Prelude

Preliminary statements and how to best utilize this sheet

"Healthy discontent is the prelude to progress."
Mahatma Gandhi

Introduction

Fluidic Ice here, and thanks for downloading *The Preparedness Encyclopedia* ! (TPE) (Pronounced "Teepee")

I'm an enthusiast minimalist prepper who began this journey in 2017 after seeing the current state of the world and where we're headed. I've gained most of my knowledge upon researching material for this document which I started to compile to be able to organize what I was learning about preparedness into one offline PDF readable on my phone. It has grown tremendously and I eventually decided to release it to the public.

This manual contains everything you should ever need to survive a disaster or the end of the world as we know it, and includes everything from Prepping Tips, Shelter Building, Weapon Guides, Food Preservation, Survival Tips, an Entire Novel, Games, Maps, Language Conversions and everything in between.

If you're new to prepping I recommend heading to the INTRODUCTION section for the official start of the document.

Throughout the creation of this guide I've spent countless weeks designing, compiling, writing, editing and disseminating the information found here which I consider to be a living document and have been actively updating and removing sections that are no longer of use or outdated. It will always be uploaded to my website (www.fluidicice.com/TPE) every year or so and with new updates and amend sections that require it. Occasionally I will release a 'silent' update which I won't post on social websites such as Reddit, therefore I recommend signing up to the TPE mailing list to get notified of new releases. (I will only email you upon new releases of TPE)

Almost all of the content has been written by a human, there is very little Artificial Intelligence (AI) text that has been used straight in this document, at most I would say 5% has been used. Even then, the text is highly vetted, checked and often edited prior to adding.
My goal in preparedness is to have 90% knowledge and 10% gear due to being part minimalist - thus the more I fill in here - the less I need to carry into the field. Living in Australia, my spelling and units may be different to your own, however the imperial conversions should be beside all values. Alternatively you can convert them yourself using the ADDENDUM > Conversions section. There may also be slight differences in information due to living in a different part of the world for details such as local stores, laws and restrictions. This guide was inspired by and is formatted similar to Wikipedia, the SAS Survival Guide and the U.S. Military Guides.

The guide should contain absolutely everything preparedness related and I challenge you to search (Ctrl+F) for something! If you search from the top of the document for a term like "Hurricane" it may take a while to find what you want due to the numerous reference to it throughout the guide. Therefore I recommend going to the likeliest category that would contain it - in this case "Natural Disasters", and search from there. If it's not in the guide and doesn't have a placeholder section, let me know and I'll add it. Below in the "Reader Tips" section are a few important things to help you read the guide.

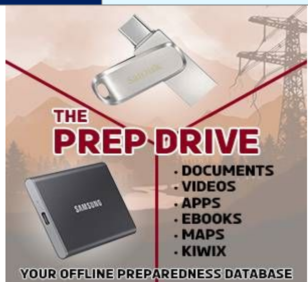
I aim to keep the size of TPE under 100mb if possible, but this may change based on future requirements. PDF versions may be slightly larger than the Excel formats but should run infinitely faster. This guide is designed to replace the internet when it goes down permanently or replace it temporarily for those situations where you can't get a signal. However I recommend you use it in conjunction with my 'Prep Drive' - a preparedness USB that contains everything I wanted on this document but couldn't due to size constraints. See scroll down for info on the Drive.

The guide was developed in Microsoft Excel, originally in a format with information in each cell, but over time has been migrated to an easier to read, or "word" style format where cells have been merged and the font size increased to remove unused space and allow easier reading on mobile devices. Rows without much (or any) information are to be filled in later, but they have been inserted so I won't forget what to add as I often come up with ideas while compiling other sections. I created TPE in excel to: Be different; To automate a lot of functions; to stop Microsoft Words annoying 'reflowing' of text and textboxes; and to give the document a very unique feel.

If hope you will find the information in this document useful in any situation you're faced with and may God will be with you throughout any disaster. TPE contains some Christian references for those sections that relate, so if you're seeking answers on 'what comes next', or millions of people vanish from the earth - take a look at the RELIGION > Christianity and MASS DESTRUCTION > The Rapture sections. I consider these an alternative to advertising throughout TPE in the hopes that it will save eternal lives. Just keep it in mind, and if it occurs come back and read it.

Support

Share TPE Share TPE to any friends, family and fellow preppers who could use it, because it may save their life in a disaster! Shares on social media sites are highly valued too.	**Donate** Your donations go a long way to producing this guide. If you can spare a dime, it will help me to continue producing great content for free and lighten the load of server costs. **https://fluidicice.com/TPE**	**Review** You could also post a video reviewing discussing TPE. After it's posted email me the link via my website so I can fix any problems pointed out.	**Purchase a Prep Drive** See Below



Prep Drive

Your Offline Preparedness Database

Are you concerned with the way the world is heading and would like a huge database of preparedness related content to help you survive **when** the internet goes down?

Prep Drive is a customisable USB which is packed full of free to use disaster preparedness documents, gear lists, survival apps, prepper eBooks, maps of your region, safety data, Kiwix files and videos from around the web. It's essentially a MUCH more detailed TPE. Just select the size of the Drive you need and then load it up with your choice of data to use on both your PC or Android phone on the go. Don't be caught off-guard.
For more info, see https://fluidicice.com/prepdrive

TPE Versions	The version number before the dot (**7**.14) is the public release version and the second number (7.**14**) is the daily iteration number for my use which acts as a failsafe against corruption - which has happened multiple times.
PDF Version	Runs extremely fast on mobile devices. Read only. This version is recommended. File Size: ~68 Mb
Excel Version	Includes hyperlinks around the sheet, external URLS for additional information and formulas. Reading and editing on Pc is recommended due to its size. It runs SLOWLY on older mobile devices. Donate $5 or more to receive this version via email. When resaving the excel document it will also create a backup version in the same location as a safeguard. File Size: ~47.1 Mb - Head to my website to donate www.fluidicice.com/TPE and click on the shop link at the top.
Mailing List	If you would like to be updated when I release a new version of TPE, sign up to the mailing list. Just head to **https://www.fluidicice.com/tpe** and scroll down to the Mailing List section and enter your email. I will only email you on the release of a new TPE version so there could be many months between emails.
External Backups	For off-site backups of TPE and my other content, see: **https://www.fluidicice.com/backups** or directly at: ● **Google Drive:** www.drive.google.com/drive/folders/1KVzoaRSuHUQl8Zj-mXPYIJ0iEi14PZc3 ● **Box:** http://app.box.com/s/jplaw5euljmybbzqk02m0o3g4y2hcm84 ● **Dropbox:** www.dropbox.com/sh/ljd2itt9tztzm1z/AADNRiWtvTr1zZ1nBVQbkkl3a

1 Reader Tips

This guide was built around the idea that it will be read prior to a disaster but will be referred to again when one occurs. However there will be a lot of people who are likely to glance at it a little, store it on their phone and only read it when they need it, which is risky. Skills need to be learnt and mastered over time as you're much more likely to survive with prior training and knowledge. However it's always better to have information than not having anything at all. I wish you the best in times of disaster and hope this guide helps you through it.

You can read the PDF in any PDF reader on Pc or Mobile, or you can read the .XLSX file in Microsoft Excel or Google Sheets. Some PDF readers such as Adobe Pro DC render the lines in the spreadsheet extra bold when zoomed out which makes the spreadsheet look 'dirty'. To fix this open DC and go: Edit > Preferences > Page Display, and Un-tick "Enhance Thin Lines".

These are the recommended programs and apps to read TPE.

$ = Purchase Required
* = Free, but there's in-app purchases OR there's a purchasable version too

Pc / Desktop / Laptop
- Adobe Reader (Free)

Searching

The best way to find what you're looking for would be by going to a section related to the topic you want information on in the 'Contents' section. Alternatively you can use find (Ctrl + F) on Pc or by using the search/find option on mobile devices to find what you're after such as "Evapotranspiration" or "Schmutzdecke".

PRELUDE | Reader Tips

Other Tips	● Coloured cells always have a purpose, such as drawing attention to an important fact or for displaying a mentioned colour. ● The number in the top left of every category is the percentage that section is complete. ## = 100%. ● Tables may have a hashed background to set them apart from the rest of the sheet and the make them easier to read. ● Very little text is coloured due to a problem when rendering the PDF which may 'bleed' the colour to random nearby text. ● Most category references will be in full capitals, such as: PREPAREDNESS and WATER to help distinguish them from other text.

For additional tips on reading and fine-tuning this document see the 'MAINTENANCE > Additional Reader Tips' section right at the bottom of TPE.

Other Tips

PRELUDE | Reader Tips | Other Tips

E-Reader Tips
Besides a phone and tablet, this guide can be read on an E-reader device which consumes much less power than regular devices which could prove effective in a grid down situation. I'm still researching ways to make it easier to read on these types of devices but if you find a section that's difficult to read on an e-reader, please let me know. I now own an E-reader and will be testing TPE on it when I get the time, however you should note that areas with dark backgrounds such as the answers in the ENTERTAINMENT section may not render correctly on e-readers.

Printing	I absolutely DO NOT recommend printing this document in its entirety for environmental reasons and the massive page count, but the best way to print the excel version is on the right. You can print certain sections by highlighting what you want to print by choosing "Print Selection" under the print menu. Otherwise on the PDF version you can find the range you want to print and input that into the print menu. (e.g. pages 52-78) *The print page counts are correct as at version 10.00.*	**Printing - A4 Portrait** ● Print Entire Workbook ● A4 Page ● Portrait ● All Margins = 0.6 ● Fit All Columns to One Page (Slightly Small Font) ~**1,958 Total Pages**	**Printing - A4 Landscape** ● Print Entire Workbook ● A4 Page ● Landscape ● All Margins = 0.6 ● Fit All Columns to One Page (Typical Sized Font) ~**4,053 Total Pages**

Page numbers, hyperlinks and descriptions of the categories

"This is the beginning of anything you want."
Unknown

1 Categories

This section contains every category in this guide including a short description and the percentage completed. Some categories have examples below them to help you find what you're looking for quicker. The following are hyperlinks to the categories.

There are 58 categories and 2332 pages in this document.

Preparedness Basics

Food and Health

Food	85% Complete	Types and the shelf life of foods, and the best foods to stock.
Field Dressing	10% Complete	How to bleed, skin, gut and prepare wild game.
Cooking	47% Complete	Cooking all types of food and food preservation methods.
Recipes	42% Complete	Step-by-step guides to cooking in the wild or homestead.
Health	80% Complete	How to keep fit, clean and healthy.

Medicine and Healing

Medical	95% Complete	General medical routines, tips and advice. Eg: Blood Groups, Triage, Medical Supplies, Body Systems and Quitting Addictions.
Medication	95% Complete	Comprehensive information on medications for treating illnesses.
Illness	100% Complete	Common illnesses and how to treat them. Eg: Radiation Sickness, Parasitic Infections, Bacterial Infections, Viral Infections, Fungal Infections, Altitude Sickness, Poisoning and Chemical illnesses.
Injury	97% Complete	Common types of injuries and how to treat them. Eg: Surface Wounds, Internal Injuries, Open Wounds, Avulsions, Burns, Anaphylaxis, Heat Stroke, Hypothermia, Motion Sickness, Asphyxiation, Drowning, Carbon Monoxide Poisoning, Bites, Childbirth and Toothaches.
Emotional	95% Complete	Recovering from emotional problems and signs to look out for. Eg: Depression, Anxiety, Stress, Confidence, Relaxation, Dementia, Grief, New Parents and Body Image.
Natural Remedies	94% Complete	Natural remedies and how to utilize raw healing plants.

Disaster Preparedness

Natural Disasters	97% Complete	Preparing for and surviving any natural disasters. Eg: Landslides, Avalanche, Earthquake, Sinkhole, Volcano, Flood, Tsunami, Blizzard, Hurricane, Drought, Thunderstorm, Heatwave, Cold Wave, Tornado, Wildfire, Meteorite and Solar Flare.
Man-Made Disasters	77% Complete	Surviving any man-made disasters you may encounter. Eg: Chemical Spills, Dam Failure, Power Failure, Nuclear Accidents, Pandemics, Zombie Apocalypse, Riots, Protests, War, Economic Collapse, Hyperinflation, Overpopulation, Famine, Terrorism and Cyber Attacks.
Personal Disasters	36% Complete	Disasters that can happen to you and your family personally. Eg: House Fire, Car Crash, Plane Crash, Theft, Mugging, Illness & Injury, Bankruptcy, Physical Abuse, Sexual Abuse, Past Trauma, Family Deaths, Separation, Displacement and Addiction.
Disaster Triggers	93% Complete	Any adverse effects that may be triggered from disasters.
Mass Destruction	98% Complete	Disasters that could end life on entire continents or earth completely. Eg: Supervolcano, Nuclear War, EMPs, Artificial Intelligence Uprising, Solar Flare, Gamma-Ray Burst, Large Asteroids, Alien Invasion and Biblical Disasters.

Modern Conveniences

Electricity	88% Complete	Power generation, schematics and battery types. Eg: Power Usage, Fuses, Solar, Dynamo, The Grid, Batteries, Componentry, Repairs and Schematics.
Light	94% Complete	Generating light and understanding lighting. Eg: Measurement, Colour, Sources, Light Operation, Luminescence, Beacon, Concealment and Darkness.
Fuel	76% Complete	All types of fuels from solid to liquid to gas and its effectiveness.

Modern Conveniences

Transport	70% Complete	How to use any air, sea or land transportation.
Geography	95% Complete	Locations around the world and the risks associated with them.
Locations	95% Complete	Details the survival uses of modern buildings & vehicles.
Communication	87% Complete	Any form of contact from radio to smoke signals and chalk markings.

Population and People

Population	35% Complete	Details on prepper circles, gangs and surviving with others.
Economy	25% Complete	Storing valuables, precious metals and maintaining a portfolio.
Religion	99% Complete	Details on religions, quotes and ethics. Eg: Christianity, Islam, Hinduism, Buddhism, Sikhism, Judaism, Atheism, Quotes and Ethics.
Language	68% Complete	Foreign alphabets and translations of words and phrases. Eg: Arabic, Chinese, French, German, Hindi, Italian, Japanese, Korean, Portuguese, Russian, Spanish and Phrase Translations.
Entertainment	99% Complete	An endless source of enjoyment during disasters. Eg: Card Games, Board Games, Puzzles, Brain Teasers, Riddles, Facts, Electronic Games, Stories and Poetry.

Skills and Crafting

Skills	71% Complete	Skills one should possess prior to a disaster and how to train them.
Crafting	25% Complete	Projects and crafting ideas for your home or campsite. Eg: Crafting Furniture, Clothing, Soap, Sewing & Knitting, Whittling, Woodworking, Blacksmithing, Fletching and Glass Crafts.
Knots	97% Complete	Tying knots and using rope skills like rappelling
Materials	71% Complete	Uses and types of materials such as wood, metal and plastic. Eg: Periodic Table, Chemistry, Alternative Uses, Woods, Metals, Polymers, Glass and Dangerous Goods.
Leadership	20% Complete	How to lead your family, small group or town post-disaster. Eg: Self Leadership, Family Leadership, Group Leadership, Town Leadership, Town Law, Discipline and Jobs.
Homesteading	32% Complete	Creating a sustainable lifestyle in a self-sufficient off-grid home.

Resource Harvesting

Gardening	71% Complete	How to grow any type of food, herbs and flowers. Eg: Gardening Methods, Soil, Seed Banks, Growing Vegetables, Fruit, Herbs, Spices and Nuts, Growing in-edible plants, Permaculture and Pests & Diseases.
Hunting	7% Complete	How to track, hunt and trap any type of animal.
Fishing	85% Complete	Fishing tips for any style, weather condition or region.
Plants	90% Complete	Identification tips for plants to determine its uses and edibility. Eg: Plant Identification, Tree Identification, Plant Nutrition, Foraging and the Edibility Test.

Animals	55% Complete	Animal tracks, types, poisonous creatures and edibility.
Animal Husbandry	15% Complete	Raising and sustaining animals for food or companionship.
Meteorology	78% Complete	Types of weather, clouds, planets and space phenomena. Eg: Weather Benefits, The Atmosphere, The Solar System, Clouds, Earth's Cycles and Weather Phenomenon.

Protection

Weapons	50% Complete	Information, tips and handling of modern weapons.
Offence	12% Complete	Using weapons, crafting your own and hand to hand combat. Eg: Unarmed, Kung-Fu, Krav Maga, Hand Weapons, Sword & Knife Offence, Blunt Weapons, Slings, Bows and Crossbows, Fire Based Weapons, Explosives, Improvised Weapons and Verbal Offence.
Defence	33% Complete	Self defence from attackers, animals and pests. Eg: Non Lethal, Unarmed, Bladed Defence, Armour, Insect Defence, Shelter Reinforcement, Bullet Defence, Military Defence, Verbal Defence, Safety and Security.
Warfare	70% Complete	The components and aim of large scale warfare. Eg: Army Personnel, Army Hierarchy, Intelligence Agencies, War Materiel such as Battleships, Submarines, Jet Fighters and Tanks, Electronic Warfare, Space Warfare, Traps & Explosives and War Targets.
Security	48% Complete	Camouflage, infiltration and awareness tips. Eg: Security, Surveillance, Hacking, Lockpicking, Camouflage, Stealth Camping, Concealment, Military Tactics, Tracking, Evasion, Infiltration and Awareness.

Maintenance and Tools

Prelude	100% Complete	Preliminary statements and how to best utilize this sheet.
Contents	100% Complete	Page numbers, hyperlinks and descriptions of the categories.
Addendum	75% Complete	A selection of additional information to compliment TPE. Eg: Preparedness Media, Conversions, Dictionary.
Maintenance	100% Complete	Document updates, user tips, credits and FAQs.

2 Shortcuts

These are hyperlinks to the most common questions relating to preparedness and survival. If you're looking for a specific category such as 'Water' have a look at the categories section below to check if there's a heading for it already.

Common Questions

How can I find something I'm looking for?	Use 'Ctrl + F' to search on PCs, or use the built-in search/find feature on mobile devices.			
How do I start prepping?	Read the 'Introduction' section:			INTRODUCTION
How do I start a bug out bag?	Read the 'Introduction' and 'Gear' sections:		INTRODUCTION	GEAR
What gear should I buy?	Read the 'Gear' section:			GEAR
Should I bug out?	Read the 'Preparedness > Bugging In & Out' sections:			PREPAREDNESS
How can I learn about different disasters?	Read these sections:	NATURAL DISASTERS	MAN-MADE DISASTERS	PERSONAL DISASTERS
What skills should I learn?	Read the 'Skills' section:			SKILLS
How can I be a grey man?	Read the 'Security > Grey Man' section:			SECURITY
How can I monitor disasters around the planet?	Read the 'Preparedness > Situation Monitoring' section:			PREPAREDNESS
Where should I go during a disaster?	Have a look at the 'Locations' and 'Geography' sections:		LOCATIONS	GEOGRAPHY
Where can I find other preparedness resources?	Have a look at the 'Addendum > Media' section:			ADDENDUM

How can I start a homestead?	Read the 'Homesteading' and 'Animal Husbandry' sections:	HOMESTEADING	ANIMAL HUSBANDRY
What do I do after a car/plane crash?	Read the 'Disaster Recovery > Personal Disasters' section:		PERSONAL DISASTERS
Is this edible?	Read the 'Plants' and 'Food' sections:	PLANTS	FOOD
How can I get clean water?	Read the 'Water' section:		WATER
How can I get food?	Read the 'Food', 'Cooking', 'Fishing', 'Hunting' and 'Gardening' categories:	FOOD	COOKING
		FISHING	HUNTING
How can I defend myself?	Read the 'Weapons' and 'Defence' sections:	WEAPONS	DEFENCE
I'm lost.	Read the 'Navigation' and 'Geography' sections.	NAVIGATION	GEOGRAPHY
I can't understand someone.	Use the 'Language' section to translate foreign words and phrases.		LANGUAGE
I'm sick!	Read the 'Illness' and 'Medical' sections:	ILLNESS	MEDICAL
I'm injured!	Read the 'Injury' and 'Medical' sections:	INJURY	MEDICAL
I'm depressed.	Read the 'Emotional' section:		EMOTIONAL
I'm bored.	Read, and play games in the 'Entertainment' section:		ENTERTAINMENT
People have vanished!	Read the 'Mass Destruction > The Rapture' section:		MASS DESTRUCTION
Why is the world going insane?	Read the 'Christianity' section:		RELIGION
How can I support you?	You can donate on my website:	**https://www.fluidicice.com/tpe**

Introduction

An introduction to preparedness and related categories

"A smile is always the best form of introduction."
Sanam Sri

Introduction

This section is designed to get you started on the path of preparedness if you aren't sure where to begin. It includes descriptions of the essentials of preparedness and how each category can be used to your benefit.

Purpose	The aim of INTRODUCTION is to give those with little-to-no experience with prepping a solid foundational knowledge about what it's all about and how they can get started. It lightly covers all the basics such as survival, planning, gear, fire, water, food and shelter as well as many of the skills involved. After this it dives into steps you can take to begin your preparedness journey to become more self-sufficient and ready for whatever may come your way. If you're proficient with preparedness and already know the basics, I recommend you skip this section.
Lost?	• If you're already adept at prepping I recommend starting at the PREPAREDNESS section. • If you're looking for a collection of preparedness websites, books, blogs, videos and podcasts, see the ADDENDUM > Media section. • For a list of terms you may not know, see the ADDENDUM > Dictionary section.

Contents

1 Preparedness

Preparedness refers to a set of actions that are taken as precautionary measures in the face of potential disasters. Whether that means it's a personal disaster such as a job loss or a loved one's death, or a global event such as a meteor impacting earth.

Preparedness also involves mitigation strategies to reduce the impact of a disaster to your daily routine such as having solar power and batteries in case the grid fails. With at least some electricity during an outage you reduce your dependency on others while somewhat going about your typical day. There's a lot to comprehend relating to preparedness so this should be your first section to read after this introduction.

"Preparedness refers to a set of actions that are taken as precautionary measures in the face of potential disasters."

Why Prepare?

John stretched contentedly on his couch, remote in hand, ready for a relaxing evening of whatever reality TV gem awaited him. He flicked on the television, a soft hum filling the living room, but his comfortable sigh caught in his throat. The screen, instead of showcasing domestic dramas or celebrity antics, blared with chaotic, wind-whipped scenes. A reporter, barely audible over a furious roar, battled against an unseen force, her words swallowed by the maelstrom. The graphic beneath her face screamed "CATEGORY 5 HURRICANE MAKES LANDFALL IN CUBA."

John, a man who scoffed at preppers and their doomsday scenarios, felt a chill that had nothing to do with his air conditioning. He stared, wide-eyed and suddenly very small, at the raw, terrifying power of nature unfolding just a few hundred miles from his own oblivious, seemingly secure world. A strange, uneasy sense of security washed over him, a relief that he was safe and sound here in Minnesota, far from hurricane territory.

While John sat in stunned disbelief, a few miles away, Angela watched the same terrifying images flickering across her screen but with a sense of comfort, mingled with genuine empathy for those in Cuba. She glanced around her cozy living room, her gaze lingering on the pantry door, knowing the shelves within were stacked high with dehydrated meals, canned goods, and water purification tablets – enough to sustain her family for months. Her meticulously packed bug-out bags and INCH (I'm Never Coming Home) bags leaned against the wall of her spare room, ready at a moment's notice.

A quick peek out the window confirmed that she was comfortably prepared: the emergency generator sat securely in the shed, next to neatly stacked jerrycans of fuel. In the distance, the familiar glint of the lake offered another resource. Angela sighed, a quiet sense of readiness settling over her amidst the unfolding chaos on the television.

Not only are preppers perpetually ready for any disaster, with resources and supplies stocked up, but they actively try to further their knowledge through experience and practise. A good way to accomplish this is by researching disasters that have previously occurred in your area while looking for ways to mitigate any risks that occurred because of it. Ask yourself why you want to prep.

● Is it to help protect and feed your family in times of disaster?
● Do you not like the way the world is headed?
● Do you want the peace of mind and knowledge that comes with being prepared?
● Do you not trust the current system or government in place?
● Or do you just want to be more self-reliant without being dependant on anyone else?

Any of these reasons are perfect to get you started - as long as you have a goal in mind and a bit of spare cash.

Unfortunately many people today don't worry or care about disasters until they're right on the doorstep. They naively believe everything will be fine and that the shops will always be open. This lack of judgement is what causes panic buying and a lack of resources in the first place, because the majority of people who are unprepared do their regular shop, compounded by those who buy a few extra items and finally those who buy insane amounts of the staple ingredients stripping the shelves clean and attempting to become 'instant preppers'. The obvious difference with preppers is the timing of the purchases.

Prepping is a choice that occurs before disaster

You can't expect to simply 'buy' your way into becoming a prepper. You'll be lacking all the essential skills required to make the best use of the gear and food you have. This type of individual will likely: fumble with their water filter, they'll have to read the instructions on their headlamp before they can use it, they'll make mistakes when bugging out and most importantly they won't know what to do when their resources run out.

Prepping is a choice that occurs **before** disaster. They purchase supplies when a disaster is the furthest thing on peoples mind and the shops are stocked full of everything imaginable, not to mention they can wait to get items on sale to pay even less. However this doesn't stop those who are unprepared for a disaster labelling preppers as selfish hoarders when a disaster DOES occur. This is just spiteful jealousy talking as anyone has the opportunity to be a prepper, but most people choose to enjoy life in the moment rather than worry about the future and an event which 'might' not happen. The difference between these people is that preppers spend time, money and effort getting ready over many years with the knowledge that there will always be another disaster.

In a disaster, anyone who's unprepared, whether that's a family member, a friend or a stranger may even try to forcefully take what preppers owns if the situation gets bad enough, therefore the need to defend oneself with force (or the threat of force) if required. But keep in mind that they're still human and have families to feed, so some preppers take the time to create mini survival kits for friends, family and neighbors to help appease their utter unpreparedness in the moment.

In many ways non preppers are prepared for all sorts of situations. The only reason why someone would buy home and contents insurance or car insurance is the chance that it may burn down, be stolen or destroyed in any freak accident. The difference here is that preppers are insuring their own life by taking control back fromthe external entities such as the government and utility companies. Some other ways that the general population prepares is by buying food for the week or putting away spare money for emergencies. Preppers just take the everyday concepts of preparation and push the boundaries even further, such storing food for a year or converting their spare cash to gold and silver to use for bartering and as a hedge against inflation and economic crashes.

Another way to look at it is that we're only 3 meals away from anarchy. Three meals because generally shops only have a 3 days supply of food for their local populations, and if this runs out or there's a disaster, it puts a strain on any nearby shops who have to compensate for it. However during disasters this chain reaction keeps proliferating outwards until the desire for food or the ability to get to the shop drops.

For example if a major earthquake in central U.S.A. cuts off the roads between the east and west, shops won't be able to restock their supplies. In response people will start to panic, rushing down to the shops loading up their car with as much food and water as they can carry which will further destabilize the delicate "Just In Time" methodology of shop deliveries. As shops run out of essentials people will begin travelling further and further just to get a meal and eventually some of them **will** become violent over a can of food. This is exactly the situation preppers try to avoid by planning ahead and having food, water, medication, weapons and more on hand. We try to look ahead at all the possibilities for interruption to our daily routine and reduce dependencies to outside companies and organisations whether it's food, gas, fuel, electricity, internet or even entertainment.

People often cite a lack of money as a reason for being unprepared or unable to prep, this is largely inaccurate as you can slowly build a stockpile of food even if you buy 1 additional long life item per shopping trip. Due to the relative rarity of disasters you can achieve quite a large supply by doing this over many years... because eventually a disaster will hit your area. The only reason why you wouldn't be able to prep is if you have a debilitating health condition or you're living on the streets and don't have an income. Start a prepping fund or bank account and slowly put money into it to help pay for the resources you, and your family need to survive. The rest of this document will help you to get started on this journey and will guide you on the best purchases to make.

If you're getting started with prepping you might not have someone available to offer support and answer your questions when you become stuck or you aren't sure of how to proceed next. This is where the internet comes in. You can find endless knowledge on websites, YouTube, podcasts, blogs and so much more. To get started I recommend taking a look at YouTube, typing in any questions you have and getting answers instantly. If you want recommendations on channels and websites take a look at the MEDIA section in this guide where I outline a lot of the highest rated content producers for preparedness. It's not as fun to prep alone, so if you find yourself needing some interaction with other preppers try looking up some prepping forums or even better some prepping events and take a friend along. You should always be careful when meeting people on the internet, particularly when you prep because there's always the chance they're after your money, supplies or your life. Therefore prepping is a hushed kind of hobby - not because people will think you're crazy, but because all those who aren't prepared will come knocking down your door during a disaster if they (even family members) know you have food and supplies when they don't.

Prepping is best done in a family situation where everyone can learn and prep together which makes it so much more enjoyable. Unfortunately there's a lot of people who begin prepping without a spouse on their side, and some who are even against it. As much as they offer their reasoning for prepping, their partner simply can't see a plausible future in which the earth comes to a cataclysmic end. It's not their fault, everyone is different and has different priorities in life. One thing that is certain however, is that once a person has gone through a disaster without being prepared, they will absolutely be prepared from then on.

We're dependant on so many complex systems in our fragile society, most of which we forget even exist such as the on-time arrival of food trucks, the power grid, fuel trucks and gas stations, water purification grid and the garbage removal trucks. If you're prepping correctly you should be becoming less reliant on these government assets and more self-reliant every day. If the water system fails you should have a way to acquire water from the surrounds or have it stored up in your house. If the rubbish trucks stop coming you should either be consuming a small amount of waste or have a way to deal with it hygienically to avoid illnesses.

I challenge you to begin prepping today if you aren't already, because the more people that are prepared - the less panic and chaos there will be during disasters. Not only will you be able to sustain yourself and your family through periods of hardship but the peace of mind is unbelievable as you know that you'll have a hot meal no matter the circumstances.

Firstly an explanation of the tools and helpful categories within this guide.
There's a few categories that don't directly apply to preparedness but still may help you navigating this document including: PRELUDE, CONTENTS and ADDENDUM These either give you additional information about TPE or help you in finding what you're looking for.

It only takes the threat of losing <u>anything</u> for people to panic buy <u>everything</u>

PREPAREDNESS	The primary category for preparedness containing bugging in, bugging out, preparing for a disaster and rehearsals.
PRELUDE	An introduction to The Preparedness Encyclopedia contains useful reader tips.
CONTENTS	A list of every category in TPE and a short description on each one.
INTRODUCTION	Outlines the practise of preparedness in a simple manner including first steps to take for those just getting started.
ADDENDUM	A selection of extra content included with TPE such as a dictionary, other preparedness websites and conversions.
MAINTENANCE	Additional usage tips, version control, credits and FAQs.

2 Survival Essentials

The rusty Cessna rattled like a tin can in a tumble dryer, its single propeller slicing through the humid Indonesian air. Below, emerald islands dotted a turquoise canvas, a postcard-perfect view that was doing little to calm my nerves. This was our summer getaway "budget" air tour, and every creak and groan of the ancient plane fortified the idea that I should have reached a little deeper into my pockets. My two friends, Sarah and Ben were strapped in behind me, equally mesmerized and mildly terrified. Beside them, two other passengers, a man and a woman in crisp, albeit rumpled, business attire, sat with serious expressions, their gazes fixed on the vast expanse outside, looking every bit like they were evaluating a new market.

Suddenly, a strangled gasp ripped through the cockpit. Our pilot, a man whose girth seemed to defy the Cessna's modest dimensions, slumped forward, his face a ghastly shade of purple. A terrifying thud echoed as his head hit the instrument panel. My heart hammered against my ribs. He was gone. A heart attack. Mid-flight.

Panic clawed at my throat, but years of watching aviation documentaries kicked in. "Okay, okay, deep breaths," I muttered, hands already gripping the yoke. The ground was rushing up, a dizzying blur of green and blue. "Sarah, Ben, we have a problem!" I yelled, my voice hoarse. Their stunned faces in the rearview mirror confirmed they understood. "He's gone. I need to land this thing."

My eyes darted, searching for anything flat, anything stable. Then I saw it – a thin, sandy strip of beach stretching along the edge of a small, uninhabited island. It was our only shot. I wrestled with the controls which were partially impeded by the sheer mass of the pilot, while the Cessna bucked and swayed like a drunken bird. The ground raced towards us, and I yanked back on the yoke, praying for a miracle.

The impact was brutal. A screech of tortured metal, the sickening crunch of collapsing structure. We skidded, bounced, and finally ground to a halt in a shower of sand, the plane skewed at an impossible angle. Silence, deafening and absolute, followed the chaos.

I fumbled with my seatbelt, my body aching. "Everyone okay?" I croaked, turning around. Sarah was pale but her eyes were wide and focused. Ben, however, was slumped against the fuselage, a dark stain rapidly spreading across his side. "Oh god," Sarah whispered, her voice trembling. "Ben... he's bleeding bad." His breathing was shallow, his eyes glazed with shock and pain. The landing gear was shattered, a wing twisted into an unrecognizable mess. Our pilot was dead. Ben was bleeding, badly. We were marooned on a remote island, the vast ocean stretching around us, and a growing dread told me that without immediate help, Ben's life would drain away with every crimson drop.

We've likely all played these kinds of games growing up, choosing only one type of food or movie that you would survive the rest of your life on. Unfortunately reality is much more ominous, with possible injuries, deaths, the fear of an unknown piece of land and what it contains, the real threat of dying with every decision and the lack of almost every resource needed for survival. This is where the survival category comes in handy, containing information on surviving in some of earth's most hostile environments such as deserts, forests and the arctic as well as tips on the usefulness of various terrains and weather phenomena local to each region.

If you're interested in what you need to do in the scenario above I recommend taking a look at the "PERSONAL DISASTERS > Disaster Recovery" section which contains a step by step procedure of the actions you should consider taking. As a side project I recommend watching 'Cast Away' starring Tom Hanks who is stuck on a tropical island and has to survive and return to civilization.

SURVIVAL	A category that contains tips on outdoor survival in various continents, climates and terrains.
PERSONAL DISASTERS	This category contains a step by step guide on how to proceed in a survival situation such as a plane crash, a car crash or becoming lost etc.

Survival can be distilled down to a few key requirements for staying alive: Hope, Air, Shelter, Water, Food and Company.

Hope
You can only survive 3 seconds without hope. This is arguably the most important one as people simply won't be able to see the good in staying alive anymore and will give up trying to survive. On the other hand you often hear about people who are up against such profound odds that they shouldn't have survived their ordeal. These people have such strong hope that they would even cut their own limbs off to free themselves to continue living. Your source of hope could be seeing family members again, religion, getting old and dying naturally or even just surviving this disaster.

ENTERTAINMENT	Contains a huge array of entertainment and games to keep your mind occupied and sharp if you're stuck with nothing else to do.
EMOTIONAL	Lists the most common emotional problems one can expect in a life and how to handle them.
MEDICAL	General medical tips such as wound care and blood type compatibility.
ILLNESS	Contains most illnesses that can befall you including those that impact airway.
RELIGION	If you're feeling without hope read some Bible passages or famous quotes to lift your spirits.

Air
It takes about 3 minutes without air before you either suffocate or drown. This is your number one priority in a survival situation and will come to the front of your mind as soon as the air supply is cut off, such as when diving underwater for too long. Occasionally you won't even realise you're lacking air, such as using a generator indoors which slowly fills the room with carbon monoxide causing you to feel nauseous and eventually pass out.

Shelter
You can last about 3 hours without shelter in extreme conditions such as snow or blizzards. This makes seeking shelter essential in those or similar circumstances such as bear country. In fairer climates shelter isn't as necessary early on but it's still worth looking for a shelter early on in case of surprises. It can protect you from the elements like heat, cold, wind, rain and snow as well as from dangerous creatures and camouflage from prying eyes such as other humans who wish to cause you harm and assist in giving you a good nights sleep through the comfort and perceived protection they provide. You should be well versed in creating your own wilderness shelters from any sourced materials as this will be a huge advantage in any survival situation.

SHELTER	This is the primary category for shelter featuring every type of shelter from a stick teepee to a nuclear bunker.
HOMESTEADING	How to create and maintain your own homestead.
KNOTS	Contains all the most useful type of knots for survival and construction situations and how to tie them.

Water
As you probably know you can survive around 3 days without water. However this is reduced considerably if you're performing heavy work or sweating profusely under a hot sun. Water is a necessity for life and can luckily be found almost everywhere on earth, even if deserts if you know where to look. Knowing how to find water when it doesn't seem like there's any and understanding the fundamentals of purifying it with makeshift materials is essential to living off the land and surviving any kind of disaster.

WATER	A section dedicated to locating, acquiring, filtering and storing water.

Food
It takes about 3 weeks to die of starvation. This may seem like a long time but over the duration your body will slowly break down and begin consuming itself for energy. Food should only be consumed if you have an ample supply of water as it takes a lot to digest it. Knowing how to source your own food from the wild either by hunting or growing it are great skills every survivalist or prepper should invest in.

If you aren't planning on sourcing your own, you should invest in a stockpile of various long life and shelf stable foods to cover any future disasters for extended periods. Some people rely on their ability to forage food from the wild as they travel around. This could be highly dangerous when there's a lack of food as a lot of people will be starving and will seek any way to acquire it. There's also the possibility of wild food not growing due to a flood, drought or other environment destroying disaster.

FOOD	Contains a list of most known foods with details on each one including their shelf life in the air, fridge and freezer.
COOKING	Different ways of cooking food whether in the outback or a modern kitchen.
RECIPES	Features lots of food, drink and entrée recipes designed to be cooked in the wild or the kitchen.
HEALTH	How to stay fit, healthy, and clean under any circumstances.
FIELD DRESSING	Outlines which creatures and animals are edible and how to prepare them for cooking.
GARDENING	How to grow your own foods from fruit to vegetables to nuts.
PLANTS	Identifying edible plants and food in the wild and how to harvest them correctly.
FISHING	Different fishing techniques and the best times and seasons to catch fish.
HUNTING	How to set up different traps for the situation to help catch or kill any sized creatures.

Company
The timeframe varies and may not apply for everyone, but it generally takes 3 months without company until you start to go insane. This may seem like one you can live without, but once you've gone through the toughest experience of your life and it feels like there's nobody left on earth you will start to crave company and contact of some sort or another whether it's an animal or human. We are social creatures and require contact to thrive whether or not you're introverted or extroverted.

POPULATION	Outlines the different types of countries, people, circles, gangs etc that are present in the world today.

On the Tv series 'Alone' the majority of participants had great survival skills and could potentially last indefinitely out in the wild, but the real killer after so many weeks solo was the need for human interaction which is often the primary reason they tapped out. Company could include talking to animals, AI such as chatbots or NPCs and spiritual company such as chatting to God.

If you would like to continue the plane crash scenario above, below is a list of items that you have with you, can find on the island or could salvage from the plane which would be beneficial in a survival scenario. How would you use them to survive?

From the Plane Fuselage/Cockpit
● Shelter: The intact part of the fuselage offers immediate protection from sun, rain, and wind. It can be insulated with other materials.
● Signaling: The large, metallic surface can be reflective, used to flash signals to aircraft. The bright colours of the plane (if any) can increase visibility.
● Water Collection: Tarps or large sections of metal can be angled to collect rainwater.
● Tools: Any remaining tools in the cockpit or cargo hold (e.g., wrenches, screwdrivers, fire extinguisher, small axe, first aid kit if present).
● Wiring/Cables: Can be used for cordage, snares, or electrical ignitions if carefully handled (though unlikely to be useful for power).
● Plexiglass/Windows: Can be broken to create sharp edges for cutting, or possibly used as a solar still component.
● Insulation: Found within the walls and ceiling of the plane, this can be pulled out and used for warmth, padding, or fire-starting tinder.
● Fuel (Jet Fuel/AvGas): Extremely Dangerous, but can be used as a fire accelerant.
● Batteries: If intact, they could potentially power small devices or provide a spark for fire starting.
● Metal Sheeting/Panels: Can be cut or torn to make tools, containers, or additional reflective signal panels.
● Rubber Hoses/Piping: Might be usable for siphoning water or as rudimentary cordage.

Plane Seats
● Cushions/Padding: Excellent for insulation from the ground or for comfortable bedding materials.
● Fabric: Can be torn into strips for bandages, cordage or rags.
● Metal Frames: Can be bent or broken to create makeshift tools, splints, or anchors.
● Seatbelts: Strong webbing for cordage, lashing, or tourniquets. The buckles can be used as heavy-duty clips.

Wing & Landing Gear (damaged)
● Metal Sections: Large reflective surfaces for signaling, or can be broken down for smaller metal pieces.
● Fuel Tanks (if any remaining): Again, handle fuel with extreme caution.
● Wiring/Piping: Similar to fuselage components.
● Metal Poles/Struts: Can be used as digging tools, splints, or supports for a lean-to.
● Rubber Tires: Can be cut to make shoe soles, or burned for smoke signals (toxic).

From the Pilot's Body/Uniform/Briefcase
● Fabric: Can be torn into strips for bandages, rags, or cordage. Layers provide warmth.
● Buttons/Zippers: Small metal parts for various uses (e.g., fishing hooks if resourceful).
● Shoes/Boots: Durable footwear if they fit someone.
● Paper/Documents: Can be used as tinder for fire starting, or for leaving notes.
● Pens/Pencils: For writing messages.
● Any food/water: Crucial if present.
● Maps/Charts: Potentially useful for identifying location or nearby islands.
● Electronics (phone, tablet, radio): Could potentially be charged or used for signaling if functional. Even if dead, the batteries may provide a spark.
● Tools (multi-tool, knife): Invaluable if the pilot had a personal survival kit.
● Medication: Potentially life-saving if you know the medication, but use extreme caution with unknown meds.

From Passengers
● Layers: Provide insulation against cold nights or sun protection during the day.
● Fabric: Can be torn for bandages (especially cotton or linen), rags, or strips for cordage.
● Socks: Can be used as filters, makeshift gloves, or water pre-filters.
● Shoes/Belts: Can provide durable materials.
● Business Attire: While not ideal for wilderness, suits can be layered for warmth. Ties can be used as makeshift rope or tourniquets. Shirts can be torn into bandages.

Backpacks/Luggage
● Bags themselves: Can be used for carrying water, food, or gear.
● Contents: Any personal items inside:
● Water Bottles/Food: Immediate sustenance.
● First Aid Kits: Critical in any disaster scenario.
● Knives/Multi-tools: Invaluable for cutting, prying, and general utility.
● Flashlights/Headlamps: Essential for night operations.
● Lighters/Matches: Fire starting.
● Sunscreen/Insect Repellent: Protection from environmental hazards.
● Any medications: Especially if any party members have chronic conditions.
● Glasses/Mirrors: For signaling or starting fire.
● Pens/Paper: For communication or journaling.
● Plastic Bags/Tarps: For water collection, shelter, or waterproofing.
● Ropes/Cordage (e.g., shoelaces, paracord bracelets): Multi-purpose.
● Electronics (phones, power banks): For emergency calls, light, or signal.
● Watches & Jewelry: Timekeeping, possibly a reflective surface.

From the Natural Environment (Island & Beach)
● Sand: For signaling (drawing a large SOS), fire pit insulation, or as a abrasive cleaner.
● Driftwood/Fallen Trees: For fire wood, shelter construction, or tools.
● Leaves/Foliage: For shelter insulation, bedding, or tinder (if dry).
● Vines/Plant Fibers: For cordage or lashing.
● Rocks: For fire pits, tools (if sharp-edged), marking, or as weights.
● Shells: Can be used as makeshift cutting tools or containers.
● Seawater (for distillation): Cannot be drunk directly, but can be desalinized using a solar still or boiling with condensation capture.
● Freshwater (if available): Streams, rainwater collected in natural depressions.
● Edible Plants/Fish/Shellfish: (Requires knowledge and careful identification to avoid toxicity).

3 Planning

Once you understand the basics of staying alive you should look at the most common disaster scenarios that could affect your area and work on a plan to minimise the impact to you. Begin by planning your bug-in scenario such as under what circumstances or disasters you will be bugging in and how to proceed. Read the Preparedness section on how to develop this plan in adequate detail and scope as it contains a lot of points people tend to forget about. Next work on your bug-out routes for those situations where it's not safe to stay in your home. Be sure to have backup routes in case some have been blocked by the disaster. People often have plans utilising multiple types of personal transportation such as a car, bike and hiking in those situations where one of them or both of them fails. These plans will be a lifesaver when a disaster is right around the corner as your mind will be far from easy and you'll be much more likely to forget important steps.

A couple of other plans that will be of benefit are; food and water rationing plans, contingency plans, a disaster probability plan, medical emergency plans and an extended disaster plan. These plans can be used to further plan for any eventualities or surprises that may come your way. Contingency plans should be made alongside your primary bug-in and bug-out plans in case the situation turns and you are either forced out of the home or redirected to another route. An example of each is the knowledge that your house will be flooded within 24 hours and you must leave, or an earthquake fracture which has torn a huge gap in the road, forcing you to find an alternate route to the other side.

Recommended Plans
- Bug Out Plans
- Bug In Plans
- Contingency Plans
- Disaster Probability Plans
- Food/Water Rationing Plans
- Medical Emergency Plans
- Extended Disaster Plans

Considerations
- Type of Disaster
- Number of people in your party
- Distance to your BOL
- Amount of Gear Carried
- Age of Party Members

Plan Type	Description
Grab List	An accessible list telling you exactly what to grab in a bug-out situation, as your mind will be overworked.
Bug-Out Plan	A plan to tell members of the party where to meet, the destination and a few alternate routes to get there.
Bug-In Plans	A detailed plan of how the bug-in should proceed and what to do in different scenarios.
Contingency Plans	Backup plans in case a disaster destroys your primary bug-out location or your means of getting there.
Disaster Probability Plans	A plan outlining the probabilities of different disasters and how to proceed during each of them.
Rationing Plans	When a disaster strikes this plan should be implemented quickly to prolong the life of your food and water.
Medical Emergency Plans	Plans to do if a member of the party is critically injured or needs medication when bugging in or out.
Extended Disaster Plan	This describes what to do if a disaster is prolonged far longer than you expected and your supplies are low.
Safety Plan	This plan is used to "baby proof" your house for an incoming disaster to help prevent injuries.

Planning isn't just confined to pen and paper. You should rehearse any plans you have to ensure they work as they should and it gives you a chance to shore up any weaknesses you find while implementing it. While rehearsing a bug out plan you may discover your small car can't handle the muddy mountain road conditions during heavy rain but it was fine in your previous rehearsal when it wasn't raining. You should always expect the unexpected as well because chances are your real bug out won't go the way you planned it. In the Preparedness category I've created a list of unexpected conditions that could potentially affect you whether you chose to bug in or out. During any practise scenario I recommend rolling the dice every so often to see what complications you get, and trying to survive with it.

4 Gear

The next step is to put together all the tools and equipment you'll need when implementing your Bug-Out scenario - otherwise known as creating a BOB (Bug-Out Bag). This is a bag designed to get you to a BOL (Bug-Out Location) within 3 days which should provide much more security and protection from the current disaster. The BOB is the most basic of preparedness assets, you can also work on more advanced bags such as INCH (I'm Never Coming Home) bags which are aimed at living off the land for extended worldwide disasters.

GEAR	Up to date tips on what gear to carry in your bags and details on why they should be carried. Includes an example Bug Out Bag item list.

This is the section people often start with and go crazy on by filling their bags to the brim with tons of gear they believe will help them survive in a disaster. This is due to: a) The ease of buying things and the false sense of progress is gives, and b) people tend to think that "stuff" will save them in a disaster with little effort on their part, which couldn't be further from the truth. They often miss the planning steps discussed above and believe they will "wing it" and head for the mountains in a disaster. What do you think will happen if everyone does that?

Gear - Steps to Take
- Put together a BOB
- Practise using your gear
- Try carrying your BOB long distances and see if you can handle it

Firstly you should only buy gear which provides an essential function for survival such as a knife or rope and possibly an item that makes surviving a little easier such as a book of crosswords or toilet paper. Secondly you should know your equipment inside and out by using it outside of a disaster scenario so you know how to use it without the added stress of a disaster on top. Your gear should also be based around your personal requirements, climate, country and state.

An example being that you're more likely to need water acquisition methods in humid environments than somewhere with snow. Likewise if you live in a country with gun restrictions, this will surely impact the means of self defence you carry. The gear sections contains a list of basic items you should consider carrying with you. From there you can branch out into the other items you require for your situation.

Gear List

This is an example list of BOB gear that preppers typically carry. Some of the items provide a critical function to surviving and others used in different situations based on your climate. Carrying pouches for groupings of gear aren't listed but it's recommended to have a few to be able to sort your items out so they aren't scattered all over the bag. Keep in mind this is a Bug Out Bag which should only have enough supplies to get you to a more permanent destination within three days or 72 hours.

