an object reaches zero, a kernel-mode component can delete the object. However, a driver can delete only those objects that it created, and a driver should never attempt to delete any object that it did not create.

An object is *permanent* if it was created with the OBJ_PERMANENT object attribute flag specified. (For more information about object attributes, see InitializeObjectAttributes.) A permanent object is created with an initial reference count of one, so the object is not deleted when the driver removes its last reference to the object.

To prepare a permanent object to be deleted, a driver can call the ZwMakeTemporaryObject routine to make the object temporary. A driver should only delete a permanent object that it created. Use the following steps to delete a permanent object:

1. Call **ObDereferenceObjectWithTag**.
2. Get the handle to the object. If necessary, call the appropriate **ZwOpen*Xxx*** or **ZwCreate*Xxx*** routine to get the object handle.

3. Call **ZwMakeTemporaryObject** with the handle obtained in step 2.

4. Call ZwClose with the handle obtained in step 2.

If the immediate deletion of an object by the current thread might cause a deadlock, do not call **ObDereferenceObjectWithTag** to dereference the object. Instead, call the ObDereferenceObjectDeferDeleteWithTag routine to dereference the object.

For example, such a deadlock can occur if **ObDereferenceObjectWithTag** is used to dereference a Kernel Transaction Manager (KTM) object when a higher-level driver on the driver stack is holding a lock.

For more information about object references, see Life Cycle of an Object.

The ObDereferenceObject routine is similar to **ObDereferenceObjectWithTag**, except that it does not enable the caller to write a custom tag to an object. In Windows 7 and later versions of Windows, **ObDereferenceObject** always writes a default tag value ('tIfD') to the object. A call to **ObDereferenceObject** has the same effect as a call to **ObDereferenceObjectWithTag** that specifies *Tag* = 'tIfD'.

To view an object reference trace in the Windows debugging tools, use the !obtrace kernel-mode debugger extension. In Windows 7, the **!obtrace** extension is enhanced to display object reference tags, if object reference tracing is enabled. By default, object reference tracing is turned off. Use the Global Flags Editor (Gflags) to enable object reference tracing. For more information, see Object Reference Tracing with Tags.

ObfReferenceObject function

1/25/2019 • 2 minutes to read • Edit Online

The **ObReferenceObject** routine increments the reference count to the given object.

Syntax

```
LONG_PTR ObfReferenceObject(
  PVOID Object
);
```

Parameters

`Object`

Pointer to the object. The caller obtained this parameter either when it created the object or from a preceding call to ObReferenceObjectByHandle after it opened the object.

Return Value

ObReferenceObject returns a value that is reserved for system use. Drivers must treat this value as VOID.

Remarks

ObReferenceObject simply increments the pointer reference count for an object, without making any access checks on the given object, as ObReferenceObjectByHandle and ObReferenceObjectByPointer do.

ObReferenceObject prevents deletion of the object at least until the driver subsequently calls its reciprocal, **ObDereferenceObject**, or closes the given object. The caller must decrement the reference count with **ObDereferenceObject** as soon as it is done with the object.

When the reference count for an object reaches zero, a kernel-mode component can remove the object from the system. However, a driver can remove only those objects that it created, and a driver should never attempt to remove any object that it did not create.

Requirements

Minimum supported client	Available starting with Windows 2000.

ObGetObjectSecurity function

1/25/2019 • 2 minutes to read • Edit Online

The **ObGetObjectSecurity** routine gets the security descriptor for a given object.

Syntax

```
NTSTATUS ObGetObjectSecurity(
  PVOID                Object,
  PSECURITY_DESCRIPTOR *SecurityDescriptor,
  PBOOLEAN             MemoryAllocated
);
```

Parameters

`Object`

Pointer to the object.

`SecurityDescriptor`

Pointer to a caller-supplied variable that this routine sets to the address of a buffer containing the SECURITY_DESCRIPTOR for the given object. If the given object has no security descriptor, this variable is set to **NULL** on return from **ObGetObjectSecurity**.

`MemoryAllocated`

Pointer to a caller-supplied variable that this routine sets to **TRUE** if it allocated a buffer to contain the security descriptor.

Return Value

ObGetObjectSecurity either returns STATUS_SUCCESS or an error status, such as STATUS_INSUFFICIENT_RESOURCES if it could not allocate enough memory to return the requested information.

Remarks

A successful call to **ObGetObjectSecurity** either returns a self-relative security descriptor in the buffer at **SecurityDescriptor* or it returns **NULL** at **SecurityDescriptor* if the given object has no security descriptor. For example, any unnamed object, such as an event object, has no security descriptor.

If **ObGetObjectSecurity** returns STATUS_SUCCESS, the caller must save the value returned at *MemoryAllocated*. Such a caller must pass *MemoryAllocated* in a reciprocal call to ObReleaseObjectSecurity eventually, thereby restoring the reference count on the security descriptor to its original value and releasing the buffer, if any, that was allocated by **ObGetObjectSecurity**.

ObGetObjectSecurity should only be called at IRQL Level = PASSIVE_LEVEL with APCs enabled, otherwise deadlocks or crashes may occur.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

ObReferenceObjectByHandle function

1/25/2019 • 2 minutes to read • Edit Online

The **ObReferenceObjectByHandle** routine provides access validation on the object handle, and, if access can be granted, returns the corresponding pointer to the object's body.

Syntax

```
NTSTATUS ObReferenceObjectByHandle(
  HANDLE                     Handle,
  ACCESS_MASK                DesiredAccess,
  POBJECT_TYPE               ObjectType,
  KPROCESSOR_MODE            AccessMode,
  PVOID                      *Object,
  POBJECT_HANDLE_INFORMATION HandleInformation
);
```

Parameters

`Handle`

Specifies an open handle for an object.

`DesiredAccess`

Specifies the requested types of access to the object. The interpretation of this field is dependent on the object type. Do not use any generic access rights. For more information, see ACCESS_MASK.

`ObjectType`

Pointer to the object type. *ObjectType* can be ***ExEventObjectType**, ***ExSemaphoreObjectType**, ***IoFileObjectType**, ***PsProcessType**, ***PsThreadType**, ***SeTokenObjectType**, ***TmEnlistmentObjectType**, ***TmResourceManagerObjectType**, ***TmTransactionManagerObjectType**, or ***TmTransactionObjectType**.

If *ObjectType* is not **NULL**, the operating system verifies that the supplied object type matches the object type of the object that *Handle* specifies.

`AccessMode`

Specifies the access mode to use for the access check. It must be either **UserMode** or **KernelMode**. Drivers should always specify **UserMode** for handles they receive from user address space.

`Object`

Pointer to a variable that receives a pointer to the object's body. The following table contains the pointer types.

OBJECTTYPE PARAMETER	OBJECT POINTER TYPE
***ExEventObjectType**	PKEVENT
***ExSemaphoreObjectType**	PKSEMAPHORE
***IoFileObjectType**	PFILE_OBJECT

OBJECTTYPE PARAMETER	OBJECT POINTER TYPE
***PsProcessType**	PEPROCESS or PKPROCESS
***PsThreadType**	PETHREAD or PKTHREAD
***SeTokenObjectType**	PACCESS_TOKEN
***TmEnlistmentObjectType**	PKENLISTMENT
***TmResourceManagerObjectType**	PKRESOURCEMANAGER
***TmTransactionManagerObjectType**	PKTM
***TmTransactionObjectType**	PKTRANSACTION

The structures that the pointer types reference are opaque, and drivers cannot access the structure members. Because the structures are opaque, PEPROCESS is equivalent to PKPROCESS, and PETHREAD is equivalent to PKTHREAD.

`HandleInformation`

Drivers set this to **NULL**.

Return Value

ObReferenceObjectByHandle returns STATUS_SUCCESS if the call is successful. Possible return values include the following error codes:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The *ObjectType* parameter specifies the wrong object type for the object that is identified by the *Handle* parameter.
STATUS_ACCESS_DENIED	The caller cannot be granted the requested access rights to the object.
STATUS_INVALID_HANDLE	The *Handle* parameter is not a valid object handle.

Remarks

A pointer to the object body is retrieved from the object table entry and returned to the caller by means of the *Object* parameter.

If *AccessMode* is **UserMode**, the requested access is compared to the granted access for the object. If *AccessMode* is **KernelMode**, the handle should originate in the kernel address space.

Starting with Windows 7, if *AccessMode* is **KernelMode** and handle is received from user address space, Driver Verifier issues bugcheck C4, subcode F6.

If the call succeeds, a pointer to the object body is returned to the caller and the pointer reference count is incremented. Incrementing this count prevents the object from being deleted while the pointer is being referenced. The caller must decrement the reference count with ObDereferenceObject as soon as it is done with the object.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	IrqlObPassive, TargetRelationNeedsRef, HwStorPortProhibitedDDIs

ACCESS_MASK

ObDereferenceObject

ObReferenceObject

ObReferenceObjectByPointer

ObReferenceObjectByHandleWithTag function

1/25/2019 • 3 minutes to read • Edit Online

The **ObReferenceObjectByHandleWithTag** routine increments the reference count of the object that is identified by the specified handle, and writes a four-byte tag value to the object to support object reference tracing.

Syntax

```
NTSTATUS ObReferenceObjectByHandleWithTag(
  HANDLE                     Handle,
  ACCESS_MASK                DesiredAccess,
  POBJECT_TYPE               ObjectType,
  KPROCESSOR_MODE            AccessMode,
  ULONG                      Tag,
  PVOID                      *Object,
  POBJECT_HANDLE_INFORMATION HandleInformation
);
```

Parameters

`Handle`

Specifies an open handle for an object.

`DesiredAccess`

Specifies the types of access to the object that the caller requests. This parameter is a bitmask of type ACCESS_MASK. The interpretation of this field depends on the object type. Do not use any generic access rights.

`ObjectType`

A pointer to an opaque structure that specifies the object type. This parameter points to an OBJECT_TYPE structure. Set *ObjectType* to **NULL** or to one of the following pointer values, which are declared in the Wdm.h header file: ***ExEventObjectType**, ***ExSemaphoreObjectType**, ***IoFileObjectType**, ***PsProcessType**, ***PsThreadType**, ***SeTokenObjectType**, ***TmEnlistmentObjectType**, ***TmResourceManagerObjectType**, ***TmTransactionManagerObjectType**, or ***TmTransactionObjectType**. If *ObjectType* is not **NULL**, the routine verifies that the supplied object type matches the object type of the object that the *Handle* parameter specifies.

`AccessMode`

Specifies the access mode to use for the access check. It must be either **UserMode** or **KernelMode**. Drivers should always specify **UserMode** for handles they receive from user address space.

`Tag`

Specifies a four-byte, custom tag value. For more information, see the following Remarks section.

`Object`

A pointer to a variable into which the routine writes a pointer to the object. The following table lists the *Object* pointer types that are designated by the possible *ObjectType* parameter values.

ObjectType Parameter	*Object* Pointer Type
***ExEventObjectType**	PKEVENT
***ExSemaphoreObjectType**	PKSEMAPHORE
***IoFileObjectType**	PFILE_OBJECT
***PsProcessType**	PEPROCESS or PKPROCESS
***PsThreadType**	PETHREAD or PKTHREAD
***SeTokenObjectType**	PACCESS_TOKEN
***TmEnlistmentObjectType**	PKENLISTMENT
***TmResourceManagerObjectType**	PKRESOURCEMANAGER
***TmTransactionManagerObjectType**	PKTM
***TmTransactionObjectType**	PKTRANSACTION

The structures that the pointer types reference are opaque, and drivers cannot access the structure members. Because the structures are opaque, PEPROCESS is equivalent to PKPROCESS, and PETHREAD is equivalent to PKTHREAD.

`HandleInformation`

Drivers set this parameter to **NULL**.

Return Value

ObReferenceObjectByHandleWithTag returns STATUS_SUCCESS if the call is successful. Possible error return values include the following:

Return code	Description
STATUS_OBJECT_TYPE_MISMATCH	The *ObjectType* parameter specifies the wrong object type for the object that is identified by the *Handle* parameter.
STATUS_ACCESS_DENIED	The caller does not have the required access rights to the object.
STATUS_INVALID_HANDLE	The specified handle is not valid.

Remarks

This routine does access validation of the specified object handle. If access can be granted, the routine increments the object reference count and provides an object pointer to the caller. This increment prevents the object from being deleted while the caller uses the object. When the object is no longer needed, the caller should decrement the reference count by calling the ObDereferenceObjectWithTag or ObDereferenceObjectDeferDeleteWithTag routine.

For more information about object references, see Life Cycle of an Object.

ObReferenceObjectByHandleWithTag does not close or invalidate the object handle that is specified by the *Handle* parameter. When the handle is no longer needed, the caller can close the handle by calling the ZwClose routine.

If the *AccessMode* parameter value is **KernelMode**, the requested access is always allowed. If *AccessMode* is **UserMode**, the requested access is compared to the access rights that the caller has to the object. Only highest-level drivers can safely specify the **UserMode** value for the *AccessMode* parameter.

Starting with Windows 7, if *AccessMode* is **KernelMode** and handle is received from user address space, Driver Verifier issues bugcheck C4, subcode F6.

The ObReferenceObjectByHandle routine is similar to **ObReferenceObjectByHandleWithTag**, except that it does not enable the caller to write a custom tag to an object. In Windows 7 and later versions of Windows, **ObReferenceObjectByHandle** always writes a default tag value ('tIfD') to the object. A call to **ObReferenceObjectByHandle** has the same effect as a call to **ObReferenceObjectByHandleWithTag** that specifies *Tag* = 'tIfD'.

To view an object reference trace in the Windows debugging tools, use the !obtrace kernel-mode debugger extension. The **!obtrace** extension is enhanced to display object reference tags, if object reference tracing is enabled. By default, object reference tracing is turned off. Use the Global Flags Editor (Gflags) to enable object reference tracing. For more information, see Object Reference Tracing with Tags.

Requirements

Minimum supported client	Available in Windows 7 and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Fltkernel.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

ObDereferenceObjectWithTag

ObReferenceObjectByHandle

ZwClose

ObReferenceObjectByPointer function

1/25/2019 • 2 minutes to read • Edit Online

The **ObReferenceObjectByPointer** routine increments the pointer reference count for a given object.

Syntax

```
NTSTATUS ObReferenceObjectByPointer(
  PVOID           Object,
  ACCESS_MASK     DesiredAccess,
  POBJECT_TYPE    ObjectType,
  KPROCESSOR_MODE AccessMode
);
```

Parameters

`Object`

Pointer to the object's body.

`DesiredAccess`

Specifies a mask representing the requested access to the object.

`ObjectType`

Pointer to the object type. *ObjectType* can be ***ExEventObjectType***, **ExSemaphoreObjectType**, ***IoFileObjectType***, **PsProcessType**, ***PsThreadType***, **SeTokenObjectType**, ***TmEnlistmentObjectType***, **TmResourceManagerObjectType**, ***TmTransactionManagerObjectType***, or **TmTransactionObjectType**.

> **Note** The **SeTokenObjectType** object type is supported in Windows XP and later versions of Windows.

This parameter can also be **NULL** if *AccessMode* is **KernelMode**.

`AccessMode`

Indicates the access mode to use for the access check. It must be either **UserMode** or **KernelMode**. Lower-level drivers should specify **KernelMode**.

Return Value

ObReferenceObjectByPointer returns an NTSTATUS value. Possible return values include:

Remarks

Calling this routine prevents the object from being deleted, possibly by another component's call to ObDereferenceObject or ZwClose. The caller must decrement the reference count with **ObDereferenceObject** as soon as it is done with the object.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ObReferenceObjectByPointerWithTag function

1/25/2019 • 2 minutes to read • Edit Online

The **ObReferenceObjectByPointerWithTag** routine increments the reference count of the specified object, and writes a four-byte tag value to the object to support object reference tracing.

Syntax

```
NTSTATUS ObReferenceObjectByPointerWithTag(
  PVOID           Object,
  ACCESS_MASK     DesiredAccess,
  POBJECT_TYPE    ObjectType,
  KPROCESSOR_MODE AccessMode,
  ULONG           Tag
);
```

Parameters

`Object`

A pointer to the object. The caller obtains this pointer either when it creates the object, or from a previous call to the ObReferenceObjectByHandleWithTag routine after it opens the object.

`DesiredAccess`

Specifies the types of access to the object that the caller requests. This parameter is a bitmask of type ACCESS_MASK. The interpretation of this field depends on the object type. Do not use any generic access rights.

`ObjectType`

A pointer to an opaque structure that specifies the object type. This parameter points to an OBJECT_TYPE structure. Set *ObjectType* to **NULL** or to one of the following pointer values, which are declared in the Wdm.h header file: ***ExEventObjectType***, **ExSemaphoreObjectType**, ***IoFileObjectType***, **PsProcessType**, ***PsThreadType***, **SeTokenObjectType**, ***TmEnlistmentObjectType***, **TmResourceManagerObjectType**, ***TmTransactionManagerObjectType***, or **TmTransactionObjectType**. This parameter can be **NULL** if *AccessMode* is **KernelMode**. If *ObjectType* is not **NULL**, the routine verifies that the supplied object type matches the object type of the object that the *Handle* parameter specifies.

`AccessMode`

Indicates the access mode to use for the access check. Set this parameter to one of the following **MODE** enumeration values:

- **UserMode**
- **KernelMode**

Lower-level drivers should specify **KernelMode**.

`Tag`

Specifies a four-byte, custom tag value. For more information, see the following Remarks section.

Return Value

ObReferenceObjectByPointerWithTag returns STATUS_SUCCESS if the call is successful. Possible error return values include the following:

RETURN CODE	DESCRIPTION
STA TUS _OB JEC T_T YPE _MI SM ATC H	The *ObjectType* parameter specifies the wrong object type for the object that the *Object* parameter points to, or *ObjectType* is **NULL** but *AccessMode* is **UserMode**.

Remarks

This routine does access validation of the specified object. If access can be granted, the routine increments the object reference count. This increment prevents the object from being deleted while the caller uses the object. When the object is no longer needed, the caller should decrement the reference count by calling the ObDereferenceObjectWithTag or ObDereferenceObjectDeferDeleteWithTag routine.

For more information about object references, see Life Cycle of an Object.

The ObReferenceObjectByPointer routine is similar to **ObReferenceObjectByPointerWithTag**, except that it does not enable the caller to write a custom tag to an object. In Windows 7 and later versions of Windows, **ObReferenceObjectByPointer** always writes a default tag value ('tIfD') to the object. A call to **ObReferenceObjectByPointer** has the same effect as a call to **ObReferenceObjectByPointerWithTag** that specifies *Tag* = 'tIfD'.

To view an object reference trace in the Windows debugging tools, use the !obtrace kernel-mode debugger extension. In Windows 7, the !obtrace extension is enhanced to display object reference tags, if object reference tracing is enabled. By default, object reference tracing is turned off. Use the Global Flags Editor (Gflags) to enable object reference tracing. For more information, see Object Reference Tracing with Tags.

ObDereferenceObjectWithTag

ObReferenceObjectByPointer

ZwClose

ObReferenceObjectWithTag macro

1/25/2019 • 2 minutes to read • Edit Online

The **ObReferenceObjectWithTag** routine increments the reference count of the specified object, and writes a four-byte tag value to the object to support object reference tracing.

Syntax

```
void ObReferenceObjectWithTag(
   Object,
   Tag
);
```

Parameters

`Object`

A pointer to the object. The caller obtains this pointer either when it creates the object, or from a previous call to the ObReferenceObjectByHandleWithTag routine after it opens the object.

`Tag`

Specifies a four-byte, custom tag value. For more information, see the following Remarks section.

Return Value

ObReferenceObjectWithTag returns a value that is reserved for system use. Drivers must treat this value as VOID.

Remarks

ObReferenceObjectWithTag simply increments the pointer reference count for an object, without making any access checks on the specified object. In contrast, the ObReferenceObjectByHandleWithTag and ObReferenceObjectByPointerWithTag routines verify that the caller has the required access rights to the object and fail if the caller does not have these rights.

A **ObReferenceObjectWithTag** call prevents deletion of the specified object at least until the driver either calls the ObDereferenceObjectWithTag routine, or closes the object. After the object is no longer needed, the driver must call **ObDereferenceObjectWithTag** to remove its reference to the object.

When the reference count for an object reaches zero, a kernel-mode component can delete the object. However, a driver can delete only those objects that it created, and a driver should never attempt to delete any object that it did not create.

For more information about object references, see Life Cycle of an Object.

The ObReferenceObject routine is similar to **ObReferenceObjectWithTag**, except that it does not enable the caller to write a custom tag to an object. In Windows 7 and later versions of Windows, **ObReferenceObject** always writes a default tag value ('tIfD') to the object. A call to **ObReferenceObject** has the same effect as a call to **ObReferenceObjectWithTag** that specifies *Tag* = 'tIfD'.

To view an object reference trace in the Windows debugging tools, use the !obtrace kernel-mode debugger

extension. In Windows 7, the !obtrace extension is enhanced to display object reference tags, if object reference tracing is enabled. By default, object reference tracing is turned off. Use the Global Flags Editor (Gflags) to enable object reference tracing. For more information, see Object Reference Tracing with Tags.

Requirements

ObReferenceObjectByPointerWithTag

ObRegisterCallbacks function

1/25/2019 • 2 minutes to read • Edit Online

The **ObRegisterCallbacks** routine registers a list of callback routines for thread, process, and desktop handle operations.

Syntax

```
NTSTATUS ObRegisterCallbacks(
  POB_CALLBACK_REGISTRATION CallbackRegistration,
  PVOID                     *RegistrationHandle
);
```

Parameters

`CallbackRegistration`

A pointer to an OB_CALLBACK_REGISTRATION structure that specifies the list of callback routines and other registration information.

`RegistrationHandle`

A pointer to a variable that receives a value that identifies the set of registered callback routines. The caller passes this value to the ObUnRegisterCallbacks routine to unregister the set of callbacks.

Return Value

ObRegisterCallbacks returns an NTSTATUS value. This routine might return one of the following values:

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	The specified callback routines are registered with the system.
STA TUS _FLT _IN STA NCE _AL TIT UDE _CO LLIS ION	The calling driver or another driver has already registered callback routines for the altitude that *CallBackRegistration*->**Altitude** specifies. For more information about this altitude, see the description of the **Altitude** member in OB_CALLBACK_REGISTRATION.

STATUS_INVALID_PARAMETER	One or more of the parameters that were specified in the registration was invalid. **ObRegisterCallbacks** might return this error, for example, if an invalid value for *CallBackRegistration*->**Version** is specified or if registration is attempted for object types that do not support callback routines.
STATUS_ACCESS_DENIED	The callback routines do not reside in a signed kernel binary image.
STATUS_INSUFFICIENT_RESOURCES	An attempt to allocate memory failed.

Remarks

A driver must unregister all callback routines before it unloads. You can unregister the callback routine by calling the **ObUnRegisterCallbacks** routine.

Requirements

Minimum supported client	Available starting with Windows Vista with Service Pack 1 (SP1) and Windows Server 2008.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

OB_CALLBACK_REGISTRATION

ObUnRegisterCallbacks

ObReleaseObjectSecurity function

1/25/2019 • 2 minutes to read • Edit Online

The **ObReleaseObjectSecurity** routine is the reciprocal to **ObGetObjectSecurity**.

Syntax

```
void ObReleaseObjectSecurity(
  PSECURITY_DESCRIPTOR SecurityDescriptor,
  BOOLEAN              MemoryAllocated
);
```

Parameters

`SecurityDescriptor`

Pointer to the buffered SECURITY_DESCRIPTOR to be released. The caller obtained this parameter from **ObGetObjectSecurity**

`MemoryAllocated`

Specifies the value also obtained from **ObGetObjectSecurity**.

Return Value

None

Remarks

After a successful call to ObGetObjectSecurity, a driver must call **ObReleaseObjectSecurity** eventually.

ObReleaseObjectSecurity releases any resources that were allocated by **ObGetObjectSecurity**. It also decrements the reference count on the given security descriptor.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=APC_LEVEL"

DDI compliance rules	IrqlApcLte, HwStorPortProhibitedDDIs

ObGetObjectSecurity

SECURITY_DESCRIPTOR

ObUnRegisterCallbacks function

1/25/2019 • 2 minutes to read • Edit Online

The **ObUnRegisterCallbacks** routine unregisters a set of callback routines that were registered with the ObRegisterCallbacks routine.

Syntax

```
void ObUnRegisterCallbacks(
  PVOID RegistrationHandle
);
```

Parameters

`RegistrationHandle`

A value that identifies the set of callback routines to unregister. The ObRegisterCallbacks routine provides this value when it originally registered the callback routines.

Return Value

None

Remarks

A driver that calls the **ObRegisterCallbacks** routine must call the **ObUnRegisterCallbacks** routine before the driver is unloaded.

Requirements

Minimum supported client	Available in Windows Vista with Service Pack 1 (SP1), Windows Server 2008, and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

ObRegisterCallbacks

PALLOCATE_ADAPTER_CHANNEL callback function

1/25/2019 • 2 minutes to read • Edit Online

The **AllocateAdapterChannel** routine prepares the system for a DMA operation on behalf of the target device object, and then calls the driver-supplied AdapterControl routine to carry out the DMA operation.

Syntax

```
PALLOCATE_ADAPTER_CHANNEL PallocateAdapterChannel;

NTSTATUS PallocateAdapterChannel(
  PDMA_ADAPTER DmaAdapter,
  PDEVICE_OBJECT DeviceObject,
  ULONG NumberOfMapRegisters,
  PDRIVER_CONTROL ExecutionRoutine,
  PVOID Context
)
{...}
```

Parameters

`DmaAdapter`

Pointer to the DMA_ADAPTER structure returned by IoGetDmaAdapter that represents the bus-master adapter or DMA controller.

`DeviceObject`

Pointer to the device object that represents the target device for a requested DMA operation.

`NumberOfMapRegisters`

Specifies the number of map registers to be used in the transfer. This value is the lesser of the number of map registers needed to satisfy the current transfer request, and the number of available map registers returned by IoGetDmaAdapter.

`ExecutionRoutine`

Pointer to a driver-supplied AdapterControl routine. The routine is called when the system DMA controller or bus-master adapter becomes available.

`Context`

Pointer to the driver-determined context to be passed to the AdapterControl routine.

Return Value

This routine can return one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION

STA TUS _SU CCE SS	The adapter channel has been allocated. The system will call the *AdapterControl* routine once the DMA operation can begin.
STA TUS _IN SUF FICI ENT _RE SO URC ES	The *NumberOfMapRegisters* is larger than the value returned by **IoGetDmaAdapter**. The *AdapterControl* routine will not be called.

Remarks

AllocateAdapterChannel is not a system routine that can be called directly by name. This routine is callable only by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter.

A driver calls the **AllocateAdapterControl** routine to register an AdapterControl routine that performs a DMA operation for the driver. The *AdapterControl* routine carries out a DMA operation using either the system DMA controller or a bus-master adapter.

If the DMA operation can be performed immediately, the system immediately calls *AdapterControl*. If the system DMA controller or bus-master adapter is currently in use, **AllocateAdapterChannel** queues the *AdapterControl* until the adapter becomes available. In either case, **AllocateAdapterChannel** returns STATUS_SUCCESS.

If the system lacks the resources to perform the DMA operation, **AllocateAdapterChannel** returns STATUS_INSUFFICIENT_RESOURCES. In that case, *AdapterControl* is not queued, and the driver should complete the current IRP with the appropriate error code (such as STATUS_INSUFFICIENT_RESOURCES).

This routine reserves exclusive access to a DMA controller channel and map registers for the one or more DMA operations that are required to satisfy the current IRP's transfer request for the specified device.

Only one DMA request can be queued for a device object at any one time. Therefore, the driver should not call **AllocateAdapterChannel** again for another DMA operation on the same device object until the AdapterControl routine has completed execution. In addition, a driver must not call **AllocateAdapterChannel** from within its *AdapterControl* routine.

The system passes the value of the **CurrentIrp** member of *DeviceObject* as the *Irp* parameter of *AdapterControl*. If **AllocateAdapterChannel** is called from a driver's StartIo routine, this is guaranteed to point to the IRP that *StartIo* was called to process. Otherwise, to use the *Irp* parameter of *AdapterControl*, the driver must set **CurrentIrp** to point to the current IRP before calling **AllocateAdapterChannel**.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

PALLOCATE_ADAPTER_CHANNEL_EX callback function

1/25/2019 • 4 minutes to read • Edit Online

The **AllocateAdapterChannelEx** routine allocates the resources that are needed to perform a DMA transfer, and then calls the driver-supplied AdapterControl routine to initiate the DMA transfer.

Syntax

```
PALLOCATE_ADAPTER_CHANNEL_EX PallocateAdapterChannelEx;

NTSTATUS PallocateAdapterChannelEx(
  PDMA_ADAPTER DmaAdapter,
  PDEVICE_OBJECT DeviceObject,
  PVOID DmaTransferContext,
  ULONG NumberOfMapRegisters,
  ULONG Flags,
  PDRIVER_CONTROL ExecutionRoutine,
  PVOID ExecutionContext,
  PVOID *MapRegisterBase
)
{...}
```

Parameters

`DmaAdapter`

A pointer to a DMA_ADAPTER structure. This structure is the adapter object that represents the driver's bus-master DMA device or system DMA channel. The caller obtained this pointer from a previous call to the IoGetDmaAdapter routine.

`DeviceObject`

A pointer to a DEVICE_OBJECT structure. This structure is the physical device object (PDO) that represents the target device for the requested DMA operation.

`DmaTransferContext`

A pointer to an initialized DMA transfer context. This context was initialized by a previous call to the InitializeDmaTransferContext routine. This context must be unique across all adapter allocation requests. To cancel a pending allocation request, the caller must supply the DMA transfer context for the request to the CancelAdapterChannel routine.

`NumberOfMapRegisters`

The number of map registers to use in the DMA transfer. The calling driver should set this value to the lesser of the number of map registers needed to satisfy the current transfer request, and the number of available map registers. The driver previously called the GetDmaTransferInfo routine to obtain the number of map registers needed for the transfer, and called the IoGetDmaAdapter routine to obtain the number of available map registers.

`Flags`

The adapter channel allocation flags. The following flag is supported.

FLAG	MEANING
DM A_S YN CH RO NO US_ CAL LBA CK	The **AllocateAdapterChannelEx** routine is called synchronously. If this flag is set, and the required DMA resources are not immediately available, the call fails and returns STATUS_INSUFFICIENT_RESOURCES.

If the **DMA_SYNCHRONOUS_CALLBACK** flag is set, the *ExecutionRoutine* parameter is optional and can be NULL. For more information about this flag, see the Remarks section.

`ExecutionRoutine`

A pointer to the driver-supplied AdapterControl routine that initiates the DMA transfer for the driver. The I/O manager calls the *AdapterControl* routine after the required resources are allocated for the adapter object. After the *AdapterControl* routine returns, the I/O manager automatically frees the adapter object. The I/O manager might additionally free the resources that were allocated for this object, depending on the value returned by this routine.

If the **DMA_SYNCHRONOUS_CALLBACK** flag is set, the *ExecutionRoutine* is optional and can be **NULL**. In this case, the caller can use the resources allocated by **AllocateAdapterChannelEx**, and later free these resources by calling the FreeAdapterObject routine. For more information, see the Remarks section.

`ExecutionContext`

The driver-determined, adapter-control context. This context is passed to the AdapterControl routine as the *Context* parameter.

`*MapRegisterBase`

A pointer to a variable into which the routine writes a handle to the allocated map registers. The caller can supply this handle as a parameter to the FlushAdapterBuffersEx, FlushAdapterBuffers, FreeMapRegisters, or MapTransferEx routine.

If the **DMA_SYNCHRONOUS_CALLBACK** flag is set, *MapRegisterBase* must be a valid, non-**NULL** pointer. If the *ExecutionRoutine* parameter is non-**NULL**, *MapRegisterBase* must be **NULL**. The call fails if *MapRegisterBase* is non-**NULL** and the **DMA_SYNCHRONOUS_CALLBACK** flag is not set, or if *MapRegisterBase* and *ExecutionRoutine* are both **NULL**.

Return Value

AllocateAdapterChannelEx returns STATUS_SUCCESS if the call is successful. Possible error return values include the following status codes.

RETURN CODE	DESCRIPTION

STATUS_INVALID_PARAMETERS	The routine failed due to invalid parameter values passed by the caller.
STATUS_INSUFFICIENT_RESOURCES	The routine failed to allocate resources required for the DMA transfer.

Remarks

AllocateAdapterChannelEx
is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a DMA_OPERATIONS*structure.*Drivers obtain the address of this routine by calling IoGetDmaAdapter with the **Version** member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION3. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

AllocateAdapterChannelEx allocates the resources that are required to perform a DMA operation. These resources include DMA channels and map registers. After all required resources are allocated for use by the DMA adapter, **AllocateAdapterChannelEx** calls the caller-supplied AdapterControl routine to initiate the DMA operation.

By default, **AllocateAdapterChannelEx** returns asynchronously, without waiting for the requested resource allocation to complete. After this return, the caller can, if necessary, cancel the pending allocation request by calling the CancelAdapterChannel routine.

If the calling driver sets the **DMA_SYNCHRONOUS_CALLBACK** flag, the **AllocateAdapterChannelEx** routine behaves as follows:

- If the requested DMA resources are not immediately available, **AllocateAdapterChannelEx** does not wait for resources and does not call the AdapterControl routine. Instead, **AllocateAdapterChannelEx** fails and returns STATUS_INSUFFICIENT_RESOURCES.
- The driver is not required to supply an AdapterControl routine if the **DMA_SYNCHRONOUS_CALLBACK** flag is set.
- If the driver supplies an AdapterControl routine, the **DMA_SYNCHRONOUS_CALLBACK** flag indicates that this routine is to be called in the context of the calling thread, before **AllocateAdapterChannelEx** returns.
- If the driver does not supply an AdapterControl routine, the driver can use the allocated resources after **AllocateAdapterChannelEx** returns. In this case, the driver must call FreeAdapterObject after it finishes using the allocated resources.

AllocateAdapterChannelEx is an extended version of the AllocateAdapterChannel routine. The following features are available only in the extended version:

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Desktop

MapTransferEx

PALLOCATE_COMMON_BUFFER callback function

1/25/2019 • 2 minutes to read • Edit Online

The **AllocateCommonBuffer** routine allocates memory and maps it so that it is simultaneously accessible from both the processor and a device for DMA operations.

Syntax

```
PALLOCATE_COMMON_BUFFER PallocateCommonBuffer;

PVOID PallocateCommonBuffer(
  PDMA_ADAPTER DmaAdapter,
  ULONG Length,
  PPHYSICAL_ADDRESS LogicalAddress,
  BOOLEAN CacheEnabled
)
{...}
```

Parameters

`DmaAdapter`

Pointer to the DMA_ADAPTER structure returned by IoGetDmaAdapter that represents the bus-master adapter or DMA controller.

`Length`

Specifies the number of bytes of memory to allocate.

`LogicalAddress`

Pointer to a variable that receives the logical address the device can use to access the allocated buffer. Use this address rather than calling MmGetPhysicalAddress because the system can take into account any platform-specific memory restrictions.

`CacheEnabled`

Specifies whether the allocated memory can be cached.

This parameter is ignored. The operating system determines whether to enable cached memory in the common buffer that is to be allocated. That decision is based on the processor architecture and device bus.

On computers with x86-based, x64-based, and Itanium-based processors, cached memory is enabled. It is assumed that all DMA operations performed by a device are coherent with the relevant CPU caches, which might be caching that memory. If your driver needs to disable caching, call AllocateCommonBufferEx instead.

On computers with ARM or ARM 64-based processors, the operating system does not automatically enable cached memory for all devices. The system relies on the **ACPI_CCA** method for each device to determine whether the device is cache-coherent.

Return Value

AllocateCommonBuffer returns the base virtual address of the allocated range. If the buffer cannot be allocated, it returns **NULL**.

Remarks

AllocateCommonBuffer is not a system routine that can be called directly by name. This routine is callable only by pointer from the address returned in a **DMA_OPERATIONS** structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter.

AllocateCommonBuffer supports DMA in which the device and the processor continuously communicate through system memory, as in a control structure for a bus-master DMA device.

AllocateCommonBuffer also supports subordinate devices whose drivers use a system DMA controller's autoinitialize mode.

AllocateCommonBuffer does the following:

- Allocates memory that can be reached from both the processor and the device. This memory appears contiguous to the device.
- Allocates map registers to map the buffer, if required by the system.
- Sets up a translation for the device, including loading map registers if necessary.

To use resident system memory economically, drivers should allocate as few of these buffers per device as possible. **AllocateCommonBuffer** allocates at least a page of memory, regardless of the requested *Length*. After a successful allocation requesting fewer than PAGE_SIZE bytes, the caller can access only the requested *Length*. After a successful allocation requesting more than an integral multiple of PAGE_SIZE bytes, any remaining bytes on the last allocated page are inaccessible to the caller.

If a driver needs several pages of common buffer space, but the pages need not be contiguous, the driver should make several one-page requests to **AllocateCommonBuffer** instead of one large request. This approach conserves contiguous memory.

Drivers typically call **AllocateCommonBuffer** as part of device start-up, during their response to a PnP IRP_MN_START_DEVICE request. After startup, it is possible that only one-page requests will succeed, if any.

Requirements

Minimum supported client	Available starting with Windows 2000.

IoGetDmaAdapter

PALLOCATE_COMMON_BUFFER_EX callback function

1/25/2019 • 3 minutes to read • Edit Online

The **AllocateCommonBufferEx** routine allocates memory for a common buffer and maps this memory so that it can be accessed both by the processor and by a device that performs DMA operations.

Syntax

```
PALLOCATE_COMMON_BUFFER_EX PallocateCommonBufferEx;

PVOID PallocateCommonBufferEx(
  PDMA_ADAPTER DmaAdapter,
  PPHYSICAL_ADDRESS MaximumAddress,
  ULONG Length,
  PPHYSICAL_ADDRESS LogicalAddress,
  BOOLEAN CacheEnabled,
  NODE_REQUIREMENT PreferredNode
)
{...}
```

Parameters

`DmaAdapter`

A pointer to a DMA_ADAPTER structure. This structure is the adapter object that represents the driver's bus-master DMA device or system DMA channel. The caller obtained this pointer from a previous call to the IoGetDmaAdapter routine.

`MaximumAddress`

A pointer to a variable that contains the maximum logical address for the common buffer. This parameter indicates that the buffer should be allocated from memory below this address. This parameter is optional and can be specified as NULL to indicate that there is no maximum address.

`Length`

The size, in bytes, of the common buffer that is to be allocated for the DMA operation.

`LogicalAddress`

A pointer to a variable into which this routine writes the logical address that the device can use to access the common buffer. The DMA device should use this logical address instead of the physical address that is returned by a routine such as MmGetPhysicalAddress.

`CacheEnabled`

Whether the routine must enable or disable cached memory in the common buffer that is to be allocated. If TRUE, caching is enabled. If FALSE, it is disabled. If the hardware platform does not enforce cache coherency for DMA operations, then pass FALSE. For information about this parameter on ARM or ARM 64-based processors target computers, see Remarks.

`PreferredNode`

The preferred NUMA node from which the memory is to be allocated. If N is the number of NUMA nodes in a multiprocessor system, *PreferredNode* is a number in the range 0 to N–1. For a one-processor system or a non-NUMA multiprocessor system, set *PreferredNode* to zero.

Return Value

AllocateCommonBufferEx returns the virtual address of the memory allocated for the common buffer. If the buffer cannot be allocated, NULL is returned.

Remarks

AllocateCommonBufferEx is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter with the Version member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION3. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

AllocateCommonBufferEx is an extended version of the AllocateCommonBuffer routine. The following list summarizes the features that are available only in the extended version:

- The caller can specify a maximum logical address for the common buffer that is to be allocated.
- The caller can specify a preferred NUMA node in which the common buffer is to be allocated.

On computers with ARM or ARM 64-based processors, cache settings in the system ACPI have a higher precedence than the *CacheEnabled* parameter value passed by the driver. If the **ACPI _CCA** method indicates that the device is not cache coherent, the operating system disables caching even if the driver allocates cached memory with *CacheEnabled* set to TRUE.

On computers with ARM or ARM 64-based processors, the operating system allocates an uncached common buffer as Device Memory. For more information about the buffer, see sections A3.5.1, and A3.5.6 from the ARMv7 Architecture Reference Manual.

The processor does not permit misaligned access to Device Memory. Your driver must always access data from the common buffer by using naturally-aligned operations. Most kernel routines do not accept Device Memory as input parameters. For example, a network driver cannot pass Device Memory into NdisMIndicateReceiveNetBufferLists. If your driver needs to pass data from a DMA common buffer to a kernel routine, either allocate the buffer with *CacheEnabled* set to TRUE or copy the data from the uncached common buffer into a temporary pool allocation.

For more information about DMA operations that use a common buffer, see the following topics:

Using Common Buffers Using Common-Buffer Bus-Master DMA Using Common-Buffer System DMA

PBUILD_MDL_FROM_SCATTER_GATHER_LIST callback function

1/25/2019 • 2 minutes to read • Edit Online

The **BuildMdlFromScatterGatherList** routine builds an MDL from a scatter/gather list allocated by the system.

> **Note** This routine is reserved for system use.

Syntax

```
PBUILD_MDL_FROM_SCATTER_GATHER_LIST PbuildMdlFromScatterGatherList;

NTSTATUS PbuildMdlFromScatterGatherList(
  PDMA_ADAPTER DmaAdapter,
  PSCATTER_GATHER_LIST ScatterGather,
  PMDL OriginalMdl,
  PMDL *TargetMdl
)
{...}
```

Parameters

`DmaAdapter`

Pointer to the DMA_ADAPTER structure returned by IoGetDmaAdapter that represents the bus-master adapter or DMA controller.

`ScatterGather`

Pointer to the SCATTER_GATHER_LIST structure passed to the driver's AdapterListControl routine.

`OriginalMdl`

Pointer to the original MDL that the driver used to build the scatter/gather list.

`*TargetMdl`

Pointer to a variable the routine uses to return the MDL created to hold the buffer described by the scatter/gather list. The value returned can be the same as *OriginalMdl*.

Return Value

BuildMdlFromScatterGatherList returns one of the following status codes:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The operation succeeded.

STATUS_INVALID_PARAMETER	The *OriginalMdl* parameter is **NULL**.
STATUS_INSUFFICIENT_RESOURCES	There is not enough memory available to allocate a new MDL.
STATUS_NONE_MAPPED	The system has already created a new MDL for the memory locations in the scatter/gather list. (This only happens if the routine is called twice on the same scatter/gather list.)

Remarks

BuildMdlFromScatterGatherList is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter with the **Version** member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION2. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

When a driver creates a scatter/gather list to write to a device, the system can make a copy of the data to be written, and use that copy to perform the DMA operation. Use this routine to access the memory locations in the scatter/gather list, regardless of whether those locations are a copy.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.

Target Platform	Desktop
Header	wdm.h (include Wdm.h)
IRQL	"<= DISPATCH_LEVEL"
DDI compliance rules	IrqlDispatch

IoGetDmaAdapter

SCATTER_GATHER_LIST

PBUILD_SCATTER_GATHER_LIST callback function

1/25/2019 • 2 minutes to read • Edit Online

The **BuildScatterGatherList** routine prepares the system for a DMA operation, using a driver-supplied buffer to build the scatter/gather list.

Syntax

```
PBUILD_SCATTER_GATHER_LIST PbuildScatterGatherList;

NTSTATUS PbuildScatterGatherList(
  PDMA_ADAPTER DmaAdapter,
  PDEVICE_OBJECT DeviceObject,
  PMDL Mdl,
  PVOID CurrentVa,
  ULONG Length,
  PDRIVER_LIST_CONTROL ExecutionRoutine,
  PVOID Context,
  BOOLEAN WriteToDevice,
  PVOID ScatterGatherBuffer,
  ULONG ScatterGatherLength
)
{...}
```

Parameters

`DmaAdapter`

Pointer to the DMA_ADAPTER structure returned by IoGetDmaAdapter that represents the bus-master adapter or DMA controller.

`DeviceObject`

Pointer to the device object that represents the target device for the DMA operation.

`Mdl`

Pointer to the MDL that describes the buffer specified by the **MdlAddress** member of the current IRP.

`CurrentVa`

Pointer to the current virtual address in the MDL for the buffer to be mapped for a DMA transfer operation.

`Length`

Specifies the length, in bytes, of the buffer to be mapped.

`ExecutionRoutine`

Pointer to a driver-supplied AdapterListControl routine, which is called at IRQL = DISPATCH_LEVEL when the system DMA controller or bus-master adapter is available.

`Context`

Pointer to the driver-determined context passed to *ExecutionRoutine* when it is called.

`WriteToDevice`

Indicates the direction of the DMA transfer: **TRUE** for a transfer from the buffer to the device, and **FALSE** otherwise.

`ScatterGatherBuffer`

Pointer to the caller-supplied buffer that the routine fills with a SCATTER_GATHER_LIST structure.

`ScatterGatherLength`

Return Value

BuildScatterGatherList returns one of the following values:

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	The operation is completed successfully.
STA TUS _IN SUF FICI ENT _RE SO URC ES	The system has insufficient map registers available for the transfer.
STA TUS _BU FFE R_T OO_ SM ALL	The specified *Length* is too big to fit within the buffer.

Remarks

BuildScatterGatherList is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter with the **Version** member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION2. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

BuildScatterGatherList performs the same operation as GetScatterGatherList, except that it uses the buffer supplied in the *ScatterGatherBuffer* parameter to hold the scatter/gather list that it creates. In contrast, **GetScatterGatherList** dynamically allocates a buffer to hold the scatter/gather list. If insufficient memory is available to allocate the buffer, **GetScatterGatherList** can fail with a STATUS_INSUFFICIENT_RESOURCES error. Drivers that must avoid this scenario can preallocate a buffer to hold the scatter/gather list, and use **BuildScatterGatherList** instead.

A driver can use the CalculateScatterGatherList routine to determine the size of buffer to allocate to hold the scatter/gather list.

The driver should retain the pointer to the scatter/gather list in *ScatterGatherBuffer* for use when the driver calls PutScatterGatherList. The driver must call **PutScatterGatherList** (which flushes the list) before it can access the data in the list.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)
IRQL	DISPATCH_LEVEL
DDI compliance rules	IrqlDispatch

SCATTER_GATHER_LIST

PBUILD_SCATTER_GATHER_LIST_EX callback function

1/25/2019 • 5 minutes to read • Edit Online

The **BuildScatterGatherListEx** routine allocates the resources that are required for a DMA transfer, builds a scatter/gather list, and calls the driver-supplied AdapterListControl routine to initiate the DMA transfer.

> **Note** Do not call this routine for a system DMA device.

Syntax

```
PBUILD_SCATTER_GATHER_LIST_EX PbuildScatterGatherListEx;

NTSTATUS PbuildScatterGatherListEx(
  PDMA_ADAPTER DmaAdapter,
  PDEVICE_OBJECT DeviceObject,
  PVOID DmaTransferContext,
  PMDL Mdl,
  ULONGLONG Offset,
  ULONG Length,
  ULONG Flags,
  PDRIVER_LIST_CONTROL ExecutionRoutine,
  PVOID Context,
  BOOLEAN WriteToDevice,
  PVOID ScatterGatherBuffer,
  ULONG ScatterGatherLength,
  PDMA_COMPLETION_ROUTINE DmaCompletionRoutine,
  PVOID CompletionContext,
  PVOID ScatterGatherList
)
{...}
```

Parameters

`DmaAdapter`

A pointer to a DMA_ADAPTER structure. This structure is the adapter object that represents the driver's bus-master DMA device or system DMA channel. The caller obtained this pointer from a previous call to the IoGetDmaAdapter routine.

`DeviceObject`

A pointer to a DEVICE_OBJECT structure. This structure is the physical device object (PDO) that represents the target device for the requested DMA operation.

`DmaTransferContext`

A pointer to an initialized DMA transfer context. This context was initialized by a previous call to the InitializeDmaTransferContext routine. This context must be unique across all adapter allocation requests. To cancel a pending allocation request, the caller must supply the DMA transfer context for the request to the CancelAdapterChannel routine.

`Mdl`

A pointer to an MDL chain that describes the physical page layout for a collection of locked-down buffers in virtual memory. The scatter/gather list for the DMA transfer will use the region of this memory that is specified by the *Offset* and *Length* parameters. For more information about MDL chains, see Using MDLs.

`Offset`

The starting offset for the scatter/gather DMA transfer. This parameter is a byte offset from the start of the buffer in the first MDL in the MDL chain. If the MDLs in the MDL chain specify a total of N bytes of buffer space, valid values of *Offset* are in the range 0 to N–1.

`Length`

The size, in bytes, of the DMA transfer. If the MDL chain specifies a total of N bytes of buffer space, valid values of *Length* are in the range 1 to N–*Offset*.

`Flags`

The adapter channel allocation flags. The following flag is supported.

FLAG	MEANING
DMA_SYNCHRONOUS_CALLBACK	The **BuildScatterGatherListEx** routine is called synchronously. If this flag is set, and the required DMA resources are not immediately available, the call fails and returns STATUS_INSUFFICIENT_RESOURCES.

If the **DMA_SYNCHRONOUS_CALLBACK** flag is set, the *ExecutionRoutine* parameter is optional and can be **NULL**. If this flag is not set, *ExecutionRoutine* must be a valid, non-**NULL** pointer. For more information about this flag, see the Remarks section.

`ExecutionRoutine`

A pointer to the driver-supplied AdapterListControl routine that initiates the DMA transfer for the driver. The I/O manager calls the *AdapterListControl* routine after the required resources are allocated for the adapter object. After the *AdapterListControl* routine returns, the I/O manager automatically frees the adapter object and the resources that were allocated for this object.

If the **DMA_SYNCHRONOUS_CALLBACK** flag is set, *ExecutionRoutine* is optional and can be **NULL**. If *ExecutionRoutine* is **NULL**, the caller can use the resources allocated by **BuildScatterGatherListEx**. For more information, see the Remarks section.

`Context`

The driver-determined, adapter-control context. This context is passed to the AdapterListControl routine as the *Context* parameter.

`WriteToDevice`

The direction of the DMA transfer. Set this parameter to **TRUE** for a write operation, which transfers data from memory to the device. Set this parameter to **FALSE** for a read operation, which transfers data from the device to memory.

`ScatterGatherBuffer`

A pointer to a caller-allocated buffer into which the routine writes the scatter/gather list for the DMA transfer. This list begins with a SCATTER_GATHER_LIST structure, which is followed by a **SCATTER_GATHER_ELEMENT** array.

`ScatterGatherLength`

`DmaCompletionRoutine`

Not used. Set to **NULL**.

`CompletionContext`

Not used. Set to **NULL**.

`ScatterGatherList`

A pointer to a variable into which the routine writes a pointer to the scatter/gather list for the DMA transfer. This list begins with a SCATTER_GATHER_LIST structure, which contains a pointer to a **SCATTER_GATHER_ELEMENT** array. This output pointer always matches the *ScatterGatherBuffer* parameter value.

If the **DMA_SYNCHRONOUS_CALLBACK** flag is set and the *ExecutionRoutine* parameter is **NULL**, *ScatterGatherList* must be a valid, non-**NULL** pointer. If *ExecutionRoutine* is non-**NULL**, *ScatterGatherList* is optional and can be **NULL** if the calling driver does not require the scatter/gather list. The **BuildScatterGatherListEx** call fails if the **DMA_SYNCHRONOUS_CALLBACK** flag is set and *ScatterGatherList* and *ExecutionRoutine* are both **NULL**, or if the **DMA_SYNCHRONOUS_CALLBACK** flag is not set and *ExecutionRoutine* is **NULL**.

Return Value

BuildScatterGatherListEx returns STATUS_SUCCESS if the call is successful. Possible error return values include the following status codes.

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETERS	The routine failed due to invalid parameter values passed by the caller.
STATUS_BUFFER_TOO_SMALL	The caller-supplied buffer in *ScatterGatherBuffer* is too small to contain the scatter/gather list.

STATUS_INSUFFICIENT_RESOURCES	The routine failed to allocate resources required for the DMA transfer.

Remarks

BuildScatterGatherListEx *is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a* DMA_OPERATIONS*structure.*Drivers obtain the address of this routine by calling IoGetDmaAdapter with the **Version** member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION3. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

Use **BuildScatterGatherListEx** only for bus-master adapters. Do not use this routine for a system DMA adapter.

BuildScatterGatherListEx is similar to the GetScatterGatherListEx routine, except that it requires the caller to allocate the buffer for the scatter/gather list.

For example, a driver might preallocate one or more scatter/gather buffers during device initialization. Later, a **BuildScatterGatherListEx** call that uses such a buffer can succeed in conditions of low memory availability that might cause a **GetScatterGatherListEx** call to fail.

By default, **BuildScatterGatherListEx** returns asynchronously, without waiting for the requested resource allocation to complete. After this return, the caller can, if necessary, cancel the pending allocation request by calling the CancelAdapterChannel routine.

If the calling driver sets the **DMA_SYNCHRONOUS_CALLBACK** flag, the **BuildScatterGatherListEx** routine behaves as follows:

- If the requested resources are not immediately available, **BuildScatterGatherListEx** does not wait for resources, does not build a scatter/gather list, and does not call the *AdapterListControl* routine. Instead, **BuildScatterGatherListEx** fails and returns STATUS_INSUFFICIENT_RESOURCES.
- The driver is not required to supply an *AdapterListControl* routine if the **DMA_SYNCHRONOUS_CALLBACK** flag is set.
- If the driver supplies an *AdapterListControl* routine, the **DMA_SYNCHRONOUS_CALLBACK** flag indicates that this routine is to be called in the context of the calling thread, before **BuildScatterGatherListEx** returns.
- If the driver does not supply an *AdapterListControl* routine, the driver can use the allocated resources and scatter/gather list after **BuildScatterGatherListEx** returns. In this case, the driver must supply a valid, non-**NULL** *ScatterGatherList* pointer. In addition, after the driver-initiated DMA transfer completes, the driver must call the FreeAdapterObject routine to free the resources that **BuildScatterGatherListEx** allocated for the adapter object.

BuildScatterGatherListEx is an extended version of the BuildScatterGatherList routine. The following list summarizes the features that are available only in the extended version:

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Desktop

PCALCULATE_SCATTER_GATHER_LIST_SIZE callback function

1/25/2019 • 2 minutes to read • Edit Online

The **CalculateScatterGatherList** routine calculates the size, in bytes, of scatter/gather list necessary to hold a given buffer.

Syntax

```
PCALCULATE_SCATTER_GATHER_LIST_SIZE PcalculateScatterGatherListSize;

NTSTATUS PcalculateScatterGatherListSize(
  PDMA_ADAPTER DmaAdapter,
  PMDL Mdl,
  PVOID CurrentVa,
  ULONG Length,
  PULONG ScatterGatherListSize,
  PULONG pNumberOfMapRegisters
)
{...}
```

Parameters

`DmaAdapter`

Pointer to the DMA_ADAPTER structure returned by IoGetDmaAdapter that represents the bus-master adapter or DMA controller.

`Mdl`

Either **NULL** or a pointer to the MDL that contains the buffer.

`CurrentVa`

Pointer to the virtual address of the beginning of the buffer.

`Length`

Specifies the length of the buffer, in bytes.

`ScatterGatherListSize`

Pointer to the variable the routine uses to return the size of the scatter/gather list, in bytes.

`pNumberOfMapRegisters`

Return Value

CalculateScatterGatherList returns one of the following status codes.

RETURN CODE	DESCRIPTION

STA TUS _SU CCE SS	The values returned in *ScatterGatherListSize* and *NumberOfMapRegisters* are valid.
STA TUS _IN SUF FICI ENT _RE SO URC ES	The number of map registers required exceeds the number of map registers available.
STA TUS _BU FFE R_T OO_ SM ALL	The specified *Length* is too big to fit within the buffer.

Remarks

CalculateScatterGatherList is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter with the **Version** member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION2. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

If the caller passes **NULL** for the *Mdl* parameter, the routine calculates the maximum possible size needed to hold a scatter/gather list for the specified buffer. If the caller specifies the MDL that contains the buffer in the *Mdl* parameter, the routine computes the actual size needed to hold the scatter/gather list.

A driver uses **CalculateScatterGatherList** to allocate a scatter/gather list buffer to pass to BuildScatterGatherList.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)

DMA_ADAPTER

DMA_OPERATIONS

IoGetDmaAdapter

SCATTER_GATHER_LIST

PCANCEL_ADAPTER_CHANNEL callback function

1/25/2019 • 2 minutes to read • Edit Online

The **CancelAdapterChannel** routine tries to cancel a pending request to allocate a DMA channel.

Syntax

```
PCANCEL_ADAPTER_CHANNEL PcancelAdapterChannel;

BOOLEAN PcancelAdapterChannel(
  PDMA_ADAPTER DmaAdapter,
  PDEVICE_OBJECT DeviceObject,
  PVOID DmaTransferContext
)
{...}
```

Parameters

`DmaAdapter`

A pointer to a DMA_ADAPTER structure. This structure is the adapter object that is waiting for the pending resource allocation request to be granted. The caller obtained this pointer from a previous call to the IoGetDmaAdapter routine, and the caller passed this pointer to the AllocateAdapterChannelEx, GetScatterGatherListEx, or BuildScatterGatherListEx call that requested the resource allocation.

`DeviceObject`

A pointer to a DEVICE_OBJECT structure. This structure is the physical device object (PDO) that represents the target device for the DMA operation for which the DMA channel was requested.

`DmaTransferContext`

A pointer to a DMA transfer context. This parameter value must be the same DMA transfer context that was passed to the **AllocateAdapterChannelEx**, **GetScatterGatherListEx**, or **BuildScatterGatherListEx** call that requested the adapter channel allocation.

Return Value

CancelAdapterChannel returns **TRUE** if the pending allocation request is successfully canceled. The routine returns **FALSE** if the request could not be canceled (for example, because the DMA channel was allocated before the request could be canceled).

Remarks

CancelAdapterChannel
is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a DMA_OPERATIONS*structure.*Drivers obtain the address of this routine by calling IoGetDmaAdapter with the **Version** member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION3. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

CancelAdapterChannel tries to cancel a pending allocation request that was made by an asynchronous call to an

allocation routine such as AllocateAdapterChannelEx, GetScatterGatherListEx, or BuildScatterGatherListEx. When called asynchronously, the allocation routine can return while the allocation request is still pending and before the driver-supplied execution routine (AdapterControl or AdapterListControl) is called. If **CancelAdapterChannel** successfully cancels the pending allocation request, the resources are not allocated and the execution routine is not called.

If a driver calls **AllocateAdapterChannelEx** to request resources for a driver-supplied *AdapterControl* routine, and then calls **CancelAdapterChannel** to cancel the request, **CancelAdapterChannel** can return one of the following values:

- **TRUE**, if the adapter object is waiting for the requested allocation when the **CancelAdapterChannel** call occurs. In this case, **CancelAdapterChannel** cancels the pending allocation request, and the driver's *AdapterControl* routine is not called.
- **FALSE**, if the *AdapterControl* routine was already called or is about to be called.

Similarly, if a driver calls **GetScatterGatherListEx** or **BuildScatterGatherListEx** to request resources for a driver-supplied *AdapterListControl* routine, and then calls **CancelAdapterChannel** to cancel the request, **CancelAdapterChannel** can return one of the following values:

- **TRUE**, if the adapter object is waiting for the requested allocation when the **CancelAdapterChannel** call occurs. In this case, **CancelAdapterChannel** cancels the pending allocation request, and the driver's *AdapterListControl* routine is not called.
- **FALSE**, if the *AdapterListControl* routine was already called or is about to be called.

CancelAdapterChannel can preemptively cancel future channel allocation requests that use the specified DMA transfer context. For example, if the caller supplies the same DMA transfer context to **CancelAdapterChannel** and **AllocateAdapterChannelEx**, and the **CancelAdapterChannel** call is successful and occurs before the **AllocateAdapterChannelEx** call, the allocation requested by the **AllocateAdapterChannelEx** call is automatically canceled.

Requirements

Minimum supported client	Available starting with Windows 8.

IoGetDmaAdapter

PCANCEL_MAPPED_TRANSFER callback function

1/25/2019 • 2 minutes to read • Edit Online

The **CancelMappedTransfer** routine cancels a system DMA transfer that is currently mapped to an adapter.

Syntax

```
PCANCEL_MAPPED_TRANSFER PcancelMappedTransfer;

NTSTATUS PcancelMappedTransfer(
  PDMA_ADAPTER DmaAdapter,
  PVOID DmaTransferContext
)
{...}
```

Parameters

`DmaAdapter`

A pointer to a DMA_ADAPTER structure. This structure is the adapter object that is waiting for the pending DMA transfer to complete. The caller obtained this pointer from a previous call to the IoGetDmaAdapter routine, and the caller passed this pointer to the MapTransferEx call that set up the map registers for the DMA transfer.

`DmaTransferContext`

A pointer to a DMA transfer context. This parameter value must be the same DMA transfer context that was passed to the AllocateAdapterChannelEx call that requested the adapter channel allocation.

Return Value

CancelMappedTransfer returns STATUS_SUCCESS if the call is successful. Otherwise, it returns an appropriate error code.

Remarks

CancelMappedTransfer
is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a
DMA_OPERATIONS*structure.*Drivers obtain the address of this routine by calling IoGetDmaAdapter with the **Version** member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION3. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

This routine marks the associated transfer context as canceled, which prevents any further transfers under this context. After a transfer is canceled, its completion routine is called, but the status for the transfer might be set to **DmaCancelled**.

Regardless of whether a system DMA transfer is canceled or completed, the FlushAdapterBuffers or FlushAdapterBuffersEx routine must always be called to flush any data that remains in the system DMA controller's internal cache at the end of a DMA transfer operation. After the transfer is canceled or completed, the **FlushAdapterBuffers*Xxx*** call must occur before either the DMA channel is released or the MapTransferEx routine is called to set up the map registers for a new DMA transfer.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Desktop

PCI_MSIX_MASKUNMASK_ENTRY callback function

1/25/2019 • 2 minutes to read • Edit Online

The *MaskTableEntry* routine masks an interrupt in the MSI-X hardware interrupt table.

Syntax

```
PCI_MSIX_MASKUNMASK_ENTRY PciMsixMaskunmaskEntry;

NTSTATUS PciMsixMaskunmaskEntry(
  PVOID Context,
  ULONG TableEntry
)
{...}
```

Parameters

`Context`

A pointer to interface-specific context information. The caller passes the value that is passed as the **Context** member of the PCI_MSIX_TABLE_CONFIG_INTERFACE structure for the interface.

`TableEntry`

The index of the table entry in the MSI-X hardware interrupt table.

Return Value

The *MaskTableEntry* routine might return one of the following NTSTATUS values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The operation completed successfully.
STATUS_INVALID_PARAMETER	The *TableEntry* parameter is invalid.

Remarks

If a table entry is masked, the device does not generate any interrupts that correspond to that table entry.

You can unmask the table entry by calling UnmaskTableEntry.

Requirements

Minimum supported client	Available in Windows Vista with Service Pack 1 (SP1), Windows Server 2008, and later versions of the Windows operating system.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	"<= DIRQL"

See Also

PCI_MSIX_TABLE_CONFIG_INTERFACE

UnmaskTableEntry

PCI_MSIX_SET_ENTRY callback function

1/25/2019 • 2 minutes to read • Edit Online

The *SetTableEntry* routine sets the message ID for a table entry in the MSI-X hardware interrupt table.

Syntax

```
PCI_MSIX_SET_ENTRY PciMsixSetEntry;

NTSTATUS PciMsixSetEntry(
  PVOID Context,
  ULONG TableEntry,
  ULONG MessageNumber
)
{...}
```

Parameters

`Context`

A pointer to interface-specific context information. The caller passes the value that is passed as the **Context** member of the PCI_MSIX_TABLE_CONFIG_INTERFACE structure for the interface.

`TableEntry`

The index of the table entry in the MSI-X hardware interrupt table.

`MessageNumber`

The message ID for the interrupt. This value is also the index for the interrupt's entry in the **MessageInfo** member of the IO_INTERRUPT_MESSAGE_INFO structure that describes the driver's message-signaled interrupts. The IoConnectInterruptEx function supplies a pointer to this structure.

Return Value

The *SetTableEntry* routine might return one of the following NTSTATUS values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The operation completed successfully.

STATUS_INVALID_PARAMETER	The device does not use MSI-X, or the *TableEntry* or *MessageNumber* parameters do not correspond to interrupt resources that are assigned to the device.

Remarks

By default, the operating system assigns the index of the table entry as the message ID for the interrupt. If there are more table entries than messages, the system sets the remaining table entries to correspond to message zero. The driver can use the *SetTableEntry* routine to assign a different message ID.

Requirements

Minimum supported client	Available in Windows Vista with Service Pack 1 (SP1), Windows Server 2008, and later versions of the Windows operating system.
Target Platform	Desktop

PCI_MSIX_TABLE_CONFIG_INTERFACE

PCLFS_CLIENT_ADVANCE_TAIL_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *ClfsAdvanceTailCallback* function advances the base log sequence number (LSN) of the client's log.

Syntax

```
PCLFS_CLIENT_ADVANCE_TAIL_CALLBACK PclfsClientAdvanceTailCallback;

NTSTATUS PclfsClientAdvanceTailCallback(
  PLOG_FILE_OBJECT LogFile,
  PCLFS_LSN TargetLsn,
  PVOID ClientData
)
{...}
```

Parameters

`LogFile`

A pointer to a LOG_FILE_OBJECT structure that represents the CLFS log stream whose tail should be advanced.

`TargetLsn`

A pointer to a CLFS_LSN structure that contains the LSN that the client should advance its tail to or beyond.

`ClientData`

A pointer to client-supplied information. You specify this data in the **AdvanceTailCallbackData** member of the CLFS_MGMT_CLIENT_REGISTRATION structure.

Return Value

The *ClfsAdvanceTailCallback* function should return either STATUS_PENDING or an error status. A return value of STATUS_PENDING indicates that the request to move the client's log tail will be completed asynchronously. The **ClfsMgmtAdvanceTailCallback** function must not return STATUS_SUCCESS, even if it completes synchronously.

Remarks

The *ClfsAdvanceTailCallback* function is called when CLFS management requests that the client advance its log tail.

The *ClfsAdvanceTailCallback* function must only perform a minimal amount of processing before returning. For example, the *ClfsAdvanceTailCallback* function might follow this procedure:

1. If the request cannot be processed, return an error status.
2. If the request can be processed, create and queue a work item to perform the actions that are required to move the client's tail, and then return STATUS_PENDING. For more information on queuing a worker thread, see System Worker Threads.

When a client calls the ClfsMgmtRegisterManagedClient routine to register with CLFS management, the client provides both a pointer to the *ClfsAdvanceTailCallback* function and the custom data that will be passed as a parameter to the *ClfsAdvanceTailCallback* function when this function is called.

Requirements

Minimum supported client	Supported in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at IRQL <= APC_LEVEL

ClfsAdvanceLogBase

ClfsMgmtRegisterManagedClient

ClfsMgmtTailAdvanceFailure

PCLFS_CLIENT_LFF_HANDLER_COMPLETE_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *ClfsLogGrowthCompleteCallback* function implements the actions that the client will take when space is freed in a log that had previously been full.

Syntax

```
PCLFS_CLIENT_LFF_HANDLER_COMPLETE_CALLBACK PclfsClientLffHandlerCompleteCallback;

void PclfsClientLffHandlerCompleteCallback(
  PLOG_FILE_OBJECT LogFile,
  NTSTATUS OperationStatus,
  BOOLEAN LogIsPinned,
  PVOID ClientData
)
{...}
```

Parameters

`LogFile`

A pointer to a LOG_FILE_OBJECT structure that represents the CLFS log stream whose log has finished growing.

`OperationStatus`

The status of the client's earlier request to handle a log file full condition. This will be either STATUS_SUCCESS or an error status that indicates the reason that the request could not be completed successfully.

`LogIsPinned`

If **TRUE**, specifies that the log tail is currently pinned; **FALSE** if the log tail is not pinned.

`ClientData`

A pointer to client-supplied information.

Return Value

None

Remarks

Because a call to ClfsMgmtHandleLogFileFull completes asynchronously, any actions that the client will take when the log file full condition has been handled belong in the *ClfsLogGrowthCompleteCallback* function.

If a call to the **ClfsMgmtHandleLogFileFull** routine returned returns STATUS_PENDING, then the *ClfsLogGrowthCompleteCallback* function will be invoked when the operation completes. If a different status was returned, then the *ClfsLogGrowthCompleteCallback* function will not be invoked.

The *ClfsLogGrowthCompleteCallback* function should only perform a minimal amount of processing before returning. For example, the *ClfsLogGrowthCompleteCallback* function might follow the following procedure:

1. If the value of the *OperationStatus* parameter is an error status, return.
2. If the value of the *OperationStatus* parameter is STATUS_SUCCESS, create and queue a work item to inform the client that it can resume processing.

When a client uses the ClfsMgmtRegisterManagedClient routine to register with CLFS management, the client provides both a pointer to the *ClfsLogGrowthCompleteCallback* function and the custom data that will be passed as a parameter to the *ClfsLogGrowthCompleteCallback* function when this function is called.

Requirements

Minimum supported client	Supported in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at IRQL <= APC_LEVEL

ClfsMgmtRegisterManagedClient

PCLFS_CLIENT_LOG_UNPINNED_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *ClfsLogUnpinnedCallback* function implements any actions that the client will take when a log that had previously been pinned becomes unpinned.

Syntax

```
PCLFS_CLIENT_LOG_UNPINNED_CALLBACK PclfsClientLogUnpinnedCallback;

void PclfsClientLogUnpinnedCallback(
  PLOG_FILE_OBJECT LogFile,
  PVOID ClientData
)
{...}
```

Parameters

`LogFile`

A pointer to a LOG_FILE_OBJECT structure that represents the CLFS log stream whose tail has become unpinned.

`ClientData`

A pointer to client-supplied information. You specify this data in the **LogUnpinnedCallbackData** member of the CLFS_MGMT_CLIENT_REGISTRATION structure.

Return Value

None

Remarks

If a client called the ClfsMgmtHandleLogFileFull routine and CLFS management subsequently called the client's ClfsLogGrowthCompleteCallback function with a value of **TRUE** for the *LogIsPinned* parameter, then the *ClfsLogUnpinnedCallback* function will be invoked when the log becomes unpinned.

When a client uses the ClfsMgmtRegisterManagedClient routine to register with CLFS management, the client provides both a pointer to the *ClfsLogUnpinnedCallback* function and the custom data that will be passed as a parameter to the *ClfsLogUnpinnedCallback* function when this function is called.

The *ClfsLogUnpinnedCallback* function should only perform a minimal amount of processing before returning. For example, it might create and queue a work item to inform the client that it can resume processing.

The *ClfsLogGrowthCompleteCallback* function is called before the *ClfsLogUnpinnedCallback* function.

Requirements

Minimum supported client	Supported in Windows Server 2003 R2, Windows Vista, and later versions of Windows.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at IRQL <= APC_LEVEL

ClfsMgmtHandleLogFileFull

PCONFIGURE_ADAPTER_CHANNEL callback function

1/25/2019 • 2 minutes to read • Edit Online

The **ConfigureAdapterChannel** routine invokes a custom function that is implemented by the DMA controller represented by an adapter object.

Syntax

```
PCONFIGURE_ADAPTER_CHANNEL PconfigureAdapterChannel;

NTSTATUS PconfigureAdapterChannel(
  PDMA_ADAPTER DmaAdapter,
  ULONG FunctionNumber,
  PVOID Context
)
{...}
```

Parameters

`DmaAdapter`

A pointer to a DMA_ADAPTER structure. This structure is the adapter object that represents the driver's system DMA channel. The caller obtained this pointer from a previous call to the IoGetDmaAdapter routine.

`FunctionNumber`

The number of the custom function to select. For more information, see the Remarks section.

`Context`

A pointer to the configuration parameters for the custom function that is specified by *FunctionNumber*. The function is implemented by the DMA controller and can be accessed by a device driver through the adapter object. The DMA controller and the device driver must agree on the meaning of these configuration parameters. The data that *Context* points to is opaque to the operating system.

Return Value

ConfigureAdapterChannel returns STATUS_SUCCESS if the call is successful. Possible error return values include the following status code.

RETURN VALUE	DESCRIPTION
STA TUS _NO T_I MPL EME NTE D	The DMA extension does not implement the function specified by *FunctionNumber*.

Remarks

ConfigureAdapterChannel
is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a
DMA_OPERATIONS*structure*.Drivers obtain the address of this routine by calling IoGetDmaAdapter with the **Version** member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION3. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

Use **ConfigureAdapterChannel** only for system DMA adapters. Do not use this routine for a bus-master adapter.

A particular system DMA controller might have special hardware features that device drivers can access through a set of one or more custom functions. A controller might implement more than one custom function, in which case each function is identified by a different function number. These functions abstract the DMA hardware features so that the same functions can be supported on different hardware platforms.

Typically, a custom function sets state information in the DMA controller to configure hardware features for use in subsequent DMA transfers.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

PDEVICE_RESET_HANDLER callback function

1/25/2019 • 2 minutes to read • Edit Online

The *DeviceReset* routine is used to reset and recover a malfunctioning device.

Syntax

```
PDEVICE_RESET_HANDLER PdeviceResetHandler;

NTSTATUS PdeviceResetHandler(
  PVOID InterfaceContext,
  DEVICE_RESET_TYPE ResetType,
  ULONG Flags,
  PVOID ResetParameters
)
{...}
```

Parameters

`InterfaceContext`

A pointer to interface-specific context information. The caller passes the value that is passed as the **Context** member of the DEVICE_RESET_INTERFACE_STANDARD structure for the interface.

`ResetType`

The type of reset being requested. Set this parameter to one of the following DEVICE_RESET_TYPE enumeration values.

- **FunctionLevelDeviceReset**. Specify this value to request a function-level reset, which is restricted to a specific device.
- **PlatformLevelDeviceReset**. Specify this value to request a platform-level reset, which affects a specific device and all other devices that are connected to it via the same power rail or reset line.

For more information about how function-level and platform-level resets are implemented in the device stack, see Working with the GUID_DEVICE_RESET_INTERFACE_STANDARD.

`Flags`

Set to 0. Currently, no flags are defined for this routine.

`ResetParameters`

If the caller is requesting a function-level device reset, this optional parameter can point to a FUNCTION_LEVEL_DEVICE_RESET_PARAMETERS structure that specifies a callback routine that is called when the reset is completed.

Return Value

This routine returns STATUS_SUCCESS if the requested operation succeeds. Otherwise, it returns an appropriate an NTSTATUS error code.

Remarks

If a function driver detects that the device is not functioning correctly, it should first attempt a function-level reset. If a function-level reset does not fix the issue, then the driver can attempt a more invasive platform-level reset, but a platform-level reset should only be used as the final option.

For more information about function-level and platform-level resets, see Working with the GUID_DEVICE_RESET_INTERFACE_STANDARD.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Desktop
Header	wdm.h

IRP_MN_QUERY_INTERFACE

PFLUSH_ADAPTER_BUFFERS callback function

1/25/2019 • 2 minutes to read • Edit Online

The **FlushAdapterBuffers** routine flushes any data remaining in the system DMA controller's internal cache or in a bus-master adapter's internal cache at the end of a DMA transfer operation.

Syntax

```
PFLUSH_ADAPTER_BUFFERS PflushAdapterBuffers;

BOOLEAN PflushAdapterBuffers(
  PDMA_ADAPTER DmaAdapter,
  PMDL Mdl,
  PVOID MapRegisterBase,
  PVOID CurrentVa,
  ULONG Length,
  BOOLEAN WriteToDevice
)
{...}
```

Parameters

`DmaAdapter`

Pointer to the DMA_ADAPTER structure returned by IoGetDmaAdapter that represents the bus-master adapter or DMA controller.

`Mdl`

Pointer to the MDL that describes the buffer previously passed in the driver's call to **MapTransfer**.

`MapRegisterBase`

Specifies the map registers allocated for the DMA operation. The system passes this value to the driver's AdapterControl routine.

`CurrentVa`

Pointer to the current virtual address in the buffer, described by the *Mdl*, where the I/O operation occurred. This value must be the same as the initial *CurrentVa* value passed to MapTransfer.

`Length`

Specifies the length, in bytes, of the buffer.

`WriteToDevice`

Specifies the direction of the DMA transfer operation: **TRUE** for a transfer from a buffer in system memory to the driver's device.

Return Value

FlushAdapterBuffers returns **TRUE** if any data remaining in the DMA controller's or bus-master adapter's internal cache has been successfully flushed into system memory or out to the device.

Remarks

FlushAdapterBuffers is not a system routine that can be called directly by name. This routine is callable only by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter.

To ensure that a DMA transfer is complete, every driver that performs DMA operations must call **FlushAdapterBuffers** before completing the IRP that requested the DMA transfer and before freeing the map registers.

A driver can get the initial *CurrentVa* for the start of a packet-based DMA transfer by calling MmGetMdlVirtualAddress. However, the value returned is an index into the *Mdl*, rather than a valid virtual address. If the driver must split a large transfer request into more than one DMA operation, it must update *CurrentVa* and *Length* for each DMA operation.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

PFLUSH_ADAPTER_BUFFERS_EX callback function

1/25/2019 • 3 minutes to read • Edit Online

The **FlushAdapterBuffersEx** routine flushes any data that remains in the data cache at the end of a DMA transfer operation performed by a system DMA controller or bus-master device.

Syntax

```
PFLUSH_ADAPTER_BUFFERS_EX PflushAdapterBuffersEx;

NTSTATUS PflushAdapterBuffersEx(
  PDMA_ADAPTER DmaAdapter,
  PMDL Mdl,
  PVOID MapRegisterBase,
  ULONGLONG Offset,
  ULONG Length,
  BOOLEAN WriteToDevice
)
{...}
```

Parameters

`DmaAdapter`

A pointer to a DMA_ADAPTER structure. This structure is the adapter object that represents the driver's system DMA channel or bus-master device. The caller obtained this pointer from a previous call to the IoGetDmaAdapter routine.

`Mdl`

A pointer to the MDL chain that describes the pages of memory that are to be flushed. Set this parameter to point to the MDL chain that was used for the DMA transfer. For more information, see the description of the *Mdl* parameter in GetScatterGatherListEx, BuildScatterGatherListEx, or MapTransferEx.

`MapRegisterBase`

A handle to the map registers that were previously allocated for the adapter object.

`Offset`

The starting offset relative to the start of the MDL chain to use for the flush operation. Set this parameter to the value that was used as the starting offset for the DMA transfer. For more information, see the description of the *Offset* parameter in GetScatterGatherListEx, BuildScatterGatherListEx, or MapTransferEx.

`Length`

The number of bytes of data to flush. Set this parameter to the value that was used as the transfer length for the DMA transfer. For more information, see the description of the *Length* parameter in GetScatterGatherListEx, BuildScatterGatherListEx, or MapTransferEx.

`WriteToDevice`

The direction of the DMA transfer. Set this parameter to the value that was used as the transfer direction for the DMA transfer. For more information, see the description of the *WriteToDevice* parameter in

GetScatterGatherListEx, BuildScatterGatherListEx, or MapTransferEx.

Return Value

FlushAdapterBuffersEx returns STATUS_SUCCESS if the call is successful. Possible error return values include the following status codes.

RETURN CODE	DESCRIPTION
STA TUS _IN VAL ID_ PAR AM ETE RS	The routine failed due to invalid parameter values passed by the caller.

Remarks

FlushAdapterBuffersEx
is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a DMA_OPERATIONS*structure*.Drivers obtain the address of this routine by calling IoGetDmaAdapter with the **Version** member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION3. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

FlushAdapterBuffersEx enables processor cache coherency in hardware platforms that do not implement hardware-enforced cache coherency (bus snooping). In addition, for a system DMA transfer, **FlushAdapterBuffersEx** flushes any data that remains in the system DMA controller's internal cache.

The driver that initiates a scatter/gather DMA transfer must ensure that all of the transferred data is flushed from the cache after the transfer completes. The driver should call **FlushAdapterBuffersEx** before the driver completes the IRP that requested the DMA transfer, and before the driver frees the map registers. For more information, see Flushing Cached Data during DMA Operations.

FlushAdapterBuffersEx is an extended version of the FlushAdapterBuffers routine. **FlushAdapterBuffersEx** can flush an entire scatter/gather list in one call. In contrast, to use **FlushAdapterBuffers** to flush a scatter/gather list requires a separate call for each MDL in the MDL chain.

FlushAdapterBuffersEx can be used in place of **FlushAdapterBuffers** to flush the buffer for a one-packet DMA transfer. In this case, the MDL chain that the *Mdl* parameter points to contains only one MDL. A benefit of using **FlushAdapterBuffersEx** in this way is that the caller can specify an offset into the MDL.

If **FlushAdapterBuffersEx** is called before the DMA transfer operation finishes, this call might cancel the transfer before it can finish or might cause undefined behavior.

Requirements

Minimum supported client	Available starting with Windows 8.

PFREE_ADAPTER_CHANNEL callback function

1/25/2019 • 2 minutes to read • Edit Online

The **FreeAdapterChannel** routine releases the system DMA controller when a driver has completed all DMA operations necessary to satisfy the current IRP.

Syntax

```
PFREE_ADAPTER_CHANNEL PfreeAdapterChannel;

void PfreeAdapterChannel(
  PDMA_ADAPTER DmaAdapter
)
{...}
```

Parameters

`DmaAdapter`

Pointer to the DMA_ADAPTER structure returned by IoGetDmaAdapter that represents the bus-master adapter or DMA controller.

Return Value

None

Remarks

FreeAdapterChannel is not a system routine that can be called directly by name. This routine is callable only by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter.

After a driver has transferred all the data and called FlushAdapterBuffers, it calls **FreeAdapterChannel** to release the system DMA controller that was previously allocated with a call to **AllocateAdapterChannel**.

FreeAdapterChannel frees any map registers that were allocated by an earlier call to **AllocateAdapterChannel**. A driver calls this routine only if its AdapterControl routine returns **KeepObject**.

Requirements

Minimum supported client	Available starting with Windows 2000.

MapTransfer

PFREE_ADAPTER_OBJECT callback function

1/25/2019 • 2 minutes to read • Edit Online

The **FreeAdapterObject** routine releases the specified adapter object after a driver has completed all DMA operations.

Syntax

```
PFREE_ADAPTER_OBJECT PfreeAdapterObject;

void PfreeAdapterObject(
  PDMA_ADAPTER DmaAdapter,
  IO_ALLOCATION_ACTION AllocationAction
)
{...}
```

Parameters

`DmaAdapter`

A pointer to a DMA_ADAPTER structure. This structure is the adapter object that is to be released. This object represents the driver's bus-master DMA device or system DMA channel. The caller obtained this pointer from a previous call to the IoGetDmaAdapter routine.

`AllocationAction`

The type of deallocation that the calling driver requests. Set this parameter to an IO_ALLOCATION_ACTION enumeration value. For more information, see the Remarks section.

Return Value

None

Remarks

FreeAdapterObject is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter with the **Version** member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION3. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

If *AllocationAction* = **DeallocateObject**, the **FreeAdapterObject** call releases the adapter object, and releases any map registers that might be allocated for this object.

If *AllocationAction* = **DeallocateObjectKeepRegisters**, the **FreeAdapterObject** call releases the adapter object, but does not release any map registers. In this case, the driver must explicitly release any allocated map registers by calling the FreeMapRegisters routine.

If *AllocationAction* = **KeepObject**, the **FreeAdapterObject** call has no effect.

FreeAdapterObject can be used to deallocate DMA resources that are allocated by calls to the AllocateAdapterChannelEx, GetScatterGatherListEx, and BuildScatterGatherListEx routines. If the driver calls one

of these routines synchronously, the *ExecutionRoutine* parameter is optional and can be omitted. In this case, the driver can use the adapter object and map registers that are allocated by the call. After the driver initiates the DMA transfer, the driver can call **FreeAdapterObject** to deallocate the adapter object and, if necessary, the map registers.

The FreeAdapterChannel routine is similar to **FreeAdapterObject**. **FreeAdapterChannel** always releases the adapter object and any allocated map registers. This behavior is similar to that of **FreeAdapterObject** if *AllocationAction* = **DeallocateObject**.

PFREE_COMMON_BUFFER callback function

1/25/2019 • 2 minutes to read • Edit Online

The **FreeCommonBuffer** routine frees a common buffer allocated by AllocateCommonBuffer, along with all resources the buffer uses.

Syntax

```
PFREE_COMMON_BUFFER PfreeCommonBuffer;

void PfreeCommonBuffer(
  PDMA_ADAPTER DmaAdapter,
  ULONG Length,
  PHYSICAL_ADDRESS LogicalAddress,
  PVOID VirtualAddress,
  BOOLEAN CacheEnabled
)
{...}
```

Parameters

`DmaAdapter`

Pointer to the DMA_ADAPTER structure returned by IoGetDmaAdapter that represents the bus-master adapter or DMA controller.

`Length`

Specifies the number of bytes to deallocate.

`LogicalAddress`

Specifies the logical address of the allocated memory range.

`VirtualAddress`

Pointer to the corresponding virtual address of the allocated memory range.

`CacheEnabled`

Indicates whether the allocated memory is cached.

Return Value

None

Remarks

FreeCommonBuffer is not a system routine that can be called directly by name. This routine is callable only by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter.

To release a common buffer, a driver calls **FreeCommonBuffer** to unmap both its logical and virtual addresses. The parameters passed to **FreeCommonBuffer** must match exactly those passed to and returned from

AllocateCommonBuffer. A driver cannot free part of an allocated common buffer.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop

DMA_ADAPTER

DMA_OPERATIONS

IoGetDmaAdapter

PFREE_MAP_REGISTERS callback function

1/25/2019 • 2 minutes to read • Edit Online

The **FreeMapRegisters** routine releases a set of map registers that were saved from a call to AllocateAdapterChannel.

Syntax

```
PFREE_MAP_REGISTERS PfreeMapRegisters;

void PfreeMapRegisters(
  PDMA_ADAPTER DmaAdapter,
  PVOID MapRegisterBase,
  ULONG NumberOfMapRegisters
)
{...}
```

Parameters

`DmaAdapter`

Pointer to the DMA_ADAPTER structure returned by IoGetDmaAdapter that represents the bus-master adapter or DMA controller.

`MapRegisterBase`

Specifies the map registers allocated for the DMA operation. The system passes this value to the driver's AdapterControl routine.

`NumberOfMapRegisters`

Specifies the number of map registers to be released. This value must match the number specified in an earlier call to AllocateAdapterChannel.

Return Value

None

Remarks

FreeMapRegisters is not a system routine that can be called directly by name. This routine is only callable by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter.

When the driver of a bus-master device has completed the current packet-based DMA transfer request, it calls **FreeMapRegisters** to release the map registers previously allocated by a call to AllocateAdapterChannel and retained because its *AdapterControl* routine returned **DeallocateObjectKeepRegisters**. The driver must call **FreeMapRegisters** after calling FlushAdapterBuffers.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

MapTransfer

PGET_DMA_ADAPTER_INFO callback function

1/25/2019 • 2 minutes to read • Edit Online

The **GetDmaAdapterInfo** routine retrieves information about the hardware capabilities of a system DMA channel.

Syntax

```
PGET_DMA_ADAPTER_INFO PgetDmaAdapterInfo;

NTSTATUS PgetDmaAdapterInfo(
  PDMA_ADAPTER DmaAdapter,
  PDMA_ADAPTER_INFO AdapterInfo
)
{...}
```

Parameters

`DmaAdapter`

A pointer to a DMA_ADAPTER structure. This structure is the adapter object that represents the driver's system DMA channel. The caller obtained this pointer from a previous call to the IoGetDmaAdapter routine.

`AdapterInfo`

A pointer to a caller-allocated DMA_ADAPTER_INFO structure. The routine writes information about the system DMA controller into this structure. The caller must set the **Version** member of this structure to DMA_ADAPTER_INFO_VERSION1 before calling **GetDmaAdapterInfo**.

Return Value

GetDmaAdapterInfo returns STATUS_SUCCESS if the call is successful. Possible error return values include the following status code.

RETURN CODE	DESCRIPTION
STATUS_NOT_SUPPORTED	The routine does not support the specified version of the **DMA_ADAPTER_INFO*_XXX*** structure.

Remarks

GetDmaAdapterInfo
is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a
DMA_OPERATIONS*structure.*Drivers obtain the address of this routine by calling IoGetDmaAdapter with the

Version member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION3. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

GetDmaAdapterInfo retrieves the following information:

- The maximum number of elements in a scatter/gather list that the DMA controller can process in a single scatter/gather DMA operation.
- The width, in bits, of a DMA address.

For information about the DMA adapter information that is provided by version 1 of the **DMA_ADAPTER_INFO_*XXX*** structure, see DMA_ADAPTER_INFO_V1.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Desktop

DMA_OPERATIONS

IoGetDmaAdapter

PGET_DMA_ALIGNMENT callback function

1/25/2019 • 2 minutes to read • Edit Online

The **GetDmaAlignment** routine returns the alignment requirements of the DMA system.

Syntax

```
PGET_DMA_ALIGNMENT PgetDmaAlignment;

ULONG PgetDmaAlignment(
  PDMA_ADAPTER DmaAdapter
)
{...}
```

Parameters

`DmaAdapter`

A pointer to the DMA_ADAPTER structure returned by IoGetDmaAdapter that represents the bus-master adapter or DMA controller.

Return Value

GetDmaAlignment returns the alignment requirements, in bytes, of the DMA system. The starting address and length of DMA buffers must be a multiple of this value.

Remarks

GetDmaAlignment is not a system routine that can be called directly by name. This routine is callable only by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter.

A driver can call this routine to determine alignment requirements for DMA buffers it allocates. The returned value should be used to set the **AlignmentRequirement** field in the device object. A driver may need to increase this value because of additional hardware device restrictions. For more information, see Initializing a Device Object.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

DEVICE_OBJECT

DMA_ADAPTER

DMA_OPERATIONS

IoGetDmaAdapter

PGET_DMA_TRANSFER_INFO callback function

1/25/2019 • 3 minutes to read • Edit Online

The **GetDmaTransferInfo** routine calculates the allocation requirements for a scatter/gather DMA transfer.

Syntax

```
PGET_DMA_TRANSFER_INFO PgetDmaTransferInfo;

NTSTATUS PgetDmaTransferInfo(
  PDMA_ADAPTER DmaAdapter,
  PMDL Mdl,
  ULONGLONG Offset,
  ULONG Length,
  BOOLEAN WriteOnly,
  PDMA_TRANSFER_INFO TransferInfo
)
{...}
```

Parameters

`DmaAdapter`

A pointer to a DMA_ADAPTER structure. This structure is the adapter object that represents the driver's bus-master DMA device or system DMA channel. The caller obtained this pointer from a previous call to the IoGetDmaAdapter routine.

`Mdl`

A pointer to the MDL chain that describes the pages of memory that are to be transferred. For more information, see the Remarks section.

`Offset`

The starting offset for the scatter/gather DMA transfer. This parameter is a byte offset from the start of the buffer in the first MDL in the MDL chain. If the MDLs in the MDL chain specify a total of N bytes of buffer space, valid values of *Offset* are in the range 0 to N–1.

`Length`

The length, in bytes, of the DMA transfer. If the MDL chain specifies a total of N bytes of buffer space, valid values of *Length* are in the range 1 to N–*Offset*.

`WriteOnly`

Indicates whether the transfer is a write-only operation (that is, a transfer to the device from memory). If *WriteOnly* is TRUE, information returned about the transfer might not be valid for a read transaction. This parameter might indicate that additional cache control operations are required at buffer boundaries to enforce cache coherency.

`TransferInfo`

A pointer to a caller-allocated DMA_TRANSFER_INFO structure. The caller must set the **Version** member of the structure to DMA_TRANSFER_INFO_VERSION1 before calling **GetDmaTransferInfo**.

Return Value

GetDmaTransferInfo returns STATUS_SUCCESS if the call is successful. Possible error return values include the following status codes.

RETURN CODE	DESCRIPTION
STA TUS _NO T_S UPP ORT ED	The routine does not support the specified version of the **DMA_TRANSFER_INFO_*XXX*** structure.

Remarks

GetDmaTransferInfo
is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a DMA_OPERATIONS*structure*.Drivers obtain the address of this routine by calling IoGetDmaAdapter with the **Version** member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION3. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

Use **GetDmaTransferInfo** to calculate the size of the scatter/gather buffer to allocate for the BuildScatterGatherListEx and MapTransferEx routines.

GetDmaTransferInfo replaces the CalculateScatterGatherList routine and is more convenient to use with **BuildScatterGatherListEx**.

The *Mdl*, *Offset*, and *Length* parameters together specify a collection of physical memory regions to use as a buffer for a scatter/gather DMA transfer. Each physical memory region is typically a page or part of a page. **GetDmaTransferInfo** determines the allocation requirements for this transfer. These requirements include the following:

- The number of elements in the scatter/gather list. Each element is a **SCATTER_GATHER_ELEMENT** structure that describes a physically contiguous block of memory.
- The amount of memory to allocate to hold the specified scatter/gather list. (This memory allocation includes the space required for the scatter/gather list that describes the I/O buffer but not for the I/O buffer itself.)
- The number of map registers required to translate the physical addresses in the scatter/gather list to logical addresses.

For information about the DMA transfer information that is provided by version 1 of the **DMA_TRANSFER_INFO_*XXX*** structure, see DMA_TRANSFER_INFO_V1.

An MDL describes the physical memory pages that underlie a locked-down, contiguous block of virtual memory. Typically, these physical memory pages are non-contiguous. An MDL chain is an ordered collection of MDLs that describes memory that can be used to buffer I/O data. Typically, the virtual memory regions described by the MDLs in the chain are non-contiguous. For more information about MDLs and MDL chains, see Using MDLs.

Requirements

Minimum supported client	Available starting with Windows 8.

DMA_TRANSFER_INFO_V1

IoGetDmaAdapter

MapTransferEx

PGET_SCATTER_GATHER_LIST callback function

1/25/2019 • 2 minutes to read • Edit Online

The **GetScatterGatherList** routine prepares the system for a DMA scatter/gather operation on behalf of the target device object, through either the system DMA controller or a bus-master adapter.

Syntax

```
PGET_SCATTER_GATHER_LIST PgetScatterGatherList;

NTSTATUS PgetScatterGatherList(
  PDMA_ADAPTER DmaAdapter,
  PDEVICE_OBJECT DeviceObject,
  PMDL Mdl,
  PVOID CurrentVa,
  ULONG Length,
  PDRIVER_LIST_CONTROL ExecutionRoutine,
  PVOID Context,
  BOOLEAN WriteToDevice
)
{...}
```

Parameters

`DmaAdapter`

Pointer to the DMA_ADAPTER structure returned by IoGetDmaAdapter that represents the bus-master adapter or DMA controller.

`DeviceObject`

Pointer to the device object that represents the target device for the DMA operation.

`Mdl`

Pointer to the MDL that describes the buffer at *MdlAddress* in the current IRP.

`CurrentVa`

Pointer to the current virtual address in the MDL for the buffer to be mapped for a DMA transfer operation.

`Length`

Specifies the length, in bytes, to be mapped.

`ExecutionRoutine`

Pointer to a driver-supplied AdapterListControl routine, which is called at DISPATCH_LEVEL when the system DMA controller or bus-master adapter is available.

`Context`

Pointer to the driver-determined context passed to the driver's *AdapterListControl* routine when it is called.

`WriteToDevice`

Indicates the direction of the DMA transfer: **TRUE** for a transfer from the buffer to the device, and **FALSE**

otherwise.

Return Value

This routine can return one of the following NTSTATUS values.

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The operation succeeded.
STATUS_INSUFFICIENT_RESOURCES	The routine could not allocate sufficient memory or the number of map registers required for the transfer is larger than the value returned by IoGetDmaAdapter.
STATUS_BUFFER_TOO_SMALL	The buffer is too small for the requested transfer.

Remarks

The **GetScatterGatherList** routine dynamically allocates a buffer to hold the scatter/gather list. For possible NTSTATUS values if the buffer allocation fails, see the return value.

GetScatterGatherList is not a system routine that can be called directly by name. This routine is callable only by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter.

As soon as the appropriate DMA channel and any necessary map registers are available, **GetScatterGatherList** creates a scatter/gather list, initializes the map registers, and then calls the driver-supplied AdapterListControl routine to carry out the I/O operation.

GetScatterGatherList combines the actions of the AllocateAdapterChannel and MapTransfer routines for drivers that perform scatter/gather DMA. **GetScatterGatherList** determines how many map registers are required for the transfer, allocates the map registers, maps the buffers for DMA, and fills in the scatter/gather list. It then calls the supplied AdapterListControl routine, passing a pointer to the scatter/gather list in *ScatterGather*. The driver should retain this pointer for use when calling PutScatterGatherList. Note that **GetScatterGatherList** does not have the queuing restrictions that apply to **AllocateAdapterChannel**.

In its *AdapterListControl* routine, the driver should perform the I/O. On return from the driver-supplied routine,

GetScatterGatherList keeps the map registers but frees the DMA adapter structure. The driver must call **PutScatterGatherList** (which flushes the buffers) before it can access the data in the buffer.

This routine can handle chained MDLs, provided that the total number of map registers required by all chained MDLs does not exceed the number of map registers that are available.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows. Not supported in Windows 98 or Windows Me.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

PutScatterGatherList

SCATTER_GATHER_LIST

PGET_SCATTER_GATHER_LIST_EX callback function

1/25/2019 • 6 minutes to read • Edit Online

The **GetScatterGatherListEx** routine allocates the resources that are required for a DMA transfer, builds a scatter/gather list, and calls the driver-supplied AdapterListControl routine to initiate the DMA transfer.

> **Note** Do not call this routine for a system DMA device.

Syntax

```
PGET_SCATTER_GATHER_LIST_EX PgetScatterGatherListEx;

NTSTATUS PgetScatterGatherListEx(
  PDMA_ADAPTER DmaAdapter,
  PDEVICE_OBJECT DeviceObject,
  PVOID DmaTransferContext,
  PMDL Mdl,
  ULONGLONG Offset,
  ULONG Length,
  ULONG Flags,
  PDRIVER_LIST_CONTROL ExecutionRoutine,
  PVOID Context,
  BOOLEAN WriteToDevice,
  PDMA_COMPLETION_ROUTINE DmaCompletionRoutine,
  PVOID CompletionContext,
  PSCATTER_GATHER_LIST *ScatterGatherList
)
{...}
```

Parameters

`DmaAdapter`

A pointer to a DMA_ADAPTER structure. This structure is the adapter object that represents the driver's bus-master DMA device. The caller obtained this pointer from a previous call to the IoGetDmaAdapter routine.

`DeviceObject`

A pointer to a DEVICE_OBJECT structure. This structure is the physical device object (PDO) that represents the target device for the requested DMA operation.

`DmaTransferContext`

A pointer to an initialized DMA transfer context. This context was initialized by a previous call to the InitializeDmaTransferContext routine. This context must be unique across all adapter allocation requests. To cancel a pending allocation request, the caller must supply the DMA transfer context for the request to the CancelAdapterChannel routine.

`Mdl`

A pointer to an MDL chain that describes the physical page layout for a collection of locked-down buffers in virtual memory. The scatter/gather list for the DMA transfer will use the region of this memory that is specified by the *Offset* and *Length* parameters. For more information about MDL chains, see Using MDLs.

`Offset`

The starting offset for the scatter/gather DMA transfer. This parameter is a byte offset from the start of the buffer in the first MDL in the MDL chain. If the MDLs in the MDL chain specify a total of N bytes of buffer space, valid values of *Offset* are in the range 0 to N−1.

`Length`

The length, in bytes, of the DMA transfer. If the MDL chain specifies a total of N bytes of buffer space, valid values of *Length* are in the range 1 to N−*Offset*.

`Flags`

The adapter channel allocation flags. The following flag is supported.

FLAG	MEANING
DM A_S YN CH RO NO US_ CAL LBA CK	The **GetScatterGatherListEx** routine is called synchronously. If this flag is set, and the required DMA resources are not immediately available, the call fails and returns STATUS_INSUFFICIENT_RESOURCES.

If the **DMA_SYNCHRONOUS_CALLBACK** flag is set, the *ExecutionRoutine* parameter is optional and can be NULL. If this flag is not set, *ExecutionRoutine* must be a valid, non-**NULL** pointer. For more information about this flag, see the Remarks section.

`ExecutionRoutine`

A pointer to the driver-supplied AdapterListControl routine that initiates the DMA transfer for the driver. The I/O manager calls the *AdapterListControl* routine after the required resources are allocated for the adapter object. After the *AdapterListControl* routine returns, the I/O manager automatically frees the adapter object and the resources that were allocated for this object.

If the **DMA_SYNCHRONOUS_CALLBACK** flag is set, the *ExecutionRoutine* parameter is optional and can be NULL. If this parameter is NULL, the caller can use the resources allocated by **GetScatterGatherListEx** to perform the DMA transfer after **GetScatterGatherListEx** returns. For more information, see the Remarks section.

`Context`

The driver-determined, adapter-control context. This context is passed to the AdapterListControl routine as the *Context* parameter.

`WriteToDevice`

The direction of the DMA transfer. Set this parameter to TRUE for a write operation, which transfers data from memory to the device. Set this parameter to FALSE for a read operation, which transfers data from the device to memory.

`DmaCompletionRoutine`

Not used. Set to **NULL**.

`CompletionContext`

Not used. Set to **NULL**.

`*ScatterGatherList`

A pointer to a variable into which the routine writes a pointer to the allocated scatter/gather list. This parameter points to a SCATTER_GATHER_LIST structure. The routine allocates this structure and the **SCATTER_GATHER_ELEMENT** array that it points to.

The *ScatterGatherList* parameter is optional and can be NULL if the *ExecutionRoutine* parameter is non-NULL.

If the **DMA_SYNCHRONOUS_CALLBACK** flag is set and the *ExecutionRoutine* parameter is **NULL**, *ScatterGatherList* must be a valid, non-**NULL** pointer. If *ExecutionRoutine* is non-**NULL**, *ScatterGatherList* is optional and can be **NULL** if the calling driver does not require the scatter/gather list. The **GetScatterGatherListEx** call fails if the **DMA_SYNCHRONOUS_CALLBACK** flag is set and *ScatterGatherList* and *ExecutionRoutine* are both **NULL**, or if the **DMA_SYNCHRONOUS_CALLBACK** flag is not set and *ExecutionRoutine* is **NULL**.

Return Value

GetScatterGatherListEx returns STATUS_SUCCESS if the call is successful. Possible error return values include the following status codes.

RETURN CODE	DESCRIPTION
STA TUS _IN VAL ID_ PAR AM ETE RS	The routine failed due to invalid parameter values passed by the caller.
STA TUS _IN SUF FICI ENT _RE SO URC ES	The routine failed to allocate resources required for the DMA transfer.

Remarks

GetScatterGatherListEx
is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a DMA_OPERATIONS*structure.*Drivers obtain the address of this routine by calling IoGetDmaAdapter with the **Version** member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION3. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

Use **GetScatterGatherListEx** only for bus-master adapters. Do not use this routine for a system DMA adapter.

The driver of a bus-master device can use **GetScatterGatherListEx** to combine the operations performed by the AllocateAdapterChannelEx and MapTransferEx routines into a one call. **GetScatterGatherListEx** performs the following operations:

1. Allocates the resources that are required for the DMA transfer.
2. Builds a scatter/gather list based on the values of the *Mdl*, *Offset*, and *Length* parameters.
3. Calls the driver-supplied AdapterListControl routine and supplies the scatter/gather list to this routine as a parameter.

The allocated resources are automatically released after the *AdapterListControl* routine returns. If **GetScatterGatherListEx** is called synchronously (that is, if the **DMA_SYNCHRONOUS_CALLBACK** flag is set), the *AdapterListControl* routine can be omitted. In this case, the caller uses the allocated resources to initiate the DMA transfer after **GetScatterGatherListEx** returns. The caller must explicitly release these resources.

By default, **GetScatterGatherListEx** returns asynchronously, without waiting for the requested resource allocation to complete. After this return, the caller can, if necessary, cancel the pending allocation request by calling the CancelAdapterChannel routine.

If the calling driver sets the **DMA_SYNCHRONOUS_CALLBACK** flag, the **GetScatterGatherListEx** routine behaves as follows:

- If the requested resources are not immediately available, **GetScatterGatherListEx** does not wait for resources, does not build a scatter/gather list, and does not call the *AdapterListControl* routine. Instead, **GetScatterGatherListEx** fails and returns STATUS_INSUFFICIENT_RESOURCES.
- The driver is not required to supply an *AdapterListControl* routine if the **DMA_SYNCHRONOUS_CALLBACK** flag is set.
- If the driver supplies an *AdapterListControl* routine, the **DMA_SYNCHRONOUS_CALLBACK** flag indicates that this routine is to be called in the context of the calling thread, before **GetScatterGatherListEx** returns.
- If the driver does not supply an *AdapterListControl* routine, the driver can use the allocated resources and scatter/gather list after **GetScatterGatherListEx** returns. In this case, the driver must supply a valid, non-NULL *ScatterGatherList* pointer. In addition, after the driver initiates the DMA transfer, the driver must call the FreeAdapterObject routine to free the resources that **GetScatterGatherListEx** allocated for the adapter object.

GetScatterGatherListEx is an extended version of the GetScatterGatherList routine. The following features are available only in the extended version:

GetScatterGatherListEx is similar to the BuildScatterGatherListEx routine, except that **GetScatterGatherListEx** automatically allocates the buffer for the scatter/gather list.

Requirements

Minimum supported client	Available starting with Windows 8.

PINITIALIZE_DMA_TRANSFER_CONTEXT callback function

1/25/2019 • 2 minutes to read • Edit Online

The **InitializeDmaTransferContext** routine initializes an opaque DMA transfer context that is used to track pending allocations of DMA resources.

Syntax

```
PINITIALIZE_DMA_TRANSFER_CONTEXT PinitializeDmaTransferContext;

NTSTATUS PinitializeDmaTransferContext(
  PDMA_ADAPTER DmaAdapter,
  PVOID DmaTransferContext
)
{...}
```

Parameters

`DmaAdapter`

A pointer to a DMA_ADAPTER structure. This structure is the adapter object that represents the driver's bus-master DMA device or system DMA channel. The caller obtained this pointer from a previous call to the IoGetDmaAdapter routine.

`DmaTransferContext`

A pointer to a caller-allocated buffer into which **InitializeDmaTransferContext** writes the initial values for the DMA transfer context. This context is opaque to the caller. The caller must allocate a buffer that is large enough to contain the DMA transfer context. The size, in bytes, of this context is specified by the **DMA_TRANSFER_CONTEXT_SIZE_V1** constant in the Wdm.h header file.

Return Value

InitializeDmaTransferContext returns STATUS_SUCCESS if the call is successful. Possible error return values include the following status codes.

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETERS	This routine failed due to invalid parameter values passed by the caller.

Remarks

InitializeDmaTransferContext
is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a
DMA_OPERATIONS*structure*.Drivers obtain the address of this routine by calling IoGetDmaAdapter with the **Version** member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION3. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

An initialized DMA transfer context must be supplied as a parameter to the AllocateAdapterChannelEx, GetScatterGatherListEx, or BuildScatterGatherListEx routine. Each of these routines writes information about the requested DMA resource allocation to the DMA transfer context. This information is opaque to the caller. To cancel a pending allocation request, the caller must supply the DMA transfer context for the request to the CancelAdapterChannel routine.

The DMA transfer context that is supplied to **AllocateAdapterChannelEx**, **GetScatterGatherListEx**, or **BuildScatterGatherListEx** must be unique across all adapter allocation requests.

Requirements

PINTERFACE_DEREFERENCE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *InterfaceDereference* routine decrements the reference count on a driver-defined interface.

Syntax

```
PINTERFACE_DEREFERENCE PinterfaceDereference;

void PinterfaceDereference(
  PVOID Context
)
{...}
```

Parameters

`Context`

A pointer to interface-specific context information. The caller passes the value that is passed as the **Context** member of the INTERFACE structure for the interface.

Return Value

None

Remarks

You can use the InterfaceReference routine to increment the reference count for the interface.

The driver that imports the interface is responsible for calling the *InterfaceDereference* routine to decrement the reference count after the driver is no longer using the interface. For example, a driver that requests a pointer to the interface by sending an IRP_MN_QUERY_INTERFACE request calls *InterfaceDereference*. Also, a driver that receives a pointer to the interface to another driver must call *InterfaceDereference*.

Requirements

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)

PMAP_TRANSFER callback function

1/25/2019 • 2 minutes to read • Edit Online

The **MapTransfer** routine sets up map registers for an adapter object to map a DMA transfer from a locked-down buffer.

Syntax

```
PMAP_TRANSFER PmapTransfer;

PHYSICAL_ADDRESS PmapTransfer(
  PDMA_ADAPTER DmaAdapter,
  PMDL Mdl,
  PVOID MapRegisterBase,
  PVOID CurrentVa,
  PULONG Length,
  BOOLEAN WriteToDevice
)
{...}
```

Parameters

`DmaAdapter`

Pointer to the DMA adapter object returned by IoGetDmaAdapter and previously passed to AllocateAdapterChannel for the current IRP's transfer request.