Water
- 1x 1L Metal Water Bottle
- 1x 1L Folding Bottle
- 15-30x Water Purification Tablets
- 1-2x Unlubricated Condoms
- 1x Small Water Filter (Sawyer, Katadyn, MSR)

Food & Cooking
- 3-6x Meals
- 3-5x Energy/Hiking Bars
- 1x Stove
- 1x Fuel
- 1x Cooking Pot
- 0-1x Cup
- 1x Utensils
- 1x Scrubber

Clothing
- 1x Lightweight Clothes
- 1x Warm Clothes
- 1x Rain Poncho
- 1x Walking Boots
- 2x Underwear
- 1x Hat
- 1x Gloves
- 1x Shemagh
- 1x Eyewear
- 2x Pairs of Socks

Shelter
- 1x Shelter
- 1x Ground Pad
- 1x Sleeping Bag
- 1x Groundsheet
- 1x Wool Blanket

You should only buy a backpack once you have the gear you want to put inside. Purchasing the bag first is a common mistake as it could be too small for everything you require or too big causing you to fill up every nook and cranny with nice, but unnecessary gear. Make sure you're able to lift the bag as well or it will be useless when you're bugging out. A good standard for calculating the ideal weight of your BOB is: Your Weight ÷ 3. No bag which will be carried on your back should weigh more than 35kgs (66 pounds).

There's so much more to your gear than just having a list with no explanations for each item, what they can be used for and why it's worth its weight in your backpack.

Each of these items is described in much more detail in the Gear section with explanations on why it's necessary, the cost, size differences, recommended brands and alternative uses.

For a list of gear in the other preparedness bags, see the GEAR section.

Hygiene ● 1x Hand Sanitizer ● 1x Pack Towel ● 1x Toilet Paper ● 1x Toothbrush ● 1x Med. Toothpaste ● ?x Feminine Products	**Medical** ● 1x First Aid Kit ● 10x Isopropyl Wipes ● 5g Potassium Permanganate ● 30x Band-Aids ● 6x Butterfly Sutures ● 10x Wound Dressings ● 2-3x Surgical Blades ● 1x Clotting Powder ● 60g Oral Rehydration Salts (ORS) or (3 Packets) ● 3x Needles (S, M, L)	**Medication** ● 10x Analgesics (Panadol, Asprin, Nurofen) ● 8x Intestinal Sedatives (Imodium, Lomotil) ● 6x Antihistamines (Benadryl, Polaramine) ● 4x Anti-Malaria Tablet ● 30x Antibiotics (Penicillin, Amoxycilin) ● 3x Iosat (Radiation Tablets)	**Tools** ● 1x Knife ● 1x Multitool ● 1x Flexible Saw ● 1x Pen & Book (in a waterproof zip-lock bag)
Light & Fire ● 1x Flint Rod & Striker ● 1x BIC Lighter ● 1x Headlamp ● 2-3x Batteries ● 1x Candle ● 1x Fresnel Lens ● 1-2x Tritium Light ● 1x Torch ● 0-3x Glowstick	**Communication & Navigation** ● 1x Mobile Phone ● 1x Charger Cable ● 1x Compass ● 2x Local Map ● 1x Map Case ● 5x Signal Flares ● 1x Radio ● 1x Solar Panel (15-30W) ● 1x Power Bank (10K mAh) ● 1x Whistle ● 1x Binoculars	**Self Defence** ● 1x Weapon ● 25-50 Rounds Ammo ● 1x 50ml Insect Repellent	**Misc** ● 1x Backpack ● $300-$500 USD Cash ● 1x Brew Kit ● 0-10oz Barterable Coins ● 20m Thread ● 50m Fishing Line ● 5x Hooks ● 5x Small Sinkers ● 1x1m Latex Tubing ● 1x N95 Face Mask ● ID Documents ● 1 Deck of Playing Cards ● 1-2 Morale Boosters

It's always good to have redundancy of the essential items in your kit such as water, fire and medical gear. Fire can be achieved with a match, lighter or a lens. However did you know that you can use a clear spherical bag of water to start a fire instead of a lens? It's also lighter and smaller and provides the additional function of storing and purifying water. Purification, because a bag of water when placed in direct sunlight for 5-7 hours will kill the bacteria, viruses and protozoa in it. This is known as SODIS (SOlar DISinfection). When deciding on equipment to add to your BOB ask yourself what functions this item provides and try to think about any other useful ways it can be utilized.

Most people add way too many items into their BOB when they first start prepping, but this is a step everyone must take to learn what they need and don't need. The key here is to get out into the wild and find out what items you use the most and try to eliminate the ones you don't use or only use once. It's better to have an item you don't need when you're starting out rather than finding you desperately need something when you're in a disaster situation.

Disaster can happen at any time so ensure you're packed and ready to leave at a moments notice.	Your BOB should essentially be a living, breathing asset where you monitor the numbers and expiry dates of items inside, keeping them fresh or "rotated" and in a perpetually ready state in the event of a sudden disaster. There's no use "borrowing" an item from it and then having to hunt it down when disaster strikes, or worse - forgetting to put it back in. Some people keep their bag on them at all times and in the car when they're at work so they're able to make it home quickly, living solely off those supplies. Disaster can happen at any time so ensure you're packed and ready to leave at a moments notice.

Starting a BOB

You're probably wondering which of the above items would be best to purchase first if you're tight on cash with a disaster looming. This section guides you on your first 15 purchases for your Bug-Out Bag which fulfill the basic requirements of survival in the wild. This list doesn't include items under $20 which can be picked up for relatively cheap such as paracord. Therefore there are differences between this list and the "Top 10 Survival Items" list.

The 'Recommended Buys' below are my own thoughts on the products and may even be something I own. They are not sponsored in any way.

$** = Below Average **$$** = Average Price **$$$ = Above Average

Water Bottle	First you need a way to obtain, store and purify water. I recommend a stainless steel or titanium, single-walled water bottle. A bottle which is metal and single-walled allows you to boil water inside it, which takes care of the water purification and water storage aspects of survival. This should only cost between $20-$50 to buy but can reach up to $100 for titanium. You want to pick one which can easily stack with a pot too!	**Recommended Buys** ● Klean Kanteen 1182ml Bottle $$ ● Keith Titanium 1.8L Canteen $$$ ● Grayl Geopress $$$
Water Filter	Besides boiling water in your bottle you should have a simpler method of purifying it on the go. This is where a high quality water filter comes in. It's recommended, but not essential to buy a filter which also removes viruses, but this comes at a higher cost and they often take up more space. These can cost you between $30 to $500.	**Recommended Buys** ● Sawyer Mini $ ● Kayadyn Pocket Water Filter $$$ ● MSR Guardian $$$ ● Survivor Filter Pro $$
Knife	A water bottle and a knife are two of the most essential items if you're lost and trying to return to civilization again. You can use it to defend yourself, baton wood, build a shelter, hunt with, feather wood, start a fire, signal for help, gut animals and so much more. Don't cheap out on your knife because it will be used daily in any survival situation. You should pay between $100 to $300 for a fixed-blade, full tang knife.	**Recommended Buys** ● KA-BAR Becker BK2 $$ ● Schrade SCHF57 $ ● Fallkniven A1 $$$ ● KA-BAR USMC Knife $$
Shelter	Since it's more frequent to bug-out than bug-in during disasters you'll want a comfortable shelter which is light and portable. Ideally it should weigh less than 2kgs (4.4lbs) and is easily attachable to your backpack. You have the choice between a tent, swag, bivy or hammock depending on what you prefer. Don't cheap out on your shelter or it may fail you when you need it most and you certainly don't want a wet sleeping bag in the middle of the night. Set aside $200-$1,000 for a lightweight shelter of hard-wearing fabric.	**Recommended Buys** ● Snugpak Ionosphere $$ ● Marmot Tungsten Ultralight $$$ ● Carinthia Observer $$$ ● The North Face VE 25 $$$
Sleeping Bag	Sure, you could get by without a sleeping bag while you bug out if you're in a warm climate, but with a disaster occurring do you really want to risk a good night's sleep in favour of saving a bit of weight and money?	**Recommended Buys** ● Sea to Summit Trek II $$$ ● Snugpak Softie Elite 3 $$ ● Coleman 0°F Mummy $

Mattress	You won't get much sleep lying on the cold, hard ground. Thankfully there's lightweight portable mattresses which you can either blow up or leave to self-inflate over a few minutes.	**Recommended Buys** • KLYMIT Static V $ • Sleepingo Camping Pad $ • HiHiker Camping Pad $ • Sea to Summit Sleeping Mat $$ • Sea to Summit Comfort Deluxe $$$
Groundsheet	This sheet can be used to protect your tent from punctures, provide additional shelter configurations, collect rain, store water, build a solar still and more. Throw in about 30m (100ft) of paracord with it and you can do almost anything.	**Recommended Buys** • Tarp/Canvas $ • Tyvek Sheet $$ • Cuben Fiber $$$
Food	Next on the essentials list is food. Generally you only want 3 days worth of food in your BOB which should be enough to get you to your destination. You have quite a range of tasty options available today, in the form of MREs, ration bars, canned meals and freeze-dried meals. Freeze-dried meals are generally the best option because of how light they are, but if there isn't any water on your route then pick something that contains the water already.	**Recommended Buys** • Mountain House (USA) $$ • Backpackers Pantry (USA) $$ • Back Country Cuisine (AUS) $$ • Campers Pantry (AUS) $$
Camping Stove	You will probably need to cook while bugging out, and with today's technology you can have a hot meal within a few minutes. You can either heat water and pour it into a freeze-dried meal or heat the food directly. Alternatively you can buy a chemical heating bag which does the same for a fraction of the weight - although they are one use only. There's also many other methods you can cook with, but these are either messy or complicated to utilize. Don't forget the fuel if you opt for a gas stove.	**Recommended Buys** • BRS 3000-T $ • MSR Pocket Rocket 2 $$ • SOTO WindMaster $$ • Flameless Heater Bag $
Cooking Pot	If you're going to be eating food from a tin or packet you'll probably need to put it into something to heat up. That's where the pot comes in handy. Not only can you cook food in it but it can boil water, be used to brew coffee and more. Therefore I recommend getting one which fits snugly around your water bottle. Add a spork or any other cutlery you want to finish it off.	**Recommended Buys** • Stanley Adventure Cook Set 24oz $ • Toaks Titanium 750ml Pot $$
Torch	You're probably going to need some form of light during your bug-out and this is where a torch or headlamp comes in. They come in all shapes and sizes and have a lot of useful features, but all you need is something weather resistant and provides a decent amount of light for up to 3 nights. If you want to go stealth, get a light with a red LED on it as well as a white light. Don't forget the spare batteries!	**Recommended Buys** • Olight H2R (2300 lm) $$ • Olight i3E EOS (90 lm) $ • Black Diamond Spot 325 $$ • Olight X7R Marauder (12k lm) $$$
Radio	You probably won't have a mobile signal during a large scale disaster which is where a radio comes in. These can be small in size and may even already be built-in to your phone. I recommend one which has either a dynamo handle or solar panels and acts as a power bank from which you can charge your other devices.	**Recommended Buys** • RunningSnail Emergency Radio $ • FosPower Emergency Radio $ • Kaito KA500 $$
Map, Compass & Plans	Since you'll be travelling to your Bug-Out Location (BOL) during a potentially environment-altering disaster it's best to have a printed map and a compass so you can alter your course, if for some reason you can't use your original route. You should also print your Bug-Out Plan so you have it ready in your pack in zero hour.	**Recommended Buys** • Printed Local Maps $ • Silva Explorer 2.0 $
Medical Kit	This isn't technically one item, but as a kit it's an invaluable asset during any disaster because you're much more likely to injure yourself, or be injured during a disaster. You can either purchase a pre-packed kit or choose the bag and items yourself for a custom setup. See above for the recommended contents of this medical kit, or the GEAR section if you want a full spec-sheet of each item.	**Recommended Buys** • Build one yourself, or buy from a reputable company
Backpack	You should buy your backpack once you have the items you want to store inside it so you don't buy one that's too big and try to stuff it full of gear. Look for a backpack suited to your frame and which can hold up to about 1/3 of your body weight.	**Recommended Buys** • Granite Gear Crown2 $$ • Paratus 3-Day Operator's Pack $$ • Eberlestock 79 Skycrane II $$$ • Maxpedition Falcon 2 $$

Prepping at Home

This section will help you get started on 15 of the items you should be stockpiling if you're planning on bugging in through any disasters, or if you just want to be more self-sufficient.

Water	At minimum you should store barrels and bottles of water inside your home to safeguard against a cut water supply. The next step up would be to add some water tanks to your house allowing you to collect rainwater. But the ideal solution is that you would live next to a body of water which you can pump up to your house. Don't forget the filtration system if you collect rainwater or pump from a body of water.
Food	You should aim for at least a month of food per person to begin with and slowly add on from there. This will give you a strong foundation to continue prepping on as you focus on some other categories. Your pantry should be built off long life, staple ingredients such as rice, pasta, flour, sugar, potatos, onions, salt, honey, garlic, crackers, lentils, chickpeas, beans, grains, starches, herbs, spices, nuts, milk, sauces and canned foods. Beyond the kitchen you should have an established garden and everything required for the maintenance of it such as seeds, mulch, fertilizer, pots and tools.
Guns & Bullets	It's better to have one gun with a ton of bullets than lots of different guns with only a selection of bullets for each one. Better yet, choose guns which use the same bullets but have different functions. A good place to start is by researching .22 caliber bullets and 5.56 NATO bullets.

Medical Gear	You can never have enough medical supplies, especially in any disaster due to the chance of requiring any form of medical aid going up dramatically. Cover all the basics such as bandaids, bandages, thermal blankets and antiseptics. The next step up is the trauma gear such as torniquets, blood clotting powder, scalpels, chest seals, suture kit and staple kit. If you have more money to spend go for the hospital grade equipment such as a defibrilator, ventilator, drip machine, patient monitor, blood pressure meter, EKG machine, stretchers, anesthesia machines, nebulizer, patient lifters. For a complete list of medical gear see the GEAR section.
Medication	Medication is another very important one to consider. Stockpile lots of the basics such as Paracetamol (Panadol), Ibuprofen (Nurofen), Loperamide (Imodium) and Fexofenadine (Telfast). If you can, obtain a few different types of antibiotics because they may save your life in the future. You should consider any special medical requirements you or your family requires such as epi-pens and insulin and how you will acquire them and store them for the long term.
Barter/Spare Items	There's always going to be some people who either aren't prepared or have something you want, this is where barterable items can come in handy. These should be set apart from your own stocks and shouldn't be counted when you 'stocktake' your own items. They are used to give to others in need such as family and friends or to trade for something you really need. Barter items also include gold and silver coins which could become currency again if the economy fails.
Candles	When electricity isn't available you'll be sent back to the dark ages without a form of light, this is where candles will be extremely helpful. Not only will they provide a decent amount of light per candle, but they can provide warmth and a sense of hope and possibly a fire to cook over if you have enough of them. Look for the candles which burn the longest, these typically are about 2.5cm (1 in) wide and don't leave a wax 'shell' behind.
Hygiene Products	Generally the hygiene of people slips during any form of disaster which opens the door to some scary diseases. However this is easily countered with a well stocked hygiene cupboard which could include: hand sanitiser, toilet paper, cloths & towels, a working tap, toothbrushes & toothpaste, kitchen sprays, disinfectant, hand soap, a bucket shower and feminine hygiene products.
Fuel	If you're stuck at home for long periods you'll need fuel to power everything. Firstly wood is important as a source of fuel and for house repairs as discussed below. Petrol should be stored to help generate electricity and to keep your car running if it's necessary to travel. Finally gas fuel will provide a source of heat and flames to cook on if you don't have electricity anymore.
Hardware Supplies	Hardware supplies are essential to stock up on. You don't know what kind of disaster may hit your house, whether it's a flood, earthquake or hurricane, but if you stock up on wood, planks, rope, duct tape, screws & nails you know that you'll be able to fix most of the damage.
Clothing & Fabrics	Fabrics are great for repairing any clothing which may be damaged over time - if you're in it for the long haul. They can also be fashioned into other needs such as curtains or keep you warm during an exceptionally cold blizzard. Spare clothing is also important to keep because your clothes will certainly take a beating during any disaster. Mattresses are another great product to have a couple of spares of. They can be used for sleeping on, baterting or for protection during hurricanes.
Solar Panels & Batteries	Batteries are critical in any disaster to help you power your devices. I recommend stocking up on AAA, AA, C, D, 9v, and maybe a car battery or two. Power Banks are ideal to keep mobiles and tablets operational. Deep Cycle Marine batteries can also be extremely useful when combined with a solar setup to be able to power multiple electronics or even a small household. If you have a lot to spend, go for a large scale solar setup with a power bank to fulfill most your electrical needs.
Electronics	Even if the power goes out, electronics such as mobile phones, tablets, torches, radios, CB radios, fans, LED lights and portable solar panels are still essential in daily life since our dependence on them has grown. Even if you don't use them, they can be traded to people who are without for something else you need. If you're electrically minded you should keep a box of electric bits and pieces so you're able to repair electronics that break down.
Knowledge	Start a library on every preparedness, survival and homesteading book imaginable. You can use this to expand your knowledge and broaden your horizons if for example society goes back to the dark ages and you need to know how to blacksmith or forage. They can also provide a source of entertainment, so don't forget the novels and childrens books if you have kids.
Morale Items	If you're going to hunker down inside your house for long periods of time you're going to need something to keep entertained with. Morale items could be board games, card games, tv shows, music, video games, puzzles or books. Find out what each person enjoys the most and have a customised variety for each of them.

Terms

There are quite a lot of prepper terms you may see throughout this document which you may not understand such as: BOB, WROL and TEOTWAWKI. A complete list can be found in the 'ADDENDUM > Dictionary' category but a few of the more popular ones are to the right.	**BO** = Bug Out **BI** = Bug In **BOB** = Bug Out Bag **BIB** = Bug In Bag **BOL** = Bug Out Location **BOP** = Bug Out Plan **BOV** = Bug Out Vehicle **SHTF** = S*** (or Stuff) Hits The Fan **WROL** = Without Rule Of Law **BSTS** = Better Safe Than Sorry **GOOD** = Get Out Of Dodge	**EDC** = Every Day Carry (Kit) **CCW** = Concealed Carry Weapon **EMP** = ElectroMagnetic Pulse **EOD** = End Of Days **FAK** = First Aid Kit **IFAK** = Individual First Aid Kit **PFAK** = Personal First Aid Kit **JIC** = Just In Case **MRE** = Meal Ready to Eat **NBC** = Nuclear Biological Chemical **TPTB** = The Powers That Be	**PSK** = Personal Survival Kit **GHB** = Get Home Bag **INCH** = I'm Not Coming Home (Bag) **TEOTWAWKI** = The End Of The World As We Know IT

Term Descriptions

These are the terms you may come across throughout this document. Learn them now so you don't have to keep coming back to them. There are more definitions in the ADDENDUM section.

- **Bug Out Bag:** A simple backpack or bag of survival items that you have ready to go when you need to bug out. Your bug out bag should consist of basic items that will allow you to survive for at least three days.
- **Bug Out Location:** A designated location outside of the danger zone that you bug out too.
- **Bug Out Vehicle:** A vehicle that is large enough to transport you, your family, and your supplies, and can also go off-road in case roads are blocked.
- **Bugging In:** Refers to staying at home during a disaster.
- **Bugging Out:** Refers to evacuating your home during a disaster, either by your own choice or because you are ordered to.
- **Alpha Strategy:** Storing extra supplies for the purposes of trade or personal use in a disaster.
- **Ballistic Wampum:** Ammunition stored for disaster preparedness purposes.
- **Big Berkey:** A family water filtration system that can remove harmful bacteria and toxins from water.
- **Doomer:** Somebody who believes disaster is coming and chaos will ensue. These are hardcore preppers.
- **Electromagnetic Pulse:** A weapon that when detonated in the atmosphere would knock out all electronics within a certain radius.
- **Faraday Cage:** An improvised device that can shield the electronic items inside from an EMP attack or solar flare.
- **Food Insurance:** Refers to the food stockpile you have in your home.
- **Gamma Lid:** An airtight lid that is used for plastic containers that are food grade.
- **Potable Water:** Water which is safe to consume.
- **Get Home Bag:** A small backpack of survival items that you keep in your vehicle should you need to abandon your car and try to get home during an urban disaster.
- **Grid Down:** Means the power grid has gone down, likely as a result of an EMP.
- **Larder:** Typically refers to a pantry, but can also be used to refer to any place where you store food for survival and disaster-related purposes.
- **Mylar Bags:** Bags that are used to provide a barrier between stored survival food and sunlight.
- **Pollyanna:** Somebody who denies that a major disaster will ever occur.
- **Preppers:** People who prepare for disaster by storing food, supplies and learning survival skills.
- **Rendezvous Point:** A pre-determined location where you meet up with your survival group before continuing to your designated bug out location.
- **Rule of Threes:** You can live for three minutes without oxygen, three hours without shelter in harsh environments, three days without water, and three weeks without food.
- **Sheeple:** Refers to people who are largely unprepared for a disaster and will follow the rest of the crowd.
- **Solar Oven:** A cardboard box lined with aluminium foil to bake food using the sun's energy.
- **Survival Cache:** A collection of survival items that you bury or hide at a location away from your home.
- **Two is One, One is None:** Always have a second piece of kit with a redundant function in case the first one fails.

5 Skills

After you start equipping your person and your BOB with some items, the next step is to develop your skills in preparedness and survival. It's no good to have 'the best' gear sitting all clean and untouched in a bag somewhere. What if it breaks on the first use? Or it was defective when you bought it but didn't test it? What if it doesn't do what you expected?

Take time out on the weekend to go into the wild and try to survive with only what you have in your backpack, this will also give you an idea of what you might be missing but you're also so close to home that it's no big deal if you forget something. There's a huge range of skills which are essential to surviving alone and quite a lot which are just beneficial to know. Some of the most important ones to practise are listed here:

Essential Skills
- Fire Lighting
- Water Purification
- Stealth and Observation
- Living off the Land
- Navigation
- Understanding Climates
- Shooting/Self Defence
- Medical Skills

Valued Skills	Valued Skills	Other Skills	
• Shelter Building • Using Natural Resources • Meteorology • Knot Tying	• Fishing • Hunting • Trapping • Gardening • Cooking	• Weaving • House Construction/Repairs • Electrical Maintenance • Blacksmithing	A great way to start is by picking a skill and trying to master it over the course of a week. Each week is a new skill and you'll progress quickly if you continually use it on your outdoor trips as well.

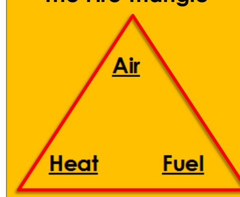
SKILLS	Skills one should possess prior to SHTF and how to train them

6 Fire

Fire is the single most important tool in the wild. With it you can cook food, purify water, provide heat, signal for help, scare predators and so much more. You should have at least 3 different ways to start a fire in your BOB such as a fresnel lens a lighter and a flint rod. To get started with fire lighting you should know the basic principles of the fire triangle. The three sides are: Air, Heat and Fuel. If you remove any one of these the fire will go out, therefore you need all three to start one as well. The best practice when learning fire lighting is to know how to extinguish them first, just in case it takes off too rapidly.

To extinguish a fire you must remove one or multiple sides of the fire triangle. This can be done by reducing the heat with water or a chemical compound such as that found in fire extinguishers. Removing the air (oxygen) from the fire by means of sealing it in an airtight area - just like a candle burning in a small space. Or by taking away the fuel source such as the logs or liquid fuel.

The Fire Triangle



INTRODUCTION Fire

Fire Lighting Methods ● Bow Drill ● Flint & Steel ● Matches ● Lighter ● Solar ● Electricity ● Chemical	To light a fire the first thing you'll need is a form of fine tinder to help catch a spark or flame. You can find a variety of natural tinders in the wild such as dusted tree bark, cats tails, leaves, cotton plants etc, but the easiest to use tinders are manufactured. Tissues, cotton balls, dryer lint and flammable liquids such as alcohol, petrol, diesel and kerosene make excellent tinders which only require a spark to ignite in most circumstances. It's recommended to have a small amount of this in a fire lighting kit to use when you aren't able to find natural materials.	**Skills to Learn** ● Extinguishing Fires ● Know the fire triangle ● Practise lighting with multiple different methods and tinders ● Wild Tinder Identification

Besides tinder you'll require kindling which are pieces of larger material - typically sticks, which give the fire more of a body to help sustain it longer. Sticks and pinecones are perfect for this as they are small enough to catch fire with a small flame yet will burn longer than tinders providing a stepping point to burning the larger materials. Finally you'll need fuel for your fire once your kindling is burning well. Logs with a diameter of 3cm and greater are the ideal choice for fuel as they are readily available in a forest and can easily be cut down to size. Be sure that the tinder, kindling and fuels are all bone dry as they won't light if there's any moisture in them. Also don't use green or fresh branches as they won't light either.

Once you have the required fuels and a lighting source for a fire there's a few important safety checks you should make before attempting to light a fire. Check that the climate and terrain is in favour of a fire. You won't get very far if it's about to pour down with rain or start snowing. Wind is also your enemy when attempting to light a fire as it will easily blow out small flames, or alternatively, encourage an established fire to spread rapidly. Have a bottle of water handy in case the fire starts to get out of control and clear out all the leaves within a 2m (6.7ft) radius before lighting it.

FIRE	Methods for starting fires, types of tinder and fire starters
FUEL	All types of fuels from solid to liquid or gas and its effectiveness

Make sure you have enough fuel to complete whatever goal you have in mind. It's better to have too much fuel than run out half way and have to restart the fire again. The final check you should make is that you won't be detected. Generally in bug out situations you don't want anyone knowing you're in the area and a fire is the easiest way people can detect you whether it's by the flicker of the campfire, the smoke rising above the trees or the smell of food coming from your camp. Sometimes having a fire is essential such as in the winter months or when water needs purifying. Fortunately there's a few ways you can have a "stealth fire", but these are mentioned in more detail in the Fire section.

Fire Lighting	To light a fire, first make a nest shaped dome with your semi-finest tinder and put the finest shaving inside it. Put this nest next to a teepee shaped bunch of kindling so that when the fire catches onto the tinder you can slide it under the kindling so it heats and climbs the sticks. You don't need the tinder if you're using a modern fire starter brick as these burn long enough to catch the kindling on fire and can also take a spark from flint to light. You should have the main fuel (logs) nearby so you can place them onto the kindling once it's burning well. Alternatively you can make another teepee from the larger sticks and logs so you can simply slide the kindling nest under it so you don't crush the fire accidentally.

When you're finished with the fire it's critical that you extinguish it - the last thing you want in an emergency is a forest fire on your tail. Embers can burn for days under a collapsed fire and if stirred up by the wind can easily trigger a forest fire under the right conditions. Water, dirt and mud are readily found in nature and are perfect for putting out fires, simply mix them together until the flames and embers die out.

7 Shelter

Having a shelter provides protection from elements and insects, keeps you warm and gives you a sense of security when you're laying there snug and ready for a good night's sleep. With today's technology comes amazing new leaps in fabrics and light weight poles allowing for compact, light, stealthy, yet durable shelters which can be set up within a few minutes. Choosing one is no easy task but it really depends on the situations it will be put into. If you know that it has to stand up to wild weather then go with a canvas swag which is highly puncture and tear proof. Needing something to keep the swarms of mosquitoes out? Go with something that's lightweight and has a very fine mesh.

SHELTER	Types of shelters, building survival shelters and shelter strengths

What if a situation arises in which you couldn't make it home to retrieve your BOB before you left? Or if you don't fancy lugging a shelter across the country on your back? You can easily build your own temporary shelter out of sourced materials or a naturally occurring feature such as a rock. You just need to know a bit of basic construction and know a few knots. I recommend you study the Shelter category for a variety of different shelters you can construct, including using natural resources such as fallen logs and rock formations which can easily be converted into shelters.	**Makeshift Shelters** ● Lean-To ● Snow Cave ● Tarp Hammock ● Bough Bed ● Leaf Hut

Shelters aren't just confined to makeshift shelters, tents, and swags but encompass any form of shelter from the elements whether that's a house, car or bus stop. These types of shelters can be used to take cover from a varying array of disasters or even just the harsh sun on a summers day and is much safer than attempting to wait it out with the elements bearing down on you. A good example is being trapped in your car during a snowstorm. You shouldn't leave the safety of even a fragile shelter such as a car in search of a house if you don't know the area and are unable to see very far. Being an enclosed space your body heat will generally remain in that space rather than being taken away by the wind.

8 Water

Water is one of the most crucial resources in a survival situation. It takes only a few hours before you can begin to feel the effects of lack of water in warm or humid conditions. In any survival condition it is vital to know how to find, filter, purify and store water. There are so many techniques that can be used to produce safe drinking water that you can do it in your home right now. A few ways are: Using bleach, distillation, filtering through cloth, chlorine tablets, filtering through charcoal, using SODIS (SOlar DISinfection) with an old plastic bottle, evapotranspiration and more. Keep in mind though, that not all techniques are equal, and water filtration is **not** the same as water purification. Filtration involves the removing of sediment and particles from water and Purification is the killing or removal of bacteria, protozoa and viruses from the water.

Natural Water Sources ● Rain ● Lakes ● Ocean ● Evapotranspiration ● Dew Collection ● Fog Harvesting ● Animals ● Plants ● Solar Still	The first thing you'll need to do is source some water. You should be able to find water nearly everywhere on earth if you look for it. These are a variety of ways water can be found in nature and around the home. Most of these methods require purification before being able to drink it, but can be utilized in an emergency. For more information on how each type can be purified see the Water section. There are a few exclusions to what kinds of water can be purified, these include: Water which contains heavy metals, water which contains dissolved pharmaceutical drugs and water which contains chemicals like cleaning solutions and factory waste water.	**Urban Water Sources** ● Taps ● Toilets ● Hot Water System ● Water Pipes ● Air Conditioners ● Fish Tank ● Cars ● Water Towers ● Fire Hydrants
Filtration Techniques ● Makeshift Water Filter ● Bank Filtration ● Carbon Filtering ● Activated Charcoal Filtering ● Sedimentation ● Coagulation	To turn water found in the environment into **potable** water (water safe to drink), it must go through a series of techniques to remove sediment, particulate and contaminants. The first step is a water filter which remove sediment in the water, whether visible or not. Sediment could be anything from stones, leaves, bugs, dirt and dust to hair. It's recommended to remove this prior to progressing to the next step of purification due to the chance of particulate becoming trapped in purification filters or even greatly reducing the purification effectiveness. An example is UV purification where the light can't shine through any solid material and therefore won't kill the bacteria on the particulate. Some techniques just require a handheld filter and others require an entire desalination plant. Similarly some can filter out salt but most of them aren't able to, so be sure to match the filter with the type of landscape you'll be living in.	**Purification Techniques** ● Manufactured Filters ● Slow Sand Filter ● Boiling ● Distillation ● Solar Pasteurisation ● SODIS ● Chlorination ● Electrolytic Purification ● UV Light ● Reverse Osmosis ● Ozonation ● Copper/Silver Ionization ● Solar Desalination
WATER	The WATER section is dedicated to locating, acquiring, filtering and storing water.	

9 Threats

In any survival situation, threats can come from a multitude of sources. Understanding and anticipating these threats is crucial for preparedness and increasing your chances of survival. They can generally be categorized as environmental, biological, and human-related.

Weather Extremes	**Heat:** Dehydration, heatstroke, sunburn, exhaustion. **Cold:** Hypothermia, frostbite, exposure. **Wind:** Wind chill, exposure, blowing debris, damage to shelter. **Rain/Snow/Ice:** Hypothermia, limited visibility, slippery terrain, flooding, avalanches. **Storms:** Thunderstorms (lightning), blizzards, hurricanes/cyclones (strong winds, flooding, storm surge), tornadoes (destructive winds).
Natural Disasters	**Floods:** Drowning, rapid current, contamination of water sources, loss of supplies. **Drought:** Lack of water, desiccation, increased fire risk. **Wildfires/Bushfires:** Burns, smoke inhalation, rapid spread, destruction of resources, limited escape routes. **Earthquakes:** Structural collapse, landslides, tsunamis (if coastal), aftershocks. **Volcanic Eruptions:** Ashfall, lava flows, lahars (mudslides), toxic gases. **Landslides/Mudslides:** Burial, crushing injuries, blocking routes. **Tsunamis:** Massive waves, drowning, widespread destruction.
Terrain & Geographical Hazards	**Rough Terrain:** Falls, sprains, fractures, getting lost. **Elevation:** Altitude sickness, thinner air. **Water Bodies:** Drowning, strong currents, hypothermia, hazards (e.g., submerged obstacles). **Quicksand/Bogs:** Entrapment, exposure. **Avalanches:** Burial, trauma. **Caves/Crevasses:** Falls, getting lost, hypothermia.
Animals	**Predators:** Attacks from large carnivores. **Venomous Creatures:** Bites/stings from snakes, spiders, scorpions, jellyfish, centipedes, certain insects (e.g., bees, wasps if allergic), marine life (stonefish, cone snails, blue-ringed octopus in Indonesia/Australia). **Aggressive Animals:** Attacks from non-predatory but aggressive animals (wild boar, monkeys, territorial birds, some herbivores like moose if provoked). **Insects:** Mosquitoes (malaria, dengue, Zika, chikungunya), ticks (Lyme disease, tick-borne encephalitis), fleas (plague), flies (various diseases, maggots).
Plants	**Poisonous Plants:** Ingestion (causing illness, organ damage, death), skin contact (rashes, burns, blisters). **Irritating Plants:** Thorns, sharp edges causing cuts and punctures.
Microorganisms & Disease	**Waterborne Pathogens:** Bacteria, viruses, parasites causing dysentery, cholera, giardia (from contaminated water). **Foodborne Illnesses:** From spoiled or improperly prepared food. **Wound Infections:** Bacteria entering open wounds, leading to sepsis, gangrene. **Respiratory Illnesses:** From exposure to cold or smoke. **Pre-existing Medical Conditions:** Exacerbation of chronic diseases (diabetes, heart conditions), lack of medication. **Pandemics/Epidemics:** Widespread infectious diseases.
Direct Conflict/Violence	**Hostile Individuals/Groups:** Robbery, assault, violence from desperate or malicious people. **Marauders/Looters:** Especially in collapsed societal scenarios. **Kidnapping/Hostage Situations**
Disaster Proliferation	This is when a current disaster situation becomes worse. For example in the cessna crash, the fuel tank could explode at a random time after the crash landing.
Accidents & Errors	**Poor Judgement/Panic:** Making rash decisions, freezing, or taking unnecessary risks. **Lack of Knowledge/Skills:** Inability to perform essential survival tasks. **Exhaustion/Fatigue:** Leading to errors, impaired judgment, reduced physical capability. **Exposure to Toxic Substances:** From industrial accidents, chemical spills, or improperly handled materials (e.g., plane fuel in your scenario). **Explosions/Fires (man-made):** From industrial incidents, intentional acts, or faulty equipment.

INTRODUCTION Threats

Psychological Threats	**Panic/Fear:** Hindering rational thought and action. **Anxiety/Stress:** Leading to poor decision-making, physical and mental breakdown. **Loneliness/Isolation:** Especially in long-term scenarios. **Hopelessness/Despair:** Loss of will to survive. **Group Dynamics:** Conflict within the group, lack of leadership, infighting.
Infrastructure Failure	**Power Outages:** Loss of light, heat/cooling, communication, refrigeration. **Communication Breakdown:** Inability to contact help or loved ones. **Supply Chain Collapse:** Lack of food, water, medicine, fuel. **Transportation System Failure:** Roads, bridges, airports unusable.

To continue the cessna crash scenario, below are some examples of the different threats that are prominent after the crash and others that you will likely encounter on the island.

Short Term Threats
● Severe Injury & Blood Loss (Ben): This is the most pressing and life-threatening concern. Without rapid and effective first aid to stop bleeding and treat shock, Ben's chances of survival are extremely low.
● Pilot's Death: While not a direct threat to the survivors, it creates a critical vacuum in terms of navigation, expertise, and any pre-existing emergency procedures or equipment the pilot might have known about or carried. It also presents a psychological shock.
● Shock (Sarah & other passengers): The extreme trauma of the crash can induce physical and psychological shock, impairing judgment, reducing ability to act, and worsening physical conditions.
● Aircraft Fire/Explosion: Though the initial impact might not have caused one, ruptured fuel lines, damaged electrical wiring, and hot engine components always pose a risk of fire or explosion immediately after a crash, especially with AvGas (highly volatile).
● Lack of Medical Supplies: The absence of a readily accessible and well-stocked first aid kit, or trained medical personnel, exacerbates Ben's injury.
● Debris Hazards: Sharp metal, glass, and other broken components from the plane pose immediate risks of cuts, punctures, and falls around the crash site.

Medium Term Threats
● Dehydration: Without a reliable source of fresh water, especially in a tropical climate, dehydration will quickly become critical. This will be exacerbated by Ben's blood loss.
● Sun/Heatstroke: Intense tropical sun can quickly lead to severe sunburn, heat exhaustion, and heatstroke.
● Rain/Humidity: Heavy tropical downpours can lead to hypothermia even in warm air, and the high humidity can make drying clothes difficult, increasing risk of fungal infections.
● Lack of Shelter: While the plane offers some immediate shelter, it's damaged. Without proper protection from sun, rain, and insects, the survivors are vulnerable.
● Infection: Ben's open wound is highly susceptible to infection from bacteria, fungi, and insect larvae (e.g., fly strike) in the tropical environment, leading to sepsis if untreated.
● Mosquitoes: High risk of diseases like Dengue, Malaria, Zika, especially at dusk and dawn. This is a very significant threat in Indonesia.
● Dangerous Animals: Venomous Snakes, Crocodiles, Wild Boar, Monkeys, Komodo Dragons, Monitor Lizards, Jellyfish, Sharks and Octopuses.

● Scorpions/Centipedes: Painful stings/bites, potentially causing severe reactions.
● Other Insects: Biting ants, flies, etc., causing discomfort and potential secondary infections.
● Marine Hazards: If exploring the coast for resources (saltwater crocodiles in estuaries, venomous marine life like stonefish, cone snails, jellyfish).
● Lack of Communication/Signaling: Without working electronics or effective signaling methods, the chances of being found are low. The ELT is critical.
● Starvation: While less immediate than water, without a food source, energy levels will rapidly decline, impacting ability to work, think, and heal.
● Psychological Deterioration: The trauma, isolation, fear, and discomfort can lead to panic, despair, conflict within the group, and impaired decision-making. The death of the pilot and the severity of Ben's injury will amplify this.
● Lack of Tools/Resources: Without basic tools (knife, fire starter, container), essential survival tasks like water purification, fire making, and shelter building become extremely difficult.
● Lack of Footwear Protection: Walking barefoot or in flimsy shoes on rough, hot, or sharp terrain (coral, rocks, debris) can lead to foot injuries, hindering mobility and increasing infection risk.

Long Term Threats
● Chronic Dehydration/Malnutrition: Leading to severe health degradation.
● Persistent Infection: Untreated or poorly treated wounds will likely lead to systemic infection.
● Resource Depletion: If they rely solely on salvaged items, these will eventually run out.
● Environmental Degradation of Supplies: Salvaged items (e.g., food, electronics) degrading due to heat, humidity, and pests.
● Loss of Hope/Motivation: Critical for psychological survival.
● Long-term Animal Encounters: Increased likelihood of dangerous encounters as survivors must range further for resources.
● Lack of Medical Expertise: Inability to diagnose or treat long-term illnesses or complex injuries.
● Search & Rescue Ceasing: If no signal is received, formal SAR operations will eventually be called off.

ANIMALS	Contains a fairly comprehensive list of different animals, both safe and dangerous, and how to deal with them.
PLANTS	This section is about different types of plants, both edible and toxic and the ways they can be used.

Preparedness

Being prepared for disasters and developing bug-out/in plans

"It wasn't raining when Noah built the ark."
Howard Ruff

Introduction

Survivalism, preppers or prepping is a movement of individuals or groups who are actively preparing for emergencies, including possible disruptions in social or political order, on scales from local to international. Survivalists often acquire emergency medical and self-defence training, stockpile food and water, prepare to become self-sufficient, and build structures that may help them survive a catastrophe.

Common preparations include the creation of a defendable retreat, haven, or bug out location (BOL) in addition to the stockpiling of food, water, clothing, seeds, weapons, agricultural equipment, and medical supplies. This section contains the fundamentals of being prepared and should link most of the other topics together.

Purpose	The aim of PREPAREDNESS is to help you come to grips with the real nature of being prepared in a world where the unexpected can happen at any moment. It starts by looking at the basic preparedness topics such as fire, water, shelter and food and then dives deeper into creating your own personalised bug-out plan, tips on rehearsing that plan and assessing any vulnerabilities you may have. It then looks into how you can monitor the world around you until one of these disasters occurs. We then get to the main section about what to do in the midst of a disaster, the considerations to take into account and the decisions to make such as bugging-in or out. The category comes to a close with some real world tips given by those with a tangible experience of disasters.
Lost?	● If you're new to prepping, I recommend reading the INTRODUCTION section first. ● If you want a list of preparedness resources, head to the ADDENDUM > Media section. ● For tips on leading your preparedness group, see the LEADERSHIP section. ● For information on keeping a positive state of mind, see the EMOTIONAL section. ● For a list of skills related to prepping, see the SKILLS section. ● If you want a bigger list of the terms of preparedness, see the ADDENDUM > Dictionary > Preparedness section.

Contents

1 Preparedness

"The superior man, when resting in safety, does not forget that danger may come.
When in a state of security he does not forget the possibility of ruin.
When all is orderly, he does not forget that disorder may come.
Thus his person is not endangered, and his States and all their clans are preserved."
Confucius

What is Prepping?	Prepping or being prepared is the conscious act of making preparations for unforseen events, disasters or catastrophes. It generally involves stocking up on the essential requirements for sustaining life such as water, food, shelter, medical etc. It is also for helping the prepper become more confident in their abilities and practising skills often for a range of different scenarios. There are many different levels of being prepared from having a simple backpack with gear to an underground bunker stocked full of resources.

What Prepping Isn't
Preppers aren't scared or worried of the future but rather prepared for anything that could arise from it, much like how students prepare for an exam rather than simply hoping they pass. In most circumstances as Gandalf puts it: "You Shall Not Pass!". Most preppers don't want disasters to strike even though their stockpiles of food, water and resources could dictate otherwise. They would rather have it and not need it. Conspiracy theories are sometimes closely linked with prepping such as preparing for aliens, the rapture, a yellowstone eruption, a pole shift or an economic reset, however this is often not the case for most preppers. Preppers deal in chances and work on mitigating them, such as a prepper in Hollywood where the chance of an earthquake is higher than any other natural disaster. So they would primarily prep for earthquakes and civil unrest. However one should always be ready for any disaster that may arise and your gear should be multi-purposed.

At the far end of the prepping spectrum are the die-hard preppers who have quit their jobs to dedicate their lives to being prepared and fitting out shipping containers and rooms full of guns. Most preppers are much more conservative and operate below the radar as the less people know they prep - the better. Prepping isn't simply having a lot of food, water, guns and vehicles primed and ready to go when you need, but equal parts gear and knowledge acquisition. The more knowledge and survival skills you have, the less gear you'll need.

FEMA recommends having a stock of three days worth of food and water in your pantry for your family. This doesn't automatically make you a prepper as you're lacking the entire preparedness mindset, the Bug-Out aspect and the survival knowledge. Prepping extends past the time your food reserves run out to encompass alternative ways to get food, water, electricity and even fuel. Below are the rules of threes showing how long you are likely to live without each basic need:

3 Seconds **without Hope**	Without hope you've got no reason to live, keep your family in mind and how you're going to feed them.
3 Minutes **without Air**	Within a few seconds without air you will begin to seek ways to get air. Ensure you have a clean oxygenated supply.
3 Hours **without Shelter**	In harsh conditions you've only got about three hours to live. Make sure you're at a safe temperature and are protected from weather and animals.
3 Days **without Water**	3L of water a day is recommended to keep you working at peak efficiency. Water must be free of contaminants and bacteria and easily acquired.
3 Weeks **without Food**	One of the lowest requirements for surviving but required nevertheless. At least one meal a day or 5,000Kj is recommended.
3 Months **without Company**	Without any form of company it will feel like there's no point to living since you can't share your experiences with anyone. One can literally go insane without interaction with another human or even animal. Watch the Tv show 'Alone' for examples.

Odds

Preparedness is about being prepared no matter the odds, because eventually it will happen. Below are the different odds of various events that could happen to anybody. Some of them you can prepare for and others you just have to hope they don't occur in your lifetime. Others seem so trivial or unlikely that you would never think you could die from that - such as a bee sting.

Wining the U.S. Lotto 1:292,000,000	**Being Dealt a Royal Flush** 1:649,740	**Being Killed by a Shark** 1:8,000,000	**Hit by Satellite Debris** 1:21,000,000,000,000	**Slipping & dying in the Shower** 1:2,232	**Tornado Destroys House** 1:10,000,000 / Year
Being Murdered 1:18,000	**Win an Academy Award** 1:11,500	**Meteor Hitting Your House** 1:182,138,880,000,000	**Dying From Any Injury** 1:1,820	**Dying from Assault** 1:16,421	**Hurricane Hits Miami** 1:25 / Year
Dying from a Fall 1:20,666	**Struck By Lightning** 1:576,000	**Killed by Asteroid** 1:74,817,414	**Death via Legal Execution** 1:127,717	**Injury from Fireworks** 1:19,556	**Dating a Millionaire** 1:216
Being Killed Next Year 1:69	**Killed By Lightning** 1:576,000	**Becoming President** 1:10,000,000	**Dying in Airplane Accident** 1:354,319	**Dying From Self Harm** 1:9,380	**Getting a Hole in One** 1:5,000
Dying from Car Accident 1:18,585	**Dying in an Explosion** 1:107,787	**Earth Asteroid Collision Within 100 Years** 1:5,000	**Dying from Exposure to Forces of Nature** 1:225,107	**Dying From Food Poisoning** 1:3,000,000	**Being an Astronaut** 1:13,200,000
Dying from Venomous Animal 1:3,441,325	**Having a Stroke** 1:6	**Getting a Flat Tyre** 1:5 / Year	**God Existing** 2:3 (Calculated by a Scientist)	**Dying from Heart Disease** 1:3	**Solar Flare (Carrington Sized)** 1:8,3 / 10 Years
Being Assaulted 1:60 / Year	**Being In A Car Accident** 1:18 / Year	**Car Broken Into/Stolen** 1:150 / Year	**Assaulted with Weapon** 1:277 / Year	**Getting Mugged** 1:500 / Year	**A Household Fire** 1:5 / Year
Getting Breast Cancer 1:9	**House Burglary** 1:38 / Year	**Developing Cancer** 1:2	**Dying in a Cataclysmic Storm** 1:27,925	**Dying Choking on Food** 1:2,482	**Dying from Wasp/Bee Stings** 1:46,744

Preparedness Levels

This is a classification of all preppers and gives a general idea of how prepared they are, what skills are known and their commitment to prepping. A lot of assumptions are made such as the amount of space the person has and that they have a job.

Level 0 (Sheeple)	Technically a prepper, but someone who doesn't participate in disaster preparedness at all. These are just ordinary people living their lives. At most they have three days of food in the pantry for power outages or strong storms.	• 0-3 Days Food & Water • No BOB & Supplies • No Preparedness Experience • 95-100% Grid Reliance
Level 1 (Wannabe Prepper)	A person who has been impacted by a disaster, TV series or other media and thought prepping is a good idea and they decide to take a few minor steps and stock a few extra items. At this stage they either fall away from prepping or pursue more information. Generally this stage is about reading, watching and understanding what preparedness is.	• 0-7 Days Food & Water • No BOB & Supplies • No Preparedness Experience • 95-100% Grid Reliance
Level 2 (Beginner Prepper)	Someone who has a weeks or so worth of food, a BOB and some action plans for disasters. People at this level are starting to get serious and often just buy, buy, buy to fill their BOB and pantry.	• 7-14 Days Food & Water • Limited BOB & Supplies • Little Preparedness Experience • 85% Grid Reliance
Level 3 (Prepper)	This type of person is becoming quite invested in being prepared for disasters with a BOB, skills and knowledge in survivalism and a month to 4 months worth of food and water per person. Usually people at this stage overfill their BOBs and generally have some simple plans for bugging out.	• 1-4 Months Food & Water • Decent BOB & Supplies • Little Preparedness Experience • 70% Grid Reliance
Level 4 (Confident Prepper)	This stage marks an increase in food and water again to around 6 months per person and they are looking into alternative bug out plans and may have a vehicle for it. They look at items critically and only keep what they need. People usually start to spread out into alternative bags such as INCH bags and GH bags. These people spend a lot of their free time preparing.	• 2-6 Months Food & Water • Decent BOB & Supplies • Decent Preparedness Experience • 60% Grid Reliance
Level 5 (Hardcore Prepper)	Preppers at level 5 have usually branched out into a working prepper pantry where they use the items they are stocking and replenish every week, have a complete lightweight BOB and extensive plans for bugging out in multiple types of disasters. They still have a job but spend most of their free time preparing.	• 3-8 Months Food & Water • Professional BOB & Supplies • Adept Preparedness Experience • 35% Grid Reliance
Level 6 (Devoted Prepper)	These people spend almost all of their free time prepping and have extensive knowledge about most aspects of preparedness. They have a stockpile of food and water from 6m-1y per person and are slowly consuming it and adding to it. They may have a plot of land and a building for a BOL stocked with some food but they definitely have multiple plans to GOOD in a SHTF situation.	• 6 Months to Infinite Food & Water • Exceptional BOB & Supplies • Expert Preparedness Experience • 0-15% Grid Reliance
Level 7 (Doomsday Prepper)	An extremely prepared person who devotes every waking second to prepping, they often have a job related to prepping or have quit their job to pursue it full time. They have many years worth of food per person, vast amounts of experience and often have bunkers or BOLs filled with supplies and often have family drills for SHTF situations.	• Infinite Food & Water • Flawless BOB & Supplies • Master Preparedness Experience • 0-5% Grid Reliance

Types of Preppers

These are the different classes of preppers you may encounter on your preparedness journey. You may fit into one class perfectly or be split up over a few different ones to help shore up some of the weaknesses. Some you want to avoid and others you should aspire to, but they all have their advantages and disadvantages.

The Sheeple (Non-Prepper)	A person who doesn't prep but can be considered a prepper at level 0. They believe that no large scale disasters will happen to them and that electricity, food and water will generally always be available on demand.	**Pros** • Less worry and stress • They save a ton of money • A swift death	**Cons** • Thirst/Hunger • Limited skills, knowledge & gear • Potential death during disasters • May have to join a gang to survive in times of complete disaster
The Hoarder	A prepper who simply stockpiles supplies such as weapons, food and water, neglecting most other things.	**Pros** • Tons of supplies • Ability to share their supplies with others • May be able to barter their supplies	**Cons** • Requires constant stockpile rotation • Limited skills • Limited knowledge • A theft target • Costly
The Accidental Prepper	People with a natural tendency to be prepared such as INTJs and related personality types. They often prep short term and for multiple scenarios without realizing it.	**Pros** • Wise in general • Prudent thinkers and planners • 'Accidentally' ready for disaster	**Cons** • Not prepared for long term disasters • Not prepared for 'rare' disasters • Limited, or no bug-out plans
The Typical Prepper	Someone with a BOB, a Bug out Plan, a stockpile for a few months and home defences. They watch other preppers online, buy useful preps and take actions to shore up their preparedness skills.	**Pros** • Solid baseline for preppers • Knowledge of a lot of preparedness skills • Keen interest in survival	**Cons** • Still a way to go to learn all the essential skills required • May suffer from prepper burnout after realizing they are only beginning • May lose interest in prepping • May find it hard to spend money on prepping vs entertainment items

The Survivalist	These preppers have honed bushcraft skills and can live off the land if the situation calls for it. They can find wild edibles, craft shelters and purify water with only what they have around them. They are often solo but this helps to greatly increase their stealth and speed up their journey.	**Pros** ● Can survive in the woods ● Plant/Animal Identification ● Medicinal plant experience ● Natural plant remedies ● Stealthy when solo	**Cons** ● Loneliness ● No stocks of food ● Plans to only bug out ● No comforts of home ● May not survive in a widespread, nature killing disaster
The Homesteader	They own a house, land and usually a farming plot and animals for self sufficiency. They are self sustainable and can grow, manufacture and recycle what they need at home.	**Pros** ● General homestead skills ● Surrounded by family ● Can save money ● Self sufficient ● Not dependant on civilization ● Ample storage space ● Can produce what they require	**Cons** ● Costly to set up ● Large area of land to protect ● Hard work to maintain ● Not inclined to bug out ● Crops can easily be stolen/destroyed ● Cold winters can eradicate their food source ● May not have access to news
The Self-Defence Prepper	In good shape, knows hand to hand combat and is concerned about smaller daily disasters. They have, or are in the armed forces and have military experience.	**Pros** ● Very fit ● Can protect themselves ● Great at stealth ● Great at teamwork ● Knowledgeable about combat	**Cons** ● Lacks preps and stockpiles ● Weak against guns ● May not trust others
The Minimalist	They keep their stockpile to a minimum and focuses on skills to further reduce the weight of their pack. They may drill holes in their toothbrush…	**Pros** ● Spends less money on fewer items ● Great skills ● Light and fast travel ● Knowledge replaces gear ● Can leave their old life easily	**Cons** ● Spends MUCH more money on ultralightweight gear ● Lack of gear when bugging-in ● May spend a lot of money on their quest for knowledge
The Know-It-All	Gains knowledge about prepping but doesn't do much to actually prepare. They can spend hours watching YouTube videos getting ideas but rarely puts any of them into action.	**Pros** ● Good knowledge on prepping ● Can lead others ● Can assist others	**Cons** ● Unprepared ● Few items ● Needs real world experience
The Economist	Focused on protecting their wealth via precious metals and stockpiles for barter in SHTF. They may also aim to profit from a disaster by bartering essentials for precious metals to sell afterwards.	**Pros** ● Can barter what they need if SHTF without stocking up on anything ● Only have to worry about stocking up on one type of resource.	**Cons** ● Neglects other preparedness areas such as knowledge and skills ● They rely on the fact that metals and tradables can be used as money and that people will be honourable
The Doomsday Prepper	Prepared for a complete global collapse for an extended period of time. They are often armed to the teeth and occasionally have a heavily fortified castle, bunker or BOL.	**Pros** ● Prepared for anything ● Comprehensive bug out plans ● Huge stockpiles ● Lots of time to prep ● Rehearses often ● Completely off-grid	**Cons** ● Costs an absolute fortune ● Often seen as paranoid ● Ridiculed ● Fixated on prepping and not enjoying life ● May quit their job to prep
The Tactical Prepper	Sees the world from a tactical perspective. They have likely been in the army and have planned very carefully for disasters and an attack on their home. They acquire a lot of tactical preps and focus on defence and stealth.	**Pros** ● Good defence from technology ● Has detailed Topographic maps and other military equipment ● Tactical Gear ● Can survive harsh environments ● Has some survival knowledge	**Cons** ● May be too tactical ● May not trust people
The Religious Prepper	Committed to their religion and often focuses on religious disasters such as the rapture and armageddon. They generally have goodwill to everyone else and will assist others in need.	**Pros** ● Community and shared beliefs ● Cares for others ● May share resources ● Won't take the lives of others ● Excellent sense of community	**Cons** ● Narrow view of potential disasters ● May be taken advantage of due to their goodwill ● May run out of supplies quickly
The Gun Enthusiast	A prepper who focuses on guns and weapons training. They have multiple guns and explosives and a variety of other weapons stockpiled. Generally they will stay and defend their land at all costs.	**Pros** ● Great gun skills ● Has a ton of ammo stockpiled ● Great marksmanship ● Advanced tactics ● May be able to make their own ammo	**Cons** ● Often ignores other skills ● May become looters when they run out of supplies ● May kill others unnecessarily
The Getaway Prepper	A prepper who will leave their usual home in the face of any danger. They have a BOL with extensive detailed plans to reach it no matter the scenario. A BOV is at the ready at all times.	**Pros** ● Always ready if they need to bug out ● Usually physically fit ● Not attached to physical possessions	**Cons** ● BOL may be looted or destroyed ● Bug in may be more beneficial ● Few supplies at home ● Weather may not permit leaving home

PREPAREDNESS Prepping Introduction Types of Preppers

The Defensive Prepper	Believes in defending their home and has taken the necessary steps to stay inside no matter what type of disaster they may face.	**Pros** ● Extensive stockpiles ● Plenty of weapons for defence ● They know their surroundings well ● They can set up strong home defences and booby traps	**Cons** ● May not have a BOL ● Possible death if the disaster is heading towards them ● No supplies if they are forced to leave ● Expensive to prep for a hurricane
The Fearful Prepper	A prepper who expects something bad to happen every day and sees the negative in the world. They check the news daily or hourly. They could possibly be into conspiracy theories.	**Pros** ● Keeps an eye out on the news ● First to know any breaking news and therefore can bug out quickly ● Can see the driving forces behind the world	**Cons** ● Puts life on hold to prep and doesn't plan for a regular life ● Always worried about disaster or embraces it and wants it to happen ● Can't see the good in the world
The Compassionate Prepper	A person who preps for the good of mankind, stocking up on knowledge, resources and skills solely to help others in disasters.	**Pros** ● Shares resources ● Helps those in need ● Builds great relationships ● Often great leaders	**Cons** ● May be taken advantage of ● May run out of resources quickly ● May be attacked or mugged

PREPAREDNESS Prepping Introduction Prepping

Prepping Deficiencies

PREPAREDNESS Prepping Introduction Prepping Deficiencies

Becoming a complacent prepper is one of the pitfalls of prepping. The following will discuss a few reasons we can become complacent and how to prevent them.

No Urgency	When things are going well we may tend to overlook the fact that anything bad could ever happen to us. We just have to turn on the news to see how much of a delusion this could be, especially today. Just because things are going well in your corner of the globe doesn't mean the violence on the other side can't affect us.
Expecting Disaster	A lot of preppers are so ready and expectant for a disaster to occur that they actively want one to happen in the back of their mind so they can finally use their preps. They spend so long researching disasters and looking at the worst of humanity that they forget to enjoy life and have fun while the going is easy. Don't forget to take time and enjoy the world around you while it's intact.
Ebb and Flow	There's a natural cycle between hard times and times when a disaster is the last thing on your mind. Sometimes we have to look past the best times and keep on prepping, as well as not becoming fearful if the worst looks like it will happen.
Attention to Detail	Always keep in mind the big picture as well as the small things such as remembering to have breakfast. You won't be very effective without keeping yourself running smoothly. In a similar way keep checking the basics of preparedness to ensure you aren't missing a critical area, or forgot you borrowed your gas stove when camping and forgot to put it back.
Self Interest	Preppers can get so caught up preparing for themselves and their family that they forget there will be a lot of other people such as friends and family who won't be prepared in a disaster. When one does strike, these people will be looking to anyone and everyone on how to proceed in these tough situations. Without any assistance they may have to resort to theft and violence to be able to stay alive which is the last thing you need from your neighbours and friends. Besides preparing for ourselves we should think about putting together a small collection of gear for our neighbours, friends and family. Not only will this help ease their survival situation, but it could turn a potential threat in a disaster into an ally. You could include long life food, water purification equipment, a torch with spare batteries or candles, some firelighters, a radio, a Bible as well as a few survival guides both on a USB or physically printed. You don't even have to make contact with them on your way to bug-out, just drop it off at their door, ring their doorbell and then bug-out.
The Easy Life	We've had such an easy life compared to the other periods of time and regions where nearly everyone sees death, violence and theft daily. Very few of us have lived through a world war or any war for that matter and with other countries boosting their arsenal we should stop being complacent and prepare like these events will happen. Although America is beginning to wake up from this easy-going lifestyle lately with a potential downfall of their entire constitution in the future.
Crying Wolf	Often we're sure a collapse is imminent or it looks like a disastrous cyclone is heading right for you but then dissipates before anything happening. After these events we can often question our preps and ask ourselves "Is this really necessary?". We should always remain steadfast in prepping and can't change our minds because of false warnings. But when you've let your guard down is potentially when disaster could happen, and then you would wish you never did.
Local Disasters	We often focus on the large scale world-changing disasters and end-times scenarios but tend to focus less on the common local disasters such as job loss, financial difficulty or the loss of a family member. We can't lose sight of preparing for the smaller things life can throw at us when we tend to only focus on the large scale disasters.
Situational Awareness	Throughout our often mundane lives are fixed patterns of repeated actions which we often automate because we do them so often. This generally happens at work when we have fixed tasks to complete over and over again and sometimes we take these actions home with us. We often don't pay attention to our surroundings during these times as it's a normal, dull day, but keeping an active mind will ensure our situational awareness is always active and alert for any trouble coming our way.
Health	We can easily become complacent about our health which may slip out of our control when we aren't taking note of what we're putting into our bodies or how much exercise we're getting. This will definitely affect our ability to survive in SHTF when the time does arise, and a person with poor health will be a risk to their prepping group and themselves.
Overconfidence	When you're sitting on a mountain of preps, months of food and enough guns to arm a small country. You may feel the need to sit back and survey the mighty empire you've constructed and become overconfident with your prepping. You may think you know it all, but I can guarantee there's always more you can learn and more research to undertake to improve your skills. Often the more you learn about preparedness the more your BOB changes. Don't let your number of possessions halt your prepping or your desire to learn.

Normalcy Bias

The normalcy bias is a mental condition which individuals experience when facing a disaster. It causes people to become vulnerable to approaching danger as they underestimate both the possibility of a disaster and its potentially dangerous impact. This often results in situations where people fail to prepare for a disaster, and that failure can be catastrophic on a state or national scale. It is a mental condition that convinces a person that since it has never happened before, it can't happen. Or "it won't happen to me." After all, this is America. We are special; however, we are not immune from natural or manmade disasters.

These are statements made those blinded by normalcy bias:
- "But that could never happen to us."
- "But, it can't last forever.
- "Well, government officials will never let it get so bad that we run out of food and water."

When God warned Noah that bad weather was coming and the earth would be inundated, he followed God's instructions that involved long term planning. And many years of hard work. He was ready when the rain began. While a global flood had never happened before, Noah thought it best to prepare for it. The normalcy bias killed everyone but Noah and his family.

There are four deadly stages of denial:
1. It won't happen.
2. If it does happen, it won't happen to me.
3. If it does happen to me, it won't be that bad.
4. If it does happen to me, and it's bad, there's nothing I can do to stop it anyway.

Are you living in normalcy bias that could end up killing you or your family? It is better to prepare and not need it than to not prepare and need it. Hope is not a plan and the state of the world will sooner or later wake you up from any optimism or wishful thinking you may be having.

Prepper Burnout

The following are signs of prepper burnout. Prepper burnout is the becoming frustrated, tired or wanting to give up prepping for various reasons.

Sign 1	They only read pessimistic new articles and ignore an encouraging outlook.
Sign 2	They don't see the beauty or pleasure in daily life, being focused on the end.
Sign 3	They spend all their money on securing goods and nothing for themselves or their entertainment.
Sign 4	They visit preparedness websites daily which can slowly reduce their optimism and outlook.

These are some simple ideas on how you can fix prepper burnout if you see it occurring.

Resolution 1	Realize that the world ending tomorrow is possible but not very likely.
Resolution 2	View prepping as a hobby and the skills you gain through it. Hobbies should be worked on in your free time and generally aren't thought about every second of every day.
Resolution 3	Find a healthy balance between prepping and enjoying life.
Resolution 4	Focus on buying food and gear you will use in daily life and which won't be just stored on a shelf.
Resolution 5	Take a break and focus on other activities or a skill that has links to prepping such as archery.

2 Prepping Basics

Prepping categories are the areas of preparedness that every prepper should embrace and have a plan for such as shelter, fire, food, fitness, medical, skills etc. This section outlines the basic supplies you'll need, how to best use them and how many you need to stock up on. For more information on any of the sections mentioned below, see the corresponding section(s).

Water Preparedness

Water is one of the most vital preps you can have due to the human body being unable to survive longer than 3 days without water. There are a few types of water shortages in disasters which are: Polluted water, low pressure and no water. Low pressure water may be able to be used for a short time before it stops coming out all together, but the others should never be used. For more information on water, water collection and water storage, see the WATER section.

What Type?
For bugging in you will want to store either pre-bottled water or tap water which has been treated to extend its storage life. For bugging out assuming you will have access to water on the route - you should bring a water filter and a backup, plus twice as much water as you think you will need for reaching your destination if there's no water along the way.

How Much?
Water is used for a wide range of applications like drinking, bathing, washing dishes and making meals. There isn't a magic number that you can reach where your water needs are sorted because everyone's situation is different. Take into account the availability of water around your area because you may be able to utilize it. Depending on the situation you may want water for flushing down the toilet if the taps aren't working. The average person uses about 50L of water per day if they have conservation in mind, so extrapolate and work out how much you will need for your party, adding about 15% just in case. For extended disasters you will want a good quality water filter which is sized on your parties size.

Water Requirements
- Number of People
- Age of People
- Bathing Needs
- Washing Req's

Food Preparedness

Besides water, food is another essential for surviving long periods of time. Be sure you have more than you think you'll need. Depending if you're planning on bugging in or out determines what type of food you should pack. The lightest foods such as freeze-dried ones are best for backpacking while canned foods are easier to prepare but weigh much more. Packaged foods have wastage which can be compressed down to a tiny size whereas cans are metal and will still take a fair amount of space after consumption.

You won't know what type of disaster is likely to hit you so you should be prepared with enough food to last at least a month. You could also grow your own food if you have the skills and space to do so. You will also need to keep your plants safe from desperate people and animals. For additional information about foods and food types see the FOOD section.

Shelter Preparedness

You're likely to only last about 3 hours in extreme weather, but having a shelter can shield you from the worst of it. To learn more about shelters and constructing shelters see the SHELTER section.

Household Preparedness	Your house is the strongest shelter you're likely to have, unless you own a bunker. You can make fortifications to it during a SHTF situation to boost your defence. Houses however stick out fairly well if they aren't in a suburb and can't often be camouflaged to prevent being a target for thieves, gangs etc.
Bug Out Shelters	Having a bug-out shelter can give you a huge boost over having to create your own from logs and leaves in an emergency situation. Modern tents or bivys are fast to set up, can be camouflaged and best of all can be dismantled quickly if there are threats in the area. Choose a correct shelter which is situational for your environment such as a four-season tent if you have large snowfalls or one with a lot of ventilation if it's a humid climate.

Fire Preparedness

Fire can be a lifesaver in many situations, but particularly in cold environments. Knowing how to start fires from the gear you have available and the resources around you is a vital skill you need for bugging out. Fire is essential for outdoor survival and if you would like to learn more see the FIRE section.

Fire Lighting	Having a variety of fire lighting tools and knowing how they work should be one of the first skills you learn. Understanding what a ferrorod and match can and can't light will assist in lighting fires. For example you can't light paper with a piezo ignition system, but gas is easily lit by it.
Tinders	Knowing what tinders are best for your chosen lighting method are basic skills needed for lighting fires.
Extinguishing Fires	Extinguishing fires is just as important as lighting them just in case they get out of hand because starting a forest fire will only worsen the current disaster.

Self Defence Preparedness

Protecting yourself and your family from being robbed is another essential skill because you'll basically be a walking Wal-Mart if you bug out on foot. Know how to wield, use and reload offensive and defensive weapons to help protect yourself and your gear. Self Defence is vital in a SHTF situation. For more information see the OFFENCE, DEFENCE and WEAPONS sections.

Non Lethal	Knowing how to protect yourself without lethal force can be situationally useful if you wish to only escape. Each life is precious no matter their past and what they may be currently doing, so knowing when to take a life or spare one is vital.
Lethal	Lethal force is necessary sometimes to protect yourself and your family from those who wish you harm. They may be wanting to kill you and take your gear or simply kill you for the fun of it, so you should know how to handle a gun if your country allows them. Taking a life can be hard on anyone so be sure you are making the right decision for your safety.
Defence Plans	Defence ranges from fortifications to your house, personal defence while hiking and even defence against mosquitos and snakes. Know what to do in each of the situations beforehand or you may be likely to make a mistake which could cost you dearly.

Medical Preparedness

There is likely going to be some injuries during any type of disaster and medical skills can go a long way to help save your life. For more information on medicine, illnesses and injuries see the corresponding MEDICAL section.

Medical Knowledge	Have at least a basic understanding of medical practices such as CPR, administering bandages and first aid. Ensure a few party members understand and can perform basic medical procedures in case the "physician" of your party is the one sick.
Medical Skills	Having medical skills and prior experience can be a life-saver. There's little use having knowledge without having put that knowledge to good use. Practise bandaging people, administering IVs, injecting epinephrine and wrapping triangular slings.
Medical Supplies	Put together a medical kit for a range of injuries and illnesses and keep tabs of when they all expire - replacing them when you need to. If a medical utensil or bandage is set to expire soon use it for your own personal learning experience and put it on yourself so you know how it works (if it's safe to do so). Applies to items such as Israeli bandages which may seem quite tricky to apply when in a real bleeding situation.
Medication	Medication will be hard to find in a SHTF situation so be sure to stock up constantly as they expire. Keep track of what you bought, how much and when they expire so you can replace them soon before. They should be stored correctly in a temperature controlled environment and should be kept away from heat, light and air.

Skills & Knowledge

It's no good to have to rely on a spreadsheet when you're actually faced with a disaster. This is where knowledge and practise comes in handy. For a list of skills and descriptions one should possess prior to SHTF, see the SKILLS section.

Know Your Gear	Learn and play with your gear BEFORE the need to use it arises. You should be proficient in every piece of your kit and know the perks and problems of each item. Without learning about your gear you may have a faulty item and it could break the first time you try to use it in a survival situation.
Hone Your Skills	You may already understand how to use an item, but when you push it's capabilities is when you really come to grips with what it can do. Have you tried using your gas canister in freezing temperatures? You may find it stops working until you warm it up. Choose a piece of gear per week and put it through its paces; for example a knife - the most crucial piece of kit. Use it to baton logs, chop trees, whittle, cut paracord, strike flint, gut meat etc. You will learn very quickly what it can and can't do. Get out into the wild - or your backyard when you can and get to know the ins and outs of everything in your BOB - from the compass to the gas stove.

Plans

You should have unique plans for almost any type of disaster that could come your way, from hurricanes to airborne viruses and even a UFO invasion. For additional information on stealth, tactics, camouflage, stealth camping and more, see the SECURITY section.

Bug Out Plans	A physical plan of what routes and actions you will take in a disaster where bugging out is your best option. Without such as plan you might as well be unprepared and will be caught off-guard and cut off from help. Street plans and maps, backup plans, bottleneck points, high population areas etc.
Bug In Plans	Just because you're bugging in during a certain disaster doesn't mean you don't need a plan. You aren't likely to be home when a disaster happens so the first step is to write a plan to get you and your family safely back home. You then need to secure your house from whatever disaster may be approaching such as blocking all vents and airflow if it's a pandemic or boarding up the windows and taping the glass if it's a hurricane.
Contingency Plans	It's extremely likely you will come across challenges and obstacles during disasters so be sure to have backup plans. What if the roads are blocked and you can't drive home from work during the start of a major disaster? What if a family member is in hospital when riots break out and moving them may kill them?
Situational Awareness	Knowing what's happening around you at all times isn't just a fictional Jason Bourne skill. You should train your mind to always know the exits, be able to read body language, interpret signs and see danger before it occurs. You should also know what's going on in the world at all times so you can be ahead of the curve when large scale or man-made disasters approach.

Physical Preparedness

You should be physically prepared at all times in case you're required to bug out over long distances at short notice, particularly if you have to escape on foot.

Physical Stress	During a bug out your body will often be pushed to its limits - especially if you're on foot and have a bag packed to the brim of gear. Know your limits prior to a disaster and try to strength your body by getting accustomed to your bug out route and the weight of your pack.
Change Stress	If you're used to a familiar routine it will certainly be a shock if you have to drop that life and bug in or out, even if you have ample supplies. This occurs particularly if you have a desk job and a fairly sedentary life which will make it tough to adapt to the requirements of long distance hiking.
Sleep Stress	Your body will be used to waking up at a certain time and getting a good amount of sleep per night. However you may need to stay up all night peeking out the window to ensure your continued survival. To minimize the impact it could have on your sleep try to keep as much of your old sleeping patterns as you can, setting night watches can help you sleep more securely. You could change your sleeping routine entirely such as sleeping during the day while you have the night watch, that way there will be people awake at all times of the day. The LEADERSHIP section has more tips on night watches.

Mental Preparedness

It's not enough to simply be materialistically or physically prepared but mentally prepared for anything that may happen.

Change Fatigue	You may still be in a pre-disaster state of mind and have to adapt to a changed way of thinking when the worst happens. The mind will have to go from a "Safe" state to a "Warning" state due to the increase of unpredictability of people during any disaster.
Entertainment Preparedness	If you're stuck in the same location for weeks or months at a time you will need something to keep your mind entertained. If you're bored I recommend taking a look at the ENTERTAINMENT section in this guide.
Kids Stress	Having kids is stressful enough but they could become unbearable if cooped up in a room for weeks at a time so being prepared kid-wise is vital. Have some entertainment for them like games, cards, books or handheld digital devices.
Emotional Preparedness	There's bound to be uncertainty in your mind during any form of disaster which is affecting or could affect your family. Be sure to have - and to stick with your bug in/out plan and act on it before things get worse. During the disaster you could lose a close friend or family member which will make it extremely tough to maintain emotional stability over this period. Your decision making may decline substantially and could cause you to have an accident - further risking lives.

Information Preparedness

Information preparedness is a collection of documentation, certificates, passports, maps, bug-in/out plans and guides like TPE all stored in one easily accessible location or USB for quick retrieval. You absolutely don't want to have to go looking for your passport at the last minute if you don't know where it is. Some people don't want to let the past go and will often want to keep memorabilia such as family photos. It's better to scan these and have them on a USB stick already in your BOB rather than having too many physical photos or grabbing them on the way out the door. See the "Important Documents" section under GEAR for more information.

Spiritual Preparedness

What's the point of prepping for survival if you're eventually going to die one day anyway? Chances are, you're probably going to be facing some tough disasters and other trials throughout life, so you need to stand firm in your faith because you may not survive the next disaster. How certain are you that there IS, or ISN'T something after this life?

Religion often is a vital aspect of what makes us who we are, so hold firm in your faith and pack a small Bible, cross or other item which will help you in any disaster. If you haven't thought much about religion but are interested and wondering if there is a God, take a look at the RELIGION section.

Spiritual Items
- Bible
- Cross
- Digital Bible
- Traditional Food
- Pendant/Necklace

3 Prepping Goals

These are preparedness goals of various types to help you start out on your preparedness journey. The aim is to get you off the ground and more prepared every week for an entire year. A Year till a Year. That's what this preparedness plan will help you achieve. This means that after a year after starting this plan, you will have enough resources, skills and knowledge to survive a whole year (for one person) if the worst does happen. Of course, if you have the time and money or other people you are prepping for, you could double or triple the recommendations in this guide to reach your goals quicker, or set additional goals you would like to achieve.

Each week has a theme and goals for Gear, Knowledge and Skills. It's assumed you start at week 1 with no prepping knowledge whatsoever. This section could also be used as a 'recommended reading' guide for TPE as it refers to every other section. The words in capitals refer to the categories throughout this guide. Not all the purchases below should go into the Bug-Out Bag (BOB), some (such as bulk amounts of batteries) should be stored in the house for future use.

Preparedness Goals Month 1

Week 1 Focus: Water Filter	Week 2 Focus: Food Stores	Week 3 Focus: Backpack	Week 4 Focus: Planning
Gear ☐ Buy a water filter (e.g. Sawyer Mini) ☐ Buy a cheap headlamp & btty's ☐ Buy 3-4 canned meals next shop. ☐ Buy a 20L/5gal+ water container. ☐ Buy a crate of water bottles	**Gear** ☐ Buy 10-12 canned meals ☐ Buy another 20L/5gal+ water jug ☐ Buy a portable stove & gas ☐ Buy a mini camping pot for the stove to cook your canned food	**Gear** ☐ Buy the SAS Survival Handbook ☐ Buy 6 canned meals ☐ Buy a backpack to put your gear ☐ Go through the BOB list in GEAR and buy <u>cheap</u> items from each category to stock it with. (<$5-10ea)	**Gear** ☐ Buy a USB for prepping. Ideally one that can plug into a phone and a PC (double-ended). Search 'Fluidicice Prep Drive'. ☐ Buy 6 canned meals ☐ Add clothes to your BOB
Knowledge ☐ Read the INTRODUCTION ☐ Read the WATER category ☐ Start a list of all your gear and update it every week.	**Knowledge** ☐ Read through PREPAREDNESS ☐ Read the FOOD category ☐ Research your region's highest disaster risks & make a list of them.	**Knowledge** ☐ Read through the SAS Handbook ☐ Read through the GEAR section. ☐ Create a list of the gear in your BOB & keep it updated	**Knowledge** ☐ Download emergency information, documents and PDF's for your local area & put on USB. ☐ Find your local emergency no's
Skills ☐ Set up your water filter. ☐ Test your water filter at home. ☐ Test your water filter outside. ☐ Fill the water container.	**Skills** ☐ Write the purchase date on all your cans from this point on. ☐ Fill the water container. ☐ Cook up a canned meal on your stove.	**Skills** ☐ Create your personalised disaster plans in the PREPAREDNESS > Disaster Preparedness section ☐ Discuss the plans with the family ☐ Practise with the gear your bought	**Skills** ☐ Make a list of your valuables to grab during bugging-out. ☐ Print copies of your important documents and store in your BOB. ☐ Put your important documents on a 'prepping' USB.
Prep Tracker Water: 2 Days & 3 Years Filtered Food: 1 Day	**Prep Tracker** Water: 3 Days & 3 Years Filtered Food: 5 Days	**Prep Tracker** Water: 3 Days & 3 Years Filtered Food: 7 Days	**Prep Tracker** Water: 3 Days & 3 Years Filtered Food: 9 Days

Preparedness Goals Month 2

Week 5 Focus: Shelter	Week 6 Focus: Communication	Week 7 Focus: First Aid	Week 8 Focus: Get Home Bag
Gear ☐ Buy a tent ☐ Buy a mattress ☐ Buy a sleeping bag ☐ Buy a tarp ☐ Buy 2x 20L/5gal+ water containers ☐ Buy 6 canned meals	**Gear** ☐ Buy a portable AM/FM radio ☐ Buy a CB radio (2 is preferred) ☐ Buy a loud whistle ☐ Buy a signalling mirror ☐ Buy 6 canned meals	**Gear** ☐ Buy or build a basic first aid kit ☐ Buy bulk OTC medications. (Aspirin, Paracet, Imodium, Ibuprof) ☐ Buy "The Survival Medicine Handbook" ☐ Buy 6 canned meals	**Gear** ☐ Buy a small Get Home backpack ☐ Go through the GH list in GEAR and buy <u>cheap</u> items from each category to stock it with. (<$5-10ea) ☐ Buy 6 canned meals ☐ Buy another 20L/5gal+ water jug
Knowledge ☐ Read the SHELTER section ☐ Learn the different types of tents ☐ Learn about the different types of mattresses and sleeping bags	**Knowledge** ☐ Learn how to use the AM/FM radio's advanced features ☐ Learn how to use the CB radio(s) ☐ Read the COMMUNICATION sect.	**Knowledge** ☐ Learn CPR and DRSABCD. ☐ Read through "The Survival Medicine Handbook". ☐ Learn the items in your medic kit.	**Knowledge** ☐ Learn what a Get Home bag is and how you can best stock it with the items you need most. ☐ Read the Get Home GEAR list
Skills ☐ Set up your tent in the backyard twice. See how fast you can do it. ☐ Go camping at a nearby site for a night to test the gear. ☐ List what items you needed and ones you didn't use at all.	**Skills** ☐ Learn how to use the radio's advanced features ☐ Learn how to use the CB radio ☐ Use the mirror and whistle to communicate to a friend.	**Skills** ☐ Take a CPR course. ☐ Try using some of the items in your First Aid kit. ☐ Practise bandaging and treating various ailments.	**Skills** ☐ Try all the gear in your Get Home kit so you know how it all works. ☐ Try walking for an hour with your bag and see if it's light enough. ☐ Work out your routes home.
Prep Tracker Water: 5 Days & 3 Years Filtered Food: 11 Days	**Prep Tracker** Water: 5 Days & 3 Years Filtered Food: 13 Days	**Prep Tracker** Water: 5 Days & 3 Years Filtered Food: 15 Days	**Prep Tracker** Water: 6 Days & 6 Years Filtered Food: 17 Days

Preparedness Goals Month 3

Week 9 Focus: Electrical	**Week 10** Focus: Self-Defence	**Week 11** Focus: Food Preservation	**Week 12** Focus: Fitness
Gear ☐ Buy a quality & bright torch ☐ Buy lots of batteries for the torch ☐ Buy a solar blanket/mat with USBs ☐ Buy a power bank for your phone ☐ Buy 6 canned meals	**Gear** ☐ Purchase a way to defend yourself. (Gun, Bow, Sword, Taser, Bear Spray & Ammo for it) ☐ Buy 6 canned meals	**Gear** ☐ Buy the equipment needed in the skills section to preserve 7 days worth of food. Mylar bagging rice and beans is fairly cheap and easy. ☐ Buy another 20L/5gal+ water jug	**Gear** ☐ Buy some gear that will help you get into your chosen activity, but avoid activities that are costly to get into. You're only getting a feel for it and may swap to another activity if you hate the first one.
Knowledge ☐ Read the ELECTRICITY section. ☐ Learn how to use your solar blanket. ☐ Learn how to use the power bank	**Knowledge** ☐ Learn about your weapon, how to safely use it, dissasamble it and maintain it properly. ☐ Read through OFFENCE	**Knowledge** ☐ Read through the FOOD PRESERVATION section ☐ Thoroughly research the method.	**Knowledge** ☐ Read the HEALTH section.
Skills ☐ Test the solar blanket and power bank together to create a device recharging system. Avoid getting the power bank too hot.	**Skills** ☐ Take an instructor led course on your weapon (if applicable). ☐ Practise/Train with your weapon. ☐ Safely practise with the unloaded weapon around the house/yard.	**Skills** ☐ Find a food preservation method you want to try (canning, drying, mylar bagging) ☐ Try your hand at preserving a weeks worth of food with your chosen method.	**Skills** ☐ Start and continue a weekly fitness regime like jogging, soccer, pilates, walking etc.
Prep Tracker Water: 6 Days & 6 Years Filtered Food: 19 Days	**Prep Tracker** Water: 6 Days & 6 Years Filtered Food: 21 Days	**Prep Tracker** Water: 7 Days & 6 Years Filtered Food: 28 Days	**Prep Tracker** Water: 7 Days & 6 Years Filtered Food: 28 Days Recurring: Fitness

Preparedness Goals Month 4

Week 13 Focus: Gardening	**Week 14** Focus: Protection	**Week 15** Focus: Hygiene	**Week 16** Focus: Stealth
Gear ☐ Buy the equipment, tools, seeds or seedlings needed to grow your chosen vegetable. ☐ Buy 6 canned meals ☐ Preserve another 7 days of food.	**Gear** ☐ Buy items that you can use to secure your home. (Window dowel, gate locks, security cameras, spotlights, fire extinguishers, door bolts, etc)	**Gear** ☐ Buy a camping toilet. ☐ Buy toilet paper or an alternative. ☐ Buy lots of bin bags. ☐ Buy cleaning supplies. ☐ Buy Calcium Hypochlorite (CH). ☐ Buy 6 canned meals	**Gear** ☐ Ensure you have 'Grey Man' clothes and backpack. ☐ Buy a faraday bag for your EDC digital devices. ☐ Buy 6 canned meals
Knowledge ☐ Choose a veg you want to grow and thoroughly research it. Microgreens are great to start with. ☐ Read the GARDENING section.	**Knowledge** ☐ Read the DEFENCE category. ☐ Create a home evacuation plan ☐ Watch videos on the channel "Active Self Protection".	**Knowledge** ☐ Research the best ways to deal with rubbish and toilet waste. ☐ Research CH as it is dangerous. ☐ Read the HYGIENE section.	**Knowledge** ☐ Read the SECURITY section. ☐ Learn how digital devices can be tracked by governments.
Skills ☐ Plant and maintain your veges daily and eat them if they are successful. ☐ Continue to research and improve on your growing technique.	**Skills** ☐ Learn situational awareness and avoid using your phone in public ☐ Learn a martial art if you have the ability and the funds.	**Skills** ☐ Find someone who is also getting started with prepping to aid your progress either locally or online. Don't share how many preps you have.	**Skills** ☐ Try camping stealthily (legally) with your BOB and avoid being detected, or start in your backyard. ☐ Make a list of items you used and those you didn't need.
Prep Tracker Water: 7 Days & 6 Years Filtered Food: 35 Days + Garden Recurring: Fitness, Garden	**Prep Tracker** Water: 7 Days & 6 Years Filtered Food: 37 Days + Garden Recurring: Fitness, Garden	**Prep Tracker** Water: 7 Days & 6 Years Filtered Food: 37 Days + Garden Recurring: Fitness, Garden	**Prep Tracker** Water: 7 Days & 6 Years Filtered Food: 37 Days + Garden Recurring: Fitness, Garden

Preparedness Goals Month 5

Week 17 Focus: Teamwork	**Week 18** Focus: Medical Supplies	**Week 19** Focus: Fire	**Week 20** Focus: Construction
Gear ☐ Buy some cheap preps for giving to the neighbours during a disaster. (Headlamp & btty's, water, food) ☐ Buy a second water filter (better quality than the first if possible) ☐ Buy 6 canned meals	**Gear** ☐ Buy a bag for a large First Aid kit ☐ Buy the items to stock the First Aid kit, as per the book below. (Bandages, gauze, saline, tools, creams, prescribed meds, splints, ice packs, tape, pins, antiseptics)	**Gear** ☐ Buy a flint and steel (if you don't) ☐ Buy 20-100 BIC lighters ☐ Buy a portable camping stove and gas cans ☐ Buy 7 canned meals	**Gear** ☐ Buy a tarpaulin (if you don't) ☐ Buy some paracord ☐ Buy a WaterBOB but don't fill it unless you anticipate a disaster, or you don't need the bath.
Knowledge ☐ Get to know your neighbours & exchange numbers with them. ☐ Learn your local surroundings, paths, plants, shortcuts, buildings.	**Knowledge** ☐ Read through the 'Medical Supplies' section in "The Survival Medicine Handbook". ☐ Brush up on the rest of the book.	**Knowledge** ☐ Read the FIRE section ☐ Learn about the danger of fire ☐ Learn how to use fire extinguishers ☐ Learn about Carbon Monoxide	**Knowledge** ☐ Study various kinds of knots that can be used with shelters. ☐ Read the CRAFTING section
Skills ☐ Find someone who is also getting started with prepping to aid your progress either locally or online. Don't share how many preps you have.	**Skills** ☐ Try bandaging a family member ☐ Practise cleaning a wound ☐ Practise dealing with choking ☐ Practise making an arm sling ☐ Practise splinting a break ☐ Learn how to use a tourniquet.	**Skills** ☐ Try and create fire using three different methods of your choice. ☐ Try making fire with flint & steel ☐ Cook a canned meal on your gas stove (using one of your older cans)	**Skills** ☐ Craft a shelter of your choosing from sticks and a tarp and sleep the night in it. ☐ Try feathering a stick with a knife ☐ Start a fire and cook over the open flames.
Prep Tracker Water: 7 Days & 6 Years Filtered Food: 38 Days + Garden Recurring: Fitness, Garden	**Prep Tracker** Water: 7 Days & 6 Years Filtered Food: 38 Days + Garden Recurring: Fitness, Garden	**Prep Tracker** Water: 7 Days & 6 Years Filtered Food: 40 Days + Garden Recurring: Fitness, Garden	**Prep Tracker** Water: 7 Days & 6 Years Filtered Food: 40 Days + Garden Recurring: Fitness, Garden

Preparedness Goals Month 6

Week 21 Focus: Household Power	Week 22 Focus: Planning	Week 23 Focus:	Week 24 Focus:
Gear ☐ Buy a battery power station ☐	**Gear** ☐ ☐ ☐	**Gear** ☐ ☐ ☐ ☐	**Gear** ☐ ☐ ☐ ☐
Knowledge ☐ Learn how to use the power station and all its useful features ☐ Read the 'ELECTRICITY > Batteries' section	**Knowledge** ☐ ☐ ☐	**Knowledge** ☐ ☐ ☐	**Knowledge** ☐ ☐ ☐
Skills ☐ ☐ ☐ ☐	**Skills** ☐ Review the plans you made back in week 4 and update them based on your new knowledge ☐	**Skills** ☐ ☐ ☐ ☐	**Skills** ☐ ☐ ☐ ☐

By now, you should be well prepared for any disaster that comes your way by combining your Gear, Knowledge and Skills that you have gained throughout this course.

4 Disaster Preparedness

These are templates for disaster-specific preparedness plans. Use them as a baseline to draw up your own plans based on your own circumstances.

Disaster Plan Template

This disaster plan is a blank template for you to fill in your own information. There are examples below if you want to see them filled out. The template can work for almost any disaster but will need to be modified slightly since some disasters have pre-warning and others occur instantly. I recommend you create disaster plans for the ones that occur most frequently in your area. Here is a list to help you get started:

Wildfire	Flood	Power Loss	Heatwave	Storm	Civil Unrest
Fuel Shortage	Drought	Hurricane / Cyclone	Resource Deficiency	Chemical Leak	Radiation Leak
Tsunami	Earthquake	Volcano	Landslide	Blizzard	Avalanche

Below are a also couple of tags which can be swapped out on different disasters based on their risk and damage.

The Disaster Chance:	No Chance	Low Chance	Med Chance	High Chance	Extr. Chance
The Disaster Damage:	No Damage	Low Damage	Mod Damage	High Damage	Extr. Damage

The start of the disaster plan template.

____________ Disaster Plan

DISASTERNAME	Situation:

Plan Last Updated: 2024-09-23

This is the end of the disaster plan template.

Example Disaster Plans

This is a completed example of the disaster plan template above. The plan starts and ends where the red hashed background is. These documents are designed to be printed as a one-pager and be as simple to follow as possible.

Earthquake Disaster Plan Example

This is an example of an earthquake disaster plan. You will note that there are quite a few differences between this and the wildfire plan since they are fairly different natural disasters, but overall you should adjust the plan to suit your own needs.

Earthquake Disaster Plan

EARTHQUAKE	Situation: An earthquake which has caused damage to the building.
	Disaster Plan For: Brendale, BRISBANE, QLD
	Causes: Plate Movement, Solar Events, Large Explosions.
	Risk Season: No typical risk season but they may coincide with solar maximums.
	After-Plan: Shelter in place if the house is still sturdy.
	Disaster Risks: Falling Objects, Collapsing House, Landslides, Volcano, House Fires, No Water/Power/Sewage, Blocked Roads.
	Disaster Spontaneity: Instantly with little to no warning.
	May Trigger: Landslides, Avalanches, Volcanic Eruption, Power Outages, Water Outages, Gas Outages, House Fires, Food Shortages.
Low Chance High Damage	**Chance and Damage of this Event** Brisbane does not sit near any major plate boundaries therefore the chance is extremely low for an earthquake above magnitude 5. The destruction caused could potentially be devastating if a strong (mag 6+) earthquake strikes locally.

At-Risk Groups:	• The Elderly - They may not be able to take shelter. • Children - May not know what to do during an earthquake. • People with asthma - Due to the dust that would be disturbed.	• High-Rise Dwellers - Taller buildings are more at risk of falling. • City Dwellers - Lack of resources, taller buildings, more people.	
Preventative Measures:	• Bolted large pieces of furniture to the wall.	• The house has been reinforced against earthquakes	
Pre-Disaster Maintenance	☐ Secure loose items which could fall ☐ Protect glass preps from falling (Jars) ☐ Know the safest places in the house	☐ Ensure everyone knows the plan ☐ ☐	☐ ☐ ☐

Away From Home Plan

Earthquake Warning	Post-Earthquake
Contact the household and start the preparedness earthquake plan. Let them know your plans.	Attempt to make contact with the household. Try to return home, noting that there could be significant damage or blocked roads along the way. Members at home should initiate the shelter at home plan.

Shelter At Home Plan

Imminent Disaster	☐ Notify household members of the potential earthquake	☐ Get everyone to a safe room or safe position	☐ Alert/text others of the earthquake	☐ Cut the power / blow out any candles	☐

Response 1 (Post-Disaster)	☐ Assess your current health ☐ Assess the health of household members ☐ Keep open a pathway to escape quickly (chock the doors) ☐ Assess the building damage - Leave if the building is unsafe ☐ Secure loose items in preparation for aftershocks	☐ Put on a mask if there is dust debis ☐ Turn off the electricity ☐ Turn off the gas ☐ Clean up the most dangerous hazards ☐ Assess the need to stay vs leaving
Response 2 (Post-Disaster)	☐ Assess the mental state of household members ☐ Put on shoes (if there is broken glass or other hazards) ☐ Check on the neighbours (Assist in health related issues) ☐ (No power after 1 day) Prepare the generator ☐ Fill water containers & bath with water	☐ Prepare the fire extinguishers ☐ ☐ ☐ ☐

Response 3 (Post-Disaster)	☐ Initiate conservation of resources ☐ Begin eating the spoilable food first ☐ (24H no power) Begin cooking the meats in the fridge ☐ ☐		☐ ☐ ☐ ☐ ☐
Conditional Tasks	☐ (No Power) Initiate the no-power disaster plan ☐ (Power) Charge the power stations/power banks ☐ (Water Leaks) Turn off the water - after filling containers/bath	☐ ☐ ☐	☐ ☐ ☐
During the Disaster	• Keep an eye on the structural stability • Listen to the radio for updates •	• • •	• • •
Monitor the News	• • •	• • •	
Shelter Evac Point	My Nearest Shelter Evacuation Point is: ________________________________	Use a shelter if your house is structurally unsound or has been destroyed.	

Evacuation Plan

Evacuate When...	• The destruction of the house is too great and there is a clear evacuation route. • The house is unstable.		
Aim	To leave the dangerous building to stay in a stable building. Bug-out could last to a few months depending on building repairs.		
⚠ Evacuate	☐ Ensure all members are in the car ☐ Ensure all gear is packed ☐ Bring tree moving/chopping devices ☐ Turn off water/gas/electricity if it isn't already ☐ Lock up what you can of the house	☐ Notify the neighbours ☐ ☐ ☐ ☐	☐ ☐ ☐ ☐ ☐
Location	1. Luke's House Ph: ☐ I will attempt to travel here	2. Dad's House Ph: ☐ I will attempt to travel here	3. Bug-Out Location 3 Ph: ☐ I will attempt to travel here
Routes	☐ Via Samford (40m) ☐ Via Logan (40m)	☐ Via The Gap ☐ Via Strathpine	☐ Route 1 ☐ Route 2
Safety	☐ Are the traffic lights out? ☐ ☐	☐ Are the traffic lights out? ☐ ☐	☐ Are the traffic lights out? ☐ ☐
Route Hazards	• •	• •	• •
Route Blocked	If a route is blocked, attempt to travel via an alternative route. If all alternatives are blocked, change the destination or survive outside the home if it's unstable.		

Plan Last Updated: 2024-09-23

Wildfire Disaster Plan Example

This is an example of a wildfire disaster plan. You will note that there are quite a few differences between this and the earthquake plan since they are fairly different natural disasters.

Wildfire Disaster Plan

WILDFIRE

Situation: An approaching wildfire which will likely reach the house.

Disaster Plan For: Toowoomba, QLD
Causes: Naturally Ignited Fire, Backburning, Arson.
Risk Season: July, August, September, October, November, December, January, February. (8 months)
Plan: Early evacuation recommended in most cases, especially if mandated to evacuate.
Disaster Risks: Flames, heat, lack of oxygen, smoke & ash particulate, explosions, low visibility, water outage, gas & electrical outage.
Disaster Spontaneity: Fires can begin and spread rapidly if the conditions are optimal.
May Trigger: Power Outages, Water Outages, Gas Outages, Food Shortages.

High Chance
High Damage

Chance and Damage of this Event
The mountainous terrain, steep slopes, multiple tall trees and thick scrub surrounding the house are condusive to wildfires spreading rapidly. There is bushland in fairly close proximity to the home. If the nearby trees are alight, there is a high chance that the house could catch on fire.

At-Risk Groups:	• Those surrounded by bushland • Individuals with Asthma	• People living remotely •	
Preventative Measures:	• Cleared the trees and bushes within 20m of the house.	•	
Pre-Disaster Maintenance	☐ Store wood away from house ☐ Ensure hoses reach everywhere ☐ Replace flyscreens with steel ones	☐ Clear gutters of debris ☐ Trim low lying branches ☐ Trim bushes leading to the house	☐ Clear fallen leaves ☐ ☐

Away From Home Plan

Fire Watch in Effect	Fire Warning in Effect	Fire Evacuation in Effect
Contact the members at home, who should begin preparing the house for the fire and start packing for a possible evacuation. Return home to help pack.	Contact the members at home, who should begin preparing the house for the fire and start packing for a likely evacuation. Return home to help pack if there is time.	Contact the members at home, let them know they should evacuate after packing the essentials and meet you at the chosen destination.