`Mdl`

Pointer to one of the following: the MDL that describes the buffer at **MdlAddress** in the current IRP or the MDL that describes the common buffer set up by the driver of a subordinate device (auto-initialize mode).

`MapRegisterBase`

Specifies the map registers allocated for the DMA operation. The system passes this value to the driver's AdapterControl routine.

`CurrentVa`

Pointer to the current virtual address of the data to be transferred for a DMA transfer operation.

`Length`

Specifies the length, in bytes, to be mapped. If the driver indicated that its device was a bus master with scatter/gather support when it called IoGetDmaAdapter, the value of *Length* on return from **MapTransfer** indicates how many bytes were mapped. Otherwise, the input and output values of *Length* are identical.

`WriteToDevice`

Indicates the direction of the transfer operation: **TRUE** for a transfer from the locked-down buffer to the device.

Return Value

MapTransfer returns the logical address of the region mapped, which the driver of a bus-master adapter can use. Drivers of devices that use a system DMA controller cannot use this value and should ignore it.

Remarks

MapTransfer is not a system routine that can be called directly by name. This routine is callable only by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter.

The *DmaAdapter* must have already been allocated as a result of the driver's preceding call to AllocateAdapterChannel.

The number of map registers that can be set up cannot exceed the maximum returned when the driver called IoGetDmaAdapter.

A driver can get the initial *CurrentVa* for the start of a packet-based DMA transfer by calling MmGetMdlVirtualAddress. However, the value returned is an index into the *Mdl*, rather than a valid virtual address. If the driver must split a large transfer request into more than one DMA operation, it must update *CurrentVa* and *Length* for each DMA operation.

The driver of a bus-master device with scatter/gather support can use the returned logical address and updated *Length* value to build a scatter/gather list, calling **MapTransfer** repeatedly until it has used all available map registers for the transfer operation. However, such a driver could more simply use the GetScatterGatherList routine.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop

PMAP_TRANSFER_EX callback function

1/25/2019 • 7 minutes to read • Edit Online

The **MapTransferEx** routine sets up map registers to map the physical addresses in a scatter/gather list to the logical addresses that are required to do a DMA transfer.

Syntax

```
PMAP_TRANSFER_EX PmapTransferEx;

NTSTATUS PmapTransferEx(
  PDMA_ADAPTER DmaAdapter,
  PMDL Mdl,
  PVOID MapRegisterBase,
  ULONGLONG Offset,
  ULONG DeviceOffset,
  PULONG Length,
  BOOLEAN WriteToDevice,
  PSCATTER_GATHER_LIST ScatterGatherBuffer,
  ULONG ScatterGatherBufferLength,
  PDMA_COMPLETION_ROUTINE DmaCompletionRoutine,
  PVOID CompletionContext
)
{...}
```

Parameters

`DmaAdapter`

A pointer to a DMA_ADAPTER structure. This structure is the adapter object that represents the driver's bus-master DMA device or system DMA channel. The caller obtained this pointer from a previous call to the IoGetDmaAdapter routine.

`Mdl`

A pointer to an MDL chain that describes the physical page layout for a collection of locked-down buffers in virtual memory. The scatter/gather list for the DMA transfer will use the region of this memory that is specified by the *Offset* and *Length* parameters. For more information about MDL chains, see Using MDLs.

`MapRegisterBase`

A handle to the map registers that are allocated for the adapter object. The caller previously obtained this handle from the AllocateAdapterChannelEx routine.

`Offset`

A byte offset from the start of the memory that is described by the MDL chain. This offset specifies the start of the I/O data buffer that is used for the DMA transfer. If a scatter/gather list is supplied to the caller, this offset determines the starting address of the first buffer fragment in the list. If the MDLs in the MDL chain describe a total of N bytes of memory, valid values of *Offset* are in the range 0 to N−1. For more information, see Remarks.

`DeviceOffset`

The byte offset of the target device's data register or FIFO from the device's base address. This parameter applies to devices that have multiple FIFOs that can be accessed by a system DMA controller. This parameter is used only for

system DMA transfers. For bus-master transfers, set this parameter to zero.

`Length`

A pointer to a variable that contains the length, in bytes, of the I/O data buffer that is used for the DMA transfer. On entry, this variable contains the length requested by the calling driver. Before returning, the routine writes the actual length of the mapped buffer to this variable. The value of **Length* on return from **MapTransferEx** indicates how many bytes were mapped. If the number of map registers and the scatter/gather buffer size are sufficient to map the entire length requested by the caller, the input and output values of **Length* are identical. If the MDLs in the MDL chain describe a total of N bytes of memory, valid values of **Length* are in the range 0 to N–*Offset*.

`WriteToDevice`

The direction of the DMA transfer. Set this parameter to **TRUE** for a write operation, which transfers data to the device from memory. Set this parameter to **FALSE** for a read operation, which transfers data from the device to memory.

`ScatterGatherBuffer`

A pointer to a caller-allocated buffer into which the routine writes the scatter/gather list for the DMA transfer. This list begins with a SCATTER_GATHER_LIST structure, which is immediately followed by a **SCATTER_GATHER_ELEMENT** array. For a driver that uses a bus-master DMA device, *ScatterGatherBuffer* is a required parameter. For a driver that uses a system DMA controller, the *ScatterGatherBuffer* parameter is optional and can be **NULL**. For more information, see Remarks.

`ScatterGatherBufferLength`

The size, in bytes, of the buffer that the *ScatterGatherBuffer* parameter points to. The allocated buffer size must be large enough to contain the scatter/gather list, plus internal data that the operating system stores in this buffer. To determine the required buffer size, call the GetDmaTransferInfo or CalculateScatterGatherList routine. If *ScatterGatherBuffer* is **NULL**, set *ScatterGatherBufferLength* to zero.

`DmaCompletionRoutine`

A pointer to a caller-supplied DmaCompletionRoutine routine to be called when the DMA transfer completes. This routine is called if the target device uses a system DMA controller that generates a DMA-completion interrupt. The *DmaCompletionRoutine* routine is called at DISPATCH_LEVEL after the DMA transfer completes. For a system DMA adapter, this parameter is optional and can be **NULL**. For a bus-master adapter, set this parameter to **NULL**.

`CompletionContext`

The driver-determined context for the *DmaCompletionRoutine* routine. This context is supplied as the *CompletionContext* parameter to the *DmaCompletionRoutine* routine. If the *DmaCompletionRoutine* parameter is **NULL**, set *CompletionContext* to **NULL**.

Return Value

MapTransferEx returns STATUS_SUCCESS if the call is successful. Possible error return values include the following status codes.

RETURN CODE	DESCRIPTION

STATUS_INVALID_PARAMETERS	The routine failed due to invalid parameter values passed by the caller.
STATUS_BUFFER_TOO_SMALL	The caller-supplied buffer in *ScatterGatherBuffer* is too small to contain the scatter/gather list.
STATUS_INSUFFICIENT_RESOURCES	The routine failed to allocate resources required for the DMA transfer.
STATUS_CANCELLED	This transfer was canceled.

Remarks

MapTransferEx *is not a system routine that can be called directly by name. This routine can be called only by pointer from the address returned in a* DMA_OPERATIONS*structure.*Drivers obtain the address of this routine by calling IoGetDmaAdapter with the **Version** member of the *DeviceDescription* parameter set to DEVICE_DESCRIPTION_VERSION3. If **IoGetDmaAdapter** returns **NULL**, the routine is not available on your platform.

For a transfer that uses a system DMA controller, the caller can, as an option, supply a DmaCompletionRoutine callback routine that is called when the transfer finishes. The operating system schedules this callback in response to the DMA completion interrupt from the system DMA controller.

The number of map registers that can be set up by **MapTransferEx** cannot exceed the maximum that the driver obtained from IoGetDmaAdapter.

The *Mdl*, *Offset*, and *Length* parameters describe the I/O data buffer for the requested DMA transfer. The number

of allocated map registers might not be sufficient to map all of the memory in this buffer, or the scatter/gather buffer pointed to by *ScatterGatherBuffer* might not be large enough to describe the entire buffer. **MapTransferEx** writes an output value to **Length* to tell the driver how much of the buffer memory for the requested DMA transfer was mapped by the routine. The routine writes a scatter/gather list to the buffer pointed to by *ScatterGatherBuffer*. This list describes the buffer fragments that were successfully mapped by the routine.

If a call to **MapTransferEx** is successful, **MapTransferEx** writes the **Length* output value before it returns. If the caller specifies a *DmaCompletionRoutine*, the updated **Length* output value is always written before the *DmaCompletionRoutine* runs. For more information, see Multiple calls to MapTransferEx.

The *Offset* parameter specifies the starting offset in the MDL chain that describes the memory in the I/O data buffer. For example, assume that the MDL chain contains two MDLs, MDL_1 and MDL_2, and that MDL_1 describes N_1 bytes of memory, and MDL_2 describes N_2 bytes. If *Offset* = N, where $N_1 < N < N_1 + N_2$, the buffer contains none of the memory described by MDL_1, and starts at an offset of $N - N_1$ bytes in the memory described by MDL_2.

If the transfer uses a system DMA controller, the caller can set *ScatterGatherBuffer* = NULL, in which case **MapTransferEx** uses an internally allocated, default buffer to hold the scatter/gather list. The default buffer is guaranteed to be large enough to contain a scatter/gather list of at least one element. If the default buffer is used for a scatter/gather transfer of many elements, many calls to **MapTransferEx** might be required complete the transfer. If the DMA controller hardware supports scatter/gather transfers, the use of the default buffer might degrade performance.

If *ScatterGatherBuffer* is non-NULL and *ScatterGatherBufferSize* specifies a size that is too small to contain a scatter/gather list of at least one element, **MapTransferEx** fails and returns STATUS_INVALID_PARAMETER.

MapTransferEx is an extended version of the MapTransfer routine. The extended version has these advantages:

- **MapTransferEx** can process all of the buffer fragments in an MDL chain in one call, but **MapTransfer** can process only one physically contiguous buffer fragment per call.
- **MapTransferEx** can generate an entire scatter/gather list in one call, but **MapTransfer** can generate only one scatter/gather list element per call.
- **MapTransferEx** can map all of the buffer fragments in a scatter/gather list in one call, but **MapTransfer** can map only one physically contiguous buffer fragment per call.
- **MapTransferEx** requires only the starting offset for the entire scatter/gather list, but **MapTransfer** requires a starting virtual address for each physically contiguous buffer fragment.
- A **MapTransferEx** call can map a buffer that extends through one or more MDLs, but a **MapTransfer** call can map only one physically contiguous buffer fragment in the memory that is described by an MDL.
- For a system DMA transfer, **MapTransferEx** enables the caller to supply a *DmaCompletionRoutine* callback routine to receive notification after the transfer completes, but **MapTransfer** does not provide a way to notify the caller when a DMA transfer completes.

Each successful call to **MapTransferEx** must be followed by a corresponding call to the FlushAdapterBuffersEx routine. The **FlushAdapterBuffersEx** call that follows a **MapTransferEx** call must occur before the next **MapTransferEx** call occurs. The **FlushAdapterBuffersEx** call is required even if a call to the CancelMappedTransfer routine succeeds in canceling the mapped transfer requested by the preceding **MapTransferEx** call.

For more information, see Using the MapTransferEx Routine.

PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *ComponentActiveConditionCallback* callback routine notifies the driver that the specified component completed a transition from the idle condition to the active condition.

Syntax

```
PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK PoFxComponentActiveConditionCallback;

void PoFxComponentActiveConditionCallback(
  PVOID Context,
  ULONG Component
)
{...}
```

Parameters

`Context`

A pointer to the device context. The device driver uses this context to store information about the current power state of the device. The device driver specified this pointer in the **DeviceContext** member of the PO_FX_DEVICE structure that the driver used to register the device with the power management framework (PoFx). This context is opaque to PoFx.

`Component`

Specifies the index that identifies the component. This parameter is an index into the **Components** array in the **PO_FX_DEVICE** structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N–1.

Return Value

None.

Remarks

A component's hardware registers can be accessed only when the component is in the active condition. Do not rely on the Fx power state of a component to determine whether the component can be accessed. If the component is in the F0 state and is in the idle condition, the component might be about to switch to another Fx state.

To gain access to a component that is in the idle condition, the driver can call the PoFxActivateComponent routine to switch the component to the active condition. If the component is not already in the active condition when **PoFxActivateComponent** is called, PoFx initiates the transition to the active condition, and then calls the *ComponentActiveConditionCallback* routine to notify the driver when the transition is complete.

The driver receives a *ComponentActiveConditionCallback* callback whenever the component completes a transition to the active condition, regardless of whether the driver called **PoFxActivateComponent** to initiate the transition. For example, the Windows kernel might activate the component on behalf of the driver before sending a Plug and Play IRP or a system set-power IRP to the driver.

Examples

To define a *ComponentActiveConditionCallback* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *ComponentActiveConditionCallback* callback routine that is named `MyComponentActiveConditionCallback`, use the PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK type as shown in this code example:

```
PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK MyComponentActiveConditionCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyComponentActiveConditionCallback(
    PVOID Context,
    ULONG Component
    )
  {
      // Function body
  }
```

The PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

PoFxActivateComponent

PO_FX_COMPONENT_CRITICAL_TRANSITION_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *ComponentCriticalTransitionCallback* callback routine handles a transition of the specified component between the F0 (fully on) and low-power F*x* component power states.

Syntax

```
PO_FX_COMPONENT_CRITICAL_TRANSITION_CALLBACK PoFxComponentCriticalTransitionCallback;

void PoFxComponentCriticalTransitionCallback(
  PVOID Context,
  ULONG Component,
  BOOLEAN Active
)
{...}
```

Parameters

`Context`

A pointer to the device context. The device driver uses this context to store information about the current power state of the device. This context is driver-defined and is opaque to PoFx. The driver specified this pointer in the **DeviceContext** member of the PO_FX_CORE_DEVICE structure that the driver used to register the device with the Windows power management framework (PoFx).

`Component`

The index that identifies the component. This parameter is an index into the **Components** array in the **PO_FX_CORE_DEVICE** structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Active`

Indicates whether this notification is for a transition to the F0 component power state. If TRUE, the component has just completed a transition from a low-power F*x* state to F0. If FALSE, the component is about to start a transition from F0 to a low-power F*x* state.

Return Value

None.

Remarks

This callback routine is implemented by a device driver, and is called by PoFx. PoFx calls this routine to notify the driver of power transitions of device components.

The **ComponentCriticalTransitionCallback** member of the PO_FX_CORE_DEVICE structure is a pointer to a *ComponentCriticalTransitionCallback* callback routine. A pointer to a **PO_FX_CORE_DEVICE** structure is passed as an input parameter in the PoFxRegisterCoreDevice call that registers a core device with the Windows power management framework (PoFx).

To handle calls to this routine, the device driver saves or restores the register state or other hardware context of the

specified component in the device.

If *Active* = TRUE, PoFx has called this routine *after* the component completed a transition from a low-power F*x* state to F0. In this call, the routine restores the previously saved hardware context of the component.

If *Active* = FALSE, PoFx has called this routine *before* the component starts a pending transition from F0 to a low-power F*x* state. In this call, the routine saves the component's hardware context so that this context can later be restored.

For more information about F*x* component power states, see Component-Level Power Management.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	wdm.h (include Wudfwdm.h)

PO_FX_CORE_DEVICE

PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *ComponentIdleConditionCallback* callback routine notifies the driver that the specified component completed a transition from the active condition to the idle condition.

Syntax

```
PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK PoFxComponentIdleConditionCallback;

void PoFxComponentIdleConditionCallback(
  PVOID Context,
  ULONG Component
)
{...}
```

Parameters

`Context`

A pointer to the device context. The device driver uses this context to store information about the current power state of the device. The device driver specified this pointer in the **DeviceContext** member of the PO_FX_DEVICE structure that the driver used to register the device with the power management framework (PoFx). This context is opaque to PoFx.

`Component`

The index that identifies the component. This parameter is an index into the **Components** array in the **PO_FX_DEVICE** structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N–1.

Return Value

None.

Remarks

When the driver no longer needs to access a component that is in the active condition, the driver should call the PoFxIdleComponent routine to switch the component to the idle condition. In response to the **PoFxIdleComponent** call, PoFx initiates the transition to the idle condition, and then calls the *ComponentIdleConditionCallback* routine to notify the driver when this transition is complete.

The driver must call **PoFxCompleteIdleCondition** in response to every *ComponentIdleConditionCallback* callback. The **PoFxCompleteIdleCondition** call can occur either during the *ComponentIdleConditionCallback* callback or after the callback returns. The driver should complete any work that requires access to the hardware component before the call to **PoFxCompleteIdleCondition**. After this call, the component might not stay in the F0 power state.

A component can be safely accessed only when the component is in the active condition. Do not rely on the Fx power state of a component to determine whether the component can be accessed. If the component is in the F0

state and is in the idle condition, the component might be about to switch to another Fx state.

Examples

To define a *ComponentIdleConditionCallback* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *ComponentIdleConditionCallback* callback routine that is named `MyComponentIdleConditionCallback`, use the PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK type as shown in this code example:

```
PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK MyComponentIdleConditionCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyComponentIdleConditionCallback(
    PVOID Context,
    ULONG Component
    )
  {
      // Function body
  }
```

The PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

PO_FX_DEVICE

PoFxCompleteIdleCondition

PO_FX_COMPONENT_IDLE_STATE_CALLBACK callback function

1/25/2019 • 4 minutes to read • Edit Online

The *ComponentIdleStateCallback* callback routine notifies the driver of a pending change to the Fx power state of the specified component.

Syntax

```
PO_FX_COMPONENT_IDLE_STATE_CALLBACK PoFxComponentIdleStateCallback;

void PoFxComponentIdleStateCallback(
  PVOID Context,
  ULONG Component,
  ULONG State
)
{...}
```

Parameters

`Context`

A pointer to the device context. The device driver uses this context to store information about the current power state of the device. The device driver specified this pointer in the **DeviceContext** member of the PO_FX_DEVICE structure that the driver used to register the device with the power management framework (PoFx). This context is opaque to PoFx.

`Component`

Specifies the component number. This parameter is an index into the **Components** array in the **PO_FX_DEVICE** structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N-1.

`State`

Specifies the new Fx power state that the component will change to. If this parameter is zero, the new state is F0; if this parameter is one, the new state is F1; and so on.

Return Value

None.

Remarks

When PoFx calls the driver's *ComponentIdleStateCallback* routine, the driver might need to prepare for the pending Fx state change. After any necessary preparations are completed, the driver must call the PoFxCompleteIdleState routine to notify PoFx that the driver completed its response to the *ComponentIdleStateCallback* callback. The **PoFxCompleteIdleState** call can occur either before or after the *ComponentIdleStateCallback* routine returns.

If the component is to switch from F0 to a low-power Fx state in which the device will lose the hardware state of

the component, the driver must save the component's hardware state before the transition to the new Fx state occurs. If the component is to switch from a low-power Fx state to F0, and the hardware state was previously saved, the driver should restore the hardware state after power is restored to the component.

For some devices, the power state of a component might be controlled in the device hardware. For these devices, the driver is typically responsible for changing the power state of the component. For other devices, the power state of a component might be controlled by hardware that is external to the device, and the driver typically must rely on PoFx to configure the power state of the component.

If the driver is responsible for configuring the power state of the component, the driver should change the power state in response to the *ComponentIdleStateCallback* callback. For a transition from F0 to a low-power Fx state, the component is in F0 on entry to the *ComponentIdleStateCallback* routine, and the driver must switch the component the new Fx state before calling **PoFxCompleteIdleState**. For a transition from a low-power Fx state to F0, the component is in the low-power Fx state on entry to the *ComponentIdleStateCallback* routine, and the driver must switch the component to F0 before calling **PoFxCompleteIdleState**.

If the driver is not responsible for configuring the power state of the component, the driver should assume that the component is always in the F0 state on entry to the *ComponentIdleStateCallback* routine. For a pending transition from F0 to a low-power Fx state, the transition to the new Fx state does not occur until after the driver calls **PoFxCompleteIdleState**. For a transition from a low-power Fx state to F0, the transition to F0 occurs before the *ComponentIdleStateCallback* routine is called.

PoFx never calls the *ComponentIdleStateCallback* routine to switch directly from one low-power Fx state to another low-power Fx state. For example, PoFx might need to switch a component from one low-power Fx state to another in response to a call to the PoFxSetComponentLatency, PoFxSetComponentResidency, or PoFxSetComponentWake routine. In this case, PoFx first calls the *ComponentIdleStateCallback* routine to switch from the old Fx state to F0, and then calls the *ComponentIdleStateCallback* routine a second time to switch from F0 to the new Fx state.

Examples

To define a *ComponentIdleStateCallback* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *ComponentIdleStateCallback* callback routine that is named `MyComponentIdleStateCallback`, use the PO_FX_COMPONENT_IDLE_STATE_CALLBACK type as shown in this code example:

```
PO_FX_COMPONENT_IDLE_STATE_CALLBACK MyComponentIdleStateCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyComponentIdleStateCallback(
    PVOID Context,
    ULONG Component,
    ULONG State
    )
  {
      // Function body
  }
```

The PO_FX_COMPONENT_IDLE_STATE_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the PO_FX_COMPONENT_IDLE_STATE_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

PO_FX_COMPONENT_PERF_STATE_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *ComponentPerfStateCallback* callback routine notifies the driver that its request to change the performance state of a component is complete.

Syntax

```
PO_FX_COMPONENT_PERF_STATE_CALLBACK PoFxComponentPerfStateCallback;

void PoFxComponentPerfStateCallback(
  PVOID Context,
  ULONG Component,
  BOOLEAN Succeeded,
  PVOID RequestContext
)
{...}
```

Parameters

`Context`

A pointer to the device context. The device driver uses this context to store information about the current power state of the device. The device driver specified this pointer in the **DeviceContext** member of the PO_FX_DEVICE structure that the driver used to register the device with the power management framework (PoFx). This context is opaque to PoFx.

`Component`

Specifies the index that identifies the component. This parameter is an index into the **Components** array in the **PO_FX_DEVICE** structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Succeeded`

If TRUE, the platform extension plug-in (PEP) succeeded the performance state change. If FALSE, the PEP failed the performance state change. For more information, see the Remarks section.

`RequestContext`

Pointer to the optional driver or device context that was specified by the *Context* parameter of the PoFxIssueComponentPerfStateChange or PoFxIssueComponentPerfStateChangeMultiple routine.

Return Value

None.

Remarks

When a device driver requests a performance state change by calling the PoFxIssueComponentPerfStateChange or PoFxIssueComponentPerfStateChangeMultiple routine, PoFx calls the *ComponentPerfStateCallback* routine to

notify the driver when the request is complete.

To specify a *ComponentPerfStateCallback* routine, use the *ComponentPerfStateCallback* parameter of the PoFxRegisterComponentPerfStates routine when the driver registers for performance state management by PoFx. The *ComponentPerfStateCallback* routine may be the same for all components and all devices.

If *Succeeded* is TRUE, the driver should perform whatever work is necessary to change the performance state in the hardware. If *Succeeded* is FALSE, the driver may choose to do nothing or retry the request with the same performance state or an alternate performance state.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Desktop
Header	wdm.h
IRQL	Called at IRQL <= DISPATCH_LEVEL.

PoFxIssueComponentPerfStateChange

PoFxIssueComponentPerfStateChangeMultiple

PoFxRegisterDevice

PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *DevicePowerNotRequiredCallback* callback routine notifies the device driver that the device is not required to stay in the D0 power state.

Syntax

```
PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK PoFxDevicePowerNotRequiredCallback;

void PoFxDevicePowerNotRequiredCallback(
  PVOID Context
)
{...}
```

Parameters

`Context`

A pointer to the device context. The device driver uses this context to store information about the current power state of the device. The device driver specified this pointer in the **DeviceContext** member of the PO_FX_DEVICE structure that the driver used to register the device with the power management framework (PoFx). This context is opaque to PoFx.

Return Value

None.

Remarks

When PoFx calls the driver's *DevicePowerNotRequiredCallback* routine, the driver must first decide whether to initiate a transition to a low-power Dx state (by sending an IRP_MN_SET_POWER request down the device stack) or to remain in the D0 state. Next, without waiting for any Dx transition to complete, the driver must call the PoFxCompleteDevicePowerNotRequired routine to notify PoFx that the driver completed its response to the *DevicePowerNotRequiredCallback* callback. The driver can call **PoFxCompleteDevicePowerNotRequired** before or after the *DevicePowerNotRequiredCallback* routine returns.

When a device is in the D0 state, and the Fx state or active/idle condition of a component in the device changes, PoFx evaluates whether the device can enter a low-power Dx state or must remain in the D0 state. If the device can enter a low-power Dx state, PoFx calls the driver's *DevicePowerNotRequiredCallback* routine.

If the device enters a low-power Dx state in response to a *DevicePowerNotRequiredCallback* callback, but PoFx later determines that the device must enter the D0 state, PoFx calls the driver's DevicePowerRequiredCallback routine. In response to this call, the device must enter the D0 state.

Examples

To define a *DevicePowerNotRequiredCallback* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV),

and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *DevicePowerNotRequiredCallback* callback routine that is named `MyDevicePowerNotRequiredCallback`, use the PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK type as shown in this code example:

```
PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK MyDevicePowerNotRequiredCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyDevicePowerNotRequiredCallback(
    PVOID Context
    )
  {
      // Function body
  }
```

The PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Supported starting with Windows 8.
Target Platform	Desktop
Header	wdm.h (include Wudfwdm.h)
IRQL	Called at IRQL <= DISPATCH_LEVEL.

PoFxRegisterDevice

PO_FX_DEVICE_POWER_REQUIRED_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *DevicePowerRequiredCallback* callback routine notifies the device driver that the device must enter and remain in the D0 power state.

Syntax

```
PO_FX_DEVICE_POWER_REQUIRED_CALLBACK PoFxDevicePowerRequiredCallback;

void PoFxDevicePowerRequiredCallback(
  PVOID Context
)
{...}
```

Parameters

`Context`

A pointer to the device context. The device driver uses this context to store information about the current power state of the device. The device driver specified this pointer in the **DeviceContext** member of the PO_FX_DEVICE structure that the driver used to register the device with the power management framework (PoFx). This context is opaque to PoFx.

Return Value

None.

Remarks

After PoFx calls the driver's *DevicePowerRequiredCallback* routine, the driver must initiate a transition to the D0 state by sending a D0 IRP (an IRP_MN_SET_POWER request) down the device stack, if the device is not already in the D0 state. After the driver completes (and all lower drivers complete) handling of this request, the driver must call the PoFxReportDevicePoweredOn routine. The **PoFxReportDevicePoweredOn** call notifies PoFx that the device completed its response to the *DevicePowerRequiredCallback* call. The driver can call **PoFxReportDevicePoweredOn** during or after the *DevicePowerRequiredCallback* call.

Each time the *DevicePowerRequiredCallback* routine is called, the driver must respond by calling **PoFxReportDevicePoweredOn**. The **PoFxReportDevicePoweredOn** call can occur either during or after the *DevicePowerRequiredCallback* call. The driver must call **PoFxReportDevicePoweredOn** regardless of whether no D0 IRP is required, the D0 IRP request fails, or the dispatched D0 IRP succeeds or fails.

PoFx calls the *DevicePowerRequiredCallback* routine only if PoFx previously called the driver's DevicePowerNotRequiredCallback routine to notify the driver that the device was not required to stay in the D0 state.

The call to the *DevicePowerRequiredCallback* routine can occur at any time after the driver calls PoFxCompleteDevicePowerNotRequired to complete a *DevicePowerNotRequiredCallback* callback. The *DevicePowerRequiredCallback* call does not necessarily occur as a result of an action taken by the driver, such as

requesting that a component change to the active condition.

Examples

To define a *DevicePowerRequiredCallback* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *DevicePowerRequiredCallback* callback routine that is named `MyDevicePowerRequiredCallback`, use the PO_FX_DEVICE_POWER_REQUIRED_CALLBACK type as shown in this code example:

```
PO_FX_DEVICE_POWER_REQUIRED_CALLBACK MyDevicePowerRequiredCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyDevicePowerRequiredCallback(
    PVOID Context
    )
  {
      // Function body
  }
```

The PO_FX_DEVICE_POWER_REQUIRED_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the PO_FX_DEVICE_POWER_REQUIRED_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Supported starting with Windows 8.
Target Platform	Desktop
Header	wdm.h (include Wudfwdm.h)

PO_FX_POWER_CONTROL_CALLBACK callback function

1/25/2019 • 3 minutes to read • Edit Online

The *PowerControlCallback* callback routine performs a power control operation that is requested by the power management framework (PoFx).

Syntax

```
PO_FX_POWER_CONTROL_CALLBACK PoFxPowerControlCallback;

NTSTATUS PoFxPowerControlCallback(
  PVOID DeviceContext,
  LPCGUID PowerControlCode,
  PVOID InBuffer,
  SIZE_T InBufferSize,
  PVOID OutBuffer,
  SIZE_T OutBufferSize,
  PSIZE_T BytesReturned
)
{...}
```

Parameters

`DeviceContext`

`PowerControlCode`

A pointer to the power control code. This code is a GUID value that specifies the requested operation.

`InBuffer`

A pointer to the buffer that contains the input data for the operation. The format for the data in this buffer depends on the power control code specified by the *PowerControlCode* parameter. The *InBuffer* parameter is optional and can be specified as NULL if the specified operation requires no input data.

`InBufferSize`

The size, in bytes, of the input buffer that is pointed to by the *InBuffer* parameter. If *InBuffer* is NULL, this parameter is zero.

`OutBuffer`

A pointer to the buffer to which the callback routine writes the output data from the operation. The format for the data in this buffer depends on the power control code specified by the *PowerControlCode* parameter. The *OutBuffer* parameter is optional and can be specified as NULL if the specified operation produces no output data.

`OutBufferSize`

The size, in bytes, of the output buffer that is pointed to by the *OutBuffer* parameter. If *OutBuffer* is NULL, this parameter is zero.

`BytesReturned`

A pointer to a location into which the routine writes the number of bytes of data that were written to the buffer that is pointed to by *OutBuffer*. The number of bytes written must be less than or equal to *OutBufferSize*. This parameter is optional and can be specified as NULL if the caller does not need to know how many bytes were written to the output buffer.

Return Value

The *PowerControlCallback* routine returns STATUS_SUCCESS if the call is successful. Otherwise, it returns an appropriate error code.

Remarks

PoFx calls this routine to send a power control request directly to the device driver. A power control request is similar to an I/O control request (IOCTL). Unlike an IOCTL, however, a power control request is sent directly to the driver and is not observed by other device drivers in the device stack. During a *PowerControlCallback* call, the driver synchronously performs the requested operation.

This routine is optional. A device driver that does not support power control operations is not required to implement a *PowerControlCallback* routine.

The device driver can call the PoFxPowerControl routine to send a power control request to PoFx.

For more information about power control requests, see PoFxPowerControl.

Examples

To define a *PowerControlCallback* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *PowerControlCallback* callback routine that is named `MyPowerControlCallback`, use the PO_FX_POWER_CONTROL_CALLBACK type as shown in this code example:

```
PO_FX_POWER_CONTROL_CALLBACK MyPowerControlCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
NTSTATUS
  MyPowerControlCallback(
    PVOID Context,
    LPCGUID PowerControlCode,
    PVOID InBuffer,
    SIZE_T InBufferSize,
    PVOID OutBuffer,
    SIZE_T OutBufferSize,
    PSIZE_T BytesReturned
    )
  {
      // Function body
  }
```

The PO_FX_POWER_CONTROL_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the PO_FX_POWER_CONTROL_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Supported starting with Windows 8.
Target Platform	Desktop
Header	wdm.h (include Wudfwdm.h)
IRQL	Called at IRQL <= DISPATCH_LEVEL.

POB_POST_OPERATION_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *ObjectPostCallback* routine is called by the operating system after a process or thread handle operation occurs.

Syntax

```
POB_POST_OPERATION_CALLBACK PobPostOperationCallback;

void PobPostOperationCallback(
  PVOID RegistrationContext,
  POB_POST_OPERATION_INFORMATION OperationInformation
)
{...}
```

Parameters

`RegistrationContext`

The context that the driver specifies as the *CallBackRegistration*->**RegistrationContext** parameter of the ObRegisterCallbacks routine. The meaning of this value is driver-defined.

`OperationInformation`

A pointer to an OB_POST_OPERATION_INFORMATION structure that specifies the parameters of the handle operation.

Return Value

None

Remarks

Use the ObRegisterCallbacks routine to register an *ObjectPostCallback* routine, and use the ObUnRegisterCallbacks routine to unregister the routine.

An *ObjectPostCallback* routine is called after an operation on a process handle or thread handle completes, whereas an ObjectPreCallback routine is called before the operation occurs. The *OperationInformation* parameter of the *ObjectPreCallback* routine is a pointer to an OB_PRE_OPERATION_INFORMATION structure, which contains information that you can modify. In contrast, the *OperationInformation* parameter of the *ObjectPostCallback* routine is a pointer to an OB_POST_OPERATION_INFORMATION structure. The contents of this structure are informational and you cannot modify them.

This routine is called at PASSIVE_LEVEL in an arbitrary thread context with normal kernel APCs disabled. Special kernel APCs are not disabled. For more information about APCs, see Types of APCs.

Requirements

Minimum supported client	Available starting with Windows Server 2008.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at PASSIVE_LEVEL (see Remarks section).

ObjectPreCallback

POB_PRE_OPERATION_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *ObjectPreCallback* routine is called by the operating system when a process or thread handle operation occurs.

Syntax

```
POB_PRE_OPERATION_CALLBACK PobPreOperationCallback;

OB_PREOP_CALLBACK_STATUS PobPreOperationCallback(
  PVOID RegistrationContext,
  POB_PRE_OPERATION_INFORMATION OperationInformation
)
{...}
```

Parameters

`RegistrationContext`

The context that the driver specifies as the *CallBackRegistration*->**RegistrationContext** parameter of the ObRegisterCallbacks routine. The meaning of this value is driver-defined.

`OperationInformation`

A pointer to an OB_PRE_OPERATION_INFORMATION structure that specifies the parameters of the handle operation.

Return Value

ObjectPreCallback returns an OB_PREOP_CALLBACK_STATUS value. Drivers must return OB_PREOP_SUCCESS.

Remarks

Use the ObRegisterCallbacks routine to register an *ObjectPreCallback* routine, and use the ObUnRegisterCallbacks routine to unregister the routine.

This routine is called at PASSIVE_LEVEL in an arbitrary thread context with normal kernel APCs disabled. Special kernel APCs are not disabled. For more information about APCs, see Types of APCs.

Requirements

Minimum supported client	Available starting with Windows Server 2008.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at PASSIVE_LEVEL (see Remarks section).

ObjectPostCallback

PoCallDriver function

1/25/2019 • 2 minutes to read • Edit Online

The **PoCallDriver** routine passes a power IRP to the next-lower driver in the device stack. (Windows Server 2003, Windows XP, and Windows 2000 only.)

Syntax

```
NTSTATUS PoCallDriver(
  PDEVICE_OBJECT        DeviceObject,
  __drv_aliasesMem PIRP Irp
);
```

Parameters

`DeviceObject`

A pointer to the driver-created DEVICE_OBJECT to which the IRP is to be routed.

`Irp`

A pointer to an IRP.

Return Value

PoCallDriver returns STATUS_SUCCESS to indicate success. It returns STATUS_PENDING if it has queued the IRP.

Remarks

Beginning with Windows Vista, drivers should call IoCallDriver, not **PoCallDriver** to pass a power IRP to the next-lower driver. However, on Windows Server 2003, Windows XP, and Windows 2000, drivers must call **PoCallDriver**, not **IoCallDriver** to pass a power IRP to the next-lower driver. On Windows Server 2003, Windows XP, an Windows 2000, drivers must also call PoStartNextPowerIrp before calling **PoCallDriver**.

A driver that requires a new IRP should call PoRequestPowerIrp. A driver must not allocate its own power IRP.

When passing a power IRP down to the next-lower driver, the caller should use IoSkipCurrentIrpStackLocation or IoCopyCurrentIrpStackLocationToNext to set the IRP stack location, then call **PoCallDriver**. Use **IoCopyCurrentIrpStackLocationToNext** if processing the IRP requires setting an IoCompletion routine, or **IoSkipCurrentStackLocation** if no *IoCompletion* routine is required.

When a device is powering up, its drivers must set *IoCompletion* routines to perform start-up tasks (initializing the device, restoring context, and so on) after the bus driver has set the device in the working state. Set *IoCompletion* routines before calling **PoCallDriver**.

When a device is powering down, its drivers must perform necessary power-down tasks before passing the IRP to the next lower driver. After the IRP has reached the bus driver, the device will be powered off and its drivers will no longer have access to it. On Windows Server 2003, Windows XP, and Windows 2000, an *IoCompletion* routine that is associated with a power-down IRP is only required to call **PoStartNextPowerIrp**.

Only one inrush IRP can be active in the system at a time. When passing a power-up IRP for a device that requires

inrush current (in other words, the DO_POWER_INRUSH flag is set in the device object), **PoCallDriver** checks whether another inrush IRP is already active. If so, **PoCallDriver** queues the current IRP for handling after the previous IRP completes, and then returns STATUS_PENDING. For more information about inrush IRPs, see Setting Device Object Flags for Power Management.

If an IRP_MN_SET_POWER or IRP_MN_QUERY_POWER request is already active for *DeviceObject*, **PoCallDriver** queues this IRP and returns STATUS_PENDING.

On Windows 2000 and later systems, pageable drivers (the DO_POWER_PAGABLE flag is set in the device object) must call **PoCallDriver** at IRQL = PASSIVE_LEVEL. Drivers that cannot be paged (DO_POWER_PAGABLE is not set in the device object) or that require inrush current (DO_POWER_INRUSH is set in the device object) can call **PoCallDriver** at IRQL = PASSIVE_LEVEL or DISPATCH_LEVEL.

On Windows 98/Me, all drivers call **PoCallDriver** at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

PoStartNextPowerIrp

PoClearPowerRequest function

1/25/2019 • 2 minutes to read • Edit Online

The **PoClearPowerRequest** routine decrements the count for the specified power request type.

Syntax

```
NTSTATUS PoClearPowerRequest(
  PVOID              PowerRequest,
  POWER_REQUEST_TYPE Type
);
```

Parameters

`PowerRequest`

A pointer to a power request object that was created by the PoCreatePowerRequest routine.

`Type`

The type of the power request. Set this parameter to the following POWER_REQUEST_TYPE enumeration value:

- **PowerRequestSystemRequired**

Return Value

PoClearPowerRequest returns STATUS_SUCCESS if the call is successful. If the call fails, possible error return codes include the following:

RETURN CODE	DESCRIPTION
STATUS_UNSUPPORTED	Parameter *Type* is set to an unsupported value.

Remarks

A driver can call the PoSetPowerRequest routine to request that the power manager override several types of default power behavior, which are specified as POWER_REQUEST_TYPE enumeration values. To restore the default behavior, the driver cancels the request by calling the **PoClearPowerRequest** routine.

The power manager maintains a count of the active requests for each power request type. The **PoSetPowerRequest** routine increments the count for the specified power request type by one. The **PoClearPowerRequest** routine decrements the count by one. A nonzero count indicates that requests from one or more components are active. After the count decrements to zero, the power manager restores the default behavior for the specified power request type.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

See Also

POWER_REQUEST_TYPE

PoCreatePowerRequest

PoSetPowerRequest

PoCreatePowerRequest function

1/25/2019 • 2 minutes to read • Edit Online

The **PoCreatePowerRequest** routine creates a power request object.

Syntax

```
NTSTATUS PoCreatePowerRequest(
  PVOID                    *PowerRequest,
  PDEVICE_OBJECT           DeviceObject,
  PCOUNTED_REASON_CONTEXT Context
);
```

Parameters

`PowerRequest`

A pointer to a location into which the routine writes a pointer to the newly created power request object. If the call fails, the routine writes **NULL** to this location.

`DeviceObject`

A pointer to the device object of the caller (a DEVICE_OBJECT structure).

`Context`

A pointer to a COUNTED_REASON_CONTEXT structure that describes why the caller is creating the power request object. This parameter is optional and can be set to **NULL**.

Return Value

PoCreatePowerRequest returns STATUS_SUCCESS if the call is successful. If the call fails, possible error return codes include the following:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The *DeviceObject* parameter is **NULL**.

STA **TUS** **_IN** **SUF** **FICI** **ENT** **_RE** **SO** **URC** **ES**	There is not enough memory available to create a power request object.

Remarks

This routine creates a power request object. To enable power requests, the caller should create one power request object and use that object for all calls to the PoSetPowerRequest and PoClearPowerRequest routines.

A driver can use power requests to override certain aspects of the computer's default power behavior. For example, a driver for a TV receiver device can use power requests to prevent the power manager from automatically blanking the display during extended periods of time in which no user interaction occurs.

When the power request object is no longer needed, the caller must delete the object by calling the PoDeletePowerRequest routine. The driver must delete the power request object before it deletes the device object that was used to create the power request object.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

PoCreatePowerRequest

PoEndDeviceBusy function

1/25/2019 • 2 minutes to read • Edit Online

The **PoEndDeviceBusy** routine marks the end of a period of time in which the device is busy.

Syntax

```
void PoEndDeviceBusy(
  PULONG IdlePointer
);
```

Parameters

`IdlePointer`

A pointer to an idle counter. This is a pointer value that was previously returned by the PoRegisterDeviceForIdleDetection routine. Because **PoRegisterDeviceForIdleDetection** might return a **NULL** pointer, the caller must verify that the pointer is non-**NULL** before it calls **PoEndDeviceBusy**.

Return Value

None

Remarks

The PoStartDeviceBusy and **PoEndDeviceBusy** routines mark the start and end of a time period in which a device is busy. Each call to **PoStartDeviceBusy** must be followed by a corresponding call to **PoEndDeviceBusy**. For more information about how these routines work together, see PoStartDeviceBusy.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

PoRegisterDeviceForIdleDetection

PoStartDeviceBusy

PoFxActivateComponent function

1/25/2019 • 4 minutes to read • Edit Online

The **PoFxActivateComponent** routine increments the activation reference count on the specified component.

Syntax

```
void PoFxActivateComponent(
  POHANDLE Handle,
  ULONG    Component,
  ULONG    Flags
);
```

Parameters

`Handle`

A handle that represents the registration of the device with the power management framework (PoFx). The device driver previously received this handle from the PoFxRegisterDevice routine.

`Component`

The index that identifies the component. This parameter is an index into the **Components** array in the PO_FX_DEVICE structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Flags`

The flags for the activation operation. Set this member to zero or to one of the following flag **PO_FX_FLAG_*XXX*** bits:

These two flag bits are mutually exclusive. For more information, see Remarks.

VALUE	MEANING
PO_FX_FLAG_BLOCKING 0x1	Make the condition change synchronous. If this flag is set, the routine that requests the condition change does not return control to the calling driver until the component hardware completes the transition to the new condition. This flag can be used only if the caller is running at IRQL < DISPATCH_LEVEL.

PO_FX_FLAG_ASYNC_ONLY 0x2	Make the condition change fully asynchronous. If this flag is set, the calling driver's callback routine is called from a thread other than the thread in which the routine that requests the condition change is called. Thus, the routine that requests the condition change always returns asynchronously without waiting for the callback to complete.

Return Value

None.

Remarks

Before a device driver can access a component in a device, the driver must first call **PoFxActivateComponent** to obtain an activation reference to the component. If the component is not already in the active condition, this call initiates a transition from the idle condition to the active condition. When this transition completes, PoFx calls the driver's ComponentActiveConditionCallback routine to notify the driver. The driver can access the hardware registers in a component only when the component is in the active condition.

If the component is already in the active condition when **PoFxActivateComponent** is called, no transition is required, and the *ComponentActiveConditionCallback* routine is not called.

After a component enters the active condition, it remains in the active condition for as long as the driver holds one or more activation references on the component. To release an activation reference, the driver calls the PoFxIdleComponent routine. When the driver releases the last activation reference on a component, **PoFxIdleComponent** initiates a transition from the active condition to the idle condition. A component that is in the idle condition can potentially enter a low-power Fx state.

If *Flags* = **PO_FX_FLAG_BLOCKING**, the **PoFxActivateComponent** call is synchronous. If the component is already in the active condition, the call increments the activation reference count and returns without waiting. Otherwise, **PoFxActivateComponent** waits to return until the component completes the transition to the active condition. In this case, if the component is not already in the F0 state when the call occurs, **PoFxActivateComponent** calls the driver's *ComponentIdleStateCallback* routine to initiate the transition to F0. After the component enters the F0 state, **PoFxActivateComponent** calls the driver's *ComponentActiveConditionCallback* routine to inform the driver that the component is in the active condition. These callbacks occur in the same thread as the call to **PoFxActivateComponent**, and **PoFxActivateComponent** returns only after the *ComponentActiveConditionCallback* callback returns.

If *Flags* = **PO_FX_FLAG_ASYNC_ONLY**, the **PoFxActivateComponent** call is asynchronous. If the component is already in the active condition, the call increments the activation reference count and returns. Otherwise, **PoFxActivateComponent** schedules the *ComponentIdleStateCallback* (if necessary) and *ComponentActiveConditionCallback* callbacks to occur in another thread, and then returns without waiting for either callback to occur. The callbacks can occur before or after **PoFxActivateComponent** returns. The driver relies on the *ComponentActiveConditionCallback* callback to determine when the component completes the transition to the active condition.

The driver can set *Flags* = 0 to indicate that it does not care whether the **PoFxActivateComponent** call is synchronous or asynchronous. In this case, PoFx decides whether to make the call synchronous or asynchronous.

Two or more code paths in the same driver might need to concurrently access a particular component. The **PoFxActivateComponent** and **PoFxIdleComponent** routines use activation reference counts to enable the various parts of the driver to independently maintain access to the component without requiring the driver to

centrally manage access to the component.

PoFx maintains an activation reference count for each component in a device. A **PoFxActivateComponent** call increments this count by one, and a **PoFxIdleComponent** call decrements the count by one. When the count is nonzero, the component either is in the active condition or is in the process of switching to the active condition. A component that has a count of zero either is in the idle condition or is in the process of switching to the idle condition.

When a **PoFxActivateComponent** call causes the activation reference count to increment from 0 to 1, **PoFxActivateComponent** initiates a transition from the idle condition to the active condition. When a **PoFxIdleComponent** call causes the count to decrement from 1 to 0, **PoFxIdleComponent** initiates a transition from the active condition to the idle condition.

PoFx notifies the driver when a transition between the active condition and idle condition occurs. A *ComponentActiveConditionCallback* callback notifies the driver of a transition to the active condition, and a ComponentIdleConditionCallback callback notifies the driver of a transition to the idle condition. When a **PoFxActivateComponent** or **PoFxIdleComponent** call simply increments or decrements the activation reference count without causing such a transition, the driver receives no notification.

Requirements

Minimum supported client	Available starting with Windows 8.

PoFxIdleComponent

PoFxRegisterDevice

PoFxCompleteDevicePowerNotRequired function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxCompleteDevicePowerNotRequired** routine notifies the power management framework (PoFx) that the calling driver has completed its response to a call to the driver's DevicePowerNotRequiredCallback callback routine.

Syntax

```
void PoFxCompleteDevicePowerNotRequired(
  POHANDLE Handle
);
```

Parameters

`Handle`

A handle that represents the registration of the device with PoFx. The device driver previously received this handle from the PoFxRegisterDevice routine.

Return Value

None.

Remarks

After PoFx calls the driver's DevicePowerNotRequiredCallback callback routine, the driver must respond by calling **PoFxCompleteDevicePowerNotRequired**.

PoFx calls the driver's *DevicePowerNotRequiredCallback* routine to inform the driver that the device is no longer required to remain in the D0 state. In response to this call, the driver can choose to enter a low-power Dx state or to remain in the D0 state. After the driver has completed its response to the *DevicePowerNotRequiredCallback* call, the driver calls **PoFxCompleteDevicePowerNotRequired** to inform PoFx. The **PoFxCompleteDevicePowerNotRequired** call can occur either during or after the *DevicePowerNotRequiredCallback* call.

DevicePowerNotRequiredCallback

PoFxRegisterDevice

PoFxCompleteIdleCondition function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxCompleteIdleCondition** routine informs the power management framework (PoFx) that the specified component has completed a pending change to the idle condition.

Syntax

```
void PoFxCompleteIdleCondition(
  POHANDLE Handle,
  ULONG    Component
);
```

Parameters

`Handle`

A handle that represents the registration of the device with PoFx. The device driver previously received this handle from the PoFxRegisterDevice routine.

`Component`

The index that identifies the component. This parameter is an index into the **Components** array in the PO_FX_DEVICE structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N−1.

Return Value

None.

Remarks

After PoFx calls the driver's ComponentIdleConditionCallback callback routine, the driver must respond by calling **PoFxCompleteIdleCondition**.

When PoFx calls the driver's *ComponentIdleConditionCallback* routine, the driver initiates a transition to the idle condition in the specified component. After this transition is complete, the driver calls **PoFxCompleteIdleCondition** to notify PoFx. The **PoFxCompleteIdleCondition** call can occur either during or after the *ComponentIdleConditionCallback* call.

PO_FX_DEVICE

PoFxRegisterDevice

PoFxCompleteIdleState function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxCompleteIdleState** routine informs the power management framework (PoFx) that the specified component has completed a pending change to an Fx state.

Syntax

```
void PoFxCompleteIdleState(
  POHANDLE Handle,
  ULONG    Component
);
```

Parameters

`Handle`

A handle that represents the registration of the device with PoFx. The device driver previously received this handle from the PoFxRegisterDevice routine.

`Component`

The index that identifies the component. This parameter is an index into the **Components** array in the PO_FX_DEVICE structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N−1.

Return Value

None,

Remarks

After PoFx calls the driver's ComponentIdleStateCallback callback routine, the driver must respond by calling **PoFxCompleteIdleState**.

PoFx calls the driver's *ComponentIdleStateCallback* routine to tell the driver to switch the specified component to a new Fx power state. After the driver completes the transition to the new Fx state, the driver calls **PoFxCompleteIdleState** to inform PoFx. The **PoFxCompleteIdleState** call can occur either during or after the *ComponentIdleStateCallback* call.

ComponentIdleStateCallback

PO_FX_DEVICE

PoFxRegisterDevice

PoFxIdleComponent function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxIdleComponent** routine decrements the activation reference count on the specified component.

Syntax

```
void PoFxIdleComponent(
  POHANDLE Handle,
  ULONG    Component,
  ULONG    Flags
);
```

Parameters

`Handle`

A handle that represents the registration of the device with the power management framework (PoFx). The device driver previously received this handle from the PoFxRegisterDevice routine.

`Component`

The index that identifies the component. This parameter is an index into the **Components** array in the PO_FX_DEVICE structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Flags`

The flags for the idle operation. Set this member to zero or to one of the following flag PO_FX_FLAG_XXX bits:

- **PO_FX_FLAG_BLOCKING**
- **PO_FX_FLAG_ASYNC_ONLY**

These two flag bits are mutually exclusive. For more information, see Remarks.

Return Value

None.

Remarks

A device driver calls **PoFxIdleComponent** to release an activation reference to a component in a device. The driver obtained the activation reference in a previous call to the PoFxActivateComponent routine. The driver should hold an activation reference on a component only while the driver needs to access the component. To hold an activation reference on a component that is not being used prevents the component from entering a low-power Fx state.

If the driver holds no other activation references to the component, **PoFxIdleComponent** initiates a transition from the active condition to the idle condition. When this transition completes, PoFx calls the driver's ComponentIdleConditionCallback routine to notify the driver. If the driver retains one or more additional activation references on the component, the component stays in the active condition, and the *ComponentIdleConditionCallback* routine is not called.

PoFx maintains an activation reference count for each component in the device. The **PoFxActivateComponent** routine increments this count, and **PoFxIdleComponent** decrements it. The component remains in the active condition while this count is nonzero. When the driver releases its last activation reference to a component, the count decrements to zero and the component enters the idle condition. After the component enters the idle condition, PoFx can potentially switch the component to a low-power Fx state. For more information, see PoFxActivateComponent.

If *Flags* = **PO_FX_FLAG_BLOCKING**, the **PoFxIdleComponent** call is synchronous. In this case, **PoFxIdleComponent** waits to return until the component completes the transition to the idle condition. **PoFxIdleComponent** calls the driver's *ComponentIdleConditionCallback* callback routine to inform the driver that the component is in the idle condition. This callback occurs in the same thread as the call to **PoFxIdleComponent**, and **PoFxIdleComponent** returns only after the *ComponentIdleConditionCallback* callback returns.

If *Flags* = **PO_FX_FLAG_ASYNC_ONLY**, the **PoFxIdleComponent** call is asynchronous. In this case, **PoFxIdleComponent** schedules the *ComponentIdleConditionCallback* callback to occur in another thread, and then returns without waiting for the callback to occur. The callback can occur before or after **PoFxIdleComponent** returns. The driver should rely on the *ComponentIdleConditionCallback* callback to determine when the component completes the transition to the idle condition. Until this callback occurs, the driver should assume that the component might still be in the active condition.

The driver can set *Flags* = 0 to indicate that it does not care whether the **PoFxIdleComponent** call is synchronous or asynchronous. In this case, PoFx decides whether to make the call synchronous or asynchronous.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	wdm.h

PO_FX_DEVICE

PO_FX_FLAG_XXX

PoFxActivateComponent

PoFxRegisterDevice

PoFxIssueComponentPerfStateChange function

1/25/2019 • 3 minutes to read • Edit Online

The **PoFxIssueComponentPerfStateChange** routine submits a request to place a device component in a particular performance state.

Syntax

```
void PoFxIssueComponentPerfStateChange(
  POHANDLE                 Handle,
  ULONG                    Flags,
  ULONG                    Component,
  PPO_FX_PERF_STATE_CHANGE PerfChange,
  PVOID                    Context
);
```

Parameters

`Handle`

A handle that represents the registration of the device with PoFx. The device driver previously received this handle from the PoFxRegisterDevice routine.

`Flags`

The flags that modify the behavior of the performance state change operation. Set this member to zero or to one of the following flag **PO_FX_FLAG_*XXX*** bits:

These two flag bits are mutually exclusive. For more information, see Remarks.

VALUE	MEANING
PO_FX_FLAG_BLOCKING 0x1	Make the condition change synchronous. If this flag is set, the routine that requests the condition change does not return control to the calling driver until the component hardware completes the transition to the new condition. This flag can be used only if the caller is running at IRQL < DISPATCH_LEVEL.
PO_FX_FLAG_ASYNC_ONLY 0x2	Make the condition change fully asynchronous. If this flag is set, the calling driver's callback routine is called from a thread other than the thread in which the routine that requests the condition change is called. Thus, the routine that requests the condition change always returns asynchronously without waiting for the callback to complete.

`Component`

The index that identifies the component. This parameter is an index into the **Components** array in the PO_FX_DEVICE structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`PerfChange`

A pointer to a PO_FX_PERF_STATE_CHANGE structure that represents the new performance state of the component.

`Context`

A pointer to the context for the ComponentPerfStateCallback callback routine. This parameter is optional. It is provided so that a driver or device context can be passed to the callback routine. If this parameter is not used, it must be set to NULL.

Return Value

None

Remarks

When a driver calls **PoFxIssueComponentPerfStateChange**, the power management framework (PoFx) requests the platform extension plug-in (PEP) to place the component's performance state set in the specified performance state. This routine may be used with both discrete and range-based types of performance state sets. For more information about discrete and range-based performance state sets, see PO_FX_PERF_STATE_TYPE.

If *Flags* = **PO_FX_FLAG_BLOCKING**, the **PoFxIssueComponentPerfStateChange** call is synchronous. In this case, **PoFxIssueComponentPerfStateChange** waits to return until the component completes the performance state transition. The driver's ComponentPerfStateCallback routine is called to inform the driver that the component's performance state change is complete. This callback occurs in the same thread as the call to **PoFxIssueComponentPerfStateChange**, and **PoFxIssueComponentPerfStateChange** returns only after the *ComponentPerfStateCallback* callback returns.

If *Flags* = **PO_FX_FLAG_ASYNC_ONLY**, the **PoFxIssueComponentPerfStateChange** call is asynchronous. In this case, **PoFxIssueComponentPerfStateChange** schedules the ComponentPerfStateCallback routine to occur in another thread, and then returns without waiting for the callback to occur. The callback can occur before or after **PoFxIssueComponentPerfStateChange** returns. The driver should rely on the *ComponentPerfStateCallback* routine to determine when the component completes the transition to the new performance state.

The driver can set *Flags* = 0 to indicate that it does not care whether the **PoFxIssueComponentPerfStateChange** call is synchronous or asynchronous. In this case, PoFx decides the synchronicity of the call based on whether the PEP uses a synchronous or asynchronous request to issue the performance state change to the component.

If *Flags* = **PO_FX_FLAG_ASYNC_ONLY** or no flags are passed, this routine requires an IRQL of <= DISPATCH_LEVEL. If *Flags* = **PO_FX_FLAG_BLOCKING**, this routine requires an IRQL of <= APC_LEVEL.

This function will always result in a call to the ComponentPerfStateCallback routine regardless of the synchronicity of the call. Because the PEP may choose to deny the request to change the performance state, the driver must wait until receiving the callback before committing the performance state to hardware.

Only a single call of the **PoFxIssueComponentPerfStateChange** routine is allowed at a time per component, regardless of whether the call is synchronous or asynchronous. After issuing a performance state change request, the driver must wait until the ComponentPerfStateCallback is received before calling this routine again, even if the request involves a different performance state set. If this routine is called again before waiting until the *ComponentPerfStateCallback* is received, a bugcheck will occur.

Requirements

Minimum supported client	Available starting with Windows 10.
Target Platform	Universal
Header	wdm.h
Library	Ntoskrnl.lib
DLL	Ntoskrnl.exe
IRQL	"<= APC_LEVEL or <= DISPATCH_LEVEL (See Remarks section)"

Device Performance State Management

PO_FX_PERF_STATE_TYPE

PoFxIssueComponentPerfStateChangeMultiple

PoFxRegisterComponentPerfStates

PoFxIssueComponentPerfStateChangeMultiple function

1/25/2019 • 3 minutes to read • Edit Online

The **PoFxIssueComponentPerfStateChangeMultiple** routine submits a request to change the performance states in multiple performance state sets simultaneously for a device component.

Syntax

```
void PoFxIssueComponentPerfStateChangeMultiple(
  POHANDLE                  Handle,
  ULONG                     Flags,
  ULONG                     Component,
  ULONG                     PerfChangesCount,
  PO_FX_PERF_STATE_CHANGE [] PerfChanges,
  PVOID                     Context
);
```

Parameters

`Handle`

A handle that represents the registration of the device with PoFx. The device driver previously received this handle from the PoFxRegisterDevice routine.

`Flags`

The flags that modify the behavior of the performance state change operation. Set this member to zero or to one of the following flag **PO_FX_FLAG_*XXX*** bits:

These two flag bits are mutually exclusive. For more information, see Remarks.

VALUE	MEANING
PO_FX_FLAG_BLOCKING 0x1	Make the condition change synchronous. If this flag is set, the routine that requests the condition change does not return control to the calling driver until the component hardware completes the transition to the new condition. This flag can be used only if the caller is running at IRQL < DISPATCH_LEVEL.

PO_FX_FLAG_ASYNC_ONLY 0x2	Make the condition change fully asynchronous. If this flag is set, the calling driver's callback routine is called from a thread other than the thread in which the routine that requests the condition change is called. Thus, the routine that requests the condition change always returns asynchronously without waiting for the callback to complete.

`Component`

The index that identifies the component. This parameter is an index into the **Components** array in the PO_FX_DEVICE structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`PerfChangesCount`

The number of performance state change requests contained in the *PerfChanges* array.

`PerfChanges`

The first element in an array of PO_FX_PERF_STATE_CHANGE structures that represent the performance states the driver intends to transition to. Each array element represents a single performance state change request.

`Context`

A pointer to the context for the ComponentPerfStateCallback callback routine. This parameter is optional. It is provided so that a driver or device context can be passed to the callback routine. If this parameter is not used, it must be set to NULL.

Return Value

None

Remarks

A driver calls **PoFxIssueComponentPerfStateChangeMultiple**, the power management framework (PoFx) will request the platform extension plug-in (PEP) to place the component's performance state sets in the specified performance states. This routine may be used with both discrete and range-based types of performance state sets. For more information about discrete and range-based performance state sets, see PO_FX_PERF_STATE_TYPE.

If *Flags* = **PO_FX_FLAG_BLOCKING**, the **PoFxIssueComponentPerfStateChangeMultiple** call is synchronous. In this case, **PoFxIssueComponentPerfStateChangeMultiple** waits to return until the component completes the performance state transition. The driver's ComponentPerfStateCallback routine is called to inform the driver that the component's performance state change is complete. This callback occurs in the same thread as the call to **PoFxIssueComponentPerfStateChangeMultiple**, and **PoFxIssueComponentPerfStateChangeMultiple** returns only after the *ComponentPerfStateCallback* callback returns.

If *Flags* = **PO_FX_FLAG_ASYNC_ONLY**, the **PoFxIssueComponentPerfStateChangeMultiple** call is asynchronous. In this case, **PoFxIssueComponentPerfStateChangeMultiple** schedules the ComponentPerfStateCallback routine to occur in another thread, and then returns without waiting for the callback to occur. The callback can occur before or after **PoFxIssueComponentPerfStateChangeMultiple** returns. The driver should rely on the *ComponentPerfStateCallback* routine to determine when the component completes the transition to the new performance state.

The driver can set *Flags* = 0 to indicate that it does not care whether the

PoFxIssueComponentPerfStateChangeMultiple call is synchronous or asynchronous. In this case, PoFx decides the synchronicity of the call based on whether the PEP uses a synchronous or asynchronous request to issue the performance state change to the component.

If *Flags* = **PO_FX_FLAG_ASYNC_ONLY** or no flags are passed, this routine requires an IRQL of <= DISPATCH_LEVEL. If *Flags* = **PO_FX_FLAG_BLOCKING**, this routine requires an IRQL of <= APC_LEVEL.

This function will always result in a call to the ComponentPerfStateCallback routine regardless of the synchronicity of the call. Because the PEP may choose to deny the request to change the performance states, the driver must wait until receiving the callback before committing the performance states to hardware.

Only a single call of the **PoFxIssueComponentPerfStateChangeMultiple** routine is allowed at a time per component, regardless of whether the call is synchronous or asynchronous. After issuing a performance state change request, the driver must wait until the ComponentPerfStateCallback is received before calling this routine again, even if the request involves a different performance state set. If this routine is called again before waiting until the *ComponentPerfStateCallback* is received, a bugcheck will occur.

Device Performance State Management

PO_FX_PERF_STATE_TYPE

PoFxIssueComponentPerfStateChange

PoFxRegisterComponentPerfStates

PoFxNotifySurprisePowerOn function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxNotifySurprisePowerOn** routine notifies the power management framework (PoFx) that a device was turned on as a side effect of supplying power to some other device.

Syntax

```
void PoFxNotifySurprisePowerOn(
  PDEVICE_OBJECT Pdo
);
```

Parameters

`Pdo`

A pointer to a physical device object (PDO). This parameter points to a DEVICE_OBJECT structure that represents the physical device that was turned on as a side effect. The caller is always the bus driver that enumerated the PDO.

Return Value

None.

Remarks

Device drivers should not call this routine. This routine should be called only by bus drivers.

A bus driver calls this routine to inform PoFx that a device that is not currently being used was incidentally turned on at the same time as a second device. For example, the first device might share a power rail with the second device. Thus, power cannot be supplied to the second device without supplying power, as a side effect, to the first device. Because the first device is not being used, this device should be configured to consume as little power as possible.

To request a transition to a D0 power state, a device driver sends an IRP_MN_SET_POWER request down its device stack. Through the PDO in this stack, the bus driver that is the parent of this device receives the request and responds by supplying power to the device. However, if the bus driver cannot turn on this device without also turning on a second, unused device, the bus driver can call **PoFxNotifySurprisePowerOn** to reduce the power consumed by the unused device.

On entry to **PoFxNotifySurprisePowerOn**, the device represented by the *Pdo* parameter is in an uninitialized D0 power state. In this state, all of the components in the device are typically turned on. In response to the **PoFxNotifySurprisePowerOn** call, PoFx configures the device in an initialized D0 state. During this configuration, PoFx switches as many components as it can to low-power Fx power states. If possible, PoFx configures the device in a "hot D3" state, which is really a D0 state in which all of the individual components in the device are turned off.

PoFxNotifySurprisePowerOn can configure only a device that was registered with PoFx when the device was previously turned off. However, unless the bus driver knows that a device is not registered, the bus driver should call **PoFxNotifySurprisePowerOn** when the device is turned on as a side effect.

If the bus driver fails to call this routine when the device is turned on, the device hardware might stay in the fully on state for an indefinite time, during which PoFx assumes that the device remains in the D3 (fully off) power state.

Call **PoFxNotifySurprisePowerOn** only if the device was turned on incidentally, as a side effect of turning on some other device. If the bus driver restores power to a device in response to a DevicePowerRequiredCallback callback or an IRP_MN_SET_POWER request for a D0 transition, call the PoFxReportDevicePoweredOn routine instead to inform PoFx when power is restored to the device.

IRP_MN_SET_POWER

PoFxReportDevicePoweredOn

PoFxPowerControl function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxPowerControl** routine sends a power control request to the power management framework (PoFx).

Syntax

```
NTSTATUS PoFxPowerControl(
  POHANDLE Handle,
  LPCGUID  PowerControlCode,
  PVOID    InBuffer,
  SIZE_T   InBufferSize,
  PVOID    OutBuffer,
  SIZE_T   OutBufferSize,
  PSIZE_T  BytesReturned
);
```

Parameters

`Handle`

A handle that represents the registration of the device with PoFx. The device driver previously received this handle from the PoFxRegisterDevice routine.

`PowerControlCode`

A pointer to the power control code. This code is a GUID value that specifies the requested operation.

`InBuffer`

A pointer to a caller-allocated buffer that contains the input data for the operation. The format for the data in this buffer depends on the power control code specified by the *PowerControlCode* parameter. The *InBuffer* parameter is optional and can be specified as NULL if the specified operation requires no input data.

`InBufferSize`

The size, in bytes, of the input buffer that is pointed to by the *InBuffer* parameter. If *InBuffer* is NULL, set *InBufferSize* to zero.

`OutBuffer`

A pointer to a caller-allocated buffer that is to contain the output data from the operation. The format for the data in this buffer depends on the power control code specified by the *PowerControlCode* parameter. The *OutBuffer* parameter is optional and can be specified as NULL if the specified operation produces no output data.

`OutBufferSize`

The size, in bytes, of the output buffer that is pointed to by the *OutBuffer* parameter. If *OutBuffer* is NULL, set *OutBufferSize* to zero.

`BytesReturned`

A pointer to a location into which the routine writes the number of bytes of data that were written to the buffer that is pointed to by *OutBuffer*. The number of bytes written will be less than or equal to *OutBufferSize*. This parameter is optional and can be specified as **NULL** if the caller does not need to know how many bytes were written to the

output buffer.

Return Value

PoFxPowerControl returns **STATUS_SUCCESS** if the requested operation succeeds. Possible error return values include the following status code.

RETURN CODE	DESCRIPTION
STATUS_NOT_IMPLEMENTED	The requested power control operation is not implemented.
STATUS_NOT_SUPPORTED	The power engine plug-in (PEP) does not acknowledge support for this device.

Remarks

A device driver calls this routine to send a power control request directly to PoFx. A power control request is similar to an I/O control request (IOCTL). Unlike an IOCTL, however, a power control request is sent directly to PoFx and is not observed by other device drivers in the device stack. During a **PoFxPowerControl** call, PoFx synchronously performs the requested operation.

Similarly, PoFx can send a power control request directly to the device driver. The driver handles this request in its PowerControlCallback routine.

PoFx delegates the handling of all power control requests to the power engine plug-in (PEP). The PEP is an optional software component that performs power management tasks that are specific to a particular product line of processor or System on a Chip (SoC) modules. If the hardware vendor for the processor or SoC supplies a PEP for a hardware platform, this PEP might handle custom power control requests from a device driver, or might send custom power control requests to the driver's *PowerControlCallback* routine. The vendor can specify a set of *PowerControlCode* GUIDs and define the operations that are designated by these GUIDs. As an option, a device driver can contain platform-specific code to handle or to send requests for these operations.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal
Header	wdm.h

Library	Ntoskrnl.lib
DLL	Ntoskrnl.exe
IRQL	"<= DISPATCH_LEVEL"

PoFxRegisterDevice

PowerControlCallback

PoFxPowerOnCrashdumpDevice function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxPowerOnCrashdumpDevice** routine requests that a crash-dump device be turned on.

Syntax

```
NTSTATUS PoFxPowerOnCrashdumpDevice(
  POHANDLE Handle,
  PVOID    Context
);
```

Parameters

`Handle`

A handle that represents the registration of the crash-dump device with the Windows power management framework (PoFx). The device driver previously received this handle from the PoFxRegisterDevice routine.

`Context`

A pointer to a device-specific context. This pointer is passed as an input parameter to the PowerOnDumpDeviceCallback callback routine that is implemented by the platform extension plug-in (PEP) for the device. The context information is stored in a format that is defined by the device driver and is understood by the PEP. This context is opaque to the operating system. The driver can set this parameter to NULL if the PEP does not require a context.

Return Value

PoFxPowerOnCrashdumpDevice returns STATUS_SUCCESS if the routine succeeds in turning on power to the device. Possible error return values include the following status codes.

RETURN VALUE	DESCRIPTION
STA TUS _IN VAL ID_P ARA MET ER	Not a valid handle value.
STA TUS _UN SUC CES SFU L	The PEP for this device does not implement a *PowerOnDumpDeviceCallback* callback routine; or the PEP failed to turn on the device.

Remarks

The driver for a crash-dump device calls this routine to request that the platform extension plug-in (PEP) turn the device on so that a crash dump can be saved. All devices in the crash-dump device chain (which might include a storage controller, a PCI controller, and so on) must be turned on before a crash-dump file can be written to disk.

For more information about crash dumps, see Kernel-Mode Dump Files.

This routine can be called at IRQL <= HIGH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 8.1.
Target Platform	Windows
Header	wdm.h (include Pepfx.h)
Library	Ntoskrnl.lib
IRQL	"<= HIGH_LEVEL"

PoFxRegisterDevice

PowerOnDumpDeviceCallback

PoFxQueryCurrentComponentPerfState function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxQueryCurrentComponentPerfState** routine retrieves the active performance state in a component's performance state set.

Syntax

```
NTSTATUS PoFxQueryCurrentComponentPerfState(
  POHANDLE   Handle,
  ULONG      Flags,
  ULONG      Component,
  ULONG      SetIndex,
  PULONGLONG CurrentPerf
);
```

Parameters

`Handle`

A handle that represents the registration of the device with power management framework (PoFx). The device driver previously received this handle from the PoFxRegisterDevice routine.

`Flags`

Set to 0. Currently, no flags are defined for this routine.

`Component`

The index that identifies the component whose performance state is being retrieved. This parameter is an index into the **Components** array in the PO_FX_DEVICE structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N−1.

`SetIndex`

The index that identifies the performance state set whose performance is being queried. This parameter is an index into the **PerfStateSets** array in the PO_FX_COMPONENT_PERF_INFO structure that the device driver used to register the component performance states with PoFx. If the **PerfStateSets** array contains N elements, performance state set indexes range from 0 to N−1.

`CurrentPerf`

A pointer to variable in which the current performance state for the specified performance state set is returned. For more information about the value that is returned, see Remarks.

Return Value

PoFxQueryCurrentComponentPerfState returns **STATUS_SUCCESS** if the requested operation succeeds. Possible error return values include the following status codes.

RETURN CODE	DESCRIPTION

STA TUS _IN VAL ID_ PAR AM ETE R	The caller supplied an invalid index for the component or component state set.

Remarks

A driver can call the **PoFxQueryCurrentComponentPerfState** routine to retrieve the current performance state of a given performance state set for a component. If the call succeeds, the *CurrentPerf* parameter is overwritten with a pointer to a value that specifies the current performance state of the set. This value may be one of the following, depending on the contents of the PO_FX_COMPONENT_PERF_SET structure that the driver passed to the PoFxRegisterComponentPerfStates routine:

- For a performance state set that represents a continuous distribution of performance states, this is a value between the **Minimum** and **Maximum** members of the PO_FX_COMPONENT_PERF_SET structure.
- For a performance state set that represents a discrete number of performance states, this value is an index into the **States** member of the PO_FX_COMPONENT_PERF_SET structure .

This call always executes synchronously.

Requirements

Minimum supported client	Available starting with Windows 10.

PO_FX_COMPONENT_PERF_INFO

PO_FX_COMPONENT_PERF_SET

PoFxRegisterComponentPerfStates

PoFxRegisterComponentPerfStates function

1/25/2019 • 4 minutes to read • Edit Online

The **PoFxRegisterComponentPerfStates** routine registers a device component for performance state management by the power management framework (PoFx).

Syntax

```
NTSTATUS PoFxRegisterComponentPerfStates(
  POHANDLE                              Handle,
  ULONG                                 Component,
  ULONGLONG                             Flags,
  PPO_FX_COMPONENT_PERF_STATE_CALLBACK ComponentPerfStateCallback,
  PPO_FX_COMPONENT_PERF_INFO           InputStateInfo,
  PPO_FX_COMPONENT_PERF_INFO           *OutputStateInfo
);
```

Parameters

`Handle`

A handle that represents the registration of the device with PoFx. The device driver previously received this handle from the PoFxRegisterDevice routine.

`Component`

The index that identifies the component whose performance states will be managed. This parameter is an index into the **Components** array in the PO_FX_DEVICE structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N−1.

`Flags`

The flags that modify the behavior of the performance state registration. Set this member to zero or to one of the following flag **PO_FX_FLAG_PERF_*XXX*** bits:

VALUE	MEANING
PO_FX_FLAG_PERF_POTION_AL 0x1	Indicates that the driver can change performance states without assistance from the platform extension plug-in (PEP), or that the driver is registering performance states with PoFx for logging purposes only. If this flag is set, the **PoFxRegisterComponentPerfStates** call will still succeeded if the PEP does not support performance states for the component.

PO_FX_FLAG_PERF_QUERY_ON_F0 0x2	For some devices, the PEP may need to a place a performance state set for a component into a certain performance state (known as a *nominal performance state*) when it idles the component. Drivers set this flag if the component contains nominal performance states, in which case PoFx will query the PEP to determine the current performance state when the component transitions to F0.
PO_FX_FLAG_PERF_QUERY_ON_ALLID LE_STATES 0x4	For some devices, the PEP may need to a place a performance state set for a component into a certain performance state (known as a *nominal performance state*) when it transitions the component between idle states. Drivers set this flag if this component contains nominal performance states, in which case PoFx will query the PEP to determine the current performance state when the component transitions between idle states.

`ComponentPerfStateCallback`

A pointer to a ComponentPerfStateCallback routine. This routine is called when PoFx has completed logging and notifying the PEP about a performance state transition that is initiated by the driver's call to PoFxIssueComponentPerfStateChange or PoFxIssueComponentPerfStateChangeMultiple. This callback may be the same for all components and all devices; PoFx provides the device handle and component index in each completion call.

`InputStateInfo`

If the driver provides performance state info, this parameter contains a pointer to a driver allocated PO_FX_COMPONENT_PERF_INFO structure that provides performance state information to PoFx. If the driver requires performance state information from the PEP, this parameter must be set to NULL.

`OutputStateInfo`

If the driver requires performance state information from the PEP, after a successful registration this parameter contains a pointer to a PO_FX_COMPONENT_PERF_INFO structure that provides performance state information defined by the PEP. If the driver provides performance state info, this parameter must be set to NULL.

The memory allocated for this parameter is managed by PoFx, and the driver should not free this memory when the device is removed. The lifetime of this memory is guaranteed to exceed the lifetime of the PoFx component that contains these performance state sets.

Return Value

PoFxRegisterComponentPerfStates returns **STATUS_SUCCESS** if PoFx accepts the device's registration of performance states. If any of the necessary information is not provided or incorrect, registration will fail with a return code other than **STATUS_SUCCESS**. Possible error return values include the following status codes.

RETURN CODE	DESCRIPTION
STATUS_NOT_IMPLEMENTED	The *Flags* parameter does not include the **PO_FX_FLAG_PERF_PEP_OPTIONAL** flag and the PEP is not able to provide performance state management for this device.
STATUS_INVALID_PARAMETER	Both *InputStateInfo* and *OutputStateInfo* are NULL or both of these parameters are not NULL, or there are no performance state sets in the PO_FX_COMPONENT_PERF_INFO structure that was assigned to the *InputStateInfo* parameter.

Remarks

Note that PoFx performs a deep-copy of the device's structures into its memory.

Either the driver or the platform extension plug-in (PEP) may provide information about the performance states supported by each component:

- If the driver provides performance state information, the driver must set the *InputStateInfo* parameter to a pointer to a PO_FX_COMPONENT_PERF_INFO structure that contains the performance state information. Otherwise, the driver must set this parameter to NULL.
- If the PEP provides performance state information, the driver must set the *OutputStateInfo* parameter to a valid pointer to a PO_FX_COMPONENT_PERF_INFO structure that receives the performance state information. Otherwise, the driver must set this parameter to NULL.

If the PEP does not support performance states, the driver may register for performance state support with PoFx for logging purposes only.

If the driver registers for performance state support for logging purposes only, or if the driver can function correctly with or without PEP support for performance state management, the driver must set the **PO_FX_FLAG_PERF_PEP_OPTIONAL** flag in the *Flags* parameter. If the flag is set, the registration call will succeed even if the PEP does not provide support for performance states.

If the driver requires the PEP to provide performance state information, the driver cannot set the **PO_FX_FLAG_PERF_PEP_OPTIONAL** flag in the *Flags* parameter.

PoFxRegisterDevice

PoFxRegisterCrashdumpDevice function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxRegisterCrashdumpDevice** routine registers a crash-dump device.

Syntax

```
NTSTATUS PoFxRegisterCrashdumpDevice(
  POHANDLE Handle
);
```

Parameters

`Handle`

A handle that represents the registration of the crash-dump device with the Windows power management framework (PoFx). The device driver previously received this handle from the PoFxRegisterDevice routine.

Return Value

PoFxRegisterCrashdumpDevice returns STATUS_SUCCESS if the routine successfully registers the crash-dump device. Possible error return values include the following status codes.

RETURN VALUE	DESCRIPTION
STA TUS _IN VAL ID_P ARA MET ER	Not a valid handle value.
STA TUS _UN SUC CES SFU L	There is no PEP for this device.

Remarks

This routine is called by the driver for a crash-dump device to inform PoFx that the device is part of the crash-dump device chain. Several devices (storage controller, PCI controller, and so on) might need to be turned on so that the Windows kernel can write a crash-dump file to disk. When a fatal system error occurs, the kernel tries to turn on the crash-dump devices and save the crash-dump file.

The driver must call PoFxRegisterDevice to register the device with PoFx before calling **PoFxRegisterCrashdumpDevice**.

The driver for a crash-dump device can call the PoFxPowerOnCrashdumpDevice routine to request that the PEP turn the device on.

For more information about crash dumps, see Kernel-Mode Dump Files.

PoFxRegisterCrashdumpDevice must be called at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 8.1.
Target Platform	Windows
Header	wdm.h (include Pepfx.h)
Library	Ntoskrnl.lib
IRQL	PASSIVE_LEVEL

PoFxPowerOnCrashdumpDevice

PoFxRegisterDevice

PoFxRegisterDevice function

1/25/2019 • 3 minutes to read • Edit Online

The **PoFxRegisterDevice** routine registers a device with the power management framework (PoFx).

Syntax

```
NTSTATUS PoFxRegisterDevice(
  PDEVICE_OBJECT Pdo,
  PPO_FX_DEVICE  Device,
  POHANDLE       *Handle
);
```

Parameters

`Pdo`

A pointer to a physical device object (PDO). This parameter points to a DEVICE_OBJECT structure that represents the physical device that is being registered. The caller is the power policy owner for the device, which is typically the device's function driver.

`Device`

A pointer to a caller-allocated PO_FX_DEVICE structure that contains the registration information for the device. This structure contains pointers to a set of callback routines that are implemented by the device driver. PoFx calls these routines to communicate with the driver.

`Handle`

A pointer to a location into which the routine writes a handle that represents the registration of the device with PoFx. The device driver passes this handle as an input parameter to the other **PoFx*Xxx*** routines that it calls. The driver must first call **PoFxRegisterDevice** to register the device before the driver calls any other **PoFx*Xxx*** routines to power-manage the device.

Return Value

PoFxRegisterDevice returns **STATUS_SUCCESS** if the routine successfully registers the device. Possible error return values include the following status codes.

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	*Pdo* is NULL; or the **PPO_FX_DEVICE** structure has an invalid version number or a component count of zero; or the number of idle states specified for a component is zero; or the description of an idle state is invalid.

STATUS_DEVICE_NOT_READY	The device is not ready.
STATUS_INSUFFICIENT_RESOURCES	Insufficient resources are available to complete the registration.

Remarks

A device driver typically calls this routine from the driver's IRP_MN_START_DEVICE request handler. The driver must not call this routine before the device receives an **IRP_MN_START_DEVICE** request. The device receives the first **IRP_MN_START_DEVICE** request when the device is being started for the first time. The device receives an additional **IRP_MN_START_DEVICE** request each time the device is restarted after being stopped for resource balancing. A **PoFxRegisterDevice** call to register a device that is already registered is a fatal error and causes a bug check. Note that PoFx performs a deep-copy of the device structures into its memory.

Before the driver calls **PoFxRegisterDevice**, the device must meet the following conditions:

- The device (that is, the PDO) is not already registered with PoFx.
- The device is in the D0 (fully on) power state.
- The device is in the running condition.
- Every component in the device is in the F0 (fully on) power state.
- Every component is in the active condition.

By registering the device with PoFx, the driver assumes the responsibility for informing PoFx when a component is actively being used and when the component is idle. While the device is registered, the driver must call the PoFxActivateComponent routine to gain access to a component's hardware registers, and the driver must call the PoFxIdleComponent routine to notify PoFx when the driver no longer requires access to the component.

After a driver calls **PoFxRegisterDevice** to register a device with PoFx, all components in the device are fully on and in the active condition so that the driver can finish initializing the hardware. To start active power management, the driver must call the PoFxStartDevicePowerManagement routine.

By default, **PoFxStartDevicePowerManagement** switches all components to the idle condition. If the driver requires a component to be in the active condition immediately after power management starts, the driver must explicitly activate the component by calling the **PoFxActivateComponent** routine, and this call must occur after the **PoFxRegisterDevice** call but before the **PoFxStartDevicePowerManagement** call.

Typically, the Kernel-Mode Driver Framework (KMDF) driver for a single-component device does not call **PoFxRegisterDevice** to register the device with PoFx. Instead, this driver receives a PoFx registration handle when KMDF calls the driver's EvtDeviceWdmPostPoFxRegisterDevice callback function. For more information, see

Supporting Multiple Functional Power States for Single-Component Devices.

For information about how the KMDF driver for a multiple-component device registers with PoFx, see Supporting Multiple Functional Power States for Multiple-Component Devices.

PO_FX_DEVICE

PoFxActivateComponent

PoFxIdleComponent

PoFxStartDevicePowerManagement

PoFxReportDevicePoweredOn function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxReportDevicePoweredOn** routine notifies the power management framework (PoFx) that the device completed the requested transition to the D0 (fully on) power state.

Syntax

```
void PoFxReportDevicePoweredOn(
  POHANDLE Handle
);
```

Parameters

`Handle`

A handle that represents the registration of the device with the power management framework (PoFx). The device driver previously received this handle from the PoFxRegisterDevice routine.

Return Value

None.

Remarks

The driver for a registered device must call **PoFxReportDevicePoweredOn** after either of the following occurrences:

- PoFx calls the driver's DevicePowerRequiredCallback callback routine to notify the driver that the device must enter the D0 power state.
- PoFx sends the driver an S0 IRP (an IRP_MN_SET_POWER request) to notify the driver of a pending system transition to the S0 power state.

In response to either occurrence, the driver sends D0 IRP (an **IRP_MN_SET_POWER** request) down its device stack to initiate a transition to the D0 power state, if the device is not already in the D0 state. After the driver completes (and all lower drivers complete) the transition to the D0 state, the driver calls **PoFxReportDevicePoweredOn** to notify PoFx.

Each time the *DevicePowerRequiredCallback* routine is called, the driver must respond by calling **PoFxReportDevicePoweredOn**. The **PoFxReportDevicePoweredOn** call can occur either during or after the *DevicePowerRequiredCallback* call. The driver must call **PoFxReportDevicePoweredOn** regardless of whether no D0 IRP is required, the D0 IRP request fails, or the dispatched D0 IRP succeeds or fails.

During a system transition to the S0 state, PoFx sends the driver an **IRP_MN_SET_POWER** request to notify the driver of the pending S0 transition. In response, the driver must complete this request as soon as possible, switch the device to the D0 power state, and call **PoFxReportDevicePoweredOn**. For more information, see Handling a System Set-Power IRP in a Device Power Policy Owner.

On entry to **PoFxReportDevicePoweredOn**, the device might be in an uninitialized D0 power state in which all of the components in the device are turned on. In response to the **PoFxReportDevicePoweredOn** call, PoFx configures the device in an initialized D0 state. During this configuration, PoFx switches as many components as it

can to low-power Fx power states.

IRP_MN_SET_POWER

PoFxRegisterDevice

PoFxSetComponentLatency function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxSetComponentLatency** routine specifies the maximum latency that can be tolerated in the transition from the idle condition to the active condition in the specified component.

Syntax

```
void PoFxSetComponentLatency(
  POHANDLE  Handle,
  ULONG     Component,
  ULONGLONG Latency
);
```

Parameters

`Handle`

A handle that represents the registration of the device with the power management framework (PoFx). The device driver previously received this handle from the PoFxRegisterDevice routine.

`Component`

The index that identifies the component. This parameter is an index into the **Components** array in the PO_FX_DEVICE structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Latency`

The maximum latency, in 100-nanosecond units, that can be tolerated in the specified component. For more information, see Remarks.

Return Value

None.

Remarks

The calling driver supplies a maximum latency that clients of the device can tolerate in the specified component. This latency is the time required to complete a transition from the idle condition to the active condition. PoFx uses this latency as a hint to improve performance.

When the component switches from the active condition to the idle condition, PoFx selects an appropriate low-power Fx state for the component to enter. After this transition completes, the time required to switch back to the active condition depends on the selected Fx state. PoFx tries to select an Fx state that does not violate the maximum latency requirement.

For example, if a driver supports power states F0, F1, and F2 in the specified component, the F2 state represents a lower power setting than the F1 state. Typically, the time T2 required to wake (to the fully on state, F0) from F2 is longer than the time T1 required to wake from F1. If the maximum latency is greater than T1 but less than T2, PoFx can safely switch the component to the F1 state and still meet the maximum latency requirement. However, PoFx avoids switching the component to the F2 state because doing so violates this requirement.

The device driver can call **PoFxSetComponentLatency** each time a change in conditions requires a change in the maximum latency. After each call, the new maximum latency remains in effect until the driver calls **PoFxSetComponentLatency** again to update it.

If a component is in the idle condition when **PoFxSetComponentLatency** is called, PoFx might change the component's current Fx state to accommodate the new maximum latency specified by the caller.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal

PO_FX_DEVICE

PoFxRegisterDevice

PoFxSetComponentResidency function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxSetComponentResidency** routine sets the estimated time for how long a component is likely to remain idle after the component enters the idle condition.

Syntax

```
void PoFxSetComponentResidency(
  POHANDLE  Handle,
  ULONG     Component,
  ULONGLONG Residency
);
```

Parameters

`Handle`

A handle that represents the registration of the device with the power management framework (PoFx). The device driver previously received this handle from the PoFxRegisterDevice routine.

`Component`

The index that identifies the component. This parameter is an index into the **Components** array in the PO_FX_DEVICE structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Residency`

The estimated residency time, in 100-nanosecond units. This parameter is a hint to PoFx about how long the component is likely to remain idle after a transition from the active condition to the idle condition. For more information, see Remarks.

Return Value

None.

Remarks

The calling driver supplies an estimated residency time that PoFx can use as a hint to improve performance. PoFx uses this hint to select an appropriate low-power Fx state for a component that is in the idle condition.

The device driver can call **PoFxSetComponentResidency** each time a change in circumstances requires a change in the estimated residency time. After each call, the new estimated residency time remains in effect until the driver calls **PoFxSetComponentResidency** again to update it.

If a component is in the idle condition when **PoFxSetComponentResidency** is called, PoFx might change the component's Fx state to accommodate the new estimated residency time specified by the caller.

Requirements

IRQL	"<= DISPATCH_LEVEL"

PoFxSetComponentWake function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxSetComponentWake** routine indicates whether the driver arms the specified component to wake whenever the component enters the idle condition.

Syntax

```
void PoFxSetComponentWake(
  POHANDLE Handle,
  ULONG    Component,
  BOOLEAN  WakeHint
);
```

Parameters

`Handle`

A handle that represents the registration of the device with the power management framework (PoFx). The device driver previously received this handle from the PoFxRegisterDevice routine.

`Component`

The index that identifies the component. This parameter is an index into the **Components** array in the PO_FX_DEVICE structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`WakeHint`

Whether the driver arms the component to wake whenever the component enters the idle condition. If TRUE, the driver arms the component to wake. If FALSE, the driver does not arm the component to wake.

Return Value

None.

Remarks

Before a component enters a low-power Fx state, the driver might arm the component to automatically wake in response to an input signal from an external source (for example, if the user pushes a button). The *WakeHint* parameter informs PoFx whether the driver arms the component to wake. If a component is armed to wake, PoFx will not switch the component to a low-power Fx state from which the component cannot wake.

When a device is registered with PoFx, the registration information for each component in the device is contained in a separate PO_FX_COMPONENT structure. The **DeepestWakeableIdleState** member of this structure specifies the deepest Fx state from which the component can wake.

The device driver can call **PoFxSetComponentWake** each time a change in conditions requires a change in the *WakeHint* value. After each call, the new *WakeHint* value remains in effect until the driver calls **PoFxSetComponentWake** again to update it.

If a component is in the idle condition when **PoFxSetComponentWake** is called, PoFx might change the

component's Fx state to accommodate the new *WakeHint* parameter value specified by the caller.

Requirements

PO_FX_COMPONENT

PoFxSetDeviceIdleTimeout function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxSetDeviceIdleTimeout** routine specifies the minimum time interval from when the last component of the device enters the idle condition to when the power management framework (PoFx) calls the driver's DevicePowerNotRequiredCallback routine.

Syntax

```
void PoFxSetDeviceIdleTimeout(
  POHANDLE  Handle,
  ULONGLONG IdleTimeout
);
```

Parameters

`Handle`

A handle that represents the registration of the device with PoFx. The device driver previously received this handle from the PoFxRegisterDevice routine.

`IdleTimeout`

The idle time-out interval in 100-nanosecond units. For more information, see Remarks.

Return Value

None.

Remarks

This routine specifies a time-out interval for PoFx to apply to future calls to the driver's DevicePowerNotRequiredCallback callback routine. By default, this time-out interval is zero, in which case PoFx might call the *DevicePowerNotRequiredCallback* routine just as soon as the device is ready to switch to a low-power Dx state. However, a driver might prefer to delay this transition and to keep the device in the D0 power state for some additional time-out interval. In this case, if the device becomes active before the end of the time-out interval, and is therefore required to stay in the D0 state, the pending *DevicePowerNotRequiredCallback* call is no longer required and is canceled by PoFx.

For example, to improve performance and reduce wear, a storage device driver might want to prevent a spinning drive from entering D3 and slowing down until the drive has been idle for a sufficiently long time. To simplify this driver's implementation of the *DevicePowerNotRequiredCallback* callback routine, the **PoFxSetDeviceIdleTimeout** routine enables the driver to automatically delay the D3 transition without requiring the driver to set up a timer.

The time-out interval starts when all components of the device complete their transitions to the idle condition. Typically, PoFx waits until the end of the time-out interval to call the *DevicePowerNotRequiredCallback* routine. However, if PoFx is preparing to enter a low-power system state, PoFx might end the time-out interval early. In any case, when PoFx calls the driver's *DevicePowerNotRequiredCallback* routine, the driver should switch to the low-power Dx state without further delay.

The device driver can call **PoFxSetDeviceIdleTimeout** each time a change in conditions requires a change in the idle time-out interval. After each call, the new idle time-out interval remains in effect until the driver calls **PoFxSetDeviceIdleTimeout** again to update it.

PoFxRegisterDevice

PoFxSetTargetDripsDevicePowerState function

1/25/2019 • 2 minutes to read • Edit Online

This routine is called to notify the power manager of the device's target device power state for DRIPS. The driver can override the DRIPS constraint provided by the PEP.

Syntax

```
NTSTATUS PoFxSetTargetDripsDevicePowerState(
  POHANDLE           Handle,
  DEVICE_POWER_STATE TargetState
);
```

Parameters

`Handle`

A handle that represents the registration of the device with PoFx. The device driver previously received this handle from the PoFxRegisterDevice routine.

`TargetState`

Specifies the target DRIPS device power state. Possible values are defined in the DEVICE_POWER_STATE enumeration. This value must be lower than the existing device constraint. A device power state of **PowerDeviceUnspecified** resets to the PEP provided constraint.

Return Value

Returns STATUS_SUCCESS if the target state was accepted.

Requirements

Minimum supported client	Windows 10, version 1709
Minimum supported server	Windows Server 2016
Target Platform	Windows
Header	wdm.h
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode)

PoFxStartDevicePowerManagement function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxStartDevicePowerManagement** routine completes the registration of a device with the power management framework (PoFx) and starts device power management.

Syntax

```
void PoFxStartDevicePowerManagement(
  POHANDLE Handle
);
```

Parameters

`Handle`

A handle that represents the registration of the device with the power management framework (PoFx). The device driver previously received this handle from the PoFxRegisterDevice routine.

Return Value

None.

Remarks

After a driver calls the PoFxRegisterDevice routine to register a device with PoFx, all components in the device are fully on and in the active condition so that the driver can finish initializing the hardware. To start active power management, the driver must call **PoFxStartDevicePowerManagement**. By default, this call switches all components to the idle condition.

After **PoFxStartDevicePowerManagement** switches a component to the idle condition, PoFx might immediately start calling the driver's callback routines, even before **PoFxStartDevicePowerManagement** returns. PoFx calls the driver's ComponentIdleConditionCallback callback routine to indicate that a component has switched to the idle condition. The driver must not access a component that is in the idle condition. Before the driver can access the component, the driver must call the PoFxActivateComponent and wait for PoFx to call the driver's ComponentActiveConditionCallback callback routine. This callback informs the driver that the component is in the active condition and can safely be accessed.

If the driver requires a component to be in the active condition immediately after power management starts, the driver must explicitly activate the component by calling the **PoFxActivateComponent** routine, and this call must occur after the **PoFxRegisterDevice** call but before the **PoFxStartDevicePowerManagement** call.

Requirements

Minimum supported client	Available starting with Windows 8.

ComponentIdleConditionCallback

PoFxActivateComponent

PoFxRegisterDevice

PoFxUnregisterDevice function

1/25/2019 • 2 minutes to read • Edit Online

The **PoFxUnregisterDevice** routine removes the registration of a device from the power management framework (PoFx).

Syntax

```
void PoFxUnregisterDevice(
  POHANDLE Handle
);
```

Parameters

`Handle`

A handle that represents the registration of the device with PoFx. The device driver previously received this handle from the PoFxRegisterDevice routine.

Return Value

None.

Remarks

The driver that owns the power policy for a device must unregister the device from PoFx when the device is removed. The Plug and Play (PnP) manager can remove the device stack from the PnP tree only after the device is unregistered.

To unregister the device, the driver calls **PoFxUnregisterDevice** during the handling of an IRP_MN_REMOVE_DEVICE or IRP_MN_SURPRISE_REMOVAL request, whichever is received first. This call should occur after the driver no longer requires access to the device's hardware.

A device driver that calls this routine must previously have called the PoFxRegisterDevice routine to register the device with PoFx.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Universal

IRP_MN_SURPRISE_REMOVAL

PoFxRegisterDevice

PoGetSystemWake function

1/25/2019 • 2 minutes to read • Edit Online

The **PoGetSystemWake** routine determines whether a specified IRP has been marked as waking the system from a sleeping state.

Syntax

```
BOOLEAN PoGetSystemWake(
  PIRP Irp
);
```

Parameters

`Irp`

A pointer to an IRP.

Return Value

PoGetSystemWake returns one of the following:

RETURN CODE	DESCRIPTION
TRUE	The specified IRP did cause the system to wake.
FALSE	The specified IRP did not cause the system to wake.

Remarks

A driver calls **PoGetSystemWake** to determine if a specified IRP contributed to waking the system from a sleep state.

A driver in a wait/wake chain should call **PoGetSystemWake** on its own wait/wake IRP at completion to determine if the driver should also call PoSetSystemWake for child wait/wake IRPs that the driver is about to complete. This ensures that system wake information properly propagates throughout the entire wait/wake chain.

It is possible that several IRPs are causing the system to wake. In this case, **PoGetSystemWake** would return **TRUE** for all of the IRPs contributing to the wake event.

Requirements

Minimum supported client	Available starting with Windows Vista.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

PoSetSystemWake

PopEntryList function

1/25/2019 • 2 minutes to read • Edit Online

The **PopEntryList** routine removes the first entry from a singly linked list of SINGLE_LIST_ENTRY structures.

Syntax

```
PSINGLE_LIST_ENTRY PopEntryList(
  PSINGLE_LIST_ENTRY ListHead
);
```

Parameters

`ListHead`

Pointer to the SINGLE_LIST_ENTRY structure that represents the head of the list. On return, *ListHead*->**Next** points to the beginning of the list with the first entry removed.

Return Value

PopEntryList returns a pointer to the entry removed from the list, or **NULL** if the list is currently empty.

Remarks

PopEntryList removes the first entry from the list by setting *ListHead*->**Next** to point to the second entry in the list.

For information about using this routine when implementing a singly linked list, see Singly and Doubly Linked Lists.

Callers of **PopEntryList** can be running at any IRQL. If **PopEntryList** is called at IRQL >= DISPATCH_LEVEL, the storage for *ListHead* and the list entries must be resident.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
IRQL	Any level (see Remarks section)

PoQueryWatchdogTime function

1/25/2019 • 2 minutes to read • Edit Online

The **PoQueryWatchdogTime** routine indicates whether the power manager has enabled a watchdog time-out counter for any power IRP that is currently assigned to the device stack.

Syntax

```
BOOLEAN PoQueryWatchdogTime(
  PDEVICE_OBJECT Pdo,
  PULONG         SecondsRemaining
);
```

Parameters

`Pdo`

A pointer to a physical device object (PDO). This parameter points to a DEVICE_OBJECT structure that represents a physical device.

`SecondsRemaining`

A pointer to a location into which the routine writes the time, in seconds, that remains before the next power watchdog time-out is set to occur.

Return Value

PoQueryWatchdogTime returns **TRUE** if a watchdog-enabled power IRP is currently assigned to the device stack. Otherwise, it returns **FALSE**.

Remarks

This routine enables kernel-mode drivers to monitor watchdog time-out counters that the power manager has enabled to keep track of power IRPs that it has issued. If one or more watchdog time-out counters are currently enabled, the routine returns **TRUE** and provides the amount of time that remains before the next time-out.

For example, a driver that experiences delays when shutting down a device can call this routine to determine how much time remains before the driver must respond to a power IRP to prevent a controlled shutdown (a bug check) of the operating system.

The power manager sets a watchdog time-out counter when it issues a power IRP to the device stack. The time-out period for this counter is typically several minutes. If a device in the stack is unresponsive and causes the IRP to stall for the time-out period, the power manager treats this condition as an unrecoverable error and initiates a controlled shutdown of the operating system.

If more than one power watchdog time-out is currently enabled, the routine sets **SecondsRemaining* to the time that remains to the next time-out.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

DEVICE_OBJECT

PoRegisterDeviceForIdleDetection function

1/25/2019 • 3 minutes to read • Edit Online

The **PoRegisterDeviceForIdleDetection** routine enables or cancels idle detection and sets idle time-out values for a device.

Syntax

```
PULONG PoRegisterDeviceForIdleDetection(
  PDEVICE_OBJECT     DeviceObject,
  ULONG              ConservationIdleTime,
  ULONG              PerformanceIdleTime,
  DEVICE_POWER_STATE State
);
```

Parameters

`DeviceObject`

A pointer to the driver-created DEVICE_OBJECT for the device. On Windows 2000 and later systems, this parameter can point to a physical device object (PDO) or a functional device object (FDO). On Windows 98/Me, this parameter must point to the PDO of the underlying device.

`ConservationIdleTime`

Sets the time-out value (in seconds) to apply when the system power policy optimizes for energy conservation. Specify zero to disable idle detection when conservation policy is in effect.

`PerformanceIdleTime`

Sets the time-out value (in seconds) to apply when the system power policy optimizes for performance. Specify zero to disable idle detection when performance policy is in effect.

`State`

Specifies the device power state to be requested in an IRP_MN_SET_POWER request when either *ConservationIdleTime* or *PerformanceIdleTime* has been met. Possible values are the DEVICE_POWER_STATE values.

Return Value

PoRegisterDeviceForIdleDetection returns a pointer to the idle counter to indicate that idle detection has been enabled. It returns **NULL** to indicate that idle detection has been disabled, that an idle counter could not be allocated, or that one or both of the time-out values were invalid.

Remarks

PoRegisterDeviceForIdleDetection enables drivers to use the idle detection mechanism provided by the power manager. Drivers call **PoRegisterDeviceForIdleDetection** for any of the following reasons:

- To enable idle detection for the device and set initial idle time-out values
- To change the idle time-out values for a device

- To disable idle detection for a device

After enabling a device for idle detection, a driver calls PoSetDeviceBusy whenever the device is in use, passing the non-**NULL** idle pointer returned by **PoRegisterDeviceForIdleDetection**. Calling **PoSetDeviceBusy** restarts the idle countdown. Note that a driver must not pass a **NULL** pointer to **PoSetDeviceBusy**.

Whenever the device satisfies the current idle time-out value, the power manager sends an **IRP_MN_SET_POWER** request to the top of the device stack, specifying device power state *State*. In response to the IRP, each driver performs any device-specific tasks required before the power state transition, then passes the IRP to the next-lower driver. When the IRP reaches the bus driver, that driver puts the device in the requested lower power state and completes the IRP.

PoRegisterDeviceForIdleDetection sets time-out values for both conservation and performance. The *ConservationIdleTime* value applies when the system power policy optimizes for conservation; the *PerformanceIdleTime* value applies when the system power policy optimizes for performance. Typically, the applicable policy depends upon the power source: when running with AC power, the system optimizes for performance, and when running off a battery, the system optimizes for conservation.

Certain devices can specify time-out values of -1 to use the standard power policy time-outs for their device class. The standard time-out values provide for better system integration for supported standard device classes. At present, WDM supports this feature for devices of type FILE_DEVICE_DISK and FILE_DEVICE_MASS_STORAGE. **PoRegisterDeviceForIdleDetection** returns **NULL** if -1 is specified for a device of an unsupported type. (For information about device types, see Specifying Device Types.)

Only one idle detection can be set per device. Subsequent calls to **PoRegisterDeviceForIdleDetection** change the idle detection values.

If both *ConservationIdleTime* and *PerformanceIdleTime* are zero, this routine cancels all idle detection for the device and returns **NULL**.

PoRegisterDeviceForIdleDetection can free a driver from the need to perform its own idle detection. However, drivers can also implement their own idle detection.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

PoSetDeviceBusy

PoRegisterPowerSettingCallback function

1/25/2019 • 4 minutes to read • Edit Online

The **PoRegisterPowerSettingCallback** routine registers a power-setting callback routine to receive notifications of changes in the specified power setting.

Syntax

```
NTSTATUS PoRegisterPowerSettingCallback(
  PDEVICE_OBJECT          DeviceObject,
  LPCGUID                 SettingGuid,
  PPOWER_SETTING_CALLBACK Callback,
  PVOID                   Context,
  PVOID                   *Handle
);
```

Parameters

`DeviceObject`

A pointer to a DEVICE_OBJECT structure that is associated with the caller of this routine. This parameter is optional. It is used internally only for debugging purposes. If this parameter is not supplied, it must be set to **NULL**.

`SettingGuid`

A pointer to the GUID that represents the power setting for this registration. When the specified power setting changes, the power manager calls the callback routine to notify the driver of the change and to supply the new value of the setting. For more information, see Remarks.

`Callback`

A pointer to a caller-implemented power-setting callback routine that the power manager calls when the specified power setting changes. For the functional prototype for the callback routine, see Power-Setting Callback.

`Context`

A pointer to the context for the callback routine. This parameter is optional. It is provided so that a driver or device context can be passed to the callback routine. If this parameter is not used, it must be set to **NULL**.

`Handle`

A handle that the power manager uses to represent the callback routine. A driver must subsequently supply this handle in a call to PoUnregisterPowerSettingCallback to unregister the callback routine.

Return Value

PoRegisterPowerSettingCallback returns one of the following:

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	The routine registered the callback routine.
STATUS_INSUFFICIENT_RESOURCES	The routine could not allocate the system resources that are required to register the callback routine.

Remarks

A driver calls **PoRegisterPowerSettingCallback** to register a callback routine with the power manager. The power manager subsequently calls this callback routine to notify the driver after there is a change to the specified power setting. In addition, the power manager initializes the power setting of the driver by immediately calling the callback routine and passing the current value of the power setting. The power manager initializes the power setting of the driver this way regardless of whether the power setting has actually changed.

A driver should call **PoRegisterPowerSettingCallback** for each power setting that the driver needs to monitor. Drivers should call this routine in their DriverEntry routine during initialization. Typically, most drivers pass a pointer to a device extension in the *Context* parameter.

To unregister a power-setting callback, call the PoUnregisterPowerSettingCallback routine.

Typically, Kernel-Mode Driver Framework (KMDF) drivers should call **PoRegisterPowerSettingCallback** from their EvtDeviceSelfManagedIoInit callback function, and should call **PoUnregisterPowerSettingCallback** from their EvtDeviceSelfManagedIoCleanup callback function. These drivers should not call **PoRegisterPowerSettingCallback** from their EvtDriverDeviceAdd callback function; otherwise, the power-setting callback routine might be called before the driver stack is completely built.

The callback routine that is registered for a particular power setting is called when a transition in power state occurs that changes the value of the setting, or when the power manager changes the value of the setting. For example, if *SettingGuid* points to the GUID value GUID_LIDSWITCH_STATE_CHANGE, the callback routine is called when the lid to a laptop computer clicks open or closed. The *Value* parameter passed to the callback routine in this example points to a ULONG value that is 1 if the state of the lid switch changed from closed to open, and is 0 if the state of the lid switch changed from open to closed. For more information, see the power-setting GUID definitions and extensive comments in the Wdm.h header file.

The initial call to a callback routine might occur immediately, before the **PoRegisterPowerSettingCallback** call that registers the routine returns.

PoRegisterPowerSettingCallback can be called only at IRQL = PASSIVE_LEVEL.

Power-Setting Callback

The function prototype of the power-setting callback routine is as follows:

```
NTSTATUS
POWER_SETTING_CALLBACK (
  _In_ LPCGUID SettingGuid,
  _In_ PVOID Value,
  _In_ ULONG ValueLength,
  _Inout_opt_ PVOID Context
);
```

The power-setting callback parameters are:

SettingGuid
A pointer to a GUID that represents the power setting that changed. Power settings and their corresponding GUIDs are defined in Wdm.h.

Value A pointer to the new value of the power setting that changed.

ValueLength A value of type ULONG that specifies the size, in bytes, of the new power setting value.

Context
The pointer to the context that a driver supplied in the call to **PoRegisterPowerSettingCallback** that registered the callback routine.

The power manager calls a power-setting callback at IRQL = PASSIVE_LEVEL. #### Examples To define a power-setting callback routine, you must first provide a function declaration that identifies the type of callback function you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system. For example, to define a power-setting callback routine that is named `MyPowerSettingCallback`, use the POWER_SETTING_CALLBACK type as shown in this code example:

```
POWER_SETTING_CALLBACK MyPowerSettingCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
NTSTATUS
  MyPowerSettingCallback(
    LPCGUID SettingGuid,
    PVOID Value,
    ULONG ValueLength,
    PVOID Context
    )
  {
      // Function body
  }
```

The POWER_SETTING_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the POWER_SETTING_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For

information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Available starting with Windows Vista.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL (see Remarks section)

EvtDriverDeviceAdd

PoUnregisterPowerSettingCallback

PoRegisterSystemState function

1/25/2019 • 2 minutes to read • Edit Online

The **PoRegisterSystemState** routine registers the system as busy due to certain activity.

Syntax

```
PVOID PoRegisterSystemState(
  PVOID           StateHandle,
  EXECUTION_STATE Flags
);
```

Parameters

`StateHandle`

A pointer to a caller-supplied buffer for a registration state handle. The size, in bytes, of the buffer is **sizeof**(ULONG). If **NULL**, this is a new registration. If non-**NULL**, this parameter points to a handle that was returned by a previous call to **PoRegisterSystemState**.