Shelter At Home Plan

Prepare 1 (Essential Tasks)	☐ Pack the cars for evac (Reversed In) ☐ Clear debris around house ☐ Centralise flammables ☐ Fill drinking water containers ☐ Shut & seal all windows/doors ☐ Don heat-resistant shoes (if possible)	☐ Ready particle gas masks ☐ Don protective clothing ☐ Inform the fire brigade ☐ Turn off the Gas ☐ Turn off the Electricity ☐ Pack the Flexi Blue Protection Bag	☐ ☐ ☐ ☐ ☐ ☐
Prepare 2 (Important Tasks)	☐ Seal car vents & gaps ☐ Prepare pets for evac ☐ Fill the bath/sink/buckets ☐ Ready the garden hoses ☐ Shave face(s) ready for mask ☐	☐ Prepare fire extinguishers ☐ Remove curtains ☐ Move furniture from windows ☐ ☐ ☐	☐ ☐ ☐ ☐ ☐ ☐
Prepare 3 (Regular Tasks)	☐ Waterproof Evac Gear ☐ Soak the grass/ground ☐ Point LPG relief valves away ☐ Plug downpipes & fill with water ☐ Mow the lawn ☐	☐ Keep a ladder for roof access ☐ Service the car, ensure it works ☐ ☐ ☐ ☐	☐ ☐ ☐ ☐ ☐ ☐

During the Disaster	• Monitor the Radio/TV updates (below) • Inspect the whole house every 10m. • Track the fire's progress on a map.	• Stay inside, away from windows. • Visually check the fire every 15 mins. • Stay hydrated.	• • •
Monitor News	• Tv Stations • Radio Stations • News Websites	• https://www.qfes.qld.gov.au/Current-Incidents • •	
Shelter Evac Point	My Nearest Shelter Evacuation Point is: __________________________________	If you chose to shelter in your properly prepared home but still need to evacuate but are unable to leave because the routes are now blocked, you should flee to the nearby evac point such as a lake, river, burnt ground or concrete bunker.	

Evacuation Plan

Evacuate When…	• Ordered to evacuate. • You deem it necessary and the roads are still clear. If some members of the household are away and you need to evacuate, text the others the Bug-Out Location.		
Aim	To avoid the flames entirely, or to avoid the particulate if it's causing health issues. Bug-out could last up to a few weeks.		
Evacuate	☐ Ensure all members are in the car ☐ Ensure all gear is packed ☐ Have fire-mitigation devices ready ☐ Put on particle gas masks (if needed) ☐ Recirculate Car Air	☐ Check driving visibility ☐ ☐ ☐ ☐	☐ ☐ ☐ ☐ ☐
Location	1. Luke's House Ph: ☐ I will attempt to travel here	2. Dad's House Ph: ☐ I will attempt to travel here	3. Casper's House Ph: ☐ I will attempt to travel here
Routes	☐ Via Samford (15m) ☐ Via Logan (25m)	☐ Via The Gap (35m) ☐ Via Strathpine (40m)	☐ Via Richmond (1h 5m) ☐ Via Fernvale (1h 15m)
Safety	☐ Are the traffic lights out? ☐ ☐	☐ Are the traffic lights out? ☐ ☐	☐ Are the traffic lights out? ☐ ☐
Route Hazards	• •	• •	• •
Route Blocked	If a route is blocked, attempt to travel via an alternative route. If all alternatives are blocked, change the destination.		

Plan Last Updated: 2024-09-23

This is the end of the disaster plans. These plans are available on my Prep Drive in a much better looking format as I had to condense the versions you see to conform to the layout of TPE.

5 Advanced Planning

When **S**tuff (or S***) **H**its **T**he **F**an it's indicative of a large scale event occurring which preppers see as a potential bug-out event. So planning for a SHTF scenario is the plan that you will utilize when one of these disastrous scenarios takes place. Having this plan ready before a disaster breaks out is essential: to keep your mind focused on what you need to do when you're worried beyond belief; to cover multiple scenarios so you're ready for anything; and to cover alternative routes and backup plans if things go wrong.

Keep the plans sealed with your bug out bag in a secure and waterproof location, ensuring everyone knows where to find it when needed. You should have secure digital versions as well which are easily accessible on an external USB so they can't be hacked and used against you. If you're the type of person who is worried easy and paranoid about people finding out about your preps you can design the bug out plans on a permanently offline computer.

Planning	Plan your bug out routes well before any incident and keep it updated as roads and circumstances change. Ensure multiple routes to reach your destination in varying disaster scenarios. Calculate how many people you need to feed for how long and prep for that goal. Research the bug out destination for natural threats and nearby towns as well as visibility from the sky and surrounding bush colour/type for camo. Store hidden underground caches along various routes to your bug out location to restock from if you are looted or run out of supplies. Know your area thoroughly and exactly where you stored any caches as the terrain may change from time to time.

Plan Template

The following will be a template for a bug in/out plan with 2 redundancy routes.

Overview

Below is an example of a bug out plan. The first section with the white background gives details about the coloured section to the right. All information, locations and names are made up except for the map which are real locations. Any coloured background section to the right is a part of the bug out document, so ignore any white background cells which break up the colour. Or you can look for the full-length header below stating where the document starts and ends.

PLAN TEMPLATE - DOCUMENT START

Operation Name
The operation name is the identifying name of the plan/mission, often with a specific disaster in mind such as a world war. The name generally has something to do with the disaster.

"Operation Jericho"
O@H2500RB16004

Bugging Out Parameters
You may like to include a number of parameters to assist in giving detailed flexible plans without divulging any information via the phone. As long as you have a legend for what each character means you'll have no problem creating a code for others. It's best to keep the parameters to less than 10 characters or it may become cumbersome to say and there's more chance that the letters and positions may be mixed up.

Operation Jericho (It could relate to an ancient battle or war)
"O @H 2500 RB 1600 4" (The codename of the operation)
↑ 4 = Party Members (The number of members who are part of this operation)
↑ 1600 = Leave Time (24h) (In this case it's 4pm)
↑ R = Route Name. B = Bulbasaur - the codename of the grassland route discussed further below.
↑ 2500 = Meeting Time (24h) (In this case it's meet ASAP - since 2500 hours doesn't exist.)
↑ @H = Home. The location for the meeting point. You could pre-specify any location as long as it's in the document everyone has.
↑ O = Bug Out, It could also be 'I' for Bug In.

Bugging In Parameters
Bugging in parameters will be slightly different to the above because you won't need a route.

Operation El-Dorado (Remember not to relate the codename to any real aspects of the operation)
"I @H 0815 RN 1000 4" (The codename of the operation)
↑ 4 = Party Members (The number of members who are part of this operation)
↑ 1000 = Leave Time (24h) (In this case it's 10am)
↑ RN = Route Name. N = None, since we're bugging in.
↑ 0815 = Meeting Time (24h) (In this case it's 8:15 am)
↑ @H = Home. The location for the meeting point.
↑ I = Bug In.

It would be best to create your own operational coding system so that nobody outside the plan can understand what you mean. Organise the letters and number however you wish, but try not to make it too long because the chance for errors grows. When you tell someone the code you should use the NATO Phonetic Alphabet to help avoid discrepancies. A complete list of important information to convey in the codename via parameters can be found below:

Parameter	Description
Operation Name	You can have a lot of different operations with different names for various disasters that may arise.
Bugging In/Out?	Lets your party know if they're bugging in or out.
Meeting Time	Lets your party know the time to meet to discuss further plans or prepare to bug out. You could use ! as 'right now'.
Meeting Destination	Lets your party know the destination to meet to discuss plans further.
Leave Time	(Bugging Out) Lets your party know the time which they will be leaving.
Destination	(Bugging Out) Lets the party know which destination they will be heading to.
Meeting Route	(Bugging Out) The route which the party will be taking. Example: @B (For Bulbasaur)
!	A modifier which goes on the start of an operation which means, this plan is highly time sensitive. Example: !OPB41600
Leave Without	This can be used to tell a segment of your party to leave ASAP and that you will all rendezvous at the destination.

Plan Designer / Leader
The name of the party leader and designer of the plan. This person will also be the deciding factor on whether or not to initiate the plan. 2IC is the 'second in command'.

Plan Designer: Fluidic Ice
Plan Leader: Fluidic Ice
2IC: Julia Styles

Natural Disaster Type
Worldwide Nuclear War

Destination
Station Homestead

Party
1. Luke Styles (29) (Father)
2. Julia Styles (27) (Mother)
3. Lily Styles (8) Diabetic
4. John Styles (5)

Bug-Out Triangle
75% Speed
25% Supplies
0% Safety

The aim is to get out of the major cities and away from civilization as soon as possible while taking whatever you can.

Disaster Type: This is the type of disaster that this plan is designed for. It can however be adapted for other scenarios through the use of parameters. It's best to have a few different disaster scenarios as the effects - and your plans could vary wildly and are wholly dependant on which one occurs.

Destination: The chosen destination for this operation.
Party: The names and ages of everyone in the party.
Bug-Out Triangle: Your chosen route preference between speed, supplies or safety.

Objectives The objectives that should have been fulfilled on completion of the mission.	**Primary Objectives** • Reach the bug-out location with the family and the supplies needed to survive for 6 months	**Secondary Objectives** • Retrieve weapons from cache #12 • Refill water at Wilson's Well if required	**Tertiary Objectives** • None

These include stops for refuelling, toilet breaks or to dig up caches etc and any other objectives that may be of benefit to complete but aren't necessary. There should be a primary objective at the minimum and secondary objectives which don't need to be completed. Tertiary objectives may come in which are very minor and will only give a small boost to something. At all costs the primary objective must be completed and should be outlined in detail what should be accomplished. At minimum you would want all your party members to reach the BOL alive and in good health with your vehicles in good condition and everyone in high spirits.

	Name (Callsign)	Role	Age & Gender	Contact	Strengths	Weaknesses	Armed	BOB Weight & Items	Medical Conditions
Details about the party members including fields such as: Role, Name, Callsign, Age, Gender, Mobile, Work, Strengths, Weaknesses, etc…	**Member 1** **Luke Styles (Fluidic Ice)**	Party Leader	Age: 29 Gender: Male	**Home** (00) 0000 0000 **Mobile** 00-0000-0000 **Work** 0000-0000	• Strategy • Tactics • Preparedness	• No Weapons Training	No	15 Kg • Shelter • Food • Cash	None
Add any information you feel is necessary to know about your party members so you can quickly refer back to it.	**Member 2** **Julia Styles (Hashbrown)**	Second in Command	Age: 27 Gender: Female	**Home** (00) 0000 0000 **Mobile** 00-0000-0000 **Work** 0000-0000	• Cooking • Fire Lighting	• Firearms • Stealth	No	11 Kg • Shelter • Food • Water Purification	Hayfever
	Member 3 **Lily Styles (Booklet)**	Child	Age: 8 Gender: Female	N/A	• Reading	• Child	No	3 Kg • Entertainment • Water • Food	Diabetic
	Member 4 **John Styles (Scooby)**	Child	Age: 5 Gender: Male	N/A	• Tiny Size	• Child • Loud • Low Strength	No	None • N/A	None

Rendezvous Point: The point where everyone in your party will meet up when the mission is activated.	**Rendezvous Point** Meet at 123 Oak Street, Fakeville, MT. **Rendezvous Time** Meet 1 hour (or less) after the communication which initiated the plan.	**Destination** 331 Bugout Road, Preparednessland, 24410 **Route Choice** M = Mountainous G = Grassland O = Oceanside	**Specialist Bags** P = Pandemic V = Volcanic H = Hurricane **Initiation** Anyone can initiate this plan via discussion with the party leader.

Rendezvous Time: The time that everyone should be at the meeting location to leave for the BOL. Party members should aim for that time or earlier or risk being left behind if time is of the essence.
Destination: The destination or destinations of the BOL or site which are considered generally safe. There may be a pre-destination which is a semi-safe location where the party stops to wait for others who were left behind. This lets people escape the traffic of the city while not abandoning their companions.
Route Choice: The selection of the route based on the leaders decision of hazards along each and possible blockages.
Specialist Bags: If you have multiple bags packed ready to go you can name the type of equipment you need for this situation such as the pandemic bag. Example bags are as follows: Nuclear Bag, Pandemic Bag, Wet Bag, Cold Bag etc. Each bag can have a letter related to it so it's easier to specify which bags you need without discussing it over the phone.
Initiation: Details on how to set this plan into motion if you feel the need to bug-out. Anyone in the party can start this process but ultimately the leader will be the decision maker. Generally the initiation will involve talking to the party leader on the phone and mentioning your worries or the reasons to bug out now.

The Bug-Out triangle lets you prioritize one corner but then the other two will be reduced.

Bug-Out Triangle
• Speed
• Supplies
• Safety

Each route could have a different priority such as safety or speed, so take note of which corner of the triangle this route is. The bug-out triangle is explained further down in the Bug Out Planning section.

*Sheet Continued Below - Just follow along with the coloured sections ignoring full sized rows which give additional information.

Route Planning

This section is split into routes after the main section which are shown by different colours. Multiple routes ensure a redundancy plan in case one of them is blocked. Darkened headings under the row on the left represent that each heading is repeated for each route planned.

The name and type of the routes. You can codename each route for stealth and to use with the operation name as discussed above.	**Mountainous Route (Primary Route)** Quick Route Codename: Geodude (or G)	**Grassland Route (Secondary Route)** Safe Route Codename: Bulbasaur (or B)	**Oceanside Route (Tertiary Route)** Wilderness Route Codename: Magikarp (or M)
A satellite or Google map of the route, showing the separate legs and any notable features like hazards. I recommend creating the map in an app such as Alpine Quest then create a screenshot and using that as a printed map. This isn't the only map of the route that should be relied upon you should have an offline digital map as well.			
Maps should be as highly detailed as possible and it's worth having a separate map for each route as well as each stage of each route to show the smaller sections in higher detail. The maps above are screenshots from Google Maps which are a great program to use to calculate your route. Note: These maps are fictional bug-out routes, I selected them because they vaguely match the route names.

The directions of the route from the starting point to the destination. Include street names, visible landmarks and what you'll see if you've gone the wrong way.	**Route Description** A rocky and mountainous route which is picked for its small countryside villages and few major roads. The roads are slower and there's a chance of debris on the roads but bugging out early should counter this.	**Route Description** A generally easy going and flat route with a few farm houses and small villages along the way. The road is wide, straight and very fast but the roads are often occupied by large semi-trailers making deliveries to larger towns.	**Route Description** A seaside route going through a few minor cities and avoiding major ones. There are a lot of people living along this route but this will be mostly eliminated by bugging out early.
This breaks each route down into 3-5 checkpoints and has a little written about each leg of the journey.	**General Directions** **1.** Leave the city on the M3 and follow for 80kms, **2.** Turn onto Mountain Court and follow for 117kms, **3.** Merge onto Dire St and continue for 203kms, **4.** Go down Country Lane for 23kms, **5.** Disembark and continue on foot NNE for 2km.	**General Directions** **1.** Leave the city on the M3 and follow for 30kms, **2.** Take the rocky road exit and follow for 50kms, **3.** Turn onto the country expressway and follow for 306kms, **4.** Go down Country Lane for 23kms, **5.** Disembark and continue on foot NNE for 2km.	**General Directions** **1.** Leave the city on the M1 and follow for 85kms, **2.** Follow the Seaside View Road for 247kms, **3.** Go down Bullock Road for 62kms, **4.** Disembark and continue on foot NW for 3km.
Route Distance The distance the route is in total and each section of the leg. **Route Travel Time** The total estimated travel time for the route.	**Total Route Distance** **427 km** **Total Route Travel Time** **7h 35m**	**Total Route Distance** **411 km** **Total Route Travel Time** **7h 03m**	**Total Route Distance** **397 km** **Total Route Travel Time** **7h 57m**
Stages These are the different stages in this route with the estimated travel times between each of them factoring in stops. Add as many stages as you have.	**5 Stages** 1: City - 80km, 1h 40m 2: Outskirts - 120km, 2h 10m 3: Forest - 200km, 2h 40m 4: Lane - 23km, 0h 40m 5: Hiking - 2km, 0h 25m	**5 Stages** 1: City - 30km, 1h 00m 2. Rocky - 50km, 1h 10m 3. Country - 306km, 3h 50m 4. Lane - 23km, 0h 45m 5. Hiking - 2km, 0h 18m	**4 Stages** 1: City - 85km, 2h 10m 2: Seaside - 247km, 5h 30m 3: Inland - 62km, 0h 55m 4: Hiking - 3km, 0h 22m
Stops A list of all the possible places you can stop on this particular route for driver swaps, toilet breaks etc. Ensure the location is scouted out prior to adding it as it may be home to a hidden array of dangers such as animals or homes.	**Stops** 1. Andale City - Fuel/Toilet 2. Lewis Park - Toilet 3. Crow Lookout - Toilet 4. Dan's Well - Toilet	**Stops** 1. Andale City - Fuel/Toilet 2. Lambdas Farm - Toilet 3. Point Cape - Toilet 4. Dan's Well - Toilet	**Stops** 1. Muldave - Fuel/Toilet 2. Anchor Rest - Toilet 3. Yum Cha Lookout - Toilet 4. Lone Pine - Toilet
Route Speed Posted speed limits generally aren't a problem when SHTF, however if you bug out early there's a good chance police will still be in force.	**Route Speed** Average - 65k/h Minimum - 40k/h Maximum -110k/h	**Route Speed** Average - 85k/h Minimum - 60k/h Maximum -120k/h	**Route Speed** Average - 60k/h Minimum - 40k/h Maximum -110k/h
Transport A list of the transport forms used in the bug-out including points where transport is swapped from car > bike > hiking for example. ● Type of Transport ● Fuel Tank Size ● Km/Tank ● Seating Arrangements ● Gear in the Vehicle	**Route Transportation** ● Car - 425 km ● Walking - 2 km	**Route Transportation** ● Car - 409 km ● Walking - 2 km	**Route Transportation** ● Car - 394 km ● Walking - 3 km
Advantages Advantages to choosing this route such as speed or lack of population. **Disadvantages** Any disadvantages on this route like mostly uphill or slower speed limits. Disadvantages are not hazards, try to keep them separate.	**Route Advantages** ● Very Few People/Houses ● Few Towns ● Little Traffic **Route Disadvantages** ● Mountainous ● Slow Around Corners ● Longer Travel Time	**Route Advantages** ● Flat Landscape ● Safest Route ● Small Travel Time **Route Disadvantages** ● Easily Visible from Sky ● Few Trees ● Police Patrols	**Route Advantages** ● Ocean Views ● Fresh Air ● Flat Roads ● Fastest Route **Route Disadvantages** ● Populated ● Larger Villages ● More Traffic ● Low Lying Areas
Hazards A detailed description of the hazards found on the route such as slippery slopes, unstable trees and high population areas. Mark the hazards on the map with a small symbol wherever they may occur. Other hazards may include low lying land, falling rocks, avalanche prone areas, military bases and sharp cliffs.	**Route Hazards** ● Falling Rocks ● Narrow Roads ● No Guard Rails ● Slippery When Wet	**Route Hazards** ● Wild Animals ● Motorbike Gangs Nearby ● Big Trucks	**Route Hazards** ● Flooding ● Gangs ● Military Bases

Other Considerations The following are a few other idea you could mark on the map for each leg. • Lit/Unlit roads • Low-lying Roads • Flood Plains • Open Areas • Planted Forest • Total Traffic Lights • Major Roads • Traffic Prone Roads	**Other Considerations** • 8 Traffic Light Sets • Few Street Lights • 2 Bridges	**Other Considerations** • 7 Traffic Light Sets • Dirt Roads • 1 Bridge	**Other Considerations** • 12 Traffic Light Sets • Roads Lit Well • 5 Bridges • 2 Pedestrian Crossings
Further Considerations **Traffic Lights:** The number of traffic lights on the route - which could greatly affect the time taken to bug-out. **Major Roads:** Major roads in the country will often be the first to be clogged with traffic so take note if any of your routes use these roads and for how many kilometres. List how many km's on major roads are included on this route.			
Stages			
	Stage 1 - City Stage	**Stage 1 - City Stage**	**Stage 1 - City Stage**
Distance The total distance of this stage. **Travel Time** The ETA for this stage with the specified vehicles.	**Stage 1 Distance** 80km **Stage 1 Travel Time** 1h 40m	**Stage 1 Distance** 30km **Stage 1 Travel Time** 1h 00m	**Stage 1 Distance** 85km **Stage 1 Travel Time** 2h 10m
Stage Hazards A list of any and all potential hazards on that route. **Transportation** Shows the changes in transportation on this route (if any), such as if you swap between a car, bike or on foot prior to reaching the next stage or your destination.	**Stage 1 Hazards** • Blocked Roads • Extreme Traffic • No Traffic Light Power • Riots **Stage 1 Transport** Car	**Stage 1 Hazards** • Blocked Roads • Extreme Traffic • No Traffic Light Power • Riots **Stage 1 Transport** Car	**Stage 1 Hazards** • Blocked Roads • Extreme Traffic • No Traffic Light Power • Riots **Stage 1 Transport** Car
Detailed Directions These are GPS styled directions detailing exactly which roads to take on this route. If you aren't using roads for your bug out route you should use GPS coordinates instead.	**Stage 1 Detailed Directions** Leave the house and turn left onto Alpine Street and follow for 400m. Turn right onto Blueberry Street and continue for 2km. Turn right onto Narraway Street continuing for 2.6km then merge onto the M3 and continue for 75km.	**Stage 1 Detailed Directions** Leave the house and turn left onto Alpine Street and follow for 400m. Turn right onto Blueberry Street and continue for 2km. Turn right onto Narraway Street continuing for 2.6km then merge onto the M3 and continue for 25km.	**Stage 1 Detailed Directions** Leave the house and turn left onto Alpine Street and follow for 400m. Turn right onto Blueberry Street and continue for 7km. Turn left onto Bean Road continuing for 10.6km then merge onto the M1 and continue for 67km.
Tips List any tips for the route that may help your journey such as locations of toilets, water fountains, landmarks etc.	**Stage 1 Tips** • Ensure the toilet won't be needed until the first stop.	**Stage 1 Tips** • Ensure the toilet won't be needed until the first stop.	**Stage 1 Tips** • Ensure the toilet won't be needed until the first stop.
	Stage 2 - Outskirts Stage	**Stage 2 - Rocky Stage**	**Stage 2 - Seaside Stage**
The majority of the routes shouldn't overlap but having the final stage overlap should be fine.	**Stage 2 Distance** 117km **Stage 2 Travel Time** 2h 10m	**Stage 2 Distance** 50km **Stage 2 Travel Time** 1h 10m	**Stage 2 Distance** 247km **Stage 2 Travel Time** 5h 30m
List all hazards that may occur during travel on this stage no matter how unlikely. You can also rate them according to risk or occurrence chance.	**Stage 2 Hazards** • Rocks on the Road • Winding Roads • Fallen Branches **Stage 2 Transport** Car	**Stage 2 Hazards** • Rocks on the Road • Muddy when Wet **Stage 2 Transport** Car	**Stage 2 Hazards** No hazards **Stage 2 Transport** Car
	Stage 2 Detailed Directions Look for the #117 Exit "Standale Road" and follow for 33kms, Merge onto Mountain Court and follow for 84kms.	**Stage 2 Detailed Directions** Take the rocky road exit and follow for 50kms. There's a restroom right before the turn off for country expressway.	**Stage 2 Detailed Directions** Merge onto Seaside View Road for 244kms and follow through multiple cities. Turn left onto Dolphin Esp. and 1km down look for the public toilets. On completion follow Dolphin Esp. for 2km before merging onto Bullock Road.
Add as many extra "Tip" rows as necessary for the stage.	**Stage 2 Tips** • The exit to Standale Road can easily be missed, watch for it.	**Stage 2 Tips** • One lane crossing bridge low to the water 40kms into the road.	**Stage 2 Tips** • The toilets are for public use and are locked up after 7pm nightly. Look for a stone brick building with a navy colorbond roof.
	Stage 3 - Forest Stage	**Stage 3 - Country Stage**	**Stage 3 - Inland Stage**

	Stage 3 Distance 203km **Stage 3 Travel Time** 2h 40m	**Stage 3 Distance** 306km **Stage 3 Travel Time** 3h 50m	**Stage 3 Distance** 62km **Stage 3 Travel Time** 0h 55m
	Stage 3 Hazards ● Fallen Branches ● Rocks on the Road **Stage 3 Transport** Car	**Stage 3 Hazards** ● Wild Animals on Road ● No Lighting **Stage 3 Transport** Car	**Stage 3 Hazards** ● Few refuelling points ● Rocks on the Road **Stage 3 Transport** Car
	Stage 3 Detailed Directions Watch for and merge onto Dire St and continue for 203kms. There's a fuel point first thing on this road to the left for refuelling.	**Stage 3 Detailed Directions** Turn left onto the country expressway and follow for 206 kms. Then turn onto Twin Oak Road and continue for 100 kms watching out for Country Lane.	**Stage 3 Detailed Directions** Go down Bullock Road for 62kms. This road has no lighting and half of it is dirt making travel slower. Look for the shelter at the end of the road to park the car in.
	Stage 3 Tips ● The refuel point is the last stage you can get fuel at so be sure to stop and fill the spare tanks if necessary. ● Country lane is a small road easily missed if you're not keeping an eye out for it.	**Stage 3 Tips** ● Country lane is a small road easily missed if you're not keeping an eye out for it. ● A few stop shelters along country expressway for toilet breaks if required.	**Stage 3 Tips** ● None
	Stage 4 - Lane Stage	**Stage 4 - Lane Stage**	**Stage 4 - Hiking Stage**
	Stage 4 Distance 23km **Stage 4 Travel Time** 0h 40m	**Stage 4 Distance** 23km **Stage 4 Travel Time** 0h 45m	**Stage 4 Distance** 3km **Stage 4 Travel Time** 0h 22m
	Stage 4 Hazards ● Rocks on Road ● Fallen Trees **Stage 4 Transport** Car	**Stage 4 Hazards** ● Rocks on Road ● Fallen Trees **Stage 4 Transport** Car	**Stage 4 Hazards** ● Tiredness ● Slippery Hill ● Hypothermia if Snowy **Stage 4 Transport** Hiking
	Stage 4 Detailed Directions Follow the signs for Country Lane and follow for 23kms. The majority of the road is dirt and care needs to be taken.	**Stage 4 Detailed Directions** Follow the signs for Country Lane and follow for 23kms. The majority of the road is dirt and care needs to be taken.	**Stage 4 Detailed Directions** After parking and camouflaging the car, head east until you find the cul-der-sac signifying end of country lane which is about 1km away and marked by a car shelter. Then head towards the hill to the North. In 400m you will exit the tree line and the house to the NE on another larger hill. Head towards the house using the log crossing to the north.
	Stage 4 Tips ● This road has no lighting and loose stones so care needs to be taken. ● There's 3 cattle grids on Country Lane.	**Stage 4 Tips** ● This road has no lighting and loose stones so care needs to be taken. ● There's 3 cattle grids on Country Lane.	**Stage 4 Tips** ● Ensure the car is camouflaged well so it's not stolen as easily if it's needed again. ● On arrival take note to proceed slowly and observe the cabin 30m prior to entering to ensure it's safe.
	Stage 5 - Hiking Stage	**Stage 5 - Hiking Stage**	
	Stage 5 Distance 2km **Stage 5 Travel Time** 0h 25m	**Stage 5 Distance** 2km **Stage 5 Travel Time** 0h 18m	
	Stage 5 Hazards ● Tiredness ● Hypothermia if Rainy or Snowy **Stage 5 Transport** Hiking	**Stage 5 Hazards** ● Tiredness ● Hypothermia if Rainy or Snowy **Stage 5 Transport** Hiking	
	Stage 5 Detailed Directions After parking the car head towards the hill to the North. In 400m you will exit the tree line and see the house to the NE on another larger hill. Head towards the house avoiding the small river by using the log crossing to the north.	**Stage 5 Detailed Directions** After parking the car head towards the hill to the North. In 400m you will exit the tree line and see the house to the NE on another larger hill. Head towards the house avoiding the small river by using the log crossing to the north.	

If you want to break your routes down into further stages you can add more below.	**Stage 5 Tips** ● On arrival take note to proceed slowly and observe the cabin 30m prior to entering to ensure it's safe.	**Stage 5 Tips** ● On arrival take note to proceed slowly and observe the cabin 30m prior to entering to ensure it's safe.	
	Arrival		
Arrival The procedures and actions to take upon arrival of your destination.	☐ **Check Perimeter** Do not enter the house immediately but spread the party out and monitor the area for about 30m to ensure it's safe. ☐ **Check Exterior** With your party, approach the house from all sides at once and check for any damage. ☐ **Check Interior** Someone may be hidden inside so check each room thoroughly for intruders. ☐ **Unpack** It may take a few trips to get your gear from the car to the house if you over-packed per person. Go slow and take care not to injure yourself.		

Checklists

These are some recommended checklists to have on your bug-out plan to ensure you're ready for the journey. Tick the box off once you've completed the item or cross it out with a line if it's not applicable. Here are the other symbols in the set if you are re-creating this sheet elsewhere: ☐☒☑. (https://fsymbols.com/signs/tick/)

	Packing Checklist		
Packing Checklist (Checklist of items to bring outside of a bag) Have a checklist of the items that should be packed for the trip.	**Packing Checklist** ☐ Party Members ☐ Bug-Out Bags ☐ Trip Food/Water ☐ Medical Kit ☐ SCAR Bags if Required	☐ Weapons/Ammo ☐ Medication ☐ Bug Out Plans ☐ GPS / Navigation ☐ Paper Maps ☐ Pets	
	Car Checklist		
Car Checklist (Checklist to ensure the car is ready) Ensure the car is ready to go with fuel, fluids and disaster precautions added such as air vents taped or snow chains on.	**Car Checklist** ☐ Car Packed ☐ Fuel Tank Full ☐ Spare Fuel ☐ Air Vents Taped Closed ☐ Spare Tyre ☐ Oil Level ☐ Coolant Fluid	☐ Washer Fluid ☐ Tyre Pressure (+Spare) ☐ Brake Fluid ☐ Clutch Fluid ☐ Power Steering Fluid ☐ Oil Filter Check ☐ Air Filter Check ☐ Tyre Wear Level	☐ Lighting Check ☐ Indicator Check ☐ Fuse Check ☐ Wiper Blade Check ☐ Fire Extinguisher/Blanket ☐ Box of Caltrops
	House Bug In Checklist		
House Bug In Checklist (How to prepare the house for your bug in)	**Bug In Checklist** ☐ Store water in containers ☐ Tape up windows ☐ Board up unused Doors ☐ Seal Light Leaks ☐ Seal Air Gaps	☐ Set up night watches ☐ Turn off Gas ☐ Charge Electronics ☐ Loose Item Removal ☐ Designate a bunker room ☐ Ration Supplies	☐ Adapt Electrical Circuit
	House Bug Out Checklist		
House Bug Out Checklist (How to prepare the house for your departure)	**Bug Out Checklist** ☐ Windows Locked/Barricaded ☐ Doors Locked/Barricaded ☐ Water Off ☐ Electricity Off ☐ Gas Off	☐ Valuables Hidden ☐ Toilets Clean ☐ Unplug Electronics ☐ Discard Rubbish ☐ Eat Perishable Food ☐ Loose Item Removal	
	Bike Checklist		
Bike Checklist (Checklist to ensure the bike is ready)	**Bike Checklist** ☐ Tyres Pumped ☐ Trailer Attached ☐ Phone/GPS Holder ☐ Spare Tyre ☐ Tyre Patch Kit	☐ Spare Chain ☐ Maintenance Tools ☐ Bottle Holder ☐ Bags Packed ☐ Side Bags ☐ Brakes Tested	☐ Air Pump ☐ Full Water Bottles ☐ Helmet ☐ Bike Lock & Chain
	Hiking Checklist		
Hiking Checklist (Checklist to ensure you are ready for the hike)	**Hiking Checklist** ☐ Shoe Condition Adequate ☐ Adjusted & Fitted Backpack ☐ Hiking Pole ☐ Tied Laces ☐ Full Water Bottles	☐ Bag Weight Acceptable ☐ Correct Clothing for Weather / Season	

Procedure

A written plan of how you hope to proceed when disaster strikes.

	Step 1 - Initiation

	Initiation To initiate the plan in a time of urgency or discuss the prospect of bugging out/in contact the developer of the plan.	**Contact** Attempt to communicate with all other adult participants involved in the plan and explain which plan is being initiated and why. Use a code if required to keep others from knowing what you're doing. Make sure you know the route they will take to return home in case something happens along the way.	**No Contact** If no contact is available proceed with the plan but wait before leaving for the destination. Not having communications should be a sure sign to start preparing.
	Step 2 - Packing		
Packing Time The estimated time it will take to pack the vehicle with the supplies needed to bug-out	**At Home** Those already at the rendezvous point will begin packing the BOBs into the car and complete the pre-leave checks.	**Charging** Ensure your devices are charged up in the time you've got before leaving.	**Lock Up** Lock the house and bring any loose items in the back yard inside if there's time spare. The nature of the disaster will specify what has to be done.
	Step 3 - Monitor		
	Keep the news on and take note of any changes in the situation. Use multiple news sources in case there's bias in some of them. Use the changing information and what you currently know to update the plan on the fly to avoid obstacles or slowdowns. Your plan may change entirely from bugging out to bugging in due to weather based scenarios, so check the news every 15 minutes.		
	Step 4 - Leave		
	Leave If all party members have made it to the rendezvous location in time and the vehicle is packed, leave for the destination according to the plan.		
	No Show In certain situations it may be needed to leave for the destination without someone. If this occurs be sure to leave them instructions on when you left, the route you took and leave some supplies for them to make it. If contact has been made and the agreed time to leave has arrived: 1. Attempt contact again 2. Wait ~30m longer 3. Leave a note of the time you left and the route number taken, then leave. Only leave if your plan has contingency plans for no shows and what action plan to proceed with.		
	No Show - Contact Made / Known Route If the starting location of the person missing was known consider the possibility of driving along their route and keep and eye open.		

PLAN TEMPLATE - DOCUMENT END

Combined Planning

This section involves planning for anything that can be applied to both bugging in or out.

Team Bonding	A team that intimately knows each other is less susceptible to fights when the situation gets tough. Knowing how different members react to different scenarios as well as how they react with each other is an import factor in diffusing conflict. If everyone has slept in a crowded room with each other previously, it will be a lot less startling to discover that someone snores badly when the situation is already tough, and gives people the opportunity to plan ahead and bring ear buds.	
Leadership	Establishing a leader is essential to keep the decisions to one person who has had training in preparedness. Although people may rebel against the leader they always have the decision to leave the party and go their own way. As a prepper you should be leading the party if you feel up to the part. You could however delegate the tough-talk and strength to someone else who takes your advice and guidance wholeheartedly. For more information, see the LEADERSHIP category.	
Disputes	There are always going to be disputes and personality clashes in an apocalyptic scenario. It's how they are handled that will determine what comes out of them. Trying to keep everyone happy, optimistic and with high morale is essential for a seamless team and it will make the whole SHTF scenario a little easier. The best way to resolve conflict is splitting the difference, unless extenuating circumstances mean someone should get more than the other person. Disputes should never be settled by sacrificing food and other supplies to one person, or any other means which would decrease the survivability of the team.	**Dispute Outcomes** • Win / Win • Win / Lose • Lose / Win • Lose / Lose
Party Leavers	If an individual or individuals leave the party to go off for themselves they could take insider knowledge of how many people, resources and guns you have with you as well as your future plans. This can be a huge threat to your safety as they could return with other survivors they've teamed up with to take what you have. It's recommended you immediately change your location, route and tactics in this event to throw them off the scent.	
Knowledge	Ensure everyone knows the plan well including the supplies being brought, the redundancy plans and any failsafe's. If everyone knows how to use the tools in the BOBs then anyone can purify water, cook food and use gas stoves. Basic medical knowledge should also be shared among the group such as applying bandages and slings as well as any specialized medications that any party members require like an epinephrine auto injector. At least 20% of your party should have some form of advanced medical training in areas such as CPR, what to do in choking, dislocation, burns, breaks and drowning situations. The leader should always play their cards close to their chest and avoid telling people things they don't need to know, such as hidden caches. If the leader keeps details to themselves and they are robbed at gunpoint by their own party members, they still have the ability to survive by making it to a cache and plan from there.	

Bug In Planning

Helping you plan for bugging in and what preparations are required to have ready when the time arises. As always you shouldn't rely on a plan to always bugging in no matter what. Every situation should be weighed up and decided on when the time comes.

Supplies Duration	You should have a rough estimate as to how long the disaster should last, if it's longer than 6 months it may be recommended to bug out after that time. Ensure you have a supply cache that will last you at least the length of your estimated bug-in period plus 50%.	
Ration Plan	Even if you believe you have enough supplies to outlast a disaster you could be wrong and may perish from lack of food or water if the disaster prolongs itself. Develop a ration plan and stick to it, taking into account people's age, gender, strength, illnesses and medication requirements.	**Items to Ration** ● Water ● Food ● Ammunition ● Electricity ● Energy ● Time
House Reinforcements	It's wise to have a collection of planks, nails and a hammer handy if you need to block off access to certain areas. Duct tape will help to prevent shattered glass from showering your floors. Move heavier items behind access points such as doors and windows to make it hard to intruders to enter. Charge all your batteries so you're ready when the power goes out. Ensure your generator won't cause carbon monoxide poisoning and won't be stolen.	
Defensive Weapons	Your weapons should be primed and ready for use any point in time, but exercise caution around them. SHTF is not the time for shooting practice so keep quiet and avoid attracting attention.	
Day/Night Watch	Start a day and night watch as early as possible and get into a routine of checking the perimeter without showing yourself. For more information see the SECURITY section.	

Bug Out Planning

Helping you plan for bugging out and what preparations are required to have ready when the time arises. As always you shouldn't rely on a plan to always bugging out no matter what. Every situation should be weighed up and decided on when the time comes.

Route Planning

Choosing a route can be difficult as it's hard to gauge from a map what dangers you may encounter along the way. It's best to choose three different routes each primarily based in on of the features below.

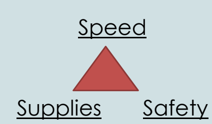
Safe Route	A route which has few natural hazards such as slippery roads, falling rocks, flooding or a lack of guard rails on mountain passes.
Uncrowded Route	A route which is as free of as much population as possible such as houses, cities, suburbs, or likely places people will gather.
Clear Route	A route which will have the least likely number of obstructions such as flooded roads, downed trees, mud/rock/snowslides etc.
Fastest Route	The route which will take the least amount of time at any time of the day, assuming there's no traffic or blockages.
Evasion Route	A route which is calculated on the day to avoid a certain new element such as an area infected with a virus or radiation. It also gives you the element of surprise against anyone attempting to ambush people.
Stealth Route	A route where you try to stay out of sight from as many people as possible, using the small country roads and avoiding all cities and towns. The route should be generally surrounded by vegetation and you should be difficult to spot from the ground and air. There's more likely to be road blockages on this route due to the number of trees etc hiding you from view.

Bug-Out Triangle

The Bug-Out triangle lets you prioritize what's most important to you when bugging out. You can choose one point on the triangle to specialize in, however you can't focus on them all. This applies to all modes of bug out transport from driving to hiking. You can however find a balance between them all so that you don't specialize in any one of them primarily.

If you want to go for ultimate speed when bugging out you will either need fewer supplies or compromise safety which can lead to injury. If you want a ton of supplies then your speed will be ultimately sacrificed and due to being weighed down, your safety will also be reduced. And finally safety, everyone knows speed can kill and if you're on foot, fewer items will let you keep your footing easier and won't put your centre of gravity off.

Bug-Out Triangle



Some reasons for choosing **Speed** are:
- There's a disaster rapidly approaching and you want to get out of its path as fast as possible.
- You want to leave town before other people realize they should leave too.
- The roads will be closed, flooded or destroyed in the near future.

Some reasons for choosing **Supplies** are:
- You're leaving town permanently. (I'm Never Coming Home)
- You don't know how long you will be away from home.
- There's no or few supplies where you're going.

Some reasons for choosing **Safety** are:
- The route is dangerous, wet, snowy or is an unknown route.
- You have to stay under the radar to avoid being detected.
- You're likely to be injured if you continue at a regular pace.

Sometimes it may be necessary to change your tactics part way through a bug-out. For example if you started with Speed but come across an icy part of the road, you will have to prioritize Safety and slow down or risk sliding off the road. Another example would be if you chose Supplies but due to the change in course of a disaster you need to get to your bug out location faster, therefore you may have to drop some gear to be able to lighten the load and quicken the pace.

Gear Grabbing

PREPAREDNESS Advanced Planning Bug-Out Planning Gear Grabbing

Essential Gear

In general your BOB should be packed and ready to grab and go at a moments notice, however there's a few reasons why some items won't always be stored in the bag. Some of the below items are stored in containers and therefore require a key. You do NOT want to waste time searching for a key to your safe or weapons locker in an emergency because it could cost you your life. Ensure you either have your keys on you at all times or you know exactly where they are and can easily get to them without going through multiple security barriers.

Borrowed Items	If you're the type to borrow items from your pack when you go camping or hiking you should be sure to return them immediately afterwards.
On Display	Some items such as family pictures will be displayed on mantles and desks, so be sure you know where they are and grab them before you go if you want them. An alternative is to have digital versions or duplicates in your pack.
Refrigerated Items	Medicines and drugs should be stored at a cooler ambient temperature, therefore you should only grab these at the last minute to maximise their life.
Valuables	You may have a separate location for your valuables such as a safe or they could be diversified around your home or work office, or even perhaps a safety deposit box.
SCAR Bags	You may have specific bags for this type of emergency stored around the house, in addition to your primary BOB like pandemic medical gear.
Weapons	Weapons are generally stored in special containers to ensure their compliance with the law, therefore you have to remember to grab them before you leave.
Volatiles	Volatiles are items which have to be stored separately from general living quarters due to the hazard they pose to general safety. These kinds of items can include: Gas Canisters, Fuel (Petrol, Diesel, LPG) and dangerous chemicals such as kerosene, calcium hypochlorite (used in water purification) and Shellite.

Unessential Gear

Before you need to bug-out there may be a bit of spare time to grab a few extra items around your home, particularly if you're never coming back. The following list provides ideas on the most important non-essential items.

Digital Records	Computer hard drives and other storage media could prove useful if you aren't ever coming home and you rely on your files. There may also be personal files on them which shouldn't get into the hands of anyone else.
Memories	Photographs, memorabilia, personal items etc can provide a vital function in keeping up morale.
Important Documents	Leaving any important documents (such as your birth certificate) in your home could end in a stolen identity. You should either bring these documents with you, including copies or burn them - in the case of copies.
Spares	Grab any spare pantry snacks, food, water, gas canisters, batteries and candles you have around your home if you're bugging out via car and have some spare time.

PREPAREDNESS Advanced Planning Pet Pet Bug Out

Pet Bug Out

The best way to protect your family from the effects of a disaster is to have a disaster plan. If you are a pet owner, that plan must include your pets. Being prepared can save their life. Different disasters require different responses. But whether the disaster is a hurricane or a hazardous spill, you may have to evacuate your home. In the event of a disaster, if you must evacuate, the most important thing you can do to protect your pets is to evacuate them, too. Leaving pets behind, even if you try to create a safe place for them, is likely to result in their being injured, lost, or worse. So prepare now for the day when you and your pets may have to leave your home.

Pet Safe Place	Remember that Red Cross disaster shelters cannot accept pets because of states' health and safety regulations and other considerations. Service animals who assist people with disabilities are the only animals allowed in Red Cross shelters. It may be difficult, if not impossible, to find shelter for your animals in the midst of a disaster, so plan ahead. Do not wait until disaster strikes to do your research.

Contact hotels and motels outside your immediate area to check policies on accepting pets and restrictions on number, size, and species. Ask if "no pet" policies could be waived in an emergency. Keep a list of "pet friendly" places, including phone numbers, with other disaster information and supplies. If you have notice of an impending disaster, call ahead for reservations. Ask friends, relatives, or others outside the affected area whether they could shelter your animals.

If you have more than one pet, they may be more comfortable if kept together, but be prepared to house them separately. Prepare a list of boarding facilities and veterinarians who could shelter animals in an emergency; include 24-hour phone numbers. Ask local animal shelters if they provide emergency shelter or foster care for pets in a disaster. Animal shelters may be overburdened caring for the animals they already have as well as those displaced by a disaster, so this should be your last resort.

Pet Disaster Supplies Kit	Whether you are away from home for a day or a week, you'll need essential supplies. Keep items in an accessible place and store them in sturdy containers that can be carried easily (duffel bags, covered trash containers, etc.). Your pet disaster supplies kit should include:	● Medications and medical records (stored in a waterproof container) and a first aid kit ● Sturdy leashes, harnesses, and/or carriers to transport pets safely and ensure that your animals can't escape ● Current photos of your pets in case they get lost ● Food, potable water, bowls, cat litter/pan, and can opener ● Information on feeding schedules, medical conditions, behaviour problems, and the name and number of your veterinarian ● Pet beds and toys, if easily transportable

Know What To Do	Often, warnings are issued hours, even days, in advance. At the first hint of disaster, act to protect your pet. Call ahead to confirm emergency shelter arrangements for you and your pets. Check to be sure your pet disaster supplies are ready to take at a moment's notice. Bring all pets into the house so that you won't have to search for them if you have to leave in a hurry. Make sure all dogs and cats are wearing collars and securely fastened, up-to-date identification. Attach the phone number and address of your temporary shelter, if you know it, or of a friend or relative outside the disaster area. You can buy temporary tags or put adhesive tape on the back of your pet's ID tag, adding information with an indelible pen.

Tips	You may not be home when the evacuation order comes. Find out if a trusted neighbour would be willing to take your pets and meet you at a prearranged location. This person should be comfortable with your pets, know where your animals are likely to be, know where your pet disaster supplies kit is kept, and have a key to your home. If you use a pet sitting service, they may be available to help, but discuss the possibility well in advance. Planning and preparation will enable you to evacuate with your pets quickly and safely. But bear in mind that animals react differently under stress. Outside your home and in the car, keep dogs securely leashed. Transport cats in carriers. Don't leave animals unattended anywhere they can run off. The most trustworthy pets may panic, hide, try to escape, or even bite or scratch. And, when you return home, give your pets time to settle back into their routines. Consult your veterinarian if any behaviour problems persist.

Pet Evacuation

Take your pets with you. Many people mistakenly leave their companion animals behind when they evacuate during an emergency, thinking their pet's instincts will prevent them from being harmed. Nothing could be farther from the truth. Companion animals depend on us for their survival, much as children do.

- Take your supplies with you. At evacuation sites, you should have, or be able to readily obtain, food, water, veterinary care, handling equipment, and generators if necessary.
- Photograph your pet. Carry a photo of your pet for identification purposes.
- Transport your pet safely. Use secure pet carriers and keep your pet on a leash or in a harness.
- Find a pet-friendly hotel. Because most emergency shelters do not admit pets, call hotels in a safe location and ask if you can bring your pet. If the hotel has a no-pets policy, ask the manager if the hotel can waive the policy during the disaster.
- Carry a list of emergency telephone numbers with you. This should include your veterinarian, local animal control, local animal shelters, the Red Cross, and any other individual or group you might need to contact during the disaster.

- Foster your pet. If you and your pet cannot stay together, call friends, family members, veterinarians, or boarding kennels in a safe area to arrange safe foster care.
- Have supplies on hand. Be sure to pack a week's worth of food, water, medication, cat litter, or any other supplies your pet needs on a regular basis.
- Plan your evacuation and leave in plenty of time. Do not wait until the last minute to evacuate. When rescue officials come to your door, they may not allow you to take your pets with you.
- Evacuate animals as soon as possible. Be ready to leave once the evacuation is ordered.
- Set up safe transportation. Make sure that you have available trucks, trailers, or other vehicles suitable for transporting farm animals or arrange to have experienced animal handlers and drivers to transport them.

- Arrange your evacuation route in advance.
- Arrange for a place to house your animals.
- Plan an alternate evacuation route. Alternate routes should be mapped out in case the planned route becomes inaccessible.
- Work with the state department of agriculture. If your animals cannot be evacuated, your state department of agriculture can provide on-farm oversight.
- Identify your pet. Securely fasten a current identification tag to your pet's collar. If you face evacuation, it is a good idea to attach to the collar the phone number of a friend or family member who is well out of disaster range. That way, anyone who finds your pet will be able to reach a person who knows how to contact you.