`Flags`

Indicates the type of activity, as specified by a bitwise OR of one or more of the following values:

ES_SYSTEM_REQUIRED

The system is not idle, regardless of apparent load.

ES_DISPLAY_REQUIRED

Use of the display is required.

ES_USER_PRESENT

A user is present.

ES_CONTINUOUS

The settings are continuous and should remain in effect until explicitly changed.

Return Value

PoRegisterSystemState returns a handle to be used later to change or unregister the system busy state. It returns **NULL** if the handle could not be allocated.

Remarks

PoRegisterSystemState registers the system busy state as indicated by the flags. The registration persists until the caller explicitly changes it with another call to **PoRegisterSystemState** or cancels it with a call to PoUnregisterSystemState.

The *Flags* parameter specifies the type of activity in progress. Drivers can specify any combination of the flags.

Setting ES_CONTINUOUS makes the busy state persist until a driver explicitly changes or cancels it by calling **PoRegisterSystemState** or **PoUnregisterSystemState**.

A driver can set the system busy state to request that the power manager avoid system power state transitions out

of the system working state (S0) while driver activity is occurring. Note, however, that under some circumstances (such as a critically low battery) the power manager may override this request and put the system to sleep anyway.

To set the system power state, call PoSetSystemState.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=APC_LEVEL"

PoSetSystemState

PoUnregisterSystemState

PoRequestPowerIrp function

1/25/2019 • 3 minutes to read • Edit Online

The **PoRequestPowerIrp** routine allocates a power IRP and sends it to the top driver in the device stack for the specified device.

Syntax

```
NTSTATUS PoRequestPowerIrp(
  PDEVICE_OBJECT          DeviceObject,
  UCHAR                   MinorFunction,
  POWER_STATE             PowerState,
  PREQUEST_POWER_COMPLETE CompletionFunction,
  __drv_aliasesMem PVOID  Context,
  PIRP                    *Irp
);
```

Parameters

`DeviceObject`

A pointer to the target DEVICE_OBJECT for the IRP. In Windows 2000 and later versions of Windows, this parameter can point to a physical device object (PDO) or a functional device object (FDO). In Windows 98/Me, this parameter must point to the PDO of the underlying device.

`MinorFunction`

Specifies one of the following minor power IRP codes: IRP_MN_QUERY_POWER, IRP_MN_SET_POWER, or IRP_MN_WAIT_WAKE.

`PowerState`

Specifies a POWER_STATE value to pass in the IRP. For **IRP_MN_SET_POWER** and **IRP_MN_QUERY_POWER**, specify the requested new device power state. Possible values are DEVICE_POWER_STATE values.

For **IRP_MN_WAIT_WAKE**, specify the lowest (least-powered) system power state from which the device should be allowed to wake the system. Possible values are SYSTEM_POWER_STATE values.

`CompletionFunction`

A pointer to the caller's PowerCompletion callback routine. The I/O manager calls this routine when the IRP has completed. This parameter is optional and can be set to **NULL** if no *PowerCompletion* callback routine is needed.

`Context`

A pointer to a caller-supplied context to be passed through to the *PowerCompletion* callback. When the caller requests a device set-power IRP in response to a system set-power IRP, *Context* should contain the system set-power IRP that triggered the request.

`Irp`

A pointer to a caller-supplied variable in which **PoRequestPowerIrp** returns a pointer to the IRP that it allocates. Specify a value for *Irp* only if the *MinorFunction* parameter is set to **IRP_MN_WAIT_WAKE**. Otherwise, this parameter should always be **NULL** because the IRP might be completed before **PoRequestPowerIrp** returns,

causing this parameter to point to memory that has already been discarded.

Return Value

PoRequestPowerIrp returns one of the following:

RETURN CODE	DESCRIPTION
STATUS_PENDING	The IRP has been sent.
STATUS_INSUFFICIENT_RESOURCES	The routine could not allocate the IRP.
STATUS_INVALID_PARAMETER_2	*MinorFunction* does not signify a valid minor power IRP code.

Remarks

A device power policy owner calls this routine to send a wait/wake, query, or set-power IRP.

A driver calls **PoRequestPowerIrp**—not IoAllocateIrp—to allocate and send a power IRP that has minor IRP code **IRP_MN_SET_POWER**, **IRP_MN_QUERY_POWER**, or **IRP_MN_WAIT_WAKE**. (A driver must call **IoAllocateIrp** to send a power IRP with minor IRP code IRP_MN_POWER_SEQUENCE.)

If **PoRequestPowerIrp** returns a status value of STATUS_PENDING, the routine successfully allocated a device power IRP and sent it to the top of the device stack for the device. After the bus driver and all other drivers have completed the IRP, and the I/O manager has called all IoCompletion routines set by drivers as they passed the IRP down the device stack, the I/O manager calls the PowerCompletion routine and passes to this routine the specified *Context* value. If **PoRequestPowerIrp** returns a status other than STATUS_PENDING, the routine did not send a device power IRP and the *PowerCompletion* routine is not called.

The *PowerCompletion* routine performs any additional tasks the sender of the IRP requires after all other drivers have completed the IRP. It need not free the IRP; the power manager does that. In Windows 2000 and later versions of Windows, the *PowerCompletion* routine can be called at IRQL = PASSIVE_LEVEL or IRQL = DISPATCH_LEVEL. In Windows 98/Me, the *PowerCompletion* routine is always called at IRQL = PASSIVE_LEVEL, and drivers must complete IRPs at IRQL = PASSIVE_LEVEL.

A device power policy owner calls **PoRequestPowerIrp** to send a device query- or set-power IRP when it receives a system query- or set-power IRP. The driver should set an *IoCompletion* routine in the system IRP and pass the system IRP to the next lower driver. The *IoCompletion* routine calls **PoRequestPowerIrp** to send the device IRP, passing the system IRP in the *Context* parameter. The *Context* parameter is subsequently passed to the *PowerCompletion* routine for the device IRP. In the *PowerCompletion* routine, the driver can complete the system IRP. For more information, see Sending IRP_MN_QUERY_POWER or IRP_MN_SET_POWER for Device Power States and Wait/Wake Callback Routines.

Drivers can use the returned *Irp* to cancel an **IRP_MN_WAIT_WAKE** IRP. Drivers that are requesting other types of power IRPs must pass **NULL** for this parameter.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

PoSetDeviceBusyEx function

1/25/2019 • 2 minutes to read • Edit Online

The **PoSetDeviceBusyEx** routine notifies the power manager that the device associated with the specified idle counter is busy.

Syntax

```
void PoSetDeviceBusyEx(
  PULONG IdlePointer
);
```

Parameters

`IdlePointer`

A pointer to an idle counter. This is a pointer value that was previously returned by the PoRegisterDeviceForIdleDetection routine. Because **PoRegisterDeviceForIdleDetection** might return a **NULL** pointer, the caller must verify that the pointer is non-**NULL** before it calls **PoSetDeviceBusyEx**.

Return Value

None

Remarks

This routine is a direct replacement for the PoSetDeviceBusy macro. If you are writing new driver code for Windows Vista with Service Pack 1 (SP1) and later versions of Windows, call **PoSetDeviceBusyEx** instead of **PoSetDeviceBusy**.

A driver calls the **PoSetDeviceBusyEx** and **PoRegisterDeviceForIdleDetection** routines to enable system idle detection for its device. If a device that is registered for idle detection stays idle for the driver-specified time-out period, the power manager sends an IRP_MN_SET_POWER request to put the device in a requested sleep state.

PoSetDeviceBusyEx reports that the device is busy, so that the power manager can restart its idle countdown. If the device is in a sleep state, **PoSetDeviceBusyEx** does not change the state of the device. That is, it does not cause the system to send an **IRP_MN_SET_POWER** request to awaken the device.

PoSetDeviceBusyEx is designed for use with I/O operations that are relatively brief compared to the time-out period of the idle counter. For longer operations that might exceed this period, use the PoStartDeviceBusy and PoEndDeviceBusy routines instead.

A driver that makes multiple requests for brief I/O operations should call **PoSetDeviceBusyEx** for every I/O request that it makes.

Requirements

Minimum supported client	Available starting with Windows Vista with SP1.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

PoSetPowerRequest function

1/25/2019 • 2 minutes to read • Edit Online

The **PoSetPowerRequest** routine increments the count for the specified power request type.

Syntax

```
NTSTATUS PoSetPowerRequest(
  PVOID             PowerRequest,
  POWER_REQUEST_TYPE Type
);
```

Parameters

`PowerRequest`

A pointer to a power request object that was created by the PoCreatePowerRequest routine.

`Type`

The type of power request. Set this parameter to the following POWER_REQUEST_TYPE enumeration value:

- **PowerRequestSystemRequired**

Return Value

PoSetPowerRequest returns STATUS_SUCCESS if the call is successful. If the call fails, possible error return codes include the following:

RETURN CODE	DESCRIPTION
STATUS_UNSUPPORTED_TYPE	The *Type* parameter is set to an unsupported value.

Remarks

A driver can call the **PoSetPowerRequest** routine to request that the power manager override several types of default power behavior, which are specified as POWER_REQUEST_TYPE enumeration values. To restore the default behavior, the driver cancels the request by calling the PoClearPowerRequest routine.

The power manager maintains a count of the active requests for each power request type. The **PoSetPowerRequest** routine increments the count for the specified power request type by one. The **PoClearPowerRequest** routine decrements the count by one. A nonzero count indicates that requests from one or more components are active. After the count decrements to zero, the computer reverts to the default behavior for the specified power request type.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

POWER_REQUEST_TYPE

PoClearPowerRequest

PoCreatePowerRequest

PoSetPowerState function

1/25/2019 • 2 minutes to read • Edit Online

The **PoSetPowerState** routine notifies the system of a change in the device power state for a device.

Syntax

```
POWER_STATE PoSetPowerState(
  PDEVICE_OBJECT   DeviceObject,
  POWER_STATE_TYPE Type,
  POWER_STATE      State
);
```

Parameters

`DeviceObject`

A pointer to the target DEVICE_OBJECT.

`Type`

Indicates a POWER_STATE_TYPE value. Drivers must specify **DevicePowerState**.

`State`

Specifies the power state to be set. Drivers must specify a DEVICE_POWER_STATE value.

Return Value

On Windows 2000 and later versions of the operating system, **PoSetPowerState** returns the previous power state. On Windows 98/Me, **PoSetPowerState** returns the state passed in *State*.

Remarks

PoSetPowerState notifies the power manager of the new power state for a device. Each driver in a device stack (filter, function, and bus drivers) must call **PoSetPowerState** to inform the power manager of a change in the power state of its corresponding device object. For example:

- A driver calls this routine after receiving a device set-power request and before calling PoStartNextPowerIrp. When handling a PnP IRP_MN_START_DEVICE request, the driver should call **PoSetPowerState** to notify the power manager that the device is in the D0 state.
- If the device is powering down, the driver must call **PoSetPowerState** before leaving the D0 state. In addition, the driver must be able to process client requests before **PoSetPowerState** returns.
- If the device is powering up, the driver must call **PoSetPowerState** after the device is successfully put into the D0 state.

For more information about powering a device up and down, see Handling IRP_MN_SET_POWER for Device Power States.

Callers of **PoSetPowerState** must be running at IRQL <= APC_LEVEL except when setting state to D0. When setting state to D0, callers can be running at IRQL <= DISPATCH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

PoStartNextPowerIrp

PoSetSystemState function

1/25/2019 • 2 minutes to read • Edit Online

Drivers call the **PoSetSystemState** routine to indicate that the system is active.

Syntax

```
void PoSetSystemState(
  EXECUTION_STATE Flags
);
```

Parameters

`Flags`

Indicates the system activity, as specified by a bitwise OR of one or more of the following values:

ES_SYSTEM_REQUIRED

The system is not idle, regardless of apparent load.

ES_DISPLAY_REQUIRED

Use of the display is required.

ES_USER_PRESENT

A user is present.

Return Value

None

Remarks

A driver calls **PoSetSystemState** to set flags indicating that system activity is occurring. Unlike PoRegisterSystemState, this routine does not allow the driver to set a persistent busy state.

The *Flags* parameter specifies the type of activity occurring. Drivers can specify any combination of the flags.

Drivers can set the system busy state to request that the system avoid leaving of the working state while driver activity is occurring. Note, however, that under some circumstances (such as a critically low battery) the power manager may override this request and put the system to sleep anyway.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

PoSetSystemWake function

1/25/2019 • 2 minutes to read • Edit Online

The **PoSetSystemWake** routine marks the specified IRP as one that contributed to waking the system from a sleep state.

Syntax

```
void PoSetSystemWake(
  PIRP Irp
);
```

Parameters

`Irp`

A pointer to the wait/wake IRP.

Return Value

None

Remarks

Drivers call **PoSetSystemWake** to mark an IRP_MN_WAIT_WAKE IRP as contributing to waking the system from a sleep state. By default, wait/wake IRPs are considered to be device wake-up IRPs. It is the responsibility of the terminal device in a wait/wake chain to determine if it woke the system and to call **PoSetSystemWake** for the terminal wait/wake IRP. When a driver calls **PoSetSystemWake** on an IRP, it is marked as having contributed to waking the system from a sleep state. Only one driver in a stack needs to call this routine, and it should normally be the bus driver in a driver stack.

All other drivers in a wait/wake chain can call PoGetSystemWake for their own wait/wake IRPs at completion to determine if they should call **PoSetSystemWake** on any child wait/wake IRPs that they are about to complete. This ensures that system wake information properly progresses throughout the wait/wake chain.

After a wait/wake IRP completes, the power manager checks if the IRP is marked as a system wake IRP. If the IRP is marked as a system wake IRP, the power manager adds the IRP to an internal list of the devices that woke the system. However, the power manager only keeps track of the most specific devices that work the system. For example, if device A is added as a device that woke the system, and then device B—a child of device A—is also added, the power manager only retains device B in the list because device B is the most specific. If the power manager cannot determine the most specific device that woke the system, the power manager might keep track of more than one device that reported it woke the system.

The power manager logs an Event Tracing for Windows (ETW) event (viewable in the global system channel) that includes information about which devices woke the system.

Requirements

Minimum supported client	Available starting with Windows Vista.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= DISPATCH_LEVEL"

PoGetSystemWake

PoStartDeviceBusy function

1/25/2019 • 2 minutes to read • Edit Online

The **PoStartDeviceBusy** routine marks the start of a period of time in which the device is busy.

Syntax

```
void PoStartDeviceBusy(
  PULONG IdlePointer
);
```

Parameters

`IdlePointer`

A pointer to an idle counter. This is a pointer value that was previously returned by the PoRegisterDeviceForIdleDetection routine. Because **PoRegisterDeviceForIdleDetection** might return a **NULL** pointer, the caller must verify that the pointer is non-**NULL** before it calls **PoStartDeviceBusy**.

Return Value

None

Remarks

The **PoStartDeviceBusy** and PoEndDeviceBusy routines mark the start and end of a time period in which a device is busy. Each call to **PoStartDeviceBusy** must be followed by a corresponding call to **PoEndDeviceBusy**.

For each device, the power manager maintains a count of the number of outstanding **PoStartDeviceBusy** calls for which it has not yet received a corresponding **PoEndDeviceBusy** call. A **PoStartDeviceBusy** call increments the busy count by one. A **PoEndDeviceBusy** call decrements the busy count by one. A nonzero busy count disables the idle counter for the device. After the busy count reaches zero, the power manager resets the idle counter to the time-out period and enables the counter.

Rather than use the **PoStartDeviceBusy** and **PoEndDeviceBusy** routines to reset the idle counter, you can call the PoSetDeviceBusyEx routine (or the PoSetDeviceBusy macro). To disable the idle counter during an extended busy period, a driver can call the **PoRegisterDeviceForIdleDetection** routine to disable and enable idle notifications at the start and end of the busy period. However, **PoStartDeviceBusy** and **PoEndDeviceBusy** are typically more convenient to use for this purpose, and you should consider using these routines in new code that you write for Windows 7 and later versions of Windows.

Requirements

Minimum supported client	Available starting with Windows 7.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

PoSetDeviceBusy

PoStartNextPowerIrp function

1/25/2019 • 2 minutes to read • Edit Online

The **PoStartNextPowerIrp** routine signals the power manager that the driver is ready to handle the next power IRP. (Windows Server 2003, Windows XP, and Windows 2000 only.)

Syntax

```
void PoStartNextPowerIrp(
  PIRP Irp
);
```

Parameters

`Irp`

A pointer to an IRP in which the major function code is IRP_MJ_POWER.

Return Value

None

Remarks

Starting with Windows Vista, the driver is not required to call **PoStartNextPowerIrp** and a call to this routine does not perform a power management operation. However, on Windows Server 2003, Windows XP, and Windows 2000, **PoStartNextPowerIrp** must be called by every driver in a device stack after the driver is finished with the previous power IRP, if any, and is ready to handle the next power IRP. It must be called once by each driver for every IRP_MN_QUERY_POWER or IRP_MN_SET_POWER request.

Although power IRPs are completed only once, typically by the bus driver for a device, each driver in the device stack must call **PoStartNextPowerIrp** as the IRP travels down or back up the stack. Even if a driver fails the IRP, the driver must nevertheless call **PoStartNextPowerIrp** to signal the power manager that it is ready to handle another power IRP.

The driver must call **PoStartNextPowerIrp** while the current IRP stack location points to the current driver. Therefore, this routine must be called before IoCompleteRequest, IoSkipCurrentIrpStackLocation, and PoCallDriver. As a general rule, a driver should call **PoStartNextPowerIrp** from its *IoCompletion* routine associated with the IRP or from the callback routine it passed to PoRequestPowerIrp.

Bus drivers must call **PoStartNextPowerIrp** before completing each IRP.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

PoUnregisterPowerSettingCallback function

1/25/2019 • 2 minutes to read • Edit Online

The **PoUnregisterPowerSettingCallback** routine unregisters a power-setting callback routine that a driver previously registered by calling the PoRegisterPowerSettingCallback routine.

Syntax

```
NTSTATUS PoUnregisterPowerSettingCallback(
  PVOID Handle
);
```

Parameters

`Handle`

A handle to a callback routine that a driver registered by calling **PoRegisterPowerSettingCallback**.

Return Value

PoUnregisterPowerSettingCallback returns one of the following:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The callback routine was unregistered.
STATUS_INVALID_PARAMETER	The *Handle* value is not a valid handle to a power setting callback routine.

Remarks

A driver calls **PoUnregisterPowerSettingCallback** to unregister a power setting callback routine that the driver previously registered by calling **PoRegisterPowerSettingCallback**.

A driver must call **PoUnregisterPowerSettingCallback** to unregister each callback routine that it previously registered. All callback routines registered by a driver should be unregistered in the *Unload* routine of the driver.

Requirements

Minimum supported client	Available starting with Windows Vista.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

PoUnregisterSystemState function

1/25/2019 • 2 minutes to read • Edit Online

The **PoUnregisterSystemState** routine cancels a system state registration created by PoRegisterSystemState.

Syntax

```
void PoUnregisterSystemState(
  PVOID StateHandle
);
```

Parameters

`StateHandle`

A pointer to a handle previously returned by **PoRegisterSystemState**.

Return Value

None

Remarks

This routine cancels a system busy state registration established by **PoRegisterSystemState** and frees the associated *StateHandle*.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

PPUT_DMA_ADAPTER callback function

1/25/2019 • 2 minutes to read • Edit Online

The **PutDmaAdapter** routine frees a DMA_ADAPTER structure previously allocated by IoGetDmaAdapter.

Syntax

```
PPUT_DMA_ADAPTER PputDmaAdapter;

void PputDmaAdapter(
  PDMA_ADAPTER DmaAdapter
)
{...}
```

Parameters

`DmaAdapter`

Pointer to the DMA_ADAPTER structure to be released.

Return Value

None

Remarks

PutDmaAdapter is not a system routine that can be called directly by name. This routine is callable only by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter.

PutDmaAdapter frees a DMA adapter object previously allocated by **IoGetDmaAdapter**. Drivers should call **PutDmaAdapter** after completing DMA operations and freeing any map registers and common buffer allocated with this adapter object. After **PutDmaAdapter** returns, the driver can no longer use the DMA adapter object.

A driver must call **PutDmaAdapter** when it receives a PnP IRP_MN_STOP_DEVICE request.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	"<= DISPATCH_LEVEL"
DDI compliance rules	IrqlDispatch

IoGetDmaAdapter

PPUT_SCATTER_GATHER_LIST callback function

1/25/2019 • 2 minutes to read • Edit Online

The **PutScatterGatherList** routine frees the previously allocated map registers and scatter/gather list used in scatter/gather DMA.

Syntax

```
PPUT_SCATTER_GATHER_LIST PputScatterGatherList;

void PputScatterGatherList(
  PDMA_ADAPTER DmaAdapter,
  PSCATTER_GATHER_LIST ScatterGather,
  BOOLEAN WriteToDevice
)
{...}
```

Parameters

`DmaAdapter`

Pointer to the DMA_ADAPTER structure returned by IoGetDmaAdapter that represents the bus-master adapter or DMA controller.

`ScatterGather`

Pointer to a SCATTER_GATHER_LIST structure previously returned by GetScatterGatherList.

`WriteToDevice`

Indicates the direction of the DMA transfer: specify **TRUE** for a transfer from the buffer to the device, and **FALSE** otherwise.

Return Value

None

Remarks

PutScatterGatherList is not a system routine that can be called directly by name. This routine is callable only by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter.

Drivers should call **PutScatterGatherList** after completing scatter/gather I/O. This routine flushes the adapter buffers, frees the map registers, and unmaps and frees the associated MDLs. Additionally, the routine frees the scatter/gather list if it was previously allocated by GetScatterGatherList.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows. Not supported in Windows 98 or Windows Me.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

PREAD_DMA_COUNTER callback function

1/25/2019 • 2 minutes to read • Edit Online

The **ReadDmaCounter** routine returns the number of bytes remaining to be transferred during the current subordinate DMA operation.

Syntax

```
PREAD_DMA_COUNTER PreadDmaCounter;

ULONG PreadDmaCounter(
  PDMA_ADAPTER DmaAdapter
)
{...}
```

Parameters

`DmaAdapter`

Pointer to the adapter object previously returned by IoGetDmaAdapter representing the system DMA controller channel currently in use.

Return Value

ReadDmaCounter returns the number of bytes remaining to be transferred in the current DMA operation.

Remarks

ReadDmaCounter is not a system routine that can be called directly by name. This routine is callable only by pointer from the address returned in a DMA_OPERATIONS structure. Drivers obtain the address of this routine by calling IoGetDmaAdapter.

ReadDmaCounter can be called only by drivers of subordinate DMA devices. Usually, the caller is the driver of a subordinate device that uses a system DMA controller's autoinitialize mode.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

PREENUMERATE_SELF callback function

1/25/2019 • 2 minutes to read • Edit Online

A *ReenumerateSelf* routine requests that a bus driver reenumerate a child device.

Syntax

```
PREENUMERATE_SELF PreenumerateSelf;

void PreenumerateSelf(
  PVOID Context
)
{...}
```

Parameters

`Context`

A pointer to interface-specific context information. The caller passes the value that is passed as the **Context** member of the REENUMERATE_SELF_INTERFACE_STANDARD structure.

Return Value

None

Remarks

The REENUMERATE_SELF_INTERFACE_STANDARD interface structure supplies a pointer to the *ReenumerateSelf* routine.

If the bus driver can process the request at the time of the routine call, the bus driver asynchronously reports the device as missing in a subsequent IRP_MN_QUERY_DEVICE_RELATIONS BusRelations query. This report causes the current device instance to receive IRP_MN_SURPRISE_REMOVAL and IRP_MN_REMOVE_DEVICE requests. After the surprise removal has been processed, a new instance of the device is enumerated and the driver's AddDevice routine is called to rebuild the device stack.

Requirements

Minimum supported client	Available in Windows Vista.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h)
IRQL	PASSIVE_LEVEL

ProbeForRead function

1/25/2019 • 2 minutes to read • Edit Online

The **ProbeForRead** routine checks that a user-mode buffer actually resides in the user portion of the address space, and is correctly aligned.

Syntax

```
void ProbeForRead(
  const volatile VOID *Address,
  SIZE_T              Length,
  ULONG               Alignment
);
```

Parameters

`Address`

Specifies the beginning of the user-mode buffer.

`Length`

Specifies the length, in bytes, of the user-mode buffer.

`Alignment`

Specifies the required alignment, in bytes, of the beginning of the user-mode buffer.

Return Value

None

Remarks

If the specified range of memory is not within the user-mode address range, **ProbeForRead** raises the STATUS_ACCESS_VIOLATION exception. If the beginning of the address range is not aligned on the byte boundary that is specified by *Alignment*, **ProbeForRead** raises the STATUS_DATATYPE_MISALIGNMENT exception.

Kernel-mode drivers must use **ProbeForRead** to validate read access to buffers that are allocated in user space. It is most commonly used during METHOD_NEITHER I/O to validate the user buffer pointed to by **Irp -> UserBuffer**.

Drivers must call **ProbeForRead** inside a **try/except** block. If the routine raises an exception, the driver should complete the IRP with the appropriate error. Note that subsequent accesses by the driver to the user-mode buffer must also be encapsulated within a **try/except** block: a malicious application could have another thread deleting, substituting, or changing the protection of user address ranges at any time (even after or during a call to **ProbeForRead** or **ProbeForWrite**). For more information, see Handling Exceptions.

Do not use this routine on kernel-mode addresses; it will raise an exception.

If **Irp->RequestorMode** = **KernelMode**, the **Irp->AssociatedIrp.SystemBuffer** and **Irp->UserBuffer** fields do not contain user-mode addresses, and a call to **ProbeForRead** to probe a buffer pointed to by either field will raise

an exception.

If *Length* = 0, **ProbeForRead** does no checking of the address. In this case, the routine does not raise an exception for an address that is misaligned or is outside the range of valid user addresses.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ProbeForWrite

ProbeForWrite function

1/25/2019 • 2 minutes to read • Edit Online

The **ProbeForWrite** routine checks that a user-mode buffer actually resides in the user-mode portion of the address space, is writable, and is correctly aligned.

Syntax

```
void ProbeForWrite(
  volatile VOID *Address,
  SIZE_T        Length,
  ULONG         Alignment
);
```

Parameters

`Address`

Specifies the beginning of the user-mode buffer.

`Length`

Specifies the length, in bytes, of the user-mode buffer.

`Alignment`

Specifies the required alignment, in bytes, of the beginning of the user-mode buffer.

Return Value

None

Remarks

If the specified range of memory is not a valid user-mode address range or is not writable (no access, read-only, and so on), **ProbeForWrite** raises the STATUS_ACCESS_VIOLATION exception. If the beginning of the address range is not aligned on the byte boundary that is specified by *Alignment*, **ProbeForWrite** raises the STATUS_DATATYPE_MISALIGNMENT exception.

Kernel-mode drivers must use **ProbeForWrite** to validate write access to buffers allocated in user space. It is most commonly used during METHOD_NEITHER I/O to validate the user buffer pointed to by **Irp->UserBuffer**.

Drivers must call **ProbeForWrite** inside a **try/except** block. If the routine raises an exception, the driver should complete the IRP with the appropriate error. Note that subsequent accesses by the driver to the user-mode buffer must also be encapsulated within a **try/except** block: a malicious application could have another thread deleting, substituting, or changing the protection of user address ranges at any time (even after or during a call to **ProbeForRead** or **ProbeForWrite**). For more information, see Handling Exceptions.

Do not use this routine on kernel-mode addresses; it will raise an exception.

If **Irp->RequestorMode** = **KernelMode**, the **Irp->AssociatedIrp.SystemBuffer** and **Irp->UserBuffer** fields do not contain user-mode addresses, and a call to **ProbeForWrite** to probe a buffer pointed to by either field will raise an exception.

If *Length* = 0, **ProbeForWrite** does no checking of the address. In this case, the routine does not raise an exception for an address that is misaligned or is outside the range of valid user addresses.

PROCESSOR_HALT_ROUTINE callback function

1/25/2019 • 2 minutes to read • Edit Online

A *Halt* callback routine transitions the processor to an idle state.

Syntax

```
PROCESSOR_HALT_ROUTINE ProcessorHaltRoutine;

NTSTATUS ProcessorHaltRoutine(
  PVOID Context
)
{...}
```

Parameters

`Context`

A pointer to a PEP-defined processor-halt context. This pointer is the *Context* parameter value that the PEP previously passed to the ProcessorHalt routine.

Return Value

A *Halt* callback routine may or may not return. If this routine does return, it returns STATUS_SUCCESS to indicates that the processor successfully entered the idle state. Otherwise, it returns an appropriate error status code.

Remarks

This routine is implemented by the platform extension plug-in (PEP) and is called by the Windows power management framework (PoFx). The ProcessorHalt routine accepts a pointer to a *Halt* callback routine as a parameter.

The PEP's *Halt* routine is called at the same IRQL at which the PEP called **ProcessorHalt**.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	wdm.h (include Pepfx.h)
IRQL	See Remarks.

PEP_CRASHDUMP_INFORMATION

ProcessorHalt

PsCreateSystemThread function

1/25/2019 • 3 minutes to read • Edit Online

The **PsCreateSystemThread** routine creates a system thread that executes in kernel mode and returns a handle for the thread.

Syntax

```
NTSTATUS PsCreateSystemThread(
  PHANDLE            ThreadHandle,
  ULONG              DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  HANDLE             ProcessHandle,
  PCLIENT_ID         ClientId,
  PKSTART_ROUTINE    StartRoutine,
  PVOID              StartContext
);
```

Parameters

`ThreadHandle`

Points to a variable that will receive the handle. The driver must close the handle with ZwClose once the handle is no longer in use. This handle is a kernel handle for Windows Vista and later versions of Windows. In earlier versions of Windows, the handle might not be a kernel handle.

`DesiredAccess`

Specifies the ACCESS_MASK value that represents the requested types of access to the created thread.

`ObjectAttributes`

Points to a structure that specifies the object's attributes. OBJ_PERMANENT, OBJ_EXCLUSIVE, and OBJ_OPENIF are not valid attributes for a thread object. On Windows XP and later versions of Windows, if the caller is not running in the system process context, it must set the OBJ_KERNEL_HANDLE attribute for *ObjectAttributes*. Drivers for Microsoft Windows 2000 and Windows 98/Me must only call **PsCreateSystemThread** from the system process context. For Windows Vista and later versions of Windows, the handle will be a kernel handle.

`ProcessHandle`

Specifies an open handle for the process in whose address space the thread is to be run. The caller's thread must have PROCESS_CREATE_THREAD access to this process. If this parameter is not supplied, the thread will be created in the initial system process. This value should be **NULL** for a driver-created thread. Use the **NtCurrentProcess** macro, defined in Ntddk.h, to specify the current process.

`ClientId`

Points to a structure that receives the client identifier of the new thread. This value should be **NULL** for a driver-created thread.

`StartRoutine`

The entry point for the newly created system thread. This parameter is a function pointer to a ThreadStart routine that receives a single argument, which is the *StartContext* parameter value supplied by the caller.

`StartContext`

Supplies a single argument that is passed to the thread when it begins execution.

Return Value

PsCreateSystemThread returns STATUS_SUCCESS if the thread was created.

Remarks

Drivers that create device-dedicated threads call this routine, either when they initialize or when I/O requests begin to come in to such a driver's Dispatch routines. For example, a driver might create such a thread when it receives an asynchronous device control request.

PsCreateSystemThread creates a kernel-mode thread that begins a separate thread of execution within the system. Such a system thread has no TEB or user-mode context and runs only in kernel mode.

If the input *ProcessHandle* is **NULL**, the created thread is associated with the system process. Such a thread continues running until either the system is shut down or the thread terminates itself by calling **PsTerminateSystemThread**.

Starting with Windows XP, driver routines that run in a process context other than that of the system process must set the OBJ_KERNEL_HANDLE attribute for the *ObjectAttributes* parameter of **PsCreateSystemThread**. This restricts the use of the handle returned by **PsCreateSystemThread** to processes running in kernel mode. Otherwise, the thread handle can be accessed by the process in whose context the driver is running. Drivers can set the OBJ_KERNEL_HANDLE attribute as follows.

```
InitializeObjectAttributes(&ObjectAttributes, NULL, OBJ_KERNEL_HANDLE, NULL, NULL);
```

Drivers for Windows 2000 and Windows 98/Me must call **PsCreateSystemThread** only from the system process context.

For more information about the *StartContext* parameter, see ThreadStart.

The newly created system thread runs at PASSIVE_LEVEL inside a critical region with normal kernel APCs disabled.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

PsIsSystemThread

PsGetVersion function

1/25/2019 • 2 minutes to read • Edit Online

This function is obsolete in Windows XP and later versions of the Windows operating system. Use RtlGetVersion instead.

PsGetVersion returns caller-selected information about the current version of the NT-based operating system.

Syntax

```
BOOLEAN PsGetVersion(
  PULONG          MajorVersion,
  PULONG          MinorVersion,
  PULONG          BuildNumber,
  PUNICODE_STRING CSDVersion
);
```

Parameters

`MajorVersion`

Points to a caller-supplied variable that this routine sets to the major version of the operating system. This optional parameter can be **NULL**.

`MinorVersion`

Points to a caller-supplied variable that this routine sets to the minor version of the operating system. This optional parameter can be **NULL**.

`BuildNumber`

Points to a caller-supplied variable that this routine sets to the current build number of the operating system. This optional parameter can be **NULL**.

`CSDVersion`

Points to a caller-allocated buffer in which this routine returns the current service-pack version as a Unicode string only during system driver initialization. This optional parameter can be **NULL**.

Return Value

PsGetVersion returns whether the system is a checked or free build, as follows:

RETURN CODE	DESCRIPTION
TRUE (1)	Checked build of the operating system.

FAL SE (0)	Free build of the operating system.

Remarks

PsGetVersion returns the requested information, depending on which optional parameter(s) the caller supplies.

To retrieve the current service-pack number, it is easier and more efficient to make an application-level call within the Win32 environment than to call **PsGetVersion** during system driver initialization, which then must parse the string it returns at *CSDVersion*. When the registry is initialized, a driver cannot obtain this string from **PsGetVersion**, but must read the **CmCSDVersionString** value from the registry.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

PsQueryTotalCycleTimeProcess function

1/25/2019 • 2 minutes to read • Edit Online

The **PsQueryTotalCycleTimeProcess** routine returns the accumulated cycle time for the specified process.

Syntax

```
ULONG64 PsQueryTotalCycleTimeProcess(
  PEPROCESS Process,
  PULONG64  CycleTimeStamp
);
```

Parameters

`Process`

A pointer to an EPROCESS structure that serves as the kernel object for the process.

`CycleTimeStamp`

A pointer to a ULONG64 variable to which the routine writes the current cycle counter value for the process.

Return Value

PsQueryTotalCycleTimeProcess returns the accumulated cycle time for the specified process.

Remarks

This routine uses the time stamp counter to get the number of processor clock cycles used by the specified process.

Requirements

Minimum supported client	Available in Windows 8 and later versions of Windows.
Target Platform	Universal
Header	wdm.h
Library	Ntoskrnl.lib
IRQL	PASSIVE_LEVEL

EPROCESS

PsTerminateSystemThread function

1/25/2019 • 2 minutes to read • Edit Online

The **PsTerminateSystemThread** routine terminates the current system thread.

Syntax

```
NTSTATUS PsTerminateSystemThread(
  NTSTATUS ExitStatus
);
```

Parameters

`ExitStatus`

Specifies the status of the terminating system thread.

Return Value

PsTerminateSystemThread does not return if it successfully terminates the calling thread. If the routine cannot terminate the thread (for example, if the thread is not a system thread), the routine returns an error NTSTATUS value.

Remarks

A system thread calls **PsTerminateSystemThread** to terminate itself. A driver that creates its own threads must ensure that each such thread terminates. The driver must not terminate any threads that the system or other drivers created.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

PTM_RM_NOTIFICATION callback function

1/25/2019 • 2 minutes to read • Edit Online

A resource manager's *ResourceManagerNotification* callback routine receives and handles transaction notifications.

Syntax

```
PTM_RM_NOTIFICATION PtmRmNotification;

NTSTATUS PtmRmNotification(
  PKENLISTMENT EnlistmentObject,
  PVOID RMContext,
  PVOID TransactionContext,
  ULONG TransactionNotification,
  PLARGE_INTEGER TmVirtualClock,
  ULONG ArgumentLength,
  PVOID Argument
)
{...}
```

Parameters

`EnlistmentObject`

A pointer to an enlistment object. The *ResourceManagerNotification* callback routine is receiving a notification for the enlistment that this object represents.

`RMContext`

The value that the resource manager previously specified for the *RMKey* parameter of the TmEnableCallbacks routine.

`TransactionContext`

The value that the resource manager previously specified for the *EnlistmentKey* parameter of the ZwCreateEnlistment routine.

`TransactionNotification`

One of the TRANSACTION_NOTIFY_*XXX* values that are defined in Ktmtypes.h. This value specifies the type of transaction notification that KTM sent to the caller.

`TmVirtualClock`

A pointer to a location that contains the virtual clock value at the time that KTM prepared the notification for delivery to the resource manager. If the callback routine increases this value before it returns, KTM updates the virtual clock to the new value. (Typically, resource managers do not modify the virtual clock value.)

`ArgumentLength`

The length, in bytes, of the buffer that the *Argument* parameter points to. This parameter is zero if a buffer is not available.

`Argument`

A pointer to a buffer that contains notification-specific arguments. This parameter is **NULL** if the notification that

the *TransactionNotification* parameter specifies does not require an argument buffer.

For a list of notifications that include an additional argument buffer, see the Remarks section of TRANSACTION_NOTIFICATION.

Return Value

ResourceManagerNotification callback routine must return STATUS_SUCCESS or another status value for which NT_SUCCESS(**status**) equals **TRUE** if the operation is successful.

Typically, the resource manager returns STATUS_SUCCESS if it services the notification synchronously and STATUS_PENDING if it services the notification asynchronously, but it can return STATUS_PENDING in either case. However, the resource manager can return STATUS_PENDING only for notifications that it responds to by calling one of the **Tm*Xxx*Complete** or **Zw*Xxx*Complete** routines.

In other words, if the resource manager must respond to a notification by calling one of the **Tm*Xxx*Complete** or **Zw*Xxx*Complete** routines, it can return STATUS_PENDING for the notification and later call the appropriate **Tm*Xxx*Complete** or **Zw*Xxx*Complete** routine.

If an error occurs, the callback routine must return a status value for which NT_SUCCESS(status) equals **FALSE**.

Remarks

To register a *ResourceManagerNotification* callback routine, your resource manager must call TmEnableCallbacks.

Note that *ResourceManagerNotification* callback routines receive a pointer, instead of a handle, to an enlistment object. You can pass the enlistment object pointer to the enlistment object's TmXxx routines.

For more information about *ResourceManagerNotification* callback routines, see Creating a Resource Manager.

The *ResourceManagerNotification* callback routine is called at IRQL = PASSIVE_LEVEL, and it must return at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	PASSIVE_LEVEL (See Remarks section)

PushEntryList function

1/25/2019 • 2 minutes to read • Edit Online

The **PushEntryList** routine inserts an entry at the beginning of a singly linked list of SINGLE_LIST_ENTRY structures.

Syntax

```
void PushEntryList(
  PSINGLE_LIST_ENTRY                  ListHead,
  __drv_aliasesMem PSINGLE_LIST_ENTRY Entry
);
```

Parameters

`ListHead`

Pointer to the SINGLE_LIST_ENTRY structure that serves as the list header.

`Entry`

Pointer to SINGLE_LIST_ENTRY structure that represents the entry to be inserted on the list.

Return Value

None

Remarks

PushEntryList sets *ListHead*->**Next** to *Entry*, and *Entry*->**Next** to point to the old first entry of the list.

For information about using this routine when implementing a singly linked list, see Singly and Doubly Linked Lists.

Callers of **PushEntryList** can be running at any IRQL. If **PushEntryList** is called at IRQL >= DISPATCH_LEVEL, the storage for *ListHead* and the list entries must be resident.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
IRQL	Any level (See Remarks section)

READ_PORT_BUFFER_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_PORT_BUFFER_UCHAR** routine reads a number of bytes from the specified port address into a buffer.

Syntax

```
NTHALAPI VOID READ_PORT_BUFFER_UCHAR(
  PUCHAR Port,
  PUCHAR Buffer,
  ULONG  Count
);
```

Parameters

`Port`

Specifies the port address, which must be a mapped memory range in I/O space.

`Buffer`

Pointer to a buffer into which an array of UCHAR values is read.

`Count`

Specifies the number of bytes to be read into the buffer.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of bytes.

Callers of **READ_PORT_BUFFER_UCHAR** can be running at any IRQL, assuming the *Buffer* is resident and the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
Library	Hal.lib

IRQL	Any level (see Remarks section)

READ_PORT_BUFFER_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_PORT_BUFFER_ULONG** routine reads a number of ULONG values from the specified port address into a buffer.

Syntax

```
NTHALAPI VOID READ_PORT_BUFFER_ULONG(
  PULONG Port,
  PULONG Buffer,
  ULONG  Count
);
```

Parameters

`Port`

Specifies the port address, which must be a mapped memory range in I/O space.

`Buffer`

Pointer to a buffer into which an array of ULONG values is read.

`Count`

Specifies the number of ULONG values to be read into the buffer.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of ULONG values.

Callers of **READ_PORT_BUFFER_ULONG** can be running at any IRQL, assuming the *Buffer* is resident and the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
Library	Hal.lib

IRQL	Any level (see Remarks section)

READ_PORT_BUFFER_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_PORT_BUFFER_USHORT** routine reads a number of USHORT values from the specified port address into a buffer.

Syntax

```
NTHALAPI VOID READ_PORT_BUFFER_USHORT(
  PUSHORT Port,
  PUSHORT Buffer,
  ULONG   Count
);
```

Parameters

`Port`

Specifies the port address, which must be a mapped memory range in I/O space.

`Buffer`

Pointer to a buffer into which an array of USHORT values is read.

`Count`

Specifies the number of USHORT values to be read into the buffer.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of USHORT values.

Callers of **READ_PORT_BUFFER_USHORT** can be running at any IRQL, assuming the *Buffer* is resident and the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
Library	Hal.lib

IRQL	Any level (see Remarks section)

READ_PORT_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_PORT_UCHAR** routine reads a byte from the specified port address.

Syntax

```
NTHALAPI UCHAR READ_PORT_UCHAR(
  PUCHAR Port
);
```

Parameters

`Port`

Return Value

READ_PORT_UCHAR returns the byte that is read from the specified port address.

Remarks

Callers of **READ_PORT_UCHAR** can be running at any IRQL, assuming the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h)
Library	Hal.lib
IRQL	Any level (see Remarks section)

READ_PORT_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_PORT_ULONG** routine reads a ULONG value from the specified port address.

Syntax

```
NTHALAPI ULONG READ_PORT_ULONG(
  PULONG Port
);
```

Parameters

`Port`

Return Value

READ_PORT_ULONG returns the ULONG value that is read from the specified port address.

Remarks

Callers of **READ_PORT_ULONG** can be running at any IRQL, assuming the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h)
Library	Hal.lib
IRQL	Any level (see Remarks section)

READ_PORT_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_PORT_USHORT** routine reads a USHORT value from the specified port address.

Syntax

```
NTHALAPI USHORT READ_PORT_USHORT(
  PUSHORT Port
);
```

Parameters

`Port`

Return Value

READ_PORT_USHORT returns the USHORT value that is read from the specified port address.

Remarks

Callers of **READ_PORT_USHORT** can be running at any IRQL, assuming the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h)
Library	Hal.lib
IRQL	Any level (see Remarks section)

READ_REGISTER_BUFFER_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_BUFFER_UCHAR** routine reads a number of bytes from the specified register address into a buffer.

Syntax

```
void READ_REGISTER_BUFFER_UCHAR(
  volatile UCHAR *Register,
  PUCHAR         Buffer,
  ULONG          Count
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Buffer`

Pointer to a buffer into which an array of UCHAR values is read.

`Count`

Specifies the number of bytes to be read into the buffer.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of bytes.

Callers of **READ_REGISTER_BUFFER_UCHAR** can be running at any IRQL, assuming the *Buffer* is resident and the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe

READ_REGISTER_BUFFER_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_BUFFER_ULONG** routine reads a number of ULONG values from the specified register address into a buffer.

Syntax

```
void READ_REGISTER_BUFFER_ULONG(
  volatile ULONG *Register,
  PULONG         Buffer,
  ULONG          Count
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Buffer`

Pointer to a buffer into which an array of ULONG values is read.

`Count`

Specifies the number of ULONG values to be read into the buffer.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of ULONG values.

Callers of **READ_REGISTER_BUFFER_ULONG** can be running at any IRQL, assuming the *Buffer* is resident and the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

READ_REGISTER_BUFFER_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_BUFFER_USHORT** routine reads a number of USHORT values from the specified register address into a buffer.

Syntax

```
void READ_REGISTER_BUFFER_USHORT(
  volatile USHORT *Register,
  PUSHORT         Buffer,
  ULONG           Count
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Buffer`

Pointer to a buffer into which an array of USHORT values is read.

`Count`

Specifies the number of USHORT values to be read into the buffer.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of USHORT values.

Callers of **READ_REGISTER_BUFFER_USHORT** can be running at any IRQL, assuming the *Buffer* is resident and the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

READ_REGISTER_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_UCHAR** routine reads a byte from the specified register address.

Syntax

```
UCHAR READ_REGISTER_UCHAR(
  volatile UCHAR *Register
);
```

Parameters

`Register`

Return Value

READ_REGISTER_UCHAR returns the byte read from the specified register address.

Remarks

Callers of **READ_REGISTER_UCHAR** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

READ_REGISTER_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_ULONG** routine reads a ULONG value from the specified register address.

Syntax

```
ULONG READ_REGISTER_ULONG(
  volatile ULONG *Register
);
```

Parameters

`Register`

Return Value

READ_REGISTER_ULONG returns the ULONG value read from the specified register address.

Remarks

Callers of **READ_REGISTER_ULONG** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

READ_REGISTER_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_USHORT** routine reads a USHORT value from the specified register address.

Syntax

```
USHORT READ_REGISTER_USHORT(
  volatile USHORT *Register
);
```

Parameters

`Register`

Return Value

READ_REGISTER_USHORT returns the USHORT value read from the specified register address.

Remarks

Callers of **READ_REGISTER_USHORT** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

RemoveEntryList function

1/25/2019 • 2 minutes to read • Edit Online

The **RemoveEntryList** routine removes an entry from a doubly linked list of LIST_ENTRY structures.

Syntax

```
BOOLEAN RemoveEntryList(
  PLIST_ENTRY Entry
);
```

Parameters

`Entry`

Pointer to the LIST_ENTRY structure that represents the entry to be removed.

Return Value

RemoveEntryList returns **TRUE** if, after removal of the designated entry, the list is empty. Otherwise, the routine returns **FALSE** to indicate that the resulting list still contains one or more entries. For information, see Remarks.

> **Note** Before Microsoft Windows Server 2003, **RemoveEntryList** was defined to return VOID, not BOOLEAN.

Remarks

RemoveEntryList removes the entry by setting the **Flink** member of the entry before *Entry* to point to the entry after *Entry*, and the **Blink** member of the entry after *Entry* to point to the entry before *Entry*.

The return value can be used to detect when the last entry is removed from the list. An empty list consists of a list head only and no list entries.

> **Note** Typically, *Entry* points to an entry in a list and not to the list head. However, *Entry* can point to a list head, in which case the routine removes the list head from the list to produce a headless list. When **RemoveEntryList** is used in this way, the return value should typically be ignored. To determine whether a list is empty, use the IsListEmpty routine.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

In Windows XP and Windows 2000, **RemoveEntryList** did not return a value. Starting with Windows Server 2003, **RemoveEntryList** returns a BOOLEAN value.

Callers of **RemoveEntryList** can be running at any IRQL. If **RemoveEntryList** is called at IRQL >= DISPATCH_LEVEL, the storage for the list entries must be resident.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
IRQL	Any level (See Remarks section)

RemoveHeadList

RemoveTailList

RemoveHeadList function

1/25/2019 • 2 minutes to read • Edit Online

The **RemoveHeadList** routine removes an entry from the beginning of a doubly linked list of LIST_ENTRY structures.

Syntax

```
PLIST_ENTRY RemoveHeadList(
  PLIST_ENTRY ListHead
);
```

Parameters

`ListHead`

Pointer to the LIST_ENTRY structure that serves as the list header.

Return Value

RemoveHeadList returns a pointer to the entry removed from the list. If the list is empty, **RemoveHeadList** returns *ListHead*.

Remarks

RemoveHeadList removes the first entry from the list by setting *ListHead*->**Flink** to point to the second entry in the list. The routine sets the **Blink** member of the second entry to *ListHead*. In the event the list is empty, this is effectively a no-op.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

Callers of **RemoveHeadList** can be running at any IRQL. If **RemoveHeadList** is called at IRQL >= DISPATCH_LEVEL, the storage for *ListHead* and the list entries must be resident.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)

RemoveEntryList

RemoveTailList

RemoveTailList function

1/25/2019 • 2 minutes to read • Edit Online

The **RemoveTailList** routine removes an entry from the end of a doubly linked list of LIST_ENTRY structures.

Syntax

```
PLIST_ENTRY RemoveTailList(
  PLIST_ENTRY ListHead
);
```

Parameters

`ListHead`

Pointer to the LIST_ENTRY structure that serves as the list header.

Return Value

RemoveTailList returns a pointer to the entry that was at the tail of the list. If the list is empty, **RemoveTailList** returns *ListHead*.

Remarks

RemoveTailList removes the last entry from the list by setting *ListHead*->**Blink** to point to the second-to-last entry in the list. The routine sets the **Flink** member of the new first entry to *ListHead*. In the event the list is empty, this is effectively a no-op.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

Callers of **InsertHeadList** can be running at any IRQL. If **InsertHeadList** is called at IRQL >= DISPATCH_LEVEL, the storage for *ListHead* and the list entries must be resident.

REQUEST_POWER_COMPLETE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *PowerCompletion* callback routine completes the processing of a power IRP.

Syntax

```
REQUEST_POWER_COMPLETE RequestPowerComplete;

void RequestPowerComplete(
  PDEVICE_OBJECT DeviceObject,
  UCHAR MinorFunction,
  POWER_STATE PowerState,
  PVOID Context,
  PIO_STATUS_BLOCK IoStatus
)
{...}
```

Parameters

`DeviceObject`

A pointer to the target DEVICE_OBJECT for the completed power IRP.

`MinorFunction`

Specifies the minor function code in the power IRP. For more information, see the list of supported **IRP_MN_*XXX*** codes in the Remarks section.

`PowerState`

Specifies the device power state or system power state that was passed to the PoRequestPowerIrp routine.

`Context`

A pointer to the context that was passed to **PoRequestPowerIrp**.

`IoStatus`

A pointer to the IO_STATUS_BLOCK structure for the completed IRP.

Return Value

None

Remarks

A driver that sends a power IRP might need to perform additional tasks after all other drivers have completed the IRP. If so, the sending driver should register a *PowerCompletion* callback routine during the call to the PoRequestPowerIrp routine that allocates the IRP.

A driver's *PowerCompletion* callback routine is used only for IRP_MJ_POWER IRPs that have minor IRP codes of IRP_MN_SET_POWER, IRP_MN_QUERY_POWER, and IRP_MN_WAIT_WAKE. For more information, see Sending IRP_MN_QUERY_POWER or IRP_MN_SET_POWER for Device Power States and Wait/Wake Callback

Routines.

The I/O manager calls the sending driver's *PowerCompletion* routine only after the I/O manager has called all the IoCompletion routines that were set by other drivers as they passed the IRP down the stack. The *PowerCompletion* routine performs any additional tasks that the sender of the IRP requires after all other drivers have completed the IRP. The *PowerCompletion* routine should not free the IRP—the power manager does that.

In Windows 2000 and later versions of Windows, the *PowerCompletion* routine is called at IRQL = PASSIVE_LEVEL or IRQL = DISPATCH_LEVEL. In Windows 98/Me, the *PowerCompletion* routine is always called at IRQL = PASSIVE_LEVEL, and drivers must complete IRPs at IRQL = PASSIVE_LEVEL.

Examples

To define a *PowerCompletion* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *PowerCompletion* callback routine that is named `MyPowerCompletion`, use the REQUEST_POWER_COMPLETE type as shown in this code example:

```
REQUEST_POWER_COMPLETE MyPowerCompletion;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyPowerCompletion(
    PDEVICE_OBJECT DeviceObject,
    UCHAR MinorFunction,
    POWER_STATE PowerState,
    PVOID Context,
    PIO_STATUS_BLOCK IoStatus
    )
  {
      // Function body
  }
```

The REQUEST_POWER_COMPLETE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the REQUEST_POWER_COMPLETE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Supported in Windows 2000 and later versions of Windows.

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

RTL_QUERY_REGISTRY_ROUTINE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *QueryRoutine* routine provides information about a registry value that was requested in a preceding call to the RtlQueryRegistryValues routine.

Syntax

```
RTL_QUERY_REGISTRY_ROUTINE RtlQueryRegistryRoutine;

NTSTATUS RtlQueryRegistryRoutine(
  PWSTR ValueName,
  ULONG ValueType,
  PVOID ValueData,
  ULONG ValueLength,
  PVOID Context,
  PVOID EntryContext
)
{...}
```

Parameters

`ValueName`

Specifies the registry key that is associated with the requested registry value. This parameter is a pointer to a null-terminated, Unicode string that contains the key.

`ValueType`

Specifies the type of registry value that is stored with the specified registry key. For more information registry value types, see the definition of the *Type* parameter in KEY_VALUE_BASIC_INFORMATION.

`ValueData`

A pointer to the data value that is associated with the specified registry key. The driver must treat this value as read-only. For more information about the type of value data that *ValueData* points to, see the definition of the *Type* parameter in KEY_VALUE_BASIC_INFORMATION.

`ValueLength`

Specifies the length, in bytes, of the value that *ValueData* points to.

`Context`

Specifies the *Context* parameter value that the driver specified in the preceding call to **RtlQueryRegistryValues**.

`EntryContext`

Specifies an **EntryContext** value in a *QueryTable* array element that the driver specified in the preceding call to **RtlQueryRegistryValues**.

Return Value

QueryRoutine returns STATUS_SUCCESS if the call is successful. Otherwise, it returns an appropriate error status code. Use only status codes that are defined in the Ntstatus.h header file.

Remarks

A kernel-mode driver implements a *QueryRoutine* routine. This routine is called by the RtlQueryRegistryValues routine.

To obtain information about one or more registry values, the driver calls **RtlQueryRegistryValues** and passes a pointer, as an input parameter, to an array of **RTL_QUERY_REGISTRY_TABLE** structures. Each structure in this array contains a pointer to a driver-implemented *QueryRoutine* routine and a request for information about a particular registry value. For each structure in the array, **RtlQueryRegistryValues** calls the specified *QueryRoutine* routine and passes to this routine a set of parameters that contain the requested information about the specified registry value.

For more information about the **RTL_QUERY_REGISTRY_TABLE** structure, see RtlQueryRegistryValues.

Examples

To define a *QueryRoutine* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *QueryRoutine* callback routine that is named `MyQueryRoutine`, use the RTL_QUERY_REGISTRY_ROUTINE type as shown in this code example:

```
RTL_QUERY_REGISTRY_ROUTINE MyQueryRoutine;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
NTSTATUS
  MyQueryRoutine(
    PWSTR ValueName,
    ULONG ValueType,
    PVOID ValueData,
    ULONG ValueLength,
    PVOID Context,
    PVOID EntryContext
    )
  {
      // Function body
  }
```

The RTL_QUERY_REGISTRY_ROUTINE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the RTL_QUERY_REGISTRY_ROUTINE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Supported starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Called at PASSIVE_LEVEL.

KEY_VALUE_BASIC_INFORMATION

RtlQueryRegistryValues

RtlAnsiStringToUnicodeSize macro

1/25/2019 • 2 minutes to read • Edit Online

The **RtlAnsiStringToUnicodeSize** routine returns the number of bytes required to hold an ANSI string converted into a Unicode string.

Syntax

```
void RtlAnsiStringToUnicodeSize(
   STRING
);
```

Parameters

`STRING`

Pointer to a buffer containing the ANSI string.

Return Value

RtlAnsiStringToUnicodeSize returns the necessary size in bytes for a Unicode string buffer.

Remarks

> Casting the return value of the **RtlAnsiStringToUnicodeSize** routine to USHORT might cause a loss of data. To avoid potential problems, callers of this routine should test the return value for arithmetic overflow. Note that **RtlAnsiStringToUnicodeSize** accounts for the trailing **NULL**.

Callers of **RtlAnsiStringToUnicodeSize** must be running at IRQL = PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

See Also

RtlAnsiStringToUnicodeString

RtlxAnsiStringToUnicodeSize

RtlAnsiStringToUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

RtlAnsiStringToUnicodeString converts the given ANSI source string into a Unicode string.

Syntax

```
NTSYSAPI NTSTATUS RtlAnsiStringToUnicodeString(
  PUNICODE_STRING DestinationString,
  PCANSI_STRING   SourceString,
  BOOLEAN         AllocateDestinationString
);
```

Parameters

`DestinationString`

Pointer to a UNICODE_STRING structure to hold the converted Unicode string. If *AllocateDestinationString* is **TRUE**, the routine allocates a new buffer to hold the string data, and updates the **Buffer** member of *DestinationString* to point to the new buffer. Otherwise, the routine uses the currently-specified buffer to hold the string.

`SourceString`

Pointer to the ANSI string to be converted to Unicode.

`AllocateDestinationString`

Specifies if this routine should allocate the buffer space for the destination string. If it does, the caller must deallocate the buffer by calling RtlFreeUnicodeString.

Return Value

If the conversion succeeds, **RtlAnsiStringToUnicodeString** returns STATUS_SUCCESS. On failure, the routine does not allocate any memory.

Remarks

The translation conforms to the current system locale information.

If caller sets *AllocateDestinationString* to **TRUE**, the routine replaces the **Buffer** member of *DestinationString* with a pointer to the buffer it allocates. The old value can be overwritten even when the routine returns an error status code.

This routine is not declared in a header file. However, you can copy the following declaration to your source code:

```
```

```
NTSYSAPI
WCHAR
NTAPI
RtlAnsiCharToUnicodeChar(
    __inout PUCHAR *SourceCharacter
    );
```

You can use the following routines to convert single-byte and double-byte characters to Unicode characters:

RtlAnsiStringToUnicodeSize

RtlAnsiStringToUnicodeString

RtlMultiByteToUnicodeSize

RtlMultiByteToUnicodeN

For more information about these and other string-handling routines, see Strings.

RtlAnsiCharToUnicodeChar has security deficiencies. Consider using the **RtlAnsiStringToUnicodeString** routine instead.

If, on entry, **SourceCharacter* points to a one-byte buffer that contains the first byte of a two-byte character code, **RtlAnsiCharToUnicodeChar** overruns the buffer when it tries to read the second byte.

At system startup, the operating system determines the user language from the locale settings and installs the appropriate system ANSI code page. **RtlAnsiCharToUnicodeChar** uses this code page to convert a single-byte or double-byte character to the corresponding Unicode character.

If the system ANSI code page defines a single-byte character set (that is, the ANSI character set), **RtlAnsiCharToUnicodeChar** speeds up the conversion operation by simply zero-extending an ANSI character in the range 0x00 to 0x7f to produce the corresponding Unicode character. The routine converts the ANSI value 0x5c to the backslash character ("\"), even if the single-byte code page defines this character as the yen sign.

If, on entry, **SourceCharacter* points to an invalid character code, **RtlAnsiCharToUnicodeChar** returns the Unicode space character code, 0x0020. The following list shows examples of invalid character codes:

- The first byte of the character code is a value that is valid only as the second byte of a two-byte character code.
- The second byte of a two-byte character code is a value that is valid only as the first byte.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

RtlUnicodeStringToAnsiString

UNICODE_STRING

RtlAppendUnicodeStringToString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlAppendUnicodeStringToString** routine concatenates two Unicode strings.

Syntax

```
NTSYSAPI NTSTATUS RtlAppendUnicodeStringToString(
  PUNICODE_STRING  Destination,
  PCUNICODE_STRING Source
);
```

Parameters

`Destination`

Pointer to a buffered Unicode string.

`Source`

Pointer to the buffered string to be concatenated.

Return Value

RtlAppendUnicodeStringToString can return one of the following:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The source string was successfully appended to the destination counted string. The destination string length is updated to include the appended bytes.
STATUS_BUFFER_TOO_SMALL	The destination string length is too small to allow the source string to be concatenated. Accordingly, the destination string length is not updated.

Remarks

RtlAppendUnicodeStringToString copies bytes from the source to the specified destination string, after the current contents of the destination string and the destination length is incremented by the number of bytes copied.

The *Destination* and *Source* buffers must be resident if the caller is running at IRQL >= DISPATCH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	See Remarks section.

RtlAppendUnicodeToString

RtlAppendUnicodeToString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlAppendUnicodeToString** routine concatenates the supplied Unicode string to a buffered Unicode string.

Syntax

```
NTSYSAPI NTSTATUS RtlAppendUnicodeToString(
  PUNICODE_STRING Destination,
  PCWSTR          Source
);
```

Parameters

`Destination`

A pointer to the buffered string.

`Source`

A pointer to the null-terminated string to append to the *Destination* string.

Return Value

RtlAppendUnicodeToString can return one of the following:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The source string was successfully appended to the destination string, and the destination string length was updated to include the appended bytes.
STATUS_BUFFER_TOO_SMALL	The destination string buffer is too small to allow the source string to be appended, so the destination string length is not updated and the contents of the destination string buffer are not changed.

Remarks

RtlAppendUnicodeToString appends the source string to the end of the destination string.

If the destination buffer is not large enough to contain the string that would result from concatenating the source and destination strings (not including the null character that terminates the source string), the routine returns STATUS_BUFFER_TOO_SMALL and leaves the destination string unchanged.

The *Destination* buffer must be resident if the caller is running at IRQL >= DISPATCH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)
IRQL	See Remarks section.

RtlAreBitsClear function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlAreBitsClear** routine determines whether a given range of bits within a bitmap variable is clear.

Syntax

```
NTSYSAPI BOOLEAN RtlAreBitsClear(
  PRTL_BITMAP BitMapHeader,
  ULONG       StartingIndex,
  ULONG       Length
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`StartingIndex`

Specifies the start of the bit range to be tested. This is a zero-based value indicating the position of the first bit in the range.

`Length`

Specifies how many bits to test.

Return Value

RtlAreBitsClear returns **TRUE** if *Length*consecutive bits beginning at *StartingIndex* are clear (that is, all the bits from *StartingIndex*to (*StartingIndex*+ *Length*) -1). It returns **FALSE** if any bit in the given range is set, if the given range is not a proper subset of the bitmap, or if the given *Length* is zero.

Remarks

Callers of **RtlAreBitsClear** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlAreBitsClear** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL (See Remarks section)"

RtlInitializeBitMap

RtlAreBitsSet function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlAreBitsSet** routine determines whether a given range of bits within a bitmap variable is set.

Syntax

```
NTSYSAPI BOOLEAN RtlAreBitsSet(
  PRTL_BITMAP BitMapHeader,
  ULONG       StartingIndex,
  ULONG       Length
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`StartingIndex`

Specifies the start of the bit range to be tested. This is a zero-based value indicating the position of the first bit in the range.

`Length`

Specifies how many bits to test.

Return Value

RtlAreBitsSet returns **TRUE** if *Length*consecutive bits beginning at *StartingIndex* are set (that is, all the bits from *StartingIndex*to (*StartingIndex*+ *Length*)). It returns **FALSE** if any bit in the given range is clear, if the given range is not a proper subset of the bitmap, or if the given *Length* is zero.

Remarks

Callers of **RtlAreBitsSet** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlAreBitsSet** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.

RtlInitializeBitMap

RtlSetAllBits

RtlCheckBit macro

1/25/2019 • 2 minutes to read • Edit Online

The **RtlCheckBit** routine determines whether a particular bit in a given bitmap variable is clear or set.

Syntax

```
void RtlCheckBit(
   BMH,
   BP
);
```

Parameters

`BMH`

[in]

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`BP`

[in]

Specifies which bit to check. This is a zero-based value indicating the position of the bit to be tested.

Return Value

RtlCheckBit returns zero if the given bit is clear, or one if the given bit is set.

Remarks

Callers of **RtlCheckBit** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlCheckBit** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop

RtlCheckRegistryKey function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlCheckRegistryKey** routine checks for the existence of a given named key in the registry.

Syntax

```
NTSYSAPI NTSTATUS RtlCheckRegistryKey(
  ULONG RelativeTo,
  PWSTR Path
);
```

Parameters

`RelativeTo`

Specifies whether *Path* is an absolute registry path or is relative to a predefined key path as one of the following.

VALUE	MEANING
RTL_REGISTRY_ABSOLUTE	Path is an absolute registry path.
RTL_REGISTRY_CONTROL	Path is relative to **\Registry\Machine\System\CurrentControlSet\Control**.
RTL_REGISTRY_DEVICEMAP	Path is relative to **\Registry\Machine\Hardware\DeviceMap**.
RTL_REGISTRY_SERVICES	Path is relative to **\Registry\Machine\System\CurrentControlSet\Services**.
RTL_REGISTRY_USER	Path is relative to the registry settings for the current user. (For a system process, this is **\Users.Default**.) This is equivalent to HKEY_CURRENT_USER in user mode.
RTL_REGISTRY_WINDOWS_NT	Path is relative to **\Registry\Machine\Software\Microsoft\Windows NT\CurrentVersion**.
RTL_REGISTRY_HANDLE	This value should not be passed into this routine. Despite the redundancy of a check for the existence of an already-opened key, it has the side effect of closing the passed handle.

`Path`

Specifies the registry path according to the *RelativeTo* value. If RTL_REGISTRY_HANDLE is set, *Path* is a handle to be used directly.

Return Value

If the given named key exists in the registry along the given relative path, **RtlCheckRegistryKey** returns STATUS_SUCCESS.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RtlClearAllBits function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlClearAllBits** routine sets all bits in a given bitmap variable to zero.

Syntax

```
NTSYSAPI VOID RtlClearAllBits(
  PRTL_BITMAP BitMapHeader
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

Return Value

None

Remarks

Callers of **RtlClearAllBits** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlClearAllBits** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

RtlFindSetBitsAndClear

RtlInitializeBitMap

RtlNumberOfSetBits

RtlClearBit function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlClearBit** routine sets the specified bit in a bitmap to zero.

Syntax

```
NTSYSAPI VOID RtlClearBit(
  PRTL_BITMAP BitMapHeader,
  ULONG       BitNumber
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`BitNumber`

Specifies the zero-based index of the bit within the bitmap. The routine sets this bit to zero.

Return Value

None

Remarks

Callers of **RtlClearBit** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlClearBit** can be called at any IRQL.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.

RTL_BITMAP

RtlInitializeBitMap

RtlClearBits function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlClearBits** routine sets all bits in the specified range of bits in the bitmap to zero.

Syntax

```
NTSYSAPI VOID RtlClearBits(
  PRTL_BITMAP BitMapHeader,
  ULONG       StartingIndex,
  ULONG       NumberToClear
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`StartingIndex`

The index of the first bit in the bit range that is to be cleared. If the bitmap contains N bits, the bits are numbered from 0 to N-1.

`NumberToClear`

Specifies how many bits to clear. If the bitmap contains N bits, this parameter can be a value in the range 1 to (N - *StartingIndex*).

Return Value

This routine does not return a value.

Remarks

If the *NumberToClear* parameter is zero, **RtlClearBits** simply returns control without clearing any bits.

The sum (*StartingIndex* + *NumberToClear*) must not exceed the *SizeOfBitMap* parameter value specified in the RtlInitializeBitMap call that initialized the bitmap.

Callers of **RtlClearBits** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlClearBits** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

RtlCmDecodeMemIoResource function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlCmDecodeMemIoResource** routine provides the starting address and length of a CM_PARTIAL_RESOURCE_DESCRIPTOR structure that describes a range of memory or I/O port addresses.

Syntax

```
NTSYSAPI ULONGLONG RtlCmDecodeMemIoResource(
  PCM_PARTIAL_RESOURCE_DESCRIPTOR Descriptor,
  PULONGLONG                      Start
);
```

Parameters

`Descriptor`

A pointer to the CM_PARTIAL_RESOURCE_DESCRIPTOR structure to provide the starting address and length for.

`Start`

A pointer to a variable that receives the starting address of the range of memory or I/O port addresses.

Return Value

RtlCmDecodeMemIoResource returns the length of the address range, in bytes.

Remarks

The **Type** member of the **CM_PARTIAL_RESOURCE_DESCRIPTOR** structure must be **CmResourceTypeMemory**, **CmResourceTypeMemoryLarge**, or **CmResourceTypePort**.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

CM_PARTIAL_RESOURCE_DESCRIPTOR

RtlCmEncodeMemIoResource

RtlCmEncodeMemIoResource function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlCmEncodeMemIoResource** routine updates a CM_PARTIAL_RESOURCE_DESCRIPTOR structure to describe a range of memory or I/O port addresses.

Syntax

```
NTSYSAPI NTSTATUS RtlCmEncodeMemIoResource(
  PCM_PARTIAL_RESOURCE_DESCRIPTOR Descriptor,
  UCHAR                           Type,
  ULONGLONG                       Length,
  ULONGLONG                       Start
);
```

Parameters

`Descriptor`

A pointer to the CM_PARTIAL_RESOURCE_DESCRIPTOR structure to update.

`Type`

The resource type of the memory. This parameter can be **CmResourceTypeMemory**, **CmResourceTypeMemoryLarge**, or **CmResourceTypePort**.

`Length`

The length, in bytes, of the range of allocated addresses.

`Start`

The starting address of the range of memory or I/O port addresses.

Return Value

RtlCmEncodeMemIoResource returns an NTSTATUS value. This routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The **CM_PARTIAL_RESOURCE_DESCRIPTOR** structure has been updated.

STATUS_UNSUCCESSFUL	The specified value for *Length* cannot be encoded in a **CM_PARTIAL_RESOURCE_DESCRIPTOR** structure.
STATUS_INVALID_PARAMETER	One or more of the specified parameters are invalid.

Remarks

Addresses that are larger than 32 bits in length must satisfy certain alignment restrictions or else the routine returns STATUS_UNSUCCESSFUL.

ADDRESS LENGTH	ALIGNMENT RESTRICTION
40 bits	Lowest 8 bits must be zero.
48 bits	Lowest 16 bits must be zero.
64 bits	Lowest 32 bits must be zero.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RtlCompareMemory function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlCompareMemory** routine compares two blocks of memory and returns the number of bytes that match.

Syntax

```
NTSYSAPI SIZE_T RtlCompareMemory(
  const VOID *Source1,
  const VOID *Source2,
  SIZE_T     Length
);
```

Parameters

`Source1`

A pointer to the first block of memory.

`Source2`

A pointer to the second block of memory.

`Length`

The number of bytes to compare.

Return Value

RtlCompareMemory returns the number of bytes in the two blocks that match. If all bytes match up to the specified *Length* value, the *Length* value is returned.

Remarks

The routine starts by comparing the first byte in the first block to the first byte in the second block, and continues to compare successive bytes in the two blocks while the bytes match. The routine stops comparing bytes when it encounters the first pair of bytes that are not equal, or when the number of matching bytes equals the *Length* parameter value, whichever occurs first.

Callers of **RtlCompareMemory** can be running at any IRQL if both blocks of memory are resident.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

Library	NtosKrnl.lib; OneCoreUAP.lib on Windows 10
DLL	NtDll.dll (user mode); Kernel32.dll (user mode); NtosKrnl.exe (kernel mode)
IRQL	Any level (See Remarks section)
DDI compliance rules	BufAfterReqCompletedIntIoctlA, BufAfterReqCompletedIoctlA, BufAfterReqCompletedReadA, BufAfterReqCompletedWriteA

RtlCompareUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlCompareUnicodeString** routine compares two Unicode strings.

Syntax

```
NTSYSAPI LONG RtlCompareUnicodeString(
  PCUNICODE_STRING String1,
  PCUNICODE_STRING String2,
  BOOLEAN          CaseInSensitive
);
```

Parameters

`String1`

Pointer to the first string.

`String2`

Pointer to the second string.

`CaseInSensitive`

If **TRUE**, case should be ignored when doing the comparison.

Return Value

RtlCompareUnicodeString returns a signed value that gives the results of the comparison:

RETURN CODE	DESCRIPTION
Zero	*String1* equals *String2*.
< Zero	*String1* is less than *String2*.
> Zero	*String1* is greater than *String2*.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)

RtlEqualString

RtlConvertLongToLargeInteger function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlConvertLongToLargeInteger** routine converts the input signed integer to a signed large integer.

Syntax

```
DECLSPEC_DEPRECATED_DDK_WINXP LARGE_INTEGER NTAPI_INLINE RtlConvertLongToLargeInteger(
  LONG SignedInteger
);
```

Parameters

`SignedInteger`

Specifies an integer of type LONG.

Return Value

RtlConvertLongToLargeInteger returns the large integer result.

Remarks

This routine is not supported in Windows XP. Use native support for **__int64** instead.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

RtlConvertUlongToLargeInteger function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlConvertUlongToLargeInteger** routine converts the input unsigned integer to a signed large integer. For Windows XP and later versions of Windows, do not use this routine; use the native support for **__int64**.

Syntax

```
DECLSPEC_DEPRECATED_DDK_WINXP LARGE_INTEGER NTAPI_INLINE RtlConvertUlongToLargeInteger(
  ULONG UnsignedInteger
);
```

Parameters

`UnsignedInteger`

Specifies a value of type ULONG.

Return Value

RtlConvertUlongToLargeInteger returns the converted large integer.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

RtlCopyMemory macro

1/25/2019 • 2 minutes to read • Edit Online

The **RtlCopyMemory** routine copies the contents of a source memory block to a destination memory block.

Syntax

```
void RtlCopyMemory(
   Destination,
   Source,
   Length
);
```

Parameters

`Destination`

Datatype: void*. A pointer to the destination memory block to copy the bytes to.

`Source`

Datatype: const void*. A pointer to the source memory block to copy the bytes from.

`Length`

Datatype: size_t. The number of bytes to copy from the source to the destination.

Return Value

None

Remarks

RtlCopyMemory runs faster than **RtlMoveMemory**. However, **RtlCopyMemory** requires that the source memory block, which is defined by *Source* and *Length*, cannot overlap the destination memory block, which is defined by *Destination* and *Length*. In contrast, **RtlMoveMemory** correctly handles the case in which the source and destination memory blocks overlap.

New drivers should use the **RtlCopyMemory** routine instead of **RtlCopyBytes**.

Callers of **RtlCopyMemory** can be running at any IRQL if the source and destination memory blocks are in nonpaged system memory. Otherwise, the caller must be running at IRQL <= APC_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtDll.dll (user mode); NtosKrnl.exe (kernel mode)
IRQL	Any level (See Remarks section)

RtlMoveMemory

RtlCopyUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlCopyUnicodeString** routine copies a source string to a destination string.

Syntax

```
NTSYSAPI VOID RtlCopyUnicodeString(
  PUNICODE_STRING  DestinationString,
  PCUNICODE_STRING SourceString
);
```

Parameters

`DestinationString`

A pointer to the destination string buffer. This parameter points to a UNICODE_STRING structure.

`SourceString`

A pointer to the source string buffer. This parameter points to a **UNICODE_STRING** structure.

Return Value

None

Remarks

If *SourceString* is **NULL**, this routine sets the **Length** field of the structure pointed to by *DestinationString* to zero.

This routine does not modify the **MaximumLength** and **Buffer** fields of the structure pointed to by *DestinationString*.

The number of bytes copied from the source string is either the source string length (specified by the **Length** member of the structure pointed to by *SourceString*) or the maximum length of the destination string (specified by the **MaximumLength** member of the structure pointed to by *DestinationString*), whichever is smaller.

The caller must properly initialize all members of the structure pointed to by *DestinationString* before calling **RtlCopyUnicodeString**. Failure to initialize the **Length** or the **MaximumLength** member before calling this routine can cause a buffer overrun.

The *DestinationString* and *SourceString* buffers must be resident if the caller is running at IRQL >= DISPATCH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)
IRQL	Any level (See Remarks section)

UNICODE_STRING

RtlCreateRegistryKey function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlCreateRegistryKey** routine adds a key object in the registry along a given relative path.

Syntax

```
NTSYSAPI NTSTATUS RtlCreateRegistryKey(
  ULONG RelativeTo,
  PWSTR Path
);
```

Parameters

`RelativeTo`

Specifies whether *Path* is an absolute registry path or is relative to a predefined key path as one of the following.

VALUE	MEANING
RTL_REGISTRY_ABSOLUTE	Path is an absolute registry path.
RTL_REGISTRY_SERVICES	Path is relative to **\Registry\Machine\System\CurrentControlSet\Services**.
RTL_REGISTRY_CONTROL	Path is relative to **\Registry\Machine\System\CurrentControlSet\Control**.
RTL_REGISTRY_WINDOWS_NT	Path is relative to **\Registry\Machine\Software\Microsoft\Windows NT\CurrentVersion**.
RTL_REGISTRY_DEVICEMAP	Path is relative to **\Registry\Machine\Hardware\DeviceMap**.
RTL_REGISTRY_USER	Path is relative to **\Registry\User\CurrentUser**. (For a system process, this is **\Users.Default**.)

`Path`

Specifies the registry path according to the *RelativeTo* value.

Return Value

RtlCreateRegistryKey returns STATUS_SUCCESS if the key is created.

Remarks

RtlCreateRegistryKey creates only the keys that you specify. It does not create missing keys in the path to the specified key. If any keys in the path are missing, the call will fail. To ensure that all keys in the path exist, you must call **RtlCreateRegistryKey** once for each key in the path.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RtlCreateSecurityDescriptor function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlCreateSecurityDescriptor** routine initializes a new absolute-format security descriptor. On return, the security descriptor is initialized with no system ACL, no discretionary ACL, no owner, no primary group, and all control flags set to zero.

Syntax

```
NTSYSAPI NTSTATUS RtlCreateSecurityDescriptor(
  PSECURITY_DESCRIPTOR SecurityDescriptor,
  ULONG                Revision
);
```

Parameters

`SecurityDescriptor`

Pointer to the buffer for the SECURITY_DESCRIPTOR to be initialized.

`Revision`

Specifies the revision level to assign to the security descriptor. Set this parameter to SECURITY_DESCRIPTOR_REVISION.

Return Value

RtlCreateSecurityDescriptor can return one of the following.

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	The call completed successfully.
STA TUS _UN KN OW N_R EVIS ION	The caller specified an unsupported value for *Revision*.

Remarks

A successful call to this routine initializes a security descriptor. The fields in this descriptor are set to initial values that indicate that there are no security constraints.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)

RtlDeleteRegistryValue function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlDeleteRegistryValue** routine removes the specified entry name and the associated values from the registry along the given relative path.

Syntax

```
NTSYSAPI NTSTATUS RtlDeleteRegistryValue(
  ULONG  RelativeTo,
  PCWSTR Path,
  PCWSTR ValueName
);
```

Parameters

`RelativeTo`

Specifies whether *Path* is an absolute registry path or is relative to a predefined key path as one of the following.

VALUE	MEANING
RTL_REGISTRY_ABSOLUTE	Path is an absolute registry path.
RTL_REGISTRY_SERVICES	Path is relative to **\Registry\Machine\System\CurrentControlSet\Services**.
RTL_REGISTRY_CONTROL	Path is relative to **\Registry\Machine\System\CurrentControlSet\Control**.
RTL_REGISTRY_WINDOWS_NT	Path is relative to **\Registry\Machine\Software\Microsoft\Windows NT\CurrentVersion**.
RTL_REGISTRY_DEVICEMAP	Path is relative to **\Registry\Machine\Hardware\DeviceMap**.
RTL_REGISTRY_USER	Path is relative to **\Registry\User\CurrentUser**. (For a system process, this is **\Users.Default**.)
RTL_REGISTRY_HANDLE	Specifies that the *Path* parameter is actually a registry handle to use. This value is optional.

`Path`

Specifies the registry path according to the *RelativeTo* value. If RTL_REGISTRY_HANDLE is set, *Path* is a handle to be used directly.

`ValueName`

Pointer to the value name to be removed from the registry.

Return Value

RtlDeleteRegistryValue returns STATUS_SUCCESS if the value entry was deleted.

Note that if *RelativeTo* is set to RTL_REGISTRY_HANDLE, the following occurs:

- On Windows 98/Me and Windows NT 4.0, the routine closes the specified handle before returning.
- On Windows 2000 and later versions of Windows, the routine leaves the handle open.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RtlDowncaseUnicodeChar function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlDowncaseUnicodeChar** routine converts the specified Unicode character to lowercase.

Syntax

```
NTSYSAPI WCHAR RtlDowncaseUnicodeChar(
  WCHAR SourceCharacter
);
```

Parameters

`SourceCharacter`

Specifies the character to convert.

Return Value

RtlDowncaseUnicodeChar returns the lowercase value of the Unicode character.

Remarks

Ntoskrnl.lib supports the **RtlDowncaseUnicodeChar** routine in the WDK for Windows 7 and later versions of Windows. Ntdll.dll exports the **RtlDowncaseUnicodeChar** entry point in Windows XP and later versions of Windows.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Ntoskrnl.lib; Ntdll.lib

RtlEqualMemory macro

1/25/2019 • 2 minutes to read • Edit Online

The **RtlEqualMemory** routine compares two blocks of memory to determine whether the specified number of bytes are identical.

Syntax

```
void RtlEqualMemory(
   Destination,
   Source,
   Length
);
```

Parameters

`Destination`

Datatype: void*. A pointer to a caller-allocated block of memory to compare.

`Source`

Datatype: void*. A pointer to a caller-allocated block of memory that is compared to the block of memory to which *Source1* points.

`Length`

Datatype: size_t. Specifies the number of bytes to be compared.

Return Value

RtlEqualMemory returns TRUE if Source1 and Source2 are equivalent; otherwise, it returns FALSE.

Remarks

RtlEqualMemory begins the comparison with byte zero of each block.

Callers of **RtlEqualMemory** can be running at any IRQL if both blocks of memory are resident.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Any level (See Remarks section)

RtlCompareMemory

RtlEqualUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlEqualUnicodeString** routine compares two Unicode strings to determine whether they are equal.

Syntax

```
NTSYSAPI BOOLEAN RtlEqualUnicodeString(
  PCUNICODE_STRING String1,
  PCUNICODE_STRING String2,
  BOOLEAN          CaseInSensitive
);
```

Parameters

`String1`

Pointer to the first Unicode string.

`String2`

Pointer to the second Unicode string.

`CaseInSensitive`

If **TRUE**, case should be ignored when doing the comparison.

Return Value

RtlEqualUnicodeString returns **TRUE** if the two Unicode strings are equal; otherwise, it returns **FALSE**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)
IRQL	PASSIVE_LEVEL

RtlFillMemory macro

1/25/2019 • 2 minutes to read • Edit Online

The **RtlFillMemory** routine fills a block of memory with the specified fill value.

Syntax

```
void RtlFillMemory(
   Destination,
   Length,
   Fill
);
```

Parameters

`Destination`

Datatype: void*. A pointer to the block of memory to be filled.

`Length`

Datatype: size_t. The number of bytes in the block of memory to be filled.

`Fill`

Datatype: int. The value to fill the destination memory block with. This value is copied to every byte in the memory block that is defined by *Destination* and *Length*.

Return Value

None

Remarks

Callers of **RtlFillMemory** can be running at any IRQL if the destination memory block is in nonpaged system memory. Otherwise, the caller must be running at IRQL <= APC_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtDll.lib (user mode); NtosKrnl.lib (kernel mode)

RtlZeroMemory

RtlFindClearBits function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlFindClearBits** routine searches for a range of clear bits of a requested size within a bitmap.

Syntax

```
NTSYSAPI ULONG RtlFindClearBits(
  PRTL_BITMAP BitMapHeader,
  ULONG       NumberToFind,
  ULONG       HintIndex
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`NumberToFind`

Specifies how many contiguous clear bits will satisfy this request.

`HintIndex`

Specifies a zero-based bit position from which to start looking for a clear bit range of the given size.

Return Value

RtlFindClearBits either returns the zero-based starting bit index for a clear bit range of at least the requested size, or it returns 0xFFFFFFFF if it cannot find such a range within the given bitmap.

Remarks

For a successful call, the returned bit position is not necessarily equivalent to the given *HintIndex*. If necessary, **RtlFindClearBits** searches the whole bitmap to locate a clear bit range of the requested size. However, it starts searching for the requested range from *HintIndex*, so callers can find such a range more quickly when they can supply appropriate hints about where to start looking.

Callers of **RtlFindClearBits** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlFindClearBits** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL (See Remarks section)"

RtlFindClearBitsAndSet function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlFindClearBitsAndSet** routine searches for a range of clear bits of a requested size within a bitmap and sets all bits in the range when it has been located.

Syntax

```
NTSYSAPI ULONG RtlFindClearBitsAndSet(
  PRTL_BITMAP BitMapHeader,
  ULONG       NumberToFind,
  ULONG       HintIndex
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`NumberToFind`

Specifies how many contiguous clear bits will satisfy this request.

`HintIndex`

Specifies a zero-based bit position from which to start looking for a clear bit range of the given size.

Return Value

RtlFindClearBitsAndSet either returns the zero-based starting bit index for a clear bit range of the requested size that it set, or it returns 0xFFFFFFFF if it cannot find such a range within the given bitmap variable.

Remarks

For a successful call, the returned bit position is not necessarily equivalent to the given *HintIndex*. If necessary, **RtlFindClearBitsAndSet** searches the whole bitmap to locate a clear bit range of the requested size. However, it starts searching for the requested range from *HintIndex*, so callers can have such a range reset more quickly when they can supply appropriate hints about where to start looking.

Callers of **RtlFindClearBitsAndSet** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlFindClearBitsAndSet** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL (See Remarks section)"

RtlFindClearRuns function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlFindClearRuns** routine finds the specified number of runs of clear bits within a given bitmap.

Syntax

```
NTSYSAPI ULONG RtlFindClearRuns(
  PRTL_BITMAP     BitMapHeader,
  PRTL_BITMAP_RUN RunArray,
  ULONG           SizeOfRunArray,
  BOOLEAN         LocateLongestRuns
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`RunArray`

Pointer to the first element in a caller-allocated array for the bit position and length of each clear run found in the given bitmap variable.

`SizeOfRunArray`

Specifies the maximum number of clear runs to satisfy this request.

`LocateLongestRuns`

If **TRUE**, specifies that the routine is to search the entire bitmap for the longest clear runs it can find. Otherwise, the routine stops searching when it has found the number of clear runs specified by *SizeOfRunArray*.

Return Value

RtlFindClearRuns returns the number of clear runs found.

Remarks

If *LocateLongestRuns*is **TRUE**, the clear runs indicated at *RunArray*are sorted from longest to shortest. A clear run can consist of a single bit.

Callers of **RtlFindClearRuns** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlFindClearRuns** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RtlFindNextForwardRunClear

RtlInitializeBitMap

RtlFindFirstRunClear function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlFindFirstRunClear** routine searches for the initial contiguous range of clear bits within a given bitmap.

Syntax

```
NTSYSAPI ULONG RtlFindFirstRunClear(
  PRTL_BITMAP BitMapHeader,
  PULONG      StartingIndex
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`StartingIndex`

Pointer to a variable in which the starting index of the initial clear run in the bitmap is returned. This is a zero-based value indicating the bit position of the first clear bit in the returned range. Its value is meaningless if **RtlFindFirstRunClear** cannot find a run of clear bits.

Return Value

RtlFindFirstRunClear returns either the number of bits in the run beginning at *StartingIndex*, or zero if it cannot find a run of clear bits within the bitmap.

Remarks

A returned run can have a single clear bit. That is, once a clear bit is found, **RtlFindFirstRunClear** continues searching until it finds the next set bit, and then returns the number of clear bits in the run it found.

Callers of **RtlFindFirstRunClear** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlFindFirstRunClear** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe

RtlFindLastBackwardRunClear function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlFindLastBackwardRunClear** routine searches a given bitmap for the preceding clear run of bits, starting from the specified index position.

Syntax

```
NTSYSAPI ULONG RtlFindLastBackwardRunClear(
  PRTL_BITMAP BitMapHeader,
  ULONG       FromIndex,
  PULONG      StartingRunIndex
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`FromIndex`

Specifies a zero-based bit position at which to start looking for a clear run of bits.

`StartingRunIndex`

Pointer to a variable in which the starting index of the clear run found in the bitmap is returned. This is a zero-based value indicating the bit position of the first clear bit in the run preceding the given *FromIndex*. Its value is meaningless if **RtlFindLastBackwardRunClear** cannot find a run of clear bits.

Return Value

RtlFindLastBackwardRunClear returns the number of bits in the run beginning at *StartingRunIndex*, or zero if it cannot find a run of clear bits preceding *FromIndex* in the bitmap.

Remarks

On checked builds of Windows Vista and earlier versions of Windows, the internal implementation of the **RtlFindLastBackwardRunClear** routine can fail a bogus assertion if the caller is running at IRQL = DISPATCH_LEVEL. The failure of this assertion is harmless and can safely be ignored.

Callers of **RtlFindLastBackwardRunClear** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlFindLastBackwardRunClear** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL (see Remarks section)"

The **RtlFindLongestRunClear** routine searches for the largest contiguous range of clear bits within a given bitmap.

Syntax

```
NTSYSAPI ULONG RtlFindLongestRunClear(
  PRTL_BITMAP BitMapHeader,
  PULONG      StartingIndex
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`StartingIndex`

Pointer to a variable in which the starting index of the longest clear run in the bitmap is returned. This is a zero-based value indicating the bit position of the first clear bit in the returned range.

Return Value

RtlFindLongestRunClear returns either the number of bits in the run beginning at *StartingIndex*, or zero if it cannot find a run of clear bits within the bitmap.

Remarks

A returned run can have a single clear bit.

Callers of **RtlFindLongestRunClear** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlFindLongestRunClear** can be called at any IRQL.

RtlFindNextForwardRunClear function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlFindNextForwardRunClear** routine searches a given bitmap variable for the next clear run of bits, starting from the specified index position.

Syntax

```
NTSYSAPI ULONG RtlFindNextForwardRunClear(
  PRTL_BITMAP BitMapHeader,
  ULONG       FromIndex,
  PULONG      StartingRunIndex
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`FromIndex`

Specifies a zero-based bit position at which to start looking for a clear run of bits.

`StartingRunIndex`

Pointer to a variable in which the starting index of the clear run found in the bitmap is returned. This is a zero-based value indicating the bit position of the first clear bit in the run. Its value is meaningless if **RtlFindNextForwardRunClear** cannot find a run of clear bits.

Return Value

RtlFindNextForwardRunClear returns either the number of bits in the run beginning at *StartingRunIndex*, or zero if it cannot find a run of clear bits following *FromIndex* in the bitmap.

Remarks

Callers of **RtlFindNextForwardRunClear** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlFindNextForwardRunClear** can be called at any IRQL.

RtlInitializeBitMap

RtlFindSetBits function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlFindSetBits** routine searches for a range of set bits of a requested size within a bitmap.

Syntax

```
NTSYSAPI ULONG RtlFindSetBits(
  PRTL_BITMAP BitMapHeader,
  ULONG       NumberToFind,
  ULONG       HintIndex
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`NumberToFind`

Specifies how many contiguous set bits will satisfy this request.

`HintIndex`

Specifies a zero-based bit position around which to start looking for a set bit range of the given size.

Return Value

RtlFindSetBits either returns the zero-based starting bit index for a set bit range of the requested size, or it returns 0xFFFFFFFF if it cannot find such a range within the given bitmap variable.

Remarks

For a successful call, the returned bit position is not necessarily equivalent to the given *HintIndex*. If necessary, **RtlFindSetBits** searches the whole bitmap to locate a set bit range of the requested size. However, it starts searching for the requested range near *HintIndex*, so callers can find such a range more quickly when they can supply appropriate hints about where to start looking.

Callers of **RtlFindSetBits** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlFindSetBits** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL (See Remarks section)"

RtlFindSetBitsAndClear function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlFindSetBitsAndClear** routine searches for a range of set bits of a requested size within a bitmap and clears all bits in the range when it has been located.

Syntax

```
NTSYSAPI ULONG RtlFindSetBitsAndClear(
  PRTL_BITMAP BitMapHeader,
  ULONG       NumberToFind,
  ULONG       HintIndex
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`NumberToFind`

Specifies how many contiguous set bits will satisfy this request.

`HintIndex`

Specifies a zero-based bit position around which to start looking for a set bit range of the given size.

Return Value

RtlFindSetBitsAndClear either returns the zero-based starting bit index for a set bit range of the requested size that it cleared, or it returns 0xFFFFFFFF if it cannot find such a range within the given bitmap variable.

Remarks

For a successful call, the returned bit position is not necessarily equivalent to the given *HintIndex*. If necessary, **RtlFindSetBitsAndClear** searches the whole bitmap to locate a set bit range of the requested size. However, it starts searching for the requested range near *HintIndex*, so callers can clear such a range more quickly when they can supply appropriate hints about where to start looking.

Callers of **RtlFindSetBitsAndClear** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlFindSetBitsAndClear** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL (See Remarks section)"

RtlFreeAnsiString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlFreeAnsiString** routine releases storage that was allocated by **RtlUnicodeStringToAnsiString**.

Syntax

```
NTSYSAPI VOID RtlFreeAnsiString(
  PANSI_STRING AnsiString
);
```

Parameters

`AnsiString`

Pointer to the ANSI string buffer previously allocated by **RtlUnicodeStringToAnsiString**.

Return Value

None

Remarks

This routine does not release the Unicode string buffer passed to **RtlUnicodeStringToAnsiString**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=APC_LEVEL"

RtlUnicodeStringToAnsiString

RtlFreeUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlFreeUnicodeString** routine releases storage that was allocated by **RtlAnsiStringToUnicodeString** or **RtlUpcaseUnicodeString**.

Syntax

```
NTSYSAPI VOID RtlFreeUnicodeString(
  PUNICODE_STRING UnicodeString
);
```

Parameters

`UnicodeString`

Pointer to the Unicode string buffer previously allocated by **RtlAnsiStringToUnicodeString** or **RtlUpcaseUnicodeString**.

Return Value

None

Remarks

This routine does not release the ANSI string buffer passed to **RtlAnsiStringToUnicodeString**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=APC_LEVEL"

RtlAnsiStringToUnicodeString

RtlUpcaseUnicodeString

RtlGetVersion function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlGetVersion** routine returns version information about the currently running operating system.

Syntax

```
NTSYSAPI NTSTATUS RtlGetVersion(
  PRTL_OSVERSIONINFOW lpVersionInformation
);
```

Parameters

`lpVersionInformation`

Pointer to either a RTL_OSVERSIONINFOW structure or a RTL_OSVERSIONINFOEXW structure that contains the version information about the currently running operating system. A caller specifies which input structure is used by setting the **dwOSVersionInfoSize** member of the structure to the size in bytes of the structure that is used.

Return Value

RtlGetVersion returns STATUS_SUCCESS.

Remarks

RtlGetVersion is the kernel-mode equivalent of the user-mode **GetVersionEx** function in the Windows SDK. See the example in the Windows SDK that shows how to get the system version.

When using **RtlGetVersion** to determine whether a particular version of the operating system is running, a caller should check for version numbers that are greater than or equal to the required version number. This ensures that a version test succeeds for later versions of Windows.

Because operating system features can be added in a redistributable DLL, checking only the major and minor version numbers is not the most reliable way to verify the presence of a specific system feature. A driver should use RtlVerifyVersionInfo to test for the presence of a specific system feature.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Ntddk.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

RtlGUIDFromString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlGUIDFromString** routine converts the given Unicode string to a GUID in binary format.

Syntax

```
NTSYSAPI NTSTATUS RtlGUIDFromString(
  PCUNICODE_STRING GuidString,
  GUID             *Guid
);
```

Parameters

`GuidString`

Pointer to the buffered Unicode string to be converted to a GUID.

`Guid`

Pointer to a caller-supplied variable in which the GUID is returned.

Return Value

If the conversion succeeds, **RtlGUIDFromString** returns STATUS_SUCCESS. Otherwise, no conversion was done.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)
IRQL	PASSIVE_LEVEL

RtlStringFromGUID

RtlHashUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlHashUnicodeString** routine creates a hash value from a given Unicode string and hash algorithm.

Syntax

```
NTSYSAPI NTSTATUS RtlHashUnicodeString(
  PCUNICODE_STRING String,
  BOOLEAN          CaseInSensitive,
  ULONG            HashAlgorithm,
  PULONG           HashValue
);
```

Parameters

`String`

A pointer to a UNICODE_STRING structure that contains the Unicode string to be converted to a hash value.

`CaseInSensitive`

Specifies whether to treat the Unicode string as case sensitive when computing the hash value. If *CaseInSensitive* is **TRUE**, a lowercase and uppercase string hash to the same value.

`HashAlgorithm`

The hash algorithm to use. If *HashAlgorithm* is HASH_STRING_ALGORITHM_X65599, **RtlHashUnicodeString** uses the x65599 hashing algorithm. If *HashAlgorithm* is HASH_STRING_ALGORITHM_DEFAULT, **RtlHashUnicodeString** uses the default algorithm. Currently, the default algorithm is the x65599 hashing algorithm.

`HashValue`

A pointer to a ULONG variable that receives the hash value.

Return Value

RtlHashUnicodeString returns STATUS_SUCCESS on success, or the appropriate NTSTATUS value on failure. The routine returns a STATUS_INVALID_PARAMETER value if the Unicode string is **NULL**, *HashValue* is **NULL**, or the caller specifies an undefined value for *HashAlgorithm*.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

UNICODE_STRING

RtlInitAnsiString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlInitAnsiString** routine initializes a counted string of ANSI characters.

Syntax

```
NTSYSAPI VOID RtlInitAnsiString(
  PANSI_STRING          DestinationString,
  __drv_aliasesMem PCSZ SourceString
);
```

Parameters

`DestinationString`

A pointer to the ANSI_STRING structure to be initialized.

`SourceString`

A pointer to a null-terminated character string. This string is used to initialize the counted string pointed to by *DestinationString*.

Return Value

None

Remarks

This routine initializes a counted character string.

The routine copies the *SourceString* pointer value to the **Buffer** member of the ANSI_STRING structure pointed to by *DestinationString*. The **Length** member of this structure is set to the length, in bytes, of the source string, excluding the terminating null. The **MaximumLength** member of the structure is set to the length, in bytes, of the source string, including the terminating null. If *SourceString* is **NULL**, **Length** and **MaximumLength** are both set to zero.

RtlInitAnsiString does not alter the source string pointed to by *SourceString*.

> **Note** If the source string is longer than MAXUSHORT - 1 bytes, **RtlInitAnsiString** sets the **Length** member of the **ANSI_STRING** structure pointed to by *DestinationString* to MAXUSHORT - 1, and sets the **MaximumLength** member of this structure to MAXUSHORT. In this case, the **Length** and **MaximumLength** values misrepresent the length of the null-terminated source string, and relying on the accuracy of these values is potentially dangerous.

Callers of **RtlInitAnsiString** can be running at IRQL <= DISPATCH_LEVEL if the *DestinationString* buffer is nonpageable. Usually, callers run at IRQL = PASSIVE_LEVEL because most other **Rtl*Xxx*String** routines cannot be called at IRQL > PASSIVE_LEVEL.

The **RTL_CONSTANT_STRING** macro creates a string or Unicode string structure to hold a counted string.

```
STRING RTL_CONSTANT_STRING(
  [in]  PCSZ SourceString
);

UNICODE_STRING RTL_CONSTANT_STRING(
  [in]  PCWSTR SourceString
);
```

RTL_CONSTANT_STRING returns either a string structure or Unicode string structure.

The **RTL_CONSTANT_STRING** macro replaces the **RtlInitAnsiString**, RtlInitString, and RtlInitUnicodeString routines when passing a constant string.

You can use **RTL_CONSTANT_STRING** to initialize global variables.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (See Remarks section)

ANSI_STRING

RtlInitializeBitMap function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlInitializeBitMap** routine initializes the header of a bitmap variable.

Syntax

```
NTSYSAPI VOID RtlInitializeBitMap(
  PRTL_BITMAP             BitMapHeader,
  __drv_aliasesMem PULONG BitMapBuffer,
  ULONG                   SizeOfBitMap
);
```

Parameters

`BitMapHeader`

Pointer to an empty RTL_BITMAP structure.

`BitMapBuffer`

Pointer to caller-allocated memory for the bitmap itself. The base address of this buffer must be ULONG-aligned. The size of the allocated buffer must be an integer multiple of **sizeof**(ULONG) bytes.

`SizeOfBitMap`

Specifies the number of bits in the bitmap. This value can be any number of bits that will fit in the buffer allocated for the bitmap.

Return Value

None

Remarks

A driver can use a bitmap variable as an economical way to keep track of a set of reusable items. For example, file systems use a bitmap variable to track which clusters/sectors on a disk have already been allocated to hold file data. The system-supplied SCSI port driver uses a bitmap variable to track which queue tags have been assigned to SCSI request blocks (SRBs).

RtlInitializeBitMap must be called before any other **Rtl*Xxx*** routine that operates on a bitmap variable. The *BitMapHeader* pointer is an input parameter in all subsequent **Rtl*Xxx*** calls that operate on the caller's bitmap variable at *BitMapBuffer*. The caller is responsible for synchronizing access to the bitmap variable.

RtlInitializeBitMap initializes the caller-supplied **RTL_BITMAP** structure by copying the caller-supplied *BitMapBuffer* and *SizeOfBitMap* values into it. Subsequently, the structure can be passed to other routines to manipulate the bitmap. **RtlInitializeBitMap** does not modify the contents of the bitmap.

Callers of **RtlInitializeBitMap**, and callers of other **Rtl*Xxx*** routines that operate on an initialized bitmap variable, must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitmapHeader* is pageable. Otherwise, **RtlInitializeBitMap** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)

RtlInitString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlInitString** routine initializes a counted string of 8-bit characters.

Syntax

```
NTSYSAPI VOID RtlInitString(
  PSTRING              DestinationString,
  __drv_aliasesMem PCSZ SourceString
);
```

Parameters

`DestinationString`

A pointer to the **STRING** structure to be initialized. The Ntdef.h header file defines this structure to be identical to the ANSI_STRING structure.

`SourceString`

A pointer to a null-terminated character string. This string is used to initialize the counted string pointed to by *DestinationString*.

Return Value

None

Remarks

This routine initializes a counted character string.

The routine copies the *SourceString* pointer value to the **Buffer** member of the **STRING** structure pointed to by *DestinationString*. The **Length** member of this structure is set to the length, in bytes, of the source string, excluding the terminating null. The **MaximumLength** member of the structure is set to the length, in bytes, of the source string, including the terminating null. If *SourceString* is **NULL**, **Length** and **MaximumLength** are both set to zero.

RtlInitString does not alter the source string pointed to by *SourceString*.

> **Note** If the source string is longer than MAXUSHORT - 1 bytes, **RtlInitString** sets the **Length** member of the **STRING** structure pointed to by *DestinationString* to MAXUSHORT - 1, and sets the **MaximumLength** member of this structure to MAXUSHORT. In this case, the **Length** and **MaximumLength** values misrepresent the length of the null-terminated source string, and relying on the accuracy of these values is potentially dangerous.

Callers of **RtlInitString** can be running at IRQL <= DISPATCH_LEVEL if the *DestinationString* buffer is nonpageable. Usually, callers run at IRQL = PASSIVE_LEVEL because most other **Rtl*Xxx*String** routines cannot be called at IRQL > PASSIVE_LEVEL.

The **RTL_CONSTANT_STRING** macro creates a string or Unicode string structure to hold a counted string.