Other Pet Evacuation Tips	**Birds** Birds should be transported in a secure travel cage or carrier. In cold weather, wrap a blanket over the carrier and warm up the car before placing birds inside. During warm weather, carry a plant mister to mist the birds' feathers periodically. Do not put water inside the carrier during transport. Provide a few slices of fresh fruits and vegetables with high water content. Have a photo for identification and leg bands. If the carrier does not have a perch, line it with paper towels and change them frequently. Try to keep the carrier in a quiet area. Do not let the birds out of the cage or carrier.	**Reptiles** Snakes can be transported in a pillowcase but they must be transferred to more secure housing when they reach the evacuation site. If your snakes require frequent feedings, carry food with you. Take a water bowl large enough for soaking as well as a heating pad. When transporting house lizards, follow the same directions as for birds.	**Pocket Pets** Small mammals (hamsters, rabbits, gerbils, etc.) should be transported in secure carriers suitable for maintaining the animals while sheltered. Take bedding materials, food bowls, and water bottles.

If you must evacuate, do not leave your animals behind. Evacuate them to a prearranged safe location if they cannot stay with your during the evacuation period. If there is a possibility that disaster may strike while you are out of the house, there are precautions you can take to increase your pets' chances of survival, but they are not a substitute for evacuating with your pets.

6 Rehearsals

It's not enough to simply have a plan and route selected for disasters. You need to practice the plan as if it were real and throw in some random situations you didn't expect. This section covers the forms of rehearsals you should participate in and how to simulate random problems you may encounter along the way. You can be the controller of these random factors or you can get an external party to tell you what happens so there's no bias. You should take notes throughout the simulation to improve your plan for next time and adapt to any circumstances should they happen in the real situation.

Rehearsing Tips

Rehearse bug out plans for multiple disaster scenarios and have contingency plans in case of accidents. Keep rehearsing any skills you know, practice makes perfect and if you don't use it you lose it. Act as if any situation is real and that your life depends on getting everything right.

Complications	Different circumstances that can be applied to your bug-in/out at any time which you have to work around. The below rehearsal complications can be just thrown into any bug in or bug out situation at any point in time.
Scenarios	A whole scenario is given to you which you have to enact and then work through

How to Play

The situations below are possible events that could happen during a disaster. It only specifies the problem, you have to find a solution to it yourself. If you don't find a solution you should predict what would happen as a result from that and adapt to the situation. Ideally you will want to roll a new scenario every 2-3 hours to keep you on your toes and to represent a scenario where multiple things can go wrong.

So if you're doing an overnight adventure from 8am to 8pm the next day you would have rolled at 11am, 2pm, 5pm, 8pm, 11pm, *Break while asleep*, 8am, 11am, etc.

You could even roll the dice to see how many half-hours or full hours before the next event.
1 = 30 mins and 6 = 3 hours

Equipment ● 1 x 6 Sided Dice ● This Spreadsheet	**Rolling** Roll a 6-sided dice once to find the row you will look at. Roll again twice, adding the numbers together then minus 1. Your roll will be between 1-11 and corresponds with a cell in the row you rolled. Where column G=1 and Q=12.	The complications vary from minor alterations of your plan to severe events which can completely alter the outcome. The severity is shown via the cell number colour. Complications can be timed every x hours or happen whenever you decide (or the game master decides) on rolling one.

Roll Severity The roll severity is how much this complication will affect you.	**Minor (Green)** Small deviations	**Major (Orange)** Quite sizable deviations from the plan	**Severe (Red)** Huge deviations from the plan

Cumulative
The complications are cumulative so if your party is split up and you have previously rolled downed mobile networks, you can't simply ring them to find out where they are. There may be some that contradict each other such as a drought and heavy rain, so just go along with it and see what happens.

Difficulty Level
You can choose what level of complication severity you want to rehearse with, as the higher rows are tougher situations. If you're just starting out set a number and minus it from the row roll every time to reduce the overall row.

If you roll a row 5 and you want 2 levels easier you will read from row 3 instead of 5. You then roll the row number of the complication.

Injuries
If a simulated injury is sustained you should apply medication to the injury and not use that limb if necessary. Do not actually take medication for any simulated ailment but pretend that supply is now gone and put it in an area for consumed items. If you die it's probably best to stay away from those alive to maintain the simulation.

Have Fun
The most important factor in this is that you learn something from the simulation and have fun while doing so, if possible get some friends to be the "game master" to coordinate attacks every so often so the participants can focus on surviving.

Dice Rolls

The following is how to read and act on the information from one of the cells you rolled. Some cells have dice roll numbers at the bottom of them which provide a slightly different outcome to what is mentioned above. Some cells are dependant on your current situation and what action you take after the event. Depending on what you choose to do in that scenario, a different outcome will take place. Other cells require you to keep rolling the dice every x hours to see if an effect will take place. If a cell says "Cumulative Effect" and you roll a 3, you have to do all of the effects from 1-3.

If you don't have a dice, see the ENTERTAINMENT section for a simulated die.

Dice Rolls	**2,4,6:** Do this action if you roll any of the numbers listed.	**1-4**: Do this action if you roll any of those numbers (inclusive). So 1,2,3 or 4.	**Odd**: 1, 3, 5 **Even**: 2, 4, 6	**(3) or (1,2,6)**: Roll for each person in the party, and if the number matches any in the brackets then do the action for that person.

There are some cells which take affect on certain people in your party, depending on how many are with you. You want to assign rolls to each person so you know who it affects. Then roll the dice and apply the affect on whoever was rolled. For an odd number of people you don't have to have the same chance for everyone. You can also have a blank number where nobody is affected.	**Number of People** **1:** 1-6 or 1-3 etc. **2:** 1-3, 4-6 **3:** 1-2, 3-4, 5-6 **4:** 1-2, 3-4, 5, 6 **5:** 1, 2, 3, 4, 5 **6:** 1, 2, 3, 4, 5, 6 **7+:** (2 Rolls) 2-3, 3-4, 5-6, 7-8, 9-10, 11, 12	***Action*** This signifies when the action should be decided on and taken in relation to the dice rolls. It is either before the dice rolls or after the dice rolls. If there's no action marker then you do the action after rolling the dice.

Bug-In Rehearsals

These are the bug-in rehearsal scenarios.

Inside a House

Bug-In	Column 1	Column 2	Column 3	Column 4	Column 5	Column 6	Column 7	Column 8	Column 9	Column 10	Column 11
Bug-In Complications Row 1	**Cell 1** You see your neighbour run past your window and knock on your door seemingly panicked and making a commotion. 1-2: It's a distraction while their buddies stealthily try to enter through the back door. 3-4: They've seen a violent gang down road approaching your location and came to warn you. If you roll a 1,3 or 6 they will attempt to loot your house. 5-6: They are crazed and lunge at you with a concealed knife if you open the door.	**Cell 2** It's raining heavily and any outdoor firewood gets damp. You notice a small leak in the roof in another part of the house which has formed a small puddle on the floor. Dripping once per 2 seconds. Without patching the leak will double in output every hour.	**Cell 3** Your mains gas supply and bottled gas canisters - including camping gas has run out.	**Cell 4** The water supply to your house is knocked out and you can only get a few drips per minute.	**Cell 5** The sewage system is clogged and the toilet now contains floating faeces.	**Cell 6** A party member has accidentally burnt themselves and a large portion of their torso. They can't use their left arm.	**Cell 7** There's a solar flare which is blocking all wireless signals such as: TV, radio, GPS, wifi, 3G, 4G etc. 2 way radios still work with their range down to 1/3rd. All grid electricity is knocked out permanently.	**Cell 8** A water pipe bursts in the bathroom and soaks through any toilet paper and fabric in those rooms rendering them useless.	**Cell 9** The sky is covered in thick cloud rendering solar panels useless for weeks on end.	**Cell 10** There's a FEMA truck nearby giving out food and water to the line of people waiting. Your unfriendly neighbours notice you aren't in the line and wonder why.	**Cell 11** Some of your party (or kids) are extremely bored just sitting and waiting with nothing to do as it's too dangerous to leave the house. They begin to get restless and start making noise.

Bug-In Complications Row 2	**Cell 1** A lightning strike hits your power line inlet and kills the power permanently disabling anything plugged into the wall outlets.	**Cell 2** Your supply of wood and hexamine tablets has been exhausted.	**Cell 3** You realize all the current batteries in your torches are dead.	**Cell 4** Some of your party are divided and are adamant they want to leave the house as it's too dangerous to stay.	**Cell 5** Your diesel/petrol and other liquid fuel supplies are now depleted.	**Cell 6** There's a pandemic in your area and any gaps in your framing will possibly let in the contagious virus. Trips outside will surely infect anyone without proper protection.	**Cell 7** During the nights thieves are stealing your crops, livestock and anything else not tied down.	**Cell 8** An EMP knocks out the power to your house via a surge in the grid and fries any electronics connected to the wall socket. As it was quite a distance away the EMP doesn't affect anything not plugged in to the wall.	**Cell 9** It begins to snow heavily, freezing water mains and external water sources.	**Cell 10** Your gas grid pressure is extremely low, making it impossible to use.	**Cell 11** A screaming young child in your party is drawing unwanted attention from outside.
Bug-In Complications Row 3	**Cell 1** One of your party members has an infected cut on their leg they failed to show you earlier and are now clammy and cold.	**Cell 2** A blizzard hits your house and freezes all water pipes, and external water tanks. The snow is 3ft deep making it impossible to open outward swinging doors for 48 hours. Your power is knocked out and most outdoor plants die.	**Cell 3** The temperature is 37.5°C (100°F) outside and 95% humidity. There are bushfires approaching the area slowly filling the air with increasingly more smoke.	**Cell 4** A mudslide coats the south side of your house in 1ft, slow flowing mud pushing over anything not fixed down.	**Cell 5** A member of your party has cut themselves severely on some rusty metal and requires attention.	**Cell 6** You find your bagged and boxed supplies of rice, flour, wheat riddled with weevils and mice/rat faeces. Food stored in sealed plastic containers is safe.	**Cell 7** Two police officers knock on your door, after a few minutes of not answering they shout inside telling you there's a mandatory evacuation due to a cat 5 hurricane approaching the area. They push a letter under the door stating this.	**Cell 8** The grid electricity goes down but you have a party member who needs to keep their insulin refrigerated and they will die without it.	**Cell 9** The grid power has been knocked out and a gang of 20 local neighbours are gathering outside looking for anyone with generators or light coming from their house with unsavoury thoughts.	**Cell 10** 3/4 of your ammo store has been soaked in water and is now unusable.	**Cell 11** You realize your biggest tank of stored water has been contaminated by bacteria.
Bug-In Complications Row 4	**Cell 1** The sky is red and fairly thick with smoke as a wildfire approaches your location.	**Cell 2** Prominent points of your house are being shot at from afar on the northern side such as livestock, lights, windows, visible people, pets, solar panels and water/gas tanks. Their primary aim is for entertainment.	**Cell 3** People are walking around your house looking for an easy point to break in thinking it's abandoned like all the others in your street.	**Cell 4** A stray rocket flies into the side of the house where your food stores are kept breaking open half the cans and shattering all the glass jars.	**Cell 5** The power is knocked out to your house and won't be back on again. Stop using all wall powered electronics.	**Cell 6** A camera drone is flying around your house, likely looking for points of entry or weaknesses.	**Cell 7** A party member falls and injures their right leg. 1-2: They break their leg 3-4: Just some bleeding and minor damage. 5-6: Their leg is cut deep from sharp metal.	**Cell 8** A nuclear accident has happened in the nearest plant and has now irradiated your area. Plants grown outside will be toxic and anyone who sets foot outside will succumb to radiation poisoning without medication.	**Cell 9** All external networks are down and you receive no signal on your phone, TV, radio, GPS, etc.	**Cell 10** A fire starts in a room with an electrical heater, candle or a gas lantern/cooker which was left unattended for 5 minutes. Any supplies in that room are destroyed.	**Cell 11** You've been tagged as someone who is prepared for disasters and the government now has 5 armed agents ramming the door to confiscate all your supplies for their own use.
Bug-In Complications Row 5	**Cell 1** Ash is falling onto your roof due to a nearby volcano, it's also raining making the rock extremely heavy, the roof has about 2 hours before it collapses entirely.	**Cell 2** A magnitude 8 earthquake shakes the house knocking 75% of loose objects to the ground breaking them. Breaking glass food jars and denting cans if not secured. Half of your party sustains moderate injuries such as bruises, deep cuts and a broken bone for one member.	**Cell 3** Your house is situated in a warzone as planes shoot each other down above and bombers drop lines of bombs over populated areas. It seems likely that eventually one will hit your house.	**Cell 4** A strong storm and hail shatters 75% of your east-side windows and breaks 50% of your solar panels. 50% of animals outside are killed.	**Cell 5** You hear a window break in a far corner of the house, after a few seconds shots are fired and you lose one of your party instantly.	**Cell 6** It's heavily raining/flooding and the water is starting to flow into the lowest point of your house 5ft (+3ft every hour for 5 hours) and 1/2ft (+1 ft/hr) deep and slowly rising.	**Cell 7** The funnel of a tornado moves over your house destroying the roof in the two south-western most rooms letting rain in.	**Cell 8** A flash grenade is thrown through an open window, soon to be followed by 4 armed assailants.	**Cell 9** A plague of vermin has been into any unsecured food around the house which is now inedible.	**Cell 10** A hurricane is nearby causing a 1ft tidal surge of water equally inside your house rendering all electronics under 1ft unusable.	**Cell 11** One of your party members shows signs of a severe contagious viral infection.
Bug-In Complications Row 6	**Cell 1** You've heard that there's a tsunami heading towards your location which will arrive in 2 hours. It will reach your location for sure but the water level could bet anywhere between 1cm-2m by then.	**Cell 2** It's war and you've been instructed to keep all lights off unless the windows are fully blocked and not to make any noise. If not you will likely be a target for enemy attack or attack from street gangs.	**Cell 3** An armed gang of 8 is roaming the streets, killing people and looting houses, they will be at your house in 20 minutes.	**Cell 4** You find a party member unconscious on the floor in an enclosed room with a running generator.	**Cell 5** Riots are happening in the streets nearby as cars and houses are being set alight. They are slowly working their way down the street to your house.	**Cell 6** You hear the sound of gun fire in the street right outside. It seems two parties have engaged in combat.	**Cell 7** A gang of 30 people have surrounded your location and are attempting to break in as they know you have supplies, they occasionally shoot through windows to scare you. If they can't get in they are likely to just torch the place.	**Cell 8** You hear large aircraft and then a whistling and deafening explosion as a bomb hits the house beside yours destroying half of it and 1/4 of your house on the western side. 1/2 of your party have a variety of different wounds from shattered glass.	**Cell 9** Strong winds from a category 5 hurricane are ripping tiles off your roof and smashing windows. All external rooms have significant damage and no roof.	**Cell 10** A gun misfires into a party members right shoulder during maintenance.	**Cell 11** Thick ash from a nearby eruption is falling on your house. After 5 hours the roof of 2 external rooms will collapse. There's a 33% chance the entire roof will collapse in 7 hours, after which the roof is at capacity and will survive more ash unless it rains. There's no sign of it stopping.

Bug-In Scenarios

These are a variety of scenarios which you can enact to help shore up your household defences and skills. You have to try and work through a scenario from start to finish taking notes on the way about what you can improve.

Scenario 1	Try a home invasion rehearsal with toy guns (nerf, gel or paintball guns) to find the weak spots and possible entry points to your abode both on the offensive and defensive.
Scenario 2	A category 5 hurricane is heading towards your home, rehearse your plan for covering glass and reinforcing one room and bugging in for 3 days.
Scenario 3	A forest fire is burning out of control towards your location, the air is full with smoke and ash. It will be on your location in 2 hours.

Bug-Out Rehearsals

These are the bug-out rehearsal scenarios.

Walking / Hiking

Walking / Hiking	Column 1	Column 2	Column 3	Column 4	Column 5	Column 6	Column 7	Column 8	Column 9	Column 10	Column 11
Bug-Out Hiking Complications Row 1	**Cell 1** A black bear with 2 cubs is 150m (492ft) ahead of you and hasn't seen you yet, it isn't likely to move away even if it sees you.	**Cell 2** The air is thick with ash from a nearby volcano. Protect your lungs.	**Cell 3** A party member finds an engorged tick on themself with a bullseye rash around it. 2/4: They get lyme disease.	**Cell 4** You realize the shelter you packed has a large 20cm rip in it from rubbing against the poles and will need to be patched or you'll get wet if rained on.	**Cell 5** You trip and fall, scraping your knee. There's bits of dirt and tiny rocks in the wound. 5: It gets infected.	**Cell 6** Due to the heat, any type of fires are banned and there's a chance you will start a forest fire if you ignore the warning.	**Cell 7** There's two poisonous snakes on the path ahead of you.	**Cell 8** It's so cold your water begins to freeze and fuel canisters don't work.	**Cell 9** You forgot the toilet paper and toothbrush.	**Cell 10** One member of your party can't walk any more without a break of at least 1h.	**Cell 11** You've sprained your ankle and have to stop or limp slowly for 2 hours.
Bug-Out Hiking Complications Row 2	**Cell 1** There's no longer mobile or internet reception.	**Cell 2** Your backpack becomes wet, soaking through your firelighters and tinder rendering them useless. This affects matches, lighters and piezo ignition.	**Cell 3** You accidentally slice your hand open on a saw or knife. The cut is about 2.5cm (1in) in length and depth.	**Cell 4** All external networks are down and you receive no signal on your phone, radio, GPS, etc.	**Cell 5** It starts pouring with freezing rain for 1 hour, walk 20% slower. Hypothermia will set in without rain protection. **Without Rain Protection** 1-2: A party members gets hypothermia.	**Cell 6** Your feet have been rubbing against your shoe so long that you've got 3 blisters.	**Cell 7** You sustain a tear in your pack and items will fall out if not patched or moved to another compartment.	**Cell 8** You're heading into a slightly irradiated area. Food and water should not be consumed from nature or taps. **Eat or Drink Natural Resources** 1-5: You get minor radiation sickness.	**Cell 9** It's an extremely hot day and you're going to get burnt without protection. You also go through water twice as fast.	**Cell 10** You forgot a can opener and a gas stove. Don't use either if you have them.	**Cell 11** The ground becomes very slick/slippery due to icing over. Roll the dice every 30 minutes, if it's a 1, you fall and sustain an injury.
Bug-Out Hiking Complications Row 3	**Cell 1** It starts hailing on you with ice about 2cm wide. **Without Shelter** 1-2: A party member sustains head injuries.	**Cell 2** A formation of 5 enemy aircraft approaches from the east, likely on a bombing run in the area.	**Cell 3** There is an uncharted cliff in front of you that spans 1km (0.6mi) wide. Find a way around.	**Cell 4** You lose all GPS satellites from now on. Don't use any GPS features.	**Cell 5** You realize a pack of 6 wolves are stalking behind you looking for a moment to strike.	**Cell 6** You brought the wrong map, don't use any paper maps from now.	**Cell 7** You forgot your water filter and purification tablets and have to find other purification methods.	**Cell 8** You begin feeling altitude sickness with nausea, dizziness and dehydration. (Pretend you're at 9,000 ft)	**Cell 9** Your mobile phone somehow corrupts itself and isn't usable.	**Cell 10** You're hiking past a large village for 3km (1.8mi) with potential hostiles living there.	**Cell 11** The area you are heading into is known to have airborne viruses.
Bug-Out Hiking Complications Row 4	**Cell 1** You see a platoon of about 30 enemy soldiers about 3km (1.8mi) away to your heading your direction from the South-East.	**Cell 2** A thick fog covers the landscape reducing visibility to 20m (65ft) ahead.	**Cell 3** Due to a lasting drought all the lakes and rivers in your region have dried up. Find alternative ways to acquire water.	**Cell 4** You realize you don't have a first aid kit in your pack.	**Cell 5** Someone has seen you hiking through their private land from about 300m (984ft) away and they are yelling and running towards you. They appear to be armed.	**Cell 6** Your knee hurts every step you take and must walk slower to avoid extreme pain.	**Cell 7** You forgot to charge your spare batteries and your only remaining torch has 30m of light left.	**Cell 8** The sole of your right shoe breaks off and leaves your feet exposed to the ground.	**Cell 9** You begin throwing up the last meal you had and feel the onset of diarrhoea possibly due to your meal, but it could also have been from unsterilized water.	**Cell 10** You discover a hole in your water bottle/pack and it's all leaked out. You will become dehydrated and can't continue after 1h of hiking.	**Cell 11** A military helicopter with a powerful light is searching the area.
Bug-Out Hiking Complications Row 5	**Cell 1** A rusty nail goes into one of your party members feet, apply medical aid and limp from there. If you roll a 2 or 5 it becomes infected in 3 hours without treatment.	**Cell 2** Your primary methods of fire lighting have failed except flint and BIC lighters.	**Cell 3** There's a gang up ahead, who are likely to shake you down if seen. Stick to the shadows and make as little noise as possible.	**Cell 4** You lose your footing and fall into a lake/river. Guns, lighters, matches, fuel tablets, open food, tinder and un-waterproofed electronics don't work anymore.	**Cell 5** One of your party members accidentally steps on a rattlesnake and it bites them on the leg.	**Cell 6** You forgot to bring any cord. Don't use any cord, rope, paracord or string you have.	**Cell 7** You notice two individuals who have been following you for a long time, and believe they want to harm you.	**Cell 8** A party member is absolutely exhausted from hiking and is about to collapse. You have to set up camp within 300m overnight or rest for 2 hours.	**Cell 9** Strong winds slow your progress and push over a 40m (131ft) tall tree in your path every 2 hours. Walk around it or find another route. Walk 25% slower. 1-2: Walk 25% slower 3-4: A party member is grazed by a falling branch 5: A falling branch falls on a party members shoulder closest to a tree. (Stop using that arm) 6. A falling branch hits a party members head knocking them unconscious.	**Cell 10** You realize your party is being followed by a two individuals. These people will stop at nothing to get your gear.	**Cell 11** Your knife blade breaks clean off from the handle and can't be re-attached.

Bug-Out Hiking Complications Row 6	**Cell 1** Your mobiles stop working due to an emp. All other electronics with transistors also stop working. This includes complex torches with modes and settings other than an on/off switch.	**Cell 2** You hear a flurry of exchanged gunshots somewhere nearby.	**Cell 3** If you have a fire or a gas stove on, a spark leaps to nearby leaves and ignites a forest fire. You will be burnt to death if you don't get out within 10 minutes and at least 3km (1.8mi) away.	**Cell 4** You trip and fall down an embankment and break your leg.	**Cell 5** This location seems unfamiliar to you and you realize your GPS or compass must be faulty. Walk in a random direction for 1km (0.6mi). 1: North 2: South 3: East 4: West 5: NW 6: SE	**Cell 6** You're in a floodplain and you notice the water level rising considerably fast. Get to ground at least 30m (98ft) above where you currently are or be swept away. Wait at least 3 hours until the water subsides.	**Cell 7** An EMP kills all your electronics (excluding cars) except those protected by a faraday cage. Do not use any of it.	**Cell 8** A tree falls and tears a 50cm (1.6ft) slit in your shelter (except canvas).	**Cell 9** You are ambushed on a hike by 3 armed individuals who tell you to give them your food and water.	**Cell 10** You realize you've been walking the wrong way and are now lost. Walk in a random direction for 2km (1.2mi). 1: North 2: South 3: East 4: West 5: NW 6: SE	**Cell 11** Your fire lighting materials catch fire in your backpack and you can only save 7 items of your choice, the rest are burnt. Any items on your person or outside the bag are safe.

Cycling

Cycling	Column 1	Column 2	Column 3	Column 4	Column 5	Column 6	Column 7	Column 8	Column 9	Column 10	Column 11
Bug-Out Cycling Complications Row 1	**Cell 1** A thick fog covers the landscape reducing visibility to 50m (164ft) ahead.	**Cell 2** You hit a nail and your tyre goes flat.	**Cell 3** The receiver of your primary gun breaks. Don't use it anymore.	**Cell 4** Your drinks holder isn't secured properly and falls of your bike.	**Cell 5** The gears on one of your bikes is jammed in its current gear and you're unable to change it for the rest of the trip.	**Cell 6** It begins to snow heavily making progress slower. Move at half the speed you were.	**Cell 7** You forgot your water filter and purification tablets and have to find other purification methods.	**Cell 8** A huge downed tree lies in your path.	**Cell 9** The ground becomes very slick/slippery due to icing over. Roll the dice every 30 minutes for each party member, if it's a 2, they fall and sustain an injury.	**Cell 10** Your chain comes off the back gears.	**Cell 11** It begins raining heavily.
Bug-Out Cycling Complications Row 2	**Cell 1** One of your party members has an infected cut on their leg they failed to show you earlier and are now clammy and cold.	**Cell 2** Compasses can't be trusted due to a pole magnetic shift.	**Cell 3** You approach a flooded section of road and you aren't sure how deep the water is.	**Cell 4** It's raining which makes it harder to see and gives you more risk of slipping. Roll a dice every hour you are riding and if it's a 4, you fall off your bike and sustain an injury.	**Cell 5** As you go over bumpy terrain you don't realize most of the items in your pant pockets has fallen out. Discard all items in your pockets except 2.	**Cell 6** Your back brakes no longer work.	**Cell 7** You forgot the toilet paper and toothbrush.	**Cell 8** You're cycling past a large village for 3km (1.8mi) with potential hostiles living there.	**Cell 9** You hit a rock and fall off your bike causing a gravel rash and some minor cuts to your left leg and both hands.	**Cell 10** Your chain comes off the gears.	**Cell 11** You don't know why but your tyre keeps getting flatter over time.
Bug-Out Cycling Complications Row 3	**Cell 1** You can't seem to change gears on your bike.	**Cell 2** Snow starts to fall and the temperature drops rapidly.	**Cell 3** You hear gunfire about 1km (0.6 mi) in front of the direction you're going.	**Cell 4** A member of your party is extremely fatigued and doesn't want to continue. They need a rest of at least 1 hour.	**Cell 5** Due to a lasting drought all the lakes and rivers in your region have dried up. Find alternative ways to acquire water.	**Cell 6** It's a very hot day and you've been cycling for hours. One of your party members has some symptoms of heat stroke.	**Cell 7** A lightning storm is approaching and will bring heavy rain, hail (1 in) and lightning. It lasts 1 hour. If you seek shelter under trees roll the dice and if it's a 3 it is struck by lightning and you sustain burns over half your body. If you don't seek shelter roll the dice for each person and if it's a 2-4 they sustain hail injuries.	**Cell 8** There's a government blockage ahead only letting people with a photo and address ID through per person.	**Cell 9** Your bike slips and one of your party members falls into a lake/river. Guns, lighters, matches, fuel tablets, open food, tinder and un-waterproofed electronics carried by them don't work anymore.	**Cell 10** Lava is flowing over your route 100m (328 ft) in front of you. It spans 2km (1.2 mi) in the direction of the nearest mountain so you will have to go around.	**Cell 11** Your clothes become soaked from rain and the temperature is 10°C (50°F). (If you don't have rain protection)
Bug-Out Cycling Complications Row 4	**Cell 1** An armed gang of 8 is roaming the region ahead, killing anyone they encounter.	**Cell 2** You begin feeling altitude sickness with nausea, dizziness and dehydration.	**Cell 3** One of your party members is shot off their bike from a nearby enemy concealed in a bush. They sustain fall injuries and the bullet penetrated their lower leg and isn't life threatening.	**Cell 4** Your chain comes off the gears.	**Cell 5** Your mobiles stop working due to an emp. All other electronics with transistors also stop working. This includes complex torches with modes and settings other than an on/off switch.	**Cell 6** There's two highly venomous snakes on the path/road ahead of you and going around will take 20m longer.	**Cell 7** A minor earthquake rocks the area, causing twigs, sticks and branches to litter your route. Roll the dice every 3 hours for each party member and if it's a 5 you slip on a branch and fall off causing bruising and injury to yourself.	**Cell 8** One of your party members runs over some glass and their tyre goes flat.	**Cell 9** A blizzard seems to be approaching and will hit within 1 hour. During the blizzard you can't see more than a few yards in front of you. Seek shelter or die within 3 hours. The blizzard lasts 5 hours.	**Cell 10** There is an uncharted cliff in front of you that spans 1km (0.6mi) wide. Find a way around.	**Cell 11** You lose all GPS satellites from now on. Don't use any GPS features.
Bug-Out Cycling Complications Row 5	**Cell 1** One of your party members chains detaches from the pedal gears.	**Cell 2** You realize you're being tailed by a black SUV. These people will stop at nothing to get your gear.	**Cell 3** You've been riding over very bumpy terrain which has damaged any unprotected fragile items in your BOB. Stop using unprotected glass items including vials, glowsticks and instant ice packs.	**Cell 4** You lose all GPS satellites from now on due to an EMP. Don't use any GPS features.	**Cell 5** The front brakes on your bike stop working.	**Cell 6** You slip in a wet patch and fall off your bike causing a major gravel rash, dislocated finger and scars to your legs and hands.	**Cell 7** You realize your handlebars are loose and are starting to rotate freely.	**Cell 8** 5 random items (or 1/6) fall from one of your party members BOBs, do not use these items from now on. Roll a dice to determine the items.	**Cell 9** Someone has seen you cycling through their private land from about 300m (984ft) away and they are yelling and running towards you. They appear to be armed.	**Cell 10** You brought an empty gas canister. Don't use your biggest canister.	**Cell 11** You see a small tornado funnel forming ahead of you which will meander in a random direction once grounded. Roll the dice to determine its direction. 1 - North 2 - South 3 - East 4 - West 5 - No Movement 6 - Towards You
Bug-Out Cycling Complications Row 6	**Cell 1** Strong winds slow your progress and push over a 40m (131ft) tall tree in your path every 2 hours. Walk around it or find another route. Walk 25% slower. 1-2: Walk 25% slower 3-4: A party member is grazed by a falling branch 5: A falling branch falls on a party members shoulder closest to a tree. (Stop using that arm) 6. A falling branch hits a party members head knocking them unconscious.	**Cell 2** You fall down a drop on your bike and bend the front wheel slightly so that it is dangerous to keep riding like it is.	**Cell 3** A stick falls into the spokes of you back wheel breaking 4 spokes. There's a chance that the wheel will grow weaker and bend over time. While riding, every hour, roll the dice and if it's a 1 the wheel buckles and becomes unusable.	**Cell 4** 3 armed helicopters with a powerful search lights are coming towards you from the nearest major city. You have 2 minutes before they are on top of you. They search the area for 30 minutes before flying off. Ignore Them: If you roll a 4-6 they shoot at you killing one of your party members and injuring another. If you have camouflage they leave the area within 15 minutes instead.	**Cell 5** This area is littered with hostile enemies who will shoot you if they see any light sources (night), or you have very visible colours on you (day). Swap to camo, hide or do nothing and roll - if you roll a 2 you're shot at.	**Cell 6** One of your party members chains snaps.	**Cell 7** A party member accidentally rides over a rattlesnake. 1-2: The snake doesn't manage to bite them 3-4: The snake doesn't bite them but the member falls off their bike and sustains minor injuries. 5: The snake bites and injects venom. 6: The snake bites them but no venom was injected.	**Cell 8** A gun misfires into a party members left leg during maintenance. The bullet exits cleanly.	**Cell 9** A fall from your bike causes you to fly over the handlebars breaking your right arm and causing major cuts to the right side of your body.	**Cell 10** Something in one of your party members bags catches alight and renders all items un-usable.	**Cell 11** A non-family adult party member decides not to continue to this bug-out location and wants to go their own way taking a lot of the supplies with them. (Only if in a group)

Driving

Driving	Column 1	Column 2	Column 3	Column 4	Column 5	Column 6	Column 7	Column 8	Column 9	Column 10	Column 11
Bug-Out Driving Complications Row 1	**Cell 1** There's a huge tree on the road ahead.	**Cell 2** The region you're entering contains airborne viruses which kill anyone over 3 days if not properly protected.	**Cell 3** 5 random items (or 1/6) fall from your bug-out bag, do not use these items from now on. Roll a dice to determine the items.	**Cell 4** It's currently freezing weather and one of your inflatable sleeping pads has a hole in it.	**Cell 5** It starts pouring with rain for 1 hour, drive 20% slower. Hypothermia will set in without rain protection in about 3h.	**Cell 6** A vicious lighting storm will be on you in 30 minutes and will last 2 hours.	**Cell 7** A minor earthquake rocks the area, pushing small trees over your path. Wait 15 minutes while you clear the tree.	**Cell 8** Compasses can't be trusted due to a pole magnetic shift.	**Cell 9** Snow begins to fall and impedes your movement, move at half the speed you were going.	**Cell 10** All cell phone towers are down and you have no communication on grid based networks.	**Cell 11** Fist sized hail begins to fall accompanying rain for 1 hour. Some vehicle windows will be shattered and head injury will occur if no shelter is found.
Bug-Out Driving Complications Row 2	**Cell 1** Your biggest water storage source has leaked and is now empty. Discard all water in the largest source.	**Cell 2** You bump into an old friend on the way and he asks for supplies. If you decline he becomes more hostile and eventually wants to take it by force.	**Cell 3** You realize the shelter you packed has a large 20cm rip in it from rubbing against the poles and will need to be patched or you'll get wet if rained on.	**Cell 4** You realize you brought the wrong ammo for your main weapon. You've only got 1 clip worth of ammo.	**Cell 5** Your paper maps weren't protected from rain and are now unreadable.	**Cell 6** A formation of 5 enemy aircraft approaches from the east, likely on a bombing run in the area.	**Cell 7** You forgot the toilet paper and realize your air mattress has a hole in it.	**Cell 8** The party leader get a severe migraine, compromising their decision making.	**Cell 9** Half your food supply turns out to be mouldy. Discard half the food supply.	**Cell 10** Your young children won't stop screaming and are fearful for their lives after seeing someone die earlier.	**Cell 11** You forgot a can opener and a gas stove. Don't use either if you have them.
Bug-Out Driving Complications Row 3	**Cell 2** You hear a distant helicopter approaching, it will be on you within 1 minute, it's likely if they see you they will try to fly low and shoot your party.	**Cell 2** Ash is falling from the sky and will clog your lungs if not protected against.	**Cell 3** You begin feeling altitude sickness with nausea, dizziness and dehydration.	**Cell 4** A forest fire is rapidly approaching you from behind and will engulf you in 10 minutes.	**Cell 5** One of your party members shows signs of a severe contagious viral infection.	**Cell 6** Your backpack tears around the lowest compartment and all items in there have to be relocated or left behind.	**Cell 7** Your primary knife blade snaps from the handle rendering it useless. Adapt or don't use it anymore.	**Cell 8** There's a gang up ahead, who are likely to shake you down if seen. Stick to the shadows and make as little noise as possible.	**Cell 9** You sustain a minor elbow cut from falling or sliding off the road. If you don't have bandages roll the dice and if it's a 1 or 4 it becomes infected.	**Cell 10** You path is blocked by a gang 500m (0.3 mi) in front who will shoot on sight if you're seen within 200m (656 ft).	**Cell 11** A thick fog covers the landscape reducing visibility to 20m (65ft) ahead.
Bug-Out Driving Complications Row 4	**Cell 1** One of your party members sustains a severe cut from rusty metal, apply first aid.	**Cell 2** Your tyre pops from a rusty nail - deflate your tyre.	**Cell 3** Your mobiles stop working due to an emp. All other electronics with transistors also stop working. This includes complex torches with modes and settings other than an on/off switch.	**Cell 4** Strong winds slow your progress and push over a 40m (131ft) tall tree in your path every 2 hours. Drive around it or find another route.	**Cell 5** A non-family adult party member decides not to continue to this bug-out location and wants to go their own way taking a lot of the supplies with them. (Only if in a group)	**Cell 6** Strong wind and slippery roads slows down your progress. Drive at half the speed you were.	**Cell 7** A wild bear is in your path 100m (30ft) away and won't be scared off.	**Cell 8** You find yourself completely lost. Drive along random roads for 5-10km (3.1-6.2mi) then find your bearings again.	**Cell 9** A military helicopter with a powerful light is searching the area.	**Cell 10** You realize you're being tailed by a black SUV. These people will stop at nothing to get your gear.	**Cell 11** The cooling fan motor on your vehicle burns out and will overheat the engine if overused.
Bug-Out Driving Complications Row 5	**Cell 1** A party member stands on a camouflaged rusty bear trap and sustains a severe right leg injury. There may be more hidden.	**Cell 2** The driver slams on the brakes to avoid hitting a deer and half the party hits their heads, one person now has a concussion.	**Cell 3** Your fuel tank has a hole and is leaking fuel, fix it or stop using the car in 5k's (3.1 mi).	**Cell 4** It starts snowing heavily and within an hour it will be impossible to drive without chains or snow shoes.	**Cell 5** There's a government blockage ahead only letting people with a photo and address ID through per person.	**Cell 6** Your driver/party leader has sustained a fall and breaks their right arm.	**Cell 7** All satellites have been destroyed and you can't use GPS systems.	**Cell 8** The party leader gets a severe migraine, compromising their decision making.	**Cell 9** A fire-fight between two gangs who you didn't see breaks out in front of you and a member of your party sustains a stray bullet injury to the leg. They haven't seen you.	**Cell 10** You forgot to pack paracord and other types of cord.	**Cell 11** Your clothes become soaked from rain and the temperature is 10°C (50°F). (If you don't have rain protection)
Bug-Out Driving Complications Row 6	**Cell 1** A party member has just run out of their personal medication, but there's no sign of needing it just yet. (Insulin, Inhaler, etc.)	**Cell 2** You see a small tornado funnel forming ahead of you which is likely to meander in a random direction once grounded. Roll the dice to determine its direction. 1: North, 2: South 3: East, 4: West 5: None - slow dissipation 6: Towards You	**Cell 3** An EMP kills all your electronics (excluding cars) except those protected by a faraday cage. Do not use any of it.	**Cell 4** There's a radiation fallout zone ahead of you, it's diameter is 20km's (12.4 mi), generally too big to avoid. Take some iodine pills or you will slowly feel the adverse side effects of radiation sickness.	**Cell 5** Your party is ambushed and held at gunpoint as they take all your supplies and bags. But they are rushed and leave a random bag behind. Roll the dice to choose the bag they leave.	**Cell 6** Your transport slips and cracks the passenger side window or bends a pedal slightly if cycling. There are minor injuries to the passenger.	**Cell 7** This area is littered with hostile enemies who will shoot you if they see any light sources (night), or you have very visible colours on you (day). Swap to camo, hide or do nothing and roll - if you roll a 2 you're shot at.	**Cell 9** Something in one of your party members bags catches alight and renders all items un-usable.	**Cell 8** All your rechargeable batteries turn out to be dead and small electronics (including torches, phone and GPS) can't be used without a recharger or power bank.	**Cell 10** You see a few people 100m down the road who have seen you and are waving for you to stop and help them, but it could be an ambush. The road is narrow and you will come within 5m of them if you drive/walk past.	**Cell 11** Your party or convoy is separated due to uncontrollable circumstances by a distance of at least 500m. (Ignore if everyone is in the same vehicle)

Bug-Out Scenarios

These are a variety of scenarios which you can enact to help shore up your bug-out skills. You have to try and work through a scenario from start to finish taking notes on the way about what you can improve.

Scenario 1	Invading foreign forces have taken over multiple cities near you and are heading towards your town. They will be on your position within 12 hours.
Scenario 2	It's been raining for days and flood waters are approaching the level of your house. Flood waters are currently 15m below the elevation of your house (ground floor) but in 24 hours it is forecast to be 5m over the elevation of your house. Act as if the low lying roads before 15m of your house are flooded.
Scenario 3	

Post-Rehearsal

After the simulation is complete, you should take the notes you've written including the thoughts and ideas from other party members and improve your bug in/out plan for next time. If you realize you didn't have an epi-pen for an anaphylactic shock during the simulation then add one to your kit somewhere and ensure it's in date. The goal is to keep improving (even a little) every practise run until there's nothing else you need to add or subtract. Although there will always be new skills you can learn.

Party Questions	These are questions you can ask your party about their thoughts on the simulation to improve it for next time.	• How did you find the simulation overall? • What did you most enjoy about it? • What did you least like about it? • Do you think the simulation was an accurate representation of what could happen? • What could you have done better next time? • Do you like the current disaster plan?

7 Assessing Vulnerabilities

You're bound to have at least one weakness in your preparedness plan or preps. This section will shore up those weaknesses so one small mistake won't leave you stranded. Risk management involves taking into consideration the likelihood of any risks coupled with the damage the risk will deal if it occurs.

Gear Vulnerability

Your gear or types of gear that might have adverse affects.

Consumable Gear	You have a limited supply of consumable gear such as one use glowsticks. You should have calculated how many consumables are required to reach your destination plus 15% as a general rule.
Broken Gear	Gear may break with use or on the way to your destination. Check the state of your BOB gear every month in case an item has accidentally been broken or crushed during storage. You should have a redundancy or partial redundancy for all gear in your bag, so if something breaks on the way there's another item that can take its place even temporarily.
Spoilable Gear	Some gear may be already spoiled by the time you open it such as canned food or freeze dried food. Take into account items that go off and have an extra 30% spare for edibles such as food and water.
Electricity	You can't depend on electricity in a disaster as it would likely to be the first amenity to be taken out. Therefore you shouldn't entirely depend on your electronics such as your mobile, GPS or torch, particularly if you have no way of generating your own electricity. Not to mention that in an extended disaster, rechargeable batteries could reach their end of life before civilization returns to normal and you can't exactly replace the battery in a phone yourself even if you had a spare.
EMPs	Electronics have the potential to be rendered useless by an EMP, therefore you should always have a way to perform the same function which isn't reliant on that device. An example is having physical maps and a compass instead of using a mobile device and if possible - having a way of communicating distances without electricity such as semaphore.

Environmental Vulnerability

Your location could be your biggest vulnerability, such as having an active volcano nearby or you might be living on a tectonic plate.

Location	Living in a precarious location such as on a fault line only increases the likelihood of a disaster. As preppers it's recommended to live in a stable environment where the fewest disasters are likely to happen.
Climate	A harsh climate will make it much more difficult to reach an end destination. However the flip side is that few people will want to actively live in a harsh climate such as the arctic or a desert so you'll have less threat of people.
Creatures	Some locations have a higher than normal percentage of dangerous creatures such as Australia. It may be best to avoid these places as it falls under the same considerations as avoiding potential natural disasters.

Medical Vulnerability

Any known medically related issues that might affect your disaster plans.

Health Conditions	Some people in your party could have a health condition ranging from minor such as hay fever to diabetes which requires constant medication. Your bug out plans should take all conditions into account no matter how minor as even something as hay fever could be dangerous if your route goes past huge fields of flowers.
Accessibility	If one of your party is confined to a wheelchair or temporary crutches you may need special equipment or alternative plans to bug out safely. Be sure to account for any situations that may arise when they happen such as the broken leg of your primary bug out driver.

Team Vulnerability

Any problems that may arise with your family or bug out party.

Age	Very young or old party members won't have as much stamina or flexibility as the others in the party and may need special requirements. You're only as strong as your weakest member so make sure they are able to keep up with everyone else.
Complaints	Any complaints from other people in the party, but particularly children who aren't used to a sudden change in lifestyle. Have a method to deal with restless kids whether it's music, activities or games. Complaints by adults are harder to address as you may have justified reasons why you can't solve it straight away, this causes them to grow more discontent over time which may spread to other party members.
Betrayal	Some members of your party may choose to desert you due to poor leadership or just a change in heart. It's important to keep the loyalty of your party members or a mutiny could happen which may leave you without anything. Be sure to address concerns from party members before they become a big issue. You should know each party member intimately and have a unique relationship with each one. If possible - have an insider mole who you trust completely and will tell you any news that people are gossiping about behind your back.

Unexpected Vulnerabilities

These are vulnerabilities to your party which you cannot realistically foresee or predict. They can range from minor to catastrophic. You may be preparing for an asteroid to hit within 1,000 kms (621 mi) of your area, but you would never expect it to actually hit your house directly. This is an extreme example of the unexpected. Another example would be a 20-something party member with no history of medical problems suddenly have a major heart attack.

Management	You can't risk manage what you don't expect to happen, therefore as preppers it's best to prepare both for bugging in and out for as wide a range of scenarios as possible.

Risk Management

The sections below will help you identify, categorise and mitigate any risks that you may have relating to disasters or bugging in/out.

Managing Risks	The following is a guide on how you can gauge the approximate impact of any risks you may encounter. **1.** Make a list of every risk that you can think of relating to your bug out plan. Use a list instead of a table, but if you want draw up a table to help visualise their severity. **2.** Try to gauge the chance and the impact they will each have on your bug out plan. **3.** Calculate the severity of each risk by adding the probability chance with the impact chance. Probability No. + Impact No. = Severity **4.** Order them by the calculated severity. **5.** Work on a risk mitigation plan (explained further below) which will either reduce the severity or the chance of the risk. Work on the highest severity first.

Risk Impact

The below chart is a risk impact analysis of any risks you deem probable of occurring during a bug in/out.	**Risk Probability** The risk probability is the chance the risk has of occurring.	**Risk Impact** The risk impact is how much damage the risk will inflict if it occurs.

You first assign a probability of occurrence of the risk between 1-10 then determine the impact of the risk between 1-10 then find the risk impact from the chart. When you have the risk impact level you should take the necessary actions to mitigate or reduce the chance that rick occurs. It is not considered a risk if an event has a 0% or 100% chance of occurring. But the number range is there to cover all numbers such as 0.01% and 99.99% chances. If you create a table similar to the one below you can add as many vertical or horizontal cells as you like such as going up in 10%'s instead of 20%'s.

Risk Probability #5 (80-100% Chance)	**(6) Moderate Risk** Example: The chance of an earthquake between magnitude 3.0-4.0 in New Zealand in a week.	**(7) High Risk** Example: Your home is in a floodplain and will flood if there's a significant downpour.	**(8) Very High Risk** Example: An earthquake in the ocean triggered a tsunami, it's very likely to reach you but you don't know how big the wave will be.	**(9) Extreme Risk** Example: Multiple large economic bubbles and extremely low interest rates which could cause a recession or depression.	**(10) Catastrophic Risk** Example: A scientifically calculated high chance of an asteroid hitting earth which could wipe out life on a continent.
Risk Probability #4 (60-80% Chance)	**(5) Fair Risk** Example: Risk of house damage during a hail storm.	**(6) Moderate Risk** Example: The chance of an earthquake between magnitude 4.0-5.0 in New Zealand in a month.	**(7) High Risk** Example: Chance that you won't be able to reach your BOL in your vehicle - such as multiple downed trees.	**(8) Very High Risk** Example: Chance that you slip off the road, crash or have a medical emergency on the way to your BOL during a disaster.	**(9) Extreme Risk** Example: Very high tensions in a region which could lead to a war.
Risk Probability #3 (40-60% Chance)	**(4) Very Low Risk** Example: A storm front or tropical low which could head towards your location.	**(5) Fair Risk** Example: A meandering category 1-2 cyclone which could head towards your location.	**(6) Moderate Risk** Example: The chance of an earthquake between magnitude 5.0-6.0 in New Zealand in a year.	**(7) High Risk** Example: A meandering category 3-4 cyclone which could head towards your location.	**(8) Very High Risk** Example: A meandering category 5+ cyclone which could head towards your location.
Risk Probability #2 (20-40% Chance)	**(3) Tiny Risk** Example: Chance you forgot to pack something in your BOB you'll need later.	**(4) Very Low Risk** Example: Risk of your knife breaking within the first year of bugging out.	**(5) Fair Risk** Example: Not being able to get to your BOB during a disaster.	**(6) Moderate Risk** Example: A fault line under a major city which has a chance of a magnitude 6.0-7.0 earthquake every year.	**(7) High Risk** Example: A home invasion occurring during times of extreme hardship, riots or war.

Risk Probability #1 (0-20% Chance)	(2) Miniscule Risk Example: Your shoelace coming undone and causing you to trip.	(3) Tiny Risk Example: Chance of lightning hitting your house and knocking out your power.	(4) Very Low Risk Example: Having a car accident on the way to your bug-out location.	(5) Fair Risk Example: Chance your bug out location will be in pristine condition when you reach it.	(6) Moderate Risk Example: A fault line under a major city which has a chance of a magnitude 7.0-8.0 earthquake every year.
	Risk Impact #1 Miniscule Impact A low impact level with little damage if it occurs.	**Risk Impact #2** Low Impact Inflicts a small amount of damage if it occurs.	**Risk Impact #3** Moderate Impact A moderate impact risk will cause a fair impact on you if it occurs.	**Risk Impact #4** High Impact Inflicts substantial damage if this risk occurs.	**Risk Impact #5** Catastrophic Impact A catastrophic impact risk will cause utter devastation if it occurs.

Risk Mitigation

Ways to reduce the effects or the chance of the risk occurring. To mitigate risks you can either reduce the probability or impact of the risk or eliminate the risk completely.