```
STRING RTL_CONSTANT_STRING(
  [in]  PCSZ SourceString
);

UNICODE_STRING RTL_CONSTANT_STRING(
  [in]  PCWSTR SourceString
);
```

RTL_CONSTANT_STRING returns either a string structure or Unicode string structure.

The **RTL_CONSTANT_STRING** macro replaces the RtlInitAnsiString, **RtlInitString**, and RtlInitUnicodeString routines when passing a constant string.

You can use **RTL_CONSTANT_STRING** to initialize global variables.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

ANSI_STRING

RtlInitStringEx function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlInitStringEx** routine initializes a counted string of 8-bit characters.

Syntax

```
NTSYSAPI NTSTATUS RtlInitStringEx(
  PSTRING              DestinationString,
  __drv_aliasesMem PCSZ SourceString
);
```

Parameters

`DestinationString`

A pointer to the **STRING** structure to be initialized. The Ntdef.h header file defines this structure to be identical to the ANSI_STRING structure.

`SourceString`

A pointer to a null-terminated character string. This string is used to initialize the counted string pointed to by *DestinationString*.

Return Value

Returns STATUS_NAME_TOO_LONG if the SourceString is too long. Otherwise, this routine returns STATUS_SUCCESS.

Remarks

This routine initializes a counted character string.

The routine copies the *SourceString* pointer value to the **Buffer** member of the **STRING** structure pointed to by *DestinationString*. The **Length** member of this structure is set to the length, in bytes, of the source string, excluding the terminating null. The **MaximumLength** member of the structure is set to the length, in bytes, of the source string, including the terminating null. If *SourceString* is **NULL**, **Length** and **MaximumLength** are both set to zero.

RtlInitStringEx does not alter the source string pointed to by *SourceString*.

Callers of **RtlInitStringEx** can be running at IRQL <= DISPATCH_LEVEL if the *DestinationString* buffer is nonpageable. Usually, callers run at IRQL = PASSIVE_LEVEL because most other **Rtl*Xxx*String** routines cannot be called at IRQL > PASSIVE_LEVEL.

RtlInt64ToUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlInt64ToUnicodeString** routine converts a specified unsigned 64-bit integer value to a Unicode string that represents the value in a specified base.

Syntax

```
NTSYSAPI NTSTATUS RtlInt64ToUnicodeString(
  ULONGLONG       Value,
  ULONG           Base,
  PUNICODE_STRING String
);
```

Parameters

`Value`

Specifies the ULONGLONG value to convert.

`Base`

Specifies the base to use when converting *Value* to a string. The possible values are:

VALUE	BASE
16	Hexadecimal
8	Octal
2	Binary
0 or 10	Decimal

`String`

Pointer to the UNICODE_STRING structure that receives the string representation of *Value*. The buffer specified by the *Buffer* of *String* must be large enough to hold the result.

Return Value

RtlInt64ToUnicodeString returns an NTSTATUS value. Possible return values include :

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	The routine successfully converted *Value* to a Unicode string.

STA TUS _BU FFE R_O VER FLO W	*Value* is too large to convert, or the **UNICODE_STRING** structure is too small to hold the result.
STA TUS _IN VAL ID_ PAR AM ETE R	The specified code base is not valid. The only valid values are 0, 2, 8, 10, and 16.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

RtlIntegerToUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlIntegerToUnicodeString** routine converts an unsigned integer value to a null-terminated string of one or more Unicode characters in the specified base.

Syntax

```
NTSYSAPI NTSTATUS RtlIntegerToUnicodeString(
  ULONG           Value,
  ULONG           Base,
  PUNICODE_STRING String
);
```

Parameters

`Value`

Specifies the ULONG value to convert.

`Base`

Specifies the base to use when converting *Value* to a string. The possible values are:

VALUE	BASE
16	Hexadecimal
8	Octal
2	Binary
0 or 10	Decimal

`String`

Pointer to a UNICODE_STRING structure that receives the string representation of *Value*. The buffer specified by the *Buffer* of *String* must be large enough to hold the result.

Return Value

RtlIntegerToUnicodeString returns an NTSTATUS value. Possible return values include:

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	The routine successfully converted *Value* to a Unicode string.

STA TUS _BU FFE R_O VER FLO W	*Value* is too large to convert, or the **UNICODE_STRING** structure is too small to hold the result.
STA TUS _IN VAL ID_ PAR AM ETE R	The specified code base is not valid. The only valid values are 0, 2, 8, 10, and 16.

Syntax

```
void RtlIntPtrToUnicodeString(
   Value,
   Base,
   String
);
```

Parameters

`Value`

Specifies the ULONG_PTR value to convert.

`Base`

Specifies the base to use when converting *Value* to a string. The possible values are:

VALUE	BASE
16	Hexadecimal
8	Octal
2	Binary
0 or 10	Decimal

`String`

Pointer to a UNICODE_STRING structure that receives the string representation of *Value*. The buffer specified by the *Buffer* of *String* must be large enough to hold the result.

Return Value

RtlIntPtrToUnicodeString returns an NTSTATUS value. Possible return values include :

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The routine successfully converted Value to a Unicode string.
STATUS_BUFFER_OVERFLOW	Value is too large to convert, or the UNICODE_STRING structure is too small to hold the result.

RtlIoDecodeMemIoResource function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlIoDecodeMemIoResource** routine provides the address information that is contained in an IO_RESOURCE_DESCRIPTOR structure that describes a range of memory or I/O port addresses.

Syntax

```
NTSYSAPI ULONGLONG RtlIoDecodeMemIoResource(
  PIO_RESOURCE_DESCRIPTOR Descriptor,
  PULONGLONG              Alignment,
  PULONGLONG              MinimumAddress,
  PULONGLONG              MaximumAddress
);
```

Parameters

`Descriptor`

A pointer to the IO_RESOURCE_DESCRIPTOR structure to provide the address information for.

`Alignment`

A pointer to a variable that receives the alignment, in bytes, of the address range. This parameter can be **NULL**.

`MinimumAddress`

A pointer to a variable that receives the minimum address of the address range. This parameter can be **NULL**.

`MaximumAddress`

A pointer to a variable that receives the maximum address of the address range. This parameter can be **NULL**.

Return Value

RtlIoDecodeMemIoResource returns the length of the address range, in bytes.

Remarks

The **Type** member of the IO_RESOURCE_DESCRIPTOR structure must be **CmResourceTypeMemory**, **CmResourceTypeMemoryLarge**, or **CmResourceTypePort**.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

IO_RESOURCE_DESCRIPTOR

RtlIoEncodeMemIoResource

RtlIoEncodeMemIoResource function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlIoEncodeMemIoResource** routine updates an IO_RESOURCE_DESCRIPTOR structure to describe a range of memory or I/O port addresses.

Syntax

```
NTSYSAPI NTSTATUS RtlIoEncodeMemIoResource(
  PIO_RESOURCE_DESCRIPTOR Descriptor,
  UCHAR                   Type,
  ULONGLONG               Length,
  ULONGLONG               Alignment,
  ULONGLONG               MinimumAddress,
  ULONGLONG               MaximumAddress
);
```

Parameters

`Descriptor`

A pointer to the IO_RESOURCE_DESCRIPTOR structure to update.

`Type`

The resource type of the address range. This parameter can be **CmResourceTypeMemory**, **CmResourceTypeMemoryLarge**, or **CmResourceTypePort**.

`Length`

The length, in bytes, of the range of assignable addresses.

`Alignment`

The alignment, in bytes, of the starting address of address range.

`MinimumAddress`

The minimum address that can be assigned to the device.

`MaximumAddress`

The maximum address that can be assigned to the device.

Return Value

RtlIoEncodeMemIoResource returns an NTSTATUS value. This routine might return one of the following values:

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	The IO_RESOURCE_DESCRIPTOR structure was updated.
STATUS_UNSUCCESSFUL	The specified value for *Length* or *Alignment* could not be encoded in an **IO_RESOURCE_DESCRIPTOR** structure.
STATUS_INVALID_PARAMETER	One or more of the specified parameters were invalid.

Remarks

Addresses that are larger than 32 bits in length must satisfy certain alignment restrictions, or else the routine returns STATUS_UNSUCCESSFUL.

ADDRESS LENGTH	ALIGNMENT RESTRICTION
40 bits	Lowest 8 bits must be zero.
48 bits	Lowest 16 bits must be zero.
64 bits	Lowest 32 bits must be zero.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.

RtlIsNtDdiVersionAvailable function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlIsNtDdiVersionAvailable** routine determines if a specified version of the Microsoft Windows device driver interface (DDI) is available.

Syntax

```
BOOLEAN RtlIsNtDdiVersionAvailable(
  ULONG Version
);
```

Parameters

`Version`

The version of the Windows DDI that is available. The following table lists the possible values for the *Version* parameter.

CONSTANT	WINDOWS VERSION
NTDDI_WINBLUE	Windows 8.1
NTDDI_WIN8	Windows 8
NTDDI_WIN7	Windows 7
NTDDI_WS08	Windows Server 2008
NTDDI_VISTA	Windows Vista
NTDDI_WS03	Windows Server 2003
NTDDI_WINXP	Windows XP
NTDDI_WIN2K	Windows 2000

The NTDDI_*XXX* constants are defined in the Sdkddkver.h header file.

Additional NTDDI_*XXX* constants that specify service packs are available for the RtlIsServicePackVersionInstalled routine. Do not use these values for **RtlIsNtDdiVersionAvailable**.

Return Value

RtlIsNtDdiVersionAvailable returns **TRUE** if the version of the Windows operating system that is running is the same or later than the version that the *Version* parameter specifies. Otherwise, this routine returns **FALSE**.

Remarks

The **RtlIsNtDdiVersionAvailable** routine compares the version that the *Version* parameter specifies to the

version of the Windows operating system that is currently running.

Use the RtlIsServicePackVersionInstalled routine if you want to determine whether a particular service pack is installed.

The Windows kernel implements **RtlIsNtDdiVersionAvailable** only in Windows Vista and later versions of Windows. However, a compatibility library, Rtlver.lib, implements a version of **RtlIsNtDdiVersionAvailable** that runs in Windows 2000 and later versions of Windows. For kernel-mode drivers that include the Wdm.h header file, calls to **RtlIsNtDdiVersionAvailable** go to the version of this routine that is implemented in Rtlver.lib.

For more information about **RtlIsNtDdiVersionAvailable** and **RtlIsServicePackVersionInstalled**, see Writing Drivers for Different Versions of Windows.

Requirements

Minimum supported client	Available starting with Windows Vista. A compatibility library supports this routine in earlier versions of Windows (see Remarks section).
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	Rtlver.lib
IRQL	PASSIVE_LEVEL

RtlIsServicePackVersionInstalled

RtlIsServicePackVersionInstalled function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlIsServicePackVersionInstalled** routine determines if a specified service pack version of the Microsoft Windows device driver interface (DDI) is installed.

Syntax

```
BOOLEAN RtlIsServicePackVersionInstalled(
  ULONG Version
);
```

Parameters

`Version`

The service pack version of the Windows DDI that is available. The following table lists the possible values for *Version*.

CONSTANT	WINDOWS VERSION
NTDDI_WIN7	Windows 7 and Windows Server 2008 R2
NTDDI_WS08SP2	Windows Server 2008 with Service Pack 2 (SP2)
NTDDI_WS08	Windows Server 2008
NTDDI_VISTASP2	Windows Vista with SP2
NTDDI_VISTASP1	Windows Vista with SP1
NTDDI_VISTA	Windows Vista
NTDDI_WS03SP2	Windows Server 2003 with SP2
NTDDI_WS03SP1	Windows Server 2003 with SP1
NTDDI_WS03	Windows Server 2003
NTDDI_WINXPSP3	Windows XP with SP3
NTDDI_WINXPSP2	Windows XP with SP2
NTDDI_WINXPSP1	Windows XP with SP1
NTDDI_WINXP	Windows XP
NTDDI_WIN2KSP4	Windows 2000 with SP4

NTDDI_WIN2KSP3	Windows 2000 with SP3
NTDDI_WIN2KSP2	Windows 2000 with SP2
NTDDI_WIN2KSP1	Windows 2000 with SP1
NTDDI_WIN2K	Windows 2000

The NTDDI_*XXX* constants are defined in the Sdkddkver.h header file. The preceding table does not contain an entry for Windows Server 2008 with SP1. The first service pack to become available for Windows Server 2008 is SP2.

Return Value

RtlIsServicePackVersionInstalled returns **TRUE** if the service pack version of the Windows operating system that is running is the same or later than the version that the *Version* parameter specifies. Otherwise, this routine returns **FALSE**. **RtlIsServicePackVersionInstalled** also returns **FALSE** if the major version (for example, Windows Vista or Windows Server 2003) that *Version* specifies does not match the major version of Windows that is currently running on the computer.

Remarks

The **RtlIsServicePackVersionInstalled** routine compares the version that the *Version* parameter specifies to the version of the currently running Windows operating system.

Use the RtlIsNtDdiVersionAvailable routine to determine if a major version of Windows is running.

For more information about **RtlIsServicePackVersionInstalled** and **RtlIsNtDdiVersionAvailable**, see Header File Changes in the Windows Driver Kit.

The Windows kernel implements **RtlIsServicePackVersionInstalled** only in Windows Vista and later versions of Windows. However, a compatibility library, Rtlver.lib, implements a version of **RtlIsServicePackVersionInstalled** that runs in Windows 2000 and later versions of Windows. For kernel-mode drivers that include the Wdm.h header file, calls to **RtlIsServicePackVersionInstalled** go to the version of this routine that is implemented in Rtlver.lib.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows. A compatibility library supports this routine in earlier versions of Windows (see Remarks section).

RtlVerifyVersionInfo

RtlLengthSecurityDescriptor function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlLengthSecurityDescriptor** routine returns the size of a given security descriptor.

Syntax

```
NTSYSAPI ULONG RtlLengthSecurityDescriptor(
  PSECURITY_DESCRIPTOR SecurityDescriptor
);
```

Parameters

`SecurityDescriptor`

Pointer to a SECURITY_DESCRIPTOR.

Return Value

RtlLengthSecurityDescriptor returns the size in bytes of the descriptor.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

RtlMoveMemory macro

1/25/2019 • 2 minutes to read • Edit Online

The **RtlMoveMemory** routine copies the contents of a source memory block to a destination memory block, and supports overlapping source and destination memory blocks.

Syntax

```
void RtlMoveMemory(
   Destination,
   Source,
   Length
);
```

Parameters

`Destination`

Datatype: void*. A pointer to the destination memory block to copy the bytes to.

`Source`

Datatype: const void*. A pointer to the source memory block to copy the bytes from.

`Length`

Datatype: size_t. The number of bytes to copy from the source to the destination.

Return Value

None

Remarks

The source memory block, which is defined by *Source* and *Length*, can overlap the destination memory block, which is defined by *Destination* and *Length*.

The RtlCopyMemory routine runs faster than **RtlMoveMemory**, but **RtlCopyMemory** requires that the source and destination memory blocks do not overlap.

Callers of **RtlMoveMemory** can be running at any IRQL if the source and destination memory blocks are in nonpaged system memory. Otherwise, the caller must be running at IRQL <= APC_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

RtlNumberOfClearBits function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlNumberOfClearBits** routine returns a count of the clear bits in a given bitmap variable.

Syntax

```
NTSYSAPI ULONG RtlNumberOfClearBits(
  PRTL_BITMAP BitMapHeader
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

Return Value

RtlNumberOfClearBits returns the number of bits that are currently clear.

Remarks

Callers of **RtlNumberOfClearBits** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlNumberOfClearBits** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

RtlNumberOfSetBits function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlNumberOfSetBits** routine returns a count of the set bits in a given bitmap variable.

Syntax

```
NTSYSAPI ULONG RtlNumberOfSetBits(
  PRTL_BITMAP BitMapHeader
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

Return Value

RtlNumberOfSetBits returns a count of the bits that are currently set.

Remarks

Callers of **RtlNumberOfSetBits** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlNumberOfSetBits** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

RtlNumberOfSetBitsUlongPtr function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlNumberOfSetBitsUlongPtr** routine returns the number of bits in the specified ULONG_PTR integer value that are set to one.

Syntax

```
NTSYSAPI ULONG RtlNumberOfSetBitsUlongPtr(
  ULONG_PTR Target
);
```

Parameters

`Target`

A ULONG_PTR integer value.

Return Value

RtlNumberOfSetBitsUlongPtr returns a count of the bits in the *Target* parameter that are set to one.

Requirements

Minimum supported client	Available starting with Windows Vista.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any IRQL

RtlPrefetchMemoryNonTemporal function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlPrefetchMemoryNonTemporal** routine provides a hint to the processor that a buffer should be temporarily moved into the processor cache.

Syntax

```
NTSYSAPI VOID RtlPrefetchMemoryNonTemporal(
  PVOID  Source,
  SIZE_T Length
);
```

Parameters

`Source`

A pointer to the buffer to be moved into the processor cache.

`Length`

The length of the buffer to be moved.

Return Value

None.

Remarks

You should use this routine only for a buffer that will be written to or read from exactly once. Note that **RtlPrefetchMemoryNonTemporal** is only a hint to the processor: the buffer is not guaranteed to be moved into the cache. On x86-based and x64-based systems, this routine uses the **prefetchnta** instruction.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Ntddk.h, Wdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

RtlQueryRegistryValues function

1/25/2019 • 11 minutes to read • Edit Online

The **RtlQueryRegistryValues** routine allows the caller to query several values from the registry subtree with a single call.

Syntax

```
NTSYSAPI NTSTATUS RtlQueryRegistryValues(
  ULONG                    RelativeTo,
  PCWSTR                   Path,
  PRTL_QUERY_REGISTRY_TABLE QueryTable,
  PVOID                    Context,
  PVOID                    Environment
);
```

Parameters

`RelativeTo`

Specifies whether *Path* is an absolute registry path or is relative to a predefined path as one of the following.

VALUE	MEANING
RTL_REGISTRY_ABSOLUTE	Path is an absolute registry path.
RTL_REGISTRY_CONTROL	Path is relative to **\Registry\Machine\System\CurrentControlSet\Control**.
RTL_REGISTRY_DEVICEMAP	Path is relative to **\Registry\Machine\Hardware\DeviceMap**.
RTL_REGISTRY_SERVICES	Path is relative to **\Registry\Machine\System\CurrentControlSet\Services**.
RTL_REGISTRY_USER	Path is relative to **\Registry\User\CurrentUser**. (For a system process, this is **\User.Default**.)
RTL_REGISTRY_WINDOWS_NT	Path is relative to **\Registry\Machine\Software\Microsoft\Windows NT\CurrentVersion**.

The *RelativeTo* value can be modified by bitwise-ORing it with one of the following flags.

RTL_REGISTRY_OPTIONAL	Specifies that the key referenced by this parameter and the *Path* parameter are optional.
RTL_REGISTRY_HANDLE	Specifies that the *Path* parameter is actually a registry handle to use.

`Path`

Pointer to either an absolute registry path or a path relative to the known location specified by the *RelativeTo* parameter. Note that the names of keys in such a path must be known to the caller, including the last key in the path. If the RTL_REGISTRY_HANDLE flag is specified, this parameter is a registry handle for an already opened key to be queried directly.

`QueryTable`

Pointer to a table of one or more value names and subkey names in which the caller is interested. Each table entry contains the address of a caller-supplied QueryRoutine function that will be called for each value name that exists in the registry. The table must be terminated with a **NULL** table entry, which is a table entry with a **NULL** **QueryRoutine** member and a **NULL** **Name** member. The structure for query table entries is defined as follows:

```
typedef struct _RTL_QUERY_REGISTRY_TABLE {
    PRTL_QUERY_REGISTRY_ROUTINE QueryRoutine;
    ULONG Flags;
    PWSTR Name;
    PVOID EntryContext;
    ULONG DefaultType;
    PVOID DefaultData;
    ULONG DefaultLength;
} RTL_QUERY_REGISTRY_TABLE, *PRTL_QUERY_REGISTRY_TABLE;
```

If the caller allocates storage for the query table pointed to by the *QueryTable* parameter, the caller is responsible for releasing this storage after the **RtlQueryRegistryValues** call returns.

QueryRoutine

The address of a *QueryRoutine* function that is called with the name, type, data, and data length of a registry value. If this member and the **Name** member are both **NULL**, it marks the end of the table.

A *QueryRoutine* function is declared as follows:

```
NTSTATUS
QueryRoutine (
    IN PWSTR ValueName,
    IN ULONG ValueType,
    IN PVOID ValueData,
    IN ULONG ValueLength,
    IN PVOID Context,
    IN PVOID EntryContext
    );
```

For more information, see QueryRoutine.

Flags

Flags to control how the remaining members of the **RTL_QUERY_REGISTRY_TABLE** structure are to be interpreted. The following flag bits are defined for this member.

VALUE	MEANING

RTL_QUERY_REGISTRY_SUBKEY	The **Name** of this table entry is another path to a registry key, and all following table entries are for that key rather than the key specified by the *Path* parameter. This change in focus lasts until the end of the table or until another RTL_REGISTRY_SUBKEY or RTL_QUERY_REGISTRY_TOPKEY entry is seen. Each such entry must specify a path that is relative to the *Path* specified in the call to **RtlQueryRegistryValues**.
RTL_QUERY_REGISTRY_TOPKEY	Resets the current registry key handle to the original one specified by the *RelativeTo* and *Path* parameters. This is useful for getting back to the original node after descending into subkeys with the RTL_QUERY_REGISTRY_SUBKEY flag.
RTL_QUERY_REGISTRY_REQUIRED	Specifies that this registry value must exist if **DefaultType** = REG_NONE; otherwise, if it is not found, **RtlQueryRegistryValues** immediately exits with a status code of STATUS_OBJECT_NAME_NOT_FOUND. This exit occurs if the **Name** member is **NULL** and the current key has no subkeys, or if **Name** specifies a nonexistent subkey. (If this flag is not specified, then when no match is found for a non-**NULL** **Name**, the routine uses the **DefaultValue** member as the value. When **Name** is **NULL** and the current key has no subkeys, the routine simply skips that table entry.)
RTL_QUERY_REGISTRY_NOVALUE	Specifies that even though there is no **Name** for this table entry, all the caller wants is a callback: that is, the caller does not want to enumerate all the values under the current key. *QueryRoutine* is called with **NULL** for *ValueData*, REG_NONE for *ValueType*, and zero for *ValueLength*.
RTL_QUERY_REGISTRY_NOEXPAND	For a registry value of type REG_EXPAND_SZ or REG_MULTI_SZ, this flag overrides the default behavior, which is to preprocess the registry value before calling the QueryRoutine routine. By default, **RtlQueryRegistryValues** expands environment variable references in REG_EXPAND_SZ values, and enumerates each null-terminated string in a REG_MULTI_SZ value in a separate *QueryRoutine* call, so that the strings are presented as REG_SZ values that have the same *ValueName*. If this flag is set, *QueryRoutine* receives the raw REG_EXPAND_SZ or REG_MULTI_SZ value from the registry. For more information about the data formats for these values, see KEY_VALUE_BASIC_INFORMATION.
RTL_QUERY_REGISTRY_DIRECT	The **QueryRoutine** member is not used (and must be **NULL**), and the *EntryContext* points to the buffer to store the value. If the caller sets this flag, the caller should additionally set the RTL_QUERY_REGISTRY_TYPECHECK flag to guard against buffer overflow. For more information, see the Remarks section.
RTL_QUERY_REGISTRY_TYPECHECK	Use this flag with the RTL_QUERY_REGISTRY_DIRECT flag to verify that the REG_*XXX* type of the stored registry value matches the type expected by the caller. If the types do not match, the call fails. For more information, see the Remarks section.
RTL_QUERY_REGISTRY_DELETE	This flag is used to delete value keys after they have been queried.

Starting with Windows 2000, inbox support is provided for all flag bits in the preceding table, with the exception of

RTL_QUERY_REGISTRY_TYPECHECK. Inbox support for RTL_QUERY_REGISTRY_TYPECHECK is available starting with Windows 8. For earlier versions of Windows, support for RTL_QUERY_REGISTRY_TYPECHECK is provided through Windows Update. For more information, see Remarks.

Name

This is the name of a Value that the caller queried. If **Name** is **NULL**, the *QueryRoutine* function specified for this table entry is called for all values associated with the current registry key. If the RTL_QUERY_REGISTRY_DIRECT flag is set, a non-**NULL** value for **Name** must be provided.

EntryContext

If the RTL_QUERY_REGISTRY_DIRECT flag is set, this is a pointer to the buffer to store the result of the query operation for this key. Otherwise, this value is passed as the *EntryContext* parameter of *QueryRoutine*.

DefaultType

The least significant byte of this member specifies the REG_*XXX* type of the data to be returned, if no matching key is found and the RTL_QUERY_REGISTRY_REQUIRED flag is not specified. Specify REG_NONE for no default type. If the RTL_QUERY_REGISTRY_TYPECHECK flag is set, the most significant byte of this member specifies the REG_*XXX* type of the stored registry value that the caller expects. Bits 8 to 23 of this member are reserved and should be zero.

DefaultData

A pointer to the default value to be returned if no matching key is found and the RTL_QUERY_REGISTRY_REQUIRED flag is not specified. This member is ignored if **DefaultType** = REG_NONE. Otherwise, the type of data pointed to by **DefaultData** should conform to the registry value type specified by the **DefaultType** member. For more information registry value types, see the definition of the *Type* parameter in KEY_VALUE_BASIC_INFORMATION.

DefaultLength

Specifies the length, in bytes, of the **DefaultData** member. If **DefaultType** is REG_SZ, REG_EXPAND_SZ, or REG_MULTI_SZ, callers can optionally specify zero to indicate **RtlQueryRegistryValues** should compute the length based on the default data value. If **DefaultType** = REG_NONE, this member is ignored.

`Context`

Specifies the value passed as the *Context* parameter of a *QueryRoutine* function each time it is called.

`Environment`

Pointer to the environment used when expanding variable values in REG_EXPAND_SZ registry values, or a **NULL** pointer (optional).

Return Value

RtlQueryRegistryValues returns an NTSTATUS code. The possible return values include:

RETURN CODE	DESCRIPTION
STA **TUS** **_SU** **CCE** **SS**	The entire query table was processed successfully.

STATUS_INVALID_PARAMETER	Processing of the query table terminated with an invalid table entry. A table entry can be invalid if the specified flags require the **QueryRoutine** or **Name** member to be non-**NULL**, but a **NULL** value was provided.
STATUS_OBJECT_NAME_NOT_FOUND	The *Path* parameter does not match a valid key, or processing of the query table terminated with an entry with the RTL_QUERY_REGISTRY_REQUIRED flag set and no matching key is found. This occurs if the **Name** member is **NULL** and the current key has no subkeys, or if **Name** specifies a nonexistent subkey.
STATUS_BUFFER_TOO_SMALL	The RTL_QUERY_REGISTRY_DIRECT flag is set, and the buffer specified by **EntryContext** is too small to hold the key value data.
STATUS_OBJECT_TYPE_MISMATCH	The RTL_QUERY_REGISTRY_TYPECHECK flag is set and the type of the stored registry value does not match the type expected by the caller.

RtlQueryRegistryValues also terminates processing of the table if the *QueryRoutine* function for a table entry returns an NTSTATUS error code, and returns that error code as its result. (With one exception: If *QueryRoutine* returns STATUS_BUFFER_TOO_SMALL, the error code is ignored.)

Remarks

The caller specifies an initial key path and a table. The table contains one or more entries that describe the key values and subkey names in which the caller is interested. The table is terminated by an entry with a **NULL QueryRoutine** member and a **NULL Name** member. The table must be allocated from nonpaged pool.

> **Note** Kernel-mode drivers must specify the RTL_QUERY_REGISTRY_NOEXPAND flag to prevent calling environment variable routines. These routines are unsafe, so kernel-mode drivers should not use them.

Caution If you use the RTL_QUERY_REGISTRY_DIRECT flag, an untrusted user-mode application may be able to cause a buffer overflow. A buffer overflow can occur if a driver uses this flag to read a registry value to which the wrong type is assigned. In all cases, a driver that uses the RTL_QUERY_REGISTRY_DIRECT flag should additionally use the RTL_QUERY_REGISTRY_TYPECHECK flag to prevent such overflows.

If the RTL_QUERY_REGISTRY_TYPECHECK flag is set in a table entry, the caller must specify the expected REG_*XXX* type in the 8 most significant bits (MSBs) of the 32-bit **DefaultType** member of the table entry. As shown in the following code example, the RTL_QUERY_REGISTRY_TYPECHECK_SHIFT constant, which is defined to be 24, can be used as the shift count required to place the expected REG_*XXX* type in the 8 MSBs of the **DefaultType** member.

C++

```
RTL_QUERY_REGISTRY_TABLE QueryRegTable[2];
...
QueryRegTable[0].DefaultType = (REG_SZ << RTL_QUERY_REGISTRY_TYPECHECK_SHIFT) | REG_NONE;
...
QueryRegTable[1].DefaultType = (REG_DWORD << RTL_QUERY_REGISTRY_TYPECHECK_SHIFT) | REG_NONE;
...
```

Starting with Windows 8, if an **RtlQueryRegistryValues** call accesses an untrusted hive, and the caller sets the RTL_QUERY_REGISTRY_DIRECT flag for this call, the caller must additionally set the RTL_QUERY_REGISTRY_TYPECHECK flag. A violation of this rule by a call from user mode causes an exception. A violation of this rule by a call from kernel mode causes a 0x139 bug check (KERNEL_SECURITY_CHECK_FAILURE).

Only system hives are trusted. An **RtlQueryRegistryValues** call that accesses a system hive does not cause an exception or a bug check if the RTL_QUERY_REGISTRY_DIRECT flag is set and the RTL_QUERY_REGISTRY_TYPECHECK flag is not set. However, as a best practice, the RTL_QUERY_REGISTRY_TYPECHECK flag should always be set if the RTL_QUERY_REGISTRY_DIRECT flag is set.

Similarly, in versions of Windows before Windows 8, as a best practice, an **RtlQueryRegistryValues** call that sets the RTL_QUERY_REGISTRY_DIRECT flag should additionally set the RTL_QUERY_REGISTRY_TYPECHECK flag. However, failure to follow this recommendation does not cause an exception or a bug check.

The following is a list of system hives:

- \REGISTRY\MACHINE\HARDWARE
- \REGISTRY\MACHINE\SOFTWARE
- \REGISTRY\MACHINE\SYSTEM
- \REGISTRY\MACHINE\SECURITY
- \REGISTRY\MACHINE\SAM

Support for the RTL_QUERY_REGISTRY_TYPECHECK flag is available through Windows Update for Windows 7, Windows Vista, Windows Server 2003, and Windows XP. For more information about this update, see Vulnerabilities in Windows Kernel Could Allow Elevation of Privilege (2393802). In versions of these operating systems that do not have this update, the caller can use the RTL_QUERY_REGISTRY_TYPECHECK flag. However, this flag is ignored by the **RtlQueryRegistryValues** routine.

Starting with Windows Driver Kit (WDK) 8, the RTL_QUERY_REGISTRY_TYPECHECK flag is defined in the Wdm.h header file as follows:

```
#define RTL_QUERY_REGISTRY_TYPECHECK 0x00000100
```

If an entry does not specify the RTL_QUERY_REGISTRY_DIRECT flag, **RtlQueryRegistryValues** uses the specified *QueryRoutine* function to report the value name, type, data, and data length, in bytes, to the caller. If the **Name** member of the entry is **NULL**, **RtlQueryRegistryValues** reports every direct subkey of the key. If the key type is REG_MULTI_SZ and the RTL_QUERY_REGISTRY_NOEXPAND flag not is specified, the routine calls *QueryRoutine* separately for each individual string; otherwise the routine reports it as a single value. If an entry specifies the RTL_QUERY_REGISTRY_DIRECT flag, **RtlQueryRegistryValues** stores the value of the key in the buffer pointed to by the entry's **EntryContext** member. The format of the returned data is as follows.

KEY DATA TYPE	HOW DATA IS RETURNED
A null-terminated Unicode string (such as REG_SZ, REG_EXPAND_SZ).	**EntryContext** must point to an initialized UNICODE_STRING structure. If the **Buffer** member of **UNICODE_STRING** is **NULL**, the routine allocates storage for the string data. Otherwise, it stores the string data in the buffer that **Buffer** points to.
REG_MULTI_SZ	You must specify the RTL_QUERY_REGISTRY_NOEXPAND flag for this key data type. **EntryContext** points to an initialized **UNICODE_STRING** structure. The routine stores the key value as a single string value. Each individual component within the string is terminated by a zero. If the **Buffer** member of **UNICODE_STRING** is **NULL**, the routine allocates storage for the string data. Otherwise, it stores the string data in the buffer that **Buffer** points to.
Nonstring data with size, in bytes, <= **sizeof**(ULONG)	The value is stored in the memory location specified by **EntryContext**.
Nonstring data with size, in bytes, > **sizeof**(ULONG)	The buffer pointed to by **EntryContext** must begin with a signed LONG value. The magnitude of the value must specify the size, in bytes, of the buffer. If the sign of the value is negative, **RtlQueryRegistryValues** will only store the data of the key value. Otherwise, it will use the first ULONG in the buffer to record the value length, in bytes, the second ULONG to record the value type, and the rest of the buffer to store the value data.

If an error occurs at any stage of processing of the query table, **RtlQueryRegistryValues** stops processing the table and returns the error status.

See ZwSetValueKey for a description of the possible REG_*XXX* values.

Requirements

Minimum supported client	Available starting with Windows 2000.

RtlSecureZeroMemory function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlSecureZeroMemory** routine fills a block of memory with zeros in a way that is guaranteed to be secure.

Syntax

```
PVOID RtlSecureZeroMemory(
  PVOID  ptr,
  SIZE_T cnt
);
```

Parameters

`ptr`

Pointer to the memory buffer to be filled with zeros.

`cnt`

Specifies the number of bytes to be filled with zeros.

Return Value

None

Remarks

The effect of **RtlSecureZeroMemory** is identical to that of RtlZeroMemory, except that it is guaranteed to zero the memory location, even if it is not subsequently written to. (The compiler can optimize away a call to **RtlZeroMemory**, if it determines that the caller does not access that memory range again.)

Use **RtlSecureZeroMemory** to guarantee that sensitive information has been zeroed out. For example, suppose that a function uses a local array variable to store password information. Once the function exits, the password information can remain in the same memory location unless zeroed out by **RtlSecureZeroMemory**.

RtlSecureZeroMemory is slower than **RtlZeroMemory**; therefore, if security is not an issue, use **RtlZeroMemory** instead.

Callers of **RtlSecureZeroMemory** can be running at any IRQL if the *ptr* block is in nonpaged pool. Otherwise, the caller must be running at IRQL <= APC_LEVEL.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of Windows. (Because the routine is declared inline, the body of the routine can be included in earlier versions of the operating system.)

Target Platform	Desktop
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
IRQL	Any level (See Remarks section)

RtlZeroMemory

RtlSetAllBits function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlSetAllBits** routine sets all bits in a given bitmap variable.

Syntax

```
NTSYSAPI VOID RtlSetAllBits(
  PRTL_BITMAP BitMapHeader
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

Return Value

None

Remarks

Callers of **RtlSetAllBits** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlSetAllBits** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL (See Remarks section)"

RtlSetBits

RtlSetBit function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlSetBit** routine sets the specified bit in a bitmap to one.

Syntax

```
NTSYSAPI VOID RtlSetBit(
  PRTL_BITMAP BitMapHeader,
  ULONG       BitNumber
);
```

Parameters

`BitMapHeader`

Pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`BitNumber`

Specifies the zero-based index of the bit within the bitmap. The routine sets this bit to one.

Return Value

None

Remarks

Callers of **RtlSetBit** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlSetBit** can be called at any IRQL.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

RTL_BITMAP

RtlInitializeBitMap

RtlSetBits function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlSetBits** routine sets all bits in a given range of a given bitmap variable.

Syntax

```
NTSYSAPI VOID RtlSetBits(
  PRTL_BITMAP BitMapHeader,
  ULONG       StartingIndex,
  ULONG       NumberToSet
);
```

Parameters

`BitMapHeader`

A pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`StartingIndex`

Specifies the start of the bit range to be set. This is a zero-based value indicating the position of the first bit in the range.

`NumberToSet`

Specifies how many bits to set.

Return Value

None

Remarks

RtlSetBits simply returns control if the input *NumberToSet* is zero. *StartingIndex* plus *NumberToSet*must be less than or equal to *BitMapHeader*->**SizeOfBitMap**.

Callers of **RtlSetBits** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlSetBits** can be called at any IRQL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)
IRQL	"<= APC_LEVEL (See Remarks section)"

RtlSetDaclSecurityDescriptor function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlSetDaclSecurityDescriptor** routine sets the DACL information of an absolute-format security descriptor, or if there is already a DACL present in the security descriptor, it is superseded.

Syntax

```
NTSYSAPI NTSTATUS RtlSetDaclSecurityDescriptor(
  PSECURITY_DESCRIPTOR SecurityDescriptor,
  BOOLEAN              DaclPresent,
  PACL                 Dacl,
  BOOLEAN              DaclDefaulted
);
```

Parameters

`SecurityDescriptor`

A pointer to a SECURITY_DESCRIPTOR structure. This structure is the security descriptor to which the DACL is to be applied.

`DaclPresent`

Whether to indicate that a DACL is present in the security descriptor. If this parameter is **FALSE**, **RtlSetDaclSecurityDescriptor** sets the SE_DACL_PRESENT control flag in the security descriptor to **FALSE**. In this case, the remaining optional parameters (*Dacl* and *DaclDefaulted*) are ignored. If *DaclPresent* is **TRUE**, the SE_DACL_PRESENT flag in the security descriptor is set to **TRUE** and the remaining optional parameters are not ignored. For more information about the SE_DACL_PRESENT flag, see SECURITY_DESCRIPTOR_CONTROL.

`Dacl`

A pointer to the DACL for the security descriptor. If this parameter is **NULL**, the DACL pointer in the security descriptor is set to **NULL**. A **NULL** DACL pointer unconditionally grants all access to an object and is not the same as an empty DACL. An empty DACL denies all access to an object. If *Dacl* is non-**NULL**, the ACL structure supplied by the caller is referenced by, but not copied into, the security descriptor. The caller can allocate the **ACL** structure from paged system memory, and can call the RtlCreateAcl routine to initialize the structure.

`DaclDefaulted`

Whether the DACL was supplied by some default mechanism, or was explicitly specified by the caller. If this parameter is **TRUE**, the DACL was supplied by a default mechanism. If *DaclDefaulted* is **FALSE**, the caller explicitly specified the DACL. **RtlSetDaclSecurityDescriptor** copies the value specified for this parameter to the SE_DACL_DEFAULTED control flag in the security descriptor. For more information about the SE_DACL_DEFAULTED flag, see SECURITY_DESCRIPTOR_CONTROL.

Return Value

RtlSetDaclSecurityDescriptor can return one of the following status values.

RETURN CODE	DESCRIPTION

STA TUS _SU CCE SS	The call completed successfully.
STA TUS _UN KN OW N_R EVIS ION	The revision of the security descriptor is unknown.
STA TUS _IN VAL ID_S ECU RIT Y_D ESC R	The security descriptor is not an absolute format security descriptor.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)
IRQL	PASSIVE_LEVEL

RtlStringFromGUID function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlStringFromGUID** routine converts a given GUID from binary format into a Unicode string.

Syntax

```
NTSYSAPI NTSTATUS RtlStringFromGUID(
  REFGUID         Guid,
  PUNICODE_STRING GuidString
);
```

Parameters

`Guid`

Specifies the binary-format GUID to convert.

`GuidString`

Pointer to a caller-supplied variable in which a pointer to the converted GUID string is returned. **RtlStringFromGUID** allocates the buffer space for the string, which the caller must free by calling **RtlFreeUnicodeString**.

Return Value

If the conversion succeeds, **RtlStringFromGUID** returns STATUS_SUCCESS. Otherwise, no storage was allocated, nor was the conversion performed.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)
IRQL	PASSIVE_LEVEL

RtlTestBit function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlTestBit** routine returns the value of a bit in a bitmap.

Syntax

```
NTSYSAPI BOOLEAN RtlTestBit(
  PRTL_BITMAP BitMapHeader,
  ULONG       BitNumber
);
```

Parameters

`BitMapHeader`

Pointer to the RTL_BITMAP structure that describes the bitmap. This structure must have been initialized by the RtlInitializeBitMap routine.

`BitNumber`

Specifies the zero-based index of the bit within the bitmap. The routine returns the value of this bit.

Return Value

RtlTestBit returns the value of the bit that the *BitNumber* parameter points to.

Remarks

Callers of **RtlTestBit** must be running at IRQL <= APC_LEVEL if the memory that contains the bitmap variable is pageable or the memory at *BitMapHeader* is pageable. Otherwise, **RtlTestBit** can be called at any IRQL.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RtlTimeFieldsToTime function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlTimeFieldsToTime** routine converts **TIME_FIELDS** information to a system time value.

Syntax

```
NTSYSAPI BOOLEAN RtlTimeFieldsToTime(
  PTIME_FIELDS   TimeFields,
  PLARGE_INTEGER Time
);
```

Parameters

`TimeFields`

Pointer to the following structure, containing the time information to be converted:

```
typedef struct TIME_FIELDS {
    CSHORT Year;
    CSHORT Month;
    CSHORT Day;
    CSHORT Hour;
    CSHORT Minute;
    CSHORT Second;
    CSHORT Milliseconds;
    CSHORT Weekday;
} TIME_FIELDS;
```

Year

Specifies a value from 1601 on.

Month

Specifies a value from 1 to 12.

Day

Specifies a value from 1 to 31.

Hour

Specifies a value from 0 to 23.

Minute

Specifies a value from 0 to 59.

Second

Specifies a value from 0 to 59.

Milliseconds

Specifies a value from 0 to 999.

Weekday

Specifies a value from 0 to 6 (Sunday to Saturday).

`Time`

Pointer to a buffer, which is to contain the converted system time value as a large integer.

Return Value

RtlTimeFieldsToTime returns **TRUE** if the input *TimeFields* data was successfully converted.

Remarks

RtlTimeFieldsToTime ignores the **Weekday** value in *TimeFields*.

Callers of **RtlTimeFieldsToTime** can be running at any IRQL if both input buffers are resident.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RtlTimeToTimeFields

RtlTimeToTimeFields function

1/25/2019 • 2 minutes to read • Edit Online

The RtlTimeToTimeFields routine converts system time into a **TIME_FIELDS** structure.

Syntax

```
NTSYSAPI VOID RtlTimeToTimeFields(
  PLARGE_INTEGER Time,
  PTIME_FIELDS   TimeFields
);
```

Parameters

`Time`

Pointer to a buffer containing the absolute system time as a large integer, accurate to 100-nanosecond resolution.

`TimeFields`

Pointer to a caller-allocated buffer, which must be at least **sizeof**(**TIME_FIELDS**), to contain the returned information.

Return Value

None

Remarks

Callers of **RtlTimeToTimeFields** can be running at any IRQL if both input buffers are resident.

For more info about the **TIME_FIELDS** structure, see RtlTimeFieldsToTime function.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

RtlUlongByteSwap macro

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUlongByteSwap** routine reverses the ordering of the four bytes in a 32-bit unsigned integer value.

Syntax

```
void RtlUlongByteSwap(
   _x
);
```

Parameters

`_x`

A ULONG value to convert to a byte-swapped version.

Return Value

The byte-swapped version of the Source input parameter value.

Remarks

For example, if the *Source* parameter value is 0x12345678, the routine returns 0x78563412.

A typical use of this routine is to convert a ULONG value from little-endian byte format to big-endian byte format, and vice versa.

Use this routine instead of **ntohl** or **htonl**.

To reverse the ordering of bytes in a USHORT value, use the RtlUshortByteSwap routine. To reverse ordering of bytes in a ULONGLONG value, use the RtlUlonglongByteSwap routine.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RtlUshortByteSwap

RtlUlonglongByteSwap macro

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUlonglongByteSwap** routine reverses the ordering of the eight bytes in a 64-bit unsigned integer value.

Syntax

```
void RtlUlonglongByteSwap(
   _x
);
```

Parameters

`_x`

A ULONGLONG value to convert to a byte-swapped version.

Return Value

The byte-swapped version of the input parameter value.

Remarks

For example, if the *Source* parameter value is 0x0123456789abcdef, the routine returns 0xefcdab8967452301.

A typical use of this routine is to convert a ULONGLONG value from little-endian byte format to big-endian byte format, and vice versa.

To reverse the ordering of bytes in a USHORT value, use the RtlUshortByteSwap routine. To reverse ordering of bytes in a ULONG value, use the RtlUlongByteSwap routine.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RtlUnicodeStringToAnsiSize macro

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringToAnsiSize** routine returns the number of bytes required for a null-terminated ANSI string that is equivalent to a specified Unicode string.

Syntax

```
void RtlUnicodeStringToAnsiSize(
   STRING
);
```

Parameters

`STRING`

Pointer to the Unicode string for which to compute the number of bytes required for an equivalent null-terminated ANSI string.

Return Value

If the Unicode string can be translated into an ANSI string using the current system locale information, **RtlUnicodeStringToAnsiSize** returns the number of bytes required for an equivalent null-terminated ANSI string. Otherwise, **RtlUnicodeStringToAnsiSize** returns zero.

Remarks

The Unicode string is interpreted for the current system locale.

RtlUnicodeStringToAnsiSize performs the same operation as RtlxUnicodeStringToAnsiSize, but executes faster if the system does not use multibyte code pages.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

RtlxUnicodeStringToAnsiSize

RtlUnicodeStringToAnsiString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringToAnsiString** routine converts a given Unicode string into an ANSI string.

Syntax

```
NTSYSAPI NTSTATUS RtlUnicodeStringToAnsiString(
  PANSI_STRING     DestinationString,
  PCUNICODE_STRING SourceString,
  BOOLEAN          AllocateDestinationString
);
```

Parameters

`DestinationString`

Pointer to an ANSI_STRING structure to hold the converted ANSI string. If *AllocateDestinationString* is **TRUE**, the routine allocates a new buffer to hold the string data, and updates the **Buffer** member of *DestinationString* to point to the new buffer. Otherwise, the routine uses the currently specified buffer to hold the string.

`SourceString`

Pointer to the Unicode source string to be converted to ANSI.

`AllocateDestinationString`

TRUE if this routine is to allocate the buffer space for the *DestinationString*. If it does, the buffer must be deallocated by calling RtlFreeAnsiString.

Return Value

If the conversion succeeds, **RtlUnicodeStringToAnsiString** returns STATUS_SUCCESS. Otherwise, no storage was allocated, and no conversion was done.

Remarks

The translation is done in accord with the current system-locale information.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

ANSI_STRING

RtlAnsiStringToUnicodeString

RtlFreeAnsiString

UNICODE_STRING

RtlUnicodeStringToInteger function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringToInteger** routine converts a Unicode string representation of a number to the equivalent integer value.

Syntax

```
NTSYSAPI NTSTATUS RtlUnicodeStringToInteger(
  PCUNICODE_STRING String,
  ULONG            Base,
  PULONG           Value
);
```

Parameters

`String`

A pointer to a UNICODE_STRING structure that contains the number representation to convert to the equivalent integer value.

`Base`

A numeric value that indicates the base (or radix) of the number that the Unicode string represents. This parameter value is optional and can be set to zero.

If *Base* is zero, **RtlUnicodeStringToInteger** checks the prefix of the Unicode string to determine the base of the number:

- If the prefix is "0x", **RtlUnicodeStringToInteger** interprets the number in the string as a hexadecimal integer.
- If the prefix is "0o", **RtlUnicodeStringToInteger** interprets the number in the string as an octal integer.
- If the prefix is "0b", **RtlUnicodeStringToInteger** interprets the number in the string as a binary integer.

If the Unicode string does not contain any of these prefixes, **RtlUnicodeStringToInteger** treats the string as a base-10 integer.

`Value`

A pointer to a ULONG variable to which **RtlUnicodeStringToInteger** writes the integer value that results from conversion of the Unicode string.

Return Value

If the conversion is successful, the **RtlUnicodeStringToInteger** routine returns STATUS_SUCCESS and sets **Value* to the integer value represented by the number in the Unicode string. If the string is not empty, but does not start with a valid number representation, the routine returns STATUS_SUCCESS and sets **Value* to zero. If the string is empty, the routine fails and returns STATUS_INVALID_PARAMETER.

Remarks

This routine skips any white space at the start of the input string to find the start of the number.

If the first non-white space character in the string is a hyphen (-), the integer value written to **Value* is negative; otherwise, if the first character is a "+" or there is no sign character, the integer value written to **Value* is positive.

If the string does not contain a valid number, or if the first digit in the string is preceded by a non-white space character other than '+' or '-', the routine sets the output value to zero and returns STATUS_SUCCESS.

A substring that contains one or more valid digits is terminated by any character that is not a valid digit. For example, if *Base* = 2, valid digits are '0' and '1'. If *Base* = 8, valid digits are '0' to '7'. If *Base* = 10, valid digits are '0' to '9'. If *Base* = 16, valid digits are '0' to '9', 'a' to 'f', and 'A' to 'F'.

The following table contains examples of output values that result from various combinations of input strings and *Base* parameter values.

INPUT STRING	BASE	OUTPUT VALUE
"123"	10	123
" -345"	10	-345
"xyz"	10	0
" +678abc"	10	678
" +678abc"	16	6785724
"007"	10	7
"789"	8	7
"FGH"	16	15
" "	10	0

A related routine, RtlIntegerToUnicodeString, converts an integer value to the equivalent Unicode string representation.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)
IRQL	PASSIVE_LEVEL

RtlIntegerToUnicodeString

UNICODE_STRING

RtlUnicodeToUTF8N function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlUnicodeToUTF8N** routine converts a Unicode string to a UTF-8 string.

Syntax

```
NTSYSAPI NTSTATUS RtlUnicodeToUTF8N(
  PCHAR  UTF8StringDestination,
  ULONG  UTF8StringMaxByteCount,
  PULONG UTF8StringActualByteCount,
  PCWCH  UnicodeStringSource,
  ULONG  UnicodeStringByteCount
);
```

Parameters

`UTF8StringDestination`

A pointer to a caller-allocated destination buffer into which the routine writes the UTF-8 output string. If this parameter is **NULL**, the routine writes the required size of the output buffer to **UTF8StringActualByteCount*.

`UTF8StringMaxByteCount`

Specifies the maximum number of bytes that the routine can write to the buffer that *UTF8StringDestination* points to. If *UTF8StringDestination* = **NULL**, set *UTF8StringMaxByteCount* = 0.

`UTF8StringActualByteCount`

A pointer to a location into which the routine writes the actual number of bytes that it has written to the buffer that *UTF8StringDestination* points to. If *UTF8StringDestination* is non-**NULL**, this count never exceeds the value of *UTF8StringMaxByteCount*. If *UTF8StringDestination* is **NULL**, this count is the number of bytes that are required to contain the entire output string.

`UnicodeStringSource`

A pointer to the Unicode source string.

`UnicodeStringByteCount`

Specifies the number of bytes in the Unicode source string that the *UnicodeStringSource* parameter points to.

Return Value

RtlUnicodeToUTF8N returns STATUS_SUCCESS if the call is successful and all Unicode character codes in the input string were converted to the corresponding UTF-8 character codes in the output string. It returns STATUS_SOME_NOT_MAPPED if the call is successful but one or more input characters were invalid and were replaced by the Unicode replacement character, U+FFFD, before they were converted to UTF-8. Possible error return values include the following error codes:

RETURN CODE	DESCRIPTION

STATUS_BUFFER_TOO_SMALL	The *UTF8StringMaxByteCount* parameter specifies a buffer size that is too small to contain the entire output string.
STATUS_INVALID_PARAMETER	The *UTF8StringDestination* and *UTF8StringActualByteCount* parameters are both **NULL**.
STATUS_INVALID_PARAMETER_4	The *UnicodeStringSource* parameter is **NULL**.
STATUS_INVALID_PARAMETER_5	*UnicodeStringByteCount* is not an integer multiple of **sizeof**(WCHAR).

Remarks

The UTF-8 output string is null-terminated only if the Unicode input string is null-terminated.

The routine returns STATUS_BUFFER_TOO_SMALL if the *UTF8StringMaxByteCount* parameter specifies a buffer size that is too small to contain the entire output string. In this case, the routine writes as many UTF-8 characters as will fit in the buffer, and the **UTF8StringActualByteCount* value specifies the number of valid bytes that the routine has written to the buffer. The partial string that is contained in the output buffer might not include a terminating null character.

You can make an initial call to **RtlUnicodeToUTF8N** to obtain the required output buffer size, and then call **RtlUnicodeToUTF8N** again to obtain the Unicode output string. In the initial call, set *UTF8StringDestination* = **NULL** and *UTF8StringMaxByteCount* = 0, and the routine will write the required buffer size to **UTF8StringActualByteCount*. Next, allocate a buffer of the required size and call **RtlUnicodeToUTF8N** a second time to obtain the UTF-8 output string.

RtlUnicodeToUTF8N supports Unicode surrogate pairs. However, a surrogate leading word value that is not followed by a trailing word value, or a trailing word value that is not preceded by a leading word value, is not recognized as a valid character code and is replaced by the Unicode replacement character, U+FFFD.

RtlUnicodeToUTF8N continues to convert the input string to an output string until it reaches the end of the source buffer or the end of the destination buffer, whichever occurs first. The routine converts any null characters in the input string to null characters in the output string. If the input string contains a terminating null character, but the null character is not located at the end of the source buffer, the routine continues past the terminating null character until it reaches the end of the available buffer space.

The RtlUTF8ToUnicodeN routine converts a UTF-8 string to a Unicode string.

You can use **RtlUnicodeToUTF8N** and **RtlUTF8ToUnicode** routines to perform a lossless conversion of valid text strings between the Unicode and UTF-8 formats. However, strings that have arbitrary data values are likely to violate the Unicode rules for encoding surrogate pairs, and any information that is contained in the invalid values in an input string is lost and cannot be recovered from the resulting output string.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Ntifs.h, Wdm.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RtlUpcaseUnicodeChar function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUpcaseUnicodeChar** routine converts the specified Unicode character to uppercase.

Syntax

```
NTSYSAPI WCHAR RtlUpcaseUnicodeChar(
  WCHAR SourceCharacter
);
```

Parameters

`SourceCharacter`

Specifies the character to convert.

Return Value

RtlUpcaseUnicodeChar returns the uppercase version of the specified Unicode character.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

RtlUpperChar

RtlUshortByteSwap macro

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUshortByteSwap** routine reverses the ordering of the two bytes in a 16-bit unsigned integer value.

Syntax

```
void RtlUshortByteSwap(
   _x
);
```

Parameters

`_x`

A USHORT value to convert to a byte-swapped version.

Return Value

The byte-swapped version of the input parameter value.

Remarks

For example, if the *Source* parameter value is 0x1234, the routine returns 0x3412.

A typical use of this routine is to convert a USHORT value from little-endian byte format to big-endian byte format, and vice versa.

Use this routine instead of **ntohs** or **htons**.

To reverse the ordering of bytes in a ULONG value, use the RtlUlongByteSwap routine. To reverse ordering of bytes in a ULONGLONG value, use the RtlUlonglongByteSwap routine.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

RtlUlongByteSwap

RtlUlonglongByteSwap

RtlUTF8ToUnicodeN function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlUTF8ToUnicodeN** routine converts a UTF-8 string to a Unicode string.

Syntax

```
NTSYSAPI NTSTATUS RtlUTF8ToUnicodeN(
  PWSTR  UnicodeStringDestination,
  ULONG  UnicodeStringMaxByteCount,
  PULONG UnicodeStringActualByteCount,
  PCCH   UTF8StringSource,
  ULONG  UTF8StringByteCount
);
```

Parameters

`UnicodeStringDestination`

A pointer to a caller-allocated destination buffer into which the routine writes the Unicode output string. If this parameter is **NULL**, the routine writes the required size of the output buffer to **UnicodeStringActualByteCount*.

`UnicodeStringMaxByteCount`

Specifies the maximum number of bytes that the routine can write to the buffer that *UnicodeStringDestination* points to. If *UnicodeStringDestination* = **NULL**, set *UnicodeStringMaxByteCount* = 0.

`UnicodeStringActualByteCount`

A pointer to a location into which the routine writes the actual number of bytes that the routine has written to the buffer that *UnicodeStringDestination* points to. If *UnicodeStringDestination* is non-**NULL**, this count never exceeds the value of *UnicodeStringMaxByteCount*. If *UnicodeStringDestination* is **NULL**, this count is the number of bytes that are required to contain the entire output string.

`UTF8StringSource`

A pointer to the UTF-8 source string.

`UTF8StringByteCount`

Specifies the number of bytes in the UTF-8 source string that the *UTF8StringSource* parameter points to.

Return Value

RtlUTF8ToUnicodeN returns STATUS_SUCCESS if the call is successful and all UTF-8 character codes in the input string were converted to the corresponding Unicode character codes in the output string. It returns STATUS_SOME_NOT_MAPPED if the call is successful but one or more input characters were invalid and were converted to the Unicode replacement character, U+FFFD. Possible error return values include the following error codes:

RETURN CODE	DESCRIPTION

STATUS_BUFFER_TOO_SMALL	The *UnicodeStringMaxByteCount* parameter specifies a buffer size that is too small to contain the entire output string.
STATUS_INVALID_PARAMETER	The *UnicodeStringDestination* and *UnicodeStringActualByteCount* parameters are both **NULL**.
STATUS_INVALID_PARAMETER_4	The *UTF8StringSource* parameter is **NULL**.

Remarks

The Unicode output string is null-terminated only if the UTF-8 input string is null-terminated.

The routine returns STATUS_BUFFER_TOO_SMALL if the *UnicodeStringMaxByteCount* parameter specifies a buffer size that is too small to contain the entire output string. In this case, the routine writes as many Unicode characters as will fit in the buffer, and the **UnicodeStringActualByteCount* value specifies the number of valid bytes that the routine has written to the buffer. The partial string that is contained in the output buffer might not include a terminating null character.

You can make an initial call to **RtlUTF8ToUnicodeN** to obtain the required output buffer size, and then call **RtlUTF8ToUnicodeN** again to obtain the Unicode output string. In the initial call, set *UnicodeStringDestination* = **NULL** and *UnicodeStringMaxByteCount* = 0, and the routine will write the required buffer size to **UnicodeStringActualByteCount*. Next, allocate a buffer of the required size and call **RtlUTF8ToUnicodeN** a second time to obtain the Unicode output string.

RtlUTF8ToUnicodeN supports Unicode surrogate pairs. However, a surrogate leading word value that is not followed by a trailing word value, or a trailing word value that is not preceded by a leading word value, is not recognized as a valid character and is replaced by the Unicode replacement character, U+FFFD.

RtlUTF8ToUnicodeN continues to convert the input string to an output string until it reaches the end of the source buffer or the end of the destination buffer, whichever occurs first. The routine converts any null characters in the input string to null characters in the output string. If the input string contains a terminating null character, but the null character is not located at the end of the source buffer, the routine continues past the terminating null character until it reaches the end of the available buffer space.

The RtlUnicodeToUTF8N routine converts a Unicode string to a UTF-8 string.

You can use the **RtlUTF8ToUnicode** and **RtlUnicodeToUTF8N** routines to perform a lossless conversion of valid text strings between the UTF-8 and Unicode formats. However, strings that have arbitrary data values are likely to violate the Unicode rules for encoding surrogate pairs, and any information that is contained in the invalid values in an input string is lost and cannot be recovered from the resulting output string.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.

RtlUnicodeToUTF8N

RtlValidRelativeSecurityDescriptor function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlValidRelativeSecurityDescriptor** routine checks the validity of a self-relative security descriptor.

Syntax

```
NTSYSAPI BOOLEAN RtlValidRelativeSecurityDescriptor(
  PSECURITY_DESCRIPTOR SecurityDescriptorInput,
  ULONG                SecurityDescriptorLength,
  SECURITY_INFORMATION RequiredInformation
);
```

Parameters

`SecurityDescriptorInput`

A pointer to the buffer that contains the security descriptor in self-relative format. The buffer must begin with a SECURITY_DESCRIPTOR structure, which is followed by the rest of the security descriptor data.

`SecurityDescriptorLength`

The size of the *SecurityDescriptorInput* structure.

`RequiredInformation`

A SECURITY_INFORMATION value that specifies the information that is required to be contained in the security descriptor.

Return Value

RtlValidRelativeSecurityDescriptor returns **TRUE** if the security descriptor is valid and includes the information that the *RequiredInformation* parameter specifies. Otherwise, this routine returns **FALSE**.

Remarks

To check the validity of a security descriptor in absolute format, use RtlValidSecurityDescriptor instead.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	"<= APC_LEVEL"

SECURITY_DESCRIPTOR

SECURITY_INFORMATION

RtlValidSecurityDescriptor function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlValidSecurityDescriptor** routine checks a given security descriptor's validity.

Syntax

```
NTSYSAPI BOOLEAN RtlValidSecurityDescriptor(
  PSECURITY_DESCRIPTOR SecurityDescriptor
);
```

Parameters

`SecurityDescriptor`

Pointer to the SECURITY_DESCRIPTOR to be checked.

Return Value

RtlValidSecurityDescriptor returns **TRUE** if the given descriptor is valid.

Remarks

The routine checks the validity of an absolute-format security descriptor. To check the validity of a self-relative security descriptor, use the RtlValidRelativeSecurityDescriptor routine instead.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RtlSetDaclSecurityDescriptor

RtlValidRelativeSecurityDescriptor

SECURITY_DESCRIPTOR

RtlVerifyVersionInfo function

1/25/2019 • 3 minutes to read • Edit Online

The **RtlVerifyVersionInfo** routine compares a specified set of operating system version requirements to the corresponding attributes of the currently running version of the operating system.

Syntax

```
NTSYSAPI NTSTATUS RtlVerifyVersionInfo(
  PRTL_OSVERSIONINFOEXW VersionInfo,
  ULONG                 TypeMask,
  ULONGLONG             ConditionMask
);
```

Parameters

`VersionInfo`

Pointer to an RTL_OSVERSIONINFOEXW structure that specifies the operating system version requirements to compare to the corresponding attributes of the currently running version of the operating system.

`TypeMask`

Specifies which members of *VersionInfo* to compare with the corresponding attributes of the currently running version of the operating system. *TypeMask* is set to a logical OR of one or more of the following values.

VALUE	CORRESPONDING MEMBER
VER_BUILDNUMBER	**dwBuildNumber**
VER_MAJORVERSION	**dwMajorVersion**
VER_MINORVERSION	**dwMinorVersion**
VER_PLATFORMID	**dwPlatformId**
VER_SERVICEPACKMAJOR	**wServicePackMajor**
VER_SERVICEPACKMINOR	**wServicePackMinor**
VER_SUITENAME	**wSuiteMask**
VER_PRODUCT_TYPE	**wProductType**

`ConditionMask`

Specifies how to compare each **VersionInfo** member. To set the value of *ConditionMask*, a caller should use the **VER_SET_CONDITION** macro:

```
VER_SET_CONDITION (
        IN OUT  ULONGLONG  ConditionMask,
        IN ULONG  TypeBitMask,
        IN UCHAR  ComparisonType
        );
```

The value of *ConditionMask* is created in the following way:

- Initialize the value of *ConditionMask* to zero.
- Call **VER_SET_CONDITION** once for each *VersionInfo* member specified by *TypeMask*.
- Set the *TypeBitMask* and *ComparisonType* parameters for each call to **VER_SET_CONDITION** as follows:

TypeBitMask

Indicates the *VersionInfo* member for which the comparison type is set. *TypeBitMask* can be one of the following values.

VALUE	CORRESPONDING MEMBER
VER_BUILDNUMBER	**dwBuildNumber**
VER_MAJORVERSION	**dwMajorVersion**
VER_MINORVERSION	**dwMinorVersion**
VER_PLATFORMID	**dwPlatformId**
VER_SERVICEPACKMAJOR	**wServicePackMajor**
VER_SERVICEPACKMINOR	**wServicePackMinor**
VER_SUITENAME	**wSuiteMask**
VER_PRODUCT_TYPE	**wProductType**

ComparisonType

Specifies the comparison type that **RtlVerifyVersionInfo** uses to compare the **VersionInfo** member specified by *TypeBitMask* with the corresponding attribute of the currently running operating system.

For all values of *TypeBitMask* other than VER_SUITENAME, *ComparisonType* is set to one of the following values.

VALUE	MEANING
VER_EQUAL	The current value must be equal to the specified value.
VER_GREATER	The current value must be greater than the specified value.
VER_GREATER_EQUAL	The current value must be greater than or equal to the specified value.
VER_LESS	The current value must be less than the specified value.
VER_LESS_EQUAL	The current value must be less than or equal to the specified value.

If *TypeBitMask* is set to VER_SUITENAME, *ComparisonType* is set to of one the following values.

VALUE	MEANING
VER_AND	All product suites specified in the **wSuiteMask** member must be present in the current system.
VER_OR	At least one of the specified product suites must be present in the current system.

Return Value

RtlVerifyVersionInfo returns one of the following status values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The specified version matches the currently running version of the operating system.
STATUS_INVALID_PARAMETER	The input parameters are not valid.
STATUS_REVISION_MISMATCH	The specified version does not match the currently running version of the operating system.

Remarks

RtlVerifyVersionInfo enables a driver to easily verify the presence of a required set of operating system attributes. **RtlVerifyVersionInfo** is the kernel-mode equivalent of the user-mode **VerifyVersionInfo** function in the Windows SDK. See the example in the Windows SDK that shows how to verify the system version.

Typically, **RtlVerifyVersionInfo** returns STATUS_SUCCESS only if all comparisons succeed. However, the major version, minor version, and service pack version are tested in a sequential manner in the following way:

- If the major version exceeds the minimum required, then the minor version and service pack version are not tested. For example, if the current major version is 6.0, a test for a system greater than or equal to version 5.1 service pack 1 succeeds. The minor version and service pack version are not tested.

- If the minor version exceeds the minimum required, then the service pack version is not tested. For example, if the current major version is 5.2, a test for a system version greater than or equal to version 5.1 service pack 1 succeeds. The service pack version is not tested.
- If the major service pack version exceeds the minimum required, then the minor service pack version is not tested.

To verify a range of system versions, a driver can call **RtlVerifyVersionInfo** twice, once to verify a lower bound on the system version and once to verify an upper bound on the system version.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Ntddk.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)
IRQL	PASSIVE_LEVEL

RtlGetVersion

RtlWriteRegistryValue function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlWriteRegistryValue** routine writes caller-supplied data into the registry along the specified relative path at the given value name.

Syntax

```
NTSYSAPI NTSTATUS RtlWriteRegistryValue(
  ULONG  RelativeTo,
  PCWSTR Path,
  PCWSTR ValueName,
  ULONG  ValueType,
  PVOID  ValueData,
  ULONG  ValueLength
);
```

Parameters

`RelativeTo`

Specifies whether *Path* is an absolute registry path or is relative to a predefined path as one of the following.

VALUE	MEANING
RTL_REGISTRY_ABSOLUTE	Path is an absolute registry path.
RTL_REGISTRY_SERVICES	Path is relative to **\Registry\Machine\System\CurrentControlSet\Services**.
RTL_REGISTRY_CONTROL	Path is relative to **\Registry\Machine\System\CurrentControlSet\Control**.
RTL_REGISTRY_WINDOWS_NT	Path is relative to **\Registry\Machine\Software\Microsoft\Windows NT\CurrentVersion**.
RTL_REGISTRY_DEVICEMAP	Path is relative to **\Registry\Machine\Hardware\DeviceMap**.
RTL_REGISTRY_USER	Path is relative to **\Registry\User\CurrentUser**. (For a system process, this is **\Users.Default**.)
RTL_REGISTRY_OPTIONAL	Specifies that the key referenced by this parameter and the *Path* parameter are optional.
RTL_REGISTRY_HANDLE	Specifies that the *Path* parameter is actually a registry handle to use. This value is optional.

`Path`

Pointer to either an absolute registry path or a path relative to the known location specified by the *RelativeTo*

parameter. If the RTL_REGISTRY_HANDLE flag is specified, this parameter is a registry handle for an already opened key to be used directly.

`ValueName`

Pointer to the name of a subkey or value entry to be written into the registry.

`ValueType`

Specifies a REG_*XXX* value that determines the type of the *ValueName* parameter. For a list of the possible values, see the *Type* parameter of ZwSetValueKey.

`ValueData`

Pointer to the name of a subkey or values for its value entries (or both) to be written into the registry.

`ValueLength`

Specifies the number of bytes of *ValueData* to be written into the registry.

Return Value

RtlWriteRegistryValue returns the status of the operation, either STATUS_SUCCESS or an error status.

Remarks

If the specified key does not exist, the routine attempts to create the key. For this attempt to succeed, the new key must be a direct subkey of the key that is referred to by the *Path* parameter, and the key that *Path* refers to must have been opened for KEY_CREATE_SUB_KEY access.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RtlxAnsiStringToUnicodeSize function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlxAnsiStringToUnicodeSize** routine returns the number of bytes that are required for a null-terminated Unicode string that is equivalent to a specified ANSI string.

Syntax

```
NTSYSAPI ULONG RtlxAnsiStringToUnicodeSize(
  PCANSI_STRING AnsiString
);
```

Parameters

`AnsiString`

Pointer to the ANSI string for which to compute the number of bytes that are required for an equivalent null-terminated Unicode string.

Return Value

RtlxAnsiStringToUnicodeSize returns the number of bytes that are required for an equivalent null-terminated Unicode string, if the ANSI string can be translated into an Unicode string by using the current system locale information. Otherwise, this routine returns zero.

Remarks

The ANSI string is interpreted for the current system locale.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RtlZeroMemory macro

1/25/2019 • 2 minutes to read • Edit Online

The **RtlZeroMemory** routine fills a block of memory with zeros, given a pointer to the block and the length, in bytes, to be filled.

Syntax

```
void RtlZeroMemory(
   Destination,
   Length
);
```

Parameters

`Destination`

Datatype: void*. A pointer to the memory block to be filled with zeros.

`Length`

Datatype: size_t. The number of bytes to fill with zeros.

Return Value

None

Remarks

To zero out a memory buffer to erase security-sensitive data, use RtlSecureZeroMemory instead.

Callers of **RtlZeroMemory** can be running at any IRQL if the destination memory block is in nonpaged system memory. Otherwise, the caller must be running at IRQL <= APC_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Smclib.h, Minitape.h, Scsi.h, Storport.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

RtlSecureZeroMemory

SeAccessCheck function

1/25/2019 • 2 minutes to read • Edit Online

The **SeAccessCheck** routine determines whether the requested access rights can be granted to an object protected by a security descriptor and an object owner.

Syntax

```
BOOLEAN SeAccessCheck(
  PSECURITY_DESCRIPTOR      SecurityDescriptor,
  PSECURITY_SUBJECT_CONTEXT SubjectSecurityContext,
  BOOLEAN                   SubjectContextLocked,
  ACCESS_MASK               DesiredAccess,
  ACCESS_MASK               PreviouslyGrantedAccess,
  PPRIVILEGE_SET            *Privileges,
  PGENERIC_MAPPING          GenericMapping,
  KPROCESSOR_MODE           AccessMode,
  PACCESS_MASK              GrantedAccess,
  PNTSTATUS                 AccessStatus
);
```

Parameters

`SecurityDescriptor`

Pointer to the SECURITY_DESCRIPTOR structure that describes the security descriptor protecting the object being accessed.

`SubjectSecurityContext`

Pointer to the SECURITY_SUBJECT_CONTEXT structure that specifies the subject's captured security context.

`SubjectContextLocked`

Indicates whether the user's subject context is locked, so that it does not have to be locked again.

`DesiredAccess`

Specifies the ACCESS_MASK bitmask for the access rights that the caller is attempting to acquire. If the caller sets the MAXIMUM_ALLOWED bit, the routine performs all DACL checks. However, the routine does not do any privilege checks, unless the caller specifically requests them by setting the ACCESS_SYSTEM_SECURITY or WRITE_OWNER bits.

`PreviouslyGrantedAccess`

Specifies the ACCESS_MASK bitmask of access rights already granted, such as access rights granted as a result of holding a privilege.

`Privileges`

Pointer to a caller-supplied variable to be set to the address of the PRIVILEGE_SET structure that will be used as part of the access validation, or this parameter can be **NULL**. The returned buffer, if any, must be released by the caller with SeFreePrivileges.

`GenericMapping`

Pointer to the GENERIC_MAPPING structure associated with this object type. This value specifies the specific access rights implied by each GENERIC_*XXX* access right.

`AccessMode`

Specifies the access mode to be used in the check, either **UserMode** or **KernelMode**.

`GrantedAccess`

Pointer to a returned access mask indicating the granted access. If the caller specifies MAXIMUM_ALLOWED, and the DACL in *SecurityDescriptor* is **NULL**, then the routine returns GENERIC_ALL plus any additional access the caller explicitly requests.

`AccessStatus`

Pointer to the status value indicating why access was denied.

Return Value

If access is allowed, **SeAccessCheck** returns **TRUE**.

Remarks

SeAccessCheck might perform privilege tests for **SeTakeOwnershipPrivilege** and **SeSecurityPrivilege**, depending on the accesses being requested. It might perform additional privilege testing in future releases of the operating system.

This routine also might check whether the caller is the owner of the object in order to grant WRITE_DAC or READ_CONTROL access.

If this routine returns **FALSE**, the caller should use the returned *AccessStatus* as its return value. That is, the caller should avoid hardcoding a return value of STATUS_ACCESS_DENIED or any other specific STATUS_*XXX* value.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

PRIVILEGE_SET

SECURITY_DESCRIPTOR

SECURITY_SUBJECT_CONTEXT

SeFreePrivileges

SeValidSecurityDescriptor

SeAssignSecurity function

1/25/2019 • 2 minutes to read • Edit Online

The **SeAssignSecurity** routine builds a self-relative security descriptor for a new object, given the security descriptor of its parent directory and any originally requested security for the object.

Syntax

```
NTSTATUS SeAssignSecurity(
  PSECURITY_DESCRIPTOR      ParentDescriptor,
  PSECURITY_DESCRIPTOR      ExplicitDescriptor,
  PSECURITY_DESCRIPTOR      *NewDescriptor,
  BOOLEAN                   IsDirectoryObject,
  PSECURITY_SUBJECT_CONTEXT SubjectContext,
  PGENERIC_MAPPING          GenericMapping,
  POOL_TYPE                 PoolType
);
```

Parameters

`ParentDescriptor`

Pointer to a buffer containing the SECURITY_DESCRIPTOR for the parent directory, if any, containing the new object being created. *ParentDescriptor* can be **NULL**, or have a **NULL** system access control list (SACL) or a **NULL** discretionary access control list (DACL).

`ExplicitDescriptor`

Pointer to a buffer containing the SECURITY_DESCRIPTOR specified by the user that is applied to the new object. *ExplicitDescriptor* can be **NULL**, or have a **NULL** SACL or a **NULL** DACL.

`NewDescriptor`

Receives a pointer to the returned SECURITY_DESCRIPTOR. **SeAssignSecurity** allocates the buffer from the paged memory pool.

`IsDirectoryObject`

Specifies whether the new object is a directory object. **TRUE** indicates the object contains other objects.

`SubjectContext`

Pointer to a buffer containing the security context of the subject creating the object. This is used to retrieve default security information for the new object, such as the default owner, the primary group, and discretionary access control.

`GenericMapping`

Pointer to the GENERIC_MAPPING structure that describes the mapping from each generic right to the implied nongeneric rights.

`PoolType`

This parameter is unused. The buffer to hold the new security descriptor is always allocated from paged pool.

Return Value

SeAssignSecurity can return one of the following:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The assignment was successful.
STATUS_INVALID_OWNER	The SID provided for the owner of the target security descriptor is not one the caller is authorized to assign as the owner of an object.
STATUS_PRIVILEGE_NOT_HELD	The caller does not have the privilege (**SeSecurityPrivilege**) necessary to explicitly assign the specified system ACL.

Remarks

The final security descriptor returned to the caller may contain a mix of information, some explicitly provided from the new object's parent.

SeAssignSecurity assumes privilege checking has not been performed. This routine performs privilege checking.

The assignment of system and discretionary ACLs is governed by the logic illustrated in the following table:

	EXPLICIT (NONDEFAULT) ACL SPECIFIED	EXPLICIT DEFAULT ACL SPECIFIED	NO ACL SPECIFIED
Inheritable ACL from parent	Assign specified ACL	Assign inherited ACL	Assign inherited ACL
No inheritable ACL from parent	Assign specified ACL	Assign default ACL	Assign no ACL

An explicitly specified ACL, whether a default ACL or not, can be empty or null. The caller must be a kernel-mode client or be appropriately privileged to explicitly assign a default or nondefault system ACL.

The assignment of the new object's owner and group is governed by the following logic:

- If the passed security descriptor includes an owner, it is assigned as the new object's owner. Otherwise, the caller's token is considered to determine the owner. Within the token, the default owner, if any, is assigned. Otherwise, the caller's user ID is assigned.

- If the passed security descriptor includes a group, it is assigned as the new object's group. Otherwise, the caller's token is considered to determine the group. Within the token, the default group, if any, is assigned. Otherwise, the caller's primary group ID is assigned.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

SECURITY_DESCRIPTOR

SeDeassignSecurity

SeAssignSecurityEx function

1/25/2019 • 4 minutes to read • Edit Online

The **SeAssignSecurityEx** routine builds a self-relative security descriptor for a new object given the following optional parameters: a security descriptor of the object's parent directory, an explicit security descriptor for the object, and the object type.

Syntax

```
NTSTATUS SeAssignSecurityEx(
  PSECURITY_DESCRIPTOR      ParentDescriptor,
  PSECURITY_DESCRIPTOR      ExplicitDescriptor,
  PSECURITY_DESCRIPTOR      *NewDescriptor,
  GUID                      *ObjectType,
  BOOLEAN                   IsDirectoryObject,
  ULONG                     AutoInheritFlags,
  PSECURITY_SUBJECT_CONTEXT SubjectContext,
  PGENERIC_MAPPING          GenericMapping,
  POOL_TYPE                 PoolType
);
```

Parameters

`ParentDescriptor`

Pointer to the SECURITY_DESCRIPTOR of the parent object that contains the new object being created. *ParentDescriptor* can be **NULL**, or have a **NULL** system access control list (SACL) or a **NULL** discretionary access control list (DACL).

`ExplicitDescriptor`

Pointer to an explicit SECURITY_DESCRIPTOR that is applied to the new object. *ExplicitDescriptor* can be **NULL**, or have a **NULL** SACL or a **NULL** DACL.

`NewDescriptor`

Receives a pointer to the returned SECURITY_DESCRIPTOR. **SeAssignSecurityEx** allocates the buffer from the paged memory pool.

`ObjectType`

Pointer to a GUID for the type of object being created. If the object does not have a GUID, *ObjectType* must be set to **NULL**.

`IsDirectoryObject`

Specifies whether the new object is a directory object. If *IsDirectoryObject* is set to **TRUE**, the new object is a directory object, otherwise the new object is not a directory object.

`AutoInheritFlags`

Specifies the type of automatic inheritance that is applied to access control entries (ACE) in the access control lists (ACL) specified by *ParentDescriptor*. *AutoInheritFlags* also controls privilege checking, owner checking, and setting a default owner and group for *NewDescriptor*. *AutoInheritFlags* must be set to a logical OR of one or more of the

following values:

VALUE	MEANING
SEF_DACL_AUTO_INHERIT	ACEs in the DACL of *ParentDescriptor* are inherited by *NewDescriptor*, in addition to explicit ACEs specified by *ExplicitDescriptor*.
SEF_SACL_AUTO_INHERIT	ACEs in the SACL of *ParentDescriptor* are inherited by *NewDescriptor*, in addition to explicit ACEs specified by *ExplicitDescriptor*.
SEF_DEFAULT_DESCRIPTOR_FOR_OBJECT	*ExplicitDescriptor* is the default descriptor for the object type specified by *ObjectType*. *ExplicitDescriptor* is not used if ACEs are inherited from *ParentDescriptor*.
SEF_AVOID_PRIVILEGE_CHECK	Privilege checking is not done. This flag is useful with automatic inheritance because it avoids privilege checking on each child that needs to be updated.
SEF_AVOID_OWNER_CHECK	Owner checking is not done.
SEF_DEFAULT_OWNER_FROM_PARENT	If an owner is specified by *ExplicitDescriptor*, this flag is not used, and the owner of *NewDescriptor* is set to the owner specified by *ExplictDescriptor*. If an owner is not specified by *ExplicitDescriptor*, this flag is used in the following way: If the flag is set, the owner of *NewDescriptor* is set to the owner of *ParentDescriptor*. Otherwise, the owner of *NewDescriptor* is set to the owner specified by the *SubjectContext*.
SEF_DEFAULT_GROUP_FROM_PARENT	If a group is specified by *ExplicitDescriptor*, this flag is not used, and the group of *NewDescriptor* is set to the group specified by *ExplictDescriptor*. If a group is not specified by *ExplicitDescriptor*, this flag is used in the following way: If the flag is set, the group of *NewDescriptor* is set to the group of *ParentDescriptor*. Otherwise, the group of *NewDescriptor* is set to the group specified by the *SubjectContext*.

The assignment of system and discretionary ACLs is described in the following table:

	NONDEFAULT EXPLICIT DESCRIPTOR(1)	DEFAULT EXPLICIT DESCRIPTOR(2)	NULL EXPLICIT DESCRIPTOR
ACL is inherited from parent descriptor(3).	Assign both inherited and explicit ACLs(5)(6).	Assign inherited ACL.	Assign inherited ACL.
ACL is not inherited from parent descriptor(4).	Assign nondefault ACL.	Assign default ACL.	Assign no ACL.

Assignment Notes

1. The SEF_DEFAULT_DESCRIPTOR_FOR_OBJECT flag is not specified.
2. The SEF_DEFAULT_DESCRIPTOR_FOR_OBJECT flag is specified.
3. The auto inherit flag for an ACL is specified (SEF_DACL_AUTO_INHERIT or SEF_SACL_AUTO_INHERIT).
4. The automatic inherit flag for an ACL is not specified.
5. ACEs with the INHERITED_ACE bit set in their **AceFlags** member are not copied to the assigned security descriptor.
6. ACEs that are inherited from the parent descriptor are appended after the ACEs specified by the explicit

descriptor.

`SubjectContext`

Pointer to a security context of the subject that is creating the object. *SubjectContext* is used to retrieve default security information for the new object, including the default owner, the primary group, and discretionary access control.

`GenericMapping`

Pointer to an array of access mask values that specify the mapping between each generic rights to object-specific rights.

`PoolType`

This parameter is unused. The buffer to hold the new security descriptor is always allocated from paged pool.

Return Value

SeAssignSecurityEx returns one of the following values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The assignment was successful.
STATUS_INVALID_OWNER	The SID provided as the owner of the new security descriptor is not a SID that the caller is authorized to assign as the owner of an object.
STATUS_PRIVILEGE_NOT_HELD	The caller does not have the privilege (**SeSecurityPrivilege**) necessary to explicitly assign the specified SACL.

Remarks

SeAssignSecurityEx extends the basic operation of **SeAssignSecurity** in the following ways:

- *ObjectType* optionally specifies an object type. Object-specific inheritance is controlled by the following members of an object-specific ACE: **Flags**, **InheritedObjectType**, and **Header.AceFlags**.
- *AutoInheritFlags*specifies the type of automatic inheritance of ACEs that is used. AutoInheritFlags also controls privilege checking, owner checking, and setting a default owner and group for *NewDescriptor*.

For more information about security and access control, see the documentation on these topics in the Microsoft Windows SDK.

SeDeassignSecurity

SeDeassignSecurity function

1/25/2019 • 2 minutes to read • Edit Online

The
SeDeassignSecurity routine deallocates the memory associated with a security descriptor that was assigned using **SeAssignSecurity**.

Syntax

```
NTSTATUS SeDeassignSecurity(
  PSECURITY_DESCRIPTOR *SecurityDescriptor
);
```

Parameters

`SecurityDescriptor`

Pointer to the buffered SECURITY_DESCRIPTOR being released.

Return Value

If the deallocation succeeds, **SeDeassignSecurity** returns STATUS_SUCCESS.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

SET_D3COLD_SUPPORT callback function

1/25/2019 • 4 minutes to read • Edit Online

The *SetD3ColdSupport* routine enables or disables transitions to the D3cold device power state.

Syntax

```
SET_D3COLD_SUPPORT SetD3coldSupport;

void SetD3coldSupport(
  PVOID Context,
  BOOLEAN D3ColdSupport
)
{...}
```

Parameters

`Context`

A pointer to interface-specific context information. The caller sets this parameter to the value of the **Context** member of the D3COLD_SUPPORT_INTERFACE structure for the interface.

`D3ColdSupport`

Whether to allow transitions from D3hot to D3cold. Set to **TRUE** to enable these transitions. Otherwise, set to **FALSE.** For more information, see Remarks.

Return Value

None.

Remarks

The driver that is the power policy owner (PPO) for a device can call this routine to enable or disable transitions to the D3cold substate that might occur when the computer is in the S0 (working) system power state and is not preparing to exit S0.

If a device must be able to signal a wake event from any low-power Dx state that it enters, the driver for this device should not enable transitions to the D3cold substate unless the device can signal a wake event from this substate. Otherwise, after entering D3cold, the device will be unavailable until the computer restarts or wakes from a sleeping state.

The driver for the device can call the GetIdleWakeInfo routine to determine whether the device can signal a wake event from D3cold.

If necessary, the driver for a device can make a series of *SetD3ColdSupport* calls to alternately enable and disable D3cold transitions in response to dynamically changing conditions.

For example, a graphics device might have a large hardware context to restore after a transition from D3cold to D0. The time required to restore this context may or may not be acceptable depending on the set of tasks that the user is currently performing. In addition, the restore time might vary with this task mix. The driver might need to dynamically enable and disable transitions to D3cold as the task mix changes.

A device can enter the D3cold substate only from the D3hot substate. If the driver calls *SetD3ColdSupport* to enable transitions from D3hot to D3cold, the device may or may not enter D3cold after it enters D3hot. In response to a wake event, a device might enter D0 directly from D3hot without ever passing through D3cold.

When a device moves from D3hot to D3cold, it probably does so because the power source that it shares with some number of other devices was turned off. Some time after these devices enter D3cold, the driver for one of the devices might request a transition to D0. In response to this request, the parent bus driver or ACPI filter driver turns on the power source, and all the devices that share the power source enter their default, power-on states.

The only device driver that expects this power state change is the driver that requested the change. The drivers for the other devices must receive notification of this change so that they can properly initialize their devices to operate in D0. Only a driver that can receive this notification should enable its device to enter D3cold. Otherwise, the driver will not know when the device enters D0.

Starting with Windows 8, a WDM driver can register its device with the power framework (PoFx) and be notified by the DevicePowerRequiredCallback routine when the device enters D0. Similarly, a KMDF driver can register its device with PoFx and be notified by the EvtDeviceD0Entry event callback.

A driver that does not register its device with PoFx can still be notified of a transition to D0 if the device is armed for wake. When the bus drivers turn on the power to the device, they complete the driver's IRP_MN_WAIT_WAKE request. In response, the driver initializes its device to operate in D0.

After a power source shared by several devices turns on, the device whose driver requested the transition to D0 might be the only one of these devices that has work to do. The other devices are likely to be idle, in which case their drivers, after some time, will move these devices to D3hot.

If the driver calls *SetD3ColdSupport* to disable transitions to D3cold, D0 is the only device power state that the device can enter from D3hot.

If the driver calls *SetD3ColdSupport* to enable transitions to D3cold, these transitions might be disabled for other reasons. The driver can call the GetD3ColdCapability routine to determine whether the device is capable of entering the D3cold substate. However, a driver might not need this information. If a device is not capable of entering D3cold, calls to *SetD3ColdSupport* have no effect, but are harmless.

The *SetD3ColdSupport* routine affects only D3hot-to-D3cold transitions that might occur when the computer is in (and is not preparing to exit) the S0 state. This routine has no effect on the case in which the computer is preparing to exit S0 and enter a low-power system state. A device in the D3hot substate might always enter the D3cold substate just before the computer enters a system low-power state.

By default, before the first call to the *SetD3ColdSupport* routine, D3hot-to-D3cold transitions are disabled. To change this default so that D3hot-to-D3cold transitions are enabled before the first *SetD3ColdSupport* call, the driver package for the device can include the following two lines in the **DDInstall.HW** section of the INF file that installs the driver:

```
Include = machine.inf
Needs = PciD3ColdSupported
```

Windows 8 is the first version of Windows to support devices that can enter and exit the D3cold substate while the computer remains in the S0 state. For more information, see Device Low-Power States.

Requirements

Minimum supported client	Available starting with Windows 8.
Target Platform	Desktop
Header	wdm.h (include Wdm.h)

GetD3ColdCapability

IRP_MN_WAIT_WAKE

SeValidSecurityDescriptor function

1/25/2019 • 2 minutes to read • Edit Online

The **SeValidSecurityDescriptor** routine returns whether a given security descriptor is structurally valid.

Syntax

```
BOOLEAN SeValidSecurityDescriptor(
  ULONG                Length,
  PSECURITY_DESCRIPTOR SecurityDescriptor
);
```

Parameters

`Length`

Specifies the size in bytes of the given security descriptor.

`SecurityDescriptor`

Pointer to the self-relative SECURITY_DESCRIPTOR, which must be buffered somewhere in system space.

Return Value

SeValidSecurityDescriptor returns **TRUE** if the buffered security descriptor is structurally valid.

Remarks

SeValidSecurityDescriptor does not enforce policy. It simply checks that the given security descriptor data is formatted correctly. In particular, it checks the revision information, self relativity, owner, alignment, and, if available, SID, group, DACL, ACL, and/or SACL do not overflow the given *Length*. Consequently, callers of **SeValidSecurityDescriptor** cannot assume that a returned **TRUE** implies that the given security descriptor necessarily has valid contents.

If **SeValidSecurityDescriptor** returns **TRUE**, the given security descriptor can be passed on to another kernel-mode component because it is structurally valid. Otherwise, passing a structurally invalid security descriptor to be manipulated by another kernel-mode component can cause undefined results or even a system bug check.

To validate a security descriptor that was passed in from user mode, call **RtlValidSecurityDescriptor** rather than **SeValidSecurityDescriptor**.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe

SECURITY_DESCRIPTOR

TmCommitComplete function

1/25/2019 • 2 minutes to read • Edit Online

The **TmCommitComplete** routine notifies KTM that the calling resource manager has finished committing a transaction.

Syntax

```
NTSTATUS TmCommitComplete(
  PKENLISTMENT   Enlistment,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`Enlistment`

A pointer to an enlistment object. Your component can receive this pointer as input to a ResourceManagerNotification callback routine. Alternatively, your component can call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateEnlistment, TmCreateEnlistment, or ZwOpenEnlistment provided.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

TmCommitComplete returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_TRANSACTION_NOT_REQUESTED	The transaction or its enlistment is not in the correct state.

The routine might return other NTSTATUS values.

Remarks

The **TmCommitComplete** routine is a pointer-based version of the ZwCommitComplete routine.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwCommitComplete

ZwCreateEnlistment

ZwOpenEnlistment

TmCommitEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **TmCommitEnlistment** routine initiates the commit operation for a specified enlistment's transaction.

Syntax

```
NTSTATUS TmCommitEnlistment(
  PKENLISTMENT   Enlistment,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`Enlistment`

A pointer to an enlistment object. Your component can receive this pointer as input to a ResourceManagerNotification callback routine. Alternatively, your component can call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateEnlistment, TmCreateEnlistment, or ZwOpenEnlistment provided.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

TmCommitEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_ENLISTMENT_NOT_SUPERIOR	The caller is not a superior transaction manager for the enlistment.

STATUS_TRANSACTION_RESPONSE_NOT_ENLISTED	The caller did not register to receive TRANSACTION_NOTIFY_COMMIT_COMPLETE notifications.
STATUS_TRANSACTION_NOT_VALID	The enlistment's transaction is not in a state that enables it to be committed.
STATUS_NOT_ACTIVE	The commit operation for this transaction has already been started.
STATUS_TRANSACTION_ALREADY_ABORTED	The transaction cannot be committed because it has been rolled back.

The routine might return other NTSTATUS values.

Remarks

The **TmCommitEnlistment** routine is a pointer-based version of the ZwCommitEnlistment routine.

Only superior transaction managers can call **TmCommitEnlistment**.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

TmCommitTransaction function

1/25/2019 • 2 minutes to read • Edit Online

The **TmCommitTransaction** routine initiates a commit operation for a specified transaction.

Syntax

```
NTSTATUS TmCommitTransaction(
  PKTRANSACTION Transaction,
  BOOLEAN       Wait
);
```

Parameters

`Transaction`

A pointer to a transaction object. To obtain this pointer, your TPS component must call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateTransaction or ZwOpenTransaction provided.

`Wait`

A Boolean value that the caller sets to **TRUE** for synchronous operation or **FALSE** for asynchronous operation. If this parameter is **TRUE**, the call returns after the commit operation is complete.

Return Value

TmCommitTransaction returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_TRANSACTION_SUPERIOR_EXISTS	The caller cannot commit the transaction because a superior transaction manager exists.

STATUS_TRANSACTION_ABORTED	The transaction cannot be committed because it has been rolled back.
STATUS_TRANSACTION_COMMITTED	The transaction is already committed.
STATUS_TRANSACTION_NOT_VALID	The commit operation for this transaction has already been started.
STATUS_PENDING	Commit notifications have been queued to resource managers, and the caller specified **FALSE** for the *Wait* parameter.

The routine might return other NTSTATUS values.

Remarks

The **TmCommitTransaction** routine is a pointer-based version of the ZwCommitTransaction routine.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal

ZwOpenTransaction

TmCreateEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **TmCreateEnlistment** routine creates a new enlistment object for a transaction.

Syntax

```
NTSTATUS TmCreateEnlistment(
  PHANDLE            EnlistmentHandle,
  KPROCESSOR_MODE    PreviousMode,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  PRKRESOURCEMANAGER ResourceManager,
  PKTRANSACTION      Transaction,
  ULONG              CreateOptions,
  NOTIFICATION_MASK  NotificationMask,
  PVOID              EnlistmentKey
);
```

Parameters

`EnlistmentHandle`

A pointer to a caller-allocated variable that receives a handle to the new enlistment object if the call to **TmCreateEnlistment** succeeds.

`PreviousMode`

The processor mode of the process that will use the enlistment handle to access the enlistment object. This value must be either **UserMode** or **KernelMode**.

`DesiredAccess`

An ACCESS_MASK value that specifies the caller's requested access to the enlistment object. For more information about this parameter, see the description of the *DesiredAccess* parameter for ZwCreateEnlistment.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use the InitializeObjectAttributes routine to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**. This parameter is optional and can be **NULL**.

`ResourceManager`

A pointer to a resource manager object. To obtain this pointer, your component must call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateResourceManager or ZwOpenResourceManager provided.

`Transaction`

A pointer to a transaction object. To obtain this pointer, your component must call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateTransaction or ZwOpenTransaction provided. KTM adds this transaction to the list of transactions that the calling resource manager is handling.

`CreateOptions`

Enlistment option flags. The following table contains the only available flag.

CREATEOPTIONS FLAG	MEANING
ENLISTMENT_SUPERIOR	The caller is enlisting as a superior transaction manager for the specified transaction.

This parameter is optional and can be zero.

`NotificationMask`

A bitwise OR of the TRANSACTION_NOTIFY_*XXX* values that are defined in Ktmtypes.h. This mask value specifies the types of transaction notifications that KTM sends to the caller.

`EnlistmentKey`

A pointer to caller-defined information that uniquely identifies the enlistment. The resource manager receives this pointer when it calls ZwGetNotificationResourceManager or when KTM calls the ResourceManagerNotification callback routine. The resource manager can maintain a reference count for this key by calling TmReferenceEnlistmentKey and TmDereferenceEnlistmentKey. This parameter is optional and can be **NULL**.

Return Value

TmCreateEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The value of the *CreateOptions* or *NotificationMask* parameter is invalid, or KTM could not find the transaction that the *Transaction* parameter specifies.
STATUS_INSUFFICIENT_RESOURCES	A memory allocation failed.

STATUS_TRANSACTION_MANAGER_NOT_ONLINE	The enlistment failed because KTM or the resource manager is not in an operational state.
STATUS_TRANSACTION_NOT_ACTIVE	The enlistment failed because the transaction that the *Transaction* parameter specifies is not active.
STATUS_TRANSACTION_SUPERIOR_EXISTS	The caller tried to register as a superior transaction manager but a superior enlistment already exists.
STATUS_TM_VOLATILE	The caller is trying to register as a superior transaction manager, but the caller's resource manager object is volatile while the associated transaction manager object is not volatile.
STATUS_ACCESS_DENIED	The value of the *DesiredAccess* parameter is invalid.

The routine might return other NTSTATUS values.

Remarks

The **TmCreateEnlistment** routine is a pointer-based version of the ZwCreateEnlistment routine.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

TmDereferenceEnlistmentKey function

1/25/2019 • 2 minutes to read • Edit Online

The **TmDereferenceEnlistmentKey** routine decrements the reference count for the key of a specified enlistment object.

Syntax

```
NTSTATUS TmDereferenceEnlistmentKey(
  PKENLISTMENT Enlistment,
  PBOOLEAN     LastReference
);
```

Parameters

`Enlistment`

A pointer to an enlistment object. Your component can receive this pointer as input to a ResourceManagerNotification callback routine. Alternatively, your component can call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateEnlistment, TmCreateEnlistment, or ZwOpenEnlistment provided.

`LastReference`

A pointer to a BOOLEAN-typed variable. This variable receives **TRUE** if the reference count is zero after **TmDereferenceEnlistmentKey** decrements it. Otherwise, the variable receives **FALSE**.

Return Value

TmDereferenceEnlistmentKey returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_UNSUCCESSFUL	The reference count of the specified enlistment object is zero and cannot be decremented.

The routine might return other NTSTATUS values.

Remarks

The TmReferenceEnlistmentKey routine increments the reference count for an enlistment object's key, and the **TmDereferenceEnlistmentKey** routine decrements the count.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

TmEnableCallbacks function

1/25/2019 • 2 minutes to read • Edit Online

The **TmEnableCallbacks** routine enables a callback routine that receives transaction notifications.

Syntax

```
NTSTATUS TmEnableCallbacks(
  PKRESOURCEMANAGER   ResourceManager,
  PTM_RM_NOTIFICATION CallbackRoutine,
  PVOID               RMKey
);
```

Parameters

`ResourceManager`

A pointer to a resource manager object. To obtain this pointer, your component must call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateResourceManager or ZwOpenResourceManager provided.

`CallbackRoutine`

A pointer to a ResourceManagerNotification routine.

`RMKey`

A caller-defined context value that uniquely identifies the resource manager. The caller's *ResourceManagerNotification* routine receives this value as input.

Return Value

TmEnableCallbacks returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return the following value:

RETURN CODE	DESCRIPTION
STATUS_UNSUCCESSFUL	The *CallbackRoutine* pointer is **NULL**.

The routine might return other NTSTATUS values.

Remarks

Your resource manager can call **TmEnableCallbacks** to enable a ResourceManagerNotification callback routine. Use **TmEnableCallbacks** to enable asynchronous notifications. Use ZwGetNotificationResourceManager to

obtain notifications synchronously.

Resource managers can register one callback routine for each resource manager object.

For more information about the **TmEnableCallbacks** routine, see Creating a Resource Manager.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

TmGetTransactionId function

1/25/2019 • 2 minutes to read • Edit Online

The **TmGetTransactionId** routine retrieves a transaction object's unit of work (UOW) identifier.

Syntax

```
void TmGetTransactionId(
  PKTRANSACTION Transaction,
  PUOW          TransactionId
);
```

Parameters

`Transaction`

A pointer to a transaction object. To obtain this pointer, your component must call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateTransaction or ZwOpenTransaction provided.

`TransactionId`

A pointer to a location that receives the transaction object's UOW identifier.

Return Value

None

Remarks

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.

TmInitializeTransactionManager function

1/25/2019 • 2 minutes to read • Edit Online

The **TmInitializeTransactionManager** routine initializes a transaction manager object.

Syntax

```
NTSTATUS TmInitializeTransactionManager(
  PRKTM            TransactionManager,
  PCUNICODE_STRING LogFileName,
  PGUID            TmId,
  ULONG            CreateOptions
);
```

Parameters

`TransactionManager`

A pointer to the transaction manager object to initialize.

`LogFileName`

A pointer to a UNICODE_STRING structure that contains the path and file name of a CLFS log file stream associated with the transaction manager object.

`TmId`

Specifies a pointer to a GUID that identifies the name of the transaction manager object to initialize.

`CreateOptions`

Optional object creation flags. The following table contains the available flags.

OPTION FLAG	MEANING
TRANSACTION_MANAGER_VOLATILE	The transaction manager object will be volatile. Therefore, it will not use a log file.
TRANSACTION_MANAGER_COMMIT_DEFAULT	For internal use only.
TRANSACTION_MANAGER_COMMIT_SYSTEM_VOLUME	For internal use only.
TRANSACTION_MANAGER_COMMIT_SYSTEM_HIVES	For internal use only.
TRANSACTION_MANAGER_COMMIT_LOWEST	For internal use only.
TRANSACTION_MANAGER_CORRUPT_FOR_RECOVERY	For internal use only.
TRANSACTION_MANAGER_CORRUPT_FOR_PROGRESS	For internal use only.

Return Value

The **TmInitializeTransactionManager** routine returns STATUS_SUCCESS if the operation succeeds.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h

TmIsTransactionActive function

1/25/2019 • 2 minutes to read • Edit Online

The **TmIsTransactionActive** routine indicates whether a specified transaction is in its active state.

Syntax

```
BOOLEAN TmIsTransactionActive(
  PKTRANSACTION Transaction
);
```

Parameters

`Transaction`

A pointer to a transaction object. To obtain this pointer, your component must call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateTransaction or ZwOpenTransaction provided.

Return Value

TmIsTransactionActive returns **TRUE** if the specified transaction is in its active state. Otherwise, the routine returns **FALSE**.

Remarks

When a transaction is created, it enters its active state and remains in that state until the pre-prepare/prepare/commit sequence begins.

For more information about **TmIsTransactionActive**, and for information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

TmPrepareComplete function

1/25/2019 • 2 minutes to read • Edit Online

The **TmPrepareComplete** routine notifies KTM that the calling resource manager has finished preparing a transaction's data.

Syntax

```
NTSTATUS TmPrepareComplete(
  PKENLISTMENT   Enlistment,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`Enlistment`

A pointer to an enlistment object. Your component can receive this pointer as input to a ResourceManagerNotification callback routine. Alternatively, your component can call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateEnlistment, TmCreateEnlistment, or ZwOpenEnlistment provided.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

TmPrepareComplete returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_TRANSACTION_NOTIFY_REQUESTED	The transaction or its enlistment is not in the correct state. For example, KTM did not send a TRANSACTION_NOTIFY_PREPREPARE notification.

The routine might return other NTSTATUS values.

Remarks

The **TmPrepareComplete** routine is a pointer-based version of the ZwPrepareComplete routine.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwOpenEnlistment

ZwPrepareComplete

TmPrepareEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **TmPrepareEnlistment** routine initiates the prepare operation for a specified enlistment's transaction.

Syntax

```
NTSTATUS TmPrepareEnlistment(
  PKENLISTMENT   Enlistment,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`Enlistment`

A pointer to an enlistment object. Your component can receive this pointer as input to a ResourceManagerNotification callback routine. Alternatively, your component can call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateEnlistment, TmCreateEnlistment, or ZwOpenEnlistment provided.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

TmPrepareEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_ENLISTMENT_NOT_SUPERIOR	The caller is not a superior transaction manager for the enlistment.

STA TUS _TR AN SAC TIO N_R ESP ON SE_ NO T_E NLI STE D	The caller did not register to receive TRANSACTION_NOTIFY_PREPARE_COMPLETE notifications.
STA TUS _TR AN SAC TIO N_R EQU EST _NO T_V ALI D	The enlistment's transaction is not in a state that allows it to enter the prepare phase.
STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

The **TmPrepareEnlistment** routine is a pointer-based version of the ZwPrepareEnlistment routine.

Only superior transaction managers can call **TmPrepareEnlistment**.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

TmPrePrepareComplete function

1/25/2019 • 2 minutes to read • Edit Online

The **TmPrePrepareComplete** routine notifies KTM that the calling resource manager has finished preliminary preparation of a transaction's data.

Syntax

```
NTSTATUS TmPrePrepareComplete(
  PKENLISTMENT   Enlistment,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`Enlistment`

A pointer to an enlistment object. Your component can receive this pointer as input to a ResourceManagerNotification callback routine. Alternatively, your component can call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateEnlistment, TmCreateEnlistment, or ZwOpenEnlistment provided.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

TmPrePrepareComplete returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_TRANSACTION_NOTIFY_REQUESTED	The transaction or its enlistment is not in the correct state. For example, KTM did not send a TRANSACTION_NOTIFY_PREPARE notification.

The routine might return other NTSTATUS values.

Remarks

The **TmPrePrepareComplete** routine is a pointer-based version of the ZwPrePrepareComplete routine.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

ZwPrePrepareComplete

TmPrePrepareEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **TmPrePrepareEnlistment** routine initiates the pre-prepare operation for a specified enlistment's transaction.

Syntax

```
NTSTATUS TmPrePrepareEnlistment(
  PKENLISTMENT   Enlistment,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`Enlistment`

A pointer to an enlistment object. Your component can receive this pointer as input to a ResourceManagerNotification callback routine. Alternatively, your component can call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateEnlistment, TmCreateEnlistment, or ZwOpenEnlistment provided.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

TmPrePrepareEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_ENLISTMENT_NOT_SUPERIOR	The caller is not a superior transaction manager for the enlistment.

STA TUS _TR AN SAC TIO N_R ESP ON SE_ NO T_E NLI STE D	The caller did not register to receive TRANSACTION_NOTIFY_PREPREPARE_COMPLETE notifications.
STA TUS _TR AN SAC TIO N_R EQU EST _NO T_V ALI D	The transaction's state does not allow it to enter the pre-prepare phase.
STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

The **TmPrePrepareEnlistment** routine is a pointer-based version of the ZwPrePrepareEnlistment routine.

Only superior transaction managers can call **TmPrePrepareEnlistment**.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

TmReadOnlyEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **TmReadOnlyEnlistment** routine sets a specified enlistment to be read-only.

Syntax

```
NTSTATUS TmReadOnlyEnlistment(
  PKENLISTMENT   Enlistment,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`Enlistment`

A pointer to an enlistment object. Your component can receive this pointer as input to a ResourceManagerNotification callback routine. Alternatively, your component can call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateEnlistment, TmCreateEnlistment, or ZwOpenEnlistment provided.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

TmReadOnlyEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_TRANSACTION_NOT_REQUESTED	The transaction or its enlistment is not in the correct state. For example, an enlistment cannot be read-only if the ENLISTMENT_SUPERIOR flag was specified to ZwCreateEnlistment.

The routine might return other NTSTATUS values.

Remarks

The **TmReadOnlyEnlistment** routine is a pointer-based version of the ZwReadOnlyEnlistment routine.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.

TmRecoverEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **TmRecoverEnlistment** routine initiates a recovery operation for the transaction that is associated with a specified enlistment.

Syntax

```
NTSTATUS TmRecoverEnlistment(
  PKENLISTMENT Enlistment,
  PVOID        EnlistmentKey
);
```

Parameters

`Enlistment`

A pointer to an enlistment object. Your component can receive this pointer as input to a ResourceManagerNotification callback routine. Alternatively, your component can call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateEnlistment, TmCreateEnlistment, or ZwOpenEnlistment provided.

`EnlistmentKey`

A pointer to the enlistment key value that the resource manager previously specified as the *EnlistmentKey* parameter to ZwCreateEnlistment or TmCreateEnlistment. This parameter is optional and can be **NULL** if the resource manager did not provide an enlistment key when it called **ZwCreateEnlistment** or **TmCreateEnlistment**.

Return Value

TmRecoverEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STA TUS _OB JEC T_T YPE _MI SM ATC H	The specified handle is not a handle to an enlistment object.

STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_TRANSACTION_NOT_ACTIVE	The transaction or its enlistment is not in the correct state.
STATUS_NOTIFICATION_QUEUE_FULL	KTM has added a commit, rollback, or in-doubt notification to the resource manager's notification queue, and the resource manager is not using a ResourceManagerNotification callback routine.

The routine might return other NTSTATUS values.

Remarks

The **TmRecoverEnlistment** routine is a pointer-based version of the ZwRecoverEnlistment routine.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

For more information about recovery operations, see Handling Recovery Operations.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.

TmRecoverResourceManager function

1/25/2019 • 2 minutes to read • Edit Online

The **TmRecoverResourceManager** routine tries to recover the transaction that is associated with each enlistment of a specified resource manager object.

Syntax

```
NTSTATUS TmRecoverResourceManager(
  PKRESOURCEMANAGER ResourceManager
);
```

Parameters

`ResourceManager`

A pointer to a resource manager object. To obtain this pointer, your component must call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateResourceManager or ZwOpenResourceManager provided.

Return Value

TmRecoverResourceManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return the following value:

RETURN CODE	DESCRIPTION
STATUS_TRANSACTION_NOT_ROOT	The transaction manager that is associated with the specified resource manager is not online.

The routine might return other NTSTATUS values.

Remarks

The **TmRecoverResourceManager** routine is a pointer-based version of the ZwRecoverResourceManager routine.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwRecoverResourceManager

TmRecoverTransactionManager function

1/25/2019 • 2 minutes to read • Edit Online

The **TmRecoverTransactionManager** routine reconstructs the state of the transaction manager object (including all transactions, enlistments, and resource managers) from the recovery information that is in the log stream.

Syntax

```
NTSTATUS TmRecoverTransactionManager(
  PKTM           Tm,
  PLARGE_INTEGER TargetVirtualClock
);
```

Parameters

`Tm`

A pointer to a transaction manager object. To obtain this pointer, your TPS component must call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateTransactionManager or ZwOpenTransactionManager provided.

`TargetVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**. For more information about this parameter, see the following Remarks section. For Windows Vista, this parameter must be **NULL**.

Return Value

TmRecoverTransactionManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_NOT_IMPLEMENTED	For Windows Vista, the caller specified a non-**NULL** value for the *TargetVirtualClock* parameter.
STATUS_TM_VOLATILE	The specified transaction manager object does not have a log file, so recovery is not available.

STA TUS _UN SUC CES SFU L	The specified transaction manager object is in an unexpected state.

The routine might return other NTSTATUS values.

Remarks

The **TmRecoverTransactionManager** routine is a pointer-based version of the ZwRecoverTransactionManager routine.

Calling **TmRecoverTransactionManager** with a *TargetVirtualClock* parameter value of **NULL** is functionally equivalent to calling **ZwRecoverTransactionManager**. Calling **TmRecoverTransactionManager** with a non-**NULL** *TargetVirtualClock* parameter value is functionally equivalent to calling ZwRollforwardTransactionManager.

For more information about recovery operations, see Handling Recovery Operations.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

ZwRecoverTransactionManager

ZwRollforwardTransactionManager

TmReferenceEnlistmentKey function

1/25/2019 • 2 minutes to read • Edit Online

The **TmReferenceEnlistmentKey** routine increments the reference count for the key of a specified enlistment object and retrieves the key.

Syntax

```
NTSTATUS TmReferenceEnlistmentKey(
  PKENLISTMENT Enlistment,
  PVOID        *Key
);
```

Parameters

`Enlistment`

A pointer to an enlistment object. Your component can receive this pointer as input to a ResourceManagerNotification callback routine. Alternatively, your component can call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateEnlistment, TmCreateEnlistment, or ZwOpenEnlistment provided.

`Key`

A pointer to a variable that receives the enlistment object's enlistment key. The caller assigns an enlistment key when it calls ZwCreateEnlistment or TmCreateEnlistment.

Return Value

TmReferenceEnlistmentKey returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The *Key* parameter's value is **NULL**.

STATUS_UNSUCCESSFUL	The reference count of the specified enlistment object has been decremented to zero, so the reference count cannot be incremented.
STATUS_INSUFFICIENT_RESOURCES	The reference count is at its maximum value (0xFFFFFFFF) and cannot be incremented.

The routine might return other NTSTATUS values.

Remarks

The **TmReferenceEnlistmentKey** routine increments the reference count for an enlistment object's key value, and the TmDereferenceEnlistmentKey routine decrements the count.

If a resource manager has defined a key value for an enlistment, the resource manager receives the key value when it calls ZwGetNotificationResourceManager or when KTM calls the ResourceManagerNotification callback routine.

While a resource manager is processing a notification, it might use the key as a pointer to a temporary memory allocation, and it might use the reference count to determine when it should deallocate the memory.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

TmRenameTransactionManager function

1/25/2019 • 2 minutes to read • Edit Online

The **TmRenameTransactionManager** routine changes the identity of the transaction manager object that is stored in the CLFS log file stream contained in the log file name.

> **Warning** Changing the identity of the transaction manger object might break any cross-log transactional links that may exist.

Syntax

```
NTSTATUS TmRenameTransactionManager(
  PUNICODE_STRING LogFileName,
  LPGUID          ExistingTransactionManagerGuid
);
```

Parameters

`LogFileName`

A pointer to a UNICODE_STRING structure that contains the path and file name of a CLFS log file stream to be associated with the transaction manager object.

`ExistingTransactionManagerGuid`

A pointer to a GUID structure that represents the current name of the transaction manager object.

Return Value

The **TmRenameTransactionManager** routine returns an NTSTATUS value. If the routine fails, it returns one of the following error codes:

Requirements

Minimum supported client	Available starting with Windows Vista.
Target Platform	Universal
Header	wdm.h
IRQL	"<= APC_LEVEL"

TmRequestOutcomeEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **TmRequestOutcomeEnlistment** routine asks KTM to try to provide an immediate outcome (commit or rollback) for the transaction that is associated with a specified enlistment.

Syntax

```
NTSTATUS TmRequestOutcomeEnlistment(
  PKENLISTMENT   Enlistment,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`Enlistment`

A pointer to an enlistment object. Your component can receive this pointer as input to a ResourceManagerNotification callback routine. Alternatively, your component can call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateEnlistment, TmCreateEnlistment, or ZwOpenEnlistment provided.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

TmRequestOutcomeEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return the following value:

RETURN CODE	DESCRIPTION
STATUS_TRANSACTION_NOT_ENLISTED	The specified enlistment is a superior enlistment.