Risk Acceptance	Risk acceptance does not reduce any effects however it is still considered a strategy. This strategy is a common option when the cost of other risk management options such as avoidance or limitation may outweigh the cost of the risk itself.
Risk Avoidance	Risk avoidance is the opposite of risk acceptance. It is the action that avoids any exposure to the risk whatsoever. It's important to note that risk avoidance is usually the most expensive of all risk mitigation options.
Risk Limitation	This strategy limits a company's exposure by taking some action. It is a strategy employing a bit of risk acceptance along with a bit of risk avoidance or an average of both.
Risk Transference	Risk transference is the involvement of handing risk off to a willing third party.
Watch/Monitor	Monitor the environment for changes that affect the nature and/or the impact of the risk.
Reduce Probability	Try to reduce the probability of a risk occurring. A simple example is tying your shoelaces if they are loose to help prevent you tripping. Another example is moving away from a fault line if you live near one.
Reduce Impact	Reduce the impact of a risk by taking steps to prepare for more eventualities. For example you can install roller-shutters on every window of your house to help prevent damage from attacks, hurricanes and hail. You may get some dents, but it's better than shattered windows.
Eliminate Risk	If you have the ability to - you should eliminate risks entirely. For example if there's a risk of not being able to reach your bug-out shelter due to flooding, perhaps you should live in your bug-out location permanently. If you're concerned about tsunamis you should move at least 32km (20 mi) inland where it's almost impossible for a regular sized tsunami to reach you.

8 Situation Monitoring

Without monitoring media and news outlets you won't know what's happening in the world. It's vital to keep up to date with the news and be able to separate the facts from fiction.

Internet	Social media can spread the message pretty fast about impending disasters without any bias that the media has today. You can set keywords on news websites to notify you when certain events happen near you or when a global event takes off.
Friends & Family	The more people in your prepping party that are watching for disasters and keeping an eye on the situation can provide multiple failsafe's if one person doesn't check the news for a few hours. Everyone can ring each other and keep them all informed about a worsening situation and keep in close contact when the time to come has to bug in or bug out.
The Media	There is little (if any) unbiased media today, everyone has their own slant on information which is aimed at getting you to feel, react a or spend your money a certain way. Tv has its place, but it's better to research information yourself, from many different sources to be sure you're getting the truth. For more information on media corruption see the MEDIA section.
Government Organizations	You can sometimes opt into getting text updates to natural disasters or other events that happen in cities. These can be very helpful as you get the information straight from the source such as the weather bureau. It's not always best to trust the government whole-heartedly though.
Government Institutes	Governments will attempt to control all sensitive news released with an impact to the public and will threaten heavy fines or jail time for any media outlet that doesn't comply with these demands. Generally their main aim is to avoid a mass panic and exodus of people which will make it nearly impossible for them and other government agencies such as the police to do their jobs. They typically only look at the big picture and take action to avoid the most causalities from an event by downplaying the news even if that means a small group of people dying,

Monitoring Websites

These are useful websites to help you track and monitor the disasters around the world, whether it's volcanoes, the stock market, hurricanes, tsunamis, earthquakes and more. To have the best chance to reach your bug-out destination before the rest of the population finds out you should be constantly monitoring most of these websites. For a list of other preparedness resources, head to the ADDENDUM > Media section.

Global Monitoring & News Sites

Global Monitoring & News Sites

Emergency and Disaster Information Service	A worldwide map displaying notable disasters and emergencies around the world. ***https://rsoe-edis.org/***
AccuWeather Severe Weather	Shows the different types of severe weather such as flooding, avalanches and fires currently occurring around the world. ***https://www.accuweather.com/en/au/severe-weather***
Prepper News	A prepper news website with topics sorted into different categories to make it easier to find what you need. ***https://www.prepperwebsite.com/***
Zero Hedge	An economic news website dedicated to providing uncensored content, with a focus on the economy. ***https://www.zerohedge.com/***
Summit News	A site providing global uncensored news. **https://summit.news/**
McAlvany Intelligence Advisor	*"Our mission is to awaken, equip and mobilize multiple generations with an absolute objective truth-grid in the digital information age and empower you to prosper in ever-changing geopolitical, cultural and financial ecosystems. With over four decades of battle-tested experience, we know the ropes of gathering and delivering timely global intel."* ***https://www.mcalvanyintelligenceadvisor.com/***

Weather

Weather Maps

Windy	An invaluable website which displays: ● Worldwide Weather Radar ● Worldwide Satellite Weather View ● Worldwide Wind ● Worldwide Rain and Thunder ● Worldwide Temperature ● Worldwide Cloud Cover ● Worldwide Waves ● Worldwide Air Quality ***https://www.windy.com/***
Nullschool	A website very similar to windy.com with a few less features. It shows information on wind, water and ocean conditions. ***https://earth.nullschool.net/***

Earthquakes

Earthquake Maps

Earthquake 3D	A 3D live feed of the earthquakes occurring around the planet. You can also buy and download a much higher quality version with more features from their website. ***http://www.earthquake3d.com/***
Earthquakes USGS	A 2D live world map showing the current earthquakes. USA website. ***https://earthquake.usgs.gov/earthquakes/map/***
USGS Significant Earthquakes	A list of the most recent significant earthquakes. ***https://earthquake.usgs.gov/earthquakes/browse/significant.php***
EMSC Latest Earthquakes Worldwide	A list of the latest earthquakes worldwide. ***https://www.emsc-csem.org/Earthquake/world/***
EMSC Significant Earthquakes	A list of the latest significant earthquakes. ***https://www.emsc-csem.org/Earthquake/significant_earthquakes.php***
Earthquakes@GA	A 2D live world map showing the current earthquakes. Australian website. ***https://earthquakes.ga.gov.au/***

Active Volcanos

Current

Volcano Discovery Erupting Volcanoes	Daily updated map of currently erupting and restless volcanoes. ***https://www.volcanodiscovery.com/erupting_volcanoes.html***
Volcano Discovery	Shows the active volcanoes around the world with last eruption dates. ***https://www.volcanodiscovery.com/volcanoes/today.html***

Buoys & Tsunamis

National Data Buoy Centre	Shows the buoys around the oceans on an interactive map. They flash when they go into "Event Mode" when a change in the median wave height is detected. It is useful to track tsunamis, storm surges and other water based events. ***https://www.ndbc.noaa.gov/***

Hurricanes & Cyclones

Hurricane

National Hurricane Centre	Shows any current hurricanes around the United States only. ***https://www.nhc.noaa.gov/***
AccuWeather Hurricanes	Shows any current hurricanes & cyclones around the world. ***https://www.accuweather.com/en/hurricane***

9 Zero Hour

Zero Hour signifies an unknown date and time that a disaster worthy of preparedness action occurs. You could be anywhere when 'zero hour' strikes and your primary objective from then on is to reach your preps and gather your party together and then decide how you should proceed.

An example of zero hour is the second you hear about a nuclear exchange in your country.

Bug In or Out
When an incident occurs weigh the benefits of bugging in and out and whether it will get harder to travel as time progresses or not.

Be Ready
When the situation arises to bug out, you should be ready to grab the bags and go with enough food you will need to survive the disaster.

Be Aware
You want to be one of the first people to realize the gravity of the disaster and leave long before anyone else considers it or the roads will be parking lots.

Contact	When you first hear about a disaster that is or will affect you, the immediate action taken would be to contact your family and others whom you will meet up with. Whoever hears about the disaster first and contacts the others in the party, will give the others more time to prepare to leave work or meet up at the rendezvous point earlier. Confirm the plans you have with everyone on the phone and where they are currently as they may need assistance getting to the rendezvous point. If your family is at home already get them to start packing the car and be ready when the last person shows up. If no communications is available such as during an EMP you should follow through with the plan you set up prior to the event.
Returning Home	If you're away from your preps the first thing you'll want to do is return to a rendezvous point where your companions or family will meet up. You may not have an available mode of transport for returning home therefore you may have to walk home.
Step 1 Communicate	Communicate with your family or bug out partners if possible and tell them what's happening and to set in motion one of the plans based on the scenario. Try to use code such as: Location X or Location Delta as there's always the chance that people are listening in, or some who will ambush you there. Include what to do if communications are down such as returning home and packing the car ready. **Possibilities** ● Communication Works ● Communications Down ● Everyone is Together
Step 2 Rendezvous Point	The location you will meet if a disaster occurs. It should include an estimated timeframe of when you should expect to meet after a disaster occurs if communications are down.
Step 3 Gear Grab	Your gear is basically essential to grab before you bug out. The only reason you wouldn't is if it's already packed, you can't safely reach it or you are more likely to die trying to retrieve it. You should have your gear pre-packed in a secure, easily accessible location so you can grab it as quickly as possible.
Step 4 Depart	Set out on your selected bug-out route with your party members. If you forget anything after you leave you shouldn't return for it unless it's essential to your survival.

Considerations

Bug-In or Bug-Out	When you reach home, deciding to bug out or not can be a critical decision to make, especially in times of hardship. Hopefully at the end of this section you can make a sound decision whether you should or not. The list below are considerations you should take into account before deciding what to do. Generally you want to Bug-In as this is where all your supplies often are.
Disaster Type (Instant/Snowballing)	Whether the disaster is instant with few warning signs like an Earthquake, EMP or a Terrorist Attack, or takes a while to build or arrive such as a Hurricane, Economic Crash or Pandemic.

Instant
If the disaster is instant there would likely be more frantic people around grabbing food off the shelves and buying up critical survival items. The roads are more likely to be clogged by people trying to get out of town. The situation could get out of hand much faster than a snowballing disaster. There's often little to no time at all to bug out, as the damage is already done and you may not reach your destination. Generally it's recommended to bug-in unless you know the roads are clear to your BOL and you know things will get worse.

Snowballing
A snowballing disaster is one that progressively gets worse, just as a snowball rolling down a snowy hill will gain size and momentum. The earlier you bug out in a snowballing event, the better the chances you will reach your destination before everyone realizes and tries to leave. These disasters are harder to predict but generally tend to worsen over time. It's better to have bugged out when you didn't need to then have stayed when you should have left.

Disaster Duration

Below is the estimated durations of different disasters. This is the time until the damaging elements have subsided such as strong winds, falling ash, flames and viruses. Be warned that natural disasters may create new disasters such as riots, looting, etc, which need to be accounted for. The disaster should end when it's safe to return to your house or restart your previous life with minimal threat to your life. It's recommended to bug out in disasters with a short life such as tornadoes and severe thunderstorms as well as extremely long lasting disasters such as pandemics. You should also bug out in moderate lasting disasters such as wars and floods.

	0-2 Hours	2-12 Hours	12-24 Hours	1 Day	2-3 Days	4-7 Days	7-14 Days	14-31 Days	31-91 Days	91-182 Days	182-365 Days+
Avalanches / Landslides	0-2 Hours to 2-3 Days										
Earthquakes	0-2 Hours to 7-14 Days										
Sinkholes	0-2 Hours to 2-3 Days										

Volcanic Eruptions			12-24 Hours to 4-7 Days								
Floods	0-2 Hours to 14-31 Days										
Limnic Eruptions	0-2 Hours to 4-7 Days										
Tsunami	0-2 Hours to 2-3 Days										
Blizzards	0-2 Hours to 7-14 Days										
Cyclonic Storms				1 Day to 14-31 Days							
Droughts									31-91 Days to 182-365+ Days		
Thunderstorms	0-2 Hours to 12-24 Hours										
Hailstorms	0-2 Hours										
Heat Waves						4-7 Days to 182-365 Days+					
Tornadoes	0-2 Hours										
Wildfires	0-2 Hours to 7-14 Days										
Meteor / Airbursts	0-2 Hours to 14-31 Days										
Solar Flares / EMPs	0-2 Hours to 182-365+ Days										
Pandemics									31-91 Days to 91-365+ Days		
Civil Wars							7 Days to 91-365+ Days				
World Wars							7 Days to 182-365+ Days				
Economic Crashes							7 Days to 182-365+ Days				

Disaster Scale

The scale of the disaster is another consideration to take into account. Will the situation be just as bad at your BOL or will it be better? Below are the three categories of scale for disasters and how they affect people.

Local	Local disasters are based within a small area up to a whole state and aren't nearly as threatening as worldwide disasters as you still have the option to get external assistance from other states and countries. Generally after a local disaster occurs things tend to get better slowly. Some local disasters can create national disasters over time such as pandemics which can spread interstate and overseas fairly easily. During a local disaster it's typically best to bug out to get out of the immediate disaster zone.
National	National disasters affect an entire country and cause much more chaos. Disasters such as economic crashes, pandemics, civil war, and some hurricanes can cause them. Although these types of disasters are much larger than local ones, the country can usually still receive aid from external ones. Generally the government will assist the people as best it can however they could also declare martial law and suppress the rights of the people.
Global	If a worldwide disaster occurs, people around the world would be catatonic and there won't be help coming from other nations. It would be best to take your safety into your own hands then leave it in the hands of a government who may or may not show up, as they have bigger priorities - they may even become a preppers enemy and try to take your resources by force. Generally it would take a much longer time for this scale of disaster to equalize, which could turn into years or decades for some disasters.

Disaster Damage

There is typically damage when a disaster occurs from looting to natural disaster damage which should be taken into consideration. It is required to calculate whether you can make it to your destination or there's likely to be blockages. This row is similar to the earthquake and hurricane destruction scales.

Damage Scale 1	No damage. Disasters such as pandemics where barely any physical damage is done in the early days.
Damage Scale 2	Very light damage such as pushed over pots, loose tiles and leaves/twigs on the road.
Damage Scale 3	Light damage, roads may be shut.
Damage Scale 4	Fair damage such as small branches on roads, tipped over bins, minor looting damage.
Damage Scale 5	Moderate damage to buildings, roads and the environment. some trees may be down across roads, power lines down, snow and ice on the road.
Damage Scale 6	Trees down, power poles down, buildings could be looted, inches of snow and cars smashed. Generally this is the highest you would want to go when bugging out with a fair chance of reaching your destination.
Damage Scale 7	Considerable building damage, broken windows, rolled cars, many trees down, thick snow, collapsed walls.
Damage Scale 8	Vast damage, roofs lifted, walls collapsing, shattered glass, flipped cars, electrical poles down, very deep snow.
Damage Scale 9	Extreme damage to houses, roofs fly off, walls collapse, most trees uprooted, trash everywhere.
Damage Scale 10	Unfathomable damage to everything, roads would be blocked, most buildings would be destroyed, trees uprooted and almost nothing would be standing. If you survived and have shelter still bug-in is recommended.

Disaster Proximity

PREPAREDNESS | Zero Hour | Considerations | Disaster Proximity

How close you are to the epicentre if there is one, such as a VEI-8 volcano or a magnitude 8+ earthquake.
Ignore this question if there's no point of origin or you're equally likely to be affected by it wherever you are such as a solar flare.

10,000-20,000km	A large scale disaster has occurred on the other side of the planet. Recommend monitoring the situation.
7,000-10,000km	A large scale disaster has occurred extremely far away. Recommend monitoring the situation.
4,000-7,000km	A large scale disaster has occurred very away. Recommend monitoring the situation.
2,000-4,000km	A large scale disaster has occurred quite far away. Recommend monitoring the situation. Stock up on additional supplies before panic spreads.
1,000-2,000km	A large scale disaster has occurred some distance away. Recommend monitoring the situation. Stock up on additional supplies before panic spreads.
500-1,000km	A large scale disaster has occurred somewhat close to your area. Recommend monitoring the situation and bugging out if it gets worse. Stock up on additional supplies before panic spreads.
250-500km	A large scale disaster has occurred nearby to your area. Recommend monitoring the situation and bugging out if it gets worse and you're more likely to die if you stay where you are. Stock up on additional supplies before panic spreads.
100-250km	A large scale disaster has occurred very close to your area. Recommend bugging out if your life is at risk if you stay.
50-100km	A large scale disaster has occurred extremely close to your area. Recommend bugging out immediately if your life is at risk if you stay.
0-50km	A large scale disaster has occurred to your area. Recommend bugging out immediately if your life is at risk if you stay.

Bug-Out Risks

Ask yourself: Are there any risks with bugging out? Such as virus particles in the air, gangs roaming the streets or strong winds. The percent is the chance you will die on the way to the BOL.

Risk Level 1	**0-10% of Dying** (Almost) No risk, it's a perfectly sunny day and the birds and chirping.
Risk Level 2	**10-20% of Dying** Minor risks to personal safety such as looters, gangs and minor weather anomalies.
Risk Level 3	**20-30% of Dying** Fair risk to personal safety along your route such as marauders, gangs, virulent particles,
Risk Level 4	**30-40% of Dying** Low Moderate risk to personal safety along your route such as flooding, forest fires, insane gangs, looters, power lines and falling trees.
Risk Level 5	**40-50% of Dying** Moderate risk to personal safety along your route such as flooding, forest fires, insane gangs, looters, power lines and falling trees.
Risk Level 6	**50-60% of Dying** Moderate High to personal safety along your route such as looters, gangs and weather anomalies. It's advised to bug out if this level is reached unless the risk of bugging out is higher.
Risk Level 7	**60-70% of Dying** High risk to personal safety along your route such as looters, gangs and weather anomalies.
Risk Level 8	**70-80% of Dying** Very High risk to personal safety along your route such as violent looters and gangs going door to door, huge forest fires, rising floodwaters or a smouldering volcano.
Risk Level 9	**80-90% of Dying** Extreme risks to personal safety along your route such as flooding, radiation, volcanic eruption, street violence, bush fires and nuclear blasts.
Risk Level 10	**90-100% of Dying** Unfathomable risk, if you step outside you will almost surely die from viruses, gangs, strong winds, radiation, being shot etc. Also you are probably very likely to die inside your home as well.

Bug-In Risks

Ask yourself: Are there any risks with bugging in? Such as armed looters roaming the streets who could come door kicking, extreme winds, lava flows, tsunamis. The percent is the chance you will die staying in your house.

Risk Level 1	**0-10% of Dying** (Almost) No risk, it's a perfectly sunny day and the birds are chirping.
Risk Level 2	**10-20% of Dying** Minor risk to personal safety such as looters, gangs and minor weather anomalies.
Risk Level 3	**20-30% of Dying** Fair risk to personal safety such as looters, aftershocks, gangs and minor weather anomalies.
Risk Level 4	**30-40% of Dying** Low Moderate risk to personal safety such as looters, aftershocks, gangs and minor weather anomalies.

Risk Level 5	**40-50% of Dying** Moderate risk to personal safety such as looters, gangs and weather anomalies.
Risk Level 6	**50-60% of Dying** Moderate High risk to personal safety such as looters, gangs and weather anomalies. It's advised to bug out if this level is reached unless the risk of bugging out is higher.
Risk Level 7	**60-70% of Dying** High risk to personal safety such as looters, gangs and weather anomalies.
Risk Level 8	**70-80% of Dying** Very High risk to personal safety such as violent looters and gangs going door to door, huge forest fires, rising floodwaters or a smouldering volcano.
Risk Level 9	**80-90% of Dying** Extreme risks such as flooding, radiation, volcanic eruption, street violence, bush fires and nuclear blasts.
Risk Level 10	**90-100% of Dying** Unfathomable risk, you are almost guaranteed to die if you stay where you are from hurricanes, lava flows, radiation, rising floodwater, etc.

Weather

The weather will play a key role in your decision to bug in our bug out, clear weather provides an optimum environment to leave whereas disastrous weather will prove impossible to travel anywhere fast.

Weather Level 1	Clear weather, not a cloud in the sky. This is generally the optimum weather for bugging out.
Weather Level 2	A from 25% to 75% overcast, but overall it's still a great day.
Weather Level 3	A completely overcast day. This may be the best time to bug out in hot climates.
Weather Level 4	Consistent, Light rain is falling.
Weather Level 5	Consistent, Moderate rain.
Weather Level 6	Consistent, Heavy Rain. It may also be accompanied by a small thunderstorm. If you're after a stealthy bug-out, this is the optimum weather to leave in.
Weather Level 7	A severe thunderstorm coupled with heavy rain. It's highly recommended to bug-in at this point.
Weather Level 8	A category 1 Cyclone/Hurricane is very close to your position. It's recommended to bug-in at this point.
Weather Level 9	A category 3 Cyclone/Hurricane is very close to your position. It's highly recommended to bug-in at this point.
Weather Level 10	A category 5 Cyclone/Hurricane is very close to your position. It's definitely recommended to bug-in at this point.

Exposure Risk

How exposed you are to the elements.

Bunkered	You're safe and sound in a nuclear bunker underground somewhere and wouldn't be able to tell if a bomb went off nearby.
Protected	You're holding up in a reinforced building like a bank or mall which should withstand a cat 5 storm.
Sheltered	You're protected in a typical first-world home or building of similar construction.
Shielded	You're partially shielded by a small or weak building such as a park shelter, bus stop cove or a bridge.
Exposed	You're out in the open with no man-made cover besides what nature can provide.

Panic Level

The panic level is the level is desperation of those caught in a disaster. The higher the panic - the more chaotic the environment and the faster it will spiral out of control. As a prepper you should be keeping an eye out on the current panic level in your local area. If it gets too high (3+), you should act on it. Panic levels can be categorised by a lack of (or a perceived lack of) the essentials needed to live a normal lifestyle.

This is drawn upon on the ratings below. Below is a scale of the panic ratings an ordinary member of the public is likely to experience during hardship. The panic levels below are the average level of panic among local residents. Some may be more panicked and some may be less panicked. The panic level only applies to a mass panic relating to a disaster and doesn't apply to an individual crisis. The deviation is the percentage of how far society has deviated from its 'norms', with 0% being life as normal and 100% being EVERYONE is in survival mode.

Panic Level	Panic Ratings	Examples	Deviation	Resource Lack	Scarcity Signs
0	Business as usual. Nothing is out of the ordinary and the world's problems couldn't be further away. If there is a disaster - they are oblivious to it.	Business as usual	0%	People generally have everything they need to survive comfortably.	• Normal Life
1	An insignificant problem occurring nearby but little thought is given to it. People believe they can cope with this minor event.	A string of robberies in a distant city.	10%	People may be slightly inconvenienced by a lack of high level resources such as internet.	• No Internet • No Communications • Vast Wealth Movements • Minor Media Coverage
2	A few people such as preppers begin to comprehend the disaster and decide what action to take. Other people are in denial that anything could happen to them. People may buy a few items to balance the current situation such as candles.	A breakout of a contagious flu in your local area.	20%	People may be experiencing uncommon, but not an unusual lack of essentials like electricity.	Previous Plus: • No Electricity • Minor Media Coverage

3	This is the extent of the "normal panic" that is experienced by unprepared individuals. They will begin to worry about the disaster but may only take small actions to prepare for it.	A murderer killing weekly in a local town.	30%	People are under threat of losing their home and normality of their current lifestyle. They are under threat of losing some non-critical resources such as electricity, gas and fuel.	Previous Plus: ● Market Correction ● Moderate Media Coverage
4	Unprepared individuals begin stocking up on resources to brace for a disaster. They are fairly sure of the odds of impending doom. Some people are desperate enough to eat and drink they could start fights over resources.	A breakout of a contagious flu in an entire state or country.	40%	People are lacking or are under threat of losing some non-critical resources such as electricity, gas and fuel.	Previous Plus: ● Market Recession ● Job Cuts ● High Media Coverage
5	Everyone is quite panicked about the disaster but they are still living the same lifestyle and going to work.	A worldwide pandemic with cases detected in your local city.	50%	People's current lifestyles are revolving around protecting and stocking up on vital resources while they continue working with the loom of the threat in their mind daily.	Previous Plus: ● Market Recession ● Shops Closed ● Restricted Bank Access ● High Media Coverage
6	At this stage people may not (or can't) go to work, they are trying to prepare and stock up on all the resources they can.	Businesses begin closing, shops start to go bare.	60%	People are lacking or are under threat of losing some important resources for survival such as shelter, food and water.	Previous Plus: ● Fights over food and water in shops ● Job Scarcity ● Market Depression ● Shelter ● Banks Closed ● Excessive Media Coverage
7	Many people have left their jobs and are preparing for the disaster. They may develop plans to escape but by now the roads are completely blocked.	A large hurricane is bearing down on a town.	70%	People are lacking or are under threat of losing many important resources for survival such as shelter, food and water.	Previous Plus: ● Fights over food and water in shops ● Excessive Media Coverage
8	People are almost all exclusively focused on the disaster and most of them have suspended their old lifestyles and jobs to ensure their survival.	A virus is spreading rapidly across the globe with a high kill rate and late onset of symptoms.	80%	People are lacking some critical resources for survival such as shelter, food and water.	Previous Plus: ● Increased attacks, violence and murders ● Fights over food and water in streets ● Excessive Media Coverage
9	People are acting insane and finding food and water is their prime driving force. They would do almost anything to get what they need. Media stations are either ransacked or not watched due to no electricity.	Almost complete breakdown of society with only a very few number of people going about their normal business.	90%	People are lacking many critical resources for survival such as shelter, food and water.	Previous Plus: ● Fights over food and water in homes ● Little/No Media
10	A panic level where people would literally do anything to ensure the continued survival of themselves and their family. This level generally only occurs after a huge nationwide or worldwide disaster.	Complete breakdown of society, nobody working, shops bare or closed down. Stock Market Crash.	100%	People are lacking all critical resources for survival such as shelter, food and water.	Previous Plus: ● Fights over all food and water ● Consistent attacks, violence and murders ● No Media

Bug Out Flowchart

This is the bug out flowchart designed to assist you in making a decision whether to bug in our out in a disaster. When you get to a question, answer truthfully and follow the arrow to the next question or resolution. Blue Cells are questions. Grey cells summarise your last decision. Green cells are recommended actions of your choices. Start at Cell 6:6.

It is assumed that you're a prepper and have a BOB, INCH and GH Bags as well as a stockpile of food and water in your primary residence. The ultimate aim is to keep you and your family alive at all costs irrelevant of money, location or disaster type. You've had experience bugging out and have had trial runs to your destination in all sorts of weather.

Legend	The following cells are a legend to the diagram below. Each colour represents a different type of cell to assist in readability.	Dark blue represents the starting cell. There is only one of these.	**Response** Grey is a response to a question asked by other cells and usually provides more information about it.	**Questions** Light blue cells are questions to refine your situation further.	**Resolution** Green cells are ends to the diagram and will provide you with a recommendation on what you should do in your situation.

	Column 1	Column 2	Column 3	Column 4	Column 5	Column 6	Column 7	Column 8	Column 9	Column 10	Column 11
Row 1	**Stay** You should stay inside your house until the disaster has passed, boarding up the windows monitoring the surroundings and news for updates, rationing food and designating a reinforced room as a bunker with mattresses in it.	**Yes** I have the skills to grow, hunt, forage and fish for the food I need which still can be found in the environment. ▶	**Question 6** Do you know any family, friends, or government shelters you can stay at away from the general population who are better off than yourself? ▼▶	**Yes** I have friends or family nearby who are better off and have resources we can use. ▶	**Leave** Bug out and head for their house taking as many resources as you can with you to assist.						
Row 2	**No** I don't have the skills to support my group and live off the land, or the natural wildlife could be dead or hunted out already. ▲	**Question 5** Are there natural resources left around your home and do you possess the skills to live off the land and support your group by doing so? ◀▲	**No** I don't have family accessible nearby who are better off than us. ▼		**No** You should stay inside your house until the disaster has passed, boarding up the windows monitoring the surroundings and news for updates, rationing food and designating a reinforced room as a bunker with mattresses in it.	**Question 5** Is your house in a built-up area? ◀▲	**No** I can't leave the country for the duration of the disaster. ◀	**Question 4** Can you leave the country for the duration of the disaster? ◀▶	**Yes** You should take what you can and leave the country before things get worse, but only if the disaster is confined to your country.		
Row 3		**No** I don't have a Bug Out Location or I can't reach it safely. ▲	**Bug-In Temporarily** You should bug in until it's safe to leave for a destination with ample resources you can survive on. Monitor the situation.					**No** You don't have a BOL. ▲		**Stay** You're more likely to stay alive if you stay indoors away from the threats. Board up the windows and monitor the surroundings and news for updates, rationing food and designating a reinforced room as a bunker	
Row 4	**Yes** You should bug out to your destination shelter which should be in a remote part of the country with food and water access until the threat is well over.	**Question 4** Do you have a BOL far from civilization with ample food water and other supplies stocked inside? ◀▲	**Leave** You are more likely to survive if you left the house. ◀	**Question 3** Are you more likely to survive if you stay in your house or leave for an alternate destination? ◀▼	**Currently Underway** The disaster is well underway and people are panicking and stripping the shelves. You can't leave the country due to panic. ◀	**Question 2** What stage is this disaster in? Is it an imminent threat or is it currently well underway? ◀▶	**Imminent Threat** The disaster is a possible threat, but people generally aren't panicked yet. ▶	**Question 3** Do you have a BOL far from civilization and threats with food, water and other supplies stocked inside? ▲▶	**Yes** You should bug out to your destination shelter which should be in a remote part of the country with food and water access until the threat is well over.	**Question 4** Are you more likely to survive if you stay in your house or leave for an alternate destination? Assuming you aren't trapped inside the house. ▲▶	**Leave** You are more likely to survive if you left the house. ▼
Row 5		**Degrade** The disaster is likely to worsen and cause more damage over time as people become desperate. You should bug out permanently with an INCH bag as you still have time before people get desperate or the roads become impassable.		**Stay** You should stay inside your house until the disaster has passed, boarding up the windows monitoring the surroundings and news for updates, rationing food and designating a reinforced room as a bunker with mattresses in it.		**National Scale** The disaster affects all or most of the country and could last up to 6 months. (Solar Flare, EMP, Flood, Drought / Heat, Meteorite, War, Civil War, Terrorism, Cyclone, Employee Strikes) ▲		**Yes** You should stay inside your house until the disaster has passed, boarding up the windows monitoring the surroundings and news for updates, rationing food and designating a reinforced room as a bunker with mattresses in it.	**Question 3** Do you have enough resources to survive the disaster and aftermath plus have 50% spare in your house? ◀▲	**No** You don't have enough food and water to last the disaster comfortably. ▲	**Question 5** Do you think you have enough resources to survive the disaster and aftermath plus have 50% spare in your house? ▼
Row 6	**Improve** Your best bet is to stay in your house and monitor the news hourly for updates and have your supplies ready for bug out if needed. Stock up on resources if you can now.	**Question 3** Is this disaster likely to improve or degrade over time? ◀▲	**Imminent Threat** The disaster is a possible threat, but people generally aren't panicked yet. ◀	**Question 2** What stage is this disaster in? Is it an imminent threat or is it currently well underway? ◀▼	**Global** The disaster is happening on a global or national scale and is likely to last a few months to a year or more. The threats are almost entirely other people. (Solar Flare, EMP, Peak Oil, Food Shortage, Global War, Pandemic, The Rapture, Economic Collapse, Overpopulation) ◀	**START** **(Follow the Arrows)** **Question 1** What scale of area is the disaster affecting? Local (state), national (country) or global (worldwide) ◀▲▶	**Local Scale** The disaster is local and confined to a state or two and will last a month maximum. (Tornado, Wildfires, Volcano, Avalanche, Landslide, Limnic Eruption, Blizzard, Storms, Earthquake, Tsunami, Crash / Collisions) ▶	**Question 2** Is the disaster currently happening in your area or heading your way? ▼▶	**In Progress** The disaster is currently affecting your area and causing panic and damage. ▲	**Question 3** Do you have enough resources to survive the disaster plus 50% spare at your BOL? ▼▶	**No** I don't have enough resources to last me and my family for the estimated duration of the disaster. It's recommended you still bug out to the destination and ration what you have as the risk of dying if you stay where you are outweighs the risk of leaving.
Row 7		**Secure or No Conflict** Your house is secure and you have necessary stocks ready for the long haul. Stay inside and monitor the surroundings, ration food and water.	**Question 3** Is your current location secure or can it be secured from intruders? Is armed conflict likely in your area? ◀▼	**Currently Underway** The disaster is well underway and people are panicking, stripping the shelves and becoming desperate. ◀		**(Flowchart is Currently Incomplete)**		**Heading This Way** The disaster has a high probability of hitting your home and causing major damage. ▼		**Yes** Bug out to your destination until the disaster has passed, monitoring the news for updates and return when everything has stabilized.	**Question 5** Do you have enough resources to survive the disaster plus 50% spare at your BOL? ◀▲
Row 8			**Insecure or Conflict** The house is inadequate for reinforcements and can be breached easily. Begin fortifications immediately as it's currently your best bet of staying alive. Ration food and resources as a global disaster could last many months.				**No BOL** You don't have a BOL. ▼	**Question 3** Do you have a BOL out of the disaster zone? ◀▶	**Have a BOL** I have a BOL selected with multiple routes to it and it's away from the threat. ▶	**Question 4** Will you be able to reach your destination or are there likely to be road blockages such as trees down, traffic or gangs? ▼▶	**Reachable** There will be minimal blockages on the road and should be easily accessible. ▲
Row 9							**Question 4** Do you know any family, friends, or government shelters you can stay at? ▼▶	**Yes** You have somewhere in mind you could head towards to escape the disaster. Jump to Col:10, Row:8		**Unreachable** There are very likely to be blockages or threats to the safety of the occupants. ▼	
Row 10					**No** The only advice is to get hand-outs where you can and for creating alliances with neighbours, or at the extreme end joining a gang.		**No** There's no locations you know you can stay at. ▼			**Question 5** Are you more likely to survive if you stay in your house or leave? ▼▶	**Leave** You should bug out if staying would mean your death, even if the weather outside is terrible. Take precautions and go slow avoiding main roads.
Row 11				**Yes** You should bug out and take what supplies you can with you and return once the threat is over.	**Question 6** Do you have the skills and ability to survive in the wild, by camping or living out of your vehicle until the disaster is over? ◀▲	**No** You have no money or barter items to use in emergencies. ◀	**Question 5** Do you have a stockpile of cash for emergencies that you have access to? ◀▶	**Yes** Bug out and use the money to rent a hotel in a city outside the disaster zone.		**Stay** Bug in and secure the house, designate a secure room and fortify it until the disaster has passed.	

10 Bugging In

This section begins when you reach home, during the start of a gradually increasing disaster, or after an instant one has struck in your area. It describes what actions to take and how to prepare yourself.

Contact

First the initiator of the Bug-In plan should contact everyone in the party and tell them to enact the plan you desire. An example of this would be citing "Operation El-Dorado - I@H0815RN10004". As discussed in the 'Plan Template' section above, this code would represent:

- I - Bugging In
- @H2500 - Meeting at Home at 8:15am
- RN - Route 'None' - No bug out route since we're bugging in
- 1000 - The time the party is set to leave on this trip, but since we're bugging in it would be the time when everyone should be home.
- 4 - The number of party members participating in this bug-out

The initiator of a plan can usually only be the party leader - A predefined person who leads the party. However you can discuss with the party who is able to initiate a plan, otherwise party members will have to raise their concerns with the party leader and go from there.

This stage ends with everyone knowing that the Bug-In plan has initiated.

Gather

Once you've contacted everyone or have been contacted by the party leader you need to kick it into gear and stop whatever you're doing and prepare. Wherever you are, (such as the workplace) they should grab any supplies or get home bags you have nearby and prepare to meet the rest of the party at the requested time. If the designated rendezvous (meetup) time is a few hours ahead and the trip there will only take 10 minutes, you may want to consider picking up additional supplies on the way and refuel your vehicle.

It's better to bring more gear than you need back home rather than getting there and needing to go back to pick something up. Don't take any unnecessary risks purchasing any other equipment or food you don't need, as it's better you make it to the meeting location safely than narrowly making it back with an angry tailgater, who you snatched the last can of beans from earlier.

This stage ends with every party member at the rendezvous point along with all the gear they need to Bug-In.

Fortify

Once you're at the meeting location you can begin preparing for whatever disaster may be coming. An example would be fortifying your house for the onslaught of a hurricane by covering the windows and removing loose objects from the back yard. Even if you've decided to bug in, it's always a good idea to have the car packed and ready to go in the event that the situation changes and you have to leave immediately.

During this stage you should continually check the news for updates on the situation whether it's improving or deteriorating. If it's improving, don't drop the plot before the threat is gone entirely and if it's deteriorating, try to work faster and focus on the most vulnerable parts of the house first.

For more information on fortifying your house, see the DEFENCE section.

11 Bugging Out

This section begins when you've decided to bug out, before or after a disaster is unfolding in your area. It describes what actions to take and how to prepare yourself.

Contact

First the initiator of the Bug-Out plan should contact everyone in the party and tell them to enact the plan you desire. An example of this would be citing "Operation Jericho - O@H2500RB16004". As discussed in the 'Plan Template' section above, this code would represent:

- O - Bugging Out
- @H2500 - Meeting at Home ASAP (Since 2500 isn't an actual time)
- RB - Route B - The Bulbasaur Route, AKA: Grassland Route
- 1600 - The time the party is set to leave on this trip
- 4 - The number of party members participating in this bug-out

This stage ends with everyone knowing that the Bug-In plan has initiated.

Gather

Once you've contacted everyone or have been contacted by the party leader you need to kick it into gear and stop whatever you're doing and prepare. Wherever you are, (such as the workplace) you should grab any supplies or get home bags you have nearby and prepare to meet the rest of the party at the requested time. If the designated rendezvous time is a few hours ahead and the trip there will only take 10 minutes, you may want to consider picking up additional supplies on the way and refuelling your vehicle.

It's better to bring more gear than you need back to the rendezvous location rather than getting there and needing to go back to pick something up. Don't take any unnecessary risks getting any other equipment or food you don't need, as it's better you make it to the meeting location safely than narrowly making it back with an angry person on your tail who you grabbed the last can of beans from, or you cut off earlier.

This stage ends with every party member at the rendezvous point along with all the gear they need to Bug-In.

Pack

PREPAREDNESS Bug-Out Implementation Pack

Once you're at the meeting location you can begin packing to leave. Don't wait for others to make it back before packing as you may only have a limited amount of time to pull everything together - for example if there's a wildfire coming. If there's no vehicles to pack then make a pile of items to pack right beside where the vehicle will be to save a bit of time.

Bug Out

This is the stage where you leave your home and begin your journey to your Bug Out Location (BOL). Once you've left you shouldn't return for anything unless it's absolutely critical for your survival. During disasters every second counts and don't want to be wasting time if it risks you and your families lives.

Bug Out Routes

Avoid main roads which could be ambush zones for looters. Choose routes with minimal houses and traffic lights and an alternate route without trees and other possible downed obstacles. Store caches of food and other supplies on your route in case you're robbed along the way. You should have recorded the locations of your caches well so you can find them even if it's now overgrown.

Route Decision	Choose your desired route based on the conditions of the disaster and which point of the Bug-Out triangle you want to prioritise whether it's Speed, Supplies or Safety.

12 Real World Tips

These are tips and tricks from people who have lived through a disaster so you can learn from their experience. Even if you rehearse for a disaster you're still missing a critical element of surprise and randomness, plus you have the unknown element of knowing how those around you will react to the disaster.

If you have your own disaster experiences you would like to submit, please email them to myself using the contact info in the first page of this document, or via my website. To make it worthwhile, please have at least 10 dot points in a similar format to those below.

Fluidic Ice - Cyclone Alfred

This section was on my experiences and lessons learnt in a category 1 Cyclone that hit Brisbane in Mar 2025. It wasn't anywhere near severe as some of the other stories below, but having a preparedness oriented mind, I paid attention and took thorough notes throughout it. In the end we only lost power for 3 days; however I was sick with a cold for the duration which made the experience even more miserable.

● A cyclone in Brisbane is a rare occurence which has only happened a few times in recent history, however this one made a sharp right turn towards us and hit directly after a LOT of meandering and loops out in the ocean. There were plenty of memes about it taking its sweet time getting here that people had let their guard down. Some had said they had already gone through their cyclone supplies before it even hit.
● One of my power stations didn't last anywhere near how long I thought it would when powering my fridge. Test your equipment on the appliances you are going to be using them on beforehand and time them.
● We had mobile data during the outage, but I learnt that mobile towers (at least in Australia) have a battery backup that will last between 3 and 12 hours. After that, you may lose comms.
● It's a real pain having to wake up at night to turn the power supply to the fridges and freezers on and off to conserve power. Buy an auto timer.
● As soon as a disaster occurs, get out a notepad and make notes of lessons learnt and what you did throughout. I kept track of when I turned the fridge and freezer on and off and how long they were cooling for.
● I powered the freezer too often as I was concerned about losing the meats and drew the battery down quickly. A FULL freezer can stay unplugged for up to 48 hours and still be turned back on. 24 hours for a HALF-FULL one. However I ran ours every 12 hours to be safe even though it was 3/4 full.
● Fill your vehicles and spare fuel cans at least a week out from the disaster. Fuel becomes scarce very quickly.
● Keep showers very short and use as little hot as possible. We didn't run out of hot water over the 3 days and didn't notice any cooling of it.
● Put a "DO NOT OPEN" sign on the fridge and freezer to remind yourselves to be very efficient when using them. When we needed to open it, we had two people grabbing the items we needed and limited the open time to about 5 seconds.
● Make a list of what you know to be in the fridges and freezers if the power is already out. Better yet, make a quick video of every shelf of your fridge and freezer before the power goes out and update it as you make changes so you know what you need to eat first.
● We had no idea what temperature our fridge and freezers were during the outage. I have since bought wireless temperature sensors.
● I didn't fill our bathtub with water as it was being repaired. A Waterbob would have solved that issue and given us water to use if we needed it.
● At one point the freezer's warning light came on and I had no idea what that meant (besides being temperature related). So I have since downloaded all the manuals for our appliances to be able to look them up on my phone if it happens again.
● I wish I had a faster charger for my power stations. I only had a 15A charger when a 25A would have allowed it to charger much faster if the power temporarily came back on.
● Buy anything even remotely preparedness related AT LEAST a week before it hits. Including food, gas, camp stoves, fuel, power banks, etc.
● Since we are used to washing our hands with the hot water, we put cups over the hot tap to remind ourselves to save the hot water for showers.
● Water, bread, canned meals, milk, noodles and rice disappear from the shelves first. They started to go bare about a week prior to its arrival.
● The neighbours only had a couple of dim and broken torches to use. I offered them a headlamp but they declined. I recommend having a bucket full of different prepper items spares for those who aren't as prepared. Additionally I should have readily gone around to their houses earlier in the disaster to help out where needed and to maintain contact.
● At the start of the power outage we should have done a quick whole house clean to get stuff off the floors which can be tripped on. A couple of times we kicked our toes and stood on things which were laying around while in the dark.
● Sauces can pretty much last indefinitely outside of the fridge. Also don't take items out of the fridge which can help keep it cool - like water bottles. Just drink the tap water (if it's safe to do so).
● I could not recharge my power station with portable solar panels for two reasons. 1. On the power station I built, I forgot to flick the fuse switch to 'on', which I only realized a week after the cyclone. 2. The sky was too cloudy to get much more than a few watts out of the rainy skies.

Donexodus (Reddit) - Hurricane Irma

The following section was posted by Donexodus on Reddit regarding his experiences in Hurricane Irma on the U.S. Virgin Islands. (Posted with Permission)
https://www.reddit.com/r/preppers/comments/cyjo70/how_to_survive_a_cat5_and_the_aftermath_what_irma/

He has also posted a story on his experiences which can be found here:
https://www.reddit.com/r/preppers/comments/7vs7so/being_hit_by_the_eye_of_hurricane_irma_in_the_us/ (Part 1)
https://www.reddit.com/r/preppers/comments/7vzqfe/part_2_being_hit_by_the_eye_of_hurricane_irma_in/ (Part 2)

- Make block ice now. Take Tupperware, fill with water. Freeze it, remove when frozen and repeat. This ice can last for over a week and will turn your fridge and freezer into a cooler so you don't lose a ton of food.
- Cash is king. Withdraw beforehand.
- Chips and salsa are the best food. No refrigeration, won't spoil, and you can nibble on it anytime- even if you don't have an appetite. Out of all the food we had this was always gone immediately.
- Fix a flat! Grab a few cans. Tons of nails and debris afterwards, flat tires are almost a certainty. Even better- tire plugs and a tire inflator.
- Headlamps are infinitely better than flashlights. You can cook / function and have both hands free.
- Aluminium foil, rubbing alcohol (70%), tarps and Home Depot buckets can be used for almost anything. For example, rubbing alcohol can be put on a paper towel and used to wash, can sterilize cuts, clean countertops, start a fire, etc. Home Depot buckets can be used to transport water, store water, collect rainwater, transport things, store things to reduce clutter, and as a place to sit.
- Buy plastic plates, forks, knives, cups, etc. Doing dishes without running water is a pain. Have lots of garbage bags.
- Just because you have a generator doesn't mean it works. Test it now.

- Generators: You have two options- get a big one which will power more stuff, and guzzle gas, or get an inverter generator. The inverters are more expensive per kW capacity, but use almost no gas. I could run a window AC unit and fan on my (LPT wont let me post links- Google Wen 56200i) for a solid 8 hours on 1.2 gallons of gas. You cant do laundry etc, but they're silent, lightweight, and great for electronics. You'll also need a surge protector and long extension cord. NEVER EVER run one indoors- this often kills more people than the storm itself.
- Bug a salt gun. They're on amazon, and shoot salt to kill flies. Flies will be everywhere, and they cost me a lot of sleep. Every morning I'd wake up because flies were landing on me non stop. Kill them.
- A knife, twine, duct tape, gloves and paracord will come in handy literally every day.
- Get pepper spray / tear gas ASAP. A ranged- non-lethal weapon is of absolute importance. If you only have non-ranged, you put yourself at a significant disadvantage.
- Propane camping stoves are cheap and will allow you to easily cook. If not, build a 3 wall stove out of rocks and cook using downed branches and a grill grate. Or dig a hole and start a fire. After a few days though, cold food is what you'll crave.

- Spam is AMAZING! Black pepper spam, thinly sliced and fried. Serve with black beans and rice, OR take a potato, cut into fries. Sprinkle with Parmesan cheese and black pepper. You're welcome. Oh- potato's are cheap, last forever at room temp, and you can do anything with them.
- Fill your prescriptions beforehand. Snag antibiotics if you can, z-packs are great, as is ciprofloxacin. You will get sick.
- Fill your bathtub with water beforehand. Can scoop with home depot bucket to flush toilets, clean, etc. Also, adding bleach to your toilet will keep it somewhat sanitary if you can only flush once a day.
- Take pictures and videos of you're property and possessions the day before. Will help with insurance, FEMA, etc.
- Broom and dustpan- lots of debris but surprisingly good at removing water.
- If water is coming through the walls or windows consider killing the power. Our place caught on fire during Irma due to water in the walls. This happened to a lot of people during Maria as well.
- Keep electronics off the ground. If it floods and your power is on, and you're standing in the water, you'll have bad day.
- If you have an electric stove, make sure you have some sort of grill and that it has fuel. Charcoal is good and you don't necessarily need a grill for it.
- Keep a journal. Years later or for the next storm it will be priceless.

- Consider rigging a simple alarm. Pull string alarms are great. I moved into my cottage 2 months after the storms because my house was uninhabitable. I was alone, and rigging one on my gate helped me sleep a lot better.
- Do laundry and dishes beforehand, clean your house.
- Chainsaws are king! Don't forget replacement blades. Without them, you may be trapped at your house for days.
- Do not isolate yourself. Aside from safety issues, you will desperately need to be around people, whether you realize it or not. Isolation after a traumatic experience will make it significantly worse.
- Your brain won't work for a few days, super brain fog. Everyone will have PTSD, even if you were not frightened at all during the storm itself. Performing the most simple task will overload you. Imagine trying to have a conversation while loud music, a loud TV, a siren, flashing lights are surrounding you- in the middle of an earthquake. With everything around you destroyed, there's simply too much stimuli for you to process anything. Every day I'd be in the middle of a conversation with someone at the bar (meet up spot), and either myself or the person I was talking to would walk away mid sentence without saying anything. This wasn't deliberate, your brain is just full of squirrels.

- Chilli, goulash, lasagne, etc are great to make and freeze for later so you don't have to cook.
- Don't tell people what you have. If you mention having food and power people get resentful.
- Don't let too many people join you, if you do, they won't want to leave and will tell others, it snowballs super fast.
- Be home over an hour before dark.
- Time will stop and no one will know what day it is. It was day 1, day 2, etc for the first 3 weeks.
- You may disagree with this, but having a good weapon can be more important than having bottled water. If s*** really hits the fan, everything else can become a distant second in the blink of an eye. Personally, I'm pro common sense gun control, but I'll never be without a powerful semiautomatic rifle or pistol again.
- The first night you'll be ecstatic you made it through, with random bits of crying. It gets a little harder every day
- Be aware of your surroundings and of people
- Tempers will be high Day 2-6, same with rumours. Fog of war is very real in a close community with no cell service.
- Gas cans- for generator and avoiding long lines. Not sure if Florida runs out of gas or not. 4 5-gallon cans worked well for me.

- Freeze water bottles. They can be cut in half and put in a yeti to keep your drink cold all day. They can also be placed under armpits and on the side of your neck to cool off / help you sleep. You will be craving ANYTHING cold.
- Keeping morale high is the most important thing
- Keep off the road unless you absolutely must. In addition to wasting gas, awful traffic and road hazards, you're preventing emergency vehicles / recovery workers from doing their job.
- NEVER lend out something you cannot replace. I lent out all of my battery powered fans once I got my generator. When the generator went down, I was miserable, and asked several of my co-workers/friends for just one of my fans back. It took a week before ONE of the people forked one of the fans over.
- Board games books etc are great.
- Ice will be worth its weight in gold.
- Bug spray

Commented Tips

● I would suggest having a battery-powered FM radio (and extra batteries if it's battery powered, or get one which charges via USB like the one I linked) to listen to the news and get vital information.

● Also (if not too late), order a sawyer mini (best) or Lifestraw (not as good). If you don't have access to clean water it can help you stay healthy (beware of chemical contamination which cannot be removed by these).

● If you have the money, get a Garmin inReach satellite communicator (requires a (relatively cheap) subscription, down to $15ish a month). You can request SOS (much like 911), and send/receive SMS and e-mails, even without cell coverage. Excellent to keep in touch with relatives and in case of emergency. Can be used year-round when hiking, snow-mobile, skiing, … Don't tell anyone you have this…

● Download the offline map of your area on Google Maps on your phone beforehand. Can be priceless to navigate around and doesn't require internet access. Also get the Maps.Me app and download the map of your area too. Google Maps offline maps will expire and disappear from your phone after 30 days (I believe), Maps.Me maps will not.

● If the cell service in your area is out of order, use your phone in airplane mode so that it doesn't continuously and desperately looks for a cell to connect to, which will drain the battery VERY quickly. Also use it on the lowest practical brightness setting to save battery power.

● If not too late, get big USB power banks (>=10000mAh such as this one) and fully charge them beforehand. It's good as barter items and it can be nice to recharge your things when you have no access to a generator (on the go, or if you don't want to run the generator to avoid attracting attention). You can also get USB lights (this one for instance) and your powerbank doubles as a flashlight with a very long battery life.

● Get a first aid kit, and not just one with bandaids… Get a CAT tourniquet, trauma dressing, Celox (preferred) or QuikClot bandage, triangular bandage, SAM splint, … and know how to use them. Also get the basic medicines (stomach/diarrhoea relief, basic painkillers, anti-allergy, and any prescription medicine if you require any). Remember 911 service may be unavailable for some time and you need to be able to take care of injuries. Tourniquets save lives, everyone should have one readily available.

● I am a radio amateur and in these situations I like to have one or two portable radio for two-way communication but I realize it is not for everybody. Still, a pair of FRS/GMRS radio can be helpful. Please note that GMRS requires a (cheap) license in the USA. I would recommend this model which also allows to be used as a scanner and to program the NOAA weather frequencies (do it beforehand) and some local police/EMS/fire frequencies (if allowed in your jurisdiction).

● Please DO NOT use a radio made for amateur radio use, where you can transmit on any frequency, such as the UV-5R; you may interfere with emergency communications, even if you can't hear them, miles away. Please stick to the FRS/GMRS frequencies. The radio above guarantees safe operation and still allows to be used as a scanner.

● Take pictures of all your important documents (ID, properties, …) and store them in a waterproof plastic bag. Try to keep at least your passport and driver license with you during the storm…

● If you have a sump pump, try to arrange so that it can be battery powered and/or connected to your generator. If using battery power, get a battery charger and/or a generator connection, if the outage lasts and the battery runs down. Sometimes homes are not affected by the main storm but are flooded due to the lack of power around the storm and are still ruined, and that's totally preventable.

● Also, beforehand, depending of the situation you might want to BLOCK your main sewage pipe. This way you might avoid sewage backflow into your home. There are normally valves already installed but in case of serious flooding (high backpressure) they sometimes are not up to the task.

● Download a few offline movies on the Netflix app. I never lived though a hurricane but I assume after a few days/weeks, you might want some entertainment. You can also download e-books. Bonus if it's survival-related e-books."

24 Prepping Mistakes - Hurricane Helene

PinaColada-PorFavor on Reddit summarised this video: https://www.youtube.com/watch?v=hx9z2PivCnY "24 Prepping Mistakes I Made for Hurricane Helene | Lessons Learned in Disaster Preparedness" which was uploaded by Kim to the channel "Single Girls DIY".
Kim also has a longer description on her website "https://singlegirlsdiy.com/prepping-mistakes-hurricane-helene/".

● Have enough cooking redundancies: outdoor grills, electric burners, solar cookers, camping stoves, etc. obviously you'll need to be able to run them so may need propane or generators. Have other redundancies like flashlights, batteries, etc.
● Back up communications: She suggests Starlink
● Enough cookware: She did not have running water or hot water so her pans were dirty and piling up. She suggests having enough disposable cooking pans/baking pans, etc. Someone suggested wiping down with a paper towel after cooking, using a spray bottle with water and dish soap, then wiping again with paper towel, as a good hack.
● Have enough heavy duty rain gear, rain boots are so helpful in flooding situations.
● Be organized: have all your prep stuff in an easy to access location so you aren't searching all over when you need something.
● Take a shower the night before expected disaster so you start fresh/clean.
● Pack the freezer with water bottles/bags to keep stuff cold longer.
● Do laundry before expected disaster so you have plenty of clean clothes.
● Penny on ice tray trick: most know this one. Put a penny on frozen ice in the freezer so if you see the penny has fallen to the bottom, you know the ice melted and maybe the food went bad.
● Have enough insulated water bottles to keep cold liquids cold and hot liquids hot for moral boost.
● Use your stuff before disaster so you know how they actually work and you won't be figuring it out when you absolutely need it.
● Emergency radio - best for most accurate local information happening right now.
● Satellite communication - when all else is out, satellite communications are helpful. She says iPhone 14 and above have a setting for satellite use.
● Facebook - know that there's a lot of misinformation during disasters so stay skeptical and double/triple check with other sources.
● Quick cooking foods - in a disaster it is way easier to have quick cooking foods than to have to make things from scratch.
● Emergency toilets - very helpful when flush isn't working. Build up of excrement will get stinky fast. Look up different camping toilets, etc.
● Take assistance if available. It's a good way to keep in contact with community. Disaster relief places can give out food, water, toiletries, etc.
● Store things in plastic containers/totes. If in cardboard boxes, flooding can ruin things.

● Have plenty of clean towels and blankets.
● Keep windows closed if you can. Something about mold and heat coming in but understandable if you need to air the place out or need ventilation.
● Have moral boosting food on hand, her suggestion was chocolate which is often not a donated disaster food because it melts.
● Check on neighbors. Ask specific questions about what they need because if you just ask "Are you ok?" They will likely just say yes.
● Know that deliveries could take days to weeks to be available.
● Facebook groups can be very helpful to know exactly what is happening and available in your community.

Limp_Assignment_3436 (Reddit) - Texas Freeze

The following section was posted by Limp_Assignment_3436 on Reddit regarding his experiences in the Texas Freeze of February 2021.
https://www.reddit.com/r/preppers/comments/lmj166/lessons_learned_from_cold_dark_texas_apartment/

PREPAREDNESS
Real World Tips

I've been without power and water since late Sunday in an apartment. My prep is pretty solid but some things turned out unexpectedly bad. I want to share this with you so you don't make the mistakes that I did.

● Lesson #1, rice and beans are meh, and cans are useless. Rice and beans blow when you don't have convenient fuel. Chances are, if you're out of power long term, the weather will be so awful it will literally put your fire out. "Junk" food like crackers and jerky are ESSENTIAL for apartment prep. Be careful about cans too, most of my friends apartments dropped below freezing and their cans are ruined!
● Lesson #2, water is heavy!!!! I'm 8 floors up with no water, no power, and no elevators. I only have gas. I've gone up 4 times tonight and I don't think my weak ass legs could do it again. In those 4 trips I got enough water to flush the toilet 3 times and a flashlight. That's it. BTW I got this water by taking a hammer to the frozen swimming pool. It's definitely not drinkable. I had filled the tub but I woke up with it empty. MIND THE SEAL. I have enough to drink but not nearly enough to flush the toilets.

● Lesson #3. You need gas!!! Everything is out here, except gas. Against all advice, I've been heating my apartment with my gas stove. 90% of my area is out of power, and 90% of those people are freezing their asses off because they dont have gas. My friends are sheltering here because my apartment is 60 when theirs are 30 or less. Their food and water is frozen, even cans ruined, preps gone. If you can control one single thing about your next apartment make sure you have gas. There's no other way to have enough energy around for heat.
● Lesson #4 GET A BATTERY BACKED CO AND FLAMMABLE GAS SENSOR. This is the singular reason I feel safe enough to use a gas stove for heat. Battery backed units will burn about one battery every 24 hours. Plan accordingly.
● Lesson #5 charging time. I have a ton of batteries for my phone, laptop, a few general purpose I can hook up to variable boost buck converters (I'm a nerd). I ran into a big problem real fast. Most of my batteries take 4-6 hours to charge. I can't idle my car that long, nearby gas stations are sold out. Once I drained all my batteries over the initial two days I've fallen back to my two USB-C PD batteries that charge within an hour or two. All my batteries that take 3+ hours to charge are useless. Charging time is extremely important if you're relying on your car for charge. Which you are if you're in an apartment....

● Gas service is vital for apartment prep, just to repeat again. I would have used saran wrap to promise a good seal on my bathtub. I would have bought a "power station" I could charge rapidly froman inverter clipped to my car battery. The only fast charge one I know of is ECOFLOW models which charge in less than two hours. All the other big batteries I can find charge in 3+ hours. Not useful when you're burning precious fuel that will be sold out everywhere.
● Another thing, an inverter with direct to battery jumper cable style pickups is as vital as gas. That's why I can post this rant now. I cut my jumper cables to hook up this inverter and still have charged batteries when most people don't even have phones now. They've gone dark.

EDIT: Water is back but low pressure and boil notice. Again gas is saving my ass, boiling water takes ton of energy.
Stay safe y'all and if you're in apartment maybe my experience will be helpful

Gear

Selecting and using essential preparedness equipment

"Nothing makes a journey more difficult than a heavy backpack filled with nice but unnecessary things."
Randy Alcorn

Introduction

In a materialistic world we tend to gravitate towards and become attached to our items and gear. These items either complete a multitude of tasks poorly or one task very well. It's important to have a few primary redundancy items because they will break or wear out eventually. The groups and items below have been tested and tried in many survival situations and have shown they are reliable and useful. This isn't an exhaustive list, so you may want to add your own personal flair or modifications to the items. You should only carry what you are comfortable with and above all - know how to use your gear.

NOTE: There's quite a lot of prepper terms in this section so be sure to know what they all mean prior to reading. You can find definitions in the INTRODUCTION or 'ADDENDUM > Dictionary' sections. "Recommended Brands" or "Top Brands" simply refers to brands which are known to deliver, work well and have a good price to punch ratio. Most recommendations are of my own personal use combined with research.

Purpose	The aim of GEAR is to explain the typical backpacks and bags that preppers have on hand including how to pack and wear them properly. There's also a strong emphasis on keeping packs light and the need to only include the essentials for survival. It also discusses each recommended item in great detail to help you make more informed decisions when purchasing products. The end of this category covers any specialist gear you may need for unique circumstances and other gear which doesn't fit into a backpack.
Lost?	• For a more complete list of medical gear, see the MEDICAL section. • For a list of pandemic gear, see the MAN-MADE DISASTERS > Pandemic section. • For a list of recommended food, see the FOOD section. • For tips on reducing the amount of gear you have, see the HOMESTEADING > Minimalism section. • If you want to find out about other ingenious uses for common items, see the MATERIALS > Alternative Uses section. • For a complete list of portable shelters and shelter types, see the SHELTER section.

Contents

1 Preparedness Kits

This section explains the different types of 'bags' you can use to carry and store your gear. The term bag doesn't fully cover each of the below lists such as the pocket survival kit and the EDC kit, neither of which come in a bag. Generally you want your gear pre-packed and ready for an emergency at all times of the day, month and year, therefore if you borrow an item from your bag, be sure to replace it immediately after you're finished with it. Each bag has a specific purpose and are carried at different times depending on the situation. Items in the bags must be rotated out when they reach their expiry date such as food, water, glowsticks, medication and energy bars so it's recommended to keep a spreadsheet of these dates.

GEAR | Preparedness Kits

Pocket Survival Kit (PSK)

Pocket Survival Kit (PSK)

Pocket Survival Kit	Example Items
Fits into a small metal tin (altoids tin) and covers the basic survival needs excluding shelter. You should last at least five days on its supplies excluding food and water. Because only small items will fit into an altoids tin you must be extremely careful what you pack. You may end up on a tropical island with only this kit and have to survive months. This kit is easily able to be stored in a pocket, workplace, car or the home to be easily grabbed when needed. You may also want to consider having multiple kits with exactly the same items for those situations where you may not be able to grab another one, but if you can grab multiple, then you can give one away or have the redundant one as a backup.	• Thin Mirror • Small Flint Rod • Tritium Light • Small Blade • Medication • Purification Tablets

Size	Weight		
The pocket survival kit should be small enough to fit into a pocket. A recommended size would be the size of an 'Altoids' tin or approximately 2.36" (6cm) x 3.75"(9.5cm) x 0.7" (2cm) High.	Your PSK kit should be extremely lightweight and inconspicuous, typically below 150 grams (0.3 lbs).		

GEAR | Preparedness Kits

Every Day Carry (EDC)

Every Day Carry (EDC)

EDC Gear (Every Day Carry)	Example Items
This gear is carried by you every day and should be able to be presented any time. These items aren't packed into a bag but instead worn on your person such as on a belt, on your wrist or in your pocket. These items should be ones you typically use every day or ones that you won't be able to live without if SHTF that day - such as a way to start fire.	• Pocket Knife • Watch • Mobile Phone • Keys

These items aren't in a bag like the other types of gear, and are either worn on your body or can be shown to anyone 99% of the time.

Size	Weight		
Your EDC kit should all fit inside a moderate sized organising cell approximately 12cm (4.7") x 12cm (4.7") x 4cm (1.5"). But keep in mind that not all of it will be stored in this case, but instead on your body.	Your EDC kit should be very lightweight and inconspicuous, typically below 500 grams (1.1 lbs).		

This pack isn't limited to a bag but also includes clothes, wearables such as watches and a gun. The 5 C's of survival which the EDC kit generally should cover is: Cutting, Cordage, Combustion, Cover and Container.

GEAR | Preparedness Kits

Get Home Bag (GHB)

Get Home Bag (GHB)

Get Home Bag (GHB)

GH Gear (Get Home)	Example Items
These items are only to assist you getting home within 24 hours if a disaster occurs while your away from your BOB. The gear should include everything required for a trip home from work or other place where you're frequently at. The bag could also accommodate one overnight camp (if required) which will generally consist of a mylar bag to keep things minimal and lightweight. This bag would generally stay in your car or your place of work in anticipation of a disaster situation.	• Mylar Bag • Food Rations • Water • Mini Medical Kit

Size	Weight		
A GHB should be the size of a small backpack. This can be between a 10L and 20L backpack. (2.1 - 4.2 gal). Size and fit should be based off the person's size.	The GH bag should be a lightweight pack under 3kgs (6.6 lbs) which doesn't draw attention to yourself.		

The bag is designed to get you home within 24 hours and can only sustain you for this period - including overnight once. It is assumed that you won't have access to any reasonable food or clean water along the way home thus bringing your own is essential.

GEAR | Preparedness Kits

Bug Out Bag (BOB)

Bug Out Bag (BOB)

BOB Gear (Bug Out Bag)
A bag designed to only get you to your BOL (Bug-Out Location) within approximately 3 days or less - where you should have food, water and other supplies stored already. BOB's should be stored in a secure location such as a house until needed. They could also be located at your place of work if you aren't planning on travelling with others.

Size	Weight		
Your Bug Out Bag's size should be between 30L and 80L. (6.5 - 17.5 gal) Size and fit should be based off the person's size.	Your BOB should weigh at most 1/5th of your weight. For ultralight the weight should be below 5kgs (11 lbs) or 1/15th of your weight.		

These bags are typically designed to be carried on foot however - hiking frames, bikes and cars are also useful ways to transport your gear.

GEAR

I'm Never Coming Home Bag (INCH)

CH)

INCH Gear (I'm Never Coming Home)
This bag will help you stay in the wild indefinitely with it's many tools and heavy duty items. INCH bags can be extremely heavy if you're truly planning on never returning home again as they will contain everything needed to set up a shelter and live off the land long term. Despite the term "Never" used in INCH, at some point you will want to return to the suburbs - particularly years down the track when most things have settled down again.

Example Items
- Heavier Tools
- Lots of Paracord
- Redundancy Items

Size
Your INCH bag should be between 50L and 120L. (11 - 26.3 gal) Size and fit should be based off the person's size.

Weight
Your INCH bag should weigh at most 1/4th of your weight, assuming you're carrying it yourself.

Typically INCH bags are accompanied with a transport mode such as a car or a bicycle as they can weigh up to 100kg's. The bag includes more tools then all other bags which are single function to increase their longevity and efficiency. The bag only has 7 days worth of food and water for one person - therefore acquiring an income of food and water is vital early on.

Survival Comfort And Redundancies (SCAR)

SCAR (Survival Comforts And Redundancy)
The Survival Comfort And Redundancy (SCAR) bag is a term I (fluidicice) coined in response to all the spare prepper gear I accumulated that wouldn't make it into any of my other bags. Its primary purpose is to store your spare and redundant supplies to increase your comfort and give you more options when bugging out. It should be grabbed in addition to your other bags if you have the space available in your car.

However if it's not required later on, or you can't carry it any more you can safely ditch it knowing that you already have the basic gear in your BOB/INCH bags. Redundancy is key and if you're permanently bugging out and your primary tools break, what will you use? You won't last much longer without an axe, hatchet or saw to construct a shelter. Typically used when you have a limited time to bug out, these bags will boost your longevity and estimated survival time as well as provide more specialized equipment for certain scenarios, seasons or climates.

Examples
- Blankets
- Extra Clothes
- Stronger Shelter
- Backup Axe
- Backup Knife
- Larger Gas Masks
- Additional Barter Items
- Pandemic Equipment
- Cigars/Alcohol
- Folding Furniture

Size
There's really no size or weight limit to a SCAR bag, and you can have as many SCAR's as you need as long as you can lift them. I recommend either a duffel bag or a plastic tub to easily throw them into the car.

Weight
Weight shouldn't matter in a SCAR bag as it will only be used if you are using vehicle transport and have free space. However an average estimate would be 5-30kgs (11 - 66 lbs).

The bags are not meant to be hiked with and can be dumped if they are slowing you down or you have to set out on foot. Their entire function could be just to take with you regardless and decide what you need from it at your destination if you have to bug out fast. Ensure they will fit in your mode of transport as there's no point having a SCAR bag if it will only reduce visibility or slow you down. Never keep this bag if hiking on foot long distances. If you need to dump a bag on the run, this is the bag you will choose first without hesitation.

There's also no loss because the items would have been looted in your house anyway. Nearly every prepper has additional preps at home which aren't in their BOB, these items are best served in a SCAR bag which you can just grab and go with if you have the space for them. The bag is called "Survival Comforts" because it's generally not up to the standards of regular home comforts you current live in, but still improved over a regular bug out situation.

Shelter SCAR Bag
Providing a bolster to protection, camouflage, weather and comfort. You can't control the elements and nature can be deadly when it wants. Occasionally you need that strong shelter to provide safety, morale and camouflage. The additional shelter should be an add-on to your current shelter. An example being a weatherproof tarp or a top layer of a tent that's packed in this bag as it's too heavy for typical bug-out situations.

Water / Food SCAR Bag
Contains lightweight foods, extra gas, water, water filters and cooking utensils. What if it's tougher to get established at your BOL than you prepared for? What if it's winter when you bug-out and the animals are hibernating and the plants are dead?

Energy SCAR Bag
As many different types of batteries, chargers and cables you can fit inside it - but which you're still likely to use.

Items
- AAA, AA,18650 Batteries
- C, D Batteries
- 9v Batteries
- Solar Panels
- Power Banks
- Charger Cables
- Voltage Adapters

Hygiene SCAR Bag
Because you'll eventually run out of toilet paper, razors and toothpaste. A folding or rigid toilet would be a good foundation to this bag as it might take some people a bit of time to adapt to having to dig a hole and "going" in it.

Items
- Portable Toilet
- Toilet Paper
- Toilet Cleaner
- Soap
- Toothbrush & Paste

Items
- Shampoo & Conditioner
- Trowel
- Razors
- Towel & Facewashers
- Female Urine Device

Weapons SCAR Bag
A bag stuffed full of additional ammo, guns, grenades and knives. Because why not? You may need to shoot yourself out of a situation.

Barter SCAR Bag
This bag is full of tradeable items which you can use to barter for items you require. It's always advised to only trade weapons with people you know to avoid a potential situation where your weapons are used on you. It can contain almost any item but the items people are likely to need are to the right. See the ECONOMY > Bartering section for more information.

Items
- Food
- Water
- Medical Equipment
- Alcohol
- Condoms

- Cigarettes
- Tea & Coffee
- Hygiene Products
- Weapons

This bag could contain things like extra warm clothing and blankets, tool redundancies like hatchets, knives and shovels, extra camping gas, fishing snares and larger traps, long rolls of paracord or advanced medical equipment. Most preppers have spare items that didn't make it into their BOB's so why not have them in a bag themselves to grab if the need arises and you have the space available.

Car Kit

Car Kit A car kit (or Bug-Out Vehicle Kit) is a collection of survival items which you keep in your vehicle for car related emergencies. It's different to a Get-Home Bag (GHB) because it's only for vehicle related personal disasters where you will normally stay with the vehicle until it's repaired or towed. However you should also have your GHB in the vehicle anyway in the event you need to ditch the car. Be sure to keep things like your spare tyre ready to go at all times. Most of these can be packed into a plastic tub (ideally with wheels) so it can be easily moved around.			**Example Items** • Reflective Triangles • Vehicle Tools • First Aid Kit
Safety Gear Gear which will make you visible and help fix any dangerous situations. Put the high-vis vest in the glove box so it can be put on after you break down, but before you even get out of the car to avoid further accidents.		**Items** • High-Vis Vest • Headlamp & Btty's • Reflective Triangles • First Aid Kit • Whistle	• Signal Flares • Face Mask • Fire Extinguisher • Safety Glass Breaker • Seatbelt Cutter
Tools In some circumstances, you might be able to fix the vehicle yourself if you have the right knowledge and tools on you.	**Items** • Screwdrivers • Socket Set • Spare Fuses • Duct Tape • WD-40/Lubricant • Gloves • 12v Air Compressor	• 4 Way Wheel Brace • Cleaning Cloths • Shovel • Air Pump • Jack Stand • Spare Oil • Recovery Tracks • Vehicle Manual	• Spare Coolant • Water for Vehicle • Scissors • Jumper Leads • Ratchet Straps • Tow Rope • Paper & Pens • Road Maps
Preparedness Gear Include gear which will help get you through tough weather if you have to wait with the car for hours, up to days before assistance arrives (and the grid is still up). You are likely to leave most of this gear with the car if you need to "Get Home", so don't pack anything you don't mind leaving.		**Items** • Canned Food • Blankets / Pillow • Torches and Batteries • Tarps & Paracord • Umbrella • Long Life Snacks • Power Bank	• Mini Stove • Hand Warmers • Water for Drinking • Radio • Spare Clothing • Walking Shoes • Toilet Paper • Hat

2 Backpacks

Backpacks are an essential resource in the prepping community, they are designed to carry your gear and take the weight of them off your back. There are multiple types of prepping backpacks each with a unique purpose, and even though you don't need them all, they have their place in your life. Generally they are designed to hike out into the mountains with and be fairly lightweight however every person is different and so should their bag. Having a lightweight pack means you can travel further and faster allowing you to GOOD faster if SHTF. For the recommended contents of this kits, see the GEAR section.

Preparedness Kits

This section explains the different types of 'bags' you can use to carry and store your gear. The term bag doesn't fully cover each of the below lists such as the pocket survival kit and the EDC kit, neither of which come in a bag. Generally you want your gear pre-packed and ready for an emergency at all times of the day, month and year, therefore if you borrow an item from your bag, be sure to replace it immediately after you're finished with it. Each bag has a specific purpose and are carried at different times depending on the situation. Items in the bags must be rotated out when they reach their expiry date such as food, water, glowsticks, medication and energy bars so it's recommended to keep a spreadsheet of these dates.

Pocket Survival Kit (PSK)

Pocket Survival Kit Fits into a small metal tin (altoids tin) and covers the basic survival needs excluding shelter. You should last at least five days on its supplies excluding food and water. Because only small items will fit into an altoids tin you must be extremely careful what you pack. You may end up on a tropical island with only this kit and have to survive months. This kit is easily able to be stored in a pocket, workplace, car or the home to be easily grabbed when needed. You may also want to consider having multiple kits with exactly the same items for those situations where you may not be able to grab another one, but if you can grab multiple, then you can give one away or have the redundant one as a backup.			**Example Items** • Thin Mirror • Small Flint Rod • Tritium Light • Small Blade • Medication • Purification Tablets
Size The pocket survival kit should be small enough to fit into a pocket. A recommended size would be the size of an 'Altoids' tin or approximately 2.36" (6cm) x 3.75"(9.5cm) x 0.7" (2cm) High.	**Weight** Your PSK kit should be extremely lightweight and inconspicuous, typically below 150 grams (0.3 lbs).		

Every Day Carry (EDC)

EDC Gear (Every Day Carry) This gear is carried by you every day and should be able to be presented any time. These items aren't packed into a bag but instead worn on your person such as on a belt, on your wrist or in your pocket. These items should be ones you typically use every day or ones that you won't be able to live without if SHTF that day - such as a way to start fire.	**Example Items** • Pocket Knife • Watch • Mobile Phone • Keys
These items aren't in a bag like the other types of gear, and are either worn on your body or can be shown to anyone 99% of the time.	

Size Your EDC kit should all fit inside a moderate sized organising cell approximately 12cm (4.7") x 12cm (4.7") x 4cm (1.5"). But keep in mind that not all of it will be stored in this case, but instead on your body.	**Weight** Your EDC kit should be very lightweight and inconspicuous, typically below 500 grams (1.1 lbs).		

This pack isn't limited to a bag but also includes clothes, wearables such as watches and a gun. The 5 C's of survival which the EDC kit generally should cover is: Cutting, Cordage, Combustion, Cover and Container.

Get Home Bag (GHB)

GH Gear (Get Home)
These items are only to assist you getting home within 24 hours if a disaster occurs while your away from your BOB. The gear should include everything required for a trip home from work or other place where you're frequently at. The bag could also accommodate one overnight camp (if required) which will generally consist of a mylar bag to keep things minimal and lightweight. This bag would generally stay in your car or your place of work in anticipation of a disaster situation.

Example Items
- Mylar Bag
- Food Rations
- Water
- Mini Medical Kit

Size A GHB should be the size of a small backpack. This can be between a 10L and 20L backpack. (2.1 - 4.2 gal). Size and fit should be based off the person's size.	**Weight** The GH bag should be a lightweight pack under 3kgs (6.6 lbs) which doesn't draw attention to yourself.		

The bag is designed to get you home within 24 hours and can only sustain you for this period - including overnight once. It is assumed that you won't have access to any reasonable food or clean water along the way home thus bringing your own is essential.

Bug Out Bag (BOB)

BOB Gear (Bug Out Bag)
A bag designed to only get you to your BOL within approximately 3 days or less - where you should have food, water and other supplies stored already. BOB's should be stored in a secure location such as a house until needed. They could also be located at your place of work if you aren't planning on travelling with others.

Size Your Bug Out Bag's size should be between 30L and 80L. (6.5 - 17.5 gal) Size and fit should be based off the person's size.	**Weight** Your BOB should weigh at most 1/5th of your weight. For ultralight the weight should be below 5kgs (11 lbs) or 1/15th of your weight.		

These bags are typically designed to be carried on foot however - hiking frames, bikes and cars are also useful ways to transport your gear.

I'm Never Coming Home Bag (INCH)

INCH Gear (I'm Never Coming Home)
This bag will help you stay in the wild indefinitely with it's many tools and heavy duty items. INCH bags can be extremely heavy if you're truly planning on never returning home again as they will contain everything needed to set up a shelter and live off the land long term. Despite the term "Never" used in INCH, at some point you will want to return to the suburbs - particularly years down the track when most things have settled down again.

Example Items
- Heavier Tools
- Lots of Paracord
- Redundancy Items

Size Your INCH bag should be between 50L and 120L. (11 - 26.3 gal) Size and fit should be based off the person's size.	**Weight** Your INCH bag should weigh at most 1/4th of your weight, assuming you're carrying it yourself.		

Typically INCH bags are accompanied with a transport mode such as a car or a bicycle as they can weigh up to 100kg's. The bag includes more tools then all other bags which are single function to increase their longevity and efficiency. The bag only has 7 days worth of food and water for one person - therefore acquiring an income of food and water is vital early on.

Survival Comfort And Redundancies (SCAR)

SCAR (Survival Comforts And Redundancy)
The Survival Comfort And Redundancy (SCAR) bag is a term I coined in response to all the spare prepper gear I accumulated that wouldn't make it into any of my other bags. Its primary purpose is to store your spare and redundant supplies to increase your comfort and give you more redundancies during bugging out. It should be grabbed in addition to your other bags if you have the space available in your car.

However if it's not required later on, or you can't carry it any more you can safely ditch it knowing that you already have the basic gear in your BOB/INCH bags. Redundancy is key and if you're permanently bugging out and your primary tools break, what will you use? You won't last much longer without an axe, hatchet or saw to construct a shelter. Typically used when you have a limited time to bug out, these bags will boost your longevity and estimated survival time as well as provide more specialized equipment for certain scenarios, seasons or climates.

Examples
- Blankets
- Extra Clothes
- Stronger Shelter
- Backup Axe
- Backup Knife
- Larger Gas Masks
- Additional Barter Items
- Pandemic Equipment
- Cigars/Alcohol
- Folding Furniture

Size Your SCAR bag could be between 10L and 150L. (2.1 - 33 gal) Any bigger than 150L (33 gal) then this bag may be a struggle to carry depending on what's inside. This bag doesn't have to be a backpack, but could also be a duffel bag or other type of bag.	**Weight** Weight shouldn't matter in a SCAR bag as it will only be used if you are using vehicle transport and have free space. However an average estimate would be 5-30kgs (11 - 66 lbs).		

The bags are not meant to be hiked with and can be dumped if they are slowing you down or you have to set out on foot. Their entire function could be just to take with you regardless and decide what you need from it at your destination if you have to bug out fast. Ensure they will fit in your mode of transport as there's no point having a SCAR bag if it will only reduce visibility or slow you down. Never keep this bag if hiking on foot long distances. If you need to dump a bag on the run, this is the bag you will choose first without hesitation.

There's also no loss because the items would have been looted in your house anyway. Nearly every prepper has additional preps at home which aren't in their BOB, these items are best served in a SCAR bag which you can just grab and go with if you have the space for them. The bag is called "Survival Comforts" because it's generally not up to the standards of regular home comforts you current live in, but still improved over a regular bug out situation.

Shelter SCAR Bag
Providing a bolster to protection, camouflage, weather and comfort. You can't control the elements and nature can be deadly when it wants. Occasionally you need that strong shelter to provide safety, morale and camouflage. The additional shelter should be an add-on to your current shelter. An example being a weatherproof tarp or a top layer of a tent that's packed in this bag as it's too heavy for typical bug-out situations.

Water / Food SCAR Bag
Contains lightweight foods, extra gas, water, water filters and cooking utensils. What if it's tougher to get established at your BOL than you prepared for? What if it's winter when you bug-out and the animals are hibernating and the plants are dead?

Energy SCAR Bag
As many different types of batteries, chargers and cables you can fit inside it - but which you're still likely to use.

Items
- AAA, AA,18650 Batteries
- C, D Batteries
- 9v Batteries
- Solar Panels
- Power Banks
- Charger Cables
- Voltage Adapters

Hygiene SCAR Bag
Because you'll eventually run out of toilet paper, razors and toothpaste. A folding or rigid toilet would be a good foundation to this bag as it might take some people a bit of time to adapt to having to dig a hole and "going" in it.

Items
- Portable Toilet
- Toilet Paper
- Toilet Cleaner
- Soap
- Toothbrush & Paste

Items
- Shampoo & Conditioner
- Trowel
- Razors
- Towel & Face Washers
- Female Urine Device

Weapons SCAR Bag
A bag stuffed full of additional ammo, guns, grenades and knives. Because why not? You may need to shoot yourself out of a situation.

Barter SCAR Bag
This bag is full of tradeable items which you can use to barter for items you require. It's always advised to only trade weapons with people you know to avoid a potential situation where your weapons are used on you. It can contain almost any item but the items people are likely to need are to the right. See the ECONOMY > Bartering section for more information.

Items
- Food
- Water
- Medical Equipment
- Alcohol
- Condoms

- Cigarettes
- Tea & Coffee
- Hygiene Products
- Weapons

This bag could contain things like extra warm clothing and blankets, tool redundancies like hatchets, knives and shovels, extra camping gas, fishing snares and larger traps, long rolls of paracord or advanced medical equipment. Most preppers have spare items that didn't make it into their BOB's so why not have them in a bag themselves to grab if the need arises and you have the space available.

Kit Bags

Kit bags are the small bags or pouches that hold most of your equipment so it's all not just loose in your bag. They arrange your fire, water, food, medical and misc kits conveniently so all the items are in one place and easily accessible. Try to keep the kit bags as light as possible as they already have the protection of the bag around them. Use a slightly stronger bag if it's going to contain sharp items such as stoves, knives, cutlery, needles etc.

Can Hold
- Fire Lighting Equipment
- Water Equipment
- Food
- Medical Equipment
- Misc Kits
- Clothing

Kitbag Companies
Sea to Summit: Known as 'Packing Cells' by S2S.
Kifaru: They make a range of kit bags for storing your gear.
Tread Lite: An ebayer who sells Cuben Fiber kit bags.
Eagle Creek: Makes ultralight kit bags.

Dry Bags

Flexible bags which keep anything inside them dry, often by folding down the top and clipping them shut. Dry bags are often used in kayaking, canoeing, rafting, canyoning, and other outdoor activities where sensitive items would otherwise get wet. Dry bags aren't as necessary for camping unless you expect a lot of rain, or you're going to have to cross lakes and rivers.

Dry bags are NOT waterproof, they generally try to meet an IPX6 or IP66 rating meaning they are protected from heavy seas and more particularly: 'Water projected at all angles through a 12.5mm nozzle at a flow rate of 100 litres/min at a pressure of 100kN/m2 for 3 minutes from a distance of 3 meters."

Protects
- Electronics
- Clothing
- Consumables
- Water
- Tinder
- Firelighters
- Medical Gear

Packing Tips

Don't Overfill	Pack Snugly	Pull Together	Securing	Snap Shut	
If you overfill the bag it will compromise its waterproofing.	Pack items close together so they don't rattle and you conserve space.	Make sure the stiffened blades are together and that nothing is protruding from the top.	Roll the blades three times for optimum waterproofing.	Once rolled, snap the clips together to secure it and create a handle on top.	

Stuff Sacks

A stuff sack is a type of drawstring bag, usually used for storing camping items. Stuff sacks are commonly used for the storage of sleeping bags, which are otherwise bulky and difficult to manage. Generally they are just stuffed into the sack to the save time it would take to roll it up into a smaller size again.

Compression Sacks

The compression sack is a type of stuff sack designed particularly for the storage of sleeping bags in internal-frame backpacks. It is equipped with a cloth lid that is attached to the opposite (sealed) end of the sack by adjustable straps. When the straps are forcibly shortened, the sack and its non-rigid contents are reduced in size.

Bear Bags

Bags which keep in the scent of food and are thrown over high branches to prevent bears getting into them overnight. There are also bear canisters but these are generally too bulky to be carried in/on a BOB. You can find more information on bear bags in the "Safety & Security > Safety > Bear Bag" section.

Backpack Features

These are backpack features that may be present on most backpacks available today. Some features you will need and others you won't depending on your needs, location and size.

Size	Weekender (1-3 Nights)	Multiday (3-5 Nights)	Extended Trip (5+ Nights)
The size of the backpack is the first item you should look at. It's better to buy the backpack once you have your gear and ensure it all fits first.	30-50 Litres	50-80L	70L+

Adjustability / Fit
An adjustable bag can adapt from almost any body size and can take a lot of the weight off your shoulders. An adjustable bag is vitally important as you can customise it to your changing weight or even the size of someone else if you are no longer able to carry the bag. An ill-fitting backpack will cause pain at the shoulders and sometimes the hips and make your journey very uncomfortable. When fitting a backpack your height matters the most.

Frame	Internal Frame	External Frame	Frameless
A frame is very beneficial to a backpack to support the weight across multiple points on your body and make carrying it easier. Most hiking backpacks have some kind of frame to keep them stable and increase comfort. The best kind have whole bag frames in an "L" shape to distribute the weight more evenly and make carrying easier. The stronger and larger the frame however, the heavier the backpack will be and will slow you down, so be sure to find a lightweight metal.	Body-hugging internal frame packs designed to keep a hiker stable on uneven terrain.	Great if you're carrying a heavy or irregular load. They also offer good ventilation and lots of gear organization options.	For hiking fast and light where the frame is removed for weight savings.

Ventilation
Ventilation allows your body to breathe through the fabric and wick the sweat away from your body. When bugging out on foot you are sure to become very sweaty, especially if you're not physically prepared for that kind of hike. Therefore it's important to have a backpack that allows sweat to evaporate - cooling you down and keeping you drier. This type of backpack uses a suspended mesh back panel to let air escape around the sides known as a tension-mesh suspension.

Pack Access	Concealed Access	Quick Access	Top-Loading Openings	Panel Access
How many access points you have on the backpack and their distribution around the bag. A good pack will have at least 3 points of access, two of which should access the same main compartment, one at the bottom and the other at the top.	Some bags have a concealed compartment where your back goes to prevent the more valuable items being stolen.	Some items such as the medical kit and waterproof clothing will require quick access when the need arises and should be packed on top to facilitate this.	Generally what comes with backpacks today, although it's harder to reach the deeper items without pulling everything else out.	On these backpacks the whole side of the pack unzips revealing the interior making it easy to reach any item you need.

Pockets	Elasticized Side Pockets	Hipbelt Pockets	Shovel Pockets	Front Pockets
How many and what sorts of pockets are present on the bag - if any. A number of pockets on the outside of the backpack will have you store various items in easily recovered positions such as maps and navigation gear which will be used often.	These are used to hold water bottles but take up no additional space when empty.	Holds items in convenient positions so you can grab them quickly.	Flaps stitch on the front of a backpack and generally held with a buckle closure for larger lightweight items.	Often found on shovel pockets these pockets can hold small items.

Comfort / Padding
How long you can carry the bag without your back or shoulders becoming painful and forcing you to take a break. Combines with weight to make carrying less painful. The comfort of the bag is crucial when bugging out on foot, especially if you're trying to put as much distance between you and a disaster as possible. The more uncomfortable the more you'll be stopping to adjust it or take a break. More padding on a bag will often lead to a heavier backpack which controversially leads to less comfort so try to find the thin line between. Padding can be found on the waist to support the hips, on the back to help it fit to your back more comfortably and on the shoulders to pad some of the weight across a larger distance.

Weight
A very important factor when bugging out. A heavier bag will make you slower and burn energy faster. In general for an empty backpack you will want to aim around 1kg total weight to keep things lightweight. The section for total backpack weight including gear can be found in the section below.

Fabric / Materials
The type of fabric found on the backpack can range dramatically and affect the lifespan and durability of the bag as well as providing useful features like being waterproof. Consider which features you need in a backpack and look for the correct type of fabric that supports that such as being waterproof or being lightweight. The higher quality the materials used in the backpack - the more expensive and generally the heavier it becomes unless it's specially designed to be light.

Weatherproofing / Rain Cover
A rain cover encases the backpack to reduce the amount that enters the bag. A backpack cover is very cheap and can save you the heartache of opening it to find ruined food, a soggy notepad and rusted tools. The cover can also be bought in varying colours such as grey to camo to disguise its true purpose to others.

Backpack Lid
A top flap of the bag that folds up or down to shed rain easier and prevent it getting into the bag. Most hiking backpacks today come with a lid, sometimes with a zippered compartment for storing items. The lid flap sometimes attaches with clips on the front section allowing for a large item to go underneath which is usually a sleeping bag or tarp.

Stealth
How covert your backpack looks to others when bugging out. Generally size is the primary factor when looking at stealth as people will notice you a lot more when you're walking around with a camping store on your back. A camo backpack will help you when you're out in the bush but will draw attention when you're in the suburbs on foot making you more liable to being robbed. It gives the impression you're serious about survival and have some good gear. A 50L camo backpack with a grey toned rain cover would be ideal for all situations as you can use the rain cover until you reach the forests to blend in easier. Noise can be a very important factor when trying to stay hidden. You'll draw a lot of attention if you've got metal pots and pans attached to the outside banging loudly every step. Velcro and zips can also give away your position if loud enough.

Durability
How durable and hardy the backpack is against rough use. You definitely want a bag that's not going to fall apart on the first trip, or pieces falling off, so be sure to buy from a reputable brand that has good materials and zips.

Removable Daypack
A secondary bag that attaches to the primary backpack for lightweight hiking during the day. Some backpacks have a section on the front for a smaller removable backpack which lets you travel lighter from the main campsite when scouting.

Sleeping Bag Compartment
A dedicated compartment for a sleeping bag. Not a very useful option but still helpful if you're looking to keep an item separate from the others in an easy to reach location.

Attachment Points
Points all over the bag that allow various other items to attach such as hiking poles, torches and mattresses. Some backpacks have clips all over it for attaching various items you may need when hiking which can come in very handy to grab without stopping, putting the bag down and then searching for what you need. Be sure you don't over clutter the exterior of the bag as this can alter the weight distribution and cause a lot of noise if they are pots and pans. It will also draw a lot of attention to yourself if people can see what you have on you. Some attachment points are found as webbing where you're able to slide gear under the webs to hold them fairly securely. This works better with bulkier items as there's less chance of them falling out.

Hydration Reservoir
A storage location for a hydration bladder including a hole to put the tube through for drinking on the go. It's important to restore any water you lose while hiking and a water bladder section will make drinking on the go very easy. Depending on the size of the bag you should have enough space for between 1L-3L water bladders.

Fitting

After deciding on a backpack or pulling one out of the cupboard you should ensure that it fits you snugly in all the vital areas.

Torso Length Choosing the height of a bag depends on the length of your torso primarily and must be taken into consideration when looking at a backpack.	**Torso Length** Measure your torso length from the C7 vertebrae parallel to your shoulder height down to your hip shelf located at the top of your hip bone.	**Torso Length** **Pack Size / Torso Length** Extra Small - Up to 15"+ Small - 16" - 17"+ Medium - 18" - 19"+ Large - 20"+	**Waist Size** Generally backpacks support a waist size between 20-40 inches. This is a vital area to get right as they are supported 80% by the waist alone.	**Youth-Specific** Due to the size difference of youth there are specific backpacks made to accommodate their size.	**Women-Specific** Due to physiological differences, there are a number of women's backpacks available to purchase which better accommodate the change in body size,

Adjustments These are adjustments that can be made to the bag to better fit your body type and to help prevent back pain after carrying it for long periods.	**Load Lifter Straps** Stitched onto the shoulder straps and connected to the frame, these straps prevent the pack from pulling away from your body which would cause it to sag on your lumbar region.	**Sternum Strap** A horizontal mid chest strap used to connect the shoulder straps together improving stability and preventing the pack from moving abruptly when moving.

Weight

This section discusses the different weights of backpacks people use and the benefits and disadvantages to each of them.

Total Weight

This section discusses the weight of the backpack and how to lighten the load. Consumables such as food and water aren't included in the total weight of the pack. So if you're aiming for ultralight, remove the consumables before weighing. Below is a table detailing pack weights and the weight category they fall into. Remember that every person is different so you should tailor your own BOB's weight to your own size and weight. The pack weights below exclude food, water and fuel from the total weight calculation.

Name	Weight	Description	Advantages	Disadvantages
Super Ultralight	<3kg (<6.6 lbs)	The "I drill holes in my toothbrush to save weight" mentality where every gram counts. They sacrifice lots of comfort for the lightest pack possible, but they can travel rapidly across terrain. Only has the essentials.	● Rapid Movement ● Much less fatigue ● The Most "Grey Man" ● Very Resourceful	● Often Unarmed ● Almost no comfort ● Barely Weather-Proof ● Few Redundancies

Ultralight	3-5kg (6.6-13.2lbs)	A good weight for the Get Home Bag. You've done well if you can get your BOB down to this weight as travelling will be easier and you won't tire as quickly. Useful if you are escaping on foot.	• Quick Movement • Less fatigue	• Weak in combat • Little Comfort • Less Redundancies • Less Weather-Proof
Lightweight	5-10kg (13.2-22lbs)	A lighter pack allowing you to potentially reach your BOL quicker. A good step up from a moderate weight pack if you can manage to cut out some items.	• Faster Movement • Can travel longer	• Less Weather-Proof • Less Comfort
Moderate	10-15kg (22-33lbs)	A good average pack weight for your regular Bug Out Bag.	• Average Movement • Decent comfort • Good Redundancy	• Possible Theft Target
Heavy	15-20kg (33-44lbs)	Most new preppers tend to overfill their BOBs and automatically drop into this category.	• Better in combat • More Weather-Proof	• Slower Movement • Harder to carry • Possible Theft Target
Ultraheavy	20-30kg (44-66.1lbs)	This weight would be a good fit for an INCH Bag. People with bags this heavy often like their sleeping setups and don't want to compromise on a good night's sleep.	• More Redundancies • Very Weather-Proof	• Very Slow Movement • Difficult to carry • Need more breaks • A Theft Target
Super Ultraheavy	>30kg (>66.1lbs	A bag which would be a good fit for an INCH Bag if you're heading to the woods - if you can carry it. This kind of bag would be fine if your main method of transport is a car or bike for most of the journey.	• Often Heavily Armed • Lots of Redundancies • Highly Weather-Proof • Not Very Resourceful	• Glacial Movement • Painful to carry • Need regular breaks • High Theft Target

Ultraheavy'ers
Ultraheavy backpacking is not really style at all but is rather a term for people who aren't planning on carrying their backpack, but rather drive with it in the car. Generally the people with these backpacks aren't capable of carrying them long term and don't plan on even carrying them on their backs. Newbie preppers often over pack their bags until they are unable to carry them and then have to scale back what they packed - often with great difficulty. Knowledge is the best substitute for weight, the more you know the less you have to carry.

Fluid Weight Calculation

Using the fluid points system below, add up the total weight of your BOB essentials (further below). If the result is < 0 you are lighter then average, otherwise you are heavier. Write down the current weight of your items below to measure where you lie and what you should reduce in your backpack first if required. "Moderate" is the typical camper's item weight averaged between many of that class. UL'ers should aim for less than 0.

General Ultralight Ratios	Abbreviations	Fluid Weight Calculation	Example Current Weight
Super Ultraheavy: >200%	Super Ultraheavy: (SUH)	Super Ultraheavy: +3 Points	BOB = -3
Ultraheavy: <200%	Ultraheavy: (UH)	Ultraheavy: +2 Points	(BOB's weight is 20% below average)
Heavy: <150%	Heavy: (H)	Heavy: +1 Point	
Moderate: <100%	Moderate: (M)	Moderate: +0 Points	
Light: <80%	Light: (L)	Light: -1 Point	
Ultralight: <60%	Ultralight: (UL)	Ultralight: -2 Points	
Super Ultralight: <40%	Super Ultralight: (SUL)	Super Ultralight: -3 Points	

Fluid Backpack Essentials Weight

Backpack	Tent/Tarp/Bivy/Swag	Sleeping Bag & Mattress	Stove & Fuel	Cooking / Canteen Set	Survival Knife
Super Ultraheavy: >3kg	Super Ultraheavy: >7kg	Super Ultraheavy: >5kg	Super Ultraheavy: >500g	Super Ultraheavy: >750g	Super Ultraheavy: >1.5kg
Ultraheavy: <3kg	Ultraheavy: <7kg	Ultraheavy: <5kg	Ultraheavy: <300g	Ultraheavy: <750g	Ultraheavy: <1.5kg
Heavy: <2kg	Heavy: <5kg	Heavy: <4kg	Heavy: <200g	Heavy: <500g	Heavy: <1kg
Moderate: <1.5kg	Moderate: <3kg	Moderate: <3kg	Moderate: <100g	Moderate: <300g	Moderate: <800g
Light: <800g	Light: <1kg	Light: <1kg	Light: <85g	Light: <200g	Light: <600g
Ultralight: <500g	Ultralight: <600g	Ultralight: <800g	Ultralight: <60g	Ultralight: <100g	Ultralight: <200g
Super Ultralight: <300g	Super Ultralight: <400g	Super Ultralight: <500g	Super Ultralight: <40g	Super Ultralight: <75g	Super Ultralight: <100g

Ultralight: <80g	Ultralight: <40g	Ultralight: <120g			
Super Ultralight: <50g	Super Ultralight: <20g	Super Ultralight: <80g			

The 343 Method

A simple method by 'fjäderlätt' to lighten gear by limiting "The Big Three" to a total of 3kg's.