The routine might return other NTSTATUS values.

Remarks

The **TmRequestOutcomeEnlistment** routine asks KTM to try to provide an immediate outcome (result) for the

transaction. A resource manager can call **TmRequestOutcomeEnlistment** after it has called TmPrepareComplete or ZwPrepareComplete, if it later discovers that it cannot wait for an outcome because, for example, a surprise-removal of the disk has occurred. KTM might be able to force a rollback if all resource managers have not finished their prepare operations.

For information about when to use KTM's **Tm*Xxx*** routines instead of Zw*Xxx* routines, see Using TmXxx Routines.

For more information about **TmCreateEnlistment**, see Creating a Resource Manager.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.

TmRollbackComplete function

1/25/2019 • 2 minutes to read • Edit Online

The **TmRollbackComplete** routine notifies KTM that the calling resource manager has finished rolling back a transaction's data.

Syntax

```
NTSTATUS TmRollbackComplete(
  PKENLISTMENT   Enlistment,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`Enlistment`

A pointer to an enlistment object. Your component can receive this pointer as input to a ResourceManagerNotification callback routine. Alternatively, your component can call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateEnlistment, TmCreateEnlistment, or ZwOpenEnlistment provided.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

TmRollbackComplete returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return the following value:

RETURN CODE	DESCRIPTION
STATUS_TRANSACTION_NOT_REQUESTED	The transaction or its enlistment is not in the correct state.

The routine might return other NTSTATUS values.

Remarks

The **TmRollbackComplete** routine is a pointer-based version of the ZwRollbackComplete routine.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.

  PKENLISTMENT   Enlistment,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`Enlistment`

A pointer to an enlistment object. Your component can receive this pointer as input to a ResourceManagerNotification callback routine. Alternatively, your component can call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateEnlistment, TmCreateEnlistment, or ZwOpenEnlistment provided.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

TmRollbackEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return the following value:

RETURN CODE	DESCRIPTION
STA TUS _TR AN SAC TIO N_R EQU EST _NO T_V ALI D	The enlistment cannot be rolled back.

The routine might return other NTSTATUS values.

Remarks

The **TmRollbackEnlistment** routine is a pointer-based version of the ZwRollbackEnlistment routine.

TmRollbackTransaction function

1/25/2019 • 2 minutes to read • Edit Online

The **TmRollbackTransaction** routine initiates a rollback operation for a specified transaction.

Syntax

```
NTSTATUS TmRollbackTransaction(
  PKTRANSACTION Transaction,
  BOOLEAN       Wait
);
```

Parameters

`Transaction`

A pointer to a transaction object. To obtain this pointer, your component must call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateTransaction or ZwOpenTransaction provided.

`Wait`

A Boolean value that the caller sets to **TRUE** for synchronous operation or **FALSE** for asynchronous operation. If this parameter is set to **TRUE**, the call does not return until the rollback operation is complete.

Return Value

TmRollbackTransaction returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_TRANSACTION_ALREADY_COMMITTED	The transaction cannot be rolled back because it has already been committed.

STA TUS _TR AN SAC TIO N_R EQU EST _NO T_V ALI D	The transaction has not been committed but its current state does not permit rollback.
STA TUS _PE NDI NG	Rollback notifications have been queued to resource managers, and the caller specified **FALSE** for the *Wait* parameter.

The routine might return other NTSTATUS values.

Remarks

The **TmRollbackTransaction** routine is a pointer-based version of the ZwRollbackTransaction routine.

For information about when to use KTM's **Tm*Xxx*** routines instead of **Zw*Xxx*** routines, see Using TmXxx Routines.

TmSinglePhaseReject function

1/25/2019 • 2 minutes to read • Edit Online

The **TmSinglePhaseReject** routine informs KTM that the calling resource manager will not support a single-phase commit operation for a specified enlistment.

Syntax

```
NTSTATUS TmSinglePhaseReject(
  PKENLISTMENT   Enlistment,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`Enlistment`

A pointer to an enlistment object. Your component can receive this pointer as input to a ResourceManagerNotification callback routine. Alternatively, your component can call ObReferenceObjectByHandle and supply the object handle that a previous call to ZwCreateEnlistment, TmCreateEnlistment, or ZwOpenEnlistment provided.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

TmSinglePhaseReject returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return the following value:

RETURN CODE	DESCRIPTION
STATUS_TRANSACTION_NOT_REQUESTED	The transaction or its enlistment is not in the correct state.

The routine might return other NTSTATUS values.

Remarks

The **TmSinglePhaseReject** routine is a pointer-based version of the ZwSinglePhaseReject routine.

TRANSLATE_BUS_ADDRESS callback function

1/25/2019 • 2 minutes to read • Edit Online

The *TranslateBusAddress* routine translates addresses on the parent bus to logical addresses.

Syntax

```
TRANSLATE_BUS_ADDRESS TranslateBusAddress;

BOOLEAN TranslateBusAddress(
  PVOID Context,
  PHYSICAL_ADDRESS BusAddress,
  ULONG Length,
  PULONG AddressSpace,
  PPHYSICAL_ADDRESS TranslatedAddress
)
{...}
```

Parameters

`Context`

A pointer to interface-specific context information. The caller passes the value that is passed as the **Context** member of the BUS_INTERFACE_STANDARD structure for the interface.

`BusAddress`

The bus-relative address to be translated.

`Length`

The length, in bytes, of the input memory that *BusAddress* points to.

`AddressSpace`

On input, the address space in which the device's hardware address resides. A value of 0x0 signifies memory space, and a value of 0x1 signifies port I/O space. On output, *AddressSpace* indicates the address space in which the *TranslatedAddress* resides.

`TranslatedAddress`

The translated (logical) address that corresponds to the bus-relative address that the caller provides in *BusAddress*.

Return Value

The *TranslateBusAddress* routine returns **TRUE** if the translation operation succeeded and **FALSE** otherwise.

Requirements

Target Platform	Desktop

Header	wdm.h (include Ntddk.h)

WmiQueryTraceInformation function

1/25/2019 • 3 minutes to read • Edit Online

The **WmiQueryTraceInformation** routine returns information about a WMI event trace.

Syntax

```
NTSTATUS WmiQueryTraceInformation(
  TRACE_INFORMATION_CLASS TraceInformationClass,
  PVOID                   TraceInformation,
  ULONG                   TraceInformationLength,
  PULONG                  RequiredLength,
  PVOID                   Buffer
);
```

Parameters

`TraceInformationClass`

Specifies a TRACE_INFORMATION_CLASS enumerator that indicates the type of information to return about an event trace.

`TraceInformation`

A pointer to a caller-allocated output buffer where the routine returns the event trace information specified by *TraceInformationClass*.

`TraceInformationLength`

Specifies the size, in bytes, of the *TraceInformation* buffer.

`RequiredLength`

A pointer to the value returned by the routine that specifies the required size, in bytes, of the *TraceInformation* buffer. The caller should set *RequiredLength* to **NULL** if it does not use the required length information.

`Buffer`

A pointer to the query-specific input information that a caller supplies. If caller-supplied information is not required, the caller should set *Buffer* to **NULL**.

Return Value

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	Success

STATUS_INFO_LENGTH_MISMATCH	The size of the *TraceInformation* buffer is not equal to the required size for the specified event trace information.
STATUS_INVALID_HANDLE	The trace handle specified by the **HistoricalContext** member of the (PWNODE_HEADER)*Buffer* is not valid.
STATUS_INVALID_INFO_CLASS	The specified type of event trace information is not valid.
STATUS_INVALID_PARAMETER	The name of the event trace, supplied with a query to return a trace handle given its name, is not valid.
STATUS_INVALID_PARAMETER_MIX	The caller did not supply the information required for the specified event trace information.

STATUS_MORE_ENTRIES	The *TraceInformation* buffer is not large enough to hold an array of all the valid event trace handles.
STATUS_NOT_FOUND	A global logger was not found.

Remarks

For each type of event trace information specified by *TraceInformationClass*, the following table provides:

- Input requirements
- Information that **WmiQueryTraceInformation** returns in the *TraceInformation* buffer

VALUE OF*TRACECLASSINFORMATION*	INPUT REQUIREMENTS	INFORMATION RETURNED
TraceIdClass	*TraceInformationLength* is equal to the value of **sizeof**(ULONG). The size, in bytes of the *TraceInformation* buffer is greater than or equal to the value of **sizeof**(ULONG). The **HistoricalContext** member of (PWNODE_HEADER)*Buffer*specifies an event trace handle.	*(PULONG)*TraceInformation* is set to the logger ID of the event trace handle.
TraceHandleClass	*TraceInformationLength* is equal to the value of **sizeof**(TRACEHANDLE). The size, in bytes of the *TraceInformation* buffer must be greater than or equal to the value of **sizeof**(TRACEHANDLE). *(PULONG)*Buffer* is set to a logger ID.	*(PTRACEHANDLE)*TraceInformation* is set to an event trace handle for the specified logger. If the specified logger ID is zero, an event trace handle for the kernel logger is returned.

TraceEnableFlagsClass	*TraceInformationLength* is greater than or equal to the value of **sizeof**(ULONG). The size, in bytes of the *TraceInformation* buffer must be greater than or equal to the value of **sizeof**(ULONG). The **HistoricalContext** member of (PWNODE_HEADER)*Buffer*specifies an event trace handle.	*(PULONG)*TraceInformation* is set to the enable flags that are set for the specified event trace handle.
TraceEnableLevelClass	*TraceInformationLength* is set greater than or equal to the value of **sizeof**(ULONG). The size, in bytes of the *TraceInformation* buffer must be greater than or equal to the value of **sizeof**(ULONG). The **HistoricalContext** member of (PWNODE_HEADER)*Buffer*specifies an event trace handle.	*(PULONG)*TraceInformation* is set to the level for the specified event trace handle.
GlobalLoggerHandleClass	*TraceInformationLength* is equal to the value of **sizeof**(TRACEHANDLE). The size, in bytes of the *TraceInformation* buffer must be greater than or equal to the value of **sizeof**(TRACEHANDLE).	*(PTRACEHANDLE)*TraceInformation* is set to an event trace handle for the global logger.
EventLoggerHandleClass	For internal use only.	For internal use only.
AllLoggerHandlesClass	*TraceInformationLength* is set to the size, bytes, of an array of *m* TRACEHANDLE values. The size, in bytes of the *TraceInformation* buffer must be greater than or equal to the value of (*m****sizeof**(TRACEHANDLE)).	The *TraceInformation* buffer contains an array of *n* trace handles, where *n* is the minimum of *m*, the number of caller-supplied event trace handles, and the number of valid event trace handles. The routine returns a status of STATUS_MORE_ENTRIES if the *TraceInformation* buffer is too small to hold all trace handles.
TraceHandleByNameClass	*TraceInformationLength* is set to the value of **sizeof**(TRACEHANDLE). The size, in bytes, of the *TraceInformation* buffer must be greater than or equal to the value of **sizeof**(TRACEHANDLE). (PUNICODE_STRING)*Buffer* specifies a friendly trace name in Unicode format.	*(PTRACEHANDLE)*TraceInformation* is set to the event trace handle associated with the specified friendly name.

If the caller supplies a non-**NULL** *RequiredLength* pointer, **WmiQueryTraceInformation** also returns the required length for the specified event trace information.

WmiQueryTraceInformation runs at the IRQL of the caller.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	See Remarks section.

WmiTraceMessage

WmiTraceMessageVa

WmiTraceMessage function

1/25/2019 • 2 minutes to read • Edit Online

The **WmiTraceMessage** routine adds a message to the output log of a WPP software tracing session.

Syntax

```
NTSTATUS WmiTraceMessage(
  TRACEHANDLE LoggerHandle,
  ULONG       MessageFlags,
  LPCGUID     MessageGuid,
  USHORT      MessageNumber,
  ...
);
```

Parameters

`LoggerHandle`

Specifies a trace handle for a software tracing session.

`MessageFlags`

Specifies a bitwise OR of one or more message flags. See the Remarks section for details.

`MessageGuid`

Specifies a GUID that identifies the class of software trace messages.

`MessageNumber`

Identifies the message subtype. The meaning of subtypes is specific to the software trace class and the provider.

`arg5`

Return Value

WmiTraceMessage returns one of the following values:

RETURN CODE	DESCRIPTION
STA **TUS** **_SU** **CCE** **SS**	The operation completed successfully.

STATUS_INVALID_HANDLE	*LoggerHandle* is not a valid software trace handle.
STATUS_NO_MEMORY	There is insufficient buffer memory to log the message. See the Remarks section.
Other NTSTATUS value	An internal error occurred.

Remarks

A caller can use **WmiTraceMessage** or WmiTraceMessageVa to add a message to the output log of a WPP software tracing session. **WmiTraceMessage** simplifies a caller's code by handling the variable list mechanism before calling **WmiTraceMessageVa**.

A caller can set the following message flags:

FLAG	DESCRIPTION
TRACE_MESSAGE_SEQUENCE	Include a sequence number in the message. Message sequencing can only be used if it is set for the software tracing session specified by *LoggerHandle*.
TRACE_MESSAGE_GUID	*MessageGuid* specifies a GUID that identifies a software trace class. This flag must be set.
TRACE_MESSAGE_TIMESTAMP	Include a time stamp in the message.
TRACE_MESSAGE_PERFORMANCE_TIMESTAMP	This flag is not implemented and is obsolete. It must not be used.
TRACE_MESSAGE_SYSTEMINFO	Include the thread identifier (TID) and process identifier (PID) in the message.

A message will not be logged if one of the following is true:

- The total size, in bytes, of the message data and the message header is greater than the size of individual message buffers allocated for a software tracing session. (The maximum message header size is 48 bytes.)

- All message buffers allocated to software tracing session are full.

WmiTraceMessage runs at the IRQL of the caller.

Requirements

Minimum supported client	Available in Windows XP and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	See Remarks section.

WmiQueryTraceInformation

WmiTraceMessageVa

WmiTraceMessageVa function

1/25/2019 • 2 minutes to read • Edit Online

The **WmiTraceMessageVa** routine adds a message to the output log of a WPP software tracing session.

Syntax

```
NTSTATUS WmiTraceMessageVa(
  TRACEHANDLE LoggerHandle,
  ULONG       MessageFlags,
  LPCGUID     MessageGuid,
  USHORT      MessageNumber,
  va_list     MessageArgList
);
```

Parameters

`LoggerHandle`

Specifies a trace handle for a software tracing session.

`MessageFlags`

Specifies a bitwise OR of one or more message flags. See the Remarks section for details.

`MessageGuid`

Specifies a GUID that identifies a software trace class.

`MessageNumber`

Identifies the message subtype. The meaning of subtypes is specific to the software trace class and the provider.

`MessageArgList`

Provides a required list of message parameters that specify a set of message parts. The parameters are organized as a sequence of parameter pairs, where each pair specifies one part of the complete message. Each parameter pair consists of a PVOID pointer to data, followed immediately by a ULONG value that specifies the length of the data. The parameter list must be terminated by a **NULL** PVOID pointer followed by a ULONG(0).

Return Value

WmiTraceMessageVa returns one of the following values:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The operation completed successfully.

STATUS_INVALID_HANDLE	*LoggerHandle* is not a valid software trace handle.
STATUS_NO_MEMORY	There is insufficient buffer memory to log the message. See the Remarks section for more information.
OtherNTSTATUSvalue	An internal error occurred.

Remarks

A caller can use WmiTraceMessage or **WmiTraceMessageVa** to add a message to the output log of a WPP software tracing session. **WmiTraceMessage** simplifies a caller's code by handling the variable list mechanism before calling **WmiTraceMessageVa**.

A caller can set the following message flags:

FLAG	DESCRIPTION
TRACE_MESSAGE_SEQUENCE	Include a sequence number in the message. Message sequencing can only be used if it is enabled for the software tracing session specified by *LoggerHandle*.
TRACE_MESSAGE_GUID	*MessageGuid* specifies a GUID that identifies a software trace class. This flag must be set.
TRACE_MESSAGE_TIMESTAMP	Include a time stamp in the message.
TRACE_MESSAGE_PERFORMANCE_TIMESTAMP	This flag is not implemented and is obsolete. It must not be used.
TRACE_MESSAGE_SYSTEMINFO	Include the thread identifier (TID) and process identifier (PID) in the message.

WmiTraceMessageVa does not log the message if one of the following is true:

- The total size, in bytes, of the message data and the message header is greater than the size of individual message buffers allocated for a software tracing session. (The maximum message header size is 48 bytes.)

- All message buffers allocated to software tracing session are full.

WmiTraceMessageVa runs at the IRQL of the caller.

Requirements

WRITE_PORT_BUFFER_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_PORT_BUFFER_UCHAR** routine writes a number of bytes from a buffer to the specified port.

Syntax

```
NTHALAPI VOID WRITE_PORT_BUFFER_UCHAR(
  PUCHAR Port,
  PUCHAR Buffer,
  ULONG  Count
);
```

Parameters

`Port`

Pointer to the port, which must be a mapped memory range in I/O space.

`Buffer`

Pointer to a buffer from which an array of UCHAR values is to be written.

`Count`

Specifies the number of bytes to be written to the port.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of bytes.

Callers of **WRITE_PORT_BUFFER_UCHAR** can be running at any IRQL, assuming the *Buffer* is resident and the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
Library	Hal.lib
IRQL	Any level (see Remarks section)

WRITE_PORT_BUFFER_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_PORT_BUFFER_ULONG** routine writes a number of ULONG values from a buffer to the specified port address.

Syntax

```
NTHALAPI VOID WRITE_PORT_BUFFER_ULONG(
  PULONG Port,
  PULONG Buffer,
  ULONG  Count
);
```

Parameters

`Port`

Pointer to the port, which must be a mapped memory range in I/O space.

`Buffer`

Pointer to a buffer from which an array of ULONG values is to be written.

`Count`

Specifies the number of ULONG values to be written to the port.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of ULONG values.

Callers of **WRITE_PORT_BUFFER_ULONG** can be running at any IRQL, assuming the *Buffer* is resident and the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
Library	Hal.lib

IRQL	Any level (see Remarks section)

WRITE_PORT_BUFFER_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_PORT_BUFFER_USHORT** routine writes a number of USHORT values from a buffer to the specified port address.

Syntax

```
NTHALAPI VOID WRITE_PORT_BUFFER_USHORT(
  PUSHORT Port,
  PUSHORT Buffer,
  ULONG   Count
);
```

Parameters

`Port`

Pointer to the port, which must be a mapped memory range in I/O space.

`Buffer`

Pointer to a buffer from which an array of USHORT values is to be written.

`Count`

Specifies the number of USHORT values to be written to the port.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of USHORT values.

Callers of **WRITE_PORT_BUFFER_USHORT** can be running at any IRQL, assuming the *Buffer* is resident and the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h)
Library	Hal.lib

IRQL	Any level (see Remarks section)

WRITE_PORT_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_PORT_UCHAR** routine writes a byte to the specified port address.

Syntax

```
NTHALAPI VOID WRITE_PORT_UCHAR(
  PUCHAR Port,
  UCHAR  Value
);
```

Parameters

`Port`

`Value`

Return Value

None

Remarks

Callers of **WRITE_PORT_UCHAR** can be running at any IRQL, assuming the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h)
Library	Hal.lib
IRQL	Any level (see Remarks section)

WRITE_PORT_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_PORT_ULONG** routine writes a ULONG value to the specified port address.

Syntax

```
NTHALAPI VOID WRITE_PORT_ULONG(
  PULONG Port,
  ULONG  Value
);
```

Parameters

`Port`

`Value`

Return Value

None

Remarks

Callers of **WRITE_PORT_ULONG** can be running at any IRQL, assuming the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h)
Library	Hal.lib
IRQL	Any level (see Remarks section)

WRITE_PORT_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_PORT_USHORT** routine writes a USHORT value to the specified port address.

Syntax

```
NTHALAPI VOID WRITE_PORT_USHORT(
  PUSHORT Port,
  USHORT  Value
);
```

Parameters

`Port`

`Value`

Return Value

None

Remarks

Callers of **WRITE_PORT_USHORT** can be running at any IRQL, assuming the *Port* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h)
Library	Hal.lib
IRQL	Any level (see Remarks section)

WRITE_REGISTER_BUFFER_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_REGISTER_BUFFER_UCHAR** routine writes a number of bytes from a buffer to the specified register.

Syntax

```
void WRITE_REGISTER_BUFFER_UCHAR(
  volatile UCHAR *Register,
  PUCHAR         Buffer,
  ULONG          Count
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Buffer`

Pointer to a buffer from which an array of UCHAR values is to be written.

`Count`

Specifies the number of bytes to be written to the register.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of bytes.

Callers of **WRITE_REGISTER_BUFFER_UCHAR** can be running at any IRQL, assuming the *Buffer* is resident and the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

WRITE_REGISTER_BUFFER_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_REGISTER_BUFFER_ULONG** routine writes a number of ULONG values from a buffer to the specified register.

Syntax

```
void WRITE_REGISTER_BUFFER_ULONG(
  volatile ULONG *Register,
  PULONG         Buffer,
  ULONG          Count
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Buffer`

Pointer to a buffer from which an array of ULONG values is to be written.

`Count`

Specifies the number of ULONG values to be written to the register.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of ULONG values.

Callers of **WRITE_REGISTER_BUFFER_ULONG** can be running at any IRQL, assuming the *Buffer* is resident and the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

WRITE_REGISTER_BUFFER_ULONG64 function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_REGISTER_BUFFER_ULONG64** function writes a number of ULONG64 values from a buffer to the specified register.

Syntax

```
void WRITE_REGISTER_BUFFER_ULONG64(
  volatile ULONG64 *Register,
  PULONG64         Buffer,
  ULONG            Count
);
```

Parameters

`Register`

A pointer to the register, which must be a mapped range in memory space.

`Buffer`

A pointer to a buffer into which an array of ULONG64 values is to be written.

`Count`

Specifies the number of ULONG64 values to write to the register.

Return Value

This function does not return a value.

Remarks

The size of the buffer must be large enough to contain at least the specified number of bytes.

For more information, see Reading and Writing to Device Registers in UMDF 1.x Drivers.

Requirements

Minimum supported client	64-bit Windows
Target Platform	Desktop
Header	wdm.h (include Wdm.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.exe

WRITE_REGISTER_BUFFER_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_REGISTER_BUFFER_USHORT** routine writes a number of USHORT values from a buffer to the specified register.

Syntax

```
void WRITE_REGISTER_BUFFER_USHORT(
  volatile USHORT *Register,
  PUSHORT         Buffer,
  ULONG           Count
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Buffer`

Pointer to a buffer from which an array of USHORT values is to be written.

`Count`

Specifies the number of USHORT values to be written to the register.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of USHORT values.

Callers of **WRITE_REGISTER_BUFFER_USHORT** can be running at any IRQL, assuming the *Buffer* is resident and the *Register* is resident, mapped device memory.

Requirements

DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

ZwClose function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwClose** routine closes an object handle.

Syntax

```
NTSYSAPI NTSTATUS ZwClose(
  HANDLE Handle
);
```

Parameters

`Handle`

Handle to an object of any type.

Return Value

ZwClose returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure. In particular, it returns STATUS_INVALID_HANDLE if *Handle* is not a valid handle, or STATUS_HANDLE_NOT_CLOSABLE if the calling thread does not have permission to close the handle.

Remarks

ZwClose is a generic routine that operates on any type of object.

Closing an open object handle causes that handle to become invalid. The system also decrements the handle count for the object and checks whether the object can be deleted. The system does not actually delete the object until all of the object's handles are closed and no referenced pointers remain.

A driver must close every handle that it opens as soon as the handle is no longer required. Kernel handles, which are those that are opened by a system thread or by specifying the OBJ_KERNEL_HANDLE flag, can be closed only when the previous processor mode is **KernelMode**. This requirement applies both to system threads and to dispatch routines for IRPs that were issued from kernel mode. (For more information about the previous processor mode, see ExGetPreviousMode.) For example, a handle that ZwCreateKey returns to a DriverEntry routine cannot subsequently be closed by the same driver's dispatch routines. A **DriverEntry** routine runs in a system process, whereas dispatch routines usually run either in the context of the thread issuing the current I/O request, or, for lower-level drivers, in an arbitrary thread context.

A nonkernel handle can be closed only if one of two conditions is met: The previous processor mode is **KernelMode**, or the calling thread has sufficient permission to close the handle. An example of the latter occurs when the calling thread is the one that created the handle.

Callers of **ZwClose** should not assume that this routine automatically waits for all I/O to complete prior to returning.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtClose**" instead of "**ZwClose**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can

behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	IrqlZwPassive, PowerIrpDDis, ZwRegistryCreate, ZwRegistryOpen, HwStorPortProhibitedDDIs, ZwRegistryCreate(storport), ZwRegistryOpen(storport)

ZwCommitComplete function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwCommitComplete** routine notifies KTM that the calling resource manager has finished committing a transaction's data.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwCommitComplete(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SUBORDINATE_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwCommitComplete returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.
STA TUS _TR AN SAC TIO N_N OT_ REQ UES TED	The transaction or its enlistment is not in the correct state.

The routine might return other NTSTATUS values.

Remarks

A resource manager must call **ZwCommitComplete** after it has finished servicing a TRANSACTION_NOTIFY_COMMIT notification.

For more information about **ZwCommitComplete**, see Handling Commit Operations.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

TmCommitComplete

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwOpenEnlistment

ZwCommitEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwCommitEnlistment** routine initiates the commit operation for a specified enlistment's transaction.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwCommitEnlistment(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The object must represent a superior enlistment and the handle must have ENLISTMENT_SUPERIOR_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwCommitEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STATUS_ACCESS_DENIED	The caller does not have appropriate access to the enlistment object.
STATUS_ENLISTMENT_NOT_SUPERIOR	The caller is not a superior transaction manager for the enlistment.
STATUS_TRANSACTION_RESPONSE_NOT_ENLISTED	The caller did not register to receive TRANSACTION_NOTIFY_COMMIT_COMPLETE notifications.
STATUS_TRANSACTION_REQUEST_NOT_VALID	The enlistment's transaction is not in a state that allows it to be committed.

STA TUS _TR AN SAC TIO N_N OT_ ACT IVE	The commit operation for this transaction has already been started.
STA TUS _TR AN SAC TIO N_A LRE AD Y_A BO RTE D	The transaction cannot be committed because it has been rolled back.

The routine might return other NTSTATUS values.

Remarks

Only superior transaction managers can call **ZwCommitEnlistment**.

Callers of **ZwCommitEnlistment** must register to receive TRANSACTION_NOTIFY_COMMIT_COMPLETE notifications.

The **ZwCommitEnlistment** routine causes KTM to send TRANSACTION_NOTIFY_COMMIT notifications to all resource managers that have enlisted in the transaction.

For more information about **ZwCommitEnlistment**, see Creating a Superior Transaction Manager and Handling Commit Operations.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe

TmCommitEnlistment

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwOpenEnlistment

ZwCommitTransaction function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwCommitTransaction** routine initiates a commit operation for a specified transaction.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwCommitTransaction(
  HANDLE  TransactionHandle,
  BOOLEAN Wait
);
```

Parameters

`TransactionHandle`

A handle to a transaction object. Your component receives this handle from ZwCreateTransaction or ZwOpenTransaction. The handle must have TRANSACTION_COMMIT access to the object.

`Wait`

A Boolean value that the caller sets to **TRUE** for synchronous operation or **FALSE** for asynchronous operation. If this parameter is **TRUE**, the call returns after the commit operation is complete.

Return Value

ZwCommitTransaction returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The handle that was specified for the *TransactionHandle* parameter is not a handle to a transaction object.
STATUS_INVALID_HANDLE	The specified transaction object handle is invalid.

STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the transaction object.
STA TUS _TR AN SAC TIO N_S UPE RIO R_E XIS TS	The caller cannot commit the transaction because a superior transaction manager exists.
STA TUS _TR AN SAC TIO N_A LRE AD Y_A BO RTE D	The transaction cannot be committed because it has been rolled back.
STA TUS _TR AN SAC TIO N_A LRE AD Y_C OM MIT TED	The transaction is already committed.

STA TUS _TR AN SAC TIO N_R EQU EST _NO T_V ALI D	The commit operation for this transaction has already been started.
STA TUS _PE NDI NG	Commit notifications have been queued to resource managers, and the caller specified **FALSE** for the *Wait* parameter.

The routine might return other NTSTATUS values.

Remarks

For more information about how transaction clients should use the **ZwCommitTransaction** routine, see Creating a Transactional Client.

For more information about commit operations, see Handling Commit Operations.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)

TmCommitTransaction

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateTransaction

ZwOpenTransaction

ZwCreateDirectoryObject function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwCreateDirectoryObject** routine creates or opens an object-directory object.

Syntax

```
NTSYSAPI NTSTATUS ZwCreateDirectoryObject(
  PHANDLE            DirectoryHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes
);
```

Parameters

`DirectoryHandle`

Pointer to a HANDLE variable that receives a handle to the object directory.

`DesiredAccess`

Specifies an ACCESS_MASK value that determines the requested access to the object. In addition to the access rights that are defined for all types of objects (see ACCESS_MASK), the caller can specify one or more of the following access rights, which are specific to object directories:

ACCESS_MASK FLAG	TYPE OF ACCESS
DIRECTORY_QUERY	Query
DIRECTORY_TRAVERSE	Name lookup
DIRECTORY_CREATE_OBJECT	Name creation
DIRECTORY_CREATE_SUBDIRECTORY	Subdirectory creation
DIRECTORY_ALL_ACCESS	All of the preceding types

`ObjectAttributes`

Pointer to an OBJECT_ATTRIBUTES structure that contains the object's attributes, which you must have already initialized by calling InitializeObjectAttributes.

Return Value

ZwCreateDirectoryObject returns an NTSTATUS value. Possible return values include:

Remarks

Once the handle pointed to by *DirectoryHandle* is no longer in use, the driver must call ZwClose to close it.

If the caller is not running in a system thread context, it must ensure that any handles it creates are private handles.

Otherwise, the handle can be accessed by the process in whose context the driver is running. For more information, see Object Handles.

The system uses object directories to organize other types of objects, such as device objects. For more information, see Object Directories.

Note that the system does not use object directory objects to represent file-system directories, which are represented instead as file objects.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtCreateDirectoryObject**" instead of "**ZwCreateDirectoryObject**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

ACCESS_MASK

InitializeObjectAttributes

Using Nt and Zw Versions of the Native System Services Routines

ZwClose

ZwCreateEnlistment function

1/25/2019 • 4 minutes to read • Edit Online

The **ZwCreateEnlistment** routine creates a new enlistment object for a transaction.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwCreateEnlistment(
  PHANDLE            EnlistmentHandle,
  ACCESS_MASK        DesiredAccess,
  HANDLE             ResourceManagerHandle,
  HANDLE             TransactionHandle,
  POBJECT_ATTRIBUTES ObjectAttributes,
  ULONG              CreateOptions,
  NOTIFICATION_MASK  NotificationMask,
  PVOID              EnlistmentKey
);
```

Parameters

`EnlistmentHandle`

A pointer to a caller-allocated variable that receives a handle to the new enlistment object if the call to **ZwCreateEnlistment** succeeds.

`DesiredAccess`

An ACCESS_MASK value that specifies the caller's requested access to the enlistment object. In addition to the access rights that are defined for all kinds of objects (see ACCESS_MASK), the caller can specify any of the following access right flags for enlistment objects:

ACCESS_MASK FLAG	ALLOWS THE CALLER TO
ENLISTMENT_QUERY_INFORMATION	Query information about the enlistment (see ZwQueryInformationEnlistment).
ENLISTMENT_SET_INFORMATION	Set information for the enlistment (see ZwSetInformationEnlistment).
ENLISTMENT_RECOVER	Recover the enlistment (see ZwRecoverEnlistment).
ENLISTMENT_SUBORDINATE_RIGHTS	Perform operations that a resource manager that is not superior performs (see ZwRollbackEnlistment, ZwPrePrepareComplete, ZwPrepareComplete, ZwCommitComplete, ZwRollbackComplete, ZwSinglePhaseReject, ZwReadOnlyEnlistment).
ENLISTMENT_SUPERIOR_RIGHTS	Perform operations that a superior transaction manager must perform (see ZwPrepareEnlistment, ZwPrePrepareEnlistment, ZwCommitEnlistment).

Alternatively, you can specify one or more of the following ACCESS_MASK bitmaps. These bitmaps combine the flags from the previous table with the STANDARD_RIGHTS_*XXX* flags that are described on the ACCESS_MASK

reference page. You can also combine these bitmaps together with additional flags from the previous table. The following table shows how the bitmaps correspond to specific access rights.

GENERIC ACCESS RIGHT	SET OF SPECIFIC ACCESS RIGHTS
ENLISTMENT_GENERIC_READ	STANDARD_RIGHTS_READ and ENLISTMENT_QUERY_INFORMATION
ENLISTMENT_GENERIC_WRITE	STANDARD_RIGHTS_WRITE, ENLISTMENT_SET_INFORMATION, ENLISTMENT_RECOVER, ENLISTMENT_REFERENCE, ENLISTMENT_SUBORDINATE_RIGHTS, and ENLISTMENT_SUPERIOR_RIGHTS
ENLISTMENT_GENERIC_EXECUTE	STANDARD_RIGHTS_EXECUTE, ENLISTMENT_RECOVER, ENLISTMENT_SUBORDINATE_RIGHTS, and ENLISTMENT_SUPERIOR_RIGHTS
ENLISTMENT_ALL_ACCESS	STANDARD_RIGHTS_REQUIRED, ENLISTMENT_GENERIC_READ, ENLISTMENT_GENERIC_WRITE, and ENLISTMENT_GENERIC_EXECUTE

`ResourceManagerHandle`

A handle to the caller's resource manager object that was obtained by a previous call to ZwCreateResourceManager or ZwOpenResourceManager.

`TransactionHandle`

A handle to a transaction object that was obtained by a previous call to ZwCreateTransaction or ZwOpenTransaction. KTM adds this transaction to the list of transactions that the calling resource manager is handling.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use the InitializeObjectAttributes routine to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**. This parameter is optional and can be **NULL**.

`CreateOptions`

Enlistment option flags. The following table contains the only available flag.

CREATEOPTIONS FLAG	MEANING
ENLISTMENT_SUPERIOR	The caller is enlisting as a superior transaction manager for the specified transaction.

This parameter is optional and can be zero.

`NotificationMask`

A bitwise OR of TRANSACTION_NOTIFY_*XXX* values that are defined in Ktmtypes.h. This mask specifies the types of transaction notifications that KTM sends to the caller.

`EnlistmentKey`

A pointer to caller-defined information that uniquely identifies the enlistment. The resource manager receives this pointer when it calls ZwGetNotificationResourceManager or when KTM calls the ResourceManagerNotification

callback routine. The resource manager can maintain a reference count for this key by calling TmReferenceEnlistmentKey and TmDereferenceEnlistmentKey. This parameter is optional and can be **NULL**.

Return Value

ZwCreateEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_INVALID_PARAMETER	The *CreateOptions* or *NotificationMask* parameter's value is invalid, or KTM could not find the transaction that the *TransactionHandle* parameter specifies.
STATUS_INSUFFICIENT_RESOURCES	A memory allocation failed.
STATUS_TRANSACTION_MANAGER_NOT_ONLINE	The enlistment failed because KTM or the resource manager is not in an operational state.

STATUS_TRANSACTION_NOT_ACTIVE	The enlistment failed because the transaction that the *TransactionHandle* parameter specifies is not active.
STATUS_TRANSACTION_SUPERIOR_EXISTS	The caller tried to register as a superior transaction manager but a superior transaction manager already exists.
STATUS_TM_VOLATILE	The caller is trying to register as a superior transaction manager, but the caller's resource manager object is volatile while the associated transaction manager object is not volatile.
STATUS_ACCESS_DENIED	The value of the *DesiredAccess* parameter is invalid.

The routine might return other NTSTATUS values.

Remarks

A resource manager calls **ZwCreateEnlistment** to enlist in a transaction.

Resource managers that are not superior must include the ENLISTMENT_SUBORDINATE_RIGHTS flag in their access mask.

Superior transaction managers must include the ENLISTMENT_SUPERIOR_RIGHTS flag in their access masks. Typically, a superior transaction manager includes code that calls ZwRollbackEnlistment, so it must also include the ENLISTMENT_SUBORDINATE_RIGHTS flag.

A resource manager that calls **ZwCreateEnlistment** must eventually call ZwClose to close the object handle.

Your resource manager can use the *EnlistmentKey* parameter to assign a unique value to each enlistment, such as a

pointer to a data structure that contains information about the enlistment. For example, if the resource manager stores the enlistment object's handle in the structure, the resource manager can do the following:

1. Call ZwGetNotificationResourceManager to obtain a notification.
2. Obtain the enlistment key value from the TRANSACTION_NOTIFICATION structure.
3. Use the enlistment key to find the stored enlistment object handle.
4. Call routines that require the enlistment handle as input, such as ZwCommitComplete or ZwRollbackComplete.

For more information about **ZwCreateEnlistment**, see Creating a Resource Manager and Creating a Superior Transaction Manager.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

ZwCreateFile function

1/25/2019 • 16 minutes to read • Edit Online

The **ZwCreateFile** routine creates a new file or opens an existing file.

Syntax

```
NTSYSAPI NTSTATUS ZwCreateFile(
  PHANDLE            FileHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  PIO_STATUS_BLOCK   IoStatusBlock,
  PLARGE_INTEGER     AllocationSize,
  ULONG              FileAttributes,
  ULONG              ShareAccess,
  ULONG              CreateDisposition,
  ULONG              CreateOptions,
  PVOID              EaBuffer,
  ULONG              EaLength
);
```

Parameters

`FileHandle`

A pointer to a HANDLE variable that receives a handle to the file.

`DesiredAccess`

Specifies an ACCESS_MASK value that determines the requested access to the object. In addition to the access rights that are defined for all types of objects, the caller can specify any of the following access rights, which are specific to files.

ACCESS_MASK FLAG	ALLOWS CALLER TO DO THIS
FILE_READ_DATA	Read data from the file.
FILE_READ_ATTRIBUTES	Read the attributes of the file. (For more information, see the description of the *FileAttributes* parameter.)
FILE_READ_EA	Read the extended attributes (EAs) of the file. This flag is irrelevant for device and intermediate drivers.
FILE_WRITE_DATA	Write data to the file.
FILE_WRITE_ATTRIBUTES	Write the attributes of the file. (For more information, see the description of the *FileAttributes* parameter.)
FILE_WRITE_EA	Change the extended attributes (EAs) of the file. This flag is irrelevant for device and intermediate drivers.
FILE_APPEND_DATA	Append data to the file.

FILE_EXECUTE	Use system paging I/O to read data from the file into memory. This flag is irrelevant for device and intermediate drivers.

> **Note** Do not specify FILE_READ_DATA, FILE_WRITE_DATA, FILE_APPEND_DATA, or FILE_EXECUTE when you create or open a directory.

The caller can only specify a generic access right, GENERIC_*XXX*, for a file, not a directory. Generic access rights correspond to specific access rights as shown in the following table.

GENERIC ACCESS RIGHT	SET OF SPECIFIC ACCESS RIGHTS
GENERIC_READ	STANDARD_RIGHTS_READ, FILE_READ_DATA, FILE_READ_ATTRIBUTES, FILE_READ_EA, and SYNCHRONIZE.
GENERIC_WRITE	STANDARD_RIGHTS_WRITE, FILE_WRITE_DATA, FILE_WRITE_ATTRIBUTES, FILE_WRITE_EA, FILE_APPEND_DATA, and SYNCHRONIZE.
GENERIC_EXECUTE	STANDARD_RIGHTS_EXECUTE, FILE_EXECUTE, FILE_READ_ATTRIBUTES, and SYNCHRONIZE. This value is irrelevant for device and intermediate drivers.
GENERIC_ALL	FILE_ALL_ACCESS.

For example, if you specify GENERIC_READ for a file object, the routine maps this value to the FILE_GENERIC_READ bitmask of specific access rights. In the preceding table, the specific access rights that are listed for GENERIC_READ correspond to the access flags that are contained in the FILE_GENERIC_READ bitmask. If the file is actually a directory, the caller can also specify the following generic access rights.

DESIREDACCESS FLAG	ALLOWS CALLER TO DO THIS
FILE_LIST_DIRECTORY	List the files in the directory.
FILE_TRAVERSE	Traverse the directory, in other words, include the directory in the path of a file.

For more information about access rights, see ACCESS_MASK. `ObjectAttributes` A pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use InitializeObjectAttributes to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**. `IoStatusBlock` A pointer to an IO_STATUS_BLOCK structure that receives the final completion status and other information about the requested operation. In particular, the **Information** member receives one of the following values:

- FILE_CREATED
- FILE_OPENED
- FILE_OVERWRITTEN
- FILE_SUPERSEDED
- FILE_EXISTS
- FILE_DOES_NOT_EXIST

`AllocationSize` A pointer to a LARGE_INTEGER that contains the initial allocation size, in bytes, for a file that is created or overwritten. If *AllocationSize* is **NULL**, no allocation size is specified. If no file is created or overwritten, *AllocationSize* is ignored. `FileAttributes` Specifies one or more FILE_ATTRIBUTE_*XXX* flags, which represent the file attributes to set if you create or overwrite a file. The caller usually specifies FILE_ATTRIBUTE_NORMAL, which sets

the default attributes. For a list of valid FILE_ATTRIBUTE_*XXX* flags, see the CreateFile routine in the Microsoft Windows SDK documentation. If no file is created or overwritten, *FileAttributes* is ignored. `ShareAccess` Type of share access, which is specified as zero or any combination of the following flags.

***ShareAccess* flag**	**Allows other threads to do this**
FILE_SHARE_READ	Read the file
FILE_SHARE_WRITE	Write the file
FILE_SHARE_DELETE	Delete the file

Device and intermediate drivers usually set *ShareAccess* to zero, which gives the caller exclusive access to the open file. `CreateDisposition` Specifies the action to perform if the file does or does not exist. *CreateDisposition* can be one of the values in the following table.

***CreateDisposition* value**	**Action if file exists**	**Action if file does not exist**
FILE_SUPERSEDE	Replace the file.	Create the file.
FILE_CREATE	Return an error.	Create the file.
FILE_OPEN	Open the file.	Return an error.
FILE_OPEN_IF	Open the file.	Create the file.
FILE_OVERWRITE	Open the file, and overwrite it.	Return an error.
FILE_OVERWRITE_IF	Open the file, and overwrite it.	Create the file.

`CreateOptions` Specifies the options to apply when the driver creates or opens the file. Use one or more of the flags in the following table.

***CreateOptions* flag**	**Meaning**
FILE_DIRECTORY_FILE	The file is a directory. Compatible *CreateOptions* flags are FILE_SYNCHRONOUS_IO_ALERT, FILE_SYNCHRONOUS_IO_NONALERT, FILE_WRITE_THROUGH, FILE_OPEN_FOR_BACKUP_INTENT, and FILE_OPEN_BY_FILE_ID. The *CreateDisposition* parameter must be set to FILE_CREATE, FILE_OPEN, or FILE_OPEN_IF.
FILE_NON_DIRECTORY_FILE	The file is not a directory. The file object to open can represent a data file; a logical, virtual, or physical device; or a volume.
FILE_WRITE_THROUGH	System services, file-system drivers, and drivers that write data to the file must actually transfer the data to the file before any requested write operation is considered complete.
FILE_SEQUENTIAL_ONLY	All access to the file will be sequential.
FILE_RANDOM_ACCESS	Access to the file can be random, so no sequential read-ahead operations should be performed by file-system drivers or by the system.

FILE_NO_INTERMEDIATE_BUFFERING	The file cannot be cached or buffered in a driver's internal buffers. This flag is incompatible with the *DesiredAccess* parameter's FILE_APPEND_DATA flag.
FILE_SYNCHRONOUS_IO_ALERT	All operations on the file are performed synchronously. Any wait on behalf of the caller is subject to premature termination from alerts. This flag also causes the I/O system to maintain the file-position pointer. If this flag is set, the SYNCHRONIZE flag must be set in the *DesiredAccess* parameter.
FILE_SYNCHRONOUS_IO_NONALERT	All operations on the file are performed synchronously. Waits in the system that synchronize I/O queuing and completion are not subject to alerts. This flag also causes the I/O system to maintain the file-position context. If this flag is set, the SYNCHRONIZE flag must be set in the *DesiredAccess* parameter.
FILE_CREATE_TREE_CONNECTION	Create a tree connection for this file in order to open it over the network. This flag is not used by device and intermediate drivers.
FILE_COMPLETE_IF_OPLOCKED	Complete this operation immediately with an alternate success code of STATUS_OPLOCK_BREAK_IN_PROGRESS if the target file is opportunistic locked (oplock), rather than blocking the caller's thread. If the file is oplocked, another caller already has access to the file. This flag is not used by device and intermediate drivers. For information about oplock, see Opportunistic Locks.
FILE_NO_EA_KNOWLEDGE	If the extended attributes (EAs) for an existing file being opened indicate that the caller must understand EAs to properly interpret the file, **ZwCreateFile** should return an error. This flag is irrelevant for device and intermediate drivers.
FILE_OPEN_REPARSE_POINT	Open a file with a reparse point and bypass normal reparse point processing for the file. For more information, see the following Remarks section. For information about reparse point, see Reparse Points.
FILE_DELETE_ON_CLOSE	The system deletes the file when the last handle to the file is passed to ZwClose. If this flag is set, the DELETE flag must be set in the *DesiredAccess* parameter.

FILE_OPEN_BY_FILE_ID	The file name that is specified by the *ObjectAttributes* parameter includes a binary 8-byte or 16-byte file reference number or object ID for the file, depending on the file system as shown below. Optionally, a device name followed by a backslash character may proceed these binary values. For example, a device name will have the following format.
	
	`??\C:<8 bytes of binary FileID>`
	`\device\HardDiskVolume1<16 bytes of binary ObjectID>`
	
	• On NTFS, this can be a 8-byte or 16-byte reference number or object ID. A 16-byte reference number is the same as an 8-byte number padded with zeros.
	• On ReFS, this can be an 8-byte or 16-byte reference number. A 16-byte number is not related to an 8-byte number. Object IDs are not supported.
	• The FAT, ExFAT, UDFS, and CDFS file systems do not support this flag.
	
	This number is assigned by and specific to the particular file system.
	
	Note Because the filename field will partly contain a binary blob, it is incorrect to assume that this is a valid Unicode string, and more importantly may not be a null terminated string.

FILE_OPEN_FOR_BACKUP_INTENT	The file is being opened for backup intent. Therefore, the system should check for certain access rights and grant the caller the appropriate access to the file—before checking the *DesiredAccess* parameter against the file's security descriptor. This flag not used by device and intermediate drivers.
FILE_RESERVE_OPFILTER	This flag allows an application to request a Filter opportunistic lock (oplock) to prevent other applications from getting share violations. If there are already open handles, the create request will fail with STATUS_OPLOCK_NOT_GRANTED. For more information, see the following Remarks section. For information about oplock, see Opportunistic Locks.
FILE_OPEN_REQUIRING_OPLOCK	The file is being opened and an opportunistic lock (oplock) on the file is being requested as a single atomic operation. The file system checks for oplocks before it performs the create operation, and will fail the create with a return code of STATUS_CANNOT_BREAK_OPLOCK if the result would be to break an existing oplock. **Note** The FILE_OPEN_REQUIRING_OPLOCK flag is available in Windows 7, Windows Server 2008 R2 and later Windows operating systems.
FILE_SESSION_AWARE	The client opening the file or device is session aware and per session access is validated if necessary. **Note** The FILE_SESSION_AWARE flag is available starting withWindows 8.

`EaBuffer` For device and intermediate drivers, this parameter must be a **NULL** pointer. `EaLength` For device and intermediate drivers, this parameter must be zero. ## Return Value **ZwCreateFile** returns STATUS_SUCCESS on success or an appropriate NTSTATUS error code on failure. In the latter case, the caller can determine the cause of the failure by checking the *IoStatusBlock* parameter.

> **Note ZwCreateFile** might return STATUS_FILE_LOCK_CONFLICT as the return value or in the **Status** member of the **IO_STATUS_BLOCK** structure that is pointed to by the *IoStatusBlock* parameter. This would occur only if the NTFS log file is full, and an error occurs while **ZwCreateFile** tries to handle this situation.

Remarks

ZwCreateFile supplies a handle that the caller can use to manipulate a file's data, or the file object's state and attributes. For more information, see Using Files in a Driver.

Once the handle pointed to by *FileHandle* is no longer in use, the driver must call ZwClose to close it.

If the caller is not running in a system thread context, it must ensure that any handles it creates are private handles. Otherwise, the handle can be accessed by the process in whose context the driver is running. For more information, see Object Handles.

There are two alternate ways to specify the name of the file to be created or opened with **ZwCreateFile**:

1. As a fully qualified pathname, supplied in the **ObjectName** member of the input *ObjectAttributes*.
2. As pathname relative to the directory file represented by the handle in the **RootDirectory** member of the input *ObjectAttributes*.

Setting certain flags in the *DesiredAccess* parameter results in the following effects:

- For a caller to synchronize an I/O completion by waiting for the returned *FileHandle*, the SYNCHRONIZE flag must be set. Otherwise, a caller that is a device or intermediate driver must synchronize an I/O completion by using an event object.
- If the caller sets only the FILE_APPEND_DATA and SYNCHRONIZE flags, it can write only to the end of the file, and any offset information about write operations to the file is ignored. The file will automatically be extended as necessary for this type of operation.
- Setting the FILE_WRITE_DATA flag for a file also allows the caller to write beyond the end of the file. Again, the file is automatically extended as necessary.
- If the caller sets only the FILE_EXECUTE and SYNCHRONIZE flags, it cannot directly read or write any data to the file using the returned *FileHandle*. That is, all operations on the file occur through the system pager in response to instruction and data-access operations. Device and intermediate drivers should not set the FILE_EXECUTE flag.

The *ShareAccess* parameter determines whether separate threads can access the same file, possibly simultaneously. Provided that both callers have the appropriate access privileges, the file can be successfully opened and shared. If the original caller of **ZwCreateFile** does not specify FILE_SHARE_READ, FILE_SHARE_WRITE, or FILE_SHARE_DELETE, no other caller can open the file—that is, the original caller is granted exclusive access.

To successfully open a shared file, the *DesiredAccess* flags must be compatible with the *DesiredAccess* and *ShareAccess* flags of all the previous open operations that have not yet been released through . That is, the *DesiredAccess* specified to **ZwCreateFile** for a given file must not conflict with the accesses that other openers of the file have disallowed.

The *CreateDisposition* value FILE_SUPERSEDE requires that the caller have DELETE access to a existing file object. If so, a successful call to **ZwCreateFile** with FILE_SUPERSEDE on an existing file effectively deletes that file, and

then recreates it. This implies that, if the file has already been opened by another thread, it opened the file by specifying a *ShareAccess* parameter with the FILE_SHARE_DELETE flag set. Note that this type of disposition is consistent with the POSIX style of overwriting files.

The *CreateDisposition* values FILE_OVERWRITE_IF and FILE_SUPERSEDE are similar. If **ZwCreateFile** is called with a existing file and either of these *CreateDisposition* values, the file will be replaced.

Overwriting a file is semantically equivalent to a supersede operation, except for the following:

- The caller must have write access to the file, rather than delete access. This implies that, if the file has already been opened by another thread, it opened the file with the FILE_SHARE_WRITE flag set in the input *ShareAccess*.
- The specified file attributes are logically ORed with those already on the file. This implies that, if the file has already been opened by another thread, a subsequent caller of **ZwCreateFile** cannot disable existing *FileAttributes* flags but can enable additional flags for the same file. Note that this style of overwriting files is consistent with MS-DOS, Microsoft Windows 3.1, and OS/2.

The FILE_DIRECTORY_FILE *CreateOptions* value specifies that the file to be created or opened is a directory. When a directory file is created, the file system creates an appropriate structure on the disk to represent an empty directory for that particular file system's on-disk structure. If this option was specified and the given file to be opened is not a directory file, or if the caller specified an inconsistent *CreateOptions* or *CreateDisposition* value, the call to **ZwCreateFile** will fail.

The FILE_NO_INTERMEDIATE_BUFFERING *CreateOptions* flag prevents the file system from performing any intermediate buffering on behalf of the caller. Specifying this flag places the following restrictions on the caller's parameters to other **Zw*Xxx*File** routines.

- Any optional *ByteOffset* passed to ZwReadFile or ZwWriteFile must be a multiple of the sector size.
- The *Length* passed to **ZwReadFile** or **ZwWriteFile** must be an integral of the sector size. Note that specifying a read operation to a buffer whose length is exactly the sector size might result in a lesser number of significant bytes being transferred to that buffer if the end of the file was reached during the transfer.
- Buffers must be aligned in accordance with the alignment requirement of the underlying device. To obtain this information, call **ZwCreateFile** to get a handle for the file object that represents the physical device, and pass that handle to ZwQueryInformationFile. For a list of the system's FILE_*XXX*_ALIGNMENT values, see DEVICE_OBJECT.
- Calls to ZwSetInformationFile with the *FileInformationClass* parameter set to **FilePositionInformation** must specify an offset that is a multiple of the sector size.

The FILE_SYNCHRONOUS_IO_ALERT and FILE_SYNCHRONOUS_IO_NONALERT *CreateOptions* flags, which are mutually exclusive as their names suggest, specify that all I/O operations on the file will be synchronous—as long as they occur through the file object referred to by the returned *FileHandle*. All I/O on such a file is serialized across all threads using the returned handle. If either of these *CreateOptions* flags is set, the SYNCHRONIZE *DesiredAccess* flag must also be set—to compel the I/O manager to use the file object as a synchronization object. In these cases, the I/O manager keeps track of the current file-position offset, which you can pass to **ZwReadFile** and **ZwWriteFile**. Call **ZwQueryInformationFile** or **ZwSetInformationFile** to get or set this position.

If the *CreateOptions* FILE_OPEN_REPARSE_POINT flag is not specified and **ZwCreateFile** attempts to open a file with a reparse point, normal reparse point processing occurs for the file. If, on the other hand, the FILE_OPEN_REPARSE_POINT flag is specified, normal reparse processing does not occur and **ZwCreateFile** attempts to directly open the reparse point file. In either case, if the open operation was successful, **ZwCreateFile** returns STATUS_SUCCESS; otherwise, the routine returns an NTSTATUS error code. **ZwCreateFile** never returns STATUS_REPARSE.

The *CreateOptions* FILE_OPEN_REQUIRING_OPLOCK flag eliminates the time between when you open the file and request an oplock that could potentially allow a third party to open the file and get a sharing violation. An application can use the FILE_OPEN_REQUIRING_OPLOCK flag on **ZwCreateFile** and then request any oplock. This ensures that an oplock owner will be notified of any subsequent open request that causes a sharing violation.

In Windows 7, if other handles exist on the file when an application uses the FILE_OPEN_REQUIRING_OPLOCK flag, the create operation will fail with STATUS_OPLOCK_NOT_GRANTED. This restriction no longer exists starting with Windows 8.

If this create operation would break an oplock that already exists on the file, then setting the FILE_OPEN_REQUIRING_OPLOCK flag will cause the create operation to fail with STATUS_CANNOT_BREAK_OPLOCK. The existing oplock will not be broken by this create operation.

An application that uses the FILE_OPEN_REQUIRING_OPLOCK flag must request an oplock after this call succeeds, or all subsequent attempts to open the file will be blocked without the benefit of normal oplock processing. Similarly, if this call succeeds but the subsequent oplock request fails, an application that uses this flag must close its handle after it detects that the oplock request has failed.

> **Note** The FILE_OPEN_REQUIRING_OPLOCK flag is available in Windows 7, Windows Server 2008 R2 and later Windows operating systems. The Microsoft file systems that implement this flag in Windows 7 are NTFS, FAT, and exFAT.

The *CreateOptions* flag FILE_RESERVE_OPFILTER allows an application to request a Level 1, Batch, or Filter oplock to prevent other applications from getting share violations. However, FILE_RESERVE_OPFILTER is only practically useful for Filter oplocks. To use it, you must complete the following steps:

1. Issue a create request with *CreateOptions* of FILE_RESERVE_OPFILTER, *DesiredAccess* of exactly FILE_READ_ATTRIBUTES, and *ShareAccess* of exactly FILE_SHARE_READ | FILE_SHARE_WRITE | FILE_SHARE_DELETE.
    - If there are already open handles, the create request fails with STATUS_OPLOCK_NOT_GRANTED, and the next requested oplock also fails.
    - If you open with more access or less sharing will also cause a failure of STATUS_OPLOCK_NOT_GRANTED.
2. If the create request succeeds, request an oplock.
3. Open another handle to the file to do I/O.

Step three makes this practical only for Filter oplocks. The handle opened in step 3 can have a *DesiredAccess* that contains a maximum of FILE_READ_ATTRIBUTES | FILE_WRITE_ATTRIBUTES | FILE_READ_DATA | FILE_READ_EA | FILE_EXECUTE | SYNCHRONIZE | READ_CONTROL and still not break a Filter oplock. However, any *DesiredAccess* greater than FILE_READ_ATTRIBUTES | FILE_WRITE_ATTRIBUTES | SYNCHRONIZE will break a Level 1 or Batch oplock and make the FILE_RESERVE_OPFILTER flag useless for those oplock types.

NTFS is the only Microsoft file system that implements FILE_RESERVE_OPFILTER.

Callers of **ZwCreateFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtCreateFile**" instead of "**ZwCreateFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

ZwCreateKey function

1/25/2019 • 4 minutes to read • Edit Online

The **ZwCreateKey** routine creates a new registry key or opens an existing one.

Syntax

```
NTSYSAPI NTSTATUS ZwCreateKey(
  PHANDLE            KeyHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  ULONG              TitleIndex,
  PUNICODE_STRING    Class,
  ULONG              CreateOptions,
  PULONG             Disposition
);
```

Parameters

`KeyHandle`

Pointer to a HANDLE variable that receives a handle to the key.

`DesiredAccess`

Specifies an ACCESS_MASK value that determines the requested access to the object. In addition to the access rights that are defined for all types of objects (see ACCESS_MASK), the caller can specify one or more of the following access rights, which are specific to object directories:

*DESIREDACCESS*FLAG	ALLOWS CALLER TO DO THIS
KEY_QUERY_VALUE	Read key values.
KEY_SET_VALUE	Write key values.
KEY_CREATE_SUB_KEY	Create subkeys for the key.
KEY_ENUMERATE_SUB_KEYS	Read the key's subkeys.
KEY_CREATE_LINK	Create a symbolic link to the key. This flag is not used by device and intermediate drivers.
KEY_NOTIFY	Ask to receive notification when the name, value, or attributes of the key change. For more information, see ZwNotifyChangeKey.

The caller can also specify one of the following constants, which combines several ACCESS_MASK flags.

CONSTANT	CONSISTS OF THESE ACCESS_MASK FLAGS
KEY_READ	STANDARD_RIGHTS_READ, KEY_QUERY_VALUE, KEY_ENUMERATE_SUB_KEYS, and KEY_NOTIFY

KEY_WRITE	STANDARD_RIGHTS_WRITE, KEY_SET_VALUE, and KEY_CREATE_SUBKEY
KEY_EXECUTE	Same as KEY_READ.
KEY_ALL_ACCESS	STANDARD_RIGHTS_ALL, KEY_QUERY_VALUE, KEY_SET_VALUE, KEY_CREATE_SUB_KEY, KEY_ENUMERATE_SUB_KEYS, KEY_NOTIFY, and KEY_CREATE_LINK

`ObjectAttributes`

Pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use InitializeObjectAttributes to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**.

`TitleIndex`

Device and intermediate drivers set this parameter to zero.

`Class`

Pointer to a Unicode string that contains the key's object class. This information is used by the configuration manager.

`CreateOptions`

Specifies the options to apply when creating or opening a key, specified as a compatible combination of the following flags.

***CREATEOPTIONS* FLAG**	**DESCRIPTION**
REG_OPTION_VOLATILE	Key is not preserved when the system is rebooted.
REG_OPTION_NON_VOLATILE	Key is preserved when the system is rebooted.
REG_OPTION_CREATE_LINK	The newly created key is a symbolic link. This flag is not used by device and intermediate drivers.
REG_OPTION_BACKUP_RESTORE	Key should be created or opened with special privileges that allow backup and restore operations. This flag is not used by device and intermediate drivers.

`Disposition`

Pointer to a variable that receives a value indicating whether a new key was created or an existing one opened.

***DISPOSITION* VALUE**	**DESCRIPTION**
REG_CREATED_NEW_KEY	A new key was created.
REG_OPENED_EXISTING_KEY	An existing key was opened.

Return Value

ZwCreateKey returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure.

Remarks

ZwCreateKey supplies a handle that the caller can use to manipulate a registry key. For more information, see Using the Registry in a Driver.

Once the handle pointed to by *KeyHandle* is no longer in use, the driver must call ZwClose to close it.

There are two alternate ways to specify the name of the file to be created or opened with **ZwCreateKey**:

1. As a fully qualified pathname, supplied in the **ObjectName** member of the input *ObjectAttributes*. The pathnames of registry keys begin with **\Registry**.
2. As pathname relative to another registry key, represented by the handle in the **RootDirectory** member of the input *ObjectAttributes*.

If the key specified by *ObjectAttributes* does not exist, the routine attempts to create the key. For this attempt to succeed, the new key must be a direct subkey of the key that is referred to by **RootDirectory**, and the key that **RootDirectory** refers to must have been opened for KEY_CREATE_SUB_KEY access.

If the specified key already exists, it is opened and its value is not affected in any way.

The security attributes specified by *ObjectAttributes* when a key is created determine whether the specified *DesiredAccess* is granted on subsequent calls to **ZwCreateKey** and ZwOpenKey.

If the caller is not running in a system thread context, it must ensure that any handles it creates are private handles. Otherwise, the handle can be accessed by the process in whose context the driver is running. For more information, see Object Handles.

For more information about working with registry keys, see Using the Registry in a Driver.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtCreateKey**" instead of "**ZwCreateKey**".

The **NtCreateKey** routine in the Windows kernel is not directly accessible to kernel-mode drivers.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.

ZwCreateKeyTransacted function

1/25/2019 • 4 minutes to read • Edit Online

The **ZwCreateKeyTransacted** routine creates a new registry key or opens an existing one, and it associates the key with a transaction.

Syntax

```
NTSYSAPI NTSTATUS ZwCreateKeyTransacted(
  PHANDLE            KeyHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  ULONG              TitleIndex,
  PUNICODE_STRING    Class,
  ULONG              CreateOptions,
  HANDLE             TransactionHandle,
  PULONG             Disposition
);
```

Parameters

`KeyHandle`

A pointer to a HANDLE variable into which the routine writes the handle to the key.

`DesiredAccess`

Specifies the type of access to the key that the caller requests. This parameter is an ACCESS_MASK value. For more information, see the description of the *DesiredAccess* parameter of the ZwCreateKey routine.

`ObjectAttributes`

A pointer to the object attributes of the key being opened. This parameter points to an OBJECT_ATTRIBUTES structure that must have been previously initialized by the InitializeObjectAttributes routine. The caller must specify the name of the registry key as the *ObjectName* parameter in the call to **InitializeObjectAttributes**. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**.

`TitleIndex`

Device and intermediate drivers set this parameter to zero.

`Class`

Device and intermediate drivers set this parameter to **NULL**.

`CreateOptions`

Specifies the options to apply when the routine creates or opens the key. Set this parameter to zero or to the bitwise OR of one or more of the following REG_OPTION_*XXX* flag bits.

***CREATEOPTIONS* FLAG**	**DESCRIPTION**
REG_OPTION_VOLATILE	The key is not preserved after the computer restarts.

REG_OPTION_NON_VOLATILE	The key is preserved after the computer restarts.
REG_OPTION_CREATE_LINK	The key is a symbolic link. This flag is not used by device and intermediate drivers.
REG_OPTION_BACKUP_RESTORE	Open the key with special privileges that enable backup and restore operations. This flag is not used by device and intermediate drivers.

`TransactionHandle`

A handle to a transaction object. To obtain this handle, you can call the ZwCreateTransaction routine. Or, if you have a pointer to a transaction object, you can supply the pointer to the ObOpenObjectByPointer routine to obtain the corresponding transaction handle.

`Disposition`

A pointer to a location into which the routine writes one of the following values to indicate whether the call created a new key or opened an existing one.

***DISPOSITION* VALUE**	**DESCRIPTION**
REG_CREATED_NEW_KEY	A new key was created.
REG_OPENED_EXISTING_KEY	An existing key was opened.

You can set *Disposition* = **NULL** if this information is not needed.

Return Value

ZwCreateKeyTransacted returns STATUS_SUCCESS if the call successfully creates or opens the key. Possible error return values include the following:

RETURN CODE	**DESCRIPTION**
STATUS_INVALID_PARAMETER	The *ObjectAttributes* parameter is **NULL** or points to invalid information, or the *CreateOptions* parameter value specifies invalid options.

STA TUS _OB JEC T_P AT H_S YNT AX_ BA D	The registry path in the object attributes is invalid.
STA TUS _OB JEC T_N AM E_N OT_ FOU ND	The registry path in the object attributes was not found.
STA TUS _AC CES S_D ENI ED	The caller did not have the required access rights to open a handle for the named registry key.
STA TUS _IN SUF FICI ENT _RE SO URC ES	A memory allocation operation failed.

Remarks

This routine provides a handle that the caller can access a registry key with. Additionally, this routine associates the key with an active transaction.

After the handle that is pointed to by *KeyHandle* is no longer being used, the driver must call the ZwClose routine to close it.

Like **ZwCreateKeyTransacted**, the ZwOpenKeyTransacted routine associates a key with a transaction. Unlike **ZwCreateKeyTransacted**, which can create a new key or open an existing key, **ZwOpenKeyTransacted** can only open a registry key that already exists.

After a kernel-mode driver obtains a handle to a transaction (for example, by calling **ZwCreateTransaction**), the

driver can perform a series of registry operations that are part of this transaction. The driver can close the transaction either by committing to the changes that were made in the transaction or by rolling back the transaction.

After the driver successfully completes all registry operations that are part of a transaction, it can call the ZwCommitTransaction routine to commit to the changes. The driver can call the ZwRollbackTransaction routine to roll back the transaction.

During a transaction, a registry operation is part of the transaction if the system call that performs the operation meets either of the following conditions:

- The call specifies, as an input parameter, the transaction handle. For example, calls to **ZwCreateKeyTransacted** and **ZwOpenKeyTransacted** can associate one or more handles to registry keys with the transaction.
- The call specifies, as an input parameter, a registry key handle that was obtained by a call to **ZwCreateKeyTransacted** or **ZwOpenKeyTransacted** to which the transaction handle was supplied. For example, a call to the ZwSetValueKey routine can use a key handle that was obtained in this way to set the value of a registry key as part of a transaction.

For more information about kernel-mode transactions, see Using Kernel Transaction Manager.

The security descriptor in the object attributes determines whether the access rights that are specified by the *DesiredAccess* parameter are granted on later calls to routines, such as **ZwOpenKeyTransacted** that access the key, or to routines, such as **ZwCreateKeyTransacted,** that create subkeys of the key.

If the kernel-mode caller is not running in a system thread context, it must ensure that any handles it creates are kernel handles. Otherwise, the handle can be accessed by the process in whose context the driver is running. For more information, see Object Handles.

For more information about how to work with registry keys in kernel mode, see Using the Registry in a Driver.

ZwCreateResourceManager function

1/25/2019 • 3 minutes to read • Edit Online

The **ZwCreateResourceManager** routine creates a resource manager object.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwCreateResourceManager(
  PHANDLE            ResourceManagerHandle,
  ACCESS_MASK        DesiredAccess,
  HANDLE             TmHandle,
  LPGUID             ResourceManagerGuid,
  POBJECT_ATTRIBUTES ObjectAttributes,
  ULONG              CreateOptions,
  PUNICODE_STRING    Description
);
```

Parameters

`ResourceManagerHandle`

A pointer to a caller-allocated variable that receives a handle to the new resource manager object if the call to **ZwCreateResourceManager** is successful.

`DesiredAccess`

An ACCESS_MASK value that specifies the caller's requested access to the resource manager object. In addition to the access rights that are defined for all kinds of objects (see **ACCESS_MASK**), the caller can specify any of the following access right flags for resource manager objects:

ACCESS_MASK FLAG	ALLOWS THE CALLER TO
RESOURCEMANAGER_ENLIST	Enlist in transactions (see ZwCreateEnlistment).
RESOURCEMANAGER_GET_NOTIFICATION	Receive notifications about the transactions that are associated with this resource manager (see ZwGetNotificationResourceManager).
RESOURCEMANAGER_REGISTER_PROTOCOL	Not used.
RESOURCEMANAGER_QUERY_INFORMATION	Query information about the resource manager (see ZwQueryInformationResourceManager).
RESOURCEMANAGER_SET_INFORMATION	Not used.
RESOURCEMANAGER_RECOVER	Recover the resource manager (see ZwRecoverResourceManager).
RESOURCEMANAGER_COMPLETE_PROPAGATION	Not used.

Alternatively, you can specify one or more of the following generic ACCESS_MASK flags. (The STANDARD_RIGHTS_*Xxx* flags are predefined system values that are used to enforce security on system objects.)

You can also combine these generic flags with additional flags from the preceding table. The following table shows how generic access rights correspond to specific access rights.

GENERIC ACCESS RIGHT	SET OF SPECIFIC ACCESS RIGHTS
RESOURCEMANAGER_GENERIC_READ	STANDARD_RIGHTS_READ, RESOURCEMANAGER_QUERY_INFORMATION, and SYNCHRONIZE
RESOURCEMANAGER_GENERIC_WRITE	STANDARD_RIGHTS_WRITE, RESOURCEMANAGER_SET_INFORMATION, RESOURCEMANAGER_RECOVER, RESOURCEMANAGER_ENLIST, RESOURCEMANAGER_GET_NOTIFICATION, RESOURCEMANAGER_REGISTER_PROTOCOL, RESOURCEMANAGER_COMPLETE_PROPAGATION, and SYNCHRONIZE
RESOURCEMANAGER_GENERIC_EXECUTE	STANDARD_RIGHTS_EXECUTE, RESOURCEMANAGER_RECOVER, RESOURCEMANAGER_ENLIST, RESOURCEMANAGER_GET_NOTIFICATION, RESOURCEMANAGER_COMPLETE_PROPAGATION, and SYNCHRONIZE
RESOURCEMANAGER_ALL_ACCESS	STANDARD_RIGHTS_REQUIRED, RESOURCEMANAGER_GENERIC_READ, RESOURCEMANAGER_GENERIC_WRITE, and RESOURCEMANAGER_GENERIC_EXECUTE

`TmHandle`

A handle to a transaction manager object that was obtained by a previous all to ZwCreateTransactionManager or ZwOpenTransactionManager.

`ResourceManagerGuid`

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use the InitializeObjectAttributes routine to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**. This parameter is optional and can be **NULL**.

`CreateOptions`

Optional object creation flags. The following table contains the available flags, which are defined in Ktmtypes.h.

CREATEOPTIONS FLAG	MEANING
RESOURCE_MANAGER_COMMUNICATION	For internal use only.
RESOURCE_MANAGER_VOLATILE	The caller will manage volatile resources. It will be non-persistent and will not perform recovery.

This parameter is optional and can be zero.

`Description`

A pointer to a caller-supplied UNICODE_STRING structure that contains a NULL-terminated string. The string

provides a description of the resource manager. KTM stores a copy of the string and includes the string in messages that it writes to the log stream. The maximum string length is MAX_RESOURCEMANAGER_DESCRIPTION_LENGTH. This parameter is optional and can be **NULL**.

Return Value

ZwCreateResourceManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The handle that *TmHandle* specifies is not a handle to a transaction object.
STATUS_INVALID_HANDLE	The handle that *TmHandle* specifies is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the specified transaction manager object.
STATUS_TRANSACTION_OBJECT_EXPIRED	The handle that *TmHandle* specifies is closed.

STATUS_INVALID_PARAMETER	The *CreateOptions*parameter's value is invalid or the *Description* parameter's string is too long.
STATUS_TM_VOLATILE	The *CreateOptions*parameter does not specify RESOURCE_MANAGER_VOLATILE but the transaction manager that *TmHandle* specifies is volatile.
STATUS_OBJECT_NAME_COLLISION	The GUID that *ResourceManagerGuid*specifies already exists.
STATUS_ACCESS_DENIED	The value of the *DesiredAccess* parameter is invalid.

The routine might return other NTSTATUS values.

Remarks

A resource manager that calls **ZwCreateResourceManager** must eventually call ZwClose to close the object handle.

For more information about **ZwCreateResourceManager**, see Creating a Resource Manager.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

ZwCreateSection function

1/25/2019 • 3 minutes to read • Edit Online

The **ZwCreateSection** routine creates a section object.

Syntax

```
NTSYSAPI NTSTATUS ZwCreateSection(
  PHANDLE            SectionHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  PLARGE_INTEGER     MaximumSize,
  ULONG              SectionPageProtection,
  ULONG              AllocationAttributes,
  HANDLE             FileHandle
);
```

Parameters

`SectionHandle`

Pointer to a HANDLE variable that receives a handle to the section object.

`DesiredAccess`

Specifies an ACCESS_MASK value that determines the requested access to the object. In addition to the access rights that are defined for all types of objects (see ACCESS_MASK), the caller can specify any of the following access rights, which are specific to section objects:

***DESIREDACCESS* FLAG**	**ALLOWS CALLER TO DO THIS**
SECTION_EXTEND_SIZE	Dynamically extend the size of the section.
SECTION_MAP_EXECUTE	Execute views of the section.
SECTION_MAP_READ	Read views of the section.
SECTION_MAP_WRITE	Write views of the section.
SECTION_QUERY	Query the section object for information about the section. Drivers should set this flag.
SECTION_ALL_ACCESS	All of the previous flags combined with STANDARD_RIGHTS_REQUIRED.

`ObjectAttributes`

Pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use InitializeObjectAttributes to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**.

`MaximumSize`

Specifies the maximum size, in bytes, of the section. **ZwCreateSection** rounds this value up to the nearest multiple of PAGE_SIZE. If the section is backed by the paging file, *MaximumSize* specifies the actual size of the section. If the section is backed by an ordinary file, *MaximumSize* specifies the maximum size that the file can be extended or mapped to.

`SectionPageProtection`

Specifies the protection to place on each page in the section. Use one of the following four values: PAGE_READONLY, PAGE_READWRITE, PAGE_EXECUTE, or PAGE_WRITECOPY. For a description of these values, see CreateFileMapping.

`AllocationAttributes`

Specifies a bitmask of SEC_*XXX* flags that determines the allocation attributes of the section. For a description of these flags, see CreateFileMapping.

`FileHandle`

Optionally specifies a handle for an open file object. If the value of *FileHandle* is **NULL**, the section is backed by the paging file. Otherwise, the section is backed by the specified file.

Return Value

ZwCreateSection returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure. Possible error status codes include the following:

RETURN CODE	DESCRIPTION
STATUS_FILE_LOCK_CONFLICT	The file specified by the *FileHandle* parameter is locked.
STATUS_INVALID_FILE_FOR_SECTION	The file specified by *FileHandle* does not support sections.

STA TUS _IN VAL ID_ PA GE_ PR OTE CTI ON	The value specified for the *SectionPageProtection* parameter is invalid.
STA TUS _M APP ED_ FILE _SIZ E_Z ERO	The size of the file specified by *FileHandle* is zero, and *MaximumSize* is zero.
STA TUS _SE CTI ON_ TO O_B IG	The value of *MaximumSize* is too big. This occurs when either *MaximumSize* is greater than the system-defined maximum for sections, or if *MaximumSize* is greater than the specified file and the section is not writable.

Remarks

Once the handle pointed to by *SectionHandle* is no longer in use, the driver must call ZwClose to close it.

If the caller is not running in a system thread context, it must ensure that any handles it creates are private handles. Otherwise, the handle can be accessed by the process in whose context the driver is running. For more information, see Object Handles.

For more information about setting up mapped sections and views of memory, see Sections and Views.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtCreateSection**" instead of "**ZwCreateSection**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)

ZwCreateTransaction function

1/25/2019 • 4 minutes to read • Edit Online

The **ZwCreateTransaction** routine creates a transaction object.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwCreateTransaction(
  PHANDLE            TransactionHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  LPGUID             Uow,
  HANDLE             TmHandle,
  ULONG              CreateOptions,
  ULONG              IsolationLevel,
  ULONG              IsolationFlags,
  PLARGE_INTEGER     Timeout,
  PUNICODE_STRING    Description
);
```

Parameters

`TransactionHandle`

A pointer to a caller-allocated variable that receives a handle to the new transaction object, if the call to **ZwCreateTransaction** succeeds.

`DesiredAccess`

An ACCESS_MASK value that specifies the caller's requested access to the transaction object. In addition to the access rights that are defined for all kinds of objects (see ACCESS_MASK), the caller can specify any of the following flags for transaction objects.

ACCESS MASK	ALLOWS THE CALLER TO
TRANSACTION_COMMIT	Commit the transaction (see ZwCommitTransaction).
TRANSACTION_ENLIST	Create an enlistment for the transaction (see ZwCreateEnlistment).
TRANSACTION_PROPAGATE	Do not use.
TRANSACTION_QUERY_INFORMATION	Obtain information about the transaction (see ZwQueryInformationTransaction).
TRANSACTION_ROLLBACK	Roll back the transaction (see ZwRollbackTransaction).
TRANSACTION_SET_INFORMATION	Set information for the transaction (see ZwSetInformationTransaction).

Alternatively, you can specify one or more of the following ACCESS_MASK bitmaps. These bitmaps combine the flags from the previous table with the STANDARD_RIGHTS_*XXX* flags that are described on the ACCESS_MASK reference page. You can also combine these bitmaps with additional flags from the preceding table. The following

table shows how the bitmaps correspond to specific access rights.

RIGHTS BITMAP	SET OF SPECIFIC ACCESS RIGHTS
TRANSACTION_GENERIC_READ	STANDARD_RIGHTS_READ, TRANSACTION_QUERY_INFORMATION, and SYNCHRONIZE
TRANSACTION_GENERIC_WRITE	STANDARD_RIGHTS_WRITE, TRANSACTION_SET_INFORMATION, TRANSACTION_COMMIT, TRANSACTION_ENLIST, TRANSACTION_ROLLBACK, TRANSACTION_PROPAGATE, TRANSACTION_SAVEPOINT, and SYNCHRONIZE
TRANSACTION_GENERIC_EXECUTE	STANDARD_RIGHTS_EXECUTE, TRANSACTION_COMMIT, TRANSACTION_ROLLBACK, and SYNCHRONIZE
TRANSACTION_ALL_ACCESS	STANDARD_RIGHTS_REQUIRED, TRANSACTION_GENERIC_READ, TRANSACTION_GENERIC_WRITE, and TRANSACTION_GENERIC_EXECUTE
TRANSACTION_RESOURCE_MANAGER_RIGHTS	STANDARD_RIGHTS_WRITE, TRANSACTION_GENERIC_READ, TRANSACTION_SET_INFORMATION, TRANSACTION_ENLIST, TRANSACTION_ROLLBACK, TRANSACTION_PROPAGATE, and SYNCHRONIZE

Typically, a resource manager specifies TRANSACTION_RESOURCE_MANAGER_RIGHTS.

The *DesiredAccess* value cannot be zero.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use the InitializeObjectAttributes routine to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**. This parameter is optional and can be **NULL**.

`Uow`

A pointer to a GUID that KTM uses as the new transaction object's unit of work (UOW) identifier. This parameter is optional and can be **NULL**. If this parameter is **NULL**, KTM generates a GUID and assigns it to the transaction object. For more information, see the following Remarks section.

`TmHandle`

A handle to a transaction manager object that was obtained by a previous call to ZwCreateTransactionManager or ZwOpenTransactionManager. KTM assigns the new transaction object to the specified transaction manager object. If this parameter is **NULL**, KTM assigns the new transaction object to a transaction manager later, when a resource manager creates an enlistment for the transaction.

`CreateOptions`

Optional object creation flags. The following table contains the available flags, which are defined in Ktmtypes.h.

OPTION FLAG	MEANING
TRANSACTION_DO_NOT_PROMOTE	Reserved for future use.

`IsolationLevel`

Reserved for future use. Callers must set this parameter to zero.

`IsolationFlags`

Reserved for future use. Callers should set this parameter to zero.

`Timeout`

A pointer to a time-out value. If the transaction has not been committed by the time specified by this parameter, KTM rolls back the transaction. The time-out value is expressed in system time units (100-nanosecond intervals), and can specify either an absolute time or a relative time. If the value pointed to by *Timeout* is negative, the expiration time is relative to the current system time. Otherwise, the expiration time is absolute. This pointer is optional and can be **NULL** if you do not want the transaction to have a time-out value. If *Timeout* = **NULL** or * *Timeout* = 0, the transaction never times out. (You can also use ZwSetInformationTransaction to set a time-out value.)

`Description`

A pointer to a caller-supplied UNICODE_STRING structure that contains a NULL-terminated string. The string provides a description of the transaction. KTM stores a copy of the string and includes the string in messages that it writes to the log stream. The maximum string length is MAX_TRANSACTION_DESCRIPTION_LENGTH. This parameter is optional and can be **NULL**.

Return Value

ZwCreateTransaction returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The *CreateOptions* parameter contains an invalid flag, the *DesiredAccess* parameter is zero, or the *Description* parameter's string is too long.
STATUS_INSUFFICIENT_RESOURCES	KTM could not allocate system resources (typically memory).

STA TUS _IN VAL ID_ ACL	A security descriptor contains an invalid access control list (ACL).
STA TUS _IN VAL ID_S ID	A security descriptor contains an invalid security identifier (SID).
STA TUS _OB JEC T_N AM E_E XIS TS	The object name that the *ObjectAttributes* parameter specifies already exists.
STA TUS _OB JEC T_N AM E_IN VAL ID	The object name that the *ObjectAttributes* parameter specifies is invalid.
STA TUS _AC CES S_D ENI ED	The value of the *DesiredAccess* parameter is invalid.

The routine might return other NTSTATUS values.

Remarks

The caller can use the *Uow* parameter to specify a UOW identifier for the transaction object. If the caller does not specify a UOW identifier, KTM generates a GUID and assigns it to the transaction object. The caller can later obtain this GUID by calling ZwQueryInformationTransaction.

Typically, you should let KTM generate a GUID for the transaction object, unless your component communicates with another TPS component that has already generated a UOW identifier for the transaction.

To close the transaction handle, the component that called **ZwCreateTransaction** must call ZwClose. If the last transaction handle closes before any component calls ZwCommitTransaction for the transaction, KTM rolls back the transaction.

For more information about how transaction clients should use **ZwCreateTransaction**, see Creating a Transactional Client.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ZwCreateTransactionManager function

1/25/2019 • 3 minutes to read • Edit Online

The **ZwCreateTransactionManager** routine creates a new transaction manager object.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwCreateTransactionManager(
  PHANDLE            TmHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  PUNICODE_STRING    LogFileName,
  ULONG              CreateOptions,
  ULONG              CommitStrength
);
```

Parameters

`TmHandle`

A pointer to a caller-allocated variable that receives a handle to the new transaction manager object.

`DesiredAccess`

An ACCESS_MASK value that specifies the caller's requested access to the transaction manager object. In addition to the access rights that are defined for all kinds of objects (see ACCESS_MASK), the caller can specify any of the following access right flags for transaction manager objects.

ACCESS_MASK FLAG	ALLOWS THE CALLER TO
TRANSACTIONMANAGER_CREATE_RM	Create a resource manager (see ZwCreateResourceManager).
TRANSACTIONMANAGER_QUERY_INFORMATION	Obtain information about the transaction manager (see ZwQueryInformationTransactionManager and ZwEnumerateTransactionObject). Also required for ZwOpenResourceManager, ZwCreateTransaction, and ZwOpenTransaction.)
TRANSACTIONMANAGER_RECOVER	Recover the transaction manager (see ZwRecoverTransactionManager and ZwRollforwardTransactionManager).
TRANSACTIONMANAGER_RENAME	Not used.
TRANSACTIONMANAGER_SET_INFORMATION	Not used.

Alternatively, you can specify one or more of the following ACCESS_MASK bitmaps. These bitmaps combine the flags from the previous table with the STANDARD_RIGHTS_*XXX* flags that are described on the **ACCESS_MASK** reference page. You can also combine these bitmaps with additional flags from the preceding table. The following table shows how the bitmaps correspond to specific access rights.

RIGHTS BITMAP	SET OF SPECIFIC ACCESS RIGHTS

TRANSACTIONMANAGER_GENERIC_READ	STANDARD_RIGHTS_READ and TRANSACTIONMANAGER_QUERY_INFORMATION
TRANSACTIONMANAGER_GENERIC_WRITE	STANDARD_RIGHTS_WRITE, TRANSACTIONMANAGER_SET_INFORMATION, TRANSACTIONMANAGER_RECOVER, TRANSACTIONMANAGER_RENAME, and TRANSACTIONMANAGER_CREATE_RM
TRANSACTIONMANAGER_GENERIC_EXECUTE	STANDARD_RIGHTS_EXECUTE
TRANSACTIONMANAGER_ALL_ACCESS	STANDARD_RIGHTS_REQUIRED, TRANSACTIONMANAGER_GENERIC_READ, TRANSACTIONMANAGER_GENERIC_WRITE, and TRANSACTIONMANAGER_GENERIC_EXECUTE

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use the InitializeObjectAttributes routine to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**. This parameter is optional and can be **NULL**.

`LogFileName`

A pointer to a UNICODE_STRING structure that contains the path and file name of a CLFS log file stream to be associated with the transaction manager object. This parameter must be **NULL** if the *CreateOptions* parameter is TRANSACTION_MANAGER_VOLATILE. Otherwise, this parameter must be non-**NULL**. For more information, see the following Remarks section.

`CreateOptions`

Optional object creation flags. The following table contains the available flags, which are defined in Ktmtypes.h.

OPTION FLAG	MEANING
TRANSACTION_MANAGER_VOLATILE	The transaction manager object will be volatile. Therefore, it will not use a log file.
TRANSACTION_MANAGER_COMMIT_DEFAULT	For internal use only.
TRANSACTION_MANAGER_COMMIT_SYSTEM_VOLUME	For internal use only.
TRANSACTION_MANAGER_COMMIT_SYSTEM_HIVES	For internal use only.
TRANSACTION_MANAGER_COMMIT_LOWEST	For internal use only.
TRANSACTION_MANAGER_CORRUPT_FOR_RECOVERY	For internal use only.
TRANSACTION_MANAGER_CORRUPT_FOR_PROGRESS	For internal use only.

`CommitStrength`

Reserved for future use. This parameter must be zero.

Return Value

ZwCreateTransactionManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The value of an input parameter is invalid.
STATUS_INSUFFICIENT_RESOURCES	KTM could not allocate system resources (typically memory).
STATUS_LOG_CORRUPTION_DETECTED	KTM encountered an error while creating or opening the log file.
STATUS_INVALID_ACL	A security descriptor contains an invalid access control list (ACL).
STATUS_INVALID_SID	A security descriptor contains an invalid security identifier (SID).

STATUS_OBJECT_NAME_EXISTS	The object name that the *ObjectAttributes* parameter specifies already exists.
STATUS_OBJECT_NAME_COLLISION	The operating system detected a duplicate object name. The error might indicate that the log stream is already being used.
STATUS_OBJECT_NAME_INVALID	The object name that the *ObjectAttributes* parameter specifies is invalid.
STATUS_ACCESS_DENIED	The value of the *DesiredAccess* parameter is invalid.

The routine might return other NTSTATUS values.

Remarks

If the log file stream that the *LogFileName* parameter specifies does not exist, KTM calls CLFS to create the stream. If the stream already exists, KTM calls CLFS to open the stream.

Your TPS component must call ZwRecoverTransactionManager after it has called **ZwCreateTransactionManager**

If your TPS component specifies the TRANSACTION_MANAGER_VOLATILE flag in the *CreateOptions* parameter, all resource managers that are associated with the transaction manager object must specify the RESOURCE_MANAGER_VOLATILE flag when they call ZwCreateResourceManager.

A TPS component that calls **ZwCreateTransactionManager** must eventually call ZwClose to close the object handle.

For more information about how use **ZwCreateTransactionManager**, see Creating a Resource Manager.

NtCreateTransactionManager and **ZwCreateTransactionManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

ZwDeleteKey function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwDeleteKey** routine deletes an open key from the registry.

Syntax

```
NTSYSAPI NTSTATUS ZwDeleteKey(
  HANDLE KeyHandle
);
```

Parameters

`KeyHandle`

Handle to the registry key to be deleted. The handle is created by a successful call to ZwCreateKey or ZwOpenKey.

Return Value

ZwDeleteKey returns an NTSTATUS value. Possible return values include:

- **STATUS_SUCCESS**
- **STATUS_ACCESS_DENIED**
- **STATUS_INVALID_HANDLE**

Remarks

The handle must have been opened for DELETE access for this routine to succeed. For more information, see the *DesiredAccess* parameter for ZwCreateKey.

A call to **ZwDeleteKey** causes the handle that is specified in the *KeyHandle* parameter—and all other handles to the deleted key—to become invalid. After a call to **ZwDeleteKey** invalidates the key handles, you must call ZwClose to close the key handles.

For more information about working with registry keys, see Using the Registry in a Driver.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtDeleteKey**" instead of "**ZwDeleteKey**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateKey

ZwOpenKey

ZwDeleteValueKey function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwDeleteValueKey** routine deletes a value entry matching a name from an open key in the registry. If no such entry exists, an error is returned.

Syntax

```
NTSYSAPI NTSTATUS ZwDeleteValueKey(
  HANDLE          KeyHandle,
  PUNICODE_STRING ValueName
);
```

Parameters

`KeyHandle`

The handle to the registry key containing the value entry of interest. This key must have been opened with KEY_SET_VALUE set for the desired access. This handle is created by a successful call to ZwCreateKey or ZwOpenKey.

`ValueName`

Pointer to a UNICODE_STRING structure that contains the name of the value entry to delete. This parameter can be an empty string if the value entry has no name.

Return Value

ZwDeleteValueKey returns STATUS_SUCCESS or an appropriate error status representing the final completion status of the operation. Possible error status codes include the following:

RETURN CODE	DESCRIPTION
STATUS_ACCESS_DENIED	The *KeyHandle* handle does not have the KEY_SET_VALUE access.

STATUS_INSUFFICIENT_RESOURCES	Additional resources required by this function were not available.
STATUS_INVALID_HANDLE	The specified *KeyHandle* parameter was a **NULL** pointer or not a valid pointer to an open registry key.
STATUS_OBJECT_NAME_NOT_FOUND	The *ValueName* registry key entry was not found.

Remarks

The *KeyHandle* passed to **ZwDeleteValueKey** must have been opened for delete access to succeed. The *DesiredAccess* values of KEY_SET_VALUE, KEY_WRITE, and KEY_ALL_ACCESS include the KEY_SET_VALUE access mask required for delete access. For a description of possible values for *DesiredAccess*, see ZwCreateKey.

If callback functions are registered for this registry key, then these callback functions will be called.

Device drivers should not attempt to call **ZwDeleteValueKey** directly to delete value entries in a subkey of the **\Registry..\ResourceMap** key. Only the system can write or delete value entries in the **\Registry..\HardwareDescription** tree.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtDeleteValueKey**" instead of "**ZwDeleteValueKey**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Fltkernel.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwCreateKey

ZwDeleteKey

ZwEnumerateValueKey

ZwOpenKey

ZwQueryValueKey

ZwSetValueKey

ZwEnumerateKey function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwEnumerateKey** routine returns information about a subkey of an open registry key.

Syntax

```
NTSYSAPI NTSTATUS ZwEnumerateKey(
  HANDLE                KeyHandle,
  ULONG                 Index,
  KEY_INFORMATION_CLASS KeyInformationClass,
  PVOID                 KeyInformation,
  ULONG                 Length,
  PULONG                ResultLength
);
```

Parameters

`KeyHandle`

Handle to the registry key that contains the subkeys to be enumerated. The handle is created by a successful call to ZwCreateKey or ZwOpenKey.

`Index`

The index of the subkey that you want information for. If the key has *n* subkeys, the subkeys are numbered from 0 to *n*-1.

`KeyInformationClass`

Specifies a KEY_INFORMATION_CLASS enumeration value that determines the type of information to be received by the *KeyInformation* buffer. Set *KeyInformationClass* to one of the following values:

- **KeyBasicInformation**
- **KeyFullInformation**
- **KeyNodeInformation**

If any value not in this list is specified, the routine returns error code STATUS_INVALID_PARAMETER.

`KeyInformation`

Pointer to a caller-allocated buffer that receives the requested information. The *KeyInformationClass* parameter determines the type of information provided.

`Length`

Specifies the size, in bytes, of the *KeyInformation* buffer.

`ResultLength`

Pointer to a variable that receives the size, in bytes, of the registry-key information. If **ZwEnumerateKey** returns STATUS_SUCCESS, you can use the value of this variable to determine the amount of data returned. If the routine returns STATUS_BUFFER_OVERFLOW or STATUS_BUFFER_TOO_SMALL, you can use the value of this variable to determine the size of buffer required to hold the key information.

Return Value

ZwEnumerateKey returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure. Possible error code values include:

RETURN CODE	DESCRIPTION
STATUS_BUFFER_OVERFLOW	The buffer supplied is too small, and only partial data has been written to the buffer. **ResultLength* is set to the minimum size required to hold the requested information.
STATUS_BUFFER_TOO_SMALL	The buffer supplied is too small, and no data has been written to the buffer. **ResultLength* is set to the minimum size required to hold the requested information.
STATUS_INVALID_PARAMETER	The *KeyInformationClass* parameter is not a valid KEY_INFORMATION_CLASS value.
STATUS_NO_MORE_ENTRIES	The *Index* value is out of range for the registry key specified by *KeyHandle*. For example, if a key has *n* subkeys, then for any value greater than *n*-1 the routine returns STATUS_NO_MORE_ENTRIES.

Remarks

The handle must have been opened with KEY_ENUMERATE_SUB_KEYS access. This is accomplished by passing KEY_ENUMERATE_SUB_KEYS, KEY_READ, or KEY_ALL_ACCESS as the *DesiredAccess* parameter to ZwCreateKey or ZwOpenKey.

The *Index* parameter is simply a way to select among subkeys of the key referred to by the *KeyHandle*. Two calls to **ZwEnumerateKey** with the same *Index* are not guaranteed to return the same result.

For more information about working with registry keys, see Using the Registry in a Driver.

Note If the call to this function occurs in user mode, you should use the name "**NtEnumerateKey**" instead of "**ZwEnumerateKey**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

ZwEnumerateTransactionObject function

1/25/2019 • 3 minutes to read • Edit Online

The **ZwEnumerateTransactionObject** routine enumerates the KTM objects on a computer.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwEnumerateTransactionObject(
  HANDLE            RootObjectHandle,
  KTMOBJECT_TYPE    QueryType,
  PKTMOBJECT_CURSOR ObjectCursor,
  ULONG             ObjectCursorLength,
  PULONG            ReturnLength
);
```

Parameters

`RootObjectHandle`

A handle to a KTM object. The routine enumerates the child objects of the specified object. This parameter is optional and can be **NULL**. For more information about valid values for this parameter, see the table in the following Remarks section.

`QueryType`

A KTMOBJECT_TYPE-typed value that identifies the object type to enumerate. For more information about valid values for this parameter, see the table in the following Remarks section.

`ObjectCursor`

A pointer to a caller-allocated buffer that begins with a KTMOBJECT_CURSOR structure. **ZwEnumerateTransactionObject** uses the buffer to store the GUIDs of objects that it finds.

`ObjectCursorLength`

The length, in bytes, of the buffer that *ObjectCursor* points to.

`ReturnLength`

A pointer to a caller-allocated location that receives the number of bytes that **ZwEnumerateTransactionObject** returns in the *ObjectCursor* buffer, including the length of the **KTMOBJECT_CURSOR** structure and the length of all returned GUIDs.

Return Value

ZwEnumerateTransactionObject returns STATUS_SUCCESS if the operation succeeds but the routine has not enumerated all the objects. If there are no more objects to enumerate, the routine returns STATUS_NO_MORE_ENTRIES. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION

STATUS_INVALID_PARAMETER	The *QueryType* or *ObjectCursorLength* parameter's value is invalid.
STATUS_OBJECT_TYPE_MISMATCH	The handle that the *RootObjectHandle* parameter specifies is not a handle to a valid KTM object.
STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the objects that are being enumerated.

The routine might return other NTSTATUS values.

Remarks

The following table contains the valid values for the *RootObjectHandle* and *QueryType* parameters.

***QUERYTYPE* PARAMETER**	***ROOTOBJECTHANDLE* PARAMETER**	**OBJECTS ENUMERATED**
KTMOBJECT_TRANSACTION_MANAGER	**NULL**	All transaction manager objects
KTMOBJECT_RESOURCE_MANAGER	A handle to a transaction manager object. The handle must have TRANSACTIONMANAGER_QUERY_INFORMATION access to the object.	All resource manager objects that belong to the specified transaction manager object

KTMOBJECT_ENLISTMENT	A handle to a resource manager object. The handle must have RESOURCEMANAGER_QUERY_INFORMATION access to the object.	All enlistment objects that belong to the specified resource manager object
KTMOBJECT_TRANSACTION	A handle to a transaction manager object. The handle must have TRANSACTIONMANAGER_QUERY_INFORMATION access to the object.	All transaction objects that belong to the specified transaction manager object
KTMOBJECT_TRANSACTION	**NULL**	All transaction objects that belong to all transaction manager objects

Most TPS components do not have to call **ZwEnumerateTransactionObject**, but the routine might be useful if you have to write a debugging utility.

Before your component calls **ZwEnumerateTransactionObject**, it must allocate and zero the buffer that *ObjectCursor* points to. The buffer's GUID array can be large enough to receive one or more elements.

To enumerate all of the KTM objects of the specified type, your component must call **ZwEnumerateTransactionObject** repeatedly until it returns STATUS_NO_MORE_ENTRIES.

Every time that the routine is called, it fills the buffer's GUID array with as many object GUIDs that will fit. After each call, your component can use the KTMOBJECT_CURSOR structure's **ObjectIdCount** member to determine the number of object GUIDs that the routine stored in the array.

NtEnumerateTransactionObject and **ZwEnumerateTransactionObject** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Examples

The following code example shows how to enumerate all of the transaction objects on a computer. In this example, the **KTMOBJECT_CURSOR** structure's GUID array contains only one element, so each call to **ZwEnumerateTransactionObject** returns one GUID. The routine creates a Unicode string from the GUID and displays the string.

```
NTSTATUS Status;
UNICODE_STRING GuidString;
KTMOBJECT_CURSOR Cursor;
ULONG ReturnedBytes;

RtlZeroMemory(&Cursor, sizeof(Cursor));

do {
    Status = ZwEnumerateTransactionObject(
                                          NULL,
                                          KTMOBJECT_TRANSACTION,
                                          &Cursor,
                                          sizeof(Cursor),
                                          &ReturnedBytes
                                          );

    if (Status != STATUS_NO_MORE_ENTRIES) {
        RtlStringFromGUID(
                          &Cursor.ObjectIds[0],
                          &GuidString
                          );
        OutputMessage(GuidString.Buffer);
        OutputMessage(L"\r\n");
        RtlFreeUnicodeString(&GuidString);
    }
} while (Status == STATUS_SUCCESS);
if (Status == STATUS_NO_MORE_ENTRIES) {
    Status = STATUS_SUCCESS;
}
```

Using Nt and Zw Versions of the Native System Services Routines

ZwEnumerateValueKey function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwEnumerateValueKey** routine gets information about the value entries of an open key.

Syntax

```
NTSYSAPI NTSTATUS ZwEnumerateValueKey(
  HANDLE                      KeyHandle,
  ULONG                       Index,
  KEY_VALUE_INFORMATION_CLASS KeyValueInformationClass,
  PVOID                       KeyValueInformation,
  ULONG                       Length,
  PULONG                      ResultLength
);
```

Parameters

`KeyHandle`

Handle to the registry key that you want to enumerate value entries for. A successful call to ZwCreateKey or ZwOpenKey creates this handle.

`Index`

The zero-based index of the subkey that you want value information for.

`KeyValueInformationClass`

Specifies a KEY_VALUE_INFORMATION_CLASS value that determines the type of information returned in the *KeyValueInformation* buffer.

`KeyValueInformation`

Pointer to a caller-allocated buffer that receives the requested information.

`Length`

Specifies the size, in bytes, of the *KeyValueInformation* buffer.

`ResultLength`

Pointer to a variable that receives the size, in bytes, of the value information. If this routine returns STATUS_SUCCESS, the variable indicates the amount of data returned. If this routine returns STATUS_BUFFER_OVERFLOW or STATUS_BUFFER_TOO_SMALL, the variable indicates the buffer size that is required to hold the value information.

Return Value

ZwEnumerateValueKey returns STATUS_SUCCESS on success, or the appropriate error code on failure. Possible error code values include:

RETURN CODE	DESCRIPTION

STATUS_BUFFER_OVERFLOW	The buffer supplied is too small, and only partial data has been written to the buffer. **ResultLength* is set to the minimum size required to hold the requested information.
STATUS_BUFFER_TOO_SMALL	The buffer supplied is too small, and no data has been written to the buffer. **ResultLength* is set to the minimum size required to hold the requested information.
STATUS_INVALID_PARAMETER	The *KeyInformationClass* parameter is not a valid KEY_VALUE_INFORMATION_CLASS value.
STATUS_NO_MORE_ENTRIES	The *Index* value is out of range for the registry key specified by *KeyHandle*. For example, if a key has *n* subkeys, then for any value greater than *n*-1 the routine returns STATUS_NO_MORE_ENTRIES.

Remarks

The*KeyHandle* passed to **ZwEnumerateValueKey** must have been opened with KEY_QUERY_VALUE access. This is accomplished by passing KEY_QUERY_VALUE, KEY_READ, or KEY_ALL_ACCESS as the *DesiredAccess* parameter to ZwCreateKey or ZwOpenKey.

The *Index* is simply a way to select among subkeys with value entries. Two calls to **ZwEnumerateValueKey** with the same *Index* are not guaranteed to return the same results.

For more information about working with registry keys, see Using the Registry in a Driver.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtEnumerateValueKey**" instead of "**ZwEnumerateValueKey**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the

relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.

ZwQueryValueKey

ZwFlushKey function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwFlushKey** routine forces a registry key to be committed to disk.

Syntax

```
NTSYSAPI NTSTATUS ZwFlushKey(
  HANDLE KeyHandle
);
```

Parameters

`KeyHandle`

Handle to the registry key to be flushed to disk. This handle is created by a successful call to ZwCreateKey or ZwOpenKey.

Return Value

ZwFlushKey returns STATUS_SUCCESS if the key information was transferred to disk, or the appropriate error code on failure.

Remarks

You can flush changes made by ZwCreateKey or ZwSetValueKey by calling **ZwFlushKey**. This routine does not return until all the changed data that is associated with *KeyHandle* has been written to disk. **ZwFlushKey** flushes the entire registry hive for the key, which includes every subkey of the key specified.

> **Note** This routine can flush the entire registry. Accordingly, it can generate a great deal of I/O. Since the system flushes key changes automatically every few seconds, you seldom need to call **ZwFlushKey**.

For more information about working with registry keys, see Using the Registry in a Driver.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtFlushKey**" instead of "**ZwFlushKey**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal

ZwSetValueKey

ZwGetNotificationResourceManager function

1/25/2019 • 3 minutes to read • Edit Online

The **ZwGetNotificationResourceManager** routine retrieves the next transaction notification from a specified resource manager's notification queue.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwGetNotificationResourceManager(
  HANDLE                    ResourceManagerHandle,
  PTRANSACTION_NOTIFICATION TransactionNotification,
  ULONG                     NotificationLength,
  PLARGE_INTEGER            Timeout,
  PULONG                    ReturnLength,
  ULONG                     Asynchronous,
  ULONG_PTR                 AsynchronousContext
);
```

Parameters

`ResourceManagerHandle`

A handle to a resource manager object that was obtained by a previous call to ZwCreateResourceManager or ZwOpenResourceManager. The handle must have RESOURCEMANAGER_GET_NOTIFICATION access to the object.

`TransactionNotification`

A pointer to a caller-allocated buffer that receives information about the retrieved notification. The buffer must be large enough to contain a TRANSACTION_NOTIFICATION structure plus additional notification-specific arguments.

`NotificationLength`

The length, in bytes, of the buffer that the *TransactionNotification*parameter points to.

`Timeout`

A pointer to a value that specifies a relative or absolute time, in units of 100 nanoseconds. This pointer is optional and can be **NULL**.

If the pointer is **NULL**, **ZwGetNotificationResourceManager** does not return until a transaction notification is available. If a time value is specified, **ZwGetNotificationResourceManager** returns when a notification is available or after the specified time elapses, whichever comes first.

A negative value specifies a time that is relative to the current system time. For example, a relative time value of five seconds causes **ZwGetNotificationResourceManager** to time out five seconds after it is called.

A positive value specifies an absolute time, which is actually relative to 00:00, January 1, 1601. If an absolute time value is specified, the operating system adds the absolute time value to the time value that represents 00:00, January 1, 1601.

If the caller specifies a zero value (instead of a **NULL** pointer), **ZwGetNotificationResourceManager** returns immediately, whether a notification is available or not.

`ReturnLength`

An optional pointer to a variable. If this pointer is not **NULL**, and if the *NotificationLength* parameter's value is too small, **ZwGetNotificationResourceManager** supplies the required length in the variable and returns STATUS_BUFFER_TOO_SMALL.

`Asynchronous`

A ULONG value that must be zero. **ZwGetNotificationResourceManager** does not support asynchronous notifications. Use TmEnableCallbacks to enable asynchronous notifications.

`AsynchronousContext`

A pointer to a ULONG value. This pointer must be **NULL**.

Return Value

ZwGetNotificationResourceManager returns STATUS_SUCCESS if the operation succeeds and a notification is available. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_TIMEOUT	The time-out interval that *Timeout* specifies elapsed before a notification became available.
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to a resource manager object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the resource manager object.
STA TUS _BU FFE R_T OO_ SM ALL	The *NotificationLength* parameter's value is too small.

The routine might return other NTSTATUS values.

Remarks

Use the **ZwGetNotificationResourceManager** routine to obtain notifications synchronously. Use the TmEnableCallbacks routine to enable asynchronous notifications.

The received TRANSACTION_NOTIFICATION structure contains the enlistment key that the resource manager specified when it called ZwCreateEnlistment. You can use the enlistment key to identify the enlistment that the notification applies to.

For more information about the **ZwGetNotificationResourceManager** routine, see Creating a Resource Manager.

NtGetNotificationResourceManager and **ZwGetNotificationResourceManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

ZwLoadDriver function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwLoadDriver** routine loads a driver into the system.

Syntax

```
NTSYSAPI NTSTATUS ZwLoadDriver(
  PUNICODE_STRING DriverServiceName
);
```

Parameters

`DriverServiceName`

Pointer to a counted Unicode string that specifies a path to the driver's registry key, \Registry\Machine\System\CurrentControlSet\Services\<*DriverName*>, where <*DriverName*> is the name of the driver.

Return Value

ZwLoadDriver returns STATUS_SUCCESS or an appropriate error NTSTATUS value.

Remarks

ZwLoadDriver dynamically loads a device or file system driver into the currently running system.

> **Note** If the system is running in safe mode, and the driver fails to load because it is not on the safe mode list, **ZwLoadDriver** returns STATUS_SUCCESS.

A minifilter should use FltLoadFilter instead of **ZwLoadDriver** to load a supporting minifilter.

> **Note** If the call to the **ZwLoadDriver** function occurs in user mode, you should use the name "**NtLoadDriver**" instead of "**ZwLoadDriver**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

ZwUnloadDriver

ZwMakeTemporaryObject function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwMakeTemporaryObject** routine changes the attributes of an object to make it temporary.

Syntax

```
NTSYSAPI NTSTATUS ZwMakeTemporaryObject(
  HANDLE Handle
);
```

Parameters

`Handle`

Handle to an object of any type.

Return Value

ZwMakeTemporaryObject returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure.

Remarks

ZwMakeTemporaryObject is a generic routine that operates on any type of object.

An object is permanent if it was created with the OBJ_PERMANENT object attribute specified. (For more information about object attributes, see InitializeObjectAttributes.) A permanent object is created with a reference count of 1, so it is not deleted when a driver dereferences it.

An object is temporary if it is not permanent. **ZwMakeTemporaryObject** turns the specified object into a temporary object. If the object is already temporary, this routine does nothing.

A temporary object has a name only as long as its handle count is greater than zero. When the handle count reaches zero, the system deletes the object name and appropriately adjusts the object's pointer count.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtMakeTemporaryObject**" instead of "**ZwMakeTemporaryObject**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.

ZwCreateFile

ZwMapViewOfSection function

1/25/2019 • 4 minutes to read • Edit Online

The **ZwMapViewOfSection** routine maps a view of a section into the virtual address space of a subject process.

Syntax

```
NTSYSAPI NTSTATUS ZwMapViewOfSection(
  HANDLE          SectionHandle,
  HANDLE          ProcessHandle,
  PVOID           *BaseAddress,
  ULONG_PTR       ZeroBits,
  SIZE_T          CommitSize,
  PLARGE_INTEGER  SectionOffset,
  PSIZE_T         ViewSize,
  SECTION_INHERIT InheritDisposition,
  ULONG           AllocationType,
  ULONG           Win32Protect
);
```

Parameters

`SectionHandle`

Handle to a section object. This handle is created by a successful call to ZwCreateSection or ZwOpenSection.

`ProcessHandle`

Handle to the object that represents the process that the view should be mapped into. Use the ZwCurrentProcess macro to specify the current process. The handle must have been opened with PROCESS_VM_OPERATION access (described in the Microsoft Windows SDK documentation).

`BaseAddress`

Pointer to a variable that receives the base address of the view. If the value of this parameter is not **NULL**, the view is allocated starting at the specified virtual address rounded down to the next 64-kilobyte address boundary.

`ZeroBits`

Specifies the number of high-order address bits that must be zero in the base address of the section view. The value of this parameter must be less than 21 and is used only if *BaseAddress* is **NULL**—in other words, when the caller allows the system to determine where to allocate the view.

`CommitSize`

Specifies the size, in bytes, of the initially committed region of the view. *CommitSize* is meaningful only for page-file backed sections and is rounded up to the nearest multiple of PAGE_SIZE. (For sections that map files, both the data and the image are committed at section-creation time.)

`SectionOffset`

A pointer to a variable that receives the offset, in bytes, from the beginning of the section to the view. If this pointer is not **NULL**, the offset is rounded down to the next allocation-granularity size boundary.

`ViewSize`

A pointer to a SIZE_T variable. If the initial value of this variable is zero, **ZwMapViewOfSection** maps a view of the section that starts at *SectionOffset* and continues to the end of the section. Otherwise, the initial value specifies the view's size, in bytes. **ZwMapViewOfSection** always rounds this value up to the nearest multiple of PAGE_SIZE before mapping the view.

On return, the value receives the actual size, in bytes, of the view.

`InheritDisposition`

Specifies how the view is to be shared with child processes. The possible values are:

ViewShare

The view will be mapped into any child processes that are created in the future.

ViewUnmap

The view will not be mapped into child processes.

Drivers should typically specify **ViewUnmap** for this parameter.

`AllocationType`

Specifies a set of flags that describes the type of allocation to be performed for the specified region of pages. The valid flags are MEM_LARGE_PAGES, MEM_RESERVE, and MEM_TOP_DOWN. Although MEM_COMMIT is not allowed, it is implied unless MEM_RESERVE is specified. For more information about the MEM_*XXX* flags, see the description of the VirtualAlloc routine.

`Win32Protect`

Specifies the type of protection for the region of initially committed pages. Device and intermediate drivers should set this value to PAGE_READWRITE.

Return Value

ZwMapViewOfSection returns an NTSTATUS value. Possible return values include the following:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The routine successfully performed the requested operation.
STATUS_CONFLICTING_ADDRESSES	The specified address range conflicts with an address range already reserved, or the specified cache attribute type conflicts with the address range's existing cache attribute. For example, if the memory being mapped lies within a large page that is already mapped as fully cached, then it is illegal to request to map this memory as noncached or write combined.

STA TUS _IN VAL ID_ PA GE_ PR OTE CTI ON	The value specified for the *Protect* parameter is invalid.
STA TUS _SE CTI ON_ PR OTE CTI ON	The value specified for the *AllocationType* parameter is incompatible with the protection type specified when the section was created.

Remarks

Several different views of a section can be concurrently mapped into the virtual address space of one or more processes.

If the specified section does not exist or the access requested is not allowed, **ZwMapViewOfSection** returns an error.

Do not use **ZwMapViewOfSection** to map a memory range from **\Device\PhysicalMemory** into user mode—unless your driver has directly allocated the memory range through MmAllocatePagesForMdl or another method guaranteeing that no other system component has mapped the same memory range with a different MEMORY_CACHING_TYPE value.

User applications cannot access **\Device\PhysicalMemory** directly starting with Windows Server 2003 with Service Pack 1 (SP1) and can access it only if the driver passes a handle to the application.

For more information about section objects, see Section Objects and Views.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtMapViewOfSection**" instead of "**ZwMapViewOfSection**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

ZwOpenSection

ZwUnmapViewOfSection

ZwOpenEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenEnlistment** routine obtains a handle to an existing enlistment object.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwOpenEnlistment(
  PHANDLE            EnlistmentHandle,
  ACCESS_MASK        DesiredAccess,
  HANDLE             RmHandle,
  LPGUID             EnlistmentGuid,
  POBJECT_ATTRIBUTES ObjectAttributes
);
```

Parameters

`EnlistmentHandle`

A pointer to a caller-allocated variable that receives a handle to an enlistment object if the call to **ZwOpenEnlistment** succeeds.

`DesiredAccess`

An ACCESS_MASK-typed value that specifies the requested access to the enlistment object. For more information about how to specify this parameter, see the *DesiredAccess* parameter of ZwCreateEnlistment. This parameter cannot be zero.

`RmHandle`

`EnlistmentGuid`

A pointer to a GUID that identifies the enlistment. For more information, see the following Remarks section.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object's attributes. Use the InitializeObjectAttributes routine to initialize this structure, but specify only that routine's *InitializedAttributes* and *Attributes* parameters. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE flag in the *Attributes* parameter. This parameter is optional and can be **NULL**.

Return Value

ZwOpenEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION

STATUS_INVALID_HANDLE	The object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the enlistment object.
STATUS_INVALID_PARAMETER	The *DesiredAccess* parameter's value is zero, or the *EnlistmentGuid* parameter's value is **NULL**.
STATUS_ENLISTMENT_NOT_FOUND	The enlistment that the *EnlistmentGuid* parameter specifies does not exist for the resource manager that the *RmHandle* parameter specifies.
STATUS_ACCESS_DENIED	The value of the *DesiredAccess* parameter is invalid.

The routine might return other NTSTATUS values.

Remarks

Typically, a TPS component calls **ZwOpenEnlistment** after it receives an enlistment GUID from another TPS component that had previously called ZwCreateEnlistment. Most TPS designs do not require calling **ZwOpenEnlistment**.

A resource manager that calls **ZwOpenEnlistment** must eventually call ZwClose to close the object handle.

For more information about **ZwOpenEnlistment**, see Enlistment Objects.

NtOpenEnlistment and **ZwOpenEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal

ZwOpenEvent function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenEvent** routine opens a handle to an existing named event object with the specified desired access.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwOpenEvent(
  PHANDLE            EventHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes
);
```

Parameters

`EventHandle`

A pointer to a variable that will receive the event object handle. The handle includes bookkeeping information, such as a reference count and security context.

`DesiredAccess`

The ACCESS_MASK value that represents the desired types of access for the event object. The following table contains the event-specific ACCESS_MASK values.

VALUE	DESIRED ACCESS
EVENT_QUERY_STATE	Query the state of the event object.
EVENT_MODIFY_STATE	Modify the state of the event object.
EVENT_ALL_ACCESS	All possible access rights to the event object.

`ObjectAttributes`

A pointer to the object attributes structure that the caller supplied to be used for the specified object. These attributes would include the **ObjectName** and the handle attributes, for example. This parameter is initialized by calling the InitializeObjectAttributes macro.

Return Value

ZwOpenEvent returns STATUS_SUCCESS or an appropriate error status. This routine might return one of the following error status codes:

RETURN CODE	DESCRIPTION

STATUS_INSUFFICIENT_RESOURCES	Resources that this function requires could not be allocated.
STATUS_INVALID_PARAMETER	The *ObjectAttributes* structure was not supplied or contained an invalid parameter value.
STATUS_OBJECT_NAME_INVALID	The *ObjectAttributes* parameter contained an **ObjectName** in the OBJECT_ATTRIBUTES structure that was invalid.
STATUS_OBJECT_PATH_SYNTAX_BAD	The object path contained incorrect syntax. For example, the *ObjectAttributes* parameter does not contain a **RootDirectory** member, but the **ObjectName** member in the **OBJECT_ATTRIBUTES** structure is an empty string or does not start with an OBJECT_NAME_PATH_SEPARATOR character.
STATUS_OBJECT_PATH_NOT_FOUND	The path to the object was not found, indicating that it does not exist.

STA TUS _OB JEC T_N AM E_N OT_ FOU ND	The object name was not found, indicating that the object does not exist.
STA TUS _PRI VILE GE_ NO T_H ELD	The caller did not have the required privilege to create a handle with the access specified in the *DesiredAccess* parameter.

Remarks

ZwOpenEvent opens an existing named event object and creates a handle to the object with the specified desired access.

ZwOpenEvent can open either notification or synchronization events.

Events are used to coordinate execution. File system drivers can use events to enable a caller to wait for completion of the requested operation until the given event is set to the Signaled state.

Notification events can be used to notify one or more threads of execution that an event has occurred. Synchonization events can be used in the serialization of access to hardware between two otherwise unrelated drivers.

> **Note** If the call to the **ZwOpenEvent** function occurs in user mode, you should use the name "**NtOpenEvent**" instead of "**ZwOpenEvent**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

ZwOpenFile function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenFile** routine opens an existing file, directory, device, or volume.

Syntax

```
NTSYSAPI NTSTATUS ZwOpenFile(
  PHANDLE            FileHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  PIO_STATUS_BLOCK   IoStatusBlock,
  ULONG              ShareAccess,
  ULONG              OpenOptions
);
```

Parameters

`FileHandle`

Pointer to a HANDLE variable that receives a handle to the file.

`DesiredAccess`

Specifies an ACCESS_MASK value that determines the requested access to the object. For more information, see the *DesiredAccess* parameter of ZwCreateFile.

`ObjectAttributes`

Pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use InitializeObjectAttributes to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**.

`IoStatusBlock`

Pointer to an IO_STATUS_BLOCK structure that receives the final completion status and information about the requested operation.

`ShareAccess`

Specifies the type of share access for the file. For more information, see the *ShareAccess* parameter of ZwCreateFile.

`OpenOptions`

Specifies the options to apply when opening the file. For more information, see the *CreateOptions* parameter of ZwCreateFile.

Return Value

ZwOpenFile returns STATUS_SUCCESS or the appropriate NTSTATUS error code. In the latter case, the caller can find more information about the cause of the failure by checking the *IoStatusBlock* parameter.

Remarks

ZwOpenFile supplies a handle that the caller can use to manipulate a file's data, or the file object's state and attributes. **ZwOpenFile** provides a subset of the functionality provided by ZwCreateFile. For more information, see Using Files in a Driver.

Once the handle pointed to by *FileHandle* is no longer in use, the driver must call ZwClose to close it.

If the caller is not running in a system thread context, it must ensure that any handles it creates are private handles. Otherwise, the handle can be accessed by the process in whose context the driver is running. For more information, see Object Handles.

Callers of **ZwOpenFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtOpenFile**" instead of "**ZwOpenFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL (see Remarks section)
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

ACCESS_MASK

InitializeObjectAttributes

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateFile

ZwOpenKey function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenKey** routine opens an existing registry key.

Syntax

```
NTSYSAPI NTSTATUS ZwOpenKey(
  PHANDLE            KeyHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes
);
```

Parameters

`KeyHandle`

Pointer to the HANDLE variable that receives the handle to the key.

`DesiredAccess`

Specifies an ACCESS_MASK value that determines the requested access to the object. For more information, see the *DesiredAccess* parameter of ZwCreateKey.

`ObjectAttributes`

Pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use InitializeObjectAttributes to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**.

Return Value

ZwOpenKey returns STATUS_SUCCESS if the given key was opened. Otherwise, it can return an error status, including the following:

STATUS_INVALID_HANDLE

STATUS_ACCESS_DENIED

Remarks

ZwOpenKey supplies a handle that the caller can use to manipulate a registry key. The routine provides a subset of the functionality of ZwCreateKey. For more information, see Using the Registry in a Driver.

If the specified key does not exist, **ZwOpenKey** returns an error status and does not return a key handle.

Once the handle pointed to by *KeyHandle* is no longer in use, the driver must call ZwClose to close it.

ZwOpenKey ignores the security information in the structure that the *ObjectAttributes* parameter points to.

If the caller is not running in a system thread context, it must ensure that any handles it creates are private handles. Otherwise, the handle can be accessed by the process in whose context the driver is running. For more information, see Object Handles.

For more information about working with registry keys, see Using the Registry in a Driver.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtOpenKey**" instead of "**ZwOpenKey**".

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	IrqlZwPassive, PowerIrpDDis, ZwRegistryOpen, HwStorPortProhibitedDDIs, ZwRegistryCreate, ZwRegistryOpen(storport)

ZwEnumerateKey

ZwEnumerateValueKey

ZwFlushKey

ZwQueryKey

ZwQueryValueKey

ZwSetValueKey

ZwOpenKeyEx function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenKeyEx** routine opens an existing registry key.

Syntax

```
NTSYSAPI NTSTATUS ZwOpenKeyEx(
  PHANDLE            KeyHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  ULONG              OpenOptions
);
```

Parameters

`KeyHandle`

A pointer to a HANDLE variable into which the routine writes the handle to the key.

`DesiredAccess`

Specifies the type of access to the key that the caller requests. This parameter is an ACCESS_MASK value. For more information, see the description of the *DesiredAccess* parameter of the ZwCreateKey routine.

`ObjectAttributes`

A pointer to the object attributes of the key being opened. This parameter points to an OBJECT_ATTRIBUTES structure that must have been previously initialized by the InitializeObjectAttributes routine. The caller must specify the name of the registry key as the *ObjectName* parameter in the call to **InitializeObjectAttributes**. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**.

`OpenOptions`

Specifies the options to apply when opening the key. Set this parameter to zero or to the bitwise OR of one or more of the following REG_OPTION_*XXX* flag bits:

***OPENOPTIONS* FLAG**	**DESCRIPTION**
REG_OPTION_OPEN_LINK	The key is a symbolic link. This flag is not used by device and intermediate drivers.
REG_OPTION_BACKUP_RESTORE	The key should be opened with special privileges that allow backup and restore operations. This flag is not used by device and intermediate drivers.

Return Value

ZwOpenKeyEx returns STATUS_SUCCESS if the call succeeds in opening the key. Possible error return values include the following:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER_4	The *OpenOptions* parameter specifies invalid options.
STATUS_OBJECT_PATH_SYNTAX_BAD	The registry path in the object attributes is invalid.
STATUS_OBJECT_NAME_NOT_FOUND	The registry key name in the object attributes was not found.
STATUS_OBJECT_TYPE_MISMATCH	The named registry key is a symbolic link, but the REG_OPTION_OPEN_LINK flag bit is not set in *OpenOptions*.
STATUS_ACCESS_DENIED	The caller did not have the required access rights to open a handle for the named registry key.

STA **TUS** **_IN** **SUF** **FICI** **ENT** **_RE** **SO** **URC** **ES**	A memory allocation operation failed.

Remarks

This routine supplies a handle with which the caller can access a registry key. If the specified key does not exist, the routine returns an error status value and does not supply a key handle.

The ZwOpenKey routine is similar to **ZwOpenKeyEx** but does not accept an *OpenOptions* parameter. The *OpenOptions* parameter of **ZwOpenKeyEx** enables the caller to open a key that is a symbolic link, or to open a key for backup and restore operations. A call to **ZwOpenKeyEx** with *OpenOptions* = 0 is equivalent to a call to **ZwOpenKey**.

After the handle pointed to by *KeyHandle* is no longer in use, the driver must call ZwClose to close it.

ZwOpenKeyEx ignores the security information in the structure that the *ObjectAttributes* parameter points to.

If the kernel-mode caller is not running in a system thread context, it must ensure that any handles it creates are kernel handles. Otherwise, the handle can be accessed by the process in whose context the driver is running. For more information, see Object Handles.

For more information about working with registry keys in kernel mode, see Using the Registry in a Driver.

Requirements

Minimum supported client	Available in Windows 7 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ACCESS_MASK

InitializeObjectAttributes

OBJECT_ATTRIBUTES

ZwClose

ZwOpenKey

ZwOpenKeyTransacted function

1/25/2019 • 3 minutes to read • Edit Online

The **ZwOpenKeyTransacted** routine opens an existing registry key and associates the key with a transaction.

Syntax

```
NTSYSAPI NTSTATUS ZwOpenKeyTransacted(
  PHANDLE            KeyHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  HANDLE             TransactionHandle
);
```

Parameters

`KeyHandle`

A pointer to a HANDLE variable into which the routine writes the handle to the key.

`DesiredAccess`

Specifies the type of access to the key that the caller requests. This parameter is an ACCESS_MASK value. For more information, see the description of the *DesiredAccess* parameter of the ZwCreateKey routine.

`ObjectAttributes`

A pointer to the object attributes of the key being opened. This parameter points to an OBJECT_ATTRIBUTES structure that must have been previously initialized by the InitializeObjectAttributes routine. The caller must specify the name of the registry key as the *ObjectName* parameter in the call to **InitializeObjectAttributes**. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**.

`TransactionHandle`

A handle to a transaction object. To obtain this handle, you can call the ZwCreateTransaction routine. Or, if you have a pointer to a transaction object, you can supply the pointer to the ObOpenObjectByPointer routine to obtain the corresponding transaction handle.

Return Value

ZwOpenKeyTransacted returns STATUS_SUCCESS if the call successfully opens the key. Possible error return values include the following:

RETURN CODE	DESCRIPTION

STATUS_INVALID_PARAMETER	The *ObjectAttributes* parameter is **NULL** or points to invalid information.
STATUS_OBJECT_PATH_SYNTAX_BAD	The registry path in the object attributes is invalid.
STATUS_OBJECT_NAME_NOT_FOUND	The registry path in the object attributes was not found.
STATUS_ACCESS_DENIED	The caller did not have the required access rights to open a handle for the named registry key.
STATUS_INSUFFICIENT_RESOURCES	A memory allocation operation failed.

Remarks

This routine provides a handle with which the caller can access a registry key. Additionally, this routine associates the key with an active transaction.

After the handle that is pointed to by *KeyHandle* is no longer being used, the driver must call the ZwClose routine to close it.

If the specified key does not exist in the registry, **ZwOpenKeyTransacted** returns an error status value and does not supply a key handle. Unlike the ZwCreateKeyTransacted routine, the **ZwOpenKeyTransacted** routine does not create the specified key if the key does not exist. Both **ZwCreateKeyTransacted** and **ZwOpenKeyTransacted** associate a registry key with a transaction.

The ZwOpenKey routine is similar to **ZwOpenKeyTransacted**, but does not associate a key with a transaction.

After a kernel-mode driver obtains a handle to a transaction (for example, by calling **ZwCreateTransaction**), the driver can perform a series of registry operations that are part of this transaction. The driver can close the transaction either by committing to the changes that were made in the transaction or by rolling back the transaction.

After the driver successfully completes all registry operations that are part of a transaction, it can call the ZwCommitTransaction routine to commit to the changes. The driver can call the ZwRollbackTransaction routine to roll back the transaction.

During a transaction, a registry operation is part of the transaction if the system call that performs the operation meets either of the following conditions:

- The call specifies, as an input parameter, the transaction handle. For example, calls to **ZwCreateKeyTransacted** and **ZwOpenKeyTransacted** can associate one or more keys with the transaction.
- The call specifies, as an input parameter, a registry key handle that was obtained by a call to **ZwCreateKeyTransacted** or **ZwOpenKeyTransacted** to which the transaction handle was supplied. For example, a call to the ZwSetValueKey routine can use a key handle that was obtained in this way to set the value of a registry key as part of a transaction.

For more information about kernel-mode transactions, see Using Kernel Transaction Manager.

ZwOpenKeyTransacted ignores the security information in the structure that the *ObjectAttributes* parameter points to.

If the kernel-mode caller is not running in a system thread context, it must ensure that any handles it creates are kernel handles. Otherwise, the handle can be accessed by the process in whose context the driver is running. For more information, see Object Handles.

For more information about how to work with registry keys in kernel mode, see Using the Registry in a Driver.

Requirements

Minimum supported client	Available in Windows Vista and later versions of the Windows operating system.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

ZwOpenKeyTransactedEx

ZwRollbackTransaction

ZwSetValueKey

ZwOpenKeyTransactedEx function

1/25/2019 • 4 minutes to read • Edit Online

The **ZwOpenKeyTransactedEx** routine opens an existing registry key and associates the key with a transaction.

Syntax

```
NTSYSAPI NTSTATUS ZwOpenKeyTransactedEx(
  PHANDLE            KeyHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  ULONG              OpenOptions,
  HANDLE             TransactionHandle
);
```

Parameters

`KeyHandle`

A pointer to a HANDLE variable into which the routine writes the handle to the key.

`DesiredAccess`

Specifies the type of access to the key that the caller requests. This parameter is an ACCESS_MASK value. For more information, see the description of the *DesiredAccess* parameter of the ZwCreateKey routine.

`ObjectAttributes`

A pointer to the object attributes of the key being opened. This parameter points to an OBJECT_ATTRIBUTES structure that must have been previously initialized by the InitializeObjectAttributes routine. The caller must specify the name of the registry key as the *ObjectName* parameter in the call to **InitializeObjectAttributes**. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**.

`OpenOptions`

Specifies the options to apply when opening the key. Set this parameter to zero or to the bitwise OR of one or more of the following REG_OPTION_*XXX* flag bits.

***OPENOPTIONS* FLAG**	**DESCRIPTION**
REG_OPTION_OPEN_LINK	The key is a symbolic link. This flag is not used by device and intermediate drivers.
REG_OPTION_BACKUP_RESTORE	The key should be opened with special privileges that allow backup and restore operations. This flag is not used by device and intermediate drivers.

`TransactionHandle`

A handle to a transaction object. To obtain this handle, you can call the ZwCreateTransaction routine. Or, if you have a pointer to a transaction object, you can supply the pointer to the ObOpenObjectByPointer routine to obtain the corresponding transaction handle.

Return Value

ZwOpenKeyTransactedEx returns STATUS_SUCCESS if the call successfully opens the key. Possible error return values include the following:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The *ObjectAttributes* parameter is **NULL** or points to invalid information.
STATUS_INVALID_PARAMETER_4	The *OpenOptions* parameter value specifies invalid options.
STATUS_OBJECT_PATH_SYNTAX_BAD	The registry path in the object attributes is invalid.
STATUS_OBJECT_NAME_NOT_FOUND	The registry path in the object attributes was not found.

STA TUS _AC CES S_D ENI ED	The caller did not have the required access rights to open a handle for the named registry key.
STA TUS _IN SUF FICI ENT _RE SO URC ES	A memory allocation operation failed.

Remarks

This routine provides a handle with which the caller can access a registry key. Additionally, this routine associates the key with an active transaction.

After the handle that is pointed to by *KeyHandle* is no longer being used, the driver must call the ZwClose routine to close it.

If the specified key does not exist in the registry, **ZwOpenKeyTransactedEx** returns an error status value and does not supply a key handle. Unlike the ZwCreateKeyTransacted routine, the **ZwOpenKeyTransactedEx** routine does not create the specified key if the key does not exist. Both **ZwCreateKeyTransacted** and **ZwOpenKeyTransactedEx** associate a registry key with a transaction.

The ZwOpenKeyEx routine is similar to **ZwOpenKeyTransactedEx**, but does not associate a key with a transaction.

The ZwOpenKeyTransacted routine is similar to **ZwOpenKeyTransactedEx** but does not accept an *OpenOptions* parameter. The *OpenOptions* parameter of **ZwOpenKeyTransactedEx** enables the caller to open a key that is a symbolic link, or to open a key for backup and restore operations. A call to **ZwOpenKeyTransactedEx** with *OpenOptions* parameter set to zero is equivalent to a call to **ZwOpenKeyTransacted**.

After a kernel-mode driver obtains a handle to a transaction (for example, by calling **ZwCreateTransaction**), the driver can perform a series of registry operations that are part of this transaction. The driver can close the transaction either by committing to the changes that were made in the transaction or by rolling back the transaction.

After the driver successfully completes all registry operations that are part of a transaction, it can call the ZwCommitTransaction routine to commit to the changes. The driver can call the ZwRollbackTransaction routine to roll back the transaction.

During a transaction, a registry operation is part of the transaction if the system call that performs the operation meets either of the following conditions:

- The call specifies, as an input parameter, the transaction handle. For example, calls to **ZwCreateKeyTransacted** and **ZwOpenKeyTransactedEx** can associate one or more keys with the transaction.
- The call specifies, as an input parameter, a registry key handle that was obtained by a call to

ZwCreateKeyTransacted or **ZwOpenKeyTransactedEx** to which the transaction handle was supplied. For example, a call to the ZwSetValueKey routine can use a key handle that was obtained in this way to set the value of a registry key as part of a transaction.

For more information about kernel-mode transactions, see Using Kernel Transaction Manager.

ZwOpenKeyTransactedEx ignores the security information in the structure that the *ObjectAttributes* parameter points to.

If the kernel-mode caller is not running in a system thread context, it must ensure that any handles it creates are kernel handles. Otherwise, the handle can be accessed by the process in whose context the driver is running. For more information, see Object Handles.

For more information about how to work with registry keys in kernel mode, see Using the Registry in a Driver.

Requirements

ZwOpenResourceManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenResourceManager** routine returns a handle to an existing resource manager object.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwOpenResourceManager(
  PHANDLE            ResourceManagerHandle,
  ACCESS_MASK        DesiredAccess,
  HANDLE             TmHandle,
  LPGUID             ResourceManagerGuid,
  POBJECT_ATTRIBUTES ObjectAttributes
);
```

Parameters

`ResourceManagerHandle`

A pointer to a caller-allocated variable that receives the resource manager handle if the call to **ZwOpenResourceManager** succeeds.

`DesiredAccess`

An ACCESS_MASK value that specifies the caller's requested access to the resource manager object. For more information about how to specify this parameter, see the *DesiredAccess* parameter of ZwCreateResourceManager. This parameter cannot be zero.

`TmHandle`

A handle to a transaction manager object that was obtained by a previous call to ZwCreateTransactionManager or ZwOpenTransactionManager.

`ResourceManagerGuid`

A pointer to the GUID that identifies the resource manager to open.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object's attributes. Use the InitializeObjectAttributes routine to initialize this structure, but specify only that routine's *InitializedAttributes* and *Attributes* parameters. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE flag in the *Attributes* parameter. This parameter is optional and can be **NULL**.

Return Value

ZwOpenResourceManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION

STATUS_OBJECT_TYPE_MISMATCH	The handle that *TmHandle* specifies is not a handle to a transaction object.
STATUS_INVALID_HANDLE	The handle that *TmHandle* specifies is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the specified transaction manager object.
STATUS_INVALID_PARAMETER	The *DesiredAccess* parameter is zero or the *ResourceManagerGuid* parameter is invalid.
STATUS_RESOURCEMANAGER_NOT_FOUND	The specified resource manager could not be found.

STA TUS _TR AN SAC TIO NM AN AGE R_N OT_ ON LIN E	The specified transaction manager is not online.

The routine might return other NTSTATUS values.

Remarks

Typically, a TPS component calls **ZwOpenResourceManager** after it receives an enlistment GUID from another TPS component that had previously called ZwCreateResourceManager. Most TPS designs do not require calling **ZwOpenResourceManager**.

A resource manager that calls **ZwOpenResourceManager** must eventually call ZwClose to close the object handle.

For more information about **ZwOpenResourceManager**, see KTM Objects.

NtOpenResourceManager and **ZwOpenResourceManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwOpenSection function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenSection** routine opens a handle for an existing section object.

Syntax

```
NTSYSAPI NTSTATUS ZwOpenSection(
  PHANDLE            SectionHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes
);
```

Parameters

`SectionHandle`

Pointer to a HANDLE variable that receives a handle to the section object.

`DesiredAccess`

Specifies an ACCESS_MASK value that determines the requested access to the object. For more information, see the *DesiredAccess* parameter of ZwCreateSection.

`ObjectAttributes`

Pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use InitializeObjectAttributes to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**.

Return Value

ZwOpenSection returns STATUS_SUCCESS on success, or the appropriate error code on failure. Possible return values include:

Remarks

If the section does not exist or the system did not grant the requested access, the operation fails.

Once the handle pointed to by *SectionHandle* is no longer in use, the driver must call ZwClose to close it.

If the caller is not running in a system thread context, it must ensure that any handles it creates are private handles. Otherwise, the handle can be accessed by the process in whose context the driver is running. For more information, see Object Handles.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtOpenSection**" instead of "**ZwOpenSection**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ZwUnmapViewOfSection

ZwOpenSymbolicLinkObject function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenSymbolicLinkObject** routine opens an existing symbolic link.

Syntax

```
NTSYSAPI NTSTATUS ZwOpenSymbolicLinkObject(
  PHANDLE            LinkHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes
);
```

Parameters

`LinkHandle`

Pointer to a HANDLE variable that receives a handle to the symbolic link object.

`DesiredAccess`

Specifies an ACCESS_MASK value that determines the requested access to the object. The caller usually specified GENERIC_READ, so that the handle can be passed to ZwQuerySymbolicLinkObject.

`ObjectAttributes`

Pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use InitializeObjectAttributes to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**.

Return Value

ZwOpenSymbolicLinkObject returns STATUS_SUCCESS on success or the appropriate error status.

Remarks

Once the handle pointed to by *LinkHandle* is no longer in use, the driver must call ZwClose to close it.

If the caller is not running in a system thread context, it must ensure that any handles it creates are private handles. Otherwise, the handle can be accessed by the process in whose context the driver is running. For more information, see Object Handles.

> **Note** If the call to the **ZwOpenSymbolicLinkObject** function occurs in user mode, you should use the name "NtOpenSymbolicLinkObject" instead of "**ZwOpenSymbolicLinkObject**".

NtOpenSymbolicLinkObject and **ZwOpenSymbolicLinkObject** are two versions of the same Windows Native System Services routine. The **NtOpenSymbolicLinkObject** routine in the Windows kernel is not directly accessible to kernel-mode drivers. However, kernel-mode drivers can access this routine indirectly by calling the **ZwOpenSymbolicLinkObject** routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine

can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.

ACCESS_MASK

InitializeObjectAttributes

Using Nt and Zw Versions of the Native System Services Routines

ZwQuerySymbolicLinkObject

ZwOpenTransaction function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenTransaction** routine obtains a handle to an existing transaction object.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwOpenTransaction(
  PHANDLE            TransactionHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  LPGUID             Uow,
  HANDLE             TmHandle
);
```

Parameters

`TransactionHandle`

A pointer to a caller-allocated variable that receives a handle to the transaction object if **ZwOpenTransaction** returns STATUS_SUCCESS.

`DesiredAccess`

An ACCESS_MASK value that specifies the caller's requested access to the transaction object. For information about how to specify this parameter, see the *DesiredAccess* parameter of ZwCreateTransaction.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object's attributes. Use the InitializeObjectAttributes routine to initialize this structure, but specify only that routine's *InitializedAttributes* and *Attributes* parameters. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE flag in the *Attributes* parameter. The *ObjectAttributes* parameter is optional and can be **NULL**.

`Uow`

A pointer to a GUID that is a transaction object's unit of work (UOW) identifier. This GUID identifies the transaction object to open.

`TmHandle`

A handle to a transaction manager object. If this parameter is not **NULL**, KTM searches only for transaction objects that belong to the specified transaction manager object. If this parameter is **NULL**, KTM searches all transaction objects.

Return Value

ZwCreateTransaction returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION

STATUS_INVALID_PARAMETER	The *DesiredAccess* or *Uow* parameter was zero.
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to a transaction object.
STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_TRANSACTION_NOT_FOUND	KTM could not find the transaction object.
STATUS_ACCESS_DENIED	The value of the *DesiredAccess* parameter is invalid.

The routine might return other NTSTATUS values.

Remarks

Typically, a resource manager calls **ZwOpenTransaction** after it receives a transaction UOW from a transactional

client that had previously called ZwCreateTransaction.

For more information about **ZwOpenTransaction**, see Creating a Resource Manager.

NtOpenTransaction and **ZwOpenTransaction** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

InitializeObjectAttributes

OBJECT_ATTRIBUTES

Using Nt and Zw Versions of the Native System Services Routines

ZwCommitTransaction

ZwCreateTransaction

ZwQueryInformationTransaction

ZwRollbackTransaction

ZwOpenTransactionManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwOpenTransactionManager** routine obtains a handle to an existing transaction manager object.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwOpenTransactionManager(
  PHANDLE            TmHandle,
  ACCESS_MASK        DesiredAccess,
  POBJECT_ATTRIBUTES ObjectAttributes,
  PUNICODE_STRING    LogFileName,
  LPGUID             TmIdentity,
  ULONG              OpenOptions
);
```

Parameters

`TmHandle`

A pointer to a caller-allocated variable that receives a handle to the transaction manager object if **ZwOpenTransactionManager** returns STATUS_SUCCESS.

`DesiredAccess`

An ACCESS_MASK value that specifies the caller's requested access to the transaction manager object. For information about how to specify this parameter, see the *DesiredAccess* parameter of ZwCreateTransactionManager.

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that specifies the object name and other attributes. Use the InitializeObjectAttributes routine to initialize this structure. If the caller is not running in a system thread context, it must set the OBJ_KERNEL_HANDLE attribute when it calls **InitializeObjectAttributes**. This parameter is optional and can be **NULL**.

`LogFileName`

A pointer to a UNICODE_STRING structure that contains the path and file name of the log file stream that was created when the transaction manager object was created. For more information, see the *LogFileName* parameter of **ZwCreateTransactionManager**. This parameter is optional and can be **NULL**.

`TmIdentity`

A pointer to a GUID that identifies the transaction manager object. This parameter is optional and can be **NULL**.

`OpenOptions`

This parameter is not used and must be zero.

Return Value

ZwOpenTransactionManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The value of an input parameter is invalid.
STATUS_INSUFFICIENT_RESOURCES	KTM could not allocate system resources (typically memory).
STATUS_OBJECT_NAME_INVALID	The object name that the *ObjectAttributes* parameter specifies is invalid.
STATUS_LOG_CORRUPTION_DETECTED	KTM encountered an error while creating or opening the log file.
STATUS_ACCESS_DENIED	The value of the *DesiredAccess* parameter is invalid.

The routine might return other NTSTATUS values.

Remarks

The caller can identify which transaction manager object to open by using one of the following three techniques:

- Use the *LogFileName* parameter to specify the path and file name of a log file stream that was created when the transaction manager object was created.
- Use the *TmIdentity* parameter to specify the GUID that identifies the transaction manager object.
- Use the *ObjectAttributes* parameter to supply an OBJECT_ATTRIBUTES structure that contains the object name that the caller previously specified to the ZwCreateTransactionManager routine.

You must specify only one of the above-listed parameters (an object name, a log file name, or a GUID) and set the other two parameters to **NULL**.

Your TPS component must call ZwRecoverTransactionManager after it has called **ZwOpenTransactionManager**.

A TPS component that calls **ZwOpenTransactionManager** must eventually call ZwClose to close the object handle.

For more information about how to use **ZwOpenTransactionManager**, see Transaction Manager Objects and Creating a Resource Manager.

NtOpenTransactionManager and **ZwOpenTransactionManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwQueryInformationTransactionManager

ZwPrepareComplete function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwPrepareComplete** routine notifies KTM that the calling resource manager has finished preparing a transaction's data.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwPrepareComplete(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SUBORDINATE_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwPrepareComplete returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _TR AN SAC TIO N_N OT_ REQ UES TED	The transaction or its enlistment is not in the correct state.
STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

A resource manager must call **ZwPrepareComplete** after it has finished servicing a TRANSACTION_NOTIFY_PREPARE notification.

After a resource manager has called **ZwPrepareComplete**, it cannot roll back the transaction.

For more information about **ZwPrepareComplete**, see Handling Commit Operations.

NtPrepareComplete and **ZwPrepareComplete** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwOpenEnlistment

ZwPrePrepareComplete

ZwPrepareEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwPrepareEnlistment** routine initiates the prepare operation for a specified enlistment's transaction.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwPrepareEnlistment(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The object must represent a superior enlistment and the handle must have ENLISTMENT_SUPERIOR_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwPrepareEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_ENLISTMENT_NOT_SUPERIOR	The caller is not a superior transaction manager for the enlistment.

STATUS_TRANSACTION_RESPONSE_NOT_ENLISTED	The caller did not register to receive TRANSACTION_NOTIFY_PREPARE_COMPLETE notifications.
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the enlistment object.

STA TUS _TR AN SAC TIO N_R EQU EST _NO T_V ALI D	The enlistment's transaction is not in a state that allows it to enter the prepare phase.

The routine might return other NTSTATUS values.

Remarks

Only superior transaction managers can call **ZwPrepareEnlistment**.

The **ZwPrepareEnlistment** routine causes KTM to send TRANSACTION_NOTIFY_PREPARE notifications to all resource managers that have enlisted in the transaction.

Callers of **ZwPrepareEnlistment** must register to receive TRANSACTION_NOTIFY_PREPARE_COMPLETE notifications.

For more information about **ZwPrepareEnlistment**, see Creating a Superior Transaction Manager and Handling Commit Operations.

NtPrePrepareEnlistment and **ZwPrePrepareEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

TmPrepareEnlistment

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwOpenEnlistment

ZwPrePrepareComplete function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwPrePrepareComplete** routine notifies KTM that the calling resource manager has finished preliminary preparation of a transaction's data.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwPrePrepareComplete(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SUBORDINATE_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwPrePrepareComplete returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _TR AN SAC TIO N_N OT_ REQ UES TED	The transaction or its enlistment is not in the correct state.
STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

A resource manager must call **ZwPrePrepareComplete** after it has finished servicing a TRANSACTION_NOTIFY_PREPREPARE notification.

For more information about **ZwPrePrepareComplete**, see Handling Commit Operations.

NtPrePrepareComplete and **ZwPrePrepareComplete** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. ZwOpenEnlistment

ZwPrepareComplete

ZwPrePrepareEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwPrePrepareEnlistment** routine initiates the pre-prepare operation for a specified enlistment's transaction.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwPrePrepareEnlistment(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The object must represent a superior enlistment and the handle must have ENLISTMENT_SUPERIOR_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwPrePrepareEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_ENLISTMENT_NOT_SUPERIOR	The caller is not a superior transaction manager for the enlistment.

STATUS_TRANSACTION_RESPONSE_NOT_ENLISTED	The caller did not register to receive TRANSACTION_NOTIFY_PREPREPARE_COMPLETE notifications.
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the enlistment object.

STA TUS _TR AN SAC TIO N_R EQU EST _NO T_V ALI D	The enlistment's transaction is not in a state that allows it to enter the prepare phase.

The routine might return other NTSTATUS values.

Remarks

Only superior transaction managers can call **ZwPrePrepareEnlistment**.

Callers of **ZwPrePrepareEnlistment** must register to receive TRANSACTION_NOTIFY_PREPREPARE_COMPLETE notifications.

The **ZwPrePrepareEnlistment** routine causes KTM to send TRANSACTION_NOTIFY_PREPREPARE notifications to all resource managers that have enlisted in the transaction.

For more information about **ZwPrePrepareEnlistment**, see Creating a Superior Transaction Manager and Handling Commit Operations.

NtPrepareEnlistment and **ZwPrepareEnlistment** are two versions of the same Windows Native System Services routine.

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwOpenEnlistment

ZwQueryFullAttributesFile function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwQueryFullAttributesFile** routine supplies network open information for the specified file.

Syntax

```
NTSYSAPI NTSTATUS ZwQueryFullAttributesFile(
  POBJECT_ATTRIBUTES            ObjectAttributes,
  PFILE_NETWORK_OPEN_INFORMATION FileInformation
);
```

Parameters

`ObjectAttributes`

A pointer to an OBJECT_ATTRIBUTES structure that supplies the attributes to be used for the file object.

`FileInformation`

A pointer to a FILE_NETWORK_OPEN_INFORMATION structure that receives the returned file attributes information.

Return Value

ZwQueryFullAttributesFile returns STATUS_SUCCESS on success, or the appropriate error status.

Remarks

Callers of **ZwQueryFullAttributesFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

NtQueryFullAttributesFile and **ZwQueryFullAttributesFile** are two versions of the same Windows Native System Services routine. The **NtQueryFullAttributesFile** routine in the Windows kernel is not directly accessible to kernel-mode drivers. However, kernel-mode drivers can access this routine indirectly by calling the **ZwQueryFullAttributesFile** routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows XP.
Target Platform	Universal

Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

FILE_NETWORK_OPEN_INFORMATION

OBJECT_ATTRIBUTES

Using Nt and Zw Versions of the Native System Services Routines

ZwQueryInformationEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwQueryInformationEnlistment** routine retrieves information about a specified enlistment object.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwQueryInformationEnlistment(
  HANDLE                      EnlistmentHandle,
  ENLISTMENT_INFORMATION_CLASS EnlistmentInformationClass,
  PVOID                       EnlistmentInformation,
  ULONG                       EnlistmentInformationLength,
  PULONG                      ReturnLength
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_QUERY_INFORMATION access to the object.

`EnlistmentInformationClass`

An ENLISTMENT_INFORMATION_CLASS-typed enumeration value that specifies the information to be obtained. This value must be one of the following values:

- **EnlistmentBasicInformation**
- **EnlistmentRecoveryInformation**

The enumeration's **EnlistmentFullInformation** value is not used with **ZwQueryInformationEnlistment**.

`EnlistmentInformation`

A pointer to a caller-allocated buffer that receives the information that the *EnlistmentInformationClass*parameter specifies. If the *EnlistmentInformationClass* parameter's value is **EnlistmentBasicInformation**, this buffer's structure type must be ENLISTMENT_BASIC_INFORMATION. If the *EnlistmentInformationClass* parameter's value is **EnlistmentRecoveryInformation**, this buffer's type must match the caller-defined type that the caller used when it called ZwSetInformationEnlistment.

`EnlistmentInformationLength`

The length, in bytes, of the buffer that the *EnlistmentInformation* parameter points to.

`ReturnLength`

A pointer to a caller-allocated variable that receives the length, in bytes, of the information that KTM writes to the *EnlistmentInformation*buffer. This parameter is optional and can be **NULL**.

Return Value

ZwQueryInformationEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.
STATUS_INVALID_INFO_CLASS	The *EnlistmentInformationClass* parameter's value is invalid.
STATUS_INFO_LENGTH_MISMATCH	The *EnlistmentInformationLength* parameter's value is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

A resource manager can call ZwSetInformationEnlistment to set enlistment-specific recovery information for an enlistment object and then call **ZwQueryInformationEnlistment** to retrieve the recovery information.

For more information about **ZwQueryInformationEnlistment**, see Handling Recovery Operations.

Callers of **ZwQueryInformationEnlistment** must be running at IRQL = PASSIVE_LEVEL.

NtQueryInformationEnlistment and **ZwQueryInformationEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwOpenEnlistment

ZwSetInformationEnlistment

ZwQueryInformationFile function

1/25/2019 • 5 minutes to read • Edit Online

The **ZwQueryInformationFile** routine returns various kinds of information about a file object.

Syntax

```
NTSYSAPI NTSTATUS ZwQueryInformationFile(
  HANDLE                 FileHandle,
  PIO_STATUS_BLOCK       IoStatusBlock,
  PVOID                  FileInformation,
  ULONG                  Length,
  FILE_INFORMATION_CLASS FileInformationClass
);
```

Parameters

`FileHandle`

Handle to a file object. The handle is created by a successful call to ZwCreateFile or ZwOpenFile.

`IoStatusBlock`

Pointer to an IO_STATUS_BLOCK structure that receives the final completion status and information about the operation. The **Information** member receives the number of bytes that this routine actually writes to the *FileInformation* buffer.

`FileInformation`

Pointer to a caller-allocated buffer into which the routine writes the requested information about the file object. The *FileInformationClass* parameter specifies the type of information that the caller requests.

`Length`

The size, in bytes, of the buffer pointed to by *FileInformation*.

`FileInformationClass`

Specifies the type of information to be returned about the file, in the buffer that *FileInformation* points to. Device and intermediate drivers can specify any of the following FILE_INFORMATION_CLASS values.

FILE_INFORMATION_CLASS VALUE	TYPE OF INFORMATION RETURNED
FileAccessInformation	A FILE_ACCESS_INFORMATION structure. This structure contains an access mask. For more information about access masks, see ACCESS_MASK.
FileAlignmentInformation	A FILE_ALIGNMENT_INFORMATION structure. The caller can query this information as long as the file is open, without any particular requirements for *DesiredAccess*. This information is useful if the file was opened with the FILE_NO_INTERMEDIATE_BUFFERING flag specified in the *CreateOptions* parameter.

FileAllInformation	A FILE_ALL_INFORMATION structure. By combining several file-information structures into a single structure, **FILE_ALL_INFORMATION** reduces the number of queries required to obtain information about a file.
FileAttributeTagInformation	A FILE_ATTRIBUTE_TAG_INFORMATION structure. The caller must have opened the file with the FILE_READ_ATTRIBUTES flag specified in the *DesiredAccess* parameter.
FileBasicInformation	A FILE_BASIC_INFORMATION structure. The caller must have opened the file with the FILE_READ_ATTRIBUTES flag specified in the *DesiredAccess* parameter.
FileEaInformation	A FILE_EA_INFORMATION structure. This structure specifies the size of the extended attributes block that is associated with the file.
FileInternalInformation	A FILE_INTERNAL_INFORMATION structure. This structure specifies a 64-bit file ID that uniquely identifies a file in NTFS. On other file systems, this file ID is not guaranteed to be unique.
FileIoPriorityHintInformation	A FILE_IO_PRIORITY_HINT_INFORMATION structure. The caller must have opened the file with the FILE_READ_DATA flag specified in the *DesiredAccess* parameter.
FileModeInformation	A FILE_MODE_INFORMATION structure. This structure contains a set of flags that specify the mode in which the file can be accessed. These flags are a subset of the options that can be specified in the *CreateOptions* parameter of the IoCreateFile routine.
FileNameInformation	A FILE_NAME_INFORMATION structure. The structure can contain the file's full path or only a portion of it. The caller can query this information as long as the file is open, without any particular requirements for *DesiredAccess*. For more information about the file-name syntax, see the Remarks section later in this topic.
FileNetworkOpenInformation	A FILE_NETWORK_OPEN_INFORMATION structure. The caller must have opened the file with the FILE_READ_ATTRIBUTES flag specified in the *DesiredAccess* parameter.
FilePositionInformation	A FILE_POSITION_INFORMATION structure. The caller must have opened the file with the *DesiredAccess* FILE_READ_DATA or FILE_WRITE_DATA flag specified in the *DesiredAccess* parameter, and with the FILE_SYNCHRONOUS_IO_ALERT or FILE_SYNCHRONOUS_IO_NONALERT flag specified in the *CreateOptions*parameter.
FileStandardInformation	A FILE_STANDARD_INFORMATION structure. The caller can query this information as long as the file is open, without any particular requirements for *DesiredAccess*.
FileIsRemoteDeviceInformation	A FILE_IS_REMOTE_DEVICE_INFORMATION structure. The caller can query this information as long as the file is open, without any particular requirements for *DesiredAccess*.

Return Value

ZwQueryInformationFile returns STATUS_SUCCESS or an appropriate NTSTATUS error code.

Remarks

ZwQueryInformationFile returns information about the specified file object. Note that it returns zero in any member of a **FILE_*XXX*_INFORMATION** structure that is not supported by a particular device or file system.

When *FileInformationClass* = **FileNameInformation**, the file name is returned in the FILE_NAME_INFORMATION structure. The precise syntax of the file name depends on a number of factors:

- If you opened the file by submitting a full path to ZwCreateFile, **ZwQueryInformationFile** returns that full path.
- If the **ObjectAttributes->RootDirectory** handle was opened by name in a call to **ZwCreateFile**, and subsequently the file was opened by **ZwCreateFile** relative to this root-directory handle, **ZwQueryInformationFile** returns the full path.
- If the **ObjectAttributes->RootDirectory** handle was opened by file ID (using the FILE_OPEN_BY_FILE_ID flag) in a call to **ZwCreateFile**, and subsequently the file was opened by **ZwCreateFile** relative to this root-directory handle, **ZwQueryInformationFile** returns the relative path.
- However, if the user has **SeChangeNotifyPrivilege** (described in the Microsoft Windows SDK documentation), **ZwQueryInformationFile** returns the full path in all cases.
- If only the relative path is returned, the file name string will not begin with a backslash.
- If the full path and file name are returned, the string will begin with a single backslash, regardless of its location. Thus the file C:\dir1\dir2\filename.ext will appear as \dir1\dir2\filename.ext, while the file \server\share\dir1\dir2\filename.ext will appear as \server\share\dir1\dir2\filename.ext.

If **ZwQueryInformationFile** fails because of a buffer overflow, drivers that implement **FileNameInformation** should return as many WCHAR characters of the file name as will fit in the buffer and specify the full length that is required in the *FileNameLength* parameter of the FILE_NAME_INFORMATION structure. You should reissue the query by using the file name length so that you can retrieve the full file name. Drivers that do not follow this pattern might require a gradual increase in length until they retrieve the full file name. For more information about working with files, see Using Files in a Driver.

Callers of **ZwQueryInformationFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtQueryInformationFile**" instead of "**ZwQueryInformationFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL (see Remarks section)
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

ZwQueryInformationResourceManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwQueryInformationResourceManager** routine retrieves information about a specified resource manager object.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwQueryInformationResourceManager(
  HANDLE                            ResourceManagerHandle,
  RESOURCEMANAGER_INFORMATION_CLASS ResourceManagerInformationClass,
  PVOID                             ResourceManagerInformation,
  ULONG                             ResourceManagerInformationLength,
  PULONG                            ReturnLength
);
```

Parameters

`ResourceManagerHandle`

A handle to a resource manager object that was obtained by a previous call to ZwCreateResourceManager or ZwOpenResourceManager. The handle must have RESOURCEMANAGER_QUERY_INFORMATION access to the object.

`ResourceManagerInformationClass`

A RESOURCEMANAGER_INFORMATION_CLASS-typed value that specifies the information to retrieve. This value must be **ResourceManagerBasicInformation**.

`ResourceManagerInformation`

A pointer to a caller-allocated RESOURCEMANAGER_BASIC_INFORMATION structure that receives information from **ZwQueryInformationResourceManager**.

`ResourceManagerInformationLength`

The length, in bytes, of the buffer that the *ResourceManagerInformation* parameter points to.

`ReturnLength`

A pointer to a caller-allocated variable that receives the length, in bytes, of the information that KTM writes to the *ResourceManagerInformation* buffer. This parameter is optional and can be **NULL**.

Return Value

ZwQueryInformationResourceManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION

STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to a resource manager object.
STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_INVALID_INFO_CLASS	The *ResourceManagerInformationClass* parameter's value is invalid.
STATUS_BUFFER_TOO_SMALL	The buffer size that the *ResourceManagerInformationLength* parameter specifies is smaller than the RESOURCEMANAGER_BASIC_INFORMATION structure.
STATUS_BUFFER_OVERFLOW	The buffer size that the *ResourceManagerInformationLength* parameter specifies is too small to receive all the variable-length information that is available.

STA **TUS** **_AC** **CES** **S_D** **ENI** **ED**	The caller does not have appropriate access to the resource manager object.

The routine might return other NTSTATUS values.

Remarks

For more information about the **ZwQueryInformationResourceManager** routine, see Creating a Resource Manager.

NtQueryInformationResourceManager and **ZwQueryInformationResourceManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

ZwQueryInformationTransaction function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwQueryInformationTransaction** routine retrieves information about a specified transaction.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwQueryInformationTransaction(
  HANDLE                        TransactionHandle,
  TRANSACTION_INFORMATION_CLASS TransactionInformationClass,
  PVOID                         TransactionInformation,
  ULONG                         TransactionInformationLength,
  PULONG                        ReturnLength
);
```

Parameters

`TransactionHandle`

A handle to a transaction object that was obtained by a previous call to ZwCreateTransaction or ZwOpenTransaction. The handle must have TRANSACTION_QUERY_INFORMATION access to the object.

`TransactionInformationClass`

A TRANSACTION_INFORMATION_CLASS-typed value that specifies the information to obtain. The value must be one of the following values:

- **TransactionBasicInformation**
- **TransactionPropertiesInformation**
- **TransactionEnlistmentInformation**

The **TransactionFullInformation** value is not used with **ZwQueryInformationTransaction**.

`TransactionInformation`

A pointer to a caller-allocated buffer that receives the information that the *TransactionInformationClass* parameter specifies. The buffer's structure type must be TRANSACTION_BASIC_INFORMATION, TRANSACTION_PROPERTIES_INFORMATION, or TRANSACTION_ENLISTMENTS_INFORMATION.

`TransactionInformationLength`

The length, in bytes, of the buffer that the *TransactionInformation* parameter points to, including the length of any additional array elements that the caller has allocated to receive information.

`ReturnLength`

A pointer to a caller-allocated variable that receives the length, in bytes, of the information that KTM writes to the *TransactionInformation* buffer. This parameter is optional and can be **NULL**.

Return Value

ZwQueryInformationTransaction returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_INFO_CLASS	The *TransactionInformationClass* parameter's value is invalid.
STATUS_INFO_LENGTH_MISMATCH	The length of the buffer that is specified by the *TransactionInformationLength* parameter is incorrect.
STATUS_OBJECT_TYPE_MISMATCH	The handle that the *TransactionHandle*parameter specifies is not a handle to a transaction object.
STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the transaction object.

STA **TUS** **_BU** **FFE** **R_O** **VER** **FLO** **W**	The buffer that the *TransactionInformation*parameter specifies is too small.

The routine might return other NTSTATUS values.

Remarks

For more information about how to use **ZwQueryInformationTransaction**, see Creating a Transactional Client.

NtQueryInformationTransaction and **ZwQueryInformationTransaction** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

ZwQueryInformationTransactionManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwQueryInformationTransactionManager** routine retrieves information about a specified transaction manager object.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwQueryInformationTransactionManager(
  HANDLE                              TransactionManagerHandle,
  TRANSACTIONMANAGER_INFORMATION_CLASS TransactionManagerInformationClass,
  PVOID                               TransactionManagerInformation,
  ULONG                               TransactionManagerInformationLength,
  PULONG                              ReturnLength
);
```

Parameters

`TransactionManagerHandle`

A handle to a transaction manager object that was obtained by a previous call to ZwCreateTransactionManager or ZwOpenTransactionManager. The handle must have TRANSACTIONMANAGER_QUERY_INFORMATION access to the object.

`TransactionManagerInformationClass`

A TRANSACTIONMANAGER_INFORMATION_CLASS-typed enumeration value that specifies the information to be obtained. This value must be one of the following:

- **TransactionManagerBasicInformation**
- **TransactionManagerLogInformation**
- **TransactionManagerLogPathInformation**

The enumeration's **TransactionManagerOnlineProbeInformation** value is not used with **ZwQueryInformationTransactionManager**.

`TransactionManagerInformation`

A pointer to a caller-allocated buffer that receives the information that the *TransactionManagerInformationClass* parameter specifies. The buffer's structure type must be TRANSACTIONMANAGER_BASIC_INFORMATION, TRANSACTIONMANAGER_LOG_INFORMATION, TRANSACTIONMANAGER_LOGPATH_INFORMATION, or TRANSACTIONMANAGER_RECOVERY_INFORMATION.

`TransactionManagerInformationLength`

The length, in bytes, of the buffer that the *TransactionManagerInformation* parameter points to, including the length of any additional array elements that the caller has allocated to receive information.

`ReturnLength`

A pointer to a caller-allocated variable that receives the length, in bytes, of the information that KTM writes to the *TransactionManagerInformation* buffer. This parameter is optional and can be **NULL**.

Return Value

ZwQueryInformationTransactionManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_INFO_CLASS	The *TransactionManagerInformationClass* parameter's value is invalid.
STATUS_INFO_LENGTH_MISMATCH	The length of the buffer that is specified by the *TransactionManagerInformationLength*parameter is incorrect.
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to a transaction manager object.
STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the transaction manager object.

STA **TUS** **_BU** **FFE** **R_T** **OO_** **SM** **ALL**	The buffer that is specified by the *TransactionManagerInformation*parameter is too small.

The routine might return other NTSTATUS values.

Remarks

For more information about how to use **ZwQueryInformationTransactionManager**, see Using Log Streams with KTM.

NtQueryInformationTransactionManager and **ZwQueryInformationTransactionManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

ZwQueryKey function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwQueryKey** routine provides information about the class of a registry key, and the number and sizes of its subkeys.

Syntax

```
NTSYSAPI NTSTATUS ZwQueryKey(
  HANDLE                KeyHandle,
  KEY_INFORMATION_CLASS KeyInformationClass,
  PVOID                 KeyInformation,
  ULONG                 Length,
  PULONG                ResultLength
);
```

Parameters

`KeyHandle`

Handle to the registry key to obtain information about. This handle is created by a successful call to ZwCreateKey or ZwOpenKey.

`KeyInformationClass`

Specifies a KEY_INFORMATION_CLASS value that determines the type of information returned in the *KeyInformation* buffer.

`KeyInformation`

Pointer to a caller-allocated buffer that receives the requested information.

`Length`

Specifies the size, in bytes, of the *KeyInformation* buffer.

`ResultLength`

Pointer to a variable that receives the size, in bytes, of the requested key information. If **ZwQueryKey** returns STATUS_SUCCESS, the variable contains the amount of data returned. If **ZwQueryKey** returns STATUS_BUFFER_OVERFLOW or STATUS_BUFFER_TOO_SMALL, you can use the value of the variable to determine the required buffer size.

Return Value

ZwQueryKey returns STATUS_SUCCESS on success, or the appropriate error code on failure. Possible error code values include:

RETURN CODE	DESCRIPTION

STATUS_BUFFER_OVERFLOW	The buffer supplied is too small, and only partial data has been written to the buffer. **ResultLength* is set to the minimum size required to hold the requested information.
STATUS_BUFFER_TOO_SMALL	The buffer supplied is too small, and no data has been written to the buffer. **ResultLength* is set to the minimum size required to hold the requested information.
STATUS_INVALID_PARAMETER	The *KeyInformationClass* parameter is not a valid KEY_INFORMATION_CLASS value.

Remarks

The*KeyHandle* passed to **ZwQueryKey** must have been opened with KEY_QUERY_VALUE access. This is accomplished by passing KEY_QUERY_VALUE, KEY_READ, or KEY_ALL_ACCESS as the *DesiredAccess* parameter to ZwCreateKey or ZwOpenKey.

> If *KeyInformationClass* is KeyNameInformation or KeyHandleTagsInformation, the KEY_QUERY_VALUE requirement does not apply.

ZwQueryKey can be used to obtain information that you can use to allocate buffers to hold registry data, such as the maximum size of a key's value entries or subkey names, or the number of subkeys. For example, you can call **ZwQueryKey**, use the returned information to allocate a buffer for a subkey, call ZwEnumerateKey to get the name of the subkey, and pass that name to an **Rtl*Xxx*Registry** routine.

For more information about working with registry keys, see Using the Registry in a Driver.

Note If the call to this function occurs in user mode, you should use the name "**NtQueryKey**" instead of "**ZwQueryKey**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwQuerySymbolicLinkObject function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwQuerySymbolicLinkObject** routine returns a Unicode string that contains the target of a symbolic link.

Syntax

```
NTSYSAPI NTSTATUS ZwQuerySymbolicLinkObject(
  HANDLE          LinkHandle,
  PUNICODE_STRING LinkTarget,
  PULONG          ReturnedLength
);
```

Parameters

`LinkHandle`

Handle to the symbolic-link object that you want to query. This handle is created by a successful call to ZwOpenSymbolicLinkObject.

`LinkTarget`

Pointer to an initialized Unicode string that receives the target of the symbolic link.

`ReturnedLength`

contains the maximum number of bytes to copy into the Unicode string at *LinkTarget*. On output, the unsigned long integer contains the length of the Unicode string naming the target of the symbolic link.

Return Value

ZwQuerySymbolicLinkObject returns either STATUS_SUCCESS to indicate the routine completed without error or STATUS_BUFFER_TOO_SMALL if the Unicode string provided at *LinkTarget* is too small to hold the returned string.

Remarks

Before calling this routine, driver writers must ensure that the Unicode string at *LinkTarget*has been properly initialized and a buffer for the string has been allocated. The **MaximumLength** and **Buffer** members of the Unicode string must be set before calling **ZwQuerySymbolicLinkObject** or the call will fail.

If **ZwQuerySymbolicLinkObject** returns STATUS_BUFFER_TOO_SMALL drivers should examine the value returned at *ReturnedLength*. The number returned in this variable indicates the maximum length that the Unicode string for the target of the symbolic link.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtQuerySymbolicLinkObject**" instead of "**ZwQuerySymbolicLinkObject**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System

Services Routines.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

Using Nt and Zw Versions of the Native System Services Routines

ZwOpenSymbolicLinkObject

ZwQueryValueKey function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwQueryValueKey** routine returns a value entry for a registry key.

Syntax

```
NTSYSAPI NTSTATUS ZwQueryValueKey(
  HANDLE                      KeyHandle,
  PUNICODE_STRING             ValueName,
  KEY_VALUE_INFORMATION_CLASS KeyValueInformationClass,
  PVOID                       KeyValueInformation,
  ULONG                       Length,
  PULONG                      ResultLength
);
```

Parameters

`KeyHandle`

Handle to the key to read value entries from. This handle is created by a successful call to ZwCreateKey or ZwOpenKey.

`ValueName`

Pointer to the name of the value entry to obtain data for.

`KeyValueInformationClass`

A KEY_VALUE_INFORMATION_CLASS value that determines the type of information returned in the *KeyValueInformation* buffer.

`KeyValueInformation`

Pointer to a caller-allocated buffer that receives the requested information.

`Length`

Specifies the size, in bytes, of the *KeyValueInformation* buffer.

`ResultLength`

Pointer to a variable that receives the size, in bytes, of the key information. If the **ZwQueryValueKey** routine returns STATUS_SUCCESS, callers can use the value of this variable to determine the amount of data returned. If the routine returns STATUS_BUFFER_OVERFLOW or STATUS_BUFFER_TOO_SMALL, callers can use the value of this variable to determine the size of buffer required to hold the key information.

Return Value

ZwQueryValueKey returns STATUS_SUCCESS on success, or the appropriate error code on failure. Possible error code values include:

RETURN CODE	DESCRIPTION

STATUS_OBJECT_NAME_NOT_FOUND	The registry value was not available.
STATUS_BUFFER_OVERFLOW	The buffer supplied is too small, and only partial data has been written to the buffer. **ResultLength* is set to the minimum size required to hold the requested information.
STATUS_BUFFER_TOO_SMALL	The buffer supplied is too small, and no data has been written to the buffer. **ResultLength* is set to the minimum size required to hold the requested information.
STATUS_INVALID_PARAMETER	The *KeyInformationClass* parameter is not a valid **KEY_VALUE_INFORMATION_CLASS** value. **Warning** If you specify **KeyValueBasicInformation** for *KeyValueInformationClass*, Windows 98 and Windows Me return STATUS_SUCCESS even if the registry key or value name does not exist.

Remarks

The*KeyHandle* passed to **ZwQueryValueKey** must have been opened with KEY_QUERY_VALUE access. This is accomplished by passing KEY_QUERY_VALUE, KEY_READ, or KEY_ALL_ACCESS as the *DesiredAccess* parameter to ZwCreateKey or ZwOpenKey.

For more information about working with registry keys, see Using the Registry in a Driver.

Note If the call to this function occurs in user mode, you should use the name "**NtQueryValueKey**" instead of "**ZwQueryValueKey**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System

Services Routines.

ZwReadFile function

1/25/2019 • 4 minutes to read • Edit Online

The **ZwReadFile** routine reads data from an open file.

Syntax

```
NTSYSAPI NTSTATUS ZwReadFile(
  HANDLE           FileHandle,
  HANDLE           Event,
  PIO_APC_ROUTINE  ApcRoutine,
  PVOID            ApcContext,
  PIO_STATUS_BLOCK IoStatusBlock,
  PVOID            Buffer,
  ULONG            Length,
  PLARGE_INTEGER   ByteOffset,
  PULONG           Key
);
```

Parameters

`FileHandle`

Handle to the file object. This handle is created by a successful call to ZwCreateFile or ZwOpenFile.

`Event`

Optionally, a handle to an event object to set to the signaled state after the read operation completes. Device and intermediate drivers should set this parameter to **NULL**.

`ApcRoutine`

This parameter is reserved. Device and intermediate drivers should set this pointer to **NULL**.

`ApcContext`

This parameter is reserved. Device and intermediate drivers should set this pointer to **NULL**.

`IoStatusBlock`

Pointer to an IO_STATUS_BLOCK structure that receives the final completion status and information about the requested read operation. The **Information** member receives the number of bytes actually read from the file.

`Buffer`

Pointer to a caller-allocated buffer that receives the data read from the file.

`Length`

The size, in bytes, of the buffer pointed to by *Buffer*.

`ByteOffset`

Pointer to a variable that specifies the starting byte offset in the file where the read operation will begin. If an attempt is made to read beyond the end of the file, **ZwReadFile** returns an error.

If the call to ZwCreateFile set either of the **CreateOptions** flags FILE_SYNCHRONOUS_IO_ALERT or

FILE_SYNCHRONOUS_IO_NONALERT, the I/O Manager maintains the current file position. If so, the caller of **ZwReadFile** can specify that the current file position offset be used instead of an explicit **ByteOffset** value. This specification can be made by using one of the following methods:

- Specify a pointer to a LARGE_INTEGER value with the **HighPart** member set to -1 and the **LowPart** member set to the system-defined value FILE_USE_FILE_POINTER_POSITION.
- Pass a **NULL** pointer for *ByteOffset*.

ZwReadFile updates the current file position by adding the number of bytes read when it completes the read operation, if it is using the current file position maintained by the I/O Manager.

Even when the I/O Manager is maintaining the current file position, the caller can reset this position by passing an explicit *ByteOffset* value to **ZwReadFile**. Doing this automatically changes the current file position to that *ByteOffset* value, performs the read operation, and then updates the position according to the number of bytes actually read. This technique gives the caller atomic seek-and-read service.

`Key`

Device and intermediate drivers should set this pointer to **NULL**.

Return Value

ZwReadFile returns either STATUS_SUCCESS or the appropriate NTSTATUS error code.

Remarks

Callers of **ZwReadFile** must have already called ZwCreateFile with the FILE_READ_DATA or GENERIC_READ value set in the *DesiredAccess* parameter.

If the preceding call to ZwCreateFile set the FILE_NO_INTERMEDIATE_BUFFERING flag in the *CreateOptions* parameter to **ZwCreateFile**, the *Length* and *ByteOffset* parameters to **ZwReadFile** must be multiples of the sector size. For more information, see **ZwCreateFile**.

ZwReadFile begins reading from the given *ByteOffset* or the current file position into the given *Buffer*. It terminates the read operation under one of the following conditions:

- The buffer is full because the number of bytes specified by the *Length* parameter has been read. Therefore, no more data can be placed into the buffer without an overflow.
- The end of file is reached during the read operation, so there is no more data in the file to be transferred into the buffer.

If the caller opened the file with the SYNCHRONIZE flag set in *DesiredAccess*, the calling thread can synchronize to the completion of the read operation by waiting on the file handle, *FileHandle*. The handle is signaled each time that an I/O operation that was issued on the handle completes. However, the caller must not wait on a handle that was opened for synchronous file access (FILE_SYNCHRONOUS_IO_NONALERT or FILE_SYNCHRONOUS_IO_ALERT). In this case, **ZwReadFile** waits on behalf of the caller and does not return until the read operation is complete. The caller can safely wait on the file handle only if all three of the following conditions are met:

- The handle was opened for asynchronous access (that is, neither FILE_SYNCHRONOUS_IO_**XXX** flag was specified).
- The handle is being used for only one I/O operation at a time.
- **ZwReadFile** returned STATUS_PENDING.

A driver should call **ZwReadFile** in the context of the system process if any of the following conditions exist:

- The driver created the file handle that it passes to **ZwReadFile**.
- **ZwReadFile** will notify the driver of I/O completion by means of an event that the driver created.
- **ZwReadFile** will notify the driver of I/O completion by means of an APC callback routine that the driver passes to **ZwReadFile**.

File and event handles are valid only in the process context where the handles are created. Therefore, to avoid security holes, the driver should create any file or event handle that it passes to **ZwReadFile** in the context of the system process rather than the context of the process that the driver is in.

Likewise, **ZwReadFile** should be called in the context of the system process if it notifies the driver of I/O completion by means of an APC, because APCs are always fired in the context of the thread that issues the I/O request. If the driver calls **ZwReadFile** in the context of a process other than the system one, the APC could be delayed indefinitely, or it might not fire at all.

For more information about working with files, see Using Files in a Driver.

Callers of **ZwReadFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to this function occurs in user mode, you should use the name "NtReadFile" instead of "**ZwReadFile**".

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ZwReadOnlyEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwReadOnlyEnlistment** routine sets a specified enlistment to be read-only.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwReadOnlyEnlistment(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SUBORDINATE_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwReadOnlyEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _TR AN SAC TIO N_N OT_ REQ UES TED	The transaction or its enlistment is not in the correct state. For example, an enlistment cannot be read-only if the ENLISTMENT_SUPERIOR flag was specified to ZwCreateEnlistment.
STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

Your component cannot call **ZwReadOnlyEnlistment** for a superior enlistment.

For more information about **ZwReadOnlyEnlistment**, see Creating a Read-Only Enlistment.

NtReadOnlyEnlistment and **ZwReadOnlyEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwOpenEnlistment

ZwRecoverEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwRecoverEnlistment** routine initiates a recovery operation for the transaction that is associated with a specified enlistment.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwRecoverEnlistment(
  HANDLE EnlistmentHandle,
  PVOID  EnlistmentKey
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_RECOVER access to the object.

`EnlistmentKey`

A pointer to the enlistment key value that the resource manager previously specified as the *EnlistmentKey* parameter to ZwCreateEnlistment. This parameter is optional and can be **NULL** if the resource manager did not provide an enlistment key when it called **ZwCreateEnlistment**.

Return Value

ZwRecoverEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.

STATUS_INVALID_HANDLE	The object handle is invalid.
STATUS_TRANSACTION_NOT_EQUEST_NOT_VALID	The transaction or its enlistment is not in the correct state.
STATUS_PENDING	KTM has added a commit, rollback, or in-doubt notification to the resource manager's notification queue, and the resource manager is not using a ResourceManagerNotification callback routine.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

After a resource manager calls **ZwRecoverEnlistment**, KTM delivers either a TRANSACTION_NOTIFY_COMMIT, TRANSACTION_NOTIFY_ROLLBACK, or TRANSACTION_NOTIFY_INDOUBT notification for the enlistment. Therefore, unless the resource manager is using a ResourceManagerNotification callback routine, it must immediately call ZwGetNotificationResourceManager if **ZwRecoverEnlistment** returns STATUS_SUCCESS or STATUS_PENDING.

For more information about **ZwRecoverEnlistment**, see Handling Recovery Operations.

NtRecoverEnlistment and **ZwRecoverEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine

can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

TmRecoverEnlistment

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateEnlistment

ZwGetNotificationResourceManager

ZwOpenEnlistment

ZwRecoverResourceManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwRecoverResourceManager** routine tries to recover the transaction that is associated with each enlistment of a specified resource manager object.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwRecoverResourceManager(
  HANDLE ResourceManagerHandle
);
```

Parameters

`ResourceManagerHandle`

A handle to a resource manager object that was obtained by a previous call to ZwCreateResourceManager or ZwOpenResourceManager. The handle must have RESOURCEMANAGER_RECOVER access to the object.

Return Value

ZwRecoverResourceManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to a resource manager object.
STATUS_INVALID_HANDLE	An object handle is invalid.

STATUS_TRANSACTION_NOT_ENLISTED	The transaction manager that is associated with the specified resource manager is not available.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the resource manager object.

The routine might return other NTSTATUS values.

Remarks

When a resource manager calls **ZwRecoverResourceManager**, KTM sends a TRANSACTION_NOTIFY_RECOVER notification to the resource manager for each of the resource manager's enlistments. (If the enlistment is a superior enlistment, KTM sends TRANSACTION_NOTIFY_RECOVER_QUERY instead of TRANSACTION_NOTIFY_RECOVER.)

The final notification that KTM sends to the resource manager is TRANSACTION_NOTIFY_LAST_RECOVER.

For more information about **ZwRecoverResourceManager**, see Handling Recovery Operations.

NtRecoverResourceManager and **ZwRecoverResourceManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)

Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwCreateResourceManager

ZwOpenResourceManager

ZwQueryInformationResourceManager

ZwSetInformationResourceManager

ZwRecoverTransactionManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwRecoverTransactionManager** routine reconstructs the state of the transaction manager object (including all transactions, enlistments, and resource managers) from the recovery information that is in the log stream.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwRecoverTransactionManager(
  HANDLE TransactionManagerHandle
);
```

Parameters

`TransactionManagerHandle`

A handle to a transaction manager object that was obtained by a previous call to ZwCreateTransactionManager or ZwOpenTransactionManager. The handle must have TRANSACTIONMANAGER_RECOVER access to the object.

Return Value

ZwRecoverTransactionManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to a transaction manager object.
STATUS_INVALID_HANDLE	An object handle is invalid.

STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the transaction manager object.
STA TUS _TM _VO LAT ILE	The transaction manager object is volatile and, therefore, its transactions cannot be recovered.
STA TUS _UN SUC CES SFU L	The transaction manager object is not in a state that allows recovery.

The routine might return other NTSTATUS values.

Remarks

The **ZwRecoverTransactionManager** routine tries to reconstruct the state of the transaction manager object, including all transactions, enlistments, and resource managers, from the recovery information that is in the object's log stream, beginning at the last restart area that KTM created and ending at the stream's end.

To recover up to a specific virtual time, use the ZwRollforwardTransactionManager routine instead of **ZwRecoverTransactionManager**.

Your TPS component must call **ZwRecoverTransactionManager** after it has called ZwCreateTransactionManager or ZwOpenTransactionManager.

For more information about recovery operations, see Handling Recovery Operations.

NtRecoverTransactionManager and **ZwRecoverTransactionManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.

Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)
Library	NtosKrnl.lib

ZwRollforwardTransactionManager

ZwRollbackComplete function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwRollbackComplete** routine notifies KTM that the calling resource manager has finished rolling back a transaction's data.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwRollbackComplete(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SUBORDINATE_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwRollbackComplete returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _TR AN SAC TIO N_N OT_ REQ UES TED	The transaction or its enlistment is not in the correct state.
STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

A resource manager must call **ZwRollbackComplete** after it has finished servicing a TRANSACTION_NOTIFY_ROLLBACK notification.

For more information about **ZwRollbackComplete**, see Handling Rollback Operations.

NtRollbackComplete and **ZwRollbackComplete** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

ZwCreateEnlistment

ZwOpenEnlistment

ZwRollbackEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwRollbackEnlistment** routine rolls back the transaction that is associated with a specified enlistment.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwRollbackEnlistment(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SUBORDINATE_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwRollbackEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _TR AN SAC TIO N_R EQU EST _NO T_V ALI D	The enlistment cannot be rolled back.
STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

A resource manager can call **ZwRollbackEnlistment** to roll back a transaction at any time before it calls ZwPrepareComplete.

For more information about **ZwRollbackEnlistment**, see Handling Rollback Operations.

NtRollbackEnlistment and **ZwRollbackEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

ZwCreateEnlistment

ZwOpenEnlistment

ZwPrepareComplete

ZwRollbackTransaction function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwRollbackTransaction** routine initiates a rollback operation for a specified transaction.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwRollbackTransaction(
  HANDLE  TransactionHandle,
  BOOLEAN Wait
);
```

Parameters

`TransactionHandle`

A handle to a transaction object that was obtained by a previous call to ZwCreateTransaction or ZwOpenTransaction. The handle must have TRANSACTION_ROLLBACK access to the object.

`Wait`

A Boolean value that the caller sets to **TRUE** for synchronous operation or **FALSE** for asynchronous operation. If this parameter is set to **TRUE**, the call does not return until the rollback operation is complete.

Return Value

ZwRollbackTransaction returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The handle that the *TransactionHandle* parameter specifies is not a handle to a transaction object.
STATUS_INVALID_HANDLE	An object handle is invalid.

STATUS_ACCESS_DENIED	The caller does not have appropriate access to the transaction object.
STATUS_TRANSACTION_ALREADY_COMMITTED	The transaction cannot be rolled back because it has already been committed.
STATUS_TRANSACTION_NOT_ROLLBACK	The transaction has not been committed but its current state does not permit rollback.
STATUS_PENDING	Rollback notifications have been queued to resource managers, and the caller specified **FALSE** for the *Wait* parameter.

The routine might return other NTSTATUS values.

Remarks

For more information about **ZwRollbackTransaction**, see Handling Rollback Operations.

NtRollbackEnlistment and **ZwRollbackEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

Using Nt and Zw Versions of the Native System Services Routines

ZwCommitTransaction

ZwCreateTransaction

ZwOpenTransaction

ZwQueryInformationTransaction

ZwRollforwardTransactionManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwRollforwardTransactionManager** routine initiates recovery operations for all of the in-progress transactions that are assigned to a specified transaction manager.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwRollforwardTransactionManager(
  HANDLE         TransactionManagerHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`TransactionManagerHandle`

A handle to a transaction manager object that was obtained by a previous call to ZwCreateTransactionManager or ZwOpenTransactionManager. The handle must have TRANSACTIONMANAGER_RECOVER access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**. For more information about this parameter, see the following Remarks section.

Return Value

ZwRollforwardTransactionManager returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to a transaction manager object.

STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the transaction manager object.
STATUS_TM_VOLATILE	The specified transaction manager object does not have a log file, so recovery is not available.
STATUS_UNSUCCESSFUL	The specified transaction manager object is in an unexpected state.

The routine might return other NTSTATUS values.

Remarks

The **ZwRollforwardTransactionManager** routine recovers all logged activity that KTM finds in the transaction manager's log file, up to and including the virtual clock value that the *TmVirtualClock* parameter supplies.

Your component can traverse the log file incrementally by calling **ZwRollforwardTransactionManager** repetitively and setting the *VirtualClock* parameter to a higher value before each call.

If the *TmVirtualClock* parameter is **NULL**, calling **ZwRollforwardTransactionManager** is equivalent to calling ZwRecoverTransactionManager.

For more information about recovery operations, see Handling Recovery Operations.

NtRollforwardTransactionManager and **ZwRollforwardTransactionManager** are two versions of the same Windows Native System Services routine. The **NtRollforwardTransactionManager** routine in the Windows kernel is not directly accessible to kernel-mode drivers. However, kernel-mode drivers can access this routine indirectly by calling the **ZwRollforwardTransactionManager** routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the

relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later versions of Windows.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL
DDI compliance rules	PowerIrpDDis, HwStorPortProhibitedDDIs

Using Nt and Zw Versions of the Native System Services Routines

ZwCreateTransactionManager

ZwOpenTransactionManager

ZwRecoverTransactionManager

ZwSetInformationEnlistment function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwSetInformationEnlistment** routine sets information for a specified enlistment object.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwSetInformationEnlistment(
  HANDLE                      EnlistmentHandle,
  ENLISTMENT_INFORMATION_CLASS EnlistmentInformationClass,
  PVOID                       EnlistmentInformation,
  ULONG                       EnlistmentInformationLength
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SET_INFORMATION access to the object.

`EnlistmentInformationClass`

A ENLISTMENT_INFORMATION_CLASS-typed enumeration value that specifies the type of information to be set. This value must be **EnlistmentRecoveryInformation**.

The enumeration's **EnlistmentBasicInformation** and **EnlistmentFullInformation** values are not used with **ZwSetInformationEnlistment**.

`EnlistmentInformation`

A pointer to a caller-allocated buffer that contains caller-defined recovery information for the enlistment.

`EnlistmentInformationLength`

The length, in bytes, of the buffer that the *EnlistmentInformation* parameter points to.

Return Value

ZwSetInformationEnlistment returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION

STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.
STATUS_INVALID_INFO_CLASS	The *EnlistmentInformationClass* parameter's value is invalid.
STATUS_INFO_LENGTH_MISMATCH	The *EnlistmentInformationLength* parameter's value is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

A resource manager can use the **ZwSetInformationEnlistment** routine to set recovery information for an enlistment. KTM writes the recovery information to the log stream, and the resource manager can call

ZwQueryInformationEnlistment to read this information from the log stream at any time.

Each subsequent call to **ZwSetInformationEnlistment** deletes the recovery information that the previous call specified before it stores the new recovery information.

For more information about how to use **ZwSetInformationEnlistment**, see Using Log Streams with KTM.

NtSetInformationEnlistment and **ZwSetInformationEnlistment** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwCreateEnlistment

ZwOpenEnlistment

ZwQueryInformationEnlistment

ZwSetInformationFile function

1/25/2019 • 4 minutes to read • Edit Online

The **ZwSetInformationFile** routine changes various kinds of information about a file object.

Syntax

```
NTSYSAPI NTSTATUS ZwSetInformationFile(
  HANDLE                 FileHandle,
  PIO_STATUS_BLOCK       IoStatusBlock,
  PVOID                  FileInformation,
  ULONG                  Length,
  FILE_INFORMATION_CLASS FileInformationClass
);
```

Parameters

`FileHandle`

Handle to the file object. This handle is created by a successful call to ZwCreateFile or ZwOpenFile.

`IoStatusBlock`

Pointer to an IO_STATUS_BLOCK structure that receives the final completion status and information about the requested operation. The **Information** member receives the number of bytes set on the file.

`FileInformation`

Pointer to a buffer that contains the information to set for the file. The particular structure in this buffer is determined by the *FileInformationClass* parameter. Setting any member of the structure to zero tells **ZwSetInformationFile** to leave the current information about the file for that member unchanged.

`Length`

The size, in bytes, of the *FileInformation* buffer.

`FileInformationClass`

The type of information, supplied in the buffer pointed to by *FileInformation*, to set for the file. Device and intermediate drivers can specify any of the following FILE_INFORMATION_CLASS values.

***FILEINFORMATIONCLASS* VALUE**	**MEANING**
FileBasicInformation	Change the information that is supplied in a FILE_BASIC_INFORMATION structure. The caller must have opened the file with the FILE_WRITE_ATTRIBUTES flag set in the *DesiredAccess* parameter.
FileDispositionInformation	Usually, sets the **DeleteFile** member of a FILE_DISPOSITION_INFORMATION to **TRUE**, so the file can be deleted when ZwClose is called to release the last open handle to the file object. The caller must have opened the file with the DELETE flag set in the *DesiredAccess* parameter.

FileEndOfFileInformation	Change the current end-of-file information, supplied in a FILE_END_OF_FILE_INFORMATION structure. The operation can either truncate or extend the file. The caller must have opened the file with the FILE_WRITE_DATA flag set in the *DesiredAccess* parameter.
FileIoPriorityHintInformation	Change the current default IRP priority hint for the file handle. The new value is supplied in a FILE_IO_PRIORITY_HINT_INFORMATION structure. **Note** This structure must be 8-byte aligned.
FileLinkInformation	Create a hard link to an existing file, which is specified in a FILE_LINK_INFORMATION structure. Not all file systems support hard links; for example NTFS does while FAT does not.
FilePositionInformation	Change the current file information, which is stored in a FILE_POSITION_INFORMATION structure.
FileRenameInformation	Change the current file name, which is supplied in a FILE_RENAME_INFORMATION structure. The caller must have DELETE access to the file.
FileShortNameInformation	Change the current short file name, which is supplied in a FILE_NAME_INFORMATION structure. The file must be on an NTFS volume, and the caller must have opened the file with the *DesiredAccess* DELETE flag set in the *DesiredAccess* parameter.
FileValidDataLengthInformation	Change the current valid data length for the file, which is supplied in a FILE_VALID_DATA_LENGTH_INFORMATION structure. The file must be on an NTFS volume, and the caller must have opened the file with the FILE_WRITE_DATA flag set in the *DesiredAccess* parameter. Non-administrators and remote users must have the **SeManageVolumePrivilege** privilege.
FileReplaceCompletionInformation	Change or remove the I/O completion port for the specified file handle. The caller supplies a pointer to a FILE_COMPLETION_INFORMATION structure that specifies a port handle and a completion key. If the port handle is non-NULL, this handle specifies a new I/O completion port to associate with the file handle. To remove the I/O completion port associated with the file handle, set the port handle in the structure to NULL. To get a port handle, a user-mode caller can call the CreateIoCompletionPort function.

Return Value

ZwSetInformationFile returns STATUS_SUCCESS or an appropriate error status.

Remarks

ZwSetInformationFile changes information about a file. It ignores any member of a **FILE_*XXX*_INFORMATION** structure that is not supported by a particular device or file system.

If you set *FileInformationClass* to **FileDispositionInformation**, you can subsequently pass *FileHandle* to ZwClose

but not to any other **Zw*Xxx*File** routine. Because **FileDispositionInformation** causes the file to be marked for deletion, it is a programming error to attempt any subsequent operation on the handle other than closing it.

If you set *FileInformationClass* to **FilePositionInformation**, and the preceding call to **ZwCreateFile** included the FILE_NO_INTERMEDIATE_BUFFERING flag in the *CreateOptions* parameter, certain restrictions on the **CurrentByteOffset** member of the FILE_POSITION_INFORMATION structure are enforced. For more information, see ZwCreateFile.

If you set *FileInformationClass* to **FileEndOfFileInformation**, and the **EndOfFile** member of FILE_END_OF_FILE_INFORMATION specifies an offset beyond the current end-of-file mark, **ZwSetInformationFile** extends the file and pads the extension with zeros.

For more information about working with files, see Using Files in a Driver.

Callers of **ZwSetInformationFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to this function occurs in user mode, you should use the name "**NtSetInformationFile**" instead of "**ZwSetInformationFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)

ZwSetInformationResourceManager function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwSetInformationResourceManager** routine is not used.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwSetInformationResourceManager(
  HANDLE                          ResourceManagerHandle,
  RESOURCEMANAGER_INFORMATION_CLASS ResourceManagerInformationClass,
  PVOID                           ResourceManagerInformation,
  ULONG                           ResourceManagerInformationLength
);
```

Parameters

`ResourceManagerHandle`

`ResourceManagerInformationClass`

`ResourceManagerInformation`

`ResourceManagerInformationLength`

Return Value

This function does not return a value.

Remarks

NtSetInformationResourceManager and **ZwSetInformationResourceManager** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Target Platform	Windows

ZwSetInformationTransaction function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwSetInformationTransaction** routine sets information for a specified transaction.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwSetInformationTransaction(
  HANDLE                      TransactionHandle,
  TRANSACTION_INFORMATION_CLASS TransactionInformationClass,
  PVOID                       TransactionInformation,
  ULONG                       TransactionInformationLength
);
```

Parameters

`TransactionHandle`

A handle to a transaction object that was obtained by a previous call to ZwCreateTransaction or ZwOpenTransaction. The handle must have TRANSACTION_SET_INFORMATION access to the object.

`TransactionInformationClass`

A TRANSACTION_INFORMATION_CLASS-typed value that specifies the type of information to set. The value must be **TransactionPropertiesInformation**.

`TransactionInformation`

A pointer to a caller-allocated buffer that contains the information to set. The buffer's structure type must be TRANSACTION_PROPERTIES_INFORMATION.

`TransactionInformationLength`

The length, in bytes, of the buffer that the *TransactionInformation* parameter points to.

Return Value

ZwSetInformationTransaction returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_INVALID_INFO_CLASS	The *TransactionInformationClass* parameter's value is invalid.

STATUS_OBJECT_TYPE_MISMATCH	The handle that the *TransactionHandle* parameter specifies is not a handle to a transaction object.
STATUS_INVALID_HANDLE	An object handle is invalid.
STATUS_ACCESS_DENIED	The caller does not have appropriate access to the transaction object.
STATUS_INFO_LENGTH_MISMATCH	The *TransactionInformationLength*parameter's value is invalid.
STATUS_INVALID_PARAMETER	The contents of the buffer that the *TransactionInformation* buffer specifies is invalid.

The routine might return other NTSTATUS values.

Remarks

For more information about **ZwSetInformationTransaction**, see Creating a Transactional Client.

NtSetInformationTransaction and **ZwSetInformationTransaction** are two versions of the same Windows Native System Services routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

ZwCreateTransaction

ZwOpenTransaction

ZwQueryInformationTransaction

ZwSetValueKey function

1/25/2019 • 3 minutes to read • Edit Online

The **ZwSetValueKey** routine creates or replaces a registry key's value entry.

Syntax

```
NTSYSAPI NTSTATUS ZwSetValueKey(
  HANDLE          KeyHandle,
  PUNICODE_STRING ValueName,
  ULONG           TitleIndex,
  ULONG           Type,
  PVOID           Data,
  ULONG           DataSize
);
```

Parameters

`KeyHandle`

Handle to the registry key to write a value entry for. This handle is created by a successful call to ZwCreateKey or ZwOpenKey.

`ValueName`

Pointer to the name of the value entry for which the data is to be written. This parameter can be a **NULL** pointer if the value entry has no name. If a name string is specified and the given name is not unique relative to its containing key, the data for an existing value entry is replaced.

`TitleIndex`

This parameter is reserved. Device and intermediate drivers should set this parameter to zero.

`Type`

One of the following system-defined types of data to write.

***TYPE* VALUE**	**MEANING**
REG_BINARY	Binary data in any form.
REG_DWORD	A 4-byte numerical value.
REG_DWORD_LITTLE_ENDIAN	A 4-byte numerical value with the least significant byte at the lowest address. Identical to REG_DWORD.
REG_DWORD_BIG_ENDIAN	A 4-byte numerical value with the least significant byte at the highest address.
REG_EXPAND_SZ	A null-terminated Unicode string that contains unexpanded references to environment variables, such as "%PATH%".

REG_LINK	A Unicode string that names a symbolic link. This type is irrelevant to device and intermediate drivers.
REG_MULTI_SZ	An array of null-terminated strings, terminated by another zero.
REG_NONE	Data with no particular type.
REG_SZ	A null-terminated Unicode string.
REG_RESOURCE_LIST	A device driver's list of hardware resources, used by the driver or one of the physical devices it controls, in the **\ResourceMap** tree
REG_RESOURCE_REQUIREMENTS_LIST	A device driver's list of possible hardware resources it or one of the physical devices it controls can use, from which the system writes a subset into the **\ResourceMap** tree
REG_FULL_RESOURCE_DESCRIPTOR	A list of hardware resources that a physical device is using, detected and written into the **\HardwareDescription** tree by the system

Note Device drivers should not attempt to call **ZwSetValueKey** to explicitly write value entries in a subkey of the **\Registry...\ResourceMap** key. Only the system can write value entries to the **\Registry...\HardwareDescription** tree.

`Data`

Pointer to a caller-allocated buffer that contains the data for the value entry.

`DataSize`

Specifies the size, in bytes, of the *Data* buffer. If *Type* is REG_*XXX*_SZ, this value must include space for any terminating zeros.

Return Value

ZwSetValueKey returns an NTSTATUS value. Possible return values include:

Remarks

The*KeyHandle* passed to **ZwSetValueKey** must have been opened with the KEY_SET_VALUE *DesiredAccess* flag set for this call to succeed. For a description of possible values for *DesiredAccess*, see ZwCreateKey.

If the given key has no existing value entry with a name matching the given *ValueName*, **ZwSetValueKey** creates a new value entry with the given name. If a matching value entry name exists, this routine overwrites the original value entry for the given *ValueName*. Thus, **ZwSetValueKey** preserves a unique name for each value entry of any particular key. While each value entry name must be unique to its containing key, many different keys in the registry can have value entries with the same names.

For more information about working with registry keys, see Using the Registry in a Driver.

Note If the call to this function occurs in user mode, you should use the name "NtSetValueKey" instead of "**ZwSetValueKey**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the

relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwSinglePhaseReject function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwSinglePhaseReject** routine informs KTM that the calling resource manager will not support single-phase commit operations for a specified enlistment.

Syntax

```
NTSYSCALLAPI NTSTATUS ZwSinglePhaseReject(
  HANDLE         EnlistmentHandle,
  PLARGE_INTEGER TmVirtualClock
);
```

Parameters

`EnlistmentHandle`

A handle to an enlistment object that was obtained by a previous call to ZwCreateEnlistment or ZwOpenEnlistment. The handle must have ENLISTMENT_SUBORDINATE_RIGHTS access to the object.

`TmVirtualClock`

A pointer to a virtual clock value. This parameter is optional and can be **NULL**.

Return Value

ZwSinglePhaseReject returns STATUS_SUCCESS if the operation succeeds. Otherwise, this routine might return one of the following values:

RETURN CODE	DESCRIPTION
STATUS_OBJECT_TYPE_MISMATCH	The specified handle is not a handle to an enlistment object.
STATUS_INVALID_HANDLE	The object handle is invalid.

STA TUS _TR AN SAC TIO N_N OT_ REQ UES TED	The transaction or its enlistment is not in the correct state.
STA TUS _AC CES S_D ENI ED	The caller does not have appropriate access to the enlistment object.

The routine might return other NTSTATUS values.

Remarks

A resource manager can call **ZwSinglePhaseReject** when it receives a TRANSACTION_NOTIFY_SINGLE_PHASE_COMMIT notification.

For more information about **ZwSinglePhaseReject**, see Handling Commit Operations.

NtSinglePhaseReject and **ZwSinglePhaseReject** are two versions of the same Windows Native System Services routine. The **NtSinglePhaseReject** routine in the Windows kernel is not directly accessible to kernel-mode drivers. However, kernel-mode drivers can access this routine indirectly by calling the **ZwSinglePhaseReject** routine.

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	Available in Windows Vista and later operating system versions.
Target Platform	Universal
Header	wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe

ZwOpenEnlistment

ZwUnloadDriver function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwUnloadDriver** routine unloads a driver from the system.
*Use this routine with extreme caution. (See the following***Remarks***section.)*

Syntax

```
NTSYSAPI NTSTATUS ZwUnloadDriver(
  PUNICODE_STRING DriverServiceName
);
```

Parameters

`DriverServiceName`

Pointer to a counted Unicode string that specifies a path to the driver's registry key, **\Registry\Machine\System\CurrentControlSet\Services*DriverName*, where *DriverName* is the name of the driver.**

Return Value

ZwUnloadDriver returns STATUS_SUCCESS or an error NTSTATUS value such as STATUS_INVALID_DEVICE_REQUEST.

Remarks

ZwUnloadDriver dynamically unloads a device or file system driver from the currently running system.

Note that a file system filter driver cannot safely be unloaded from a running system. Thus a filter should only use
ZwUnloadDriverfor debugging purposes. It should not call this routine in a retail version of the filter.

If *DriverName* is the name of a PnP device driver, ZwUnloadDriver returns STATUS_INVALID_DEVICE_REQUEST and does not unload the driver.

A minifilter should use FltUnloadFilter instead of ZwUnloadDriver to unload a supporting minifilter.

> **Note If the call to the ZwUnloadDriver function occurs in user mode, you should use the name "NtUnloadDriver" instead of "ZwUnloadDriver".**

For calls from kernel-mode drivers, the Nt*Xxx* and Zw*Xxx* versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the Nt*Xxx* and Zw*Xxx* versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

Minimum supported client	**Available in Windows XP and later versions of Windows.**
Target Platform	**Universal**
Header	**wdm.h (include Wdm.h, Ntddk.h, Ntifs.h)**
Library	**NtosKrnl.lib**

ZwUnmapViewOfSection function

1/25/2019 • 2 minutes to read • Edit Online

The **ZwUnmapViewOfSection** routine unmaps a view of a section from the virtual address space of a subject process.

Syntax

```
NTSYSAPI NTSTATUS ZwUnmapViewOfSection(
  HANDLE ProcessHandle,
  PVOID  BaseAddress
);
```

Parameters

`ProcessHandle`

Handle to a process object that was previously passed to ZwMapViewOfSection.

`BaseAddress`

Pointer to the base virtual address of the view to unmap. This value can be any virtual address within the view.

Return Value

ZwUnmapViewOfSection returns an NTSTATUS value. Possible return values include:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The routine successfully performed the requested operation.
STATUS_ACCESS_DENIED	The caller does not have access rights to the process object or to the base virtual address of the view.

Remarks

This routine unmaps the entire view of the section that contains *BaseAddress* from the virtual address space of the specified process—even if *BaseAddress* does not point to the beginning of the view.

On return from **ZwUnmapViewOfSection**, the virtual-address region occupied by the view is no longer reserved and is available to map other views or private pages. If the view was also the last reference to the underlying

section, all committed pages in the section are decommitted, and the section is deleted.

> **Note** If the call to this function occurs in user mode, you should use the name "NtUnmapViewOfSection" instead of "**ZwUnmapViewOfSection**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

Requirements

ZwMapViewOfSection

ZwOpenSection

ZwWriteFile function

1/25/2019 • 5 minutes to read • Edit Online

The **ZwWriteFile** routine writes data to an open file.

Syntax

```
NTSYSAPI NTSTATUS ZwWriteFile(
  HANDLE           FileHandle,
  HANDLE           Event,
  PIO_APC_ROUTINE  ApcRoutine,
  PVOID            ApcContext,
  PIO_STATUS_BLOCK IoStatusBlock,
  PVOID            Buffer,
  ULONG            Length,
  PLARGE_INTEGER   ByteOffset,
  PULONG           Key
);
```

Parameters

`FileHandle`

Handle to the file object. This handle is created by a successful call to ZwCreateFile or ZwOpenFile.

`Event`

Optionally, a handle to an event object to set to the signaled state after the write operation completes. Device and intermediate drivers should set this parameter to **NULL**.

`ApcRoutine`

This parameter is reserved. Device and intermediate drivers should set this pointer to **NULL**.

`ApcContext`

This parameter is reserved. Device and intermediate drivers should set this pointer to **NULL**.

`IoStatusBlock`

Pointer to an IO_STATUS_BLOCK structure that receives the final completion status and information about the requested write operation. The **Information** member receives the number of bytes actually written to the file.

`Buffer`

Pointer to a caller-allocated buffer that contains the data to write to the file.

`Length`

The size, in bytes, of the buffer pointed to by *Buffer*.

`ByteOffset`

Pointer to a variable that specifies the starting byte offset in the file for beginning the write operation. If *Length* and *ByteOffset* specify a write operation past the current end-of-file mark, **ZwWriteFile** automatically extends the file and updates the end-of-file mark; any bytes that are not explicitly written between such old and new end-of-file

marks are defined to be zero.

If the call to ZwCreateFile set only the *DesiredAccess* flag FILE_APPEND_DATA, *ByteOffset* is ignored. Data in the given *Buffer*, for *Length* bytes, is written starting at the current end of file.

If the call to ZwCreateFile set either of the *CreateOptions* flags, FILE_SYNCHRONOUS_IO_ALERT or FILE_SYNCHRONOUS_IO_NONALERT, the I/O Manager maintains the current file position. If so, the caller of **ZwWriteFile** can specify that the current file position offset be used instead of an explicit *ByteOffset* value. This specification can be made by using one of the following methods:

- Specify a pointer to a LARGE_INTEGER value with the **HighPart** member set to -1 and the **LowPart** member set to the system-defined value FILE_USE_FILE_POINTER_POSITION.
- Pass a **NULL** pointer for *ByteOffset*.

ZwWriteFile updates the current file position by adding the number of bytes written when it completes the write operation, if it is using the current file position maintained by the I/O Manager.

Even when the I/O Manager is maintaining the current file position, the caller can reset this position by passing an explicit *ByteOffset* value to **ZwWriteFile**. Doing this automatically changes the current file position to that *ByteOffset*value, performs the write operation, and then updates the position according to the number of bytes actually written. This technique gives the caller atomic seek-and-write service.

It is also possible to cause a write operation to start at the current end of file by specifying for *ByteOffset* a pointer to a LARGE_INTEGER value with **HighPart** set to -1 and **LowPart** set to FILE_WRITE_TO_END_OF_FILE. This works regardless of whether the I/O Manager is maintaining the current file position.

`Key`

Device and intermediate drivers should set this pointer to **NULL**.

Return Value

ZwWriteFile returns STATUS_SUCCESS on success or the appropriate NTSTATUS error code on failure.

Remarks

Callers of **ZwWriteFile** must have already called ZwCreateFile with the FILE_WRITE_DATA, FILE_APPEND_DATA, or GENERIC_WRITE flag set in the *DesiredAccess* parameter. Note that having only FILE_APPEND_DATA access to a file does not allow the caller to write anywhere in the file except at the current end-of-file mark, while having FILE_WRITE_DATA access to a file does not preclude the caller from writing to or beyond the end of a file.

If the preceding call to ZwCreateFile set the *CreateOptions* flag FILE_NO_INTERMEDIATE_BUFFERING, the *Length* and *ByteOffset* parameters to **ZwWriteFile** must be an integral of the sector size. For more information, see **ZwCreateFile**.

ZwWriteFile begins the write operation to the file at *ByteOffset*, at the current file position, or at the end-of-file mark. It terminates the write operation when it has written *Length* bytes from *Buffer*. If necessary, it extends the length of the file and resets the end-of-file mark.

If the caller opened the file with the *DesiredAccess* SYNCHRONIZE flag set, the caller can wait for this routine to set the given *FileHandle* to the signaled state.

Drivers should call **ZwWriteFile** in the context of the system process in three cases:

1. The driver creates the file handle that it passes to **ZwWriteFile**.
2. **ZwWriteFile** notifies the driver of I/O completion by means of an event created by the driver.

3. **ZwWriteFile** notifies the driver of I/O completion by means of an APC callback routine that the driver passes to **ZwWriteFile**.

File and event handles are only valid in the process context where the handles are created. Therefore, to avoid security holes, the driver should create any file or event handle that it passes to **ZwWriteFile** in the context of the system process instead of the process context that the driver is in.

Likewise, **ZwWriteFile** should be called in the context of the system process if it notifies the driver of I/O completion by means of an APC, because APCs are always fired in the context of the thread issuing the I/O request. If the driver calls **ZwWriteFile** in the context of a process other than the system process, the APC could be delayed indefinitely, or it might not fire at all as the originating thread may never enter an alertable wait state.

For more information about working with files, see Using Files in a Driver.

Callers of **ZwWriteFile** must be running at IRQL = PASSIVE_LEVEL and with special kernel APCs enabled.

> **Note** If the call to this function occurs in user mode, you should use the name "NtWriteFile" instead of "**ZwWriteFile**".

For calls from kernel-mode drivers, the **Nt*Xxx*** and **Zw*Xxx*** versions of a Windows Native System Services routine can behave differently in the way that they handle and interpret input parameters. For more information about the relationship between the **Nt*Xxx*** and **Zw*Xxx*** versions of a routine, see Using Nt and Zw Versions of the Native System Services Routines.

wdmsec.h header

1/8/2019 • 2 minutes to read • Edit Online

This header header exposes security routines for kernel-mode drivers. They are used to create the device object with a security descriptor. Do not use the functions in this header directly, instead use:

- **IoCreateDeviceSecure**
- **IoValidateDeviceIoControlAccess**
- **RtlInitUnicodeString** wdmsec.h contains the following programming interfaces:

Functions

TITLE	DESCRIPTION
WdmlibIoCreateDeviceSecure	The WdmlibIoCreateDeviceSecure function (or IoCreateDeviceSecure) creates a named device object and applies the specified security settings.
WdmlibIoValidateDeviceIoControlAccess	The WdmlibIoValidateDeviceIoControlAccess function verifies that the sender of an IRP_MJ_DEVICE_CONTROL or IRP_MJ_FILE_SYSTEM_CONTROL IRP has the specified access to the device object.
WdmlibRtlInitUnicodeStringEx	The WdmlibRtlInitUnicodeStringEx function initializes a counted string of Unicode characters.

WdmlibIoCreateDeviceSecure function

1/25/2019 • 4 minutes to read • Edit Online

The **WdmlibIoCreateDeviceSecure** function (or **IoCreateDeviceSecure**) creates a named device object and applies the specified security settings.

Syntax

```
NTSTATUS WdmlibIoCreateDeviceSecure(
  PDRIVER_OBJECT   DriverObject,
  ULONG            DeviceExtensionSize,
  PUNICODE_STRING  DeviceName,
  DEVICE_TYPE      DeviceType,
  ULONG            DeviceCharacteristics,
  BOOLEAN          Exclusive,
  PCUNICODE_STRING DefaultSDDLString,
  LPCGUID          DeviceClassGuid,
  PDEVICE_OBJECT   *DeviceObject
);
```

Parameters

`DriverObject`

Pointer to the driver object for the caller. Each driver receives a pointer to its driver object in a parameter to its DriverEntry routine. WDM function and filter drivers also receive a driver object pointer in their AddDevice routines.

`DeviceExtensionSize`

Specifies the driver-determined number of bytes to be allocated for the device extension of the device object. The internal structure of the device extension is driver-defined.

`DeviceName`

Optionally points to a buffer that contains a null-terminated Unicode string that names the device object. The string must be a full path name. If a name is not supplied, the FILE_AUTOGENERATED_DEVICE_NAME flag must be present in the *DeviceCharacteristics* parameter. (To create an unnamed device object, use the IoCreateDevice routine.)

`DeviceType`

Specifies one of the system-defined FILE_DEVICE_*XXX* constants that indicate the type of device (such as FILE_DEVICE_DISK, FILE_DEVICE_KEYBOARD, and so on), or a vendor-defined value for a new type of device. For more information, see Specifying Device Types. (Because a bus driver might not have information about a device's type, a device type value for a PDO can be specified in an INF AddReg directive.)

`DeviceCharacteristics`

Specifies one or more system-defined constants, ORed together, that provide additional information about the driver's device. For a list of possible device characteristics, see DEVICE_OBJECT. For more information about how to specify device characteristics, see Specifying Device Characteristics. Most drivers specify FILE_DEVICE_SECURE_OPEN for this parameter.

`Exclusive`

Specifies if the device object represents an *exclusive device*. Most drivers set this value to **FALSE**. For more information, see Specifying Exclusive Access to Device Objects.

`DefaultSDDLString`

Specifies a string representation for the default security settings of the device object. The security that is applied to the device object is derived from this string unless the system administrator places an override in the section of the registry identified by the *DeviceClassGuid* parameter.

The security setting is specified in a subset of Security Descriptor Definition Language (SDDL). A set of predefined constants (SDDL_DEVOBJ_*XXX*) are also provided. For more information, see Securing Device Objects.

`DeviceClassGuid`

Pointer to a GUID that identifies a section of the registry containing possible overrides for the *DefaultSDDLString*, *DeviceType*, *DeviceCharacteristics*, and *Exclusive* parameters.

> **Note** You should always specify a custom class GUID. You should not specify an existing class GUID. If you specify an existing class GUID, other drivers that attempt to specify that existing class GUID might fail to install or might install with incorrect security settings.

`DeviceObject`

Pointer to a variable that receives a pointer to the newly created DEVICE_OBJECT structure. The **DEVICE_OBJECT** structure is allocated from nonpaged pool.

Return Value

WdmlibIoCreateDeviceSecure returns STATUS_SUCCESS on success, or the appropriate NTSTATUS error code on failure. A partial list of the failure codes that could be returned by this function include:

Remarks

WdmlibIoCreateDeviceSecure creates a named device object, applies the specified security settings, and returns a pointer to the object. The caller is responsible for deleting the object when it is no longer needed by calling IoDeleteDevice.

This routine is not part of the operating system. Drivers can use the routine by linking to Wdmsec.lib on Microsoft Windows 2000 and later versions of Windows. (The Wdmsec.lib library first shipped with the Microsoft Windows XP Service Pack 1 [SP1] and Windows Server 2003 editions of the Driver Development Kit [DDK] and also ships with the Windows Driver Kit [WDK].)

Any driver that creates a named device object which is not guaranteed to have its security descriptor set by the INF file must use **WdmlibIoCreateDeviceSecure**. For more information, see Creating a Device Object. The caller is responsible for setting certain members of the returned device object. For more information, see Initializing a Device Object and the device-type-specific documentation for your device.

Be careful to specify the *DeviceType* and *DeviceCharacteristics* values in the correct parameters. Both parameters use system-defined FILE_*XXX* constants and some driver writers specify the values in the wrong parameters by mistake.

The caller is responsible for setting certain fields in the returned device object, such as the **Flags** field, and for initializing the device extension with any driver-defined information. For other operations that are required on new device objects, see Initializing a Device Object and the device-type-specific documentation for your device.

The GUID specified by the *DeviceClassGuid* parameter determines the device setup class for the device object. (For more information about device setup classes, see Device Setup Classes.) Callers must provide a value so that system administrators can change the security settings for the device (for instance, to deny access to certain users). For more information, see Setting Device Object Registry Properties After Installation.

Non-WDM drivers specify a new GUID, one not already in use by an existing device setup class. Generate a new GUID by using the GuidGen.exe tool that is included in the Microsoft Windows SDK.

WDM bus drivers that handle raw-mode capable devices can specify the device setup class of the device, but only if that class is guaranteed to already have been created. Otherwise, create a new GUID.

Device objects for disks, tapes, CD-ROMs, and RAM disks are given a Volume Parameter Block (VPB) that is initialized to indicate that the volume has never been mounted on the device.

If a driver's call to **WdmlibIoCreateDeviceSecure** returns an error, the driver should release any resources that it allocated for that device.

Requirements

Minimum supported client	See Remarks section.
Target Platform	Desktop
Header	wdmsec.h (include Wdmsec.h)
Library	Wdmsec.lib
IRQL	PASSIVE_LEVEL
DDI compliance rules	MiniportOnlyWdmDevice, HwStorPortProhibitedDDIs

IoAttachDevice

IoAttachDeviceToDeviceStack

IoCreateDevice

IoCreateSymbolicLink

IoDeleteDevice

WdmlibIoValidateDeviceIoControlAccess function

1/25/2019 • 2 minutes to read • Edit Online

The **WdmlibIoValidateDeviceIoControlAccess** function verifies that the sender of an IRP_MJ_DEVICE_CONTROL or IRP_MJ_FILE_SYSTEM_CONTROL IRP has the specified access to the device object.

Syntax

```
NTSTATUS WdmlibIoValidateDeviceIoControlAccess(
  PIRP  Irp,
  ULONG RequiredAccess
);
```

Parameters

`Irp`

Specifies the IRP on which to perform the access check.

`RequiredAccess`

Specifies the type of access to the device object that the request sender must have. The caller can specify one or more of the following flags.

VALUE	MEANING
FILE_READ_ACCESS	The request sender must have read access to the device object
FILE_WRITE_ACCESS	The request sender must have write access to the device object.

Return Value

WdmlibIoValidateDeviceIoControlAccess returns an NTSTATUS value. Possible return values include:

RETURN CODE	DESCRIPTION

STATUS_SUCCESS	The request sender has the necessary access to the device object.
STATUS_ACCESS_DENIED	The request sender does not have the necessary access to the device object.
STATUS_INVALID_PARAMETER	The specified parameters are invalid. For example, if the routine is passed an IRP that is not an **IRP_MJ_DEVICE_CONTROL** or **IRP_MJ_FILE_SYSTEM_CONTROL** IRP, it returns STATUS_INVALID_PARAMETER.

Remarks

WdmlibIoValidateDeviceIoControlAccess allows drivers to perform dynamic access checks for IOCTLs. Use this routine to require more restrictive access than that specified in the IOCTL's definition. If the routine returns STATUS_ACCESS_DENIED, then the driver can complete the request with the STATUS_ACCESS_DENIED status value.

For example, if an IOCTL is defined with a *RequiredAccess* value of FILE_ANY_ACCESS, then by default any request sender with SYNCHRONIZE access to the device object can send the IOCTL. Use **WdmlibIoValidateDeviceIoControlAccess** to require more stringent security at run time. For more information about the *RequiredAccess* value of an IOCTL, see Defining I/O Control Codes.

The access checks are only performed if the **RequestorMode** member of the IRP structure is **UserMode**. If **RequestorMode** is **KernelMode**, the routine automatically returns STATUS_SUCCESS.

Requirements

Minimum supported client	Available in Windows Server 2003 and later versions of Windows. Drivers that must also work for Windows 2000 and Windows XP can instead link to Wdmsec.lib to use this routine. (The Wdmsec.lib library first shipped with the Windows XP Service Pack 1 [SP1] and Windows Server 2003 editions of the Driver Development Kit [DDK] and now ships with the Windows Driver Kit [WDK].)
Target Platform	Universal

Header	wdmsec.h (include Wdmsec.h, Wdm.h, Ntddk.h, Ntifs.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level

IRP

WdmlibRtlInitUnicodeStringEx function

1/25/2019 • 2 minutes to read • Edit Online

The **WdmlibRtlInitUnicodeStringEx** function initializes a counted string of Unicode characters.

Syntax

```
NTSTATUS WdmlibRtlInitUnicodeStringEx(
  PUNICODE_STRING DestinationString,
  PCWSTR          SourceString
);
```

Parameters

`DestinationString`

A pointer to the UNICODE_STRING structure to be initialized.

`SourceString`

A pointer to a null-terminated wide-character string. This string is used to initialize the counted string pointed to by *DestinationString*.

Return Value

None

Remarks

The routine copies the *SourceString* pointer value to the **Buffer** member of the UNICODE_STRING structure pointed to by *DestinationString*. The **Length** member of this structure is set to the length, in bytes, of the source string, excluding the terminating null. The **MaximumLength** member of the structure is set to the length, in bytes, of the source string, including the terminating null. If *SourceString* is **NULL**, **Length** and **MaximumLength** are both set to zero.

WdmlibRtlInitUnicodeStringEx does not alter the source string pointed to by *SourceString*.

> **Note** If the source string is longer than MAX_USTRING - 1 bytes, **WdmlibRtlInitUnicodeStringEx** sets the **Length** member of the **UNICODE_STRING** structure pointed to by *DestinationString* to MAX_USTRING - 2, and sets the **MaximumLength** member of this structure to MAX_USTRING. In this case, the **Length** and **MaximumLength** values misrepresent the length of the null-terminated source string, and relying on the accuracy of these values is potentially dangerous.

Callers of **WdmlibRtlInitUnicodeStringEx** can be running at IRQL <= DISPATCH_LEVEL if the *DestinationString* buffer is nonpageable. Usually, callers run at IRQL = PASSIVE_LEVEL because most other **Rtl*Xxx*String** routines cannot be called at IRQL > PASSIVE_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

wmidata.h header

1/8/2019 • 2 minutes to read • Edit Online

This header is used in providing kernel-mode Windows Management Instrumentation (WMI) extensions to WDM. For more information, see:

- Implementing WMI wmidata.h contains the following programming interfaces:

Structures

TITLE	DESCRIPTION
WMI_CHANGER_PROBLEM_DEVICE_ERROR	When the ChangerPerformDiagnostics routine performs diagnostic tests on a changer device it returns the results in a WMI_CHANGER_PROBLEM_DEVICE_ERROR structure.

wmilib.h header

1/8/2019 • 2 minutes to read • Edit Online

TThis header is used in providing kernel-mode Windows Management Instrumentation (WMI) extensions to WDM.

Drivers can use these routines in processing WMI IRPs.

- **WmiCompleteRequest**
- **WmiSystemControl**

To handle WMI IRPs by calling WmiSystemControl, a driver must implement certain required callback routines, for information, see Calling WmiSystemControl to Handle WMI IRPs

For more information, see:

- Implementing WMI wmilib.h contains the following programming interfaces:

Functions

TITLE	DESCRIPTION
WmiCompleteRequest	The WmiCompleteRequest routine indicates that a driver has finished processing a WMI request in a DpWmiXxx routine.
WmiFireEvent	The WmiFireEvent routine sends an event to WMI for delivery to data consumers that have requested notification of the event.
WmiSystemControl	The WmiSystemControl routine is a dispatch routine for drivers that use WMI library support routines to handle WMI IRPs.

Callback functions

TITLE	DESCRIPTION
WMI_EXECUTE_METHOD_CALLBACK	The DpWmiExecuteMethod routine executes a method associated with a data block. This routine is optional.
WMI_FUNCTION_CONTROL_CALLBACK	The DpWmiFunctionControl routine enables or disables notification of events, and enables or disables data collection for data blocks that the driver registered as expensive to collect. This routine is optional.
WMI_QUERY_DATABLOCK_CALLBACK	The DpWmiQueryDataBlock routine returns either a single instance or all instances of a data block. This routine is required.
WMI_QUERY_REGINFO_CALLBACK	The DpWmiQueryReginfo routine provides information about the data blocks and event blocks to be registered by a driver. This routine is required.

TITLE	DESCRIPTION
WMI_SET_DATABLOCK_CALLBACK	The DpWmiSetDataBlock routine changes all data items in a single instance of a data block. This routine is optional.
WMI_SET_DATAITEM_CALLBACK	The DpWmiSetDataItem routine changes a single data item in an instance of a data block. This routine is optional.

Structures

TITLE	DESCRIPTION
WMIGUIDREGINFO	The WMIGUIDREGINFO structure contains registration information for a given data block or event block exposed by a driver that uses the WMI library support routines.
WMILIB_CONTEXT	The WMILIB_CONTEXT structure provides registration information for a driver's data blocks and event blocks and defines entry points for the driver's WMI library callback routines.

WMIGUIDREGINFO structure

1/30/2019 • 2 minutes to read • Edit Online

The **WMIGUIDREGINFO** structure contains registration information for a given data block or event block exposed by a driver that uses the WMI library support routines.

Syntax

```
typedef struct _WMIGUIDREGINFO {
  LPCGUID Guid;
  ULONG   InstanceCount;
  ULONG   Flags;
} WMIGUIDREGINFO, *PWMIGUIDREGINFO;
```

Members

`Guid`

Pointer to the GUID that identifies the block. The memory that contains the GUID can be paged unless it is also used to call WmiFireEvent.

`InstanceCount`

Specifies the number of instances defined for the block.

`Flags`

Flag bits that indicate characteristics of the block. These flag bits are defined in the Wmistr.h header file. WMI ORs the **Flags** parameter value with the flag bits set by the driver in the *RegFlags* parameter of its DpWmiQueryReginfo routine, which apply to all of the data blocks and event blocks registered by the driver. **Flags** therefore supplements the driver's default settings for a given block.

A driver might set the following flag bit in **Flags**:

WMIREG_FLAG_INSTANCE_PDO

Requests WMI to generate static instance names from the device instance ID for the PDO. If this flag is set, the *Pdo* parameter of the driver's *DpWmiQueryReginfo* routine points to the PDO passed to the driver's AddDevice routine. WMI generates instance names from the device instance path of the PDO. Using the device instance path as a base for static instance names is efficient because such names are guaranteed to be unique. WMI automatically supplies a "friendly" name for the instance as an item in a data block that can be queried by data consumers.

A driver might also set one or more of the following flag bits:

WMIREG_FLAG_EVENT_ONLY_GUID

The block can be enabled or disabled as an event only, and cannot be queried or set. If this flag is clear, the block can also be queried or set.

WMIREG_FLAG_EXPENSIVE

Requests WMI to send an IRP_MN_ENABLE_COLLECTION request the first time a data consumer opens the data block and an IRP_MN_DISABLE_COLLECTION request when the last data consumer closes the data block. This is recommended if collecting such data affects performance, because a driver need not collect the data until a data consumer explicitly requests it by opening the block.

WMIREG_FLAG_REMOVE_GUID

Requests WMI to remove support for this block. This flag is valid only in response to a request to update registration information (IRP_MN_REGINFO or IRP_MN_REGINFO_EX with **Parameters.WMI.DataPath** set to WMIUPDATE).

Remarks

A driver that handles WMI IRPs by calling WMI library support routines builds an array of **WMIGUIDREGINFO** structures, one for each data block and event block to be registered. The driver sets the **GuidList** member of its WMILIB_CONTEXT structure to point to the first **WMIGUIDREGINFO** in the series.

Memory for this structure can be allocated from paged pool.

WMILIB_CONTEXT

WmiFireEvent

WMILIB_CONTEXT structure

1/30/2019 • 2 minutes to read • Edit Online

The **WMILIB_CONTEXT** structure provides registration information for a driver's data blocks and event blocks and defines entry points for the driver's WMI library callback routines.

Syntax

```
typedef struct _WMILIB_CONTEXT {
  ULONG                 GuidCount;
  PWMIGUIDREGINFO       GuidList;
  PWMI_QUERY_REGINFO    QueryWmiRegInfo;
  PWMI_QUERY_DATABLOCK  QueryWmiDataBlock;
  PWMI_SET_DATABLOCK    SetWmiDataBlock;
  PWMI_SET_DATAITEM     SetWmiDataItem;
  PWMI_EXECUTE_METHOD   ExecuteWmiMethod;
  PWMI_FUNCTION_CONTROL WmiFunctionControl;
} WMILIB_CONTEXT, *PWMILIB_CONTEXT;
```

Members

`GuidCount`

Specifies the number of blocks registered by the driver.

`GuidList`

Pointer to an array of **GuidCount** WMIGUIDREGINFO structures that contain registration information for each block.

`QueryWmiRegInfo`

Pointer to the driver's DpWmiQueryReginfo routine, which is a required entry point for drivers that call WMI library support routines.

`QueryWmiDataBlock`

Pointer to the driver's DpWmiQueryDataBlock routine, which is a required entry point for drivers that call WMI library support routines.

`SetWmiDataBlock`

Pointer to the driver's DpWmiSetDataBlock routine, which is an optional entry point for drivers that call WMI library support routines. If the driver does not implement this routine, it must set this member to **NULL**. In this case, WMI returns STATUS_WMI_READ_ONLY to the caller in response to any IRP_MN_CHANGE_SINGLE_INSTANCE request.

`SetWmiDataItem`

Pointer to the driver's DpWmiSetDataItem routine, which is an optional entry point for drivers that call WMI library support routines. If the driver does not implement this routine, it must set this member to **NULL**. In this case, WMI returns STATUS_WMI_READ_ONLY to the caller in response to any IRP_MN_CHANGE_SINGLE_ITEM request.

`ExecuteWmiMethod`

Pointer to the driver's DpWmiExecuteMethod routine, which is an optional entry point for drivers that call WMI library support routines. If the driver does not implement this routine, it must set this member to **NULL**. In this case, WMI returns STATUS_INVALID_DEVICE_REQUEST to the caller in response to any IRP_MN_EXECUTE_METHOD request.

`WmiFunctionControl`

Pointer to the driver's DpWmiFunctionControl routine, which is an optional entry point for drivers that call WMI library support routines. If the driver does not implement this routine, it must set this member to **NULL**. In this case, WMI returns STATUS_SUCCESS to the caller in response to any **IRP_MN_ENABLE_*XXX*** or **IRP_MN_DISABLE_*XXX*** request.

Remarks

A driver that handles WMI IRPs by calling WMI library support routines stores an initialized **WMILIB_CONTEXT** structure (or a pointer to such a structure) in its device extension. A driver can use the same **WMILIB_CONTEXT** structure for multiple device objects if each device object supplies the same set of data blocks.

When the driver receives an IRP_MJ_SYSTEM_CONTROL request, it calls WmiSystemControl with a pointer to its **WMILIB_CONTEXT** structure, a pointer to its device object, and a pointer to the IRP. **WmiSystemControl** determines whether the IRP contains a WMI request and, if so, handles the request by calling the driver's appropriate *DpWmiXxx* routine.

Memory for this structure can be allocated from paged pool.

WmiSystemControl

WMI_EXECUTE_METHOD_CALLBACK callback function

1/25/2019 • 3 minutes to read • Edit Online

The *DpWmiExecuteMethod* routine executes a method associated with a data block. This routine is optional.

Syntax

```
WMI_EXECUTE_METHOD_CALLBACK WmiExecuteMethodCallback;

NTSTATUS WmiExecuteMethodCallback(
  PDEVICE_OBJECT DeviceObject,
  PIRP Irp,
  ULONG GuidIndex,
  ULONG InstanceIndex,
  ULONG MethodId,
  ULONG InBufferSize,
  ULONG OutBufferSize,
  PUCHAR Buffer
)
{...}
```

Parameters

`DeviceObject`

Pointer to the driver's WDM DEVICE_OBJECT structure.

`Irp`

Pointer to the IRP.

`GuidIndex`

Specifies the data block by supplying a zero-based index into the list of GUIDs that the driver provided in the WMILIB_CONTEXT structure it passed to WmiSystemControl.

`InstanceIndex`

If the block specified by *GuidIndex* has multiple instances, *InstanceIndex* specifies a zero-based index value that identifies the instance.

`MethodId`

Specifies the ID of the method to execute. The driver defines the method ID as an item in a data block.

`InBufferSize`

Indicates the size in bytes of the input data. If there is no input data, *InBufferSize* is zero.

`OutBufferSize`

Indicates the number of bytes available in the buffer for output data.

`Buffer`

Pointer to a buffer that holds input data, if any, and receives output data, if any, for the method. If the buffer is too small to receive all of the output data, the driver returns STATUS_BUFFER_TOO_SMALL and calls WmiCompleteRequest with the size required.

Return Value

DpWmiExecuteMethod returns STATUS_SUCCESS or an appropriate error code such as the following:

Remarks

WMI calls a driver's *DpWmiExecuteMethod* routine after the driver calls WmiSystemControl in response to an IRP_MN_EXECUTE_METHOD request.

If a driver implements a *DpWmiExecuteMethod* routine, the driver must place the routine's address in the **ExecuteWmiMethod** member of the WMILIB_CONTEXT structure that it passes to WmiSystemControl. If a driver does not implement a *DpWmiExecuteMethod* routine, it must set **ExecuteWmiMethod** to **NULL**. In the latter case, WMI returns STATUS_INVALID_DEVICE_REQUEST to the caller in response to any **IRP_MN_EXECUTE_METHOD** request.

The driver is responsible for validating all input arguments. Specifically, the driver must do the following:

- Verify that the *GuidIndex* value is between zero and GuidCount-1, based on the **GuidCount** member of the WMILIB_CONTEXT structure.
- Verify that the driver has not flagged the specified data block for removal. If the driver recently specified the WMIREG_FLAG_REMOVE_GUID flag in a WMIGUIDREGINFO structure that is contained in a **WMILIB_CONTEXT** structure, it is possible for an additional request to arrive before the removal occurs.
- Verify that the *InstanceIndex* value is within the range of instance indexes that are supported by the driver for the data block.
- Verify that the method identifier supplied by *MethodId* is a valid identifier for the specified data block, and that the caller is allowed to execute the method.
- Verify that *Buffer* and *InBufferSize* describe a buffer that is large enough to contain the specified method's input parameters, including padding if necessary, and verify that the input parameters are valid.
- Verify that *Buffer* and *OutBufferSize* describe a buffer that is large enough to receive the specified method's output data, including padding if necessary.

Do not assume the thread context is that of the initiating user-mode application—a higher-level driver might have changed it.

If the specified method performs an operation that causes data loss, such as fetching and resetting the contents of a set of counters, the driver should validate the output buffer size before performing the operation. That way, the driver can return STATUS_BUFFER_TOO_SMALL and allow the caller to resubmit the request with a larger buffer, without prematurely resetting the counters.

After executing the method and writing any output data to the buffer, the driver calls WmiCompleteRequest to complete the request.

This routine can be pageable.

For more information about implementing this routine, see Calling WmiSystemControl to Handle WMI IRPs.

WmiCompleteRequest

WmiSystemControl

WMI_FUNCTION_CONTROL_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *DpWmiFunctionControl* routine enables or disables notification of events, and enables or disables data collection for data blocks that the driver registered as expensive to collect. This routine is optional.

Syntax

```
WMI_FUNCTION_CONTROL_CALLBACK WmiFunctionControlCallback;

NTSTATUS WmiFunctionControlCallback(
  PDEVICE_OBJECT DeviceObject,
  PIRP Irp,
  ULONG GuidIndex,
  WMIENABLEDISABLECONTROL Function,
  BOOLEAN Enable
)
{...}
```

Parameters

`DeviceObject`

Pointer to the driver's WDM DEVICE_OBJECT structure.

`Irp`

Pointer to the IRP.

`GuidIndex`

Specifies the data block by supplying a zero-based index into the list of GUIDs that the driver provided in the WMILIB_CONTEXT structure it passed to WmiSystemControl.

`Function`

Specifies what to enable or disable. **WmiEventControl** indicates an event, and **WmiDataBlockControl** indicates data collection for a block that was registered as expensive to collect (that is, a block for which the driver set WMIREG_FLAG_EXPENSIVE in **Flags** of the WMIGUIDREGINFO structure used to register the block).

`Enable`

Specifies **TRUE** to enable the event or data collection, or **FALSE** to disable it.

Return Value

DpWmiFunctionControl returns STATUS_SUCCESS or an appropriate error status such as:

Remarks

WMI calls a driver's *DpWmiFunctionControl* routine after the driver calls WmiSystemControl in response to one of the following requests:

IRP_MN_ENABLE_COLLECTION

IRP_MN_DISABLE_COLLECTION

IRP_MN_ENABLE_EVENTS

IRP_MN_DISABLE_EVENTS

If a driver implements a *DpWmiFunctionControl* routine, the driver must place the routine's address in the **WmiFunctionControl** member of the WMILIB_CONTEXT structure that it passes to WmiSystemControl. If a driver does not implement a *DpWmiFunctionControl* routine, it must set **WmiFunctionControl** to **NULL**. In the latter case, WMI returns STATUS_SUCCESS to the caller.

The driver is responsible for validating all input arguments. Specifically, the driver must do the following:

- Verify that the *GuidIndex* value is between zero and GuidCount-1, based on the **GuidCount** member of the WMILIB_CONTEXT structure.
- Verify that the driver has not flagged the specified data block for removal. If the driver recently specified the WMIREG_FLAG_REMOVE_GUID flag in a WMIGUIDREGINFO structure that is contained in a **WMILIB_CONTEXT** structure, it is possible for an additional request to arrive before the removal occurs.

It is unnecessary for the driver to check whether events or data collection are already enabled for a block, because WMI sends a single enable request when the first data consumer enables the block, and it sends a single disable request when the last data consumer disables the block. WMI will not call *DpWmiFunctionControl* to enable a block without an intervening call to disable it.

After enabling or disabling the event or data collection for the block, the driver calls WmiCompleteRequest to complete the request.

This routine can be pageable.

For more information about implementing this routine, see Calling WmiSystemControl to Handle WMI IRPs.

Requirements

Target Platform	Desktop

WmiSystemControl

WMI_QUERY_DATABLOCK_CALLBACK callback function

1/25/2019 • 3 minutes to read • Edit Online

The *DpWmiQueryDataBlock* routine returns either a single instance or all instances of a data block. This routine is required.

Syntax

```
WMI_QUERY_DATABLOCK_CALLBACK WmiQueryDatablockCallback;

NTSTATUS WmiQueryDatablockCallback(
  PDEVICE_OBJECT DeviceObject,
  PIRP Irp,
  ULONG GuidIndex,
  ULONG InstanceIndex,
  ULONG InstanceCount,
  PULONG InstanceLengthArray,
  ULONG BufferAvail,
  PUCHAR Buffer
)
{...}
```

Parameters

`DeviceObject`

Pointer to the driver's WDM DEVICE_OBJECT structure.

`Irp`

Pointer to the IRP.

`GuidIndex`

Specifies the data block by supplying a zero-based index into the list of GUIDs that the driver provided in the WMILIB_CONTEXT structure it passed to WmiSystemControl.

`InstanceIndex`

If *DpWmiQueryDataBlock* is called in response to an IRP_MN_QUERY_SINGLE_INSTANCE request, *InstanceIndex* specifies a zero-based index that indicates the instance of the specified data block to be queried. If *DpWmiQueryDataBlock* is called in response to an IRP_MN_QUERY_ALL_DATA request, *InstanceIndex*is zero.

`InstanceCount`

If *DpWmiQueryDataBlock* is called in response to an IRP_MN_QUERY_SINGLE_INSTANCE request, *InstanceCount*is 1. If *DpWmiQueryDataBlock* is called in response to an IRP_MN_QUERY_ALL_DATA request, *InstanceCount*is the number of instances to be returned.

`InstanceLengthArray`

Pointer to a caller-supplied, *InstanceCount*-sized array of ULONG elements. The driver fills in each array element to indicate the length of each instance that was returned. If *BufferAvail* is zero, *InstanceLengthArray* is **NULL**.

`BufferAvail`

Specifies the maximum number of bytes that are available to receive data in the buffer at *Buffer*. If this value is zero, the caller is requesting that the driver specify the required buffer size in its call to WmiCompleteRequest. See the Remarks section for more information.

`Buffer`

Pointer to the buffer to receive instance data. If the buffer is large enough to receive all of the data, the driver writes the instance data to the buffer with each instance aligned on an 8-byte boundary. If the buffer is too small to receive all of the data, the driver calls WmiCompleteRequest with *BufferUsed* set to the size required.

Return Value

DpWmiQueryDataBlock returns STATUS_SUCCESS or an error status such as the following:

If the driver cannot complete the request immediately, it can return STATUS_PENDING.

Remarks

WMI calls a driver's *DpWmiQueryDataBlock* routine after the driver calls WmiSystemControl in response to an IRP_MN_QUERY_SINGLE_INSTANCE or IRP_MN_QUERY_ALL_DATA request. The driver must place the address of its *DpWmiQueryDataBlock* routine in the WMILIB_CONTEXT structure that it passes to **WmiSystemControl**.

The driver is responsible for validating all input arguments. Specifically, the driver must do the following:

- Verify that the *GuidIndex* value is between zero and GuidCount-1, based on the **GuidCount** member of the WMILIB_CONTEXT structure.
- Verify that the driver has not flagged the specified data block for removal. If the driver recently specified the WMIREG_FLAG_REMOVE_GUID flag in a WMIGUIDREGINFO structure that is contained in a **WMILIB_CONTEXT** structure, it is possible for a query to arrive before the removal occurs.
- Verify that the *InstanceIndex* and *InstanceCount* values, together, specify a number of data block instances that is within the range supported by the driver for the data block. If *InstanceIndex* is nonzero, *InstanceCount* must be 1. If *InstanceIndex* is 0, *InstanceCount* must not be greater than the number of instances supported.
- Verify that the buffer described by *Buffer* and *BufferAvail* is large enough to hold all requested instances of the data block. Each instance must begin on an 8-byte boundary, and additional padding might exist between data items within each instance.

After writing instance data to the buffer, the driver calls WmiCompleteRequest to complete the request. If the buffer described by *Buffer* and *BufferAvail* is zero, or is too small to receive all the requested data, the call to **WmiCompleteRequest** must specify STATUS_BUFFER_TOO_SMALL for the *Status* parameter and the required buffer size for the *BufferUsed* parameter.

This routine can be pageable.

For more information about implementing this routine, see Calling WmiSystemControl to Handle WMI IRPs.

WmiSystemControl

WMI_QUERY_REGINFO_CALLBACK callback function

1/25/2019 • 4 minutes to read • Edit Online

The *DpWmiQueryReginfo* routine provides information about the data blocks and event blocks to be registered by a driver. This routine is required.

Syntax

```
WMI_QUERY_REGINFO_CALLBACK WmiQueryReginfoCallback;

NTSTATUS WmiQueryReginfoCallback(
  PDEVICE_OBJECT DeviceObject,
  PULONG RegFlags,
  PUNICODE_STRING InstanceName,
  PUNICODE_STRING *RegistryPath,
  PUNICODE_STRING MofResourceName,
  PDEVICE_OBJECT *Pdo
)
{...}
```

Parameters

`DeviceObject`

A pointer to the driver's WDM DEVICE_OBJECT structure.

`RegFlags`

This parameter indicates common characteristics of all blocks being registered. Any flag set in *RegFlags* is applied to all blocks. A driver can supplement *RegFlags* for a given block by setting **Flags** in the block's WMIGUIDREGINFO structure. For example, a driver might clear WMIREG_FLAG_EXPENSIVE in *RegFlags*, but set it in **Flags** to register a given block as expensive to collect.

The driver sets one of the following flags in *RegFlags*:

WMIREG_FLAG_INSTANCE_BASENAME

Requests WMI to generate static instance names from a base name provided by the driver at the *InstanceName*. WMI generates instance names by appending a counter to the base name.

WMIREG_FLAG_INSTANCE_PDO

Requests WMI to generate static instance names from the device instance ID for the PDO. If the driver sets this flag, it must also set *Pdo* to the PDO passed to the driver's AddDevice routine. WMI generates instance names from the device instance path of the PDO. Using the device instance path as a base for static instance names is efficient because such names are guaranteed to be unique. WMI automatically supplies a "friendly" name for the instance as an item in a data block that can be queried by data consumers.

A driver might also set one or more of the following flags in *RegFlags*, but more typically would set them in **Flags** of a block's WMIGUIDREGINFO structure:

WMIREG_FLAG_EVENT_ONLY_GUID

The blocks can be enabled or disabled as events only, and cannot be queried or set. If this flag is clear, the blocks can also be queried or set.

WMIREG_FLAG_EXPENSIVE

Requests WMI to send an IRP_MN_ENABLE_COLLECTION request the first time a data consumer opens a data block and an IRP_MN_DISABLE_COLLECTION request when the last data consumer closes the data block. This is recommended if collecting such data affects performance, because a driver need not collect the data until a data consumer explicitly requests it by opening the block.

WMIREG_FLAG_REMOVE_GUID

Requests WMI to remove support for the blocks. This flag is valid only in response to a request to update registration information (IRP_MN_REGINFO or IRP_MN_REGINFO_EX with **Parameters.WMI.DataPath** set to WMIUPDATE).

`InstanceName`

A pointer to a single counted Unicode string that serves as the base name for all instances of all blocks to be registered by the driver. WMI frees the string with ExFreePool. If WMIREG_FLAG_INSTANCE_BASENAME is clear, *InstanceName* is ignored.

`*RegistryPath`

A pointer to a pointer to a counted Unicode string that specifies the registry path passed to the driver's DriverEntry routine.

`MofResourceName`

A pointer to a single counted Unicode string that indicates the name of the MOF resource attached to the driver's binary image file. Typically this string would be a static defined by the driver. WMI makes a copy of this string after the driver returns from this routine. This string can be dynamically allocated by the driver. In the case of an allocated string, the driver is responsible for freeing the string which should be done after WmiSystemControl returns. If the driver does not have a MOF resource attached, it can leave *MofResourceName* unchanged.

`*Pdo`

A pointer to the physical device object (PDO) passed to the driver's AddDevice routine. If WMIREG_FLAG_INSTANCE_PDO is set, WMI uses the device instance path of this PDO as a base from which to generate static instance names. If WMIREG_FLAG_INSTANCE_PDO is clear, WMI ignores *Pdo*.

Return Value

DpWmiQueryReginfo always returns STATUS_SUCCESS.

Remarks

WMI calls a driver's *DpWmiQueryReginfo* routine after the driver calls WmiSystemControl in response to an IRP_MN_REGINFO or IRP_MN_REGINFO_EX request. The driver must place the address of its *DpWmiQueryReginfo* routine in the WMILIB_CONTEXT structure that it passes to **WmiSystemControl**.

WMI sends the IRP after a driver calls IoWMIRegistrationControl with WMIREG_ACTION_REGISTER, WMIREG_ACTION_REREGISTER, or WMIREG_ACTION_UPDATE. WMI transparently handles the differences between **IRP_MN_REGINFO** and **IRP_MN_REGINFO_EX** on behalf of the driver.

WMI does not send an IRP_MN_REGINFO or IRP_MN_REGINFO_EX request after a driver calls **IoWMIRegistrationControl** with WMIREG_ACTION_DEREGISTER, because WMI requires no further information from the driver. A driver typically deregisters its blocks in response to an IRP_MN_REMOVE_DEVICE request.

The driver provides new or updated registration information about individual blocks, or indicates blocks to remove, in the WMILIB_CONTEXT structure it passes to **WmiSystemControl**. After the initial call, which establishes the driver's registry path and MOF resource name, a driver's *DpWmiQueryReginfo* routine can change flags common to all of a driver's blocks, provide a different base name string used to generate instance names, or change the basis

for instance names from a string to the device instance path of the PDO.

The driver must not return STATUS_PENDING or block the request. The driver must not complete the request by calling WmiCompleteRequest from its *DpWmiQueryReginfo* routine or by calling IoCompleteRequest after **WmiSystemControl** returns.

This routine can be pageable.

For more information about implementing this routine, see Calling WmiSystemControl to Handle WMI IRPs.

WMI_SET_DATABLOCK_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *DpWmiSetDataBlock* routine changes all data items in a single instance of a data block. This routine is optional.

Syntax

```
WMI_SET_DATABLOCK_CALLBACK WmiSetDatablockCallback;

NTSTATUS WmiSetDatablockCallback(
  PDEVICE_OBJECT DeviceObject,
  PIRP Irp,
  ULONG GuidIndex,
  ULONG InstanceIndex,
  ULONG BufferSize,
  PUCHAR Buffer
)
{...}
```

Parameters

`DeviceObject`

Pointer to the driver's WDM DEVICE_OBJECT structure.

`Irp`

Pointer to the IRP.

`GuidIndex`

Specifies the data block by its zero-based index into the list of GUIDs provided by the driver in the WMILIB_CONTEXT structure it passed to WmiSystemControl.

`InstanceIndex`

If the block specified by *GuidIndex*has multiple instances, *InstanceIndex* specifies the instance.

`BufferSize`

Specifies the size in bytes of the buffer at *Buffer*.

`Buffer`

Pointer to a buffer that contains new values for the instance.

Return Value

DpWmiSetDataBlock returns STATUS_SUCCESS or an appropriate error status such as the following:

If the driver cannot complete the request immediately, it can return STATUS_PENDING.

Remarks

WMI calls a driver's *DpWmiSetDataBlock* routine after the driver calls WmiSystemControl in response to an

IRP_MN_CHANGE_SINGLE_INSTANCE request.

The driver is responsible for validating all input arguments. Specifically, the driver must do the following:

- Verify that the *GuidIndex* value is between zero and GuidCount-1, based on the **GuidCount** member of the WMILIB_CONTEXT structure.
- Verify that the driver has not flagged the specified data block for removal. If the driver recently specified the WMIREG_FLAG_REMOVE_GUID flag in a WMIGUIDREGINFO structure that is contained in a **WMILIB_CONTEXT** structure, it is possible for a set request to arrive before the removal occurs.
- Verify that the *InstanceIndex* value is within the range of instance indexes that are supported by the driver for the data block.
- Verify that *Buffer* and *BufferSize* describe a valid-sized data block, including any padding that exists between data items, and that the contents of the buffer are valid for the data block.
- Verify that the specified data block is one for which the driver allows caller-initiated modifications. In other words, the driver should not allow modifications to data blocks that you intended to be read-only.

Do not assume the thread context is that of the initiating user-mode application—a higher-level driver might have changed it.

If a driver implements a *DpWmiSetDataBlock* routine, the driver must place the routine's address in the **SetWmiDataBlock** member of the WMILIB_CONTEXT structure that it passes to WmiSystemControl. If a driver does not implement a *DpWmiSetDataBlock* routine, it must set **SetWmiDataBlock** to **NULL**. In the latter case, WMI returns STATUS_READ_ONLY to the caller.

This routine can be pageable.

For more information about implementing this routine, see Calling WmiSystemControl to Handle WMI IRPs.

IRP_MN_CHANGE_SINGLE_INSTANCE

WMILIB_CONTEXT

WmiSystemControl

WMI_SET_DATAITEM_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *DpWmiSetDataItem* routine changes a single data item in an instance of a data block. This routine is optional.

Syntax

```
WMI_SET_DATAITEM_CALLBACK WmiSetDataitemCallback;

NTSTATUS WmiSetDataitemCallback(
  PDEVICE_OBJECT DeviceObject,
  PIRP Irp,
  ULONG GuidIndex,
  ULONG InstanceIndex,
  ULONG DataItemId,
  ULONG BufferSize,
  PUCHAR Buffer
)
{...}
```

Parameters

`DeviceObject`

Pointer to the driver's WDM DEVICE_OBJECT structure.

`Irp`

Pointer to the IRP.

`GuidIndex`

Specifies the data block by supplying a zero-based index into the list of GUIDs that the driver provided in the WMILIB_CONTEXT structure it passed to WmiSystemControl.

`InstanceIndex`

If the block specified by *GuidIndex* has multiple instances, *InstanceIndex* is a zero-based value that specifies the instance.

`DataItemId`

Specifies the ID of the data item to set.

`BufferSize`

Specifies the size in bytes of the buffer at *Buffer*.

`Buffer`

Pointer to a buffer that contains the new value for the data item.

Return Value

DpWmiSetDataItem returns STATUS_SUCCESS or an appropriate error code such as the following:

Remarks

WMI calls a driver's *DpWmiSetDataItem* routine after the driver calls WmiSystemControl in response to an IRP_MN_CHANGE_SINGLE_ITEM request.

Do not implement *DpWmiSetDataItem* unless you are sure that a system-supplied user-mode component requires this capability. If you implement a *DpWmiSetDataItem* routine, the driver must place the routine's address in the **SetWmiDataItem** member of the WMILIB_CONTEXT structure that it passes to WmiSystemControl. If you do not implement a *DpWmiSetDataItem* routine, the driver must set **SetWmiDataItem** to **NULL**. In the latter case, WMI returns STATUS_READ_ONLY to the caller.

The driver is responsible for validating all input arguments. Specifically, the driver must do the following:

- Verify that the *GuidIndex* value is between zero and GuidCount-1, based on the **GuidCount** member of the WMILIB_CONTEXT structure.
- Verify that the driver has not flagged the specified data block for removal. If the driver recently specified the WMIREG_FLAG_REMOVE_GUID flag in a WMIGUIDREGINFO structure that is contained in a **WMILIB_CONTEXT** structure, it is possible for a set request to arrive before the removal occurs.
- Verify that the *InstanceIndex* value is within the range of instance indexes that are supported by the driver for the data block.
- Verify that the *DataItemId* value is within the range of data item identifiers that are supported by the driver for the data block.
- Verify that *Buffer* and *BufferSize* describe a valid-sized data item, and that the contents of the buffer are valid for the data item.
- Verify that the specified data item is one for which the driver allows caller-initiated modifications. In other words, the driver should not allow modifications to data items that you intended to be read-only.

Do not assume the thread context is that of the initiating user-mode application—a higher-level driver might have changed it.

This routine can be pageable.

For more information about implementing this routine, see Calling WmiSystemControl to Handle WMI IRPs.

WMILIB_CONTEXT

WmiSystemControl

WmiCompleteRequest function

1/25/2019 • 2 minutes to read • Edit Online

The **WmiCompleteRequest** routine indicates that a driver has finished processing a WMI request in a *DpWmiXxx* routine.

Syntax

```
NTSTATUS WmiCompleteRequest(
  PDEVICE_OBJECT DeviceObject,
  PIRP           Irp,
  NTSTATUS       Status,
  ULONG          BufferUsed,
  CCHAR          PriorityBoost
);
```

Parameters

`DeviceObject`

A pointer to the driver's DEVICE_OBJECT.

`Irp`

A pointer to the IRP.

`Status`

Specifies the status to return for the IRP.

`BufferUsed`

Specifies the number of bytes needed in the buffer passed to the driver's *DpWmiXxx* routine. If the buffer is too small, the driver sets *Status* to STATUS_BUFFER_TOO_SMALL and sets *BufferUsed* to the number of bytes needed for the data to be returned. If the buffer passed is large enough, the driver sets *BufferUsed* to the number of bytes actually used.

`PriorityBoost`

Specifies a system-defined constant by which to increment the run-time priority of the original thread that requested the operation. WMI calls IoCompleteRequest with *PriorityBoost* when it completes the IRP. See **IoCompleteRequest** for more information on *PriorityBoost*.

Return Value

WmiCompleteRequest returns the value that was passed to it in the *Status* parameter unless *Status* was set to STATUS_BUFFER_TOO_SMALL. If the driver set *Status* equal to STATUS_BUFFER_TOO_SMALL, **WmiCompleteRequest** builds a WNODE_TOO_SMALL structure and returns STATUS_SUCCESS. The return value from **WmiCompleteRequest** should be returned by the driver in its *DpWmiXxx* routine.

Remarks

A driver calls **WmiCompleteRequest** from a *DpWmiXxx* routine after it finishes all other processing in that

routine, or after the driver finishes all processing for a pending IRP. **WmiCompleteRequest** fills in a **WNODE_*XXX*** with any data returned by the driver and calls **IoCompleteRequest** to complete the IRP.

A driver should always return the return value from **WmiCompleteRequest** in its *DpWmiXxx* routine.

A driver must not call **WmiCompleteRequest** from its DpWmiQueryRegInfo routine.

Requirements

Minimum supported client	Available starting with Windows 2000.

WmiSystemControl

WmiFireEvent function

1/25/2019 • 2 minutes to read • Edit Online

The **WmiFireEvent** routine sends an event to WMI for delivery to data consumers that have requested notification of the event.

Syntax

```
NTSTATUS WmiFireEvent(
  PDEVICE_OBJECT DeviceObject,
  LPCGUID        Guid,
  ULONG          InstanceIndex,
  ULONG          EventDataSize,
  PVOID          EventData
);
```

Parameters

`DeviceObject`

A pointer to the driver's DEVICE_OBJECT.

`Guid`

A pointer to the GUID that represents the event block.

`InstanceIndex`

If the event block has multiple instances, specifies the index of the instance.

`EventDataSize`

Specifies the number of bytes of data at *EventData*. If no data is generated for an event, *EventData* must be zero.

`EventData`

A pointer to a driver-allocated nonpaged buffer containing data generated by the driver for the event. If no data is generated for an event, *EventData* must be **NULL**. WMI frees the buffer without further intervention by the driver.

Return Value

WmiFireEvent propagates the status returned by IoWmiWriteEvent, or returns STATUS_INSUFFICIENT_RESOURCES if it could not allocate memory for the event.

Remarks

A driver calls **WmiFireEvent** to send an event to WMI for delivery to all data consumers that have requested notification of the event. All pointers passed to **WmiFireEvent** must point to nonpagable memory, such as nonpaged pool.

The driver sends an event only if it has been previously enabled by the driver's DpWmiFunctionControl routine, which WMI calls to process an **IRP_MN_ENABLE_EVENT** request.

The driver writes any data associated with the event to the buffer at *EventData*. WMI fills in a

WNODE_SINGLE_INSTANCE structure with the data and calls IoWmiWriteEvent to deliver the event.

For more information about event tracing, see WMI Event Tracing.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

DpWmiFunctionControl

IRP_MN_ENABLE_EVENTS

WmiSystemControl

WmiSystemControl function

1/25/2019 • 2 minutes to read • Edit Online

The **WmiSystemControl** routine is a dispatch routine for drivers that use WMI library support routines to handle WMI IRPs.

Syntax

```
NTSTATUS WmiSystemControl(
  PWMILIB_CONTEXT         WmiLibInfo,
  PDEVICE_OBJECT          DeviceObject,
  PIRP                    Irp,
  PSYSCTL_IRP_DISPOSITION IrpDisposition
);
```

Parameters

`WmiLibInfo`

A pointer to a WMILIB_CONTEXT structure that contains registration information for a driver's data blocks and event blocks and defines entry points for the driver's WMI library callback routines.

`DeviceObject`

A pointer to the driver's DEVICE_OBJECT.

`Irp`

A pointer to the IRP.

`IrpDisposition`

A pointer to an enumeration value of type **SYSCTL_IRP_DISPOSITION** that indicates how the IRP was handled. **WmiSystemControl** always sets this value, even when it returns a non-success NTSTATUS code.

SYSCTL_IRP_DISPOSITION is an enumeration in Wmilib.h and contains the following values:

IrpProcessed

The IRP was processed and possibly completed. If the driver's *DpWmi*Xxx routine called by **WmiSystemControl** did not complete the IRP, the driver must call WmiCompleteRequest to complete the IRP after **WmiSystemControl** returns.

IrpNotCompleted

The IRP was processed but not completed, either because WMI detected an error and set up the IRP with an appropriate error code, or processed an IRP_MN_REGINFO or IRP_MN_REGINFO_EX request. The driver must complete the IRP by calling IoCompleteRequest.

IrpNotWmi

The IRP is not a WMI request (that is, WMI does not recognize the IRP's minor code). If the driver handles IRP_MJ_SYSTEM_CONTROL requests with this **IRP_MN_*XXX***, it should handle the IRP; otherwise, the driver should forward the IRP to the next lower driver. If the driver is the lowest-level driver, then it must complete the IRP.

IrpForward

The IRP is targeted to another device object (that is, the device object pointer at **Parameters.WMI.ProviderId** in the IRP does not match the pointer passed by the driver in its call to IoWMIRegistrationControl). The driver must forward the IRP to the next lower driver. If the driver is the lowest-level driver, then it must complete the IRP.

Return Value

WmiSystemControl returns STATUS_SUCCESS or one of the following error codes:

Remarks

When a driver receives an **IRP_MJ_SYSTEM_CONTROL** request with a WMI IRP minor code, it calls **WmiSystemControl** with a pointer to the driver's **WMILIB_CONTEXT** structure, a pointer to its device object, and a pointer to the IRP. The **WMILIB_CONTEXT** structure contains registration information for the driver's data blocks and event blocks and defines entry points for its WMI library callback routines.

WmiSystemControl confirms that the IRP is a WMI request and determines whether the block specified by the request is valid for the driver. If so, it processes the IRP by calling the appropriate *DpWmi*Xxx entry point in the driver's **WMILIB_CONTEXT** structure. WMI is running at IRQL PASSIVE_LEVEL when it calls the driver's *DpWmi*Xxx routine.

A driver must be running at IRQL PASSIVE_LEVEL when it forwards an **IRP_MJ_SYSTEM_CONTROL** request to the next-lower driver.

Requirements

Minimum supported client	Available in Windows 2000 and later versions of Windows.
Target Platform	Universal
Header	wmilib.h (include Wmilib.h)

WMILIB_CONTEXT

wmistr.h header

1/8/2019 • 2 minutes to read • Edit Online

This header declares a set of standard data structures called WNODE_XXX that WMI uses to pass data between user-mode data consumers and kernel-mode data providers such as drivers.

This header is used by kernel. For more information, see:

- WMI WNODE_XXX Structures wmistr.h contains the following programming interfaces:

Structures

TITLE	DESCRIPTION
WMIREGGUIDW	The WMIREGGUID structure contains new or updated registration information for a data block or event block.
WMIREGINFOW	The WMIREGINFO structure contains information provided by a driver to register or update its data blocks and event blocks.
WNODE_ALL_DATA	The WNODE_ALL_DATA structure contains data for all instances of a data block or event block.
WNODE_EVENT_ITEM	The WNODE_EVENT_ITEM structure contains data generated by a driver for an event.
WNODE_EVENT_REFERENCE	The WNODE_EVENT_REFERENCE structure contains information that WMI can use to query for an event that exceeds the event size limit set in the registry.
WNODE_HEADER	The WNODE_HEADER structure is the first member of all other WNODE_XXX structures. It contains information common to all such structures.
WNODE_METHOD_ITEM	The WNODE_METHOD_ITEM structure indicates a method associated with an instance of a data block and contains any input data for the method.
WNODE_SINGLE_INSTANCE	The WNODE_SINGLE_INSTANCE structure contains values for all data items in one instance of a data block.
WNODE_SINGLE_ITEM	The WNODE_SINGLE_ITEM structure contains the value of a single data item in an instance of a data block.
WNODE_TOO_SMALL	The WNODE_TOO_SMALL structure indicates the size of the buffer needed to receive output from a request.

WMIREGGUIDW structure

1/25/2019 • 4 minutes to read • Edit Online

The **WMIREGGUID** structure contains new or updated registration information for a data block or event block.

Syntax

```
typedef struct {
  GUID  Guid;
  ULONG Flags;
  ULONG InstanceCount;
  union {
    ULONG     InstanceNameList;
    ULONG     BaseNameOffset;
    ULONG_PTR Pdo;
    ULONG_PTR InstanceInfo;
  } DUMMYUNIONNAME;
} WMIREGGUIDW, *PWMIREGGUIDW;
```

Members

`Guid`

Specifies the GUID that represents the block to register or update.

`Flags`

Indicates characteristics of the block to register or update.

If a block is being registered with static instance names, a driver sets one of the following flags:

WMIREG_FLAG_INSTANCE_LIST

Indicates that the driver provides static instance names for this block in a static list following the WMIREGINFO structure in the buffer at **IrpStack->Parameters.WMI.Buffer**. If this flag is set, **InstanceNameList** is the offset in bytes from the beginning of the **WMIREGINFO** structure that contains this **WMIREGGUID** to a contiguous series of **InstanceCount** counted Unicode strings.

WMIREG_FLAG_INSTANCE_BASENAME

Requests WMI to generate static instance names from a base name provided by the driver following the **WMIREGINFO** structure in the buffer at **IrpStack->Parameters.WMI.Buffer**. WMI generates instance names by appending a counter to the base name. If this flag is set, **BaseNameOffset** is the offset in bytes from the beginning of the **WMIREGINFO** structure that contains this **WMIREGGUID** to a single counted Unicode string that serves as the base name.

WMIREG_FLAG_INSTANCE_PDO

Requests WMI to generate static instance names from the device instance ID for the PDO. If this flag is set, **InstanceInfo** points to the PDO passed to the driver's AddDevice routine. WMI generates instance names from the device instance path of the PDO. Using the device instance path as a base for static instance names is efficient because such names are guaranteed to be unique. WMI automatically supplies a "friendly" name for the instance as an item in a data block that can be queried by data consumers.

If a block is being registered with dynamic instance names, WMIREG_FLAG_INSTANCE_LIST, WMIREG_FLAG_INSTANCE_BASENAME, and WMIREG_FLAG_INSTANCE_PDO must be clear.

A driver might also set one or more of the following flags:

WMIREG_FLAG_EVENT_ONLY_GUID

The block can be enabled or disabled as an event only, and cannot be queried or set. If this flag is clear, the block can also be queried or set.

WMIREG_FLAG_EXPENSIVE

Requests WMI to send an IRP_MN_ENABLE_COLLECTION request the first time a data consumer opens the data block and an IRP_MN_DISABLE_COLLECTION request when the last data consumer closes the data block. This is recommended if collecting such data affects performance, because a driver need not collect the data until a data consumer explicitly requests it by opening the block.

WMIREG_FLAG_REMOVE_GUID

Requests WMI to remove support for this block. This flag is valid only in response to a request to update registration information (IRP_MN_REGINFO or IRP_MN_REGINFO_EX with **Parameters.WMI.DataPath** set to WMIUPDATE).

WMIREG_FLAG_TRACED_GUID

The block can be written only to a log file and can be accessed only through user-mode routines declared in evntrace.h. Only NT kernel-mode data providers set this flag.

WMIREG_FLAG_TRACE_CONTROL_GUID

The GUID acts as the control GUID for enabling or disabling the trace GUIDs associated with it in the MOF file. This flag is valid only if WMIREG_FLAG_TRACED_GUID is also set. Only NT kernel-mode data providers set this flag.

`InstanceCount`

Specifies the number of static instance names to be defined for this block. If the block is being registered with dynamic instance names, WMI ignores **InstanceCount**.

`DUMMYUNIONNAME`

`DUMMYUNIONNAME.InstanceNameList`

Indicates the offset in bytes from the beginning of the **WMIREGINFO** structure that contains this **WMIREGGUID** to a contiguous series of **InstanceCount** counted Unicode strings. This member is valid only if WMIREG_FLAG_INSTANCE_LIST is set in **Flags**. If the block is being registered with dynamic instance names, WMI ignores **InstanceNameList**.

`DUMMYUNIONNAME.BaseNameOffset`

Indicates the offset in bytes from the beginning of the **WMIREGINFO** structure that contains this **WMIREGGUID** to a single counted Unicode string that serves as a base for WMI to generate static instance names. This member is valid only if WMIREG_FLAG_INSTANCE_BASENAME is set in **Flags**. If the block is being registered with dynamic instance names, WMI ignores **BaseNameOffset**.

`DUMMYUNIONNAME.Pdo`

Pointer to the physical device object (PDO) passed to the driver's AddDevice routine. WMI uses the device instance path of this PDO as a base from which to generate static instance names. This member is valid only if WMIREG_FLAG_INSTANCE_PDO is set in **Flags**. If the block is being registered with dynamic instance names, WMI ignores **Pdo**.

`DUMMYUNIONNAME.InstanceInfo`

Reserved for use by WMI.

Remarks

A driver builds one or more **WMIREGGUID** structures in response to an IRP_MN_REGINFO or IRP_MN_REGINFO_EX request to register or update its blocks. The driver passes an array of such structures at the **WmiRegGuid** member of a **WMIREGINFO** structure, which the driver writes to the buffer at **IrpStack->Parameters.WMI.Buffer**.

A driver can register or update a block with either static or dynamic instance names. Static instance names provide best performance; however, dynamic instance names are preferred for data blocks if the number of instances or instance names change frequently. For more information about instance names, see Defining WMI Instance Names.

Requirements

Header	wmistr.h (include Wmistr.h)

See Also

IRP_MN_REGINFO

IRP_MN_REGINFO_EX

WMIREGINFO

WMIREGINFOW structure

1/25/2019 • 2 minutes to read • Edit Online

The **WMIREGINFO** structure contains information provided by a driver to register or update its data blocks and event blocks.

Syntax

```
typedef struct {
  ULONG       BufferSize;
  ULONG       NextWmiRegInfo;
  ULONG       RegistryPath;
  ULONG       MofResourceName;
  ULONG       GuidCount;
  WMIREGGUIDW WmiRegGuid[];
} WMIREGINFOW, *PWMIREGINFOW;
```

Members

`BufferSize`

Indicates the total size of the WMI registration data associated with this **WMIREGINFO** structure, calculated as follows: (**sizeof**(**WMIREGINFO**) + (**GuidCount** * **sizeof**(**WMIREGGUID**) + *additionaldata*). Additional data might include items such as the MOF resource name, registry path, and static instance names for blocks.

`NextWmiRegInfo`

If a driver handles WMI requests on behalf of another driver, as a class driver might on behalf of a miniclass driver, **NextWmiRegInfo** indicates the offset in bytes from the beginning of this **WMIREGINFO** to the next **WMIREGINFO** structure that contains WMI registration information for the other driver. Otherwise, **NextWmiRegInfo** is zero.

`RegistryPath`

Indicates the offset in bytes from the beginning of this structure to a counted Unicode string that specifies the registry path passed to the driver's DriverEntry routine. The string must be aligned on a USHORT boundary. This member should be set only in response to a WMI registration request (IRP_MN_REGINFO or IRP_MN_REGINFO_EX with **Parameters.WMI.DataPath** set to WMIREGISTER).

`MofResourceName`

Indicates the offset in bytes from the beginning of this structure to a counted Unicode string that specifies the name of the MOF resource in the driver's image file. The string must be aligned on a USHORT boundary. This member should be set only in response to a WMI registration request (IRP_MN_REGINFO or IRP_MN_REGINFO_EX with **Parameters.WMI.DataPath** set to WMIREGISTER).

`GuidCount`

Indicates the number of WMIREGGUID structures in the array at **WmiRegGuid**.

`WmiRegGuid`

Is an array of **GuidCount** WMIREGGUID structures.

Remarks

In response to a registration request (IRP_MN_REGINFO or IRP_MN_REGINFO_EX with **Parameters.WMI.DataPath** set to WMIREGISTER), a driver builds at least one **WMIREGINFO** structure and writes the **WMIREGINFO** structure to the buffer at **IrpStack->Parameters.WMI.Buffer**. The **WMIREGINFO** structure contains an array of **WMIREGGUID** structures, one for each data block or event block exposed by the driver.

If the driver handles WMI requests on behalf of another driver, it builds another **WMIREGINFO** containing an array of **WMIREGGUID** structures for each block exposed by the other driver, sets the **NextWmiRegInfo** member of the first **WMIREGINFO** to an offset in bytes from the beginning of the first **WMIREGINFO** to the beginning of the next **WMIREGINFO** in the buffer, and writes both structures to the buffer. The driver indicates the total size of both **WMIREGINFO** structures and associated data when calls **IoCompleteRequest** to complete the IRP.

A driver can use the same **WMIREGINFO** structure(s) to remove or update blocks in response to an update request (IRP_MN_REGINFO or IRP_MN_REGINFO_EX with **Parameters.WMI.DataPath** set to WMIUPDATE). If WMIREG_FLAG_REMOVE_GUID is set in the **Flags** member of a **WMIREGGUID**, WMI removes that block from the list of blocks previously registered by the driver. If WMIREG_FLAG_REMOVE_GUID is clear, WMI updates registration information for that block only if other **WMIREGGUID** members have changed—otherwise, WMI does not change to its registration information for that block.

IoCompleteRequest

WMIREGGUID

WNODE_HEADER structure

1/30/2019 • 6 minutes to read • Edit Online

The **WNODE_HEADER** structure is the first member of all other **WNODE_*XXX*** structures. It contains information common to all such structures.

Syntax

```
typedef struct _WNODE_HEADER {
  ULONG BufferSize;
  ULONG ProviderId;
  union {
    ULONG64 HistoricalContext;
    struct {
      ULONG Version;
      ULONG Linkage;
    } DUMMYSTRUCTNAME;
  } DUMMYUNIONNAME;
  union {
    ULONG         CountLost;
    HANDLE        KernelHandle;
    LARGE_INTEGER TimeStamp;
  } DUMMYUNIONNAME2;
  GUID  Guid;
  ULONG ClientContext;
  ULONG Flags;
} WNODE_HEADER, *PWNODE_HEADER;
```

Members

`BufferSize`

This member specifies the size, in bytes, of the nonpaged buffer to receive any **WNODE_*XXX*** data to be returned, including this **WNODE_HEADER** structure, additional members of a **WNODE_*XXX*** structure of the type indicated by **Flags**, and any WMI- or driver-determined data that accompanies that structure.

`ProviderId`

If **Flags** is set to WNODE_FLAG_EVENT_ITEM or WNODE_FLAG_EVENT_REFERENCE, **ProviderId** should contain the ID of the WMI provider associated with the device object. You can obtain the **ProviderId** value by calling IoWMIDeviceObjectToProviderId. If **Flags** is set to any other value, this member is reserved.

`DUMMYUNIONNAME`

`DUMMYUNIONNAME.HistoricalContext`

This member stores the handle to the event tracing session.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME`

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.Version`

This member is reserved for WMI.

`DUMMYUNIONNAME.DUMMYSTRUCTNAME.Linkage`

This member is reserved for WMI.

`DUMMYUNIONNAME2`

`DUMMYUNIONNAME2.CountLost`

Reserved

`DUMMYUNIONNAME2.KernelHandle`

This member is reserved for WMI.

`DUMMYUNIONNAME2.TimeStamp`

This member indicates the time at which a driver collected the **WNODE_*XXX*** data. This time value is expressed in absolute system time format. Absolute system time is the number of 100-nanosecond intervals since the start of the year 1601 in the Gregorian calendar. A driver can call **KeQuerySystemTime** to obtain this value. If the block is to be written to a log file (WNODE_FLAG_LOG_WNODE), an NT driver might also set WNODE_FLAG_USE_TIMESTAMP in **Flags** to request that the system logger leave the value of **TimeStamp** unchanged.

`Guid`

This member indicates the GUID that represents the data block associated with the **WNODE_*XXX*** to be returned.

`ClientContext`

This member stores the clock type for the session. Possible values are included in the following table.

VALUE	DESCRIPTION
1	Performance counter value (also called QPC, QueryPerformanceCounter, or PerfCounter)
2	System timer
3	CPU cycle

`Flags`

This member indicates the type of **WNODE_*XXX*** structure that contains the WNODE_HEADER structure:

WNODE_FLAG_ALL_DATA

The rest of a WNODE_ALL_DATA structure follows the **WNODE_HEADER** structure in the buffer.

WMI sets this flag in the **WNODE_HEADER** structure that it passes with an IRP_MN_QUERY_ALL_DATA request.

A driver sets this flag in the **WNODE_HEADER** structure of an event that consists of all instances of a data block. If the data block size is identical for all instances, a driver also sets WNODE_FLAG_FIXED_INSTANCE_SIZE.

WNODE_FLAG_EVENT_ITEM

A driver sets this flag to indicate that the **WNODE_*XXX*** structure was generated as an event. This flag is valid only if WNODE_FLAG_ALL_DATA, WNODE_FLAG_SINGLE_INSTANCE, or WNODE_FLAG_SINGLE_ITEM is also set.

WNODE_FLAG_EVENT_REFERENCE

The rest of a WNODE_EVENT_REFERENCE structure follows the **WNODE_HEADER** structure in the buffer.

A driver sets this flag when it generates an event that is larger than the maximum size specified in the registry for an event. WMI uses the information in the **WNODE_EVENT_REFERENCE** structure to request the event data and schedules such a request according to the value of WNODE_FLAG_SEVERITY_MASK.

WNODE_FLAG_METHOD_ITEM

The rest of a WNODE_METHOD_ITEM structure follows the **WNODE_HEADER** structure in the buffer.

WMI sets this flag in the **WNODE_HEADER** structure that it passes with an IRP_MN_EXECUTE_METHOD request.

WNODE_FLAG_SINGLE_INSTANCE

The rest of a WNODE_SINGLE_INSTANCE structure follows the **WNODE_HEADER** structure in the buffer.

WMI sets this flag in the **WNODE_HEADER** structure that it passes with a request to query or change an instance.

A driver sets this flag in the **WNODE_HEADER** structure of an event that consists of a single instance of a data block.

WNODE_FLAG_SINGLE_ITEM

The rest of a WNODE_SINGLE_INSTANCE structure follows the **WNODE_HEADER** structure in the buffer.

WMI sets this flag in the **WNODE_HEADER** structure that it passes with a request to change an item.

A driver sets this flag in the **WNODE_HEADER** structure of an event that consists of a single data item.

WNODE_FLAG_TOO_SMALL

The rest of a WNODE_TOO_SMALL structure follows the **WNODE_HEADER** structure in the buffer.

A driver sets this flag when it passes a **WNODE_TOO_SMALL** structure, indicating that the buffer is too small for all of the **WNODE_*XXX*** data to be returned.

In addition, **Flags** might be set with one or more of the following flags that provide additional information about the **WNODE_*XXX***:

WNODE_FLAG_FIXED_INSTANCE_SIZE

All instances of a data block are the same size. This flag is valid only if WNODE_FLAG_ALL_DATA is also set.

WNODE_FLAG_INSTANCES_SAME

The number of instances and the dynamic instance names in a **WNODE_ALL_DATA** structure to be returned are identical to those returned from the previous **WNODE_ALL_DATA** query. This flag is valid only if WNODE_FLAG_ALL_DATA is also set. This flag is ignored for data blocks registered with static instance names.

For optimized performance, a driver should set this flag if it can track changes to the number or names of its data blocks. WMI can then skip the processing required to detect and update dynamic instance names.

WNODE_FLAG_STATIC_INSTANCE_NAMES

The **WNODE_*XXX*** data to be returned does not include instance names.

WMI sets this flag before requesting **WNODE_*XXX*** data for data blocks registered with static instance names. After receiving the returned **WNODE_*XXX*** from the driver, WMI fills in the static instance names specified at registration before passing the returned **WNODE_*XXX*** to a data consumer.

WNODE_FLAG_PDO_INSTANCE_NAMES

Static instance names are based on the device instance ID of the PDO for the device. A driver requests such names by setting WMIREG_FLAG_INSTANCE_PDO in the WMIREGGUID it uses to register the block.

WMI sets this flag before requesting **WNODE_*XXX*** data for data blocks registered with PDO-based instance names.

WNODE_FLAG_SEVERITY_MASK

The driver-determined severity level of the event associated with a returned WNODE_EVENT_REFERENCE, with 0x00 indicating the least severe and 0xff indicating the most severe level.

WMI uses the value of this flag to prioritize its requests for the event data.

WNODE_FLAG_USE_TIMESTAMP

The system logger should not modify the value of **TimeStamp** set by the driver.

An NT driver might also set **Flags** to one or more of the following values for event blocks to be written to a system log file:

WNODE_FLAG_LOG_WNODE

An event block is to be sent to the system logger. The event header is a standard **WNODE_HEADER** structure. If the driver clears WNODE_FLAG_TRACED_GUID, the block will also be sent to WMI for delivery to any data consumers that have enabled the event. The driver must allocate the **WNODE_*XXX*** from pool memory. WMI frees the memory after delivering the event to data consumers.

WNODE_FLAG_TRACED_GUID

An event block is to be sent only to the system logger. It does not get sent to WMI data consumers. The event header is an **EVENT_TRACE_HEADER** structure, declared in *Evntrace.h*, instead of a **WNODE_HEADER**. The driver must allocate memory for the **WNODE_*XXX*** and free it after IoWMIWriteEvent returns. The driver can allocate such memory either from the stack or, to minimize the overhead of allocating and freeing the memory, from the driver's thread local storage if the driver creates and maintains its own thread pool.

WNODE_FLAG_USE_GUID_PTR

The **Guid** member points to a GUID in memory, rather than containing the GUID itself. The system logger dereferences the pointer before passing the data to the consumer. This flag is valid only if WNODE_FLAG_LOG_WNODE or WNODE_FLAG_TRACED_GUID are also set.

WNODE_FLAG_USE_MOF_PTR

Data that follows the fixed members of a **WNODE_*XXX*** structure consists of an array of MOF_FIELD structures, defined in Evntrace.h, that contain pointers to data and sizes rather than the data itself. The array can contain up to MAX_MOF_FIELD elements. The system logger dereferences the pointers before passing the data to the consumer This flag is valid only for blocks registered with WMIREG_FLAG_TRACED_GUID.

Remarks

In an **IRP_MN_CHANGE_*XXX*** or IRP_MN_EXECUTE_METHOD request, **BufferSize** in the IRP indicates the maximum size in bytes of the output buffer, while **BufferSize** in the input **WNODE_HEADER** for such a request indicates the size, in bytes, of the input data in the buffer.

WNODE_ALL_DATA structure

1/25/2019 • 2 minutes to read • Edit Online

The **WNODE_ALL_DATA** structure contains data for all instances of a data block or event block.

Syntax

```
typedef struct tagWNODE_ALL_DATA {
  struct _WNODE_HEADER WnodeHeader;
  ULONG                DataBlockOffset;
  ULONG                InstanceCount;
  ULONG                OffsetInstanceNameOffsets;
  union {
    ULONG                       FixedInstanceSize;
    OFFSETINSTANCEDATAANDLENGTH OffsetInstanceDataAndLength[];
  } DUMMYUNIONNAME;
} WNODE_ALL_DATA, *PWNODE_ALL_DATA;
```

Members

`WnodeHeader`

Specifies a WNODE_HEADER structure that contains information common to all **WNODE_*XXX*** structures, such as the buffer size, the GUID that represents a data block associated with a request, and flags that provide information about the **WNODE_*XXX*** data being passed or returned.

`DataBlockOffset`

Indicates the offset in bytes from the beginning of the **WNODE_ALL_DATA** structure to the beginning of data for the first instance.

`InstanceCount`

Indicates the number of instances whose data follows the fixed members of the **WNODE_ALL_DATA** in the buffer at **IrpStack->Parameters.WMI.Buffer**.

`OffsetInstanceNameOffsets`

Indicates the offset in bytes from the beginning of the **WNODE_ALL_DATA** to an array of offsets to dynamic instance names. Each instance name must be aligned on a USHORT boundary. If all instances to be returned have static instance names, WMI ignores **OffsetInstanceNameOffsets**.

`DUMMYUNIONNAME`

`DUMMYUNIONNAME.FixedInstanceSize`

Indicates the size of each instance to be returned if all such instances are the same size. This member is valid only if the driver sets WNODE_FLAG_FIXED_INSTANCE_SIZE in **WnodeHeader.Flags**.

`DUMMYUNIONNAME.OffsetInstanceDataAndLength`

If instances to be returned vary in size, **OffsetInstanceDataAndLength** is an array of **InstanceCount** **OFFSETINSTANCEDATAANDLENGTH** structures that specify the offset in bytes from the beginning of the **WNODE_ALL_DATA** to the beginning of each instance and its length. **OFFSETINSTANCEDATAANDLENGTH** is defined as follows:

```
typedef struct {
  ULONG  OffsetInstanceData;
  ULONG  LengthInstanceData;
} OFFSETINSTANCEDATAANDLENGTH, *POFFSETINSTANCEDATAANDLENGTH;
```

Each instance must be aligned on a USHORT boundary. The **OffsetInstanceDataAndLength** member is valid only if the driver clears WNODE_FLAG_FIXED_INSTANCE_SIZE in **WnodeHeader.Flags**.

Remarks

A driver fills in a **WNODE_ALL_DATA** structure in response to an IRP_MN_QUERY_ALL_DATA request. A driver might also generate a **WNODE_ALL_DATA** as an event.

After filling in the fixed members of the structure, a driver writes instance data and dynamic instance names (if any) at **DataBlockOffset** and **OffsetInstanceNameOffsets**, respectively, in the buffer at **IrpStack->Parameters.WMI.Buffer**. If WNODE_FLAG_FIXED_INSTANCE_SIZE is clear, the first offset follows the last element of the **OffsetInstanceDataAndLength** array, plus padding so the data begins on an 8-byte boundary.

Instance names must be USHORT aligned. Instance data must be QUADWORD aligned.

WNODE_EVENT_ITEM

WNODE_HEADER

WNODE_EVENT_ITEM structure

1/25/2019 • 2 minutes to read • Edit Online

The **WNODE_EVENT_ITEM** structure contains data generated by a driver for an event.

Syntax

```
typedef struct tagWNODE_EVENT_ITEM {
  struct _WNODE_HEADER WnodeHeader;
} WNODE_EVENT_ITEM, *PWNODE_EVENT_ITEM;
```

Members

`WnodeHeader`

Specifies a WNODE_HEADER structure that contains information common to all **WNODE_*XXX*** structures, such as the buffer size, the GUID that represents a data block associated with a request, and flags that provide information about the **WNODE_*XXX*** data being passed or returned.

Remarks

The **WnodeHeader** member of the **WNODE_EVENT_ITEM** structure is followed by a structure whose type depends on the flags that are set in **WnodeHeader**. Possibilities include WNODE_ALL_DATA, WNODE_SINGLE_INSTANCE, and WNODE_SINGLE_ITEM. For more information about the flags, see WNODE_HEADER.

The **ProviderId** member of the WNODE_HEADER structure for use in a **WNODE_EVENT_ITEM** structure should be initialized using IoWMIDeviceObjectToProviderId.

A driver generates only events that it has previously enabled in response to an IRP_MN_ENABLE_EVENTS request. To generate an event, a driver calls IoWMIWriteEvent and passes a pointer to the **WNODE_EVENT_ITEM**. WMI queues the event for delivery to all data consumers registered for that event.

For best performance, events should be small in size. However, if the amount of data for an event exceeds the maximum size defined in the registry, a driver can pass a WNODE_EVENT_REFERENCE, which WMI uses to query for the related **WNODE_EVENT_ITEM**. For more information about defining and generating WMI events, see Windows Management Instrumentation.

WNODE_EVENT_REFERENCE structure

1/25/2019 • 2 minutes to read • Edit Online

The **WNODE_EVENT_REFERENCE** structure contains information that WMI can use to query for an event that exceeds the event size limit set in the registry.

Syntax

```
typedef struct tagWNODE_EVENT_REFERENCE {
  struct _WNODE_HEADER WnodeHeader;
  GUID                 TargetGuid;
  ULONG                TargetDataBlockSize;
  union {
    ULONG TargetInstanceIndex;
    WCHAR TargetInstanceName[];
  } DUMMYUNIONNAME;
} WNODE_EVENT_REFERENCE, *PWNODE_EVENT_REFERENCE;
```

Members

`WnodeHeader`

Is a WNODE_HEADER structure that contains information common to all **WNODE_*XXX*** structures, such as the buffer size, the provider ID, the GUID that represents a data block associated with a request, and flags that provide information about the **WNODE_*XXX*** data being passed or returned.

`TargetGuid`

Indicates the GUID that represents the event to query.

`TargetDataBlockSize`

Indicates the size of the event.

`DUMMYUNIONNAME`

`DUMMYUNIONNAME.TargetInstanceIndex`

Indicates the index into the driver's list of static instance names for the event. This member is valid only if the event block was registered with static instance names and WNODE_FLAGS_STATIC_INSTANCE_NAMES is set in **WnodeHeader.Flags**.

`DUMMYUNIONNAME.TargetInstanceName`

Indicates the dynamic instance name of the event as a counted Unicode string. This member is valid only if WNODE_FLAGS_STATIC_INSTANCE_NAMES is clear in **WnodeHeader.Flags** and the event block was registered with dynamic instance names.

Remarks

If the amount of data for an event exceeds the maximum size set in the registry, a driver can generate a **WNODE_EVENT_REFERENCE** that specifies a WNODE_EVENT_ITEM that WMI can query to obtain the event. For more information about defining and generating WMI events, see Implementing WMI.

The **ProviderId** member of the WNODE_HEADER structure for use in a **WNODE_EVENT_REFERENCE** structure should be initialized using IoWMIDeviceObjectToProviderId.

WNODE_HEADER

WNODE_METHOD_ITEM structure

1/25/2019 • 2 minutes to read • Edit Online

The **WNODE_METHOD_ITEM** structure indicates a method associated with an instance of a data block and contains any input data for the method.

Syntax

```
typedef struct tagWNODE_METHOD_ITEM {
  struct _WNODE_HEADER WnodeHeader;
  ULONG                OffsetInstanceName;
  ULONG                InstanceIndex;
  ULONG                MethodId;
  ULONG                DataBlockOffset;
  ULONG                SizeDataBlock;
  UCHAR                VariableData[];
} WNODE_METHOD_ITEM, *PWNODE_METHOD_ITEM;
```

Members

`WnodeHeader`

Is a WNODE_HEADER structure that contains information common to all **WNODE_*XXX*** structures, such as the buffer size, the GUID that represents a data block associated with a request, and flags that provide information about the **WNODE_*XXX*** data being passed or returned.

`OffsetInstanceName`

Indicates the offset in bytes from the beginning of this structure to the dynamic instance name of this instance, aligned on a USHORT boundary. This member is valid only if WNODE_FLAG_STATIC_INSTANCE_NAMES is clear in **WnodeHeader.Flags**. If the data block was registered with static instance names, WMI ignores **OffsetInstanceName**.

`InstanceIndex`

Indicates the index of this instance into the driver's list of static instance names for this data block. This member is valid only if the data block was registered with static instance names and WNODE_FLAG_STATIC_INSTANCE_NAMES is set in **WnodeHeader.Flags**. If the data block was registered with dynamic instance names, WMI ignores **InstanceIndex**.

`MethodId`

Specifies the ID of the method to run.

`DataBlockOffset`

Indicates the offset from the beginning of an input **WNODE_METHOD_ITEM** to input data for the method, or the offset from the beginning of an output **WNODE_METHOD_ITEM** to output data from the method.

`SizeDataBlock`

Indicates the size of the input data in an input **WNODE_METHOD_ITEM**, or zero if there is no input. In an output **WNODE_METHOD_ITEM**, **SizeDataBlock** indicates the size of the output data, or zero if there is no output.

`VariableData`

Contains additional data, including the dynamic instance name if any, and the input for or output from the method aligned on an 8-byte boundary.

Remarks

WMI passes a **WNODE_METHOD_ITEM** with an IRP_MN_EXECUTE_METHOD request to specify a method to run in an instance of a data block, plus any input data required by the method.

If a method generates output, a driver overwrites the input data with the output at **DataBlockOffset** in the buffer at **IrpStack->Parameters.WMI.Buffer**, and sets **SizeDataBlock** in the **WNODE_METHOD_ITEM** to specify the size of the output data.

Requirements

WNODE_HEADER

WNODE_SINGLE_INSTANCE structure

1/25/2019 • 2 minutes to read • Edit Online

The **WNODE_SINGLE_INSTANCE** structure contains values for all data items in one instance of a data block.

Syntax

```
typedef struct tagWNODE_SINGLE_INSTANCE {
  struct _WNODE_HEADER WnodeHeader;
  ULONG                OffsetInstanceName;
  ULONG                InstanceIndex;
  ULONG                DataBlockOffset;
  ULONG                SizeDataBlock;
  UCHAR                VariableData[];
} WNODE_SINGLE_INSTANCE, *PWNODE_SINGLE_INSTANCE;
```

Members

`WnodeHeader`

Is a WNODE_HEADER structure that contains information common to all **WNODE_*XXX*** structures, such as the buffer size, the GUID that represents a data block associated with a request, and flags that provide information about the **WNODE_*XXX*** data being passed or returned.

`OffsetInstanceName`

Indicates the offset from the beginning of this structure to the dynamic instance name of this instance, aligned on a USHORT boundary. This member is valid only if WNODE_FLAG_STATIC_INSTANCE_NAMES is clear in **WnodeHeader.Flags**. If the data block was registered with static instance names, WMI ignores **OffsetInstanceName**.

`InstanceIndex`

Indicates the index of an instance registered with static instance names. This member is valid only if WNODE_FLAG_STATIC_INSTANCE_NAMES is set in **WnodeHeader.Flags**. If the data block was registered with dynamic instance names, WMI ignores **InstanceIndex**.

`DataBlockOffset`

Indicates the offset from the beginning of this structure to the beginning of the instance.

`SizeDataBlock`

Indicates the size of the data block for this instance.

`VariableData`

Contains additional data, including the dynamic instance name if any, padding so the instance begins on an 8-byte boundary, and the instance of the data block to be returned.

Remarks

WMI passes a **WNODE_SINGLE_INSTANCE** with an IRP_MN_CHANGE_SINGLE_INSTANCE request to set read/write data items in an instance of a data block. A driver can ignore values passed for read-only data items in

the instance.

A driver fills in a **WNODE_SINGLE_INSTANCE** in response to an IRP_MN_QUERY_SINGLE_INSTANCE request or to generate an event that consists of a single instance.

Requirements

Header	wmistr.h (include Wmistr.h)

WNODE_EVENT_ITEM

WNODE_HEADER

WNODE_SINGLE_ITEM structure

1/25/2019 • 2 minutes to read • Edit Online

The **WNODE_SINGLE_ITEM** structure contains the value of a single data item in an instance of a data block.

Syntax

```
typedef struct tagWNODE_SINGLE_ITEM {
  struct _WNODE_HEADER WnodeHeader;
  ULONG                OffsetInstanceName;
  ULONG                InstanceIndex;
  ULONG                ItemId;
  ULONG                DataBlockOffset;
  ULONG                SizeDataItem;
  UCHAR                VariableData[];
} WNODE_SINGLE_ITEM, *PWNODE_SINGLE_ITEM;
```

Members

`WnodeHeader`

Is a WNODE_HEADER structure that contains information common to all **WNODE_*XXX*** structures, such as the buffer size, the GUID that represents a data block associated with a request, and flags that provide information about the **WNODE_*XXX*** data being passed or returned.

`OffsetInstanceName`

Indicates the offset from the beginning of this structure to the dynamic instance name, if any, aligned on a USHORT boundary. This member is valid only if WNODE_FLAG_STATIC_INSTANCE_NAMES is clear in **WnodeHeader.Flags**. If the data block was registered with static instance names, WMI ignores **OffsetInstanceName**.

`InstanceIndex`

Indicates the index into the driver's list of static instance names of this instance. This member is valid only if the data block was registered with static instance names and WNODE_FLAG_STATIC_INSTANCE_NAMES is set in **WnodeHeader.Flags**. If the data block was registered with dynamic instance names, WMI ignores **InstanceIndex**.

`ItemId`

Specifies the ID of the data item to set.

`DataBlockOffset`

Indicates the offset from the beginning of this structure to the new value for the data item.

`SizeDataItem`

Indicates the size of the data item.

`VariableData`

Contains additional data, including the dynamic instance name if any, padding so the data value begins on an 8-byte boundary, and the new value for the data item.

Remarks

WMI passes a **WNODE_SINGLE_ITEM** with an IRP_MN_CHANGE_SINGLE_ITEM request to set the value of a data item in an instance of a data block.

A driver builds a **WNODE_SINGLE_ITEM** to generate an event that consists of a single data item.

Header	wmistr.h (include Wmistr.h)

See Also

WNODE_EVENT_ITEM

WNODE_HEADER

WNODE_TOO_SMALL structure

1/25/2019 • 2 minutes to read • Edit Online

The **WNODE_TOO_SMALL** structure indicates the size of the buffer needed to receive output from a request.

Syntax

```
typedef struct tagWNODE_TOO_SMALL {
  struct _WNODE_HEADER WnodeHeader;
  ULONG                SizeNeeded;
} WNODE_TOO_SMALL, *PWNODE_TOO_SMALL;
```

Members

`WnodeHeader`

Is a WNODE_HEADER structure that contains information common to all **WNODE_*XXX*** structures, such as the buffer size, the GUID that represents a data block associated with a request, and flags that provide information about the **WNODE_*XXX*** data being passed or returned.

`SizeNeeded`

Specifies the size of the buffer needed to receive all of the **WNODE_*XXX*** data to be returned.

Remarks

When the buffer for a WMI request is too small to receive all of the data to be returned, a driver fills in a **WNODE_TOO_SMALL** structure to indicate the required buffer size. WMI can then increase the buffer to the recommended size and issue the request again. A driver is responsible for managing any side effects caused by handling the same request more than once.

Requirements

Header	wmistr.h (include Wmistr.h)

WNODE_HEADER

wudfwdm.h header

1/8/2019 • 6 minutes to read • Edit Online

This header is used by wdf. For more information, see:

- Windows Driver Framework wudfwdm.h contains the following programming interfaces:

Functions

TITLE	DESCRIPTION
AppendTailList	The AppendTailList routine appends a doubly linked list of LIST_ENTRY structures to the tail of another doubly linked list of LIST_ENTRY structures.
ARGUMENT_PRESENT	The ARGUMENT_PRESENT macro takes an argument pointer and returns FALSE if the pointer is NULL. Otherwise, it returns TRUE.
InitializeListHead	The InitializeListHead routine initializes a LIST_ENTRY structure that represents the head of a doubly linked list.
InitializeObjectAttributes	The InitializeObjectAttributes macro initializes the opaque OBJECT_ATTRIBUTES structure, which specifies the properties of an object handle to routines that open handles.
InsertHeadList	The InsertHeadList routine inserts an entry at the head of a doubly linked list of LIST_ENTRY structures.
InsertTailList	The InsertTailList routine inserts an entry at the tail of a doubly linked list of LIST_ENTRY structures.
IsListEmpty	The IsListEmpty routine indicates whether a doubly linked list of LIST_ENTRY structures is empty.
PopEntryList	The PopEntryList routine removes the first entry from a singly linked list of SINGLE_LIST_ENTRY structures.
PushEntryList	The PushEntryList routine inserts an entry at the beginning of a singly linked list of SINGLE_LIST_ENTRY structures.
READ_REGISTER_BUFFER_UCHAR	The READ_REGISTER_BUFFER_UCHAR routine reads a number of bytes from the specified register address into a buffer.
READ_REGISTER_BUFFER_ULONG	The READ_REGISTER_BUFFER_ULONG routine reads a number of ULONG values from the specified register address into a buffer.
READ_REGISTER_BUFFER_ULONG64	The READ_REGISTER_BUFFER_ULONG64 function reads a number of ULONG64 values from the specified register address into a buffer.

TITLE	DESCRIPTION
READ_REGISTER_BUFFER_USHORT	The READ_REGISTER_BUFFER_USHORT routine reads a number of USHORT values from the specified register address into a buffer.
READ_REGISTER_UCHAR	The READ_REGISTER_UCHAR routine reads a byte from the specified register address.
READ_REGISTER_ULONG	The READ_REGISTER_ULONG routine reads a ULONG value from the specified register address.
READ_REGISTER_ULONG64	The READ_REGISTER_ULONG64 function reads a ULONG64 value from the specified register address.
READ_REGISTER_USHORT	The READ_REGISTER_USHORT routine reads a USHORT value from the specified register address.
RemoveEntryList	The RemoveEntryList routine removes an entry from a doubly linked list of LIST_ENTRY structures.
RemoveHeadList	The RemoveHeadList routine removes an entry from the beginning of a doubly linked list of LIST_ENTRY structures.
RemoveTailList	The RemoveTailList routine removes an entry from the end of a doubly linked list of LIST_ENTRY structures.
RtlAppendUnicodeStringToString	The RtlAppendUnicodeStringToString routine concatenates two Unicode strings.
RtlAppendUnicodeToString	The RtlAppendUnicodeToString routine concatenates the supplied Unicode string to a buffered Unicode string.
RtlCompareUnicodeString	The RtlCompareUnicodeString routine compares two Unicode strings.
RtlCopyUnicodeString	The RtlCopyUnicodeString routine copies a source string to a destination string.
RtlEqualUnicodeString	The RtlEqualUnicodeString routine compares two Unicode strings to determine whether they are equal.
RtlFreeUnicodeString	The RtlFreeUnicodeString routine releases storage that was allocated by RtlAnsiStringToUnicodeString or RtlUpcaseUnicodeString.
RtlInitUnicodeString	For more information, see the WdmlibRtlInitUnicodeStringEx function.
RtlInt64ToUnicodeString	The RtlInt64ToUnicodeString routine converts a specified unsigned 64-bit integer value to a Unicode string that represents the value in a specified base.
RtlIntegerToUnicodeString	The RtlIntegerToUnicodeString routine converts an unsigned integer value to a null-terminated string of one or more Unicode characters in the specified base.

TITLE	DESCRIPTION
RtlIntPtrToUnicodeString	The RtlIntPtrToUnicodeString routine converts a specified ULONG_PTR value to a Unicode string that represents the value in a specified base.
RtlUnicodeStringToInteger	The RtlUnicodeStringToInteger routine converts a Unicode string representation of a number to the equivalent integer value.
WRITE_REGISTER_BUFFER_UCHAR	The WRITE_REGISTER_BUFFER_UCHAR routine writes a number of bytes from a buffer to the specified register.
WRITE_REGISTER_BUFFER_ULONG	The WRITE_REGISTER_BUFFER_ULONG routine writes a number of ULONG values from a buffer to the specified register.
WRITE_REGISTER_BUFFER_ULONG64	The WRITE_REGISTER_BUFFER_ULONG64 function writes a number of ULONG64 values from a buffer to the specified register.
WRITE_REGISTER_BUFFER_USHORT	The WRITE_REGISTER_BUFFER_USHORT routine writes a number of USHORT values from a buffer to the specified register.
WRITE_REGISTER_UCHAR	The WRITE_REGISTER_UCHAR routine writes a byte to the specified address.
WRITE_REGISTER_ULONG	The WRITE_REGISTER_ULONG routine writes a ULONG value to the specified address.
WRITE_REGISTER_ULONG64	The WRITE_REGISTER_ULONG64 function writes a ULONG64 value to the specified address.
WRITE_REGISTER_USHORT	The WRITE_REGISTER_USHORT routine writes a USHORT value to the specified address.

Callback functions

TITLE	DESCRIPTION
DRIVER_INITIALIZE	DriverEntry is the first routine called after a driver is loaded, and is responsible for initializing the driver.
PINTERFACE_DEREFERENCE	The InterfaceDereference routine decrements the reference count on a driver-defined interface.
PINTERFACE_REFERENCE	The InterfaceReference routine increments the reference count on a driver-defined interface.
PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK	The ComponentActiveConditionCallback callback routine notifies the driver that the specified component completed a transition from the idle condition to the active condition.

TITLE	DESCRIPTION
PO_FX_COMPONENT_CRITICAL_TRANSITION_CALLBACK	The ComponentCriticalTransitionCallback callback routine handles a transition of the specified component between the F0 (fully on) and low-power Fx component power states.
PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK	The ComponentIdleConditionCallback callback routine notifies the driver that the specified component completed a transition from the active condition to the idle condition.
PO_FX_COMPONENT_IDLE_STATE_CALLBACK	The ComponentIdleStateCallback callback routine notifies the driver of a pending change to the Fx power state of the specified component.
PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK	The DevicePowerNotRequiredCallback callback routine notifies the device driver that the device is not required to stay in the D0 power state.
PO_FX_DEVICE_POWER_REQUIRED_CALLBACK	The DevicePowerRequiredCallback callback routine notifies the device driver that the device must enter and remain in the D0 power state.
PO_FX_POWER_CONTROL_CALLBACK	The PowerControlCallback callback routine performs a power control operation that is requested by the power management framework (PoFx).

Structures

TITLE	DESCRIPTION
IO_STATUS_BLOCK	A driver sets an IRP's I/O status block to indicate the final status of an I/O request, before calling IoCompleteRequest for the IRP.
CM_FULL_RESOURCE_DESCRIPTOR	The CM_FULL_RESOURCE_DESCRIPTOR structure specifies a set of system hardware resources of various types, assigned to a device that is connected to a specific bus. This structure is contained within a CM_RESOURCE_LIST structure.
CM_PARTIAL_RESOURCE_DESCRIPTOR	The CM_PARTIAL_RESOURCE_DESCRIPTOR structure specifies one or more system hardware resources, of a single type, assigned to a device.
CM_PARTIAL_RESOURCE_LIST	The CM_PARTIAL_RESOURCE_LIST structure specifies a set of system hardware resources, of various types, assigned to a device. This structure is contained within a CM_FULL_RESOURCE_DESCRIPTOR structure.
CM_RESOURCE_LIST	The CM_RESOURCE_LIST structure specifies all of the system hardware resources assigned to a device.
OBJECT_ATTRIBUTES	The OBJECT_ATTRIBUTES structure specifies attributes that can be applied to objects or object handles by routines that create objects and/or return handles to objects.

TITLE	DESCRIPTION
PO_FX_COMPONENT_IDLE_STATE	The PO_FX_COMPONENT_IDLE_STATE structure specifies the attributes of an Fx power state of a component in a device.
PO_FX_COMPONENT_PERF_INFO	The PO_FX_COMPONENT_PERF_INFO structure describes all the sets of performance states for a single component within a device.
PO_FX_COMPONENT_PERF_SET	The PO_FX_COMPONENT_PERF_SET structure represents a set of performance states for a single component within a device.
PO_FX_COMPONENT_V1	The PO_FX_COMPONENT structure describes the power state attributes of a component in a device.
PO_FX_COMPONENT_V2	The PO_FX_COMPONENT structure describes the power state attributes of a component in a device.
PO_FX_DEVICE_V1	The PO_FX_DEVICE structure describes the power attributes of a device to the power management framework (PoFx).
PO_FX_DEVICE_V2	The PO_FX_DEVICE structure describes the power attributes of a device to the power management framework (PoFx).
PO_FX_PERF_STATE	The PO_FX_PERF_STATE structure represents a performance state for a single component within a device.
PO_FX_PERF_STATE_CHANGE	The PO_FX_PERF_STATE_CHANGE structure contains information about a change to a performance state that is being requested by calling the PoFxIssueComponentPerfStateChange or PoFxIssueComponentPerfStateChangeMultiple routine.
UNICODE_STRING	The UNICODE_STRING structure is used to define Unicode strings.

Enumerations

TITLE	DESCRIPTION
DEVICE_REGISTRY_PROPERTY	The DEVICE_REGISTRY_PROPERTY enumeration identifies device properties that are stored in the registry.
INTERFACE_TYPE	The INTERFACE_TYPE enumeration indicates the bus type.
KINTERRUPT_MODE	The KINTERRUPT_MODE enumeration type indicates whether an interrupt is level-triggered or edge-triggered.
MEMORY_CACHING_TYPE	The MEMORY_CACHING_TYPE enumeration type specifies the permitted caching behavior when allocating or mapping memory.
PO_FX_PERF_STATE_TYPE	The PO_FX_PERF_STATE_TYPE enumeration contains values that describe the type of performance states in a PO_FX_COMPONENT_PERF_SET.

TITLE	DESCRIPTION
PO_FX_PERF_STATE_UNIT	The PO_FX_PERF_STATE_UNIT enumeration contains values that describe the type of unit that is controlled by the performance states in a PO_FX_COMPONENT_PERF_SET.
POOL_TYPE	The POOL_TYPE enumeration type specifies the type of system memory to allocate.

CM_FULL_RESOURCE_DESCRIPTOR structure

1/30/2019 • 2 minutes to read • Edit Online

The **CM_FULL_RESOURCE_DESCRIPTOR** structure specifies a set of system hardware resources of various types, assigned to a device that is connected to a specific bus. This structure is contained within a CM_RESOURCE_LIST structure.

Syntax

```
typedef struct _CM_FULL_RESOURCE_DESCRIPTOR {
  INTERFACE_TYPE           InterfaceType;
  ULONG                    BusNumber;
  CM_PARTIAL_RESOURCE_LIST PartialResourceList;
} CM_FULL_RESOURCE_DESCRIPTOR, *PCM_FULL_RESOURCE_DESCRIPTOR;
```

Members

`InterfaceType`

Specifies the type of bus to which the device is connected. This must be one of the types defined by INTERFACE_TYPE, in Wdm.h or Ntddk.h. (Not used by WDM drivers.)

`BusNumber`

The system-assigned, driver-supplied, zero-based number of the bus to which the device is connected. (Not used by WDM drivers.)

`PartialResourceList`

A CM_PARTIAL_RESOURCE_LIST structure.

Requirements

Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)

See Also

CM_PARTIAL_RESOURCE_LIST

CM_RESOURCE_LIST

CM_PARTIAL_RESOURCE_DESCRIPTOR structure

1/30/2019 • 9 minutes to read • Edit Online

The **CM_PARTIAL_RESOURCE_DESCRIPTOR** structure specifies one or more system hardware resources, of a single type, assigned to a device. This structure is used to create an array within a CM_PARTIAL_RESOURCE_LIST structure.

Syntax

```
typedef struct _CM_PARTIAL_RESOURCE_DESCRIPTOR {
  UCHAR  Type;
  UCHAR  ShareDisposition;
  USHORT Flags;
  union {
    struct {
      PHYSICAL_ADDRESS Start;
      ULONG            Length;
    } Generic;
    struct {
      PHYSICAL_ADDRESS Start;
      ULONG            Length;
    } Port;
    struct {
#if ...
      USHORT    Level;
      USHORT    Group;
#else
      ULONG     Level;
#endif
      ULONG     Vector;
      KAFFINITY Affinity;
    } Interrupt;
    struct {
      union {
        struct {
          USHORT    Group;
          USHORT    Reserved;
          USHORT    MessageCount;
          ULONG     Vector;
          KAFFINITY Affinity;
        } Raw;
        struct {
#if ...
          USHORT    Level;
          USHORT    Group;
#else
          ULONG     Level;
#endif
          ULONG     Vector;
          KAFFINITY Affinity;
        } Translated;
      } DUMMYUNIONNAME;
    } MessageInterrupt;
    struct {
      PHYSICAL_ADDRESS Start;
      ULONG            Length;
    } Memory;
    struct {
      ULONG Channel;
      ULONG Port;
      ULONG Reserved1;
```

```
      ULONG Reserved1;
    } Dma;
    struct {
      ULONG Channel;
      ULONG RequestLine;
      UCHAR TransferWidth;
      UCHAR Reserved1;
      UCHAR Reserved2;
      UCHAR Reserved3;
    } DmaV3;
    struct {
      ULONG Data[3];
    } DevicePrivate;
    struct {
      ULONG Start;
      ULONG Length;
      ULONG Reserved;
    } BusNumber;
    struct {
      ULONG DataSize;
      ULONG Reserved1;
      ULONG Reserved2;
    } DeviceSpecificData;
    struct {
      PHYSICAL_ADDRESS Start;
      ULONG            Length40;
    } Memory40;
    struct {
      PHYSICAL_ADDRESS Start;
      ULONG            Length48;
    } Memory48;
    struct {
      PHYSICAL_ADDRESS Start;
      ULONG            Length64;
    } Memory64;
    struct {
      UCHAR Class;
      UCHAR Type;
      UCHAR Reserved1;
      UCHAR Reserved2;
      ULONG IdLowPart;
      ULONG IdHighPart;
    } Connection;
  } u;
} CM_PARTIAL_RESOURCE_DESCRIPTOR, *PCM_PARTIAL_RESOURCE_DESCRIPTOR;
```

Members

`Type`

Identifies the resource type. The constant value specified for **Type** indicates which structure within the **u** union is valid, as indicated in the following table. (These flags are used within both **CM_PARTIAL_RESOURCE_DESCRIPTOR** and IO_RESOURCE_DESCRIPTOR structures, except where noted.)

TYPE VALUE	U MEMBER SUBSTRUCTURE
CmResourceTypePort	**u.Port**
CmResourceTypeInterrupt	**u.Interrupt** or **u.MessageInterrupt**.If the CM_RESOURCE_INTERRUPT_MESSAGE flag of **Flags** is set, use **u.MessageInterrupt**; otherwise, use **u.Interrupt**.
CmResourceTypeMemory	**u.Memory**

CmResourceTypeMemoryLarge	One of **u.Memory40**, **u.Memory48**, or **u.Memory64**.The CM_RESOURCE_MEMORY_LARGE_*XXX* flags set in the **Flags** member determines which structure is used.
CmResourceTypeDma	**u.Dma** (if CM_RESOURCE_DMA_V3 is not set) or **u.DmaV3** (if CM_RESOURCE_DMA_V3 flag is set)
CmResourceTypeDevicePrivate	**u.DevicePrivate**
CmResourceTypeBusNumber	**u.BusNumber**
CmResourceTypeDeviceSpecific	**u.DeviceSpecificData**(Not used within **IO_RESOURCE_DESCRIPTOR**.)
CmResourceTypePcCardConfig	**u.DevicePrivate**
CmResourceTypeMfCardConfig	**u.DevicePrivate**
CmResourceTypeConnection	**u.Connection**
CmResourceTypeConfigData	*Reserved for system use.*
CmResourceTypeNonArbitrated	*Not used.*

`ShareDisposition`

Indicates whether the described resource can be shared. Valid constant values are listed in the following table.

VALUE	MEANING
CmResourceShareDeviceExclusive	The device requires exclusive use of the resource.
CmResourceShareDriverExclusive	The driver requires exclusive use of the resource. (Not supported for WDM drivers.)

CmResourceShareShared	The resource can be shared without restriction.

`Flags`

Contains flag bits that are specific to the resource type, as indicated in the following table. Flags can be bitwise-ORed together as appropriate.

RESOURCE TYPE	FLAG	DEFINITION
CmResourceTypePort		
	CM_RESOURCE_PORT_MEMORY	The device is accessed in memory address space.
	CM_RESOURCE_PORT_IO	The device is accessed in I/O address space.
	CM_RESOURCE_PORT_10_BIT_DECODE	The device decodes 10 bits of the port address.
	CM_RESOURCE_PORT_12_BIT_DECODE	The device decodes 12 bits of the port address.
	CM_RESOURCE_PORT_16_BIT_DECODE	The device decodes 16 bits of the port address.
	CM_RESOURCE_PORT_POSITIVE_DECODE	The device uses "positive decode" instead of "subtractive decode". (In general, PCI devices use positive decode and ISA buses use subtractive decode.)
	CM_RESOURCE_PORT_PASSIVE_DECODE	The device decodes the port but the driver does not use it.
	CM_RESOURCE_PORT_WINDOW_DECODE	Reserved for system use.
CmResourceTypeInterrupt		
	CM_RESOURCE_INTERRUPT_LEVEL_SENSITIVE	The IRQ line is level-triggered. (These IRQs are usually sharable.)
	CM_RESOURCE_INTERRUPT_LATCHED	The IRQ line is edge-triggered.

	CM_RESOURCE_INTERRUPT_MESSAGE	If this flag is set, the interrupt is a message-signaled interrupt. Otherwise, the interrupt is a line-based interrupt. This flag can be set starting with Windows Vista.
	CM_RESOURCE_INTERRUPT_POLICY_INCLUDED	Not used with the **CM_PARTIAL_RESOURCE_DESCRIPTOR** structure. For more information about this flag, see IO_RESOURCE_DESCRIPTOR.
	CM_RESOURCE_INTERRUPT_SECONDARY_INTERRUPT	The interrupt is a secondary interrupt. This flag can be set starting with Windows 8. For more information about secondary interrupts, see GPIO Interrupts.
	CM_RESOURCE_INTERRUPT_WAKE_HINT	The interrupt is capable of waking the operating system from a low-power idle state or a system sleep state. This flag can be set starting with Windows 8. For more information about wake capabilities, see Enabling Device Wake-Up.
CmResourceTypeMemory		
	CM_RESOURCE_MEMORY_READ_WRITE	The memory range is readable and writable.
	CM_RESOURCE_MEMORY_READ_ONLY	The memory range is read-only.
	CM_RESOURCE_MEMORY_WRITE_ONLY	The memory range is write-only.
	CM_RESOURCE_MEMORY_PREFETCHABLE	The memory range is prefetchable.
	CM_RESOURCE_MEMORY_COMBINEDWRITE	Combined-write caching is allowed.
	CM_RESOURCE_MEMORY_24	The device uses 24-bit addressing.
	CM_RESOURCE_MEMORY_CACHEABLE	The memory range is cacheable.
CmResourceTypeMemoryLarge		

	CM_RESOURCE_MEMORY_LARGE_40	The memory descriptor uses the **u.Memory40** member.
	CM_RESOURCE_MEMORY_LARGE_48	The memory descriptor uses the **u.Memory48** member.
	CM_RESOURCE_MEMORY_LARGE_64	The memory descriptor uses the **u.Memory64** member.
CmResourceTypeDma		
	CM_RESOURCE_DMA_8	8-bit DMA channel
	CM_RESOURCE_DMA_16	16-bit DMA channel
	CM_RESOURCE_DMA_32	32-bit DMA channel
	CM_RESOURCE_DMA_8_AND_16	8-bit and 16-bit DMA channel
	CM_RESOURCE_DMA_BUS_MASTER	The device supports bus master DMA transfers.
	CM_RESOURCE_DMA_TYPE_A	Type A DMA
	CM_RESOURCE_DMA_TYPE_B	Type B DMA
	CM_RESOURCE_DMA_TYPE_F	Type F DMA
	CM_RESOURCE_DMA_V3	Use the **DmaV3** member instead of the **Dma** member. The **DmaV3** member is available starting with Windows 8.

`u`

`u.Generic`

`u.Generic.Start`

`u.Generic.Length`

`u.Port`

`u.Port.Start`

For raw resources: Specifies the bus-relative physical address of the lowest of a range of contiguous I/O port addresses allocated to the device.

For translated resources: Specifies the system physical address of the lowest of a range of contiguous I/O port addresses allocated to the device.

For more information about raw and translated resources, see Remarks.

`u.Port.Length`

The length, in bytes, of the range of allocated I/O port addresses.

`u.Interrupt`

`u.Interrupt.Level.#1877845754`

`u.Interrupt.Group`

Specifies the processor group number. This member exists only if the NT_PROCESSOR_GROUPS constant is defined at compile time. This member can be nonzero only on Windows 7 and later versions of Windows. The **Group** and **Affinity** members together specify a group affinity that indicates which processors the device can interrupt. To specify an affinity for any group, set **Group** to ALL_PROCESSOR_GROUPS.

`u.Interrupt.Level.#3336307498`

`u.Interrupt.Vector`

For raw resources: Specifies the device's bus-specific interrupt vector (if appropriate for the platform and bus).

For translated resources: Specifies the global system interrupt vector assigned to the device.

For more information about raw and translated resources, see Remarks.

`u.Interrupt.Affinity`

Contains a **KAFFINITY**-typed bitmask value indicating the set of processors the device can interrupt. To indicate that the device can interrupt any processor, this member is set to -1.

`u.MessageInterrupt`

`u.MessageInterrupt.DUMMYUNIONNAME`

`u.MessageInterrupt.DUMMYUNIONNAME.Raw`

`u.MessageInterrupt.DUMMYUNIONNAME.Raw.Group`

Specifies a processor group number. This member exists only if NT_PROCESSOR_GROUPS is defined at compile time. This member can be nonzero only on Windows 7 and later versions of Windows. The **Group** and **Affinity** members together specify a group affinity that indicates which processors can receive the device's interrupts. To specify an affinity for any group, set **Group** to ALL_PROCESSOR_GROUPS.

`u.MessageInterrupt.DUMMYUNIONNAME.Raw.Reserved`

Not used.

`u.MessageInterrupt.DUMMYUNIONNAME.Raw.MessageCount`

Specifies the number of message-signaled interrupts generated for this driver.

`u.MessageInterrupt.DUMMYUNIONNAME.Raw.Vector`

Specifies the device's interrupt vector.

`u.MessageInterrupt.DUMMYUNIONNAME.Raw.Affinity`

Specifies a KAFFINITY value that indicates the processors that receive the device's interrupts.

`u.MessageInterrupt.DUMMYUNIONNAME.Translated`

`u.MessageInterrupt.DUMMYUNIONNAME.Translated.Level.#1877845754`

`u.MessageInterrupt.DUMMYUNIONNAME.Translated.Group`

Specifies a processor group number. This member exists only if NT_PROCESSOR_GROUPS is defined at compile time. This member can be nonzero only on Windows 7 and later versions of Windows. The **Translated.Group** and

Translated.Affinity members together specify a group affinity that indicates which processors can receive the device's interrupts. To specify an affinity for any group, set **Translated.Group** to ALL_PROCESSOR_GROUPS.

`u.MessageInterrupt.DUMMYUNIONNAME.Translated.Level.#3336307498`

`u.MessageInterrupt.DUMMYUNIONNAME.Translated.Vector`

Specifies the device's interrupt vector.

`u.MessageInterrupt.DUMMYUNIONNAME.Translated.Affinity`

Specifies a KAFFINITY value that identifies the processors that receive the device's interrupts.

`u.Memory`

`u.Memory.Start`

For raw resources: Specifies the bus-relative physical address of the lowest of a range of contiguous memory addresses allocated to the device.

For translated resources: Specifies the system physical address of the lowest of a range of contiguous memory addresses allocated to the device.

For more information about raw and translated resources, see Remarks.

`u.Memory.Length`

Specifies the length, in bytes, of the range of allocated memory addresses.

`u.Dma`

`u.Dma.Channel`

Specifies the number of the DMA channel on a system DMA controller that the device can use.

`u.Dma.Port`

Specifies the number of the DMA port that an MCA-type device can use.

`u.Dma.Reserved1`

Not used.

`u.DmaV3`

`u.DmaV3.Channel`

Specifies the number of the DMA channel on the system DMA controller that is allocated to the device.

`u.DmaV3.RequestLine`

Specifies the number of the request line on the system DMA controller that is allocated to the device.

`u.DmaV3.TransferWidth`

Specifies the width, in bits, of the data bus that the system DMA controller that is allocated to the device uses to transfer data to or from the device.

`u.DmaV3.Reserved1`

Not used.

`u.DmaV3.Reserved2`

Not used.

`u.DmaV3.Reserved3`

Not used.

`u.DevicePrivate`

`u.DevicePrivate.Data`

`u.BusNumber`

`u.BusNumber.Start`

Specifies the lowest-numbered of a range of contiguous buses allocated to the device.

`u.BusNumber.Length`

Specifies the number of buses allocated to the device.

`u.BusNumber.Reserved`

Not used.

`u.DeviceSpecificData`

`u.DeviceSpecificData.DataSize`

Specifies the number of bytes appended to the end of the **CM_PARTIAL_RESOURCE_DESCRIPTOR** structure.

`u.DeviceSpecificData.Reserved1`

Not used.

`u.DeviceSpecificData.Reserved2`

Not used.

`u.Memory40`

`u.Memory40.Start`

For raw resources: Specifies the bus-relative physical address of the lowest of a range of contiguous memory addresses that are allocated to the device.

For translated resources: Specifies the system physical address of the lowest of a range of contiguous memory addresses that are allocated to the device.

For more information about raw and translated resources, see Remarks.

`u.Memory40.Length40`

Contains the high 32 bits of the 40-bit length, in bytes, of the range of allocated memory addresses. The lowest 8 bits are treated as zero.

`u.Memory48`

`u.Memory48.Start`

For raw resources: Specifies the bus-relative physical address of the lowest of a range of contiguous memory addresses that are allocated to the device.

For translated resources: Specifies the system physical address of the lowest of a range of contiguous memory addresses that are allocated to the device.

For more information about raw and translated resources, see Remarks.

`u.Memory48.Length48`

Contains the high 32 bits of the 48-bit length, in bytes, of the range of allocated memory addresses. The lowest 16 bits are treated as zero.

`u.Memory64`

`u.Memory64.Start`

For raw resources: Specifies the bus-relative physical address of the lowest of a range of contiguous memory addresses that are allocated to the device.

For translated resources: Specifies the system physical address of the lowest of a range of contiguous memory addresses that are allocated to the device.

For more information about raw and translated resources, see Remarks.

`u.Memory64.Length64`

Contains the high 32 bits of the 64-bit length, in bytes, of the range of allocated memory addresses. The lowest 32 bits are treated as zero.

`u.Connection`

`u.Connection.Class`

Specifies the connection class. This member is set to one of the following values.

VALUE	MEANING
CM_RESOURCE_CONNECTION_CLASS_GPIO	Access the device through one or more pins on a GPIO controller.
CM_RESOURCE_CONNECTION_CLASS_SERIAL	Access the device through a serial bus or serial port.

`u.Connection.Type`

Specifies the connection type.

If **Class** = CM_RESOURCE_CONNECTION_CLASS_GPIO, **Type** is set to the following value.

VALUE	MEANING
CM_RESOURCE_CONNECTION_TYPE_GPIO_IO	Access the device through GPIO pins that are configured for I/O.

Note A GPIO pin that is configured as an interrupt request input is accessed as an ordinary interrupt resource (**CmResourceTypeInterrupt**).

If **Class** = CM_RESOURCE_CONNECTION_CLASS_SERIAL, **Type** is set to one of the following values.

VALUE	MEANING
CM_RESOURCE_CONNECTION_TYPE_SERIAL_I2C	The device is connected to an I^2C bus.
CM_RESOURCE_CONNECTION_TYPE_SERIAL_SPI	The device is connected to an SPI bus.

CM_RESOURCE_CONNECTION_TYPE_SERIAL_UART	The device is connected to a serial port.

`u.Connection.Reserved1`

Not used.

`u.Connection.Reserved2`

Not used.

`u.Connection.IdLowPart`

Contains the lower 32 bits of the 64-bit connection ID.

`u.Connection.IdHighPart`

Contains the upper 32 bits of the 64-bit connection ID.

Remarks

A **CM_PARTIAL_RESOURCE_DESCRIPTOR** structure can describe either a raw (bus-relative) resource or a translated (system physical) resource, depending on the routine or IRP with which it is being used. For more information, see Raw and Translated Resources and IRP_MN_START_DEVICE.

Requirements

CM_PARTIAL_RESOURCE_LIST structure

1/30/2019 • 2 minutes to read • Edit Online

The **CM_PARTIAL_RESOURCE_LIST** structure specifies a set of system hardware resources, of various types, assigned to a device. This structure is contained within a CM_FULL_RESOURCE_DESCRIPTOR structure.

Syntax

```
typedef struct _CM_PARTIAL_RESOURCE_LIST {
  USHORT                          Version;
  USHORT                          Revision;
  ULONG                           Count;
  CM_PARTIAL_RESOURCE_DESCRIPTOR PartialDescriptors[1];
} CM_PARTIAL_RESOURCE_LIST, *PCM_PARTIAL_RESOURCE_LIST;
```

Members

`Version`

The version number of this structure. This value should be 1.

`Revision`

The revision of this structure. This value should be 1.

`Count`

The number of elements contained in the **PartialDescriptors** array.

`PartialDescriptors`

The first element in an array of one or more CM_PARTIAL_RESOURCE_DESCRIPTOR structures.

Remarks

This structure is the header for an array of **CM_PARTIAL_RESOURCE_DESCRIPTOR** structures. The **PartialDescriptors** member contains the first element in this array, and the **Count** member specifies the total number of array elements. If the array contains more than one element, the remaining elements in the array immediately follow the **CM_PARTIAL_RESOURCE_LIST** structure in memory. The total number of bytes occupied by the **CM_PARTIAL_RESOURCE_LIST** structure and any array elements that follow this structure is **sizeof**(**CM_PARTIAL_RESOURCE_LIST**) + (**Count** - 1) * **sizeof**(**CM_PARTIAL_RESOURCE_DESCRIPTOR**).

Requirements

Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)

CM_FULL_RESOURCE_DESCRIPTOR

CM_RESOURCE_LIST structure

1/30/2019 • 3 minutes to read • Edit Online

The **CM_RESOURCE_LIST** structure specifies all of the system hardware resources assigned to a device.

Syntax

```
typedef struct _CM_RESOURCE_LIST {
  ULONG                        Count;
  CM_FULL_RESOURCE_DESCRIPTOR List[1];
} CM_RESOURCE_LIST, *PCM_RESOURCE_LIST;
```

Members

`Count`

The number of full resource descriptors that are specified by this **CM_RESOURCE_LIST** structure. The **List** member is the header for the first full resource descriptor. For WDM drivers, **Count** is always 1.

`List`

The CM_FULL_RESOURCE_DESCRIPTOR structure that serves as the header for the first full resource descriptor. If the **CM_RESOURCE_LIST** structure contains more than one full resource descriptor, the second full resource descriptor immediately follows the first in memory, and so on. The size of each full resource descriptor depends on the length of the CM_PARTIAL_RESOURCE_DESCRIPTOR array that it contains. For more information, see the following Remarks section.

Remarks

This structure describes the assignment of hardware resources to a device. An IRP_MN_START_DEVICE IRP uses this structure to specify the resources that the Plug and Play manager assigns to a device. Drivers for legacy devices use this structure to pass their resource requirements to the IoReportResourceForDetection routine. For more information about hardware resource allocation, see Hardware Resources.

The **CM_RESOURCE_LIST** structure is a header for a larger data structure, of variable size, that contains one or more full resource descriptors. All of the data in this larger structure occupies a contiguous block of memory. Each full resource descriptor occupies a subblock within the larger block.

A full resource descriptor begins with a CM_FULL_RESOURCE_DESCRIPTOR structure, which serves as a header for an array of CM_PARTIAL_RESOURCE_DESCRIPTOR structures. The length of this array determines the size of the full resource descriptor. The last member in the **CM_FULL_RESOURCE_DESCRIPTOR** structure is a CM_PARTIAL_RESOURCE_LIST structure that contains, as its last member, the first element in this array. If the array contains more than one element, the remaining elements immediately follow, in memory, the end of the **CM_PARTIAL_RESOURCE_LIST** structure, which is also the end of the **CM_FULL_RESOURCE_DESCRIPTOR** structure.

Driver code can use pointer arithmetic to step from one full resource descriptor to the next. For example, if a parameter named *list* is a pointer to the **CM_FULL_RESOURCE_DESCRIPTOR** structure at the start of one full resource descriptor, *list* can be updated to point to the start of the next full resource descriptor as follows:

```
    list = (PCM_FULL_RESOURCE_DESCRIPTOR)(list->PartialResourceList.PartialDescriptors +
                                          list->PartialResourceList.Count);
```

In this example, `list->PartialResourceList.PartialDescriptors` is a pointer to the start of the **CM_PARTIAL_RESOURCE_DESCRIPTOR** array, and `list->PartialResourceList.Count` is the number of elements in the array. For more information about the **PartialDescriptors** and **Count** members, see CM_PARTIAL_RESOURCE_LIST. #### Examples All PnP drivers must handle IRP_MN_START_DEVICE IRPs. Typically, a driver's handler for this IRP walks the lists of assigned resources that are pointed to by the **Parameters.StartDevice.AllocatedResources** and **Parameters.StartDevice.AllocatedResourcesTranslated** members of the IO_STACK_LOCATION structure in the IRP. The following code example contains a function—named GetAssignedResources—that is called in the handler to walk each list. This function verifies that the required resources are specified in the list, and configures the device to use the resources. The GetAssignedResources function returns **TRUE** if it succeeds. Otherwise, it returns **FALSE** (probably from the **switch** statement, although the details are omitted to simplify the code example).

```
/* Process the assigned hardware resources. */

BOOLEAN GetAssignedResources(PCM_RESOURCE_LIST reslist)
{
    PCM_FULL_RESOURCE_DESCRIPTOR list;

    list = reslist->List;

    for (int ix = 0; ix < reslist->Count; ++ix)
    {
        /* Process resources in CM_FULL_RESOURCE_DESCRIPTOR block number ix. */

        for (int jx = 0; jx < list->PartialResourceList.Count; ++jx)
        {
            PCM_PARTIAL_RESOURCE_DESCRIPTOR desc;

            desc = list->PartialResourceList.PartialDescriptors + jx;

            switch (desc->Type)
            {
                /* Process element jx in PartialDescriptors array. */

                ...

            }
        }

        /* Advance to next CM_FULL_RESOURCE_DESCRIPTOR block in memory. */

        list = (PCM_FULL_RESOURCE_DESCRIPTOR)(list->PartialResourceList.PartialDescriptors +
                                              list->PartialResourceList.Count);
    }

    return TRUE;
}
```

INTERFACE_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **INTERFACE_TYPE** enumeration indicates the bus type.

Syntax

```
typedef enum _INTERFACE_TYPE {
  InterfaceTypeUndefined,
  Internal,
  Isa,
  Eisa,
  MicroChannel,
  TurboChannel,
  PCIBus,
  VMEBus,
  NuBus,
  PCMCIABus,
  CBus,
  MPIBus,
  MPSABus,
  ProcessorInternal,
  InternalPowerBus,
  PNPISABus,
  PNPBus,
  Vmcs,
  ACPIBus,
  MaximumInterfaceType
} INTERFACE_TYPE, *PINTERFACE_TYPE;
```

Constants

InterfaceTypeUndefined	Indicates that the interface type is undefined.
Internal	For internal use only.
Isa	Indicates that the interface is published by the ISA bus driver.
Eisa	Indicates that the interface is published by the EISA bus driver.
MicroChannel	Indicates that the interface is published by the MicroChannel bus driver.
TurboChannel	Indicates that the interface is published by the TurboChannel bus driver.
PCIBus	Indicates that the interface is published by the PCI bus driver.
VMEBus	Indicates that the interface is published by the VME bus driver.
NuBus	Indicates that the interface is published by the NuBus driver.

PCMCIABus	Indicates that the interface is published by the PCMCIA bus driver.
CBus	Indicates that the interface is published by the Cbus driver.
MPIBus	Indicates that the interface is published by the MPI bus driver.
MPSABus	Indicates that the interface is published by the MPSA bus driver.
ProcessorInternal	Indicates that the interface is published by the ISA bus driver.
InternalPowerBus	Indicates that the interface is published for an internal power bus. Some devices have power control ports that allow them to share power control with other devices. The Windows architecture represents these devices as slots on a virtual bus called an "internal power bus."
PNPISABus	Indicates that the interface is published by the PNPISA bus driver.
PNPBus	Indicates that the interface is published by the PNP bus driver.
Vmcs	Reserved for use by the operating system.
ACPIBus	Indicates that the interface is published by the ACPI bus driver. The ACPI bus driver enumerates devices that are described in the ACPI firmware of the hardware platform. These devices might physically reside on buses that are controlled by other bus drivers, but the ACPI bus driver must enumerate these devices because the other bus drivers cannot detect them. This interface type is defined starting with Windows 8.
MaximumInterfaceType	Marks the upper limit of the possible bus types.

KINTERRUPT_MODE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **KINTERRUPT_MODE** enumeration type indicates whether an interrupt is level-triggered or edge-triggered.

Syntax

```
typedef enum _KINTERRUPT_MODE {
  LevelSensitive,
  Latched
} KINTERRUPT_MODE;
```

Constants

LevelSensitive	The interrupt is level-triggered. This is the mode for traditional PCI line-based interrupts.
Latched	The interrupt is edge-triggered. This is the mode for PCI message-signaled interrupts.

Remarks

The interrupt mode is an electrical characteristic of the interrupt. A device signals a level-triggered interrupt by changing the voltage on the interrupt pin, and holding it there until the processor signals that the interrupt is received. In contrast, to signal an edge-triggered interrupt, the device changes the voltage state for a fixed period of time, before reverting to the original voltage state.

Requirements

Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)

IoConnectInterruptEx

KINTERRUPT_POLARITY

MEMORY_CACHING_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **MEMORY_CACHING_TYPE** enumeration type specifies the permitted caching behavior when allocating or mapping memory.

Syntax

```
typedef enum _MEMORY_CACHING_TYPE {
  MmNonCached,
  MmCached,
  MmWriteCombined,
  MmHardwareCoherentCached,
  MmNonCachedUnordered,
  MmUSWCCached,
  MmMaximumCacheType,
  MmNotMapped
} MEMORY_CACHING_TYPE;
```

Constants

MmNonCached	The requested memory should not be cached by the processor.
MmCached	The processor should cache the requested memory.
MmWriteCombined	The requested memory should not be cached by the processor, but writes to the memory can be combined by the processor.
MmHardwareCoherentCached	Reserved for system use.
MmNonCachedUnordered	Reserved for system use.
MmUSWCCached	Reserved for system use.
MmMaximumCacheType	Reserved for system use.
MmNotMapped	

Remarks

Processor translation buffers cache virtual to physical address translations. These translation buffers allow many virtual addresses to map a single physical address. However, only one caching behavior is allowed for any given physical address translation. Therefore, if a driver maps two different virtual address ranges to the same physical address, it must ensure that it specifies the same caching behavior for both. Otherwise, the processor behavior is undefined with unpredictable system results.

Requirements

Minimum supported client	Supported in Windows 2000 and later versions of Windows.
Header	wudfwdm.h (include Ntddk.h, Wdm.h, Miniport.h, Wudfwdm.h)

PINTERFACE_DEREFERENCE callback function

1/25/2019 • 2 minutes to read • Edit Online

The *InterfaceDereference* routine decrements the reference count on a driver-defined interface.

Syntax

```
PINTERFACE_DEREFERENCE PinterfaceDereference;

void PinterfaceDereference(
  PVOID Context
)
{...}
```

Parameters

`Context`

A pointer to interface-specific context information. The caller passes the value that is passed as the **Context** member of the INTERFACE structure for the interface.

Return Value

None

Remarks

You can use the InterfaceReference routine to increment the reference count for the interface.

The driver that imports the interface is responsible for calling the *InterfaceDereference* routine to decrement the reference count after the driver is no longer using the interface. For example, a driver that requests a pointer to the interface by sending an IRP_MN_QUERY_INTERFACE request calls *InterfaceDereference*. Also, a driver that receives a pointer to the interface to another driver must call *InterfaceDereference*.

Requirements

Target Platform	Desktop
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)

See Also

IO_STATUS_BLOCK structure

1/30/2019 • 2 minutes to read • Edit Online

A driver sets an IRP's I/O status block to indicate the final status of an I/O request, before calling IoCompleteRequest for the IRP.

Syntax

```
typedef struct _IO_STATUS_BLOCK {
  union {
    NTSTATUS Status;
    PVOID    Pointer;
  } DUMMYUNIONNAME;
  ULONG_PTR Information;
} *PIO_STATUS_BLOCK, IO_STATUS_BLOCK;
```

Members

`DUMMYUNIONNAME`

`DUMMYUNIONNAME.Status`

This is the completion status, either STATUS_SUCCESS if the requested operation was completed successfully or an informational, warning, or error STATUS_*XXX* value. For more information, see Using NTSTATUS values.

`DUMMYUNIONNAME.Pointer`

Reserved. For internal use only.

`Information`

This is set to a request-dependent value. For example, on successful completion of a transfer request, this is set to the number of bytes transferred. If a transfer request is completed with another STATUS_*XXX*, this member is set to zero.

Remarks

Unless a driver's dispatch routine completes an IRP with an error status value, the lowest-level driver in the chain frequently sets the IRP's I/O status block to the values that will be returned to the original requester of the I/O operation.

The IoCompletion routines of higher-level drivers usually check the I/O status block in IRPs completed by lower drivers. By design, the I/O status block in an IRP is the only information passed back from the underlying device driver to all higher-level drivers' *IoCompletion* routines.

The operating system implements support routines that write **IO_STATUS_BLOCK** values to caller-supplied output buffers. For example, see ZwOpenFile or NtOpenFile. These routines return status codes that might not match the status codes in the **IO_STATUS_BLOCK** structures. If one of these routines returns STATUS_PENDING, the caller should wait for the I/O operation to complete, and then check the status code in the **IO_STATUS_BLOCK** structure to determine the final status of the operation. If the routine returns a status code other than STATUS_PENDING, the caller should rely on this status code instead of the status code in the **IO_STATUS_BLOCK** structure.

For more information, see I/O Status Blocks.

IoSetCompletionRoutine

OBJECT_ATTRIBUTES structure

1/30/2019 • 4 minutes to read • Edit Online

The **OBJECT_ATTRIBUTES** structure specifies attributes that can be applied to objects or object handles by routines that create objects and/or return handles to objects.

Syntax

```
typedef struct _OBJECT_ATTRIBUTES {
  ULONG           Length;
  HANDLE          RootDirectory;
  PUNICODE_STRING ObjectName;
  ULONG           Attributes;
  PVOID           SecurityDescriptor;
  PVOID           SecurityQualityOfService;
} OBJECT_ATTRIBUTES;
```

Members

`Length`

The number of bytes of data contained in this structure. The InitializeObjectAttributes macro sets this member to **sizeof**(**OBJECT_ATTRIBUTES**).

`RootDirectory`

Optional handle to the root object directory for the path name specified by the **ObjectName** member. If **RootDirectory** is **NULL**, **ObjectName** must point to a fully qualified object name that includes the full path to the target object. If **RootDirectory** is non-**NULL**, **ObjectName** specifies an object name relative to the **RootDirectory** directory. The **RootDirectory** handle can refer to a file system directory or an object directory in the object manager namespace.

`ObjectName`

Pointer to a Unicode string that contains the name of the object for which a handle is to be opened. This must either be a fully qualified object name, or a relative path name to the directory specified by the **RootDirectory** member.

`Attributes`

Bitmask of flags that specify object handle attributes. This member can contain one or more of the flags in the following table.

FLAG	MEANING
OBJ_INHERIT	This handle can be inherited by child processes of the current process.

OBJ_PERMANENT	This flag only applies to objects that are named within the object manager. By default, such objects are deleted when all open handles to them are closed. If this flag is specified, the object is not deleted when all open handles are closed. Drivers can use the ZwMakeTemporaryObject routine to make a permanent object non-permanent.
OBJ_EXCLUSIVE	If this flag is set and the **OBJECT_ATTRIBUTES** structure is passed to a routine that creates an object, the object can be accessed exclusively. That is, once a process opens such a handle to the object, no other processes can open handles to this object. If this flag is set and the **OBJECT_ATTRIBUTES** structure is passed to a routine that creates an object handle, the caller is requesting exclusive access to the object for the process context that the handle was created in. This request can be granted only if the OBJ_EXCLUSIVE flag was set when the object was created.
OBJ_CASE_INSENSITIVE	If this flag is specified, a case-insensitive comparison is used when matching the name pointed to by the **ObjectName** member against the names of existing objects. Otherwise, object names are compared using the default system settings.
OBJ_OPENIF	If this flag is specified, by using the object handle, to a routine that creates objects and if that object already exists, the routine should open that object. Otherwise, the routine creating the object returns an NTSTATUS code of STATUS_OBJECT_NAME_COLLISION.
OBJ_OPENLINK	If an object handle, with this flag set, is passed to a routine that opens objects and if the object is a symbolic link object, the routine should open the symbolic link object itself, rather than the object that the symbolic link refers to (which is the default behavior).
OBJ_KERNEL_HANDLE	The handle is created in system process context and can only be accessed from kernel mode.
OBJ_FORCE_ACCESS_CHECK	The routine that opens the handle should enforce all access checks for the object, even if the handle is being opened in kernel mode.
OBJ_VALID_ATTRIBUTES	Reserved.

`SecurityDescriptor`

Specifies a security descriptor (SECURITY_DESCRIPTOR) for the object when the object is created. If this member is **NULL**, the object will receive default security settings.

`SecurityQualityOfService`

Optional quality of service to be applied to the object when it is created. Used to indicate the security impersonation level and context tracking mode (dynamic or static). Currently, the InitializeObjectAttributes macro sets this member to **NULL**.

Remarks

Use the InitializeObjectAttributes macro to initialize the members of the **OBJECT_ATTRIBUTES** structure. Note that **InitializeObjectAttributes** initializes the **SecurityQualityOfService** member to **NULL**. If you must specify

a non-**NULL** value, set the **SecurityQualityOfService** member after initialization.

To apply the attributes contained in this structure to an object or object handle, pass a pointer to this structure to a routine that accesses objects or returns object handles, such as ZwCreateFile or ZwCreateDirectoryObject.

All members of this structure are read-only. If a member of this structure is a pointer, the object that this member points to is read-only as well. Read-only members and objects can be used to acquire relevant information but must not be modified. To set the members of this structure, use the **InitializeObjectAttributes** macro.

Driver routines that run in a process context other than that of the system process must set the OBJ_KERNEL_HANDLE flag for the **Attributes** member (by using the **InitializeObjectAttributes** macro). This restricts the use of a handle opened for that object to processes running only in kernel mode. Otherwise, the handle can be accessed by the process in whose context the driver is running.

PO_FX_COMPONENT_IDLE_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_COMPONENT_IDLE_STATE** structure specifies the attributes of an Fx power state of a component in a device.

Syntax

```
typedef struct _PO_FX_COMPONENT_IDLE_STATE {
  ULONGLONG TransitionLatency;
  ULONGLONG ResidencyRequirement;
  ULONG     NominalPower;
} PO_FX_COMPONENT_IDLE_STATE, *PPO_FX_COMPONENT_IDLE_STATE;
```

Members

`TransitionLatency`

The transition latency. This latency is the amount of time, in 100-nanosecond units, that the component requires to return from this Fx state to the F0 state. For a **PO_FX_COMPONENT_IDLE_STATE** structure that specifies the attributes of the F0 state, set this member to zero.

`ResidencyRequirement`

The residency requirement. The residency requirement is the minimum amount of time, in 100-nanosecond units, that the component must spend in this Fx state to make a transition to this Fx state worthwhile. PoFx uses this member value as a hint to avoid switching a component to an Fx state unless the component is likely to remain in this state for at least the amount of time specified by **ResidencyRequirement**. For a **PO_FX_COMPONENT_IDLE_STATE** structure that describes the attributes of the F0 state, set this member to zero.

`NominalPower`

The power, in microwatts, that the component consumes in this Fx state. Set this member to **PO_FX_UNKNOWN_POWER** to indicate that PoFx should ignore (treat as negligible) the component's internal power consumption in this Fx state when PoFx evaluates which power state to switch to when the component is idle.

Remarks

The PO_FX_COMPONENT structure contains a pointer to an array of **PO_FX_COMPONENT_IDLE_STATE** structures. Each array element specifies the attributes of an Fx state. Element 0 describes F0, element 1 describes F1, and so on.

When the driver registers a device with PoFx, the driver supplies an array of **PO_FX_COMPONENT** structures. Each array element describes the power attributes of a component in the device.

Do not set **TransitionLatency** and **ResidencyRequirement** to **PO_FX_UNKNOWN_TIME** because it may prevent the power management framework (PoFx) from selecting the idle state.

Requirements

Minimum supported client	Supported starting with Windows 8.
Header	wudfwdm.h (include Wudfwdm.h)

See Also

PO_FX_COMPONENT

PO_FX_COMPONENT_PERF_INFO structure

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_COMPONENT_PERF_INFO** structure describes all the sets of performance states for a single component within a device.

Syntax

```
typedef struct _PO_FX_COMPONENT_PERF_INFO {
  ULONG                    PerfStateSetsCount;
  PO_FX_COMPONENT_PERF_SET PerfStateSets[ANYSIZE_ARRAY];
} PO_FX_COMPONENT_PERF_INFO, *PPO_FX_COMPONENT_PERF_INFO;
```

Members

`PerfStateSetsCount`

The number of elements in the array **PerfStateSets** array.

`PerfStateSets`

This member is the first element in an array of one or more PO_FX_COMPONENT_PERF_SET elements. Each **PO_FX_COMPONENT_PERF_SET** represents one set of supported performance states for a component. If the array contains more than one element, the additional elements immediately follow the first element.

Remarks

When a device driver calls the PoFxRegisterComponentPerfStates routine to register a component for performance state support with the power management framework (PoFx), the driver can supply a **PO_FX_COMPONENT_PERF_INFO** structure that describes the sets of the performance states supported by the component. The **PerfStateSets** member of the **PO_FX_COMPONENT_PERF_INFO** structure contains an array of PO_FX_COMPONENT_PERF_SET structures that represent the supported performance states.

Most drivers are expected to define a single set of performance states per component. For example, a driver might define one set of performance states to control the clock frequency for a component. However, some drivers may need to define more than one performance state set to control multiple dimensions of performance states for a component. For example, a driver might define two sets of performance states to control the clock frequency and bus bandwidth.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	wudfwdm.h (include Wudfwdm.h)

See Also

Component-Level Performance State Management

PO_FX_COMPONENT_PERF_SET

PoFxRegisterComponentPerfStates

PO_FX_COMPONENT_PERF_SET structure

2/5/2019 • 2 minutes to read • Edit Online

The **PO_FX_COMPONENT_PERF_SET** structure represents a set of performance states for a single component within a device.

Syntax

```
typedef struct _PO_FX_COMPONENT_PERF_SET {
  UNICODE_STRING        Name;
  ULONGLONG             Flags;
  PO_FX_PERF_STATE_UNIT Unit;
  PO_FX_PERF_STATE_TYPE Type;
  union {
    struct {
      ULONG             Count;
      PPO_FX_PERF_STATE States;
    } Discrete;
    struct {
      ULONGLONG Minimum;
      ULONGLONG Maximum;
    } Range;
  };
} PO_FX_COMPONENT_PERF_SET, *PPO_FX_COMPONENT_PERF_SET;
```

Members

`Name`

An optional character string used to describe the component property controlled by the performance state set. For example, "Clock frequency" or "Memory bandwidth".

`Flags`

Set to 0. Currently, no flags are defined for this member.

`Unit`

A PO_FX_PERF_STATE_UNIT value that specifies the type of unit that is controlled by the performance state set.

`Type`

A PO_FX_PERF_STATE_TYPE value that specifies the type of performance states in the set (a discrete number of states or a continuous distribution of states between a minimum and maximum value).

`Discrete`

`Discrete.Count`

The number of performance states in the set.

`Discrete.States`

A pointer to a PO_FX_PERF_STATE array. The length of this array is specified by the **Count** member. Each array element describes one power state in the set.

`Range`

`Range.Minimum`

The minimum performance state value.

`Range.Maximum`

The maximum performance state value.

Remarks

When a device driver calls the PoFxRegisterComponentPerfStates routine to register a component for performance state support with the power management framework (PoFx), the driver can supply a PO_FX_COMPONENT_PERF_INFO structure that describes the sets of the performance states supported by the component. The **PerfStateSets** member of the **PO_FX_COMPONENT_PERF_INFO** structure contains an array of **PO_FX_COMPONENT_PERF_SET** structures that represent the supported performance states.

Most drivers are expected to define a single set of performance states per component. For example, a driver might define one set of performance states to control the clock frequency for a component. However, some drivers may need to define more than one performance state set to control multiple dimensions of performance states for a component. For example, a driver might define two sets of performance states to control the clock frequency and bus bandwidth.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	wudfwdm.h (include Wudfwdm.h)

Device Performance State Management

PO_FX_COMPONENT_PERF_INFO

PoFxRegisterComponentPerfStates

PO_FX_COMPONENT_V1 structure

1/30/2019 • 3 minutes to read • Edit Online

The **PO_FX_COMPONENT** structure describes the power state attributes of a component in a device.

Syntax

```
typedef struct _PO_FX_COMPONENT_V1 {
  GUID                          Id;
  ULONG                         IdleStateCount;
  ULONG                         DeepestWakeableIdleState;
  PPO_FX_COMPONENT_IDLE_STATE IdleStates;
} PO_FX_COMPONENT_V1, *PPO_FX_COMPONENT_V1;
```

Members

`Id`

A component ID that uniquely identifies this component with respect to the other components in the device. The driver should specify a nonzero value for this member if the power management framework (PoFx) requires a component ID to distinguish this component from other, similar components in the same device. This member is optional. If this member is not used, it must be set to all zeros.

`IdleStateCount`

The number of elements in the array that is pointed to by the **IdleStates** member. Additionally, this member specifies the number of Fx power states that the component supports. A component must support at least one Fx state (F0).

`DeepestWakeableIdleState`

The index of the deepest Fx state from which the component can wake. Specify 0 for F0, 1 for F1, and so on. This index must be less than **IdleStateCount**.

`IdleStates`

A pointer to a PO_FX_COMPONENT_IDLE_STATE array. The length of this array is specified by the **IdleStateCount** member. Each array element specifies the attributes of an Fx power state that is supported by the component. Element 0 describes F0, element 1 describes F1, and so on.

Remarks

When a device driver registers a device with PoFx, the driver supplies a PO_FX_DEVICE structure that holds the registration information. This structure contains an array of **PO_FX_COMPONENT** structures. The elements in this array describe the power attributes of the individual components in the device. PoFx uses the information in this array to manage the power settings of these components.

The **Id** member contains a component ID that PoFx can use to uniquely identify a component. Do not confuse the component ID with the component index, which a routine such as PoFxActivateComponent uses to identify a component in a registered device. A component index is an index into the **Components** array in the **PO_FX_DEVICE** structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes are integer values in the range 0 to N–1. In contrast, a component ID is a

GUID value.

The **Flags** member may be set to the **PO_FX_COMPONENT_FLAG_F0_ON_DX** value if the driver specified support for **PO_FX_VERSION_V2** during registration with PoFx (that is, during the call to the PoFxRegisterDevice routine, the driver specified the value **PO_FX_VERSION_V2** for the **Version** member of the PO_FX_DEVICE structure that was passed to the *Device* parameter). If the **PO_FX_COMPONENT_FLAG_F0_ON_DX** flag is specified, PoFx will place the component into the F0 power state during Dx transitions and for wait/wake IRPs. Before dispatching a Dx IRP or wait/wake IRP to the device stack (whichever event happens first), the power manager will transition the component into the F0 state. The component will be kept in F0 until the wake/wait IRP is canceled or completed, or the Dx IRP is completed and driver has called the PoFxReportDevicePoweredOn routine (whichever event happens last).

Component dependencies

PoFx supports logical component dependencies within a device (but not across different devices). During device registration for each component, the driver can supply a number (the *ProviderCount* member) and an array of component indexes (the *Providers* member) this component depends on; these are known as *providers*. PoFx guarantees that the component will not become active until all of its providers are active.

Component dependencies form a directed graph where an edge points from a dependent component to a provider and represents a dependency. During device registration, PoFx validates the dependency graph: cycles and repeated edges are not allowed and the depth of the graph for the depth-first search traversal cannot exceed four. PoFx also sets the components' active reference count according to the dependency graph; that is, each provider's active reference count is incremented once for each component that depends on it.

During the component activation, PoFx asynchronously activates all providers first. After a component is active, PoFx checks every dependent component and continues their activation if necessary.

When the component transitions to the idle state, PoFx first makes the dependent components idle. After the driver completes the ComponentIdleConditionCallback and the platform extension plug-in (PEP) is notified that the component is idle, PoFx recursively traverses the dependency graph in breadth-first traversal and asynchronously idles each provider.

Requirements

Minimum supported client	Supported starting with Windows 8.
Header	wudfwdm.h (include Wudfwdm.h)

Component-Level Power Management

PO_FX_COMPONENT_IDLE_STATE

PO_FX_DEVICE

PO_FX_COMPONENT_V2 structure

1/30/2019 • 4 minutes to read • Edit Online

The **PO_FX_COMPONENT** structure describes the power state attributes of a component in a device.

Syntax

```
typedef struct _PO_FX_COMPONENT_V2 {
  GUID                          Id;
  ULONGLONG                     Flags;
  ULONG                         DeepestWakeableIdleState;
  ULONG                         IdleStateCount;
  PPO_FX_COMPONENT_IDLE_STATE IdleStates;
  ULONG                         ProviderCount;
  PULONG                        Providers;
} PO_FX_COMPONENT_V2, *PPO_FX_COMPONENT_V2;
```

Members

`Id`

A component ID that uniquely identifies this component with respect to the other components in the device. The driver should specify a nonzero value for this member if the power management framework (PoFx) requires a component ID to distinguish this component from other, similar components in the same device. This member is optional. If this member is not used, it must be set to all zeros.

`Flags`

This member can be set to the following flag bit: **PO_FX_COMPONENT_FLAG_F0_ON_DX**. For more information, see Remarks.

`DeepestWakeableIdleState`

The index of the deepest Fx state from which the component can wake. Specify 0 for F0, 1 for F1, and so on. This index must be less than **IdleStateCount**.

`IdleStateCount`

The number of elements in the array that is pointed to by the **IdleStates** member. Additionally, this member specifies the number of Fx power states that the component supports. A component must support at least one Fx state (F0).

`IdleStates`

A pointer to a PO_FX_COMPONENT_IDLE_STATE array. The length of this array is specified by the **IdleStateCount** member. Each array element specifies the attributes of an Fx power state that is supported by the component. Element 0 describes F0, element 1 describes F1, and so on.

`ProviderCount`

A value that specifies the number of components this component depends on. For more information, see *Component dependencies* under Remarks.

`Providers`

A pointer to an array of component indexes this component depends on. For more information, see *Component dependencies* under Remarks.

Remarks

When a device driver registers a device with PoFx, the driver supplies a PO_FX_DEVICE structure that holds the registration information. This structure contains an array of **PO_FX_COMPONENT** structures. The elements in this array describe the power attributes of the individual components in the device. PoFx uses the information in this array to manage the power settings of these components.

The **Id** member contains a component ID that PoFx can use to uniquely identify a component. Do not confuse the component ID with the component index, which a routine such as PoFxActivateComponent uses to identify a component in a registered device. A component index is an index into the **Components** array in the **PO_FX_DEVICE** structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes are integer values in the range 0 to N–1. In contrast, a component ID is a GUID value.

The **Flags** member may be set to the **PO_FX_COMPONENT_FLAG_F0_ON_DX** value if the driver specified support for **PO_FX_VERSION_V2** during registration with PoFx (that is, during the call to the PoFxRegisterDevice routine, the driver specified the value **PO_FX_VERSION_V2** for the **Version** member of the PO_FX_DEVICE structure that was passed to the *Device* parameter). If the **PO_FX_COMPONENT_FLAG_F0_ON_DX** flag is specified, PoFx will place the component into the F0 power state during Dx transitions and for wait/wake IRPs. Before dispatching a Dx IRP or wait/wake IRP to the device stack (whichever event happens first), the power manager will transition the component into the F0 state. The component will be kept in F0 until the wake/wait IRP is canceled or completed, or the Dx IRP is completed and driver has called the PoFxReportDevicePoweredOn routine (whichever event happens last).

Component dependencies

PoFx supports logical component dependencies within a device (but not across different devices). During device registration for each component, the driver can supply a number (the *ProviderCount* member) and an array of component indexes (the *Providers* member) this component depends on; these are known as *providers*. PoFx guarantees that the component will not become active until all of its providers are active.

Component dependencies form a directed graph where an edge points from a dependent component to a provider and represents a dependency. During device registration, PoFx validates the dependency graph: cycles and repeated edges are not allowed and the depth of the graph for the depth-first search traversal cannot exceed four. PoFx also sets the components' active reference count according to the dependency graph; that is, each provider's active reference count is incremented once for each component that depends on it.

During the component activation, PoFx asynchronously activates all providers first. After a component is active, PoFx checks every dependent component and continues their activation if necessary.

When the component transitions to the idle state, PoFx first makes the dependent components idle. After the driver completes the ComponentIdleConditionCallback and the platform extension plug-in (PEP) is notified that the component is idle, PoFx recursively traverses the dependency graph in breadth-first traversal and asynchronously idles each provider.

PO_FX_COMPONENT_IDLE_STATE

PO_FX_DEVICE

PO_FX_DEVICE_V1 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_DEVICE** structure describes the power attributes of a device to the power management framework (PoFx).

Syntax

```
typedef struct _PO_FX_DEVICE_V1 {
  ULONG                                    Version;
  ULONG                                    ComponentCount;
  PPO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK ComponentActiveConditionCallback;
  PPO_FX_COMPONENT_IDLE_CONDITION_CALLBACK   ComponentIdleConditionCallback;
  PPO_FX_COMPONENT_IDLE_STATE_CALLBACK       ComponentIdleStateCallback;
  PPO_FX_DEVICE_POWER_REQUIRED_CALLBACK      DevicePowerRequiredCallback;
  PPO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK  DevicePowerNotRequiredCallback;
  PPO_FX_POWER_CONTROL_CALLBACK              PowerControlCallback;
  PVOID                                    DeviceContext;
  PO_FX_COMPONENT_V1                       Components[ANYSIZE_ARRAY];
} PO_FX_DEVICE_V1, *PPO_FX_DEVICE_V1;
```

Members

`Version`

The version number of this structure. If the driver will register for performance state support with PoFx, set this member to **PO_FX_VERSION_V2**. Otherwise, set this member to **PO_FX_VERSION_V1**.

`ComponentCount`

The number of elements in the **Components** array. Additionally, this member specifies the number of components in the device.

`ComponentActiveConditionCallback`

A pointer to the ComponentActiveConditionCallback callback routine that is implemented by the device driver.

`ComponentIdleConditionCallback`

A pointer to the ComponentIdleConditionCallback callback routine that is implemented by the device driver.

`ComponentIdleStateCallback`

A pointer to the ComponentIdleStateCallback callback routine that is implemented by the device driver.

`DevicePowerRequiredCallback`

A pointer to the DevicePowerRequiredCallback callback routine that is implemented by the device driver.

`DevicePowerNotRequiredCallback`

A pointer to the DevicePowerNotRequiredCallback callback routine that is implemented by the device driver.

`PowerControlCallback`

A pointer to the PowerControlCallback callback routine that is implemented by the device driver.

`DeviceContext`

A pointer to a caller-allocated device context. This pointer is passed as a parameter to each driver-implemented callback function that is pointed to by this structure. The device driver uses this context to store information about the current power state of the device. This context is opaque to PoFx.

`Components`

This member is the first element in an array of one or more PO_FX_COMPONENT elements. If the array contains more than one element, the additional elements immediately follow the **PO_FX_DEVICE** structure. The array contains one element for each component in the device. The Fx power state of each component can be controlled independently of the Fx power states of the other components in the device. The **ANYSIZE_ARRAY** constant is defined to be 1 in the Ntdef.h header file.

Remarks

To register a device with PoFx, a driver calls the PoFxRegisterDevice routine and supplies, as a parameter, a pointer to a **PO_FX_DEVICE** structure that describes the device.

Each element in the **Components** array describes the power state attributes of one component in the device. Each component in the device is identified by its **Components** array index. Routines such as PoFxActivateComponent and PoFxCompleteIdleCondition use the array index of a component to identify the component.

A device driver is not required to implement all six callback routines. The driver can set a function pointer in the **PO_FX_DEVICE** structure to NULL if the driver does not implement the corresponding callback routine. However, certain callback routines must be implemented. Specifically, if one or more components in a device has more than one Fx state, the driver must implement ComponentIdleStateCallback, ComponentActiveConditionCallback, and ComponentIdleConditionCallback routines. Otherwise, device registration fails and PoFxRegisterDevice returns **STATUS_INVALID_PARAMETER**.

Requirements

Minimum supported client	Supported starting with Windows 8.

PO_FX_DEVICE_V2 structure

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_DEVICE** structure describes the power attributes of a device to the power management framework (PoFx).

Syntax

```
typedef struct _PO_FX_DEVICE_V2 {
  ULONG                                    Version;
  ULONGLONG                                Flags;
  PPO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK ComponentActiveConditionCallback;
  PPO_FX_COMPONENT_IDLE_CONDITION_CALLBACK   ComponentIdleConditionCallback;
  PPO_FX_COMPONENT_IDLE_STATE_CALLBACK       ComponentIdleStateCallback;
  PPO_FX_DEVICE_POWER_REQUIRED_CALLBACK      DevicePowerRequiredCallback;
  PPO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK  DevicePowerNotRequiredCallback;
  PPO_FX_POWER_CONTROL_CALLBACK              PowerControlCallback;
  PVOID                                    DeviceContext;
  ULONG                                    ComponentCount;
  PO_FX_COMPONENT_V2                       Components[ANYSIZE_ARRAY];
} PO_FX_DEVICE_V2, *PPO_FX_DEVICE_V2;
```

Members

`Version`

The version number of this structure. If the driver will register for performance state support with PoFx, set this member to **PO_FX_VERSION_V2**. Otherwise, set this member to **PO_FX_VERSION_V1**.

`Flags`

Set to 0. Currently, no flags are defined for this member.

`ComponentActiveConditionCallback`

A pointer to the ComponentActiveConditionCallback callback routine that is implemented by the device driver.

`ComponentIdleConditionCallback`

A pointer to the ComponentIdleConditionCallback callback routine that is implemented by the device driver.

`ComponentIdleStateCallback`

A pointer to the ComponentIdleStateCallback callback routine that is implemented by the device driver.

`DevicePowerRequiredCallback`

A pointer to the DevicePowerRequiredCallback callback routine that is implemented by the device driver.

`DevicePowerNotRequiredCallback`

A pointer to the DevicePowerNotRequiredCallback callback routine that is implemented by the device driver.

`PowerControlCallback`

A pointer to the PowerControlCallback callback routine that is implemented by the device driver.

`DeviceContext`

A pointer to a caller-allocated device context. This pointer is passed as a parameter to each driver-implemented callback function that is pointed to by this structure. The device driver uses this context to store information about the current power state of the device. This context is opaque to PoFx.

`ComponentCount`

The number of elements in the **Components** array. Additionally, this member specifies the number of components in the device.

`Components`

This member is the first element in an array of one or more PO_FX_COMPONENT elements. If the array contains more than one element, the additional elements immediately follow the **PO_FX_DEVICE** structure. The array contains one element for each component in the device. The Fx power state of each component can be controlled independently of the Fx power states of the other components in the device. The **ANYSIZE_ARRAY** constant is defined to be 1 in the Ntdef.h header file.

Remarks

To register a device with PoFx, a driver calls the PoFxRegisterDevice routine and supplies, as a parameter, a pointer to a **PO_FX_DEVICE** structure that describes the device.

Each element in the **Components** array describes the power state attributes of one component in the device. Each component in the device is identified by its **Components** array index. Routines such as PoFxActivateComponent and PoFxCompleteIdleCondition use the array index of a component to identify the component.

A device driver is not required to implement all six callback routines. The driver can set a function pointer in the **PO_FX_DEVICE** structure to NULL if the driver does not implement the corresponding callback routine. However, certain callback routines must be implemented. Specifically, if one or more components in a device has more than one Fx state, the driver must implement ComponentIdleStateCallback, ComponentActiveConditionCallback, and ComponentIdleConditionCallback routines. Otherwise, device registration fails and PoFxRegisterDevice returns **STATUS_INVALID_PARAMETER**.

PO_FX_PERF_STATE structure

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_PERF_STATE** structure represents a performance state for a single component within a device.

Syntax

```
typedef struct _PO_FX_PERF_STATE {
  ULONGLONG Value;
  PVOID     Context;
} PO_FX_PERF_STATE, *PPO_FX_PERF_STATE;
```

Members

`Value`

The value of this performance state. The units are specified by the **Unit** member of the PO_FX_COMPONENT_PERF_SET that contains this performance state. For example, if **Value** is 100000000 and the **Unit** member of the **PO_FX_COMPONENT_PERF_SET** is **PoFxPerfStateUnitFrequency**, this performance state represents 100 MHz.

`Context`

A pointer to additional context for the performance state that cannot be presented by the **Value** member. This data can be shared between the driver and the platform extension plug-in (PEP).

> **Note** Using the **Context** member can hinder the visualization of performance states in Windows Performance Analyzer.

Remarks

The **States** member of the PO_FX_COMPONENT_PERF_SET structure contains an array of **PO_FX_PERF_STATE** elements.

Requirements

Minimum supported client	Supported starting with Windows 10.
Header	wudfwdm.h (include Wudfwdm.h)

PO_FX_PERF_STATE_CHANGE structure

2/5/2019 • 2 minutes to read • Edit Online

The **PO_FX_PERF_STATE_CHANGE** structure contains information about a change to a performance state that is being requested by calling the PoFxIssueComponentPerfStateChange or PoFxIssueComponentPerfStateChangeMultiple routine.

Syntax

```
typedef struct _PO_FX_PERF_STATE_CHANGE {
  ULONG Set;
  union {
    ULONG     StateIndex;
    ULONGLONG StateValue;
  };
} PO_FX_PERF_STATE_CHANGE, *PPO_FX_PERF_STATE_CHANGE;
```

Members

`Set`

The index of the performance state set that is being changed within the collection of performance state sets for the component.

`StateIndex`

For sets that represent a discrete number of performance states (that is, where the **Type** member of the PO_FX_COMPONENT_PERF_SET is **PoFxPerfStateTypeDiscrete**), this member is the index of the performance state to use for the new performance level.

`StateValue`

For sets that represent a continuous distribution of performance states (that is, where the **Type** member of the PO_FX_COMPONENT_PERF_SET is **PoFxPerfStateTypeRange**), this member is the value of the performance state to use for the new performance level.

Remarks

The **PO_FX_PERF_STATE_CHANGE** structure is used for the *PerfChange* parameter of the PoFxIssueComponentPerfStateChange routine and the *PerfChanges* parameter of the PoFxIssueComponentPerfStateChangeMultiple routine.

Requirements

Minimum supported client	Supported starting with Windows 10.

PO_FX_PERF_STATE_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_PERF_STATE_TYPE** enumeration contains values that describe the type of performance states in a PO_FX_COMPONENT_PERF_SET.

Syntax

```
typedef enum _PO_FX_PERF_STATE_TYPE {
  PoFxPerfStateTypeDiscrete,
  PoFxPerfStateTypeRange,
  PoFxPerfStateTypeMaximum
} PO_FX_PERF_STATE_TYPE, *PPO_FX_PERF_STATE_TYPE;
```

Constants

PoFxPerfStateTypeDiscrete	Indicates that the performance state set contains a discrete number of states.
PoFxPerfStateTypeRange	Indicates that the performance state set contains a continuous distribution of states between a minimum and maximum value.
PoFxPerfStateTypeMaximum	This value is reserved for system use.

Remarks

The **Type** member of the PO_FX_COMPONENT_PERF_SET structure is a value from the **PO_FX_PERF_STATE_TYPE** enumeration.

Requirements

Minimum supported client	Supported starting with Windows 10.

PO_FX_PERF_STATE_UNIT Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **PO_FX_PERF_STATE_UNIT** enumeration contains values that describe the type of unit that is controlled by the performance states in a PO_FX_COMPONENT_PERF_SET.

Syntax

```
typedef enum _PO_FX_PERF_STATE_UNIT {
  PoFxPerfStateUnitOther,
  PoFxPerfStateUnitFrequency,
  PoFxPerfStateUnitBandwidth,
  PoFxPerfStateUnitMaximum
} PO_FX_PERF_STATE_UNIT, *PPO_FX_PERF_STATE_UNIT;
```

Constants

PoFxPerfStateUnitOther	Indicates that the performance states control a unit other than frequency or bandwidth.
PoFxPerfStateUnitFrequency	Indicates that the performance states control frequency, measured in Hz.
PoFxPerfStateUnitBandwidth	Indicates that the performance states control bandwidth, measured in bits per second.
PoFxPerfStateUnitMaximum	This value is reserved for system use.

Remarks

The **Unit** member of the PO_FX_COMPONENT_PERF_SET structure is a value from the **PO_FX_PERF_STATE_UNIT** enumeration.

Requirements

Minimum supported client	Supported starting with Windows 10.

POOL_TYPE Enumeration

1/30/2019 • 2 minutes to read • Edit Online

The **POOL_TYPE** enumeration type specifies the type of system memory to allocate.

Syntax

```
typedef enum _POOL_TYPE {
  NonPagedPool,
  NonPagedPoolExecute,
  PagedPool,
  NonPagedPoolMustSucceed,
  DontUseThisType,
  NonPagedPoolCacheAligned,
  PagedPoolCacheAligned,
  NonPagedPoolCacheAlignedMustS,
  MaxPoolType,
  NonPagedPoolBase,
  NonPagedPoolBaseMustSucceed,
  NonPagedPoolBaseCacheAligned,
  NonPagedPoolBaseCacheAlignedMustS,
  NonPagedPoolSession,
  PagedPoolSession,
  NonPagedPoolMustSucceedSession,
  DontUseThisTypeSession,
  NonPagedPoolCacheAlignedSession,
  PagedPoolCacheAlignedSession,
  NonPagedPoolCacheAlignedMustSSession,
  NonPagedPoolNx,
  NonPagedPoolNxCacheAligned,
  NonPagedPoolSessionNx
} POOL_TYPE;
```

Constants

NonPagedPool	*Nonpaged pool*, which is nonpageable system memory. Nonpaged pool can be accessed from any IRQL, but it is a scarce resource and drivers should allocate it only when necessary. System memory allocated with the **NonPagedPool** pool type is executable. For more information, see the description of the **NonPagedPoolExecute** pool type. Starting with Windows 8, drivers should allocate most or all of their nonpaged memory from the no-execute (NX) nonpaged pool instead of the executable nonpaged pool. For more information, see the description of the **NonPagedPoolNx** pool type.

NonPagedPoolExecute	Starting with Windows 8, **NonPagedPoolExecute** is an alternate name for the **NonPagedPool** value. This value indicates that the allocated memory is to be nonpaged and executable—that is, instruction execution is enabled in this memory. To port a driver from an earlier version of Windows, you should typically replace all or most instances of the **NonPagedPool** name in the driver source code with **NonPagedPoolNx**. Avoid replacing instances of the **NonPagedPool** name with **NonPagedPoolExecute** except in cases in which executable memory is explicitly required. For more information, see No-Execute (NX) Nonpaged Pool.
PagedPool	*Paged pool*, which is pageable system memory. Paged pool can only be allocated and accessed at IRQL < DISPATCH_LEVEL.
NonPagedPoolMustSucceed	This value is for internal use only, and is allowed only during system startup. Drivers must not specify this value at times other than system startup, because a "must succeed" request crashes the system if the requested memory size is unavailable.
DontUseThisType	Reserved for system use.
NonPagedPoolCacheAligned	Nonpaged pool, aligned on processor cache boundaries. This value is for internal use only.
PagedPoolCacheAligned	Paged pool, aligned on processor cache boundaries. This value is for internal use only.
NonPagedPoolCacheAlignedMustS	This value is for internal use only, and is allowed only during system startup. It is the cache-aligned equivalent of **NonPagedPoolMustSucceed**.
MaxPoolType	Reserved for system use.
NonPagedPoolBase	Reserved for system use.
NonPagedPoolBaseMustSucceed	Reserved for system use.
NonPagedPoolBaseCacheAligned	Reserved for system use.
NonPagedPoolBaseCacheAlignedMustS	Reserved for system use.
NonPagedPoolSession	Deprecated. Do not use.
PagedPoolSession	Deprecated. Do not use.
NonPagedPoolMustSucceedSession	Deprecated. Do not use.
DontUseThisTypeSession	Deprecated. Do not use.
NonPagedPoolCacheAlignedSession	Deprecated. Do not use.
PagedPoolCacheAlignedSession	Deprecated. Do not use.

NonPagedPoolCacheAlignedMustSSession	Deprecated. Do not use.
NonPagedPoolNx	*No-execute* (NX) nonpaged pool. This pool type is available starting with Windows 8. In contrast to the nonpaged pool designated by **NonPagedPool**, which allocates executable memory, the NX nonpaged pool allocates memory in which instruction execution is disabled. For more information, see No-Execute (NX) Nonpaged Pool. Nonpaged pool can be accessed from any IRQL, but it is a scarce resource and drivers should allocate it only when necessary.
NonPagedPoolNxCacheAligned	NX nonpaged pool, aligned on processor cache boundaries. This value is reserved for exclusive use by the operating system.
NonPagedPoolSessionNx	Reserved for exclusive use by the operating system.

UNICODE_STRING structure

1/30/2019 • 2 minutes to read • Edit Online

The **UNICODE_STRING** structure is used to define Unicode strings.

Syntax

```
typedef struct _UNICODE_STRING {
  USHORT Length;
  USHORT MaximumLength;
#if ...
  USHORT *Buffer;
#else
  PWCH   Buffer;
#endif
} UNICODE_STRING;
```

Members

`Length`

The length, in bytes, of the string stored in **Buffer**.

`MaximumLength`

The length, in bytes, of **Buffer**.

`Buffer.#4025480185`

`Buffer.#407591603`

Remarks

The **UNICODE_STRING** structure is used to pass Unicode strings. Use RtlUnicodeStringInit or RtlUnicodeStringInitEx to initialize a **UNICODE_STRING** structure.

If the string is null-terminated, **Length** does not include the trailing null character.

The **MaximumLength** is used to indicate the length of **Buffer** so that if the string is passed to a conversion routine such as RtlAnsiStringToUnicodeString the returned string does not exceed the buffer size.

Requirements

Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntdef.h)

AppendTailList function

1/25/2019 • 3 minutes to read • Edit Online

The **AppendTailList** routine appends a doubly linked list of LIST_ENTRY structures to the tail of another doubly linked list of **LIST_ENTRY** structures.

Syntax

```
void AppendTailList(
  PLIST_ENTRY ListHead,
  PLIST_ENTRY ListToAppend
);
```

Parameters

`ListHead`

A pointer to the head of the list to which the list pointed to by *ListToAppend* is to be appended. This parameter must be a valid, non-NULL pointer to the LIST_ENTRY structure that is the head of a list. This list can be empty.

`ListToAppend`

A pointer to the first entry in the list to append to the list pointed to by *ListHead*. This parameter must be a valid, non-NULL pointer to the LIST_ENTRY structure that is the first entry in a headless list. For more information, see Remarks.

Return Value

None.

Remarks

This routine constructs a list that contains all the combined entries from the input *ListHead* and *ListToAppend* lists. When the routine returns, the LIST_ENTRY structure pointed to by the *ListHead* parameter is the head of the resulting combined list. The **LIST_ENTRY** structure pointed to by the *ListToAppend* parameter is an entry in the resulting combined list.

The caller sets the *ListToAppend* parameter to point to the first entry in the list to be appended. In this regard, *AppendTailList* does not conform to the convention followed by the other doubly linked list routines that use the **LIST_ENTRY** structure. In these other routines, a parameter that represents a list points to the list head instead of to the first entry in the list. If your driver code uses a list head to represent the list to be appended, the list head must be removed from this list before the list is passed as the *ListToAppend* parameter to **AppendTailList**. For a code example that shows how to remove this list head, see Examples.

AppendTailList can be used to insert a single entry at the tail of a list, but the **Flink** and **Blink** members of the **LIST_ENTRY** structure pointed to by *ListToAppend* must first be initialized—typically, by calling the InitializeListHead routine. In contrast, the InsertTailList routine does not require the **Flink** and **Blink** members of the **LIST_ENTRY** structure pointed to by the *Entry* parameter to be initialized before the **InsertTailList** call. For this reason, **InsertTailList** might be more convenient to use to insert a single entry at the tail of a list.

A driver can access the **Flink** and **Blink** members of a **LIST_ENTRY**, but the members must only be updated by

the system routines supplied for this purpose.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

Callers of **AppendTailList** can be running at any IRQL. If **AppendTailList** is called at IRQL >= DISPATCH_LEVEL, the storage for the list entries must be memory-resident.

Examples

The following code example shows how to write a function named `MyAppendTailList` that is similar to **AppendTailList**, but that treats the *ListToAppend* parameter as a pointer to a list head instead of as a pointer to the first entry in a (headless) list. Unlike **AppendTailList**, the `MyAppendTailList` function avoids including the **LIST_ENTRY** structure pointed to by the *ListToAppend* parameter in the entries that are appended to the list pointed to by the *ListHead* parameter.

```
VOID MyAppendTailList(
    _Inout_  PLIST_ENTRY ListHead,
    _Inout_  PLIST_ENTRY ListToAppend
    )
{
    PLIST_ENTRY entry = ListToAppend->Flink;

    if (!IsListEmpty(ListToAppend))
    {
        RemoveEntryList(ListToAppend);
        InitializeListHead(ListToAppend);
        AppendTailList(ListHead, entry);
    }
}
```

The `MyAppendTailList` function in this code example treats both the *ListHead* and *ListToAppend* parameters as pointers to list heads. When this function returns, the list pointed to by *ListToAppend* is empty; that is, it consists of a list head that has no associated list entries. All of the entries that were initially in this list have been appended to the list pointed to by *ListHead*.

Requirements

Minimum supported client	Available starting with Windows Vista.

ARGUMENT_PRESENT macro

1/25/2019 • 2 minutes to read • Edit Online

The **ARGUMENT_PRESENT** macro evaluates to **FALSE** if the value of *ArgumentPointer* is **NULL**. Otherwise, it evaluates to **TRUE**.

Syntax

```
void ARGUMENT_PRESENT(
   ArgumentPointer
);
```

Parameters

`ArgumentPointer`

Specifies the value of the pointer argument to be tested.

Return Value

ARGUMENT_PRESENT returns FALSE if the value of ArgumentPointer is NULL. Otherwise, it returns TRUE.

Remarks

This macro can be called in conditional code to determine whether an optional argument has been passed in a call.

Requirements

Target Platform	Desktop
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntdef.h)

DRIVER_INITIALIZE callback function

1/25/2019 • 2 minutes to read • Edit Online

DriverEntry is the first routine called after a driver is loaded, and is responsible for initializing the driver.

Syntax

```
DRIVER_INITIALIZE DriverInitialize;

NTSTATUS DriverInitialize(
  _DRIVER_OBJECT *DriverObject,
  PUNICODE_STRING RegistryPath
)
{...}
```

Parameters

`*DriverObject`

A pointer to a DRIVER_OBJECT structure. This is the driver's driver object.

`RegistryPath`

A pointer to a counted Unicode string specifying the path to the driver's registry key.

Return Value

If the routine succeeds, it must return STATUS_SUCCESS. Otherwise, it must return one of the error status values defined in Ntstatus.h.

Remarks

The *DriverObject* parameter supplies the **DriverEntry** routine with a pointer to the driver's driver object, which is allocated by the I/O manager. The **DriverEntry** routine must fill in the driver object with entry points for the driver's standard routines.

The *DriverObject* pointer gives the driver access to *DriverObject*->**HardwareDatabase**, which points to a counted Unicode string that specifies a path to the registry's **\Registry\Machine\Hardware** tree.

The registry path string pointed to by *RegistryPath* is of the form **\Registry\Machine\System\CurrentControlSet\Services<i>DriverName**. A driver can use this path to store driver-specific information; see Registry Keys for Drivers. The **DriverEntry** routine should save a copy of the Unicode string, not the pointer, since the I/O manager frees the *RegistryPath* buffer after **DriverEntry** returns.

For more information about implementing a **DriverEntry** routine, see Writing a DriverEntry Routine.

While it is possible to name this routine something other than **DriverEntry**, doing so is not recommended. The DDK-supplied build tools automatically inform the linker that the driver's entry point is called **DriverEntry**, so giving the routine another name requires you to modify the build tools. For more information about build tools, see Building a Driver.

Examples

To define a **DriverEntry** callback routine, you must first provide a function declaration that identifies the type of

callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

To define a **DriverEntry** callback routine, use the DRIVER_INITIALIZE type as shown in this code example:

```
DRIVER_INITIALIZE DriverEntry;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
NTSTATUS
  DriverEntry(
    struct _DRIVER_OBJECT  *DriverObject,
    PUNICODE_STRING  RegistryPath
    )
  {
      // Function body
  }
```

The DRIVER_INITIALIZE function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the DRIVER_INITIALIZE function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

InitializeListHead function

1/25/2019 • 2 minutes to read • Edit Online

The **InitializeListHead** routine initializes a LIST_ENTRY structure that represents the head of a doubly linked list.

Syntax

```
void InitializeListHead(
  PLIST_ENTRY ListHead
);
```

Parameters

`ListHead`

Pointer to a LIST_ENTRY structure that serves as the list header.

Return Value

None

Remarks

The **InitializeListHead** routine sets the **Flink** and **Blink** members of *ListHead* to point to *ListHead*.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

Callers of **InitializeListHead** can be running at any IRQL. If **InitializeListHead** is called at IRQL >= DISPATCH_LEVEL the storage for *ListHead* must be resident.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
IRQL	Any level (see Remarks section)

InitializeObjectAttributes macro

1/25/2019 • 2 minutes to read • Edit Online

The **InitializeObjectAttributes** macro initializes the opaque OBJECT_ATTRIBUTES structure, which specifies the properties of an object handle to routines that open handles.

Syntax

```
void InitializeObjectAttributes(
   p,
   n,
   a,
   r,
   s
);
```

Parameters

`p`

A pointer to the OBJECT_ATTRIBUTES structure to initialize.

`n`

A pointer to a Unicode string that contains the name of the object for which a handle is to be opened. This must either be a fully qualified object name, or a relative path name to the object directory specified by the RootDirectory parameter.

`a`

Specifies one or more of the following flags:

FLAG	DESCRIPTION
OBJ_INHERIT	This handle can be inherited by child processes of the current process.
OBJ_PERMANENT	This flag only applies to objects that are named within the object manager. By default, such objects are deleted when all open handles to them are closed. If this flag is specified, the object is not deleted when all open handles are closed. Drivers can use ZwMakeTemporaryObject to delete permanent objects.
OBJ_EXCLUSIVE	Only a single handle can be open for this object.
OBJ_CASE_INSENSITIVE	If this flag is specified, a case-insensitive comparison is used when matching the ObjectName parameter against the names of existing objects. Otherwise, object names are compared using the default system settings.

FLAG	DESCRIPTION
OBJ_OPENIF	If this flag is specified to a routine that creates objects, and that object already exists then the routine should open that object. Otherwise, the routine creating the object returns an NTSTATUS code of STATUS_OBJECT_NAME_COLLISION.
OBJ_KERNEL_HANDLE	Specifies that the handle can only be accessed in kernel mode.
OBJ_FORCE_ACCESS_CHECK	The routine opening the handle should enforce all access checks for the object, even if the handle is being opened in kernel mode.

`r`

A handle to the root object directory for the path name specified in the ObjectName parameter. If ObjectName is a fully qualified object name, RootDirectory is NULL. Use **ZwCreateDirectoryObject** to obtain a handle to an object directory.

`s`

Specifies a security descriptor to apply to an object when it is created. This parameter is optional. Drivers can specify NULL to accept the default security for the object. For more information, see the following Remarks section.

Return Value

None

Remarks

InitializeObjectAttributes initializes an OBJECT_ATTRIBUTES structure that specifies the properties of an object handle to be opened. The caller can then pass a pointer to this structure to a routine that actually opens the handle.

Driver routines that run in a process context other than that of the system process must set the OBJ_KERNEL_HANDLE flag for the *Attributes* parameter. This flag restricts the use of a handle opened for that object to processes running only in kernel mode. Otherwise, the handle can be accessed by the process in whose context the driver is running.

Note that **InitializeObjectAttributes** always sets the **SecurityQualityOfService** member of OBJECT_ATTRIBUTES to **NULL**. Drivers that require a non-**NULL** value can set **SecurityQualityOfService** directly.

Requirements

Target Platform	Desktop
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntdef.h)

InsertHeadList function

1/25/2019 • 2 minutes to read • Edit Online

The **InsertHeadList** routine inserts an entry at the head of a doubly linked list of LIST_ENTRY structures.

Syntax

```
void InsertHeadList(
  PLIST_ENTRY                 ListHead,
  __drv_aliasesMem PLIST_ENTRY Entry
);
```

Parameters

`ListHead`

Pointer to the LIST_ENTRY structure that represents the head of the list.

`Entry`

Pointer to a LIST_ENTRY structure that represents the entry to be inserted into the list.

Return Value

None

Remarks

InsertHeadList updates *ListHead*->**Flink** to point to *Entry*. It updates *Entry*->**Flink** to point to the old first entry in the list, and sets *Entry*->**Blink** to *ListHead*. The **Blink** field of the original first entry is also updated to point to *Entry*.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

Callers of **InsertHeadList** can be running at any IRQL. If **InsertHeadList** is called at IRQL >= DISPATCH_LEVEL, the storage for *ListHead* and the list entries must be resident.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop

InsertTailList function

1/25/2019 • 2 minutes to read • Edit Online

The **InsertTailList** routine inserts an entry at the tail of a doubly linked list of LIST_ENTRY structures.

Syntax

```
void InsertTailList(
  PLIST_ENTRY                 ListHead,
  __drv_aliasesMem PLIST_ENTRY Entry
);
```

Parameters

`ListHead`

Pointer to the LIST_ENTRY structure that represents the head of the list.

`Entry`

Pointer to a LIST_ENTRY structure that represents the entry to be inserted in the list.

Return Value

None

Remarks

InsertTailList updates *ListHead*->**Blink** to point to *Entry*. It updates *Entry*->**Blink** to point to the old last entry in the list, and sets *Entry*->**Flink** to *ListHead*. The **Flink** of the previous last entry is updated to point to *Entry* as well.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

Callers of **InsertTailList** can be running at any IRQL. If **InsertTailList** is called at IRQL >= DISPATCH_LEVEL, the storage for *ListHead* and the list entries must be resident.

Requirements

Minimum supported client	Available starting with Windows 2000.

IsListEmpty function

1/25/2019 • 2 minutes to read • Edit Online

The **IsListEmpty** routine indicates whether a doubly linked list of LIST_ENTRY structures is empty.

Syntax

```
BOOLEAN IsListEmpty(
  const LIST_ENTRY *ListHead
);
```

Parameters

`ListHead`

Pointer to a LIST_ENTRY structure that represents the head of the list.

Return Value

IsListEmpty returns **TRUE** if there are currently no entries in the list and **FALSE** otherwise.

Remarks

IsListEmpty returns **TRUE** if *ListHead*->**Flink** refers back to *ListHead*.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

Callers of **IsListEmpty** can be running at any IRQL. If **IsListEmpty** is called at IRQL >= DISPATCH_LEVEL, the storage for *ListHead* must be resident.

Requirements

Minimum supported client	Available starting with Windows 2000.

PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *ComponentActiveConditionCallback* callback routine notifies the driver that the specified component completed a transition from the idle condition to the active condition.

Syntax

```
PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK PoFxComponentActiveConditionCallback;

void PoFxComponentActiveConditionCallback(
  PVOID Context,
  ULONG Component
)
{...}
```

Parameters

`Context`

A pointer to the device context. The device driver uses this context to store information about the current power state of the device. The device driver specified this pointer in the **DeviceContext** member of the PO_FX_DEVICE structure that the driver used to register the device with the power management framework (PoFx). This context is opaque to PoFx.

`Component`

Specifies the index that identifies the component. This parameter is an index into the **Components** array in the **PO_FX_DEVICE** structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N–1.

Return Value

None.

Remarks

A component's hardware registers can be accessed only when the component is in the active condition. Do not rely on the Fx power state of a component to determine whether the component can be accessed. If the component is in the F0 state and is in the idle condition, the component might be about to switch to another Fx state.

To gain access to a component that is in the idle condition, the driver can call the PoFxActivateComponent routine to switch the component to the active condition. If the component is not already in the active condition when **PoFxActivateComponent** is called, PoFx initiates the transition to the active condition, and then calls the *ComponentActiveConditionCallback* routine to notify the driver when the transition is complete.

The driver receives a *ComponentActiveConditionCallback* callback whenever the component completes a transition to the active condition, regardless of whether the driver called **PoFxActivateComponent** to initiate the transition. For example, the Windows kernel might activate the component on behalf of the driver before sending a Plug and Play IRP or a system set-power IRP to the driver.

Examples

To define a *ComponentActiveConditionCallback* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *ComponentActiveConditionCallback* callback routine that is named `MyComponentActiveConditionCallback`, use the PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK type as shown in this code example:

```
PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK MyComponentActiveConditionCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyComponentActiveConditionCallback(
    PVOID Context,
    ULONG Component
    )
  {
      // Function body
  }
```

The PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the PO_FX_COMPONENT_ACTIVE_CONDITION_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Supported starting with Windows 8.
Target Platform	Desktop
Header	wudfwdm.h (include Wudfwdm.h)
IRQL	Called at IRQL <= DISPATCH_LEVEL.

PoFxActivateComponent

PO_FX_COMPONENT_CRITICAL_TRANSITION_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *ComponentCriticalTransitionCallback* callback routine handles a transition of the specified component between the F0 (fully on) and low-power F*x* component power states.

Syntax

```
PO_FX_COMPONENT_CRITICAL_TRANSITION_CALLBACK PoFxComponentCriticalTransitionCallback;

void PoFxComponentCriticalTransitionCallback(
  PVOID Context,
  ULONG Component,
  BOOLEAN Active
)
{...}
```

Parameters

`Context`

A pointer to the device context. The device driver uses this context to store information about the current power state of the device. This context is driver-defined and is opaque to PoFx. The driver specified this pointer in the **DeviceContext** member of the PO_FX_CORE_DEVICE structure that the driver used to register the device with the Windows power management framework (PoFx).

`Component`

The index that identifies the component. This parameter is an index into the **Components** array in the **PO_FX_CORE_DEVICE** structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N–1.

`Active`

Indicates whether this notification is for a transition to the F0 component power state. If TRUE, the component has just completed a transition from a low-power F*x* state to F0. If FALSE, the component is about to start a transition from F0 to a low-power F*x* state.

Return Value

None.

Remarks

This callback routine is implemented by a device driver, and is called by PoFx. PoFx calls this routine to notify the driver of power transitions of device components.

The **ComponentCriticalTransitionCallback** member of the PO_FX_CORE_DEVICE structure is a pointer to a *ComponentCriticalTransitionCallback* callback routine. A pointer to a **PO_FX_CORE_DEVICE** structure is passed as an input parameter in the PoFxRegisterCoreDevice call that registers a core device with the Windows power management framework (PoFx).

To handle calls to this routine, the device driver saves or restores the register state or other hardware context of the

specified component in the device.

If *Active* = TRUE, PoFx has called this routine *after* the component completed a transition from a low-power F*x* state to F0. In this call, the routine restores the previously saved hardware context of the component.

If *Active* = FALSE, PoFx has called this routine *before* the component starts a pending transition from F0 to a low-power F*x* state. In this call, the routine saves the component's hardware context so that this context can later be restored.

For more information about F*x* component power states, see Component-Level Power Management.

A PEP can call this routine at IRQL TBD.

Requirements

Minimum supported client	Supported starting with Windows 10.
Target Platform	Windows
Header	wudfwdm.h (include Wudfwdm.h)

See Also

PO_FX_CORE_DEVICE

PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *ComponentIdleConditionCallback* callback routine notifies the driver that the specified component completed a transition from the active condition to the idle condition.

Syntax

```
PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK PoFxComponentIdleConditionCallback;

void PoFxComponentIdleConditionCallback(
  PVOID Context,
  ULONG Component
)
{...}
```

Parameters

`Context`

A pointer to the device context. The device driver uses this context to store information about the current power state of the device. The device driver specified this pointer in the **DeviceContext** member of the PO_FX_DEVICE structure that the driver used to register the device with the power management framework (PoFx). This context is opaque to PoFx.

`Component`

The index that identifies the component. This parameter is an index into the **Components** array in the **PO_FX_DEVICE** structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N–1.

Return Value

None.

Remarks

When the driver no longer needs to access a component that is in the active condition, the driver should call the PoFxIdleComponent routine to switch the component to the idle condition. In response to the **PoFxIdleComponent** call, PoFx initiates the transition to the idle condition, and then calls the *ComponentIdleConditionCallback* routine to notify the driver when this transition is complete.

The driver must call **PoFxCompleteIdleCondition** in response to every *ComponentIdleConditionCallback* callback. The **PoFxCompleteIdleCondition** call can occur either during the *ComponentIdleConditionCallback* callback or after the callback returns. The driver should complete any work that requires access to the hardware component before the call to **PoFxCompleteIdleCondition**. After this call, the component might not stay in the F0 power state.

A component can be safely accessed only when the component is in the active condition. Do not rely on the Fx power state of a component to determine whether the component can be accessed. If the component is in the F0

state and is in the idle condition, the component might be about to switch to another Fx state.

Examples

To define a *ComponentIdleConditionCallback* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *ComponentIdleConditionCallback* callback routine that is named `MyComponentIdleConditionCallback`, use the PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK type as shown in this code example:

```
PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK MyComponentIdleConditionCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyComponentIdleConditionCallback(
    PVOID Context,
    ULONG Component
    )
  {
      // Function body
  }
```

The PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the PO_FX_COMPONENT_IDLE_CONDITION_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

PO_FX_DEVICE

PoFxCompleteIdleCondition

PO_FX_COMPONENT_IDLE_STATE_CALLBACK callback function

1/25/2019 • 4 minutes to read • Edit Online

The *ComponentIdleStateCallback* callback routine notifies the driver of a pending change to the Fx power state of the specified component.

Syntax

```
PO_FX_COMPONENT_IDLE_STATE_CALLBACK PoFxComponentIdleStateCallback;

void PoFxComponentIdleStateCallback(
  PVOID Context,
  ULONG Component,
  ULONG State
)
{...}
```

Parameters

`Context`

A pointer to the device context. The device driver uses this context to store information about the current power state of the device. The device driver specified this pointer in the **DeviceContext** member of the PO_FX_DEVICE structure that the driver used to register the device with the power management framework (PoFx). This context is opaque to PoFx.

`Component`

Specifies the component number. This parameter is an index into the **Components** array in the **PO_FX_DEVICE** structure that the device driver used to register the device with PoFx. If the **Components** array contains N elements, component indexes range from 0 to N-1.

`State`

Specifies the new Fx power state that the component will change to. If this parameter is zero, the new state is F0; if this parameter is one, the new state is F1; and so on.

Return Value

None.

Remarks

When PoFx calls the driver's *ComponentIdleStateCallback* routine, the driver might need to prepare for the pending Fx state change. After any necessary preparations are completed, the driver must call the PoFxCompleteIdleState routine to notify PoFx that the driver completed its response to the *ComponentIdleStateCallback* callback. The **PoFxCompleteIdleState** call can occur either before or after the *ComponentIdleStateCallback* routine returns.

If the component is to switch from F0 to a low-power Fx state in which the device will lose the hardware state of

the component, the driver must save the component's hardware state before the transition to the new Fx state occurs. If the component is to switch from a low-power Fx state to F0, and the hardware state was previously saved, the driver should restore the hardware state after power is restored to the component.

For some devices, the power state of a component might be controlled in the device hardware. For these devices, the driver is typically responsible for changing the power state of the component. For other devices, the power state of a component might be controlled by hardware that is external to the device, and the driver typically must rely on PoFx to configure the power state of the component.

If the driver is responsible for configuring the power state of the component, the driver should change the power state in response to the *ComponentIdleStateCallback* callback. For a transition from F0 to a low-power Fx state, the component is in F0 on entry to the *ComponentIdleStateCallback* routine, and the driver must switch the component the new Fx state before calling **PoFxCompleteIdleState**. For a transition from a low-power Fx state to F0, the component is in the low-power Fx state on entry to the *ComponentIdleStateCallback* routine, and the driver must switch the component to F0 before calling **PoFxCompleteIdleState**.

If the driver is not responsible for configuring the power state of the component, the driver should assume that the component is always in the F0 state on entry to the *ComponentIdleStateCallback* routine. For a pending transition from F0 to a low-power Fx state, the transition to the new Fx state does not occur until after the driver calls **PoFxCompleteIdleState**. For a transition from a low-power Fx state to F0, the transition to F0 occurs before the *ComponentIdleStateCallback* routine is called.

PoFx never calls the *ComponentIdleStateCallback* routine to switch directly from one low-power Fx state to another low-power Fx state. For example, PoFx might need to switch a component from one low-power Fx state to another in response to a call to the PoFxSetComponentLatency, PoFxSetComponentResidency, or PoFxSetComponentWake routine. In this case, PoFx first calls the *ComponentIdleStateCallback* routine to switch from the old Fx state to F0, and then calls the *ComponentIdleStateCallback* routine a second time to switch from F0 to the new Fx state.

Examples

To define a *ComponentIdleStateCallback* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *ComponentIdleStateCallback* callback routine that is named `MyComponentIdleStateCallback`, use the PO_FX_COMPONENT_IDLE_STATE_CALLBACK type as shown in this code example:

```
PO_FX_COMPONENT_IDLE_STATE_CALLBACK MyComponentIdleStateCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyComponentIdleStateCallback(
    PVOID Context,
    ULONG Component,
    ULONG State
    )
  {
      // Function body
  }
```

The PO_FX_COMPONENT_IDLE_STATE_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the PO_FX_COMPONENT_IDLE_STATE_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Supported in Windows 8 and later versions of Windows.

PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *DevicePowerNotRequiredCallback* callback routine notifies the device driver that the device is not required to stay in the D0 power state.

Syntax

```
PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK PoFxDevicePowerNotRequiredCallback;

void PoFxDevicePowerNotRequiredCallback(
  PVOID Context
)
{...}
```

Parameters

`Context`

A pointer to the device context. The device driver uses this context to store information about the current power state of the device. The device driver specified this pointer in the **DeviceContext** member of the PO_FX_DEVICE structure that the driver used to register the device with the power management framework (PoFx). This context is opaque to PoFx.

Return Value

None.

Remarks

When PoFx calls the driver's *DevicePowerNotRequiredCallback* routine, the driver must first decide whether to initiate a transition to a low-power Dx state (by sending an IRP_MN_SET_POWER request down the device stack) or to remain in the D0 state. Next, without waiting for any Dx transition to complete, the driver must call the PoFxCompleteDevicePowerNotRequired routine to notify PoFx that the driver completed its response to the *DevicePowerNotRequiredCallback* callback. The driver can call **PoFxCompleteDevicePowerNotRequired** before or after the *DevicePowerNotRequiredCallback* routine returns.

When a device is in the D0 state, and the Fx state or active/idle condition of a component in the device changes, PoFx evaluates whether the device can enter a low-power Dx state or must remain in the D0 state. If the device can enter a low-power Dx state, PoFx calls the driver's *DevicePowerNotRequiredCallback* routine.

If the device enters a low-power Dx state in response to a *DevicePowerNotRequiredCallback* callback, but PoFx later determines that the device must enter the D0 state, PoFx calls the driver's DevicePowerRequiredCallback routine. In response to this call, the device must enter the D0 state.

Examples

To define a *DevicePowerNotRequiredCallback* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV),

and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *DevicePowerNotRequiredCallback* callback routine that is named `MyDevicePowerNotRequiredCallback`, use the PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK type as shown in this code example:

```
PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK MyDevicePowerNotRequiredCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyDevicePowerNotRequiredCallback(
    PVOID Context
    )
  {
      // Function body
  }
```

The PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the PO_FX_DEVICE_POWER_NOT_REQUIRED_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Supported starting with Windows 8.
Target Platform	Desktop
Header	wudfwdm.h (include Wudfwdm.h)
IRQL	Called at IRQL <= DISPATCH_LEVEL.

PO_FX_DEVICE_POWER_REQUIRED_CALLBACK callback function

1/25/2019 • 2 minutes to read • Edit Online

The *DevicePowerRequiredCallback* callback routine notifies the device driver that the device must enter and remain in the D0 power state.

Syntax

```
PO_FX_DEVICE_POWER_REQUIRED_CALLBACK PoFxDevicePowerRequiredCallback;

void PoFxDevicePowerRequiredCallback(
  PVOID Context
)
{...}
```

Parameters

`Context`

A pointer to the device context. The device driver uses this context to store information about the current power state of the device. The device driver specified this pointer in the **DeviceContext** member of the PO_FX_DEVICE structure that the driver used to register the device with the power management framework (PoFx). This context is opaque to PoFx.

Return Value

None.

Remarks

After PoFx calls the driver's *DevicePowerRequiredCallback* routine, the driver must initiate a transition to the D0 state by sending a D0 IRP (an IRP_MN_SET_POWER request) down the device stack, if the device is not already in the D0 state. After the driver completes (and all lower drivers complete) handling of this request, the driver must call the PoFxReportDevicePoweredOn routine. The **PoFxReportDevicePoweredOn** call notifies PoFx that the device completed its response to the *DevicePowerRequiredCallback* call. The driver can call **PoFxReportDevicePoweredOn** during or after the *DevicePowerRequiredCallback* call.

Each time the *DevicePowerRequiredCallback* routine is called, the driver must respond by calling **PoFxReportDevicePoweredOn**. The **PoFxReportDevicePoweredOn** call can occur either during or after the *DevicePowerRequiredCallback* call. The driver must call **PoFxReportDevicePoweredOn** regardless of whether no D0 IRP is required, the D0 IRP request fails, or the dispatched D0 IRP succeeds or fails.

PoFx calls the *DevicePowerRequiredCallback* routine only if PoFx previously called the driver's DevicePowerNotRequiredCallback routine to notify the driver that the device was not required to stay in the D0 state.

The call to the *DevicePowerRequiredCallback* routine can occur at any time after the driver calls PoFxCompleteDevicePowerNotRequired to complete a *DevicePowerNotRequiredCallback* callback. The *DevicePowerRequiredCallback* call does not necessarily occur as a result of an action taken by the driver, such as

requesting that a component change to the active condition.

Examples

To define a *DevicePowerRequiredCallback* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *DevicePowerRequiredCallback* callback routine that is named `MyDevicePowerRequiredCallback`, use the PO_FX_DEVICE_POWER_REQUIRED_CALLBACK type as shown in this code example:

```
PO_FX_DEVICE_POWER_REQUIRED_CALLBACK MyDevicePowerRequiredCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
VOID
  MyDevicePowerRequiredCallback(
    PVOID Context
    )
  {
      // Function body
  }
```

The PO_FX_DEVICE_POWER_REQUIRED_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the PO_FX_DEVICE_POWER_REQUIRED_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Supported starting with Windows 8.
Target Platform	Desktop
Header	wudfwdm.h (include Wudfwdm.h)
IRQL	Called at IRQL <= DISPATCH_LEVEL.

PO_FX_POWER_CONTROL_CALLBACK callback function

1/25/2019 • 3 minutes to read • Edit Online

The *PowerControlCallback* callback routine performs a power control operation that is requested by the power management framework (PoFx).

Syntax

```
PO_FX_POWER_CONTROL_CALLBACK PoFxPowerControlCallback;

NTSTATUS PoFxPowerControlCallback(
  PVOID DeviceContext,
  LPCGUID PowerControlCode,
  PVOID InBuffer,
  SIZE_T InBufferSize,
  PVOID OutBuffer,
  SIZE_T OutBufferSize,
  PSIZE_T BytesReturned
)
{...}
```

Parameters

`DeviceContext`

`PowerControlCode`

A pointer to the power control code. This code is a GUID value that specifies the requested operation.

`InBuffer`

A pointer to the buffer that contains the input data for the operation. The format for the data in this buffer depends on the power control code specified by the *PowerControlCode* parameter. The *InBuffer* parameter is optional and can be specified as NULL if the specified operation requires no input data.

`InBufferSize`

The size, in bytes, of the input buffer that is pointed to by the *InBuffer* parameter. If *InBuffer* is NULL, this parameter is zero.

`OutBuffer`

A pointer to the buffer to which the callback routine writes the output data from the operation. The format for the data in this buffer depends on the power control code specified by the *PowerControlCode* parameter. The *OutBuffer* parameter is optional and can be specified as NULL if the specified operation produces no output data.

`OutBufferSize`

The size, in bytes, of the output buffer that is pointed to by the *OutBuffer* parameter. If *OutBuffer* is NULL, this parameter is zero.

`BytesReturned`

A pointer to a location into which the routine writes the number of bytes of data that were written to the buffer that is pointed to by *OutBuffer*. The number of bytes written must be less than or equal to *OutBufferSize*. This parameter is optional and can be specified as NULL if the caller does not need to know how many bytes were written to the output buffer.

Return Value

The *PowerControlCallback* routine returns STATUS_SUCCESS if the call is successful. Otherwise, it returns an appropriate error code.

Remarks

PoFx calls this routine to send a power control request directly to the device driver. A power control request is similar to an I/O control request (IOCTL). Unlike an IOCTL, however, a power control request is sent directly to the driver and is not observed by other device drivers in the device stack. During a *PowerControlCallback* call, the driver synchronously performs the requested operation.

This routine is optional. A device driver that does not support power control operations is not required to implement a *PowerControlCallback* routine.

The device driver can call the PoFxPowerControl routine to send a power control request to PoFx.

For more information about power control requests, see PoFxPowerControl.

Examples

To define a *PowerControlCallback* callback routine, you must first provide a function declaration that identifies the type of callback routine you're defining. Windows provides a set of callback function types for drivers. Declaring a function using the callback function types helps Code Analysis for Drivers, Static Driver Verifier (SDV), and other verification tools find errors, and it's a requirement for writing drivers for the Windows operating system.

For example, to define a *PowerControlCallback* callback routine that is named `MyPowerControlCallback`, use the PO_FX_POWER_CONTROL_CALLBACK type as shown in this code example:

```
PO_FX_POWER_CONTROL_CALLBACK MyPowerControlCallback;
```

Then, implement your callback routine as follows:

```
_Use_decl_annotations_
NTSTATUS
  MyPowerControlCallback(
    PVOID Context,
    LPCGUID PowerControlCode,
    PVOID InBuffer,
    SIZE_T InBufferSize,
    PVOID OutBuffer,
    SIZE_T OutBufferSize,
    PSIZE_T BytesReturned
    )
  {
      // Function body
  }
```

The PO_FX_POWER_CONTROL_CALLBACK function type is defined in the Wdm.h header file. To more accurately identify errors when you run the code analysis tools, be sure to add the *Use_decl_annotations* annotation to your function definition. The *Use_decl_annotations* annotation ensures that the annotations that are applied to the PO_FX_POWER_CONTROL_CALLBACK function type in the header file are used. For more information about the requirements for function declarations, see Declaring Functions by Using Function Role Types for WDM Drivers. For information about *Use_decl_annotations*, see Annotating Function Behavior.

Requirements

Minimum supported client	Supported starting with Windows 8.
Target Platform	Desktop
Header	wudfwdm.h (include Wudfwdm.h)
IRQL	Called at IRQL <= DISPATCH_LEVEL.

PopEntryList function

1/25/2019 • 2 minutes to read • Edit Online

The **PopEntryList** routine removes the first entry from a singly linked list of SINGLE_LIST_ENTRY structures.

Syntax

```
PSINGLE_LIST_ENTRY PopEntryList(
  PSINGLE_LIST_ENTRY ListHead
);
```

Parameters

`ListHead`

Pointer to the SINGLE_LIST_ENTRY structure that represents the head of the list. On return, *ListHead*->**Next** points to the beginning of the list with the first entry removed.

Return Value

PopEntryList returns a pointer to the entry removed from the list, or **NULL** if the list is currently empty.

Remarks

PopEntryList removes the first entry from the list by setting *ListHead*->**Next** to point to the second entry in the list.

For information about using this routine when implementing a singly linked list, see Singly and Doubly Linked Lists.

Callers of **PopEntryList** can be running at any IRQL. If **PopEntryList** is called at IRQL >= DISPATCH_LEVEL, the storage for *ListHead* and the list entries must be resident.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
IRQL	Any level (see Remarks section)

PushEntryList

PushEntryList function

1/25/2019 • 2 minutes to read • Edit Online

The **PushEntryList** routine inserts an entry at the beginning of a singly linked list of SINGLE_LIST_ENTRY structures.

Syntax

```
void PushEntryList(
  PSINGLE_LIST_ENTRY                  ListHead,
  __drv_aliasesMem PSINGLE_LIST_ENTRY Entry
);
```

Parameters

`ListHead`

Pointer to the SINGLE_LIST_ENTRY structure that serves as the list header.

`Entry`

Pointer to SINGLE_LIST_ENTRY structure that represents the entry to be inserted on the list.

Return Value

None

Remarks

PushEntryList sets *ListHead*->**Next** to *Entry*, and *Entry*->**Next** to point to the old first entry of the list.

For information about using this routine when implementing a singly linked list, see Singly and Doubly Linked Lists.

Callers of **PushEntryList** can be running at any IRQL. If **PushEntryList** is called at IRQL >= DISPATCH_LEVEL, the storage for *ListHead* and the list entries must be resident.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
IRQL	Any level (See Remarks section)

READ_REGISTER_BUFFER_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_BUFFER_UCHAR** routine reads a number of bytes from the specified register address into a buffer.

Syntax

```
void READ_REGISTER_BUFFER_UCHAR(
  volatile UCHAR *Register,
  PUCHAR         Buffer,
  ULONG          Count
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Buffer`

Pointer to a buffer into which an array of UCHAR values is read.

`Count`

Specifies the number of bytes to be read into the buffer.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of bytes.

Callers of **READ_REGISTER_BUFFER_UCHAR** can be running at any IRQL, assuming the *Buffer* is resident and the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

READ_REGISTER_BUFFER_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_BUFFER_ULONG** routine reads a number of ULONG values from the specified register address into a buffer.

Syntax

```
void READ_REGISTER_BUFFER_ULONG(
  volatile ULONG *Register,
  PULONG         Buffer,
  ULONG          Count
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Buffer`

Pointer to a buffer into which an array of ULONG values is read.

`Count`

Specifies the number of ULONG values to be read into the buffer.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of ULONG values.

Callers of **READ_REGISTER_BUFFER_ULONG** can be running at any IRQL, assuming the *Buffer* is resident and the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

READ_REGISTER_BUFFER_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_BUFFER_USHORT** routine reads a number of USHORT values from the specified register address into a buffer.

Syntax

```
void READ_REGISTER_BUFFER_USHORT(
  volatile USHORT *Register,
  PUSHORT         Buffer,
  ULONG           Count
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Buffer`

Pointer to a buffer into which an array of USHORT values is read.

`Count`

Specifies the number of USHORT values to be read into the buffer.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of USHORT values.

Callers of **READ_REGISTER_BUFFER_USHORT** can be running at any IRQL, assuming the *Buffer* is resident and the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

READ_REGISTER_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_UCHAR** routine reads a byte from the specified register address.

Syntax

```
UCHAR READ_REGISTER_UCHAR(
  volatile UCHAR *Register
);
```

Parameters

`Register`

Return Value

READ_REGISTER_UCHAR returns the byte read from the specified register address.

Remarks

Callers of **READ_REGISTER_UCHAR** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

READ_REGISTER_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_ULONG** routine reads a ULONG value from the specified register address.

Syntax

```
ULONG READ_REGISTER_ULONG(
  volatile ULONG *Register
);
```

Parameters

`Register`

Return Value

READ_REGISTER_ULONG returns the ULONG value read from the specified register address.

Remarks

Callers of **READ_REGISTER_ULONG** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

READ_REGISTER_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **READ_REGISTER_USHORT** routine reads a USHORT value from the specified register address.

Syntax

```
USHORT READ_REGISTER_USHORT(
  volatile USHORT *Register
);
```

Parameters

`Register`

Return Value

READ_REGISTER_USHORT returns the USHORT value read from the specified register address.

Remarks

Callers of **READ_REGISTER_USHORT** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

RemoveEntryList function

1/25/2019 • 2 minutes to read • Edit Online

The **RemoveEntryList** routine removes an entry from a doubly linked list of LIST_ENTRY structures.

Syntax

```
BOOLEAN RemoveEntryList(
  PLIST_ENTRY Entry
);
```

Parameters

`Entry`

Pointer to the LIST_ENTRY structure that represents the entry to be removed.

Return Value

RemoveEntryList returns **TRUE** if, after removal of the designated entry, the list is empty. Otherwise, the routine returns **FALSE** to indicate that the resulting list still contains one or more entries. For information, see Remarks.

> **Note** Before Microsoft Windows Server 2003, **RemoveEntryList** was defined to return VOID, not BOOLEAN.

Remarks

RemoveEntryList removes the entry by setting the **Flink** member of the entry before *Entry* to point to the entry after *Entry*, and the **Blink** member of the entry after *Entry* to point to the entry before *Entry*.

The return value can be used to detect when the last entry is removed from the list. An empty list consists of a list head only and no list entries.

> **Note** Typically, *Entry* points to an entry in a list and not to the list head. However, *Entry* can point to a list head, in which case the routine removes the list head from the list to produce a headless list. When **RemoveEntryList** is used in this way, the return value should typically be ignored. To determine whether a list is empty, use the IsListEmpty routine.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

In Windows XP and Windows 2000, **RemoveEntryList** did not return a value. Starting with Windows Server 2003, **RemoveEntryList** returns a BOOLEAN value.

Callers of **RemoveEntryList** can be running at any IRQL. If **RemoveEntryList** is called at IRQL >= DISPATCH_LEVEL, the storage for the list entries must be resident.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Desktop
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
IRQL	Any level (See Remarks section)

RemoveHeadList function

1/25/2019 • 2 minutes to read • Edit Online

The **RemoveHeadList** routine removes an entry from the beginning of a doubly linked list of LIST_ENTRY structures.

Syntax

```
PLIST_ENTRY RemoveHeadList(
  PLIST_ENTRY ListHead
);
```

Parameters

`ListHead`

Pointer to the LIST_ENTRY structure that serves as the list header.

Return Value

RemoveHeadList returns a pointer to the entry removed from the list. If the list is empty, **RemoveHeadList** returns *ListHead*.

Remarks

RemoveHeadList removes the first entry from the list by setting *ListHead*->**Flink** to point to the second entry in the list. The routine sets the **Blink** member of the second entry to *ListHead*. In the event the list is empty, this is effectively a no-op.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

Callers of **RemoveHeadList** can be running at any IRQL. If **RemoveHeadList** is called at IRQL >= DISPATCH_LEVEL, the storage for *ListHead* and the list entries must be resident.

Requirements

Minimum supported client	Available starting with Windows 2000.

RemoveTailList function

1/25/2019 • 2 minutes to read • Edit Online

The **RemoveTailList** routine removes an entry from the end of a doubly linked list of LIST_ENTRY structures.

Syntax

```
PLIST_ENTRY RemoveTailList(
  PLIST_ENTRY ListHead
);
```

Parameters

`ListHead`

Pointer to the LIST_ENTRY structure that serves as the list header.

Return Value

RemoveTailList returns a pointer to the entry that was at the tail of the list. If the list is empty, **RemoveTailList** returns *ListHead*.

Remarks

RemoveTailList removes the last entry from the list by setting *ListHead*->**Blink** to point to the second-to-last entry in the list. The routine sets the **Flink** member of the new first entry to *ListHead*. In the event the list is empty, this is effectively a no-op.

For information about using this routine when implementing a doubly linked list, see Singly and Doubly Linked Lists.

Callers of **InsertHeadList** can be running at any IRQL. If **InsertHeadList** is called at IRQL >= DISPATCH_LEVEL, the storage for *ListHead* and the list entries must be resident.

RtlAppendUnicodeStringToString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlAppendUnicodeStringToString** routine concatenates two Unicode strings.

Syntax

```
NTSYSAPI NTSTATUS RtlAppendUnicodeStringToString(
  PUNICODE_STRING  Destination,
  PCUNICODE_STRING Source
);
```

Parameters

`Destination`

Pointer to a buffered Unicode string.

`Source`

Pointer to the buffered string to be concatenated.

Return Value

RtlAppendUnicodeStringToString can return one of the following:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The source string was successfully appended to the destination counted string. The destination string length is updated to include the appended bytes.
STATUS_BUFFER_TOO_SMALL	The destination string length is too small to allow the source string to be concatenated. Accordingly, the destination string length is not updated.

Remarks

RtlAppendUnicodeStringToString copies bytes from the source up to the length of the destination buffer.

The *Destination* and *Source* buffers must be resident if the caller is running at IRQL >= DISPATCH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	See Remarks section.

RtlAppendUnicodeToString

RtlAppendUnicodeToString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlAppendUnicodeToString** routine concatenates the supplied Unicode string to a buffered Unicode string.

Syntax

```
NTSYSAPI NTSTATUS RtlAppendUnicodeToString(
  PUNICODE_STRING Destination,
  PCWSTR          Source
);
```

Parameters

`Destination`

A pointer to the buffered string.

`Source`

A pointer to the null-terminated string to append to the *Destination* string.

Return Value

RtlAppendUnicodeToString can return one of the following:

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The source string was successfully appended to the destination string, and the destination string length was updated to include the appended bytes.
STATUS_BUFFER_TOO_SMALL	The destination string buffer is too small to allow the source string to be appended, so the destination string length is not updated and the contents of the destination string buffer are not changed.

Remarks

RtlAppendUnicodeToString appends the source string to the end of the destination string.

If the destination buffer is not large enough to contain the string that would result from concatenating the source and destination strings (not including the null character that terminates the source string), the routine returns STATUS_BUFFER_TOO_SMALL and leaves the destination string unchanged.

The *Destination* buffer must be resident if the caller is running at IRQL >= DISPATCH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)
IRQL	See Remarks section.

RtlAppendUnicodeStringToString

RtlCompareUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlCompareUnicodeString** routine compares two Unicode strings.

Syntax

```
NTSYSAPI LONG RtlCompareUnicodeString(
  PCUNICODE_STRING String1,
  PCUNICODE_STRING String2,
  BOOLEAN          CaseInSensitive
);
```

Parameters

`String1`

Pointer to the first string.

`String2`

Pointer to the second string.

`CaseInSensitive`

If **TRUE**, case should be ignored when doing the comparison.

Return Value

RtlCompareUnicodeString returns a signed value that gives the results of the comparison:

RETURN CODE	DESCRIPTION
Zero	*String1* equals *String2*.
< Zero	*String1* is less than *String2*.
> Zero	*String1* is greater than *String2*.

Requirements

RtlCopyUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlCopyUnicodeString** routine copies a source string to a destination string.

Syntax

```
NTSYSAPI VOID RtlCopyUnicodeString(
  PUNICODE_STRING  DestinationString,
  PCUNICODE_STRING SourceString
);
```

Parameters

`DestinationString`

A pointer to the destination string buffer. This parameter points to a UNICODE_STRING structure.

`SourceString`

A pointer to the source string buffer. This parameter points to a **UNICODE_STRING** structure.

Return Value

None

Remarks

If *SourceString* is **NULL**, this routine sets the **Length** field of the structure pointed to by *DestinationString* to zero.

This routine does not modify the **MaximumLength** and **Buffer** fields of the structure pointed to by *DestinationString*.

The number of bytes copied from the source string is either the source string length (specified by the **Length** member of the structure pointed to by *SourceString*) or the maximum length of the destination string (specified by the **MaximumLength** member of the structure pointed to by *DestinationString*), whichever is smaller.

The caller must properly initialize all members of the structure pointed to by *DestinationString* before calling **RtlCopyUnicodeString**. Failure to initialize the **Length** or the **MaximumLength** member before calling this routine can cause a buffer overrun.

The *DestinationString* and *SourceString* buffers must be resident if the caller is running at IRQL >= DISPATCH_LEVEL.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal

Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)
IRQL	Any level (See Remarks section)

UNICODE_STRING

RtlEqualUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlEqualUnicodeString** routine compares two Unicode strings to determine whether they are equal.

Syntax

```
NTSYSAPI BOOLEAN RtlEqualUnicodeString(
  PCUNICODE_STRING String1,
  PCUNICODE_STRING String2,
  BOOLEAN          CaseInSensitive
);
```

Parameters

`String1`

Pointer to the first Unicode string.

`String2`

Pointer to the second Unicode string.

`CaseInSensitive`

If **TRUE**, case should be ignored when doing the comparison.

Return Value

RtlEqualUnicodeString returns **TRUE** if the two Unicode strings are equal; otherwise, it returns **FALSE**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe (kernel mode); Ntdll.dll (user mode)
IRQL	PASSIVE_LEVEL

RtlEqualString

RtlFreeUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlFreeUnicodeString** routine releases storage that was allocated by **RtlAnsiStringToUnicodeString** or **RtlUpcaseUnicodeString**.

Syntax

```
NTSYSAPI VOID RtlFreeUnicodeString(
  PUNICODE_STRING UnicodeString
);
```

Parameters

`UnicodeString`

Pointer to the Unicode string buffer previously allocated by **RtlAnsiStringToUnicodeString** or **RtlUpcaseUnicodeString**.

Return Value

None

Remarks

This routine does not release the ANSI string buffer passed to **RtlAnsiStringToUnicodeString**.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	"<=APC_LEVEL"

See Also

RtlAnsiStringToUnicodeString

RtlUpcaseUnicodeString

RtlInitUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

For more information, see the WdmlibRtlInitUnicodeStringEx function.

Syntax

```
NTSYSAPI VOID RtlInitUnicodeString(
  PUNICODE_STRING         DestinationString,
  __drv_aliasesMem PCWSTR SourceString
);
```

Parameters

`DestinationString`

For more information, see the WdmlibRtlInitUnicodeStringEx function.

`SourceString`

For more information, see the WdmlibRtlInitUnicodeStringEx function.

Return Value

For more information, see the WdmlibRtlInitUnicodeStringEx function.

Remarks

The **RTL_CONSTANT_STRING** macro creates a string or Unicode string structure to hold a counted string.

```
STRING RTL_CONSTANT_STRING(
  [in]  PCSZ SourceString
);

UNICODE_STRING RTL_CONSTANT_STRING(
  [in]  PCWSTR SourceString
);
```

RTL_CONSTANT_STRING returns either a string structure or Unicode string structure.

The **RTL_CONSTANT_STRING** macro replaces the RtlInitAnsiString, RtlInitString, and **RtlInitUnicodeString** routines when passing a constant string.

You can use **RTL_CONSTANT_STRING** to initialize global variables.

Requirements

Minimum supported client	Available starting with Windows 2000.

Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	For more information, see the Remarks section of the WdmlibRtlInitUnicodeStringEx function.

RtlInt64ToUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlInt64ToUnicodeString** routine converts a specified unsigned 64-bit integer value to a Unicode string that represents the value in a specified base.

Syntax

```
NTSYSAPI NTSTATUS RtlInt64ToUnicodeString(
  ULONGLONG       Value,
  ULONG           Base,
  PUNICODE_STRING String
);
```

Parameters

`Value`

Specifies the ULONGLONG value to convert.

`Base`

Specifies the base to use when converting *Value* to a string. The possible values are:

VALUE	BASE
16	Hexadecimal
8	Octal
2	Binary
0 or 10	Decimal

`String`

Pointer to the UNICODE_STRING structure that receives the string representation of *Value*. The buffer specified by the *Buffer* of *String* must be large enough to hold the result.

Return Value

RtlInt64ToUnicodeString returns an NTSTATUS value. Possible return values include :

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	The routine successfully converted *Value* to a Unicode string.

STA TUS _BU FFE R_O VER FLO W	*Value* is too large to convert, or the **UNICODE_STRING** structure is too small to hold the result.
STA TUS _IN VAL ID_ PAR AM ETE R	The specified code base is not valid. The only valid values are 0, 2, 8, 10, and 16.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
Library	NtosKrnl.lib
DLL	NtosKrnl.exe
IRQL	PASSIVE_LEVEL

RtlUnicodeStringToInteger

UNICODE_STRING

RtlIntegerToUnicodeString function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlIntegerToUnicodeString** routine converts an unsigned integer value to a null-terminated string of one or more Unicode characters in the specified base.

Syntax

```
NTSYSAPI NTSTATUS RtlIntegerToUnicodeString(
  ULONG           Value,
  ULONG           Base,
  PUNICODE_STRING String
);
```

Parameters

`Value`

Specifies the ULONG value to convert.

`Base`

Specifies the base to use when converting *Value* to a string. The possible values are:

VALUE	BASE
16	Hexadecimal
8	Octal
2	Binary
0 or 10	Decimal

`String`

Pointer to a UNICODE_STRING structure that receives the string representation of *Value*. The buffer specified by the *Buffer* of *String* must be large enough to hold the result.

Return Value

RtlIntegerToUnicodeString returns an NTSTATUS value. Possible return values include:

RETURN CODE	DESCRIPTION
STA TUS _SU CCE SS	The routine successfully converted *Value* to a Unicode string.

STA TUS _BU FFE R_O VER FLO W	*Value* is too large to convert, or the **UNICODE_STRING** structure is too small to hold the result.
STA TUS _IN VAL ID_ PAR AM ETE R	The specified code base is not valid. The only valid values are 0, 2, 8, 10, and 16.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
Library	NtosKrnl.lib

UNICODE_STRING

RtlIntPtrToUnicodeString macro

1/25/2019 • 2 minutes to read • Edit Online

The **RtlIntPtrToUnicodeString** routine converts a specified ULONG_PTR value to a Unicode string that represents the value in a specified base.

Syntax

```
void RtlIntPtrToUnicodeString(
   Value,
   Base,
   String
);
```

Parameters

`Value`

Specifies the ULONG_PTR value to convert.

`Base`

Specifies the base to use when converting *Value* to a string. The possible values are:

VALUE	BASE
16	Hexadecimal
8	Octal
2	Binary
0 or 10	Decimal

`String`

Pointer to a UNICODE_STRING structure that receives the string representation of *Value*. The buffer specified by the *Buffer* of *String* must be large enough to hold the result.

Return Value

RtlIntPtrToUnicodeString returns an NTSTATUS value. Possible return values include :

RETURN CODE	DESCRIPTION
STATUS_SUCCESS	The routine successfully converted Value to a Unicode string.
STATUS_BUFFER_OVERFLOW	Value is too large to convert, or the UNICODE_STRING structure is too small to hold the result.

RETURN CODE	DESCRIPTION
STATUS_INVALID_PARAMETER	The specified code base is not valid. The only valid values are 0, 2, 8, 10, and 16.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Desktop

RtlAppendUnicodeStringToString

RtlIntegerToUnicodeString

RtlUnicodeStringToInteger

UNICODE_STRING

RtlUnicodeStringToInteger function

1/25/2019 • 2 minutes to read • Edit Online

The **RtlUnicodeStringToInteger** routine converts a Unicode string representation of a number to the equivalent integer value.

Syntax

```
NTSYSAPI NTSTATUS RtlUnicodeStringToInteger(
  PCUNICODE_STRING String,
  ULONG            Base,
  PULONG           Value
);
```

Parameters

`String`

A pointer to a UNICODE_STRING structure that contains the number representation to convert to the equivalent integer value.

`Base`

A numeric value that indicates the base (or radix) of the number that the Unicode string represents. This parameter value is optional and can be set to zero.

If *Base* is zero, **RtlUnicodeStringToInteger** checks the prefix of the Unicode string to determine the base of the number:

- If the prefix is "0x", **RtlUnicodeStringToInteger** interprets the number in the string as a hexadecimal integer.
- If the prefix is "0o", **RtlUnicodeStringToInteger** interprets the number in the string as an octal integer.
- If the prefix is "0b", **RtlUnicodeStringToInteger** interprets the number in the string as a binary integer.

If the Unicode string does not contain any of these prefixes, **RtlUnicodeStringToInteger** treats the string as a base-10 integer.

`Value`

A pointer to a ULONG variable to which **RtlUnicodeStringToInteger** writes the integer value that results from conversion of the Unicode string.

Return Value

If the conversion is successful, the **RtlUnicodeStringToInteger** routine returns STATUS_SUCCESS and sets **Value* to the integer value represented by the number in the Unicode string. If the string is not empty, but does not start with a valid number representation, the routine returns STATUS_SUCCESS and sets **Value* to zero. If the string is empty, the routine fails and returns STATUS_INVALID_PARAMETER.

Remarks

This routine skips any white space at the start of the input string to find the start of the number.

If the first non-white space character in the string is a hyphen (-), the integer value written to **Value* is negative; otherwise, if the first character is a "+" or there is no sign character, the integer value written to **Value* is positive.

If the string does not contain a valid number, or if the first digit in the string is preceded by a non-white space character other than '+' or '-', the routine sets the output value to zero and returns STATUS_SUCCESS.

A substring that contains one or more valid digits is terminated by any character that is not a valid digit. For example, if *Base* = 2, valid digits are '0' and '1'. If *Base* = 8, valid digits are '0' to '7'. If *Base* = 10, valid digits are '0' to '9'. If *Base* = 16, valid digits are '0' to '9', 'a' to 'f', and 'A' to 'F'.

The following table contains examples of output values that result from various combinations of input strings and *Base* parameter values.

INPUT STRING	BASE	OUTPUT VALUE
"123"	10	123
" -345"	10	-345
"xyz"	10	0
" +678abc"	10	678
" +678abc"	16	6785724
"007"	10	7
"789"	8	7
"FGH"	16	15
" "	10	0

A related routine, RtlIntegerToUnicodeString, converts an integer value to the equivalent Unicode string representation.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Wudfwdm.h)
Library	NtosKrnl.lib

UNICODE_STRING

WRITE_REGISTER_BUFFER_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_REGISTER_BUFFER_UCHAR** routine writes a number of bytes from a buffer to the specified register.

Syntax

```
void WRITE_REGISTER_BUFFER_UCHAR(
  volatile UCHAR *Register,
  PUCHAR         Buffer,
  ULONG          Count
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Buffer`

Pointer to a buffer from which an array of UCHAR values is to be written.

`Count`

Specifies the number of bytes to be written to the register.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of bytes.

Callers of **WRITE_REGISTER_BUFFER_UCHAR** can be running at any IRQL, assuming the *Buffer* is resident and the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

WRITE_REGISTER_BUFFER_ULONG function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_REGISTER_BUFFER_ULONG** routine writes a number of ULONG values from a buffer to the specified register.

Syntax

```
void WRITE_REGISTER_BUFFER_ULONG(
  volatile ULONG *Register,
  PULONG         Buffer,
  ULONG          Count
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Buffer`

Pointer to a buffer from which an array of ULONG values is to be written.

`Count`

Specifies the number of ULONG values to be written to the register.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of ULONG values.

Callers of **WRITE_REGISTER_BUFFER_ULONG** can be running at any IRQL, assuming the *Buffer* is resident and the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

WRITE_REGISTER_BUFFER_USHORT function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_REGISTER_BUFFER_USHORT** routine writes a number of USHORT values from a buffer to the specified register.

Syntax

```
void WRITE_REGISTER_BUFFER_USHORT(
  volatile USHORT *Register,
  PUSHORT         Buffer,
  ULONG           Count
);
```

Parameters

`Register`

Pointer to the register, which must be a mapped range in memory space.

`Buffer`

Pointer to a buffer from which an array of USHORT values is to be written.

`Count`

Specifies the number of USHORT values to be written to the register.

Return Value

None

Remarks

The size of the buffer must be large enough to contain at least the specified number of USHORT values.

Callers of **WRITE_REGISTER_BUFFER_USHORT** can be running at any IRQL, assuming the *Buffer* is resident and the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib

DLL	NtosKrnl.exe
IRQL	Any level (see Remarks section)

WRITE_REGISTER_UCHAR function

1/25/2019 • 2 minutes to read • Edit Online

The **WRITE_REGISTER_UCHAR** routine writes a byte to the specified address.

Syntax

```
void WRITE_REGISTER_UCHAR(
  volatile UCHAR *Register,
  UCHAR          Value
);
```

Parameters

`Register`

`Value`

Return Value

None

Remarks

Callers of **WRITE_REGISTER_UCHAR** can be running at any IRQL, assuming the *Register* is resident, mapped device memory.

Requirements

Minimum supported client	Available starting with Windows 2000.
Target Platform	Universal
Header	wudfwdm.h (include Wdm.h, Ntddk.h, Ntifs.h, Ioaccess.h, Miniport.h, Wudfwdm.h)
Library	NtosKrnl.lib