Numbers can be split between the three and don't have to be 1kg for each item. Such as: 1.4kg + 0.7kg + 0.9kg = 3.0kg. Done correctly, you should still have a modicum of comfort when sleeping and will put you well on the way of becoming an UL'er.

The Big Three
- Shelter (Tent/Tarp)
- Sleeping (Bag/Quilt/Pad)
- Carrying (Backpack)

Weight Reduction

A section for those who wish to reduce the weight of their backpack to make the journey easier on the shoulders and back. As always, only reduce what you can afford to lose and that won't have a huge negative impact on your survival.

Basic Reduction

Reducing the weight of your backpack is often the most difficult part as you don't want to part with gear you're attached to. The following are a few easy ways to lighten the load of your backpack.

Removing Items	Remove any items that aren't a necessity to survival. Go through each item and ask "Do I really NEED this?" and "What will happen if I don't have this?".
Multi-Purpose Items	Have one item that can be used multiple ways such as a titanium pot for boiling, eating from and drinking from.
Lighter Variants	Buy lighter materials for the necessary items such as titanium instead of stainless steel.

Location	Have the right gear for the situation and location. You don't need to bring warm clothes if you're in a warm part of the globe.
Simplicity	Forego luxury items for a simpler form of living, try to reduce the necessary items you need such as coffee or fancy shelters.
No Redundancy	Generally redundancy is key - unless it's a BOB where you're heading to a destination with all the supplies you need.
Knowledge	The more you know - the less you carry. If you can use materials nature provides you don't need to bring it yourself.
Morale	Include a small morale booster in your pack such as a chocolate bar or alcohol to make the transition to a lighter pack easier and so you have something to look forward to.
Safety First	Ensure safety comes first, don't remove items you can't live without, start slowly removing a few items each trip.

Advanced Reduction

The following methods are extreme ways you can lose every milligram from your backpack and should be looked at last if you want the lightest bag possible. There are many ways to shed weight even further - the most common exaggeration being drilling holes in your toothbrush.

Remove Packaging	Remove un-necessary packaging from your items such as excess plastic, tags and stickers.
Drill Holes	Drill holes in malleable plastics/metals which can withstand the loss and won't break.
Trim Excess	Cut the excess material from objects. If you have a tarp that is slightly too big for your needs, trim it a little for a perfect fit.
Replace Items	You can replace small items with lighter weight alternatives that do the same thing such as lighter carabineers on bags.

Packing

Pack the most important items at the top and side pockets for fast access such as medical kit, rain poncho and navigation items. Keep the heaviest items at the base of the pack and as close to your body as possible to keep the weight centred. Below is an ordered list of gear by frequency of use and how it should be stored in the backpack or on your person.

Immediate Access	Items which need to be used swiftly or which affect the health of individuals, such as a medical kit. These items should be accessible within a few seconds from your backpack or kept on you.	• First Aid Kit • Weapons • Rain Poncho • Medication	• Knife • Binoculars • Gas Mask
Frequent Access	Items which will be used at least 5 times a day and don't have an impact on health or safety. They should be stored in outer pockets.	• Compass / GPS • Maps • Phone • Water Bottle • Radio	• Whistle • Torch / Headlamp • Glasses / Sunglasses • Water Purification Tabs
Infrequent Access	Items which are used 1-2 times a day. These should be stored in outer pockets.	• Food • Clothing • Cutlery and Pots • Hygiene Products	• Fire Lighting Tools • Notepad & Pen
Uncommon Access	Items which are used about once a day.	• Fishing Kit • Hunting Kit • Morale Boosters • Cash / Money	• Trowel / TP
Rare Access	Items which may not need to be used at all or items which take up a lot of space such as a tent and sleeping bag.	• Tent / Swag / Bivy • Hatchet / Shovel • Sleeping Bag • Groundsheet	

Redundancy

Redundancy is the art of having more than one way to accomplish a task such as having some matches in your PSK and a lighter in your BOB - both which are used to start a fire. Redundancy helps if one of the items breaks or is worn out you will still have another way to accomplish that task. You could also be robbed of your pack and still have a way to light fire in your PSK which wasn't stolen.

EDC	In an EDC kit item redundancy isn't required. Any redundancy items will only weigh down the user as an EDC is meant to be wearable and light. An example is why have a spare mini torch when you have a phone with a torch built in?	**Redundancy Categories** • None
BOB	A BOB should only have a few redundancies. A BOB's primary use is to get you to your Bug Out Shelter within 3 days. If an item breaks in this time you should be able to do without it for the time being until you restock at your shelter.	**Redundancy Categories** • Fire Lighting • Self Defence
INCH	An INCH bag should have redundancies for most tools. An INCH bag should have redundancies of vital items such as two ways to cut logs, make fire and shelter etc. You aren't intending on reaching a well stocked final location therefore you should have a few backups in all major categories.	**Redundancy Categories** • Food Acquisition • Water Purification • Shelter Building • Fire Lighting • Self Defence
GH	A GH bag shouldn't have more than the most basic redundancies.	**Redundancy Categories** • Fire Lighting
SCAR	SCAR bags are basically redundancy bags so no additional duplicates are needed as these items ARE the redundancies.	

3 Gear Lists

These lists contain the most recommended gear for each preparedness bag. For more detailed information on each item see the Gear Descriptions further below. Some rows aren't applicable to some bags such as the clothing row for the PSK as the kit is too small for clothes. Items will overlap between bags in case you don't have one of the bags. So a knife will be listed in the GH, BOB and INCH bags. PP means Per Person.

Item Rating
The item rating shows the recommendation of how much this item should be in the given survival bag. All possible fields are as follows:

Essential Item	This item should always be in your survival bag as it provides critical functionality without which you could die.	**Ex: Knife / Water Bottle**
Important Item	An item that provides a strong advantage for surviving but you might be able to get by without one or make one yourself in the field.	**Ex: Tent / Paracord**
Useful Item	Items which can be used in survival situations to make life easier but by no means is required to keep you alive.	**Ex: Solar Panel / GPS**
Conditional Item	These items are based heavily on a specific condition such as your location or medical requirements.	**Ex: Thermals / Epi Pen**
Optional Item	Items which you don't need to survive but can provide a morale boost or keep you grounded.	**Ex: Coffee / Bible**

PSK Gear

PSK Gear (Pocket Survival Kit)
Fits into a small metal tin (altoids tin) and covers the very basic survival needs excluding shelter. This tin should be about 10x7x2cm to be able to fit in a pocket. This kit is designed to give you better odds of survival if it's the only thing you have on you. It may be beneficial to store it in a zip lock bag to protect the contents from liquids which also works as an additional water bag you can use later. The basic aim of a PSK is to provide fire, potable water, some medication and medical aid, a cutting utensil and a way to signal for help.

Water

Unlubricated Condom Qty: 1-2 Necessity: Essential Used as a 1L water container and for sex. Can start fires when filled with water in sunlight.	**Water Sterilization Tablets** Qty: 5 Necessity: Essential Purifies 1L of water and can be used in conjunction with the condom.	**Zip Lock Bag** Qty: 1 Necessity: Important Around 500ml (1pt). Used as a water bottle and can be placed in the sun for SODIS.			

Food & Cooking

Tin Qty: 1 Necessity: Essential The tin which holds the survival kit can be used to cook and boil water in.	**Alum Foil** Qty: 1 Necessity: Useful Can be used for signalling, reflecting heat, SODIS and a lid. An A4 piece folded down should suffice	**Snare Wire** Qty: 2 Necessity: Important Used for catching wild animals.			

Clothing

Not applicable for this kit

Shelter

Not applicable for this kit

Hygiene

Tablet Napkin Qty: 1-2 Necessity: Useful Used for cleaning, washing and as toilet paper.					

Medical

Isopropyl Wipes Qty: 5 Necessity: Essential For killing bacteria on wounds and starting fires.	**Analgesic** Qty: 3 Necessity: Essential Relieves pain. Common choices include panadol and nurofen.	**Intestinal Sedative** Qty: 3 Necessity: Essential Treats chronic and acute diarrhoea.	**Antihistamine** Qty: 2 Necessity: Important For allergies, insect bites and stings.	**Anti-Malaria Tablet** Qty: 2 Necessity: Conditional Vital in areas with malaria.	**Potassium Permanganate** Qty: 2 Grams Necessity: Important Water sterilizer and antiseptic.
Band-Aids Qty: 7 Necessity: Essential For covering minor scrapes, cuts and blisters. Waterproof and silver impregnated ones are optimal.	**Butterfly Sutures** Qty: 4 Necessity: Important Holds together the edges of clean wounds.	**IOsat** Qty: 1-2 Necessity: Conditional Helps prevent the absorption of radioactive iodine. Take 1 per day while in radiation.			

Tools

Paracord Qty: 1m Necessity: Important For building shelters, tying items and repairs.	**Duct Tape** Qty: 30cm Necessity: Useful For repairs on anything that needs it.	**Razor Blade** Qty: 2 Necessity: Essential Used as a makeshift knife for cutting, feathering, gutting, shaving and medical requirements	**Tiny Pen & Paper** Qty: 1 Tiny Pen, 1 Sheet Necessity: Useful For writing survival notes. Waterproof pens and books would be ideal.	**Flexible Saw** Qty: 1 Necessity: Important Can cut down trees with a diameter smaller than 2 inches.	

Light & Fire

Flint Rod & Striker Qty: 1 Necessity: Essential Used for starting fires. Ensure it's a thick enough rod to get 1,000 strikes.	**Matches & Striker** Qty: 5 Necessity: Important Regular, waterproof or windproof matches to use when flint fails.	**Mini BIC Lighter** Qty: 1 Necessity: Important Used in emergencies when the other methods fail you.	**Tiny LED Torch** Qty: 1 Necessity: Important A torch for illumination. Includes a fully charged battery. Aim for 90+ Lumens.	**Cotton Ball** Qty: 3 Necessity: Useful Can be used as tinder or swabbing wounds.	**Birthday Candle** Qty: 1 Necessity: Useful A candle to assist in fire lighting and transferring fire.
Tritium Light Qty: 1 Necessity: Useful A light source which softly glows via a radioactive substance tritium. Used as a marker or reading light.	**Fresnel Lens** Qty: 1 Necessity: Essential Used to start fires when the other methods fail.				

Comms & Navigation

Small Mirror Qty: 1 Necessity: Essential A mirror for signalling and medical purposes.	**Tiny Whistle** Qty: 1 Necessity: Useful For signalling others to help them find you or for communication.	**Button Compass** Qty: 1 Necessity: Essential Helps you navigate and find north.			

Self Defence

Not applicable for this kit

Misc

Tiny USB Qty: 1 Necessity: Important • Survival Guides & TPE • Family Pictures • Local Maps • Entertainment & Music • Important Documents	**Cash** Qty: $20-$100 USD Necessity: Useful For buying essentials if you find society again and it's still functioning.	**Tea Bag** Qty: 1 Necessity: Optional Great for morale if you need it, and will give you some energy.	**Needles** Qty: 2 Necessity: Useful For fixing clothing.	**Thread** Qty: 10m Necessity: Useful For fixing clothing.	**Fishing Line** Qty: 20m Necessity: Important For fishing.
Hooks Qty: 2 Necessity: Important For fishing.	**Small Sinker** Qty: 2 Necessity: Important For fishing.				

EDC Gear

EDC Gear (Every Day Carry)
This gear is carried by you every day and should be able to be presented any time. The following are ideas of equipment you can carry and aren't items you should carry. EDC items are included because if you have to leave quickly for a disaster these items should already be on you. Most of these items are optional and are carried based on personal taste.

Water

Not applicable for this kit

Food & Cooking

Not applicable for this kit

Clothing

Current Clothing Qty: 1 Necessity: Essential The clothes you're currently wearing to protest your modesty.	**Paracord Gear** Qty: 1 Necessity: Useful These are survival items made of paracord such as a belt or bracelet. Some have extra items inside.	**Eyewear** Qty: 1 Necessity: Conditional Glasses and sunglasses to retain the ability to see.			

Shelter

Not applicable for this kit

Hygiene

Not applicable for this kit

Medical

Not applicable for this kit

Tools

Watch Qty: 1 Necessity: Useful Used for telling the time, date and some other useful features such as apps, compass and alarm.	**Multitool** Qty: 1 Necessity: Important A very handy tool which performs a variety of tasks.				

Light & Fire

Flint Rod Qty: 1 Necessity: Important Flint can be carried as a necklace or weaved into the shoelace of your boot.	**Keychain Torch** Qty: 1 Necessity: Useful A torch for illumination. Includes a fully charged battery. Aim for 90+ Lumens.				

Comms & Navigation

Mobile Phone Qty: 1 Necessity: Essential Almost essential in todays society with all the functions it can provide.	**Charger Cable** Qty: 1 Necessity: Optional Used to charge your mobile if you're running low on power.				

Self Defence

Gun / Knife Qty: 1 Necessity: Conditional Depending on your country you may need protection or laws may prevent you carrying one.					

Misc

Wallet / Purse Qty: 1 Necessity: Essential For paying your way in todays society.	**Keys** Qty: 1 Necessity: Essential Gains you access to your house and car.	**Necklace** Qty: 1 Necessity: Conditional Some form of necklace. It could be modified to include a few small survival items.	**USB Drive** Qty: 1 Necessity: Important • Survival Guides & TPE • Family Pictures • Local Maps • Entertainment & Music • Important Documents	**1oz Gold/Silver Coin** Qty: 1 Necessity: Optional A valuable coin kept on you to ensure it's safe at all times.	**Cash** Qty: $10-$100 USD Necessity: Useful For buying items in your daily routine.

GH Gear

GH Gear (Get Home)
These items are only to assist you getting home within 24 hours assuming a disaster has occurred - including one overnight camp. This kit is best left in your car and shouldn't contain items that can be destroyed in extreme heat or cold.

Water

1L Water Bottle Qty: 1-2 Necessity: Essential Storage for water and used in conjunction with purification tablets.	**Water Purification Tablets** Qty: 5-10 Necessity: Essential Purifies 1L of water and can be used in conjunction with the condom.				

Food & Cooking

Energy/Hiking Bars Qty: 3-5 Necessity: Essential This should be your only food and nothing should require heating up.					

Clothing

Socks Qty: 2 Pairs Necessity: Essential You are likely to be walking all the way home so fresh socks will be a lifesaver.	**Rain Poncho** Qty: 1 Necessity: Important Helps protects you from rain, dust, ash etc.	**Walking Boots** Qty: 1 Pair Necessity: Essential You are likely to be walking all the way home so be sure to have a comfortable pair of walking boots.	**Lightweight Clothes** Qty: 1 Set Necessity: Important Fresh clothes to change into if a disaster occurs while you're in business attire.	**Eyewear** Qty: 1 Necessity: Conditional Backup glasses and sunglasses to retain the ability to see.	

Shelter

GEAR | Gear Lists | GH Gear

Light Tarp / Hootchie Qty: 1 Necessity: Important If you're too tired to keep walking this will provide some shelter while you sleep.	**Survival Blanket** Qty: 1 Necessity: Important A thermal blanket to keep you warm and protect you from some bugs.				

Hygiene

Toilet Paper Qty: 1 Roll Necessity: Useful For when you need to do number 2's in the bush. Also good for tinder.	**Toothbrush** Qty: 1 Necessity: Useful To brush your teeth with.	**Toothpaste** Qty: 1 Necessity: Useful To brush your teeth with.	**Feminine Products** Qty: A few Necessity: Conditional A lifesaver if you're in need of them.		

Medical

First Aid Kit Qty: 1 Necessity: Essential A pre-packaged kit to take care of your medical needs.	**IOsat** Qty: 3 Necessity: Conditional Helps prevent the absorption of radioactive iodine. Take 1 per day while in radiation.	**Blister Pads** Qty: 7 Necessity: Important Moleskin pads placed above a blister to prevent it rubbing further.			

Tools

Knife Qty: 1 Necessity: Essential A strong knife for a huge array of tasks.	**Paracord** Qty: 10-30m Necessity: Important For building shelters, tying items and repairs.				

Light & Fire

Flint Rod & Striker Qty: 1 Necessity: Essential Used for starting fires. Ensure it's a thick enough rod to get 1,000 strikes.	**Matches & Striker** Qty: 5 Necessity: Important Regular, waterproof or windproof matches to use when flint fails.	**Mini BIC Lighter** Qty: 1 Necessity: Important Used in emergencies when the other methods fail you.	**Headlamp** Qty: 1 Necessity: Essential A hands free torch to assist when walking at night. 1,000+ Lumens.	**Battery** Qty: 1 Necessity: Important For the headlamp if you take multiple nights to get home.	**Torch** Qty: 1 Necessity: Important A backup torch for illumination. Includes a fully charged battery. 300+ Lumens.

Comms & Navigation

Compass Qty: 1 Necessity: Important Helps you find your bearings if you're in an unfamiliar area.	**Local Map** Qty: 2 Necessity: Important Helps you find your location if you're in an unfamiliar area.	**Small Mirror** Qty: 1 Necessity: Useful A mirror for signalling and medical purposes.	**Radio** Qty: 1 Necessity: Useful An emergency radio for listening to NOAA broadcasts. Solar powered is a bonus.	**Power Bank** Qty: 1 Necessity: Useful 10,000mAh+ to charge your devices if they're low.	

Self Defence

A Weapon Qty: 1 Necessity: Conditional A weapon of your selection based on your country. Ex: Bow, Slingshot, Handgun, Rifle.	**Ammo** Qty: 10-25 Rounds Necessity: Conditional Some extra rounds for your chosen weapon.	**Insect Repellent** Qty: 1 Necessity: Useful Keeps away pesky insects and mosquitoes.			

Misc

Cash Qty: $100-$300 USD Necessity: Useful For buying essentials if you find society again and it's still functioning.	**Charger Cable** Qty: 1 Necessity: Useful Used with the power bank to charge your phone.	**N95 Face Mask** Qty: 1 Necessity: Useful Protection from airborne viruses, dust etc.			

BOB Gear

BOB Gear

BOB Gear (Bug Out Bag)
A bag designed to only get you to your BOL within 3 days where you have food and supplies stored already. If you missed it, further up is a section on backpacks including guides to how much they should weigh and how to pack them properly.

Water

1L Water Bottle Qty: 1 Necessity: Essential Storage for water and used in conjunction with purification tablets. Ensure it's full.	**Water Purification Tablets** Qty: 10-30 Necessity: Essential Purifies 1L of water and can be used in conjunction with the condom.	**Unlubricated Condom** Qty: 2-4 Necessity: Essential Used as a 1L water container and for sex. Can start fires when filled with water in sunlight.	**Water Filter** Qty: 1-2 Necessity: Essential Filters pathogens from water to render it drinkable.		

Food & Cooking

Food Qty: 3-6 Meals PP Necessity: Essential Food to survive on until you reach your BOL.	**Energy/Hiking Bars** Qty: 3-5 PP Necessity: Important These will give you energy boosts throughout the day.	**Stove** Qty: 1 Necessity: Important A stove to cook food on.	**Fuel** Qty: 1-3 Necessity: Important For powering your stove. Either fuel tablets, alcohol or gas canisters.	**Cooking Pot** Qty: 1 Necessity: Essential A metal tin, pot or pan to cook your food in and boil water with.	**Cup** Qty: 0-1 Necessity: Optional For boiling water in and having a nice hot beverage.
Utensils Qty: 1 Necessity: Important A knife / fork / spork / chopsticks etc for eating with.	**Scrubber** Qty: 1 Necessity: Important For cleaning your containers with.	**Snare Wire** Qty: 3 Necessity: Important Used for catching wild animals.			

Clothing

Lightweight Clothes Qty: 1 Set Necessity: Important Fresh clothes to change into if a disaster occurs while you're in business attire.	**Warm Clothes** Qty: 1 Set Necessity: Conditional Warm clothes to layer up with if you have to bug out in the middle of winter.	**Rain Poncho** Qty: 1 Necessity: Important Helps protects you from rain, dust, ash etc.	**Walking Boots** Qty: 1 Pair Necessity: Essential You are likely to be walking a lot so be sure to have a comfortable pair of walking boots.	**Underwear** Qty: 2 Pairs Necessity: Essential A fresh change of underwear will keep you hygienic and give you something to change into if you get wet.	**Hat** Qty: 1 Necessity: Important Important to protect yourself from the sun in warmer climates.
Gloves Qty: 1 Necessity: Important Hand protection as you're likely to be touching a lot of	**Shemagh** Qty: 1 Necessity: Important A shemagh can be used for covering the face, filtering debris from water, concealment etc.	**Eyewear** Qty: 1 Necessity: Conditional Glasses and sunglasses to retain the ability to see.	**Socks** Qty: 2 Pairs Necessity: Essential You are likely to be walking all the way home so fresh socks will be a lifesaver.		

Shelter

Shelter Qty: 1 Necessity: Essential Whether it's a tent, swag, bivy or tarp.	**Ground Pad** Qty: 1 Necessity: Essential Any type of mattress to give you some padding and distance from the cold ground.	**Sleeping Bag** Qty: 1 Necessity: Essential Keeps you warm and cosy.	**Groundsheet** Qty: 1 Necessity: Optional Used to protect your tent from punctures and tears.	**Wool Blanket** Qty: 1 Necessity: Optional Keeps you warm in colder climates.	

Hygiene

Hand Sanitizer Qty: 1 Necessity: Useful Kills germs so you don't get sick as easily. The gel or spray types are easiest.	**Pack Towel** Qty: 1 Necessity: Useful For washing yourself or drying off.	**Toilet Paper** Qty: 1 Roll Necessity: Useful For when you need to do number 2's in the bush. Also good for tinder.	**Toothbrush** Qty: 1 Necessity: Useful To brush your teeth with.	**Toothpaste** Qty: 1 Necessity: Useful To brush your teeth with.	**Feminine Products** Qty: A few Necessity: Conditional A lifesaver if you're in need of them.

Medical

First Aid Kit Qty: 1 Necessity: Essential A pre-packaged kit to take care of your medical needs.	**Isopropyl Wipes** Qty: 10 Necessity: Essential For killing bacteria on wounds and starting fires.	**Analgesic** Qty: 10 Necessity: Essential Relieves pain. Common choices include panadol and nurofen.	**Intestinal Sedative** Qty: 8 Necessity: Essential Treats chronic and acute diarrhoea.	**Antihistamine** Qty: 6 Necessity: Important For allergies, insect bites and stings.	**Anti-Malaria Tablet** Qty: 4 Necessity: Conditional Vital in areas with malaria.
Potassium Permanganate Qty: 5 Grams Necessity: Important Water sterilizer and antiseptic.	**Band-Aids** Qty: 14 Necessity: Essential For covering minor scrapes, cuts and blisters. Waterproof and silver impregnated ones are optimal.	**Butterfly Sutures** Qty: 6 Necessity: Important Holds together the edges of clean wounds.	**IOsat** Qty: 6 Necessity: Conditional Helps prevent the absorption of radioactive iodine. Take 1 per day while in radiation.	**Antibiotics** Qty: 1-2 Boxes (30ea) Necessity: Conditional Helps prevent the absorption of radioactive iodine. Take 1 per day while in radiation.	**Wound Dressings** Qty: 10 Necessity: Essential For covering larger injures. Waterproof and silver impregnated ones are optimal.
Surgical Blades Qty: 2-3 Necessity: Important For performing medical operations.					

Tools

Knife Qty: 1 Necessity: Essential A strong knife for a huge array of tasks.	**Multitool** Qty: 1 Necessity: Important A very handy tool which performs a variety of tasks.	**Flexible Saw** Qty: 1 Necessity: Important Can cut down trees with a diameter smaller than 2 inches.	**Pen & Book** Qty: 1 Pen, 1 Book Necessity: Useful For writing survival notes. Waterproof pens and books would be ideal.		

Light & Fire

GEAR | Gear Lists | BOB Gear

Flint Rod & Striker Qty: 1 Necessity: Essential Used for starting fires. Ensure it's a thick enough rod to get 1k strikes.	**Matches & Striker** Qty: 5 Necessity: Important Regular, waterproof or windproof matches to use when flint fails.	**Headlamp** Qty: 1 Necessity: Essential A hands free torch to assist when walking at night. 1,000+ Lumens.	**Battery** Qty: 2-3 Necessity: Important For the headlamp and torch.	**Candle** Qty: 1 Necessity: Useful A 2.5cm (1in) candle to provide light, assist in fire lighting and transferring fire.	**Fresnel Lens** Qty: 1 Necessity: Essential Used to start fires when the other methods fail.
Tritium Light Qty: 1-2 Necessity: Useful A light source which softly glows via a radioactive substance tritium. Used as a marker or reading light.	**Torch** Qty: 1 Necessity: Important A backup torch for illumination. Includes a fully charged battery. 300+ Lumens.	**Glowstick** Qty: 0-3 Necessity: Optional Provides instant light for 8 hours when snapped.			

Comms & Navigation

Mobile Phone Qty: 1 Necessity: Essential Almost essential in todays society with all the functions it can provide.	**Charger Cable** Qty: 1 Necessity: Optional Used to charge your mobile if you're running low on power.	**Compass** Qty: 1 Necessity: Important Helps you find your bearings if you're in an unfamiliar area.	**Local Map** Qty: 1 Necessity: Important Helps you find your location if you're in an unfamiliar area.	**Map Case** Qty: 1 Necessity: Important A transparent and waterproof map case to keep it protected from the elements.	**Signal Flares** Qty: 5 Necessity: Conditional Helps people find you when shot into the air.
Radio Qty: 1 Necessity: Useful An emergency radio for listening to NOAA broadcasts. Solar powered is a bonus.	**Solar Panel** Qty: 1 Necessity: Optional A solar panel to charge your electronics during the day.	**Power Bank** Qty: 1 Necessity: Optional 10,000mAh+ to charge your devices if they're low. Can be recharged via solar panel.	**Whistle** Qty: 1 Necessity: Useful For signalling others to help them find you or for communication.	**Binoculars** Qty: 1 Necessity: Optional Or monocular for scouting out what's ahead. Recommended in dangerous areas.	

Self Defence

A Weapon Qty: 1 Necessity: Conditional A weapon of your selection based on your country. Ex: Bow, Slingshot, Handgun, Rifle.	**Ammo** Qty: 25-50 Rounds PP Necessity: Conditional Some extra rounds for your chosen weapon.	**Insect Repellent** Qty: 1 Necessity: Useful Keeps away pesky insects and mosquitoes.			

Misc

Backpack Qty: 1 Necessity: Essential This is used to carry all the items above.	**Cash** Qty: $300-$500 USD Necessity: Useful For buying essentials if you find society again and it's still functioning.	**Brew Kit** Qty: 1 Necessity: Optional A small kit to restore morale containing tea, coffee and everything required to make them.	**Barterable Coins** Qty: 0-10oz Necessity: Optional Gold and silver coins to be used for bartering for goods if the situation arises.	**Needles** Qty: 3 Necessity: Useful For fixing clothing.	**Thread** Qty: 20m Necessity: Useful For fixing clothing.
Fishing Line Qty: 50m Necessity: Important For fishing.	**Hooks** Qty: 5 Necessity: Important For fishing.	**Small Sinkers** Qty: 5 Necessity: Important For fishing.	**Latex Tubing** Qty: 1m Necessity: Important Used for binding, as a straw, as a slingshot tube etc.	**N95 Face Mask** Qty: 1 Necessity: Useful Protection from airborne viruses, dust etc.	**ID Documents** Qty: Varies Necessity: Essential Carried identification such as your birth cert, passport, drivers licence etc.
Playing Cards Qty: 1 Deck Necessity: Optional Something to keep you entertained if you're bored.	**Morale Boosters** Qty: 1-2 Necessity: Optional Treat yourself to a small item like chocolate, alcohol or a cigar.				

INCH Gear

INCH Gear

INCH Gear (I'm Never Coming Home)
This bag will help you bug out indefinitely with it's many tools and heavy duty items, possibly with a little assistance of stored caches along the way. The INCH bag focuses on obtaining resources from nature and setting up your new life away from home.

Water

1L Water Bottle Qty: 1-3 Necessity: Essential Storage for water and used in conjunction with purification tablets. Ensure it's full.	**Water Purification Tablets** Qty: 25-100 Necessity: Essential Purifies 1L of water and can be used in conjunction with the condom.	**Unlubricated Condom** Qty: 3-5 Necessity: Essential Used as a 1L water container and for sex. Can start fires when filled with water in sunlight.	**Water Filter** Qty: 2 Necessity: Essential Filters pathogens from water to render it drinkable.		

Food & Cooking

Food Qty: 14-21 Meals PP Necessity: Essential Food to survive on until you reach your BOL.	**Energy/Hiking Bars** Qty: 5-10 PP Necessity: Important These will give you energy boosts throughout the day.	**Stove** Qty: 1-2 Necessity: Important A stove to cook food on.	**Fuel** Qty: 3-9 Necessity: Important For powering your stove. Either fuel tablets, alcohol or gas canisters.	**Cooking Pot** Qty: 1-2 Necessity: Essential A metal tin, pot or pan to cook your food in and boil water with.	**Cup** Qty: 0-1 Necessity: Optional For boiling water in and having a nice hot beverage.
Utensils Qty: 1-2 Necessity: Important A knife / fork / spork / chopsticks etc for eating with.	**Scrubber** Qty: 1 Necessity: Important For cleaning your containers with.	**Multivitamins** Qty: 5-50 Necessity: Important Helps keep your healthy as you're likely to lack essential vitamins when SHTF.			

Clothing

Lightweight Clothes Qty: 1 Set Necessity: Important Fresh clothes to change into if a disaster occurs while you're in business attire.	**Warm Clothes** Qty: 1 Set Necessity: Conditional Warm clothes to layer up with if you have to bug out in the middle of winter.	**Rain Poncho** Qty: 1 Necessity: Important Helps protects you from rain, dust, ash etc.	**Walking Boots** Qty: 1 Pair Necessity: Essential You are likely to be walking a lot so be sure to have a comfortable pair of walking boots.	**Underwear** Qty: 3 Pairs Necessity: Essential A fresh change of underwear will keep you hygienic and give you something to change into if you get wet.	**Hat** Qty: 1 Necessity: Important Important to protect yourself from the sun in warmer climates.
Gloves Qty: 1 Necessity: Important Hand protection as you're likely to be touching a lot of	**Shemagh** Qty: 1 Necessity: Important A shemagh can be used for covering the face, filtering debris from water, concealment etc.	**Eyewear** Qty: 1 Necessity: Conditional Glasses and sunglasses to retain the ability to see.	**Socks** Qty: 3 Pairs Necessity: Essential You are likely to be walking all the way home so fresh socks will be a lifesaver.		

Shelter

Shelter Qty: 1 Necessity: Essential Whether it's a tent, swag, bivy or tarp.	**Ground Pad** Qty: 1 Necessity: Essential Any type of mattress to give you some padding and distance from the cold ground.	**Sleeping Bag** Qty: 1 Necessity: Essential Keeps you warm and cosy.	**Groundsheet** Qty: 1 Necessity: Optional Used to protect your tent from punctures and tears.	**Wool Blanket** Qty: 1 Necessity: Optional Keeps you warm in colder climates.	

Hygiene

Hand Sanitizer Qty: 1 Necessity: Useful Kills germs so you don't get sick as easily. The gel or spray types are easiest.	**Pack Towel** Qty: 1 Necessity: Useful For washing yourself or drying off.	**Toilet Paper** Qty: 1 Roll Necessity: Useful For when you need to do number 2's in the bush. Also good for tinder.	**Toothbrush** Qty: 1 Necessity: Useful To brush your teeth with.	**Toothpaste** Qty: 1 Necessity: Useful To brush your teeth with.	**Feminine Products** Qty: A few Necessity: Conditional A lifesaver if you're in need of them.

Medical

First Aid Kit Qty: 1 Necessity: Essential A pre-packaged kit to take care of your medical needs.	**Isopropyl Wipes** Qty: 50 Necessity: Essential For killing bacteria on wounds and starting fires.	**Analgesic** Qty: 50 Necessity: Essential Relieves pain. Common choices include panadol and nurofen.	**Intestinal Sedative** Qty: 32 Necessity: Essential Treats chronic and acute diarrhoea.	**Antihistamine** Qty: 24 Necessity: Important For allergies, insect bites and stings.	**Anti-Malaria Tablet** Qty: 10 Necessity: Conditional Vital in areas with malaria.
Potassium Permanganate Qty: 20 Grams Necessity: Important Water sterilizer and antiseptic.	**Band-Aids** Qty: 100+ Necessity: Essential For covering minor scrapes, cuts and blisters. Waterproof and silver impregnated ones are optimal.	**Butterfly Sutures** Qty: 25 Necessity: Important Holds together the edges of clean wounds.	**IOsat** Qty: 18 Necessity: Conditional Helps prevent the absorption of radioactive iodine. Take 1 per day while in radiation.	**Antibiotics** Qty: 2-4 Boxes (30ea) Necessity: Conditional Helps prevent the absorption of radioactive iodine. Take 1 per day while in radiation.	**Wound Dressings** Qty: 50 Necessity: Essential For covering larger injures. Waterproof and silver impregnated ones are optimal.
Surgical Blades Qty: 3-5 Necessity: Important For performing medical operations.					

Tools

Knife Qty: 2-3 Necessity: Essential A strong knife for a huge array of tasks.	**Multitool** Qty: 1 Necessity: Important A very handy tool which performs a variety of tasks.	**Flexible Saw** Qty: 1 Necessity: Important Can cut down trees with a diameter smaller than 2 inches.	**Folding Saw** Qty: 1 Necessity: Important Can cut down trees with a diameter smaller than 5-7 inches.	**Hatchet/Axe** Qty: 1 Necessity: Important For felling full size trees easier during shelter building.	**Sharpening Stone** Qty: 1 Necessity: Important Keeps your knife, hatchet and other tools sharp.

Folding Shovel Qty: 1 Necessity: Important For digging holes, retrieving caches etc.	**Pen & Book** Qty: 2 Pens, 1 Book Necessity: Useful For writing survival notes. Waterproof pens and books would be ideal.	**Snare Wire** Qty: 15 Necessity: Important Used for catching wild animals.	**Traps** Qty: 15 Necessity: Important Used for catching wild animals. Traps such as lobster pots, bear traps etc.		

Light & Fire

Flint Rod & Striker Qty: 2 Necessity: Essential Used for starting fires. Ensure it's a thick enough rod to get 1k strikes.	**Matches & Striker** Qty: 20-30 Necessity: Important Regular, waterproof or windproof matches to use when flint fails. Split in half to save space.	**Headlamp** Qty: 1 Necessity: Essential A hands free torch to assist when walking at night. 1,000+ Lumens.	**Battery** Qty: 3-10 Necessity: Important For the headlamp and torch. Ensure they are rechargeable and can be used with a solar panel.	**Battery Charger** Qty: 1 Necessity: Optional A charger which can be connected to a solar panel to recharge batteries.	**Candle** Qty: 2 Necessity: Useful A 2.5cm (1in) candle to provide light, assist in fire lighting and transferring fire.
Fresnel Lens Qty: 1 Necessity: Essential Used to start fires when the other methods fail.	**Tritium Light** Qty: 1-2 Necessity: Useful A light source which softly glows via a radioactive substance tritium. Used as a marker or reading light.	**Torch** Qty: 1 Necessity: Important A backup torch for illumination. Includes a fully charged battery. 300+ Lumens.	**Glowstick** Qty: 0-3 Necessity: Optional Provides instant light for 8 hours when snapped.		

Comms & Navigation

Mobile Phone Qty: 1-2 Necessity: Essential Almost essential in todays society with all the functions it can provide.	**Charger Cable** Qty: 1-2 Necessity: Optional Used to charge your mobile if you're running low on power.	**Compass** Qty: 1-2 Necessity: Important Helps you find your bearings if you're in an unfamiliar area.	**Local Map** Qty: 2-3 Necessity: Important Helps you find your location if you're in an unfamiliar area.	**Map Case** Qty: 2-3 Necessity: Important A transparent and waterproof map case to keep it protected from the elements.	**Signal Flares** Qty: 5-10 Necessity: Conditional Helps people find you when shot into the air.
Radio Qty: 1 Necessity: Useful An emergency radio for listening to NOAA broadcasts. Solar powered is a bonus.	**Solar Panel** Qty: 1-2 Necessity: Optional A solar panel to charge your electronics during the day.	**Power Bank** Qty: 1 Necessity: Optional 10,000mAh+ to charge your devices if they're low. Can be recharged via solar panel.	**Whistle** Qty: 1 Necessity: Useful For signalling others to help them find you or for communication.	**Binoculars** Qty: 1 Necessity: Optional Or monocular for scouting out what's ahead. Recommended in dangerous areas.	

Self Defence

A Weapon Qty: 1-2 Necessity: Conditional A weapon of your selection based on your country. Ex: Bow, Slingshot, Handgun, Rifle.	**Ammo** Qty: 100-200 Rounds PP Necessity: Conditional Some extra rounds for your chosen weapon.	**Insect Repellent** Qty: 1-3 Necessity: Useful Keeps away pesky insects and mosquitoes.			

Misc

Backpack Qty: 1 Necessity: Essential This is used to carry all the items above.	**Cash** Qty: $500-$1,000 USD Necessity: Useful For buying essentials if you find society again and it's still functioning.	**Brew Kit** Qty: 1 Necessity: Optional A small kit to restore morale containing tea, coffee and everything required to make them.	**Barterable Coins** Qty: 0-100oz Necessity: Optional Gold and silver coins to be used for bartering for goods if the situation arises.	**Needles** Qty: 3-5 Necessity: Useful For fixing clothing.	**Thread** Qty: 100-200m Necessity: Useful For fixing clothing.
Fishing Line Qty: 100m-1km Necessity: Important For fishing & limited shelter construction.	**Hooks** Qty: 10-20 Necessity: Important For fishing.	**Small Sinkers** Qty: 10-20 Necessity: Important For fishing.	**Fishing Net** Qty: 1-3 Necessity: Important For the unmanned catching of larger fish.	**Yoyo Reel** Qty: 2-5 Necessity: Important For the unmanned catching of fish.	**N95 Face Mask** Qty: 1-2 Necessity: Useful Protection from airborne viruses, dust etc.
Latex Tubing Qty: 1-3m Necessity: Important Used for binding, as a straw, as a slingshot tube etc.	**Seed Bank** Qty: 1 Collection Necessity: Important A collection of heirloom seeds to begin growing food straight away.	**Identification** Qty: Varies Necessity: Essential Carried identification such as your birth cert, passport, drivers licence etc.	**Playing Cards** Qty: 1 Deck Necessity: Optional Something to keep you entertained if you're bored.	**Morale Boosters** Qty: 1-2 Necessity: Optional Treat yourself to a small item like chocolate, alcohol or a cigar.	

4 Gear Descriptions

The following section is a categorization of all the common gear people use in their preparedness bags. Each item described above will be found here in much more detail. A few items from each category will provide you with a solid starting point for any situation you may face. This gear list is only a guide to get you thinking about what you may need, however everyone's situation is different and gear should be built around you. Each item has a usefulness rating which should be used as a guide only as everything is subjective. Safety first and pack the medicine and medication you require.

Subheadings

		1. Survival Rating	**2. Top 10 Items**	**3. Water**	**4. Food**		

		5. Shelter	6. Clothing	7. Fire	8. Medical		
		9. Medication	10. First Aid Kit	11. Trauma Kit	12. Dental Kit		
		13. Hygiene	14. Tools	15. Light & Power	16. Communication		
		17. Weapons	18. Tactical	19. Morale	20. Navigation		
		21. Misc	22. Sewing Kit	23. Fishing Kit			

1 Survival Rating

The survival rating (shown right) is a simple guide in each category to assist in choosing which items are the most important in your pack. The large number is the total score of the item, dictating how useful it is to have in a survival situation based on multiple fields. The acronyms at the bottom signify which preparedness bags this item should be in. These are discussed in more detail below.

Item Name
Item Rating
5/5
EDC, BOB, INCH

Fields

These are the attributes which form the total score of each item. Each one is carefully considered and calculated with different weightings to give a good idea of its usefulness. Some don't apply to each item such as Nutrition and taste.

Size	**How much space the item will consume in your pack.** 5 - Extremely small item 1 - Large and bulky item
Weight	**How much weight the item will add to your pack.** 5 - Virtually no weight 1 - Extremely heavy
Durability / Quality	**How tough the item is and how long it's likely to last.** 5 - Likely lasts forever 1 - Will break quickly
Usefulness	**How much use the item will get.** 5 - Daily Use 1 - Very Rare Use
Rarity	**How hard the item will be to find or reproduce in a SHTF world.** 5 - Impossible to find 1 - Very common item
Shelf Life	**How long the item will last before its expiry. The item may last longer than the written date.** 5 - 30+ Years 4 - 10 to 20 Years 3 - 5 to 10 Years 2 - 1-5 Years 1 - Under 1 Year
Convenience	**How easy the item is to operate or use.** 5 - Super simple 3 - Moderately complex 1 - Very complex
Nutrition	**How many calories and nutritional benefits the food has.** 5 - Nutritionally rich 3 - Not good nor bad 1 - Bad for you
Taste	**How the product tastes.** 5 - Delicious 3 - Meh, Edible 1 - Almost Inedible
Cost	Cost isn't included in the rating total as once the item's purchased it's no longer thought about, especially in a SHTF situation. Cost also varies wildly.

Item Usefulness

These are the different tiers of gear usefulness. Some items are essential in every kit whereas others are conditional items based on other information such as your location or health.

Essential Item	This item should always be in your survival bag as it provides critical functionality without which you could die.	**Ex: Knife / Water Bottle**
Important Item	An item that provides a strong advantage for surviving but you might be able to get by without one or make one yourself in the field.	**Ex: Tent / Paracord**
Useful Item	Items which can be used in survival situations to make life easier but by no means is required to keep you alive.	**Ex: Solar Panel / GPS**
Conditional Item	These items are based heavily on a specific condition such as your location or medical requirements.	**Ex: Thermals / Epi Pen**
Optional Item	Items which you don't need to survive but can provide a morale boost or keep you grounded.	**Ex: Coffee / Bible**

Recommended Bags

The final field shows which bags this item would be beneficial inside as some items are designed for certain bags such as a hatchet in an INCH bag. The following is a complete list of bags the items could be in. SCAR bags are excluded because any item could go into them.

All Bags: This item could go into any bags but may be constrained by size in some.
Person: This item can be worn on your person such as a watch or clothing.
PSK: An item which should go into a tiny 'Pocket Survival Kit' easily about the size of an altoids tin.
EDC: An item which will suit an EDC (Every Day Carry) bag.
GH: An item which will suit a GH (Get Home) bag.
BOB: An item which will suit a BOB (Bug Out Bag).
INCH: An item which will suit an INCH (I'm Never Coming Home) bag.
Ext: This is short for external location, meaning a bug-out location, car or prepper cache.

2 Top 10 Items

The following items are arguably the most important if you're limited to carrying a few.

#1 Knife	Infinite uses such as self defence, carving containers, striking natural flint, gutting animals, cutting cordage, cutting wood, hammering, reflecting light etc. If you can only have one item, a knife is an excellent choice.
#2 Metal Bottle	Used to boil and store water, it's placed before fire because it's possible to produce fire without a ferro rod, however it's much harder to boil water with items found in nature.
#3 Flint Rod	AKA: Ferrocerium Rod. Because fire is too difficult to procure in harsh conditions without one. The knife can be used with it to produce sparks. A shorter term, but easier option to use would be a BIC lighter.
#4 Tarp	Used for erecting a shelter, capturing rain, capturing distilled water, sleeping inside, reflecting heat etc.
#5 Paracord >30m (100ft)	Used for traps, constructing shelters and furniture, suturing, rappelling, tourniquet, fishing net, fishing line, hanging etc.
#6 Medical Kit	For patching yourself up when you're ill or injured. Some injuries and illnesses can knock you down quickly when it's more important than ever to think clearly.
#7 Latex Tube	Used for crafting a bow, crossbow, slingshot, tourniquet, straw, siphoning tube.
#8 Transparent Sheeting	Used to make a shelter, build a solar still, as insulation, as a rain collector, as a ground sheet or a dry bag.
#9 Local Maps	For finding your location and working out the ideal spots to set up camp. You can estimate your position based on the topography and landmarks or build a makeshift compass.
#10 Backpack	Without this you will be trying to haul most of the items around in the tarp with a paracord knot. They can also be used for foraging, a makeshift pillow and keeping dry.

Assumptions
Similar to the style of the "Alone" Tv series where participants had to choose 10 items to take with them, but were given some such as a medical kit. It's assumed that a disaster is occurring and you've bugged out into the wild and don't want to be found. Your aim is to stay in the wild as long as possible to avoid the disaster. Generally items consisting of multiple parts aren't allowed, but that excludes a small medical kit.

Large items which are cumbersome or difficult to carry such as a whole tent or swag aren't allowed. You have typical civilian clothing on you for the time of year and you don't have any EDC gear. You start with no food or water and had to run out of the house with the clothes on your back. Having redundancies are a waste of a slot therefore if there's an overlap it's a happy coincidence.

Exclusions Some items are excluded for various reasons, they are as follows.	**Compass** There are a few ways to find direction without a compass, but without a map you're completely lost.	**Signalling Devices** You probably don't want to be found or they may try to rob or kill you. You can make a fire instead to signal.	**Technology** It's obvious that when they run out of power they will be useless, including torches.	**Guns** Left out because ammo is finite and you can make either a bow or slingshot with the latex tube.

3 Water

This section helps you choose the water related items in your kits.

Water Bottle

Water Bottle Essential Item 5/5 **GH, BOB, INCH**	A water bottle allows the transportation of water whether potable or not, when travelling between water sources and should last until you refill. It's recommended to have at least one metal container or bottle to boil water in and something to store the purified water in once complete, unless you have another purification method such as tablets or a filter. The only reason a bottle isn't needed is if you filter water directly from the source, there's ample water nearby and you aren't planning on travelling.

Bottle Types

Solid Bottle A rigid bottle which is resistant to deformation and breaking. It takes up the most amount of space. Their weight can range between mid-light to heavy in the case of Nalgene.	**Materials** • Plastic • Tritan • Glass • Ceramic	A strong yet heavy bottle which can't be compressed in any way which may be resilient to breaking if it's not made from glass or ceramics. Some materials are better than others such as Tritan which is virtually unbreakable but rather heavy.

Semi-Solid Bottle A semi-solid bottle such as those you can buy in supermarkets which can be depressed when squeezed.	**Materials** ● Plastic ● Silicon	A great medium between a solid and flexible bottle with lightweight properties. Semi solid bottles will shrink if boiling water is poured into them.
Flexible Bottle A flexible bottle is any container that can be deformed and packed down into a smaller size. They are fairly light but aren't as tough as solid bottles and may eventually break over the fold creases.	**Materials** ● Plastic ● Silicon	Flexible bottles are extremely lightweight at the cost of durability. They shouldn't be bent along the crease lines too often as it will weaken them and they will eventually split along it. A flexible bottle should be combined with another more solid bottle such as solid, semi-solid or metal.
Metal Bottle A metal bottle is the strongest type of container at the cost of weight. However you can boil water in it and it can't be broken.	**Materials** ● Aluminium ● Stainless Steel ● Titanium	The best bottle to take into the field which can be used to boil water as well as drinking from. If you can afford it - titanium has the best weight to strength ratio. Aluminium may melt in a fire depending on its thickness.
Insulated Bottle Insulated bottles generally aren't useful in the field as they are bulky, heavy, can't be used to boil water and there's not much need for keeping water hot or cold.	**Materials** ● Plastic ● Metal	Fairly useless to use as the bottle will explode if heated over a fire and will be extra heavy due to being double walled. Beneficial if you wish to heat up water prior to rehydrate a meal or have a hot drink on the move.
Hydration Bladder A hiker's best friend which allows them to drink without using their hands. They are space efficient and often quite light. They can be hard to refill and clean.	**Materials** ● Plastic ● Silicon	A fairly lightweight drinking method best used for hiking and hands free drinking. Bladders can be somewhat prone to tears so keep it on your backpack preferably in its own compartment.

Bottle Sizes

Storage size is the amount of water a bottle can hold. There are a number of reasons why you'd want a specific size bottle which are discussed below.

<= 500ml	Too small for any real BOB or purification options. 1L purification tablets could be cut in half and used if needed.
750ml	A reasonable size for hiking where water is easily accessible. 1L is still recommended however.
1L	The optimum size of a water pack which allows easy treatment of water via tablets coupled with a good amount of storage.
1.5L	1L+ is better than under 1L as you don't need to fill it up completely to use purification tablets and too much water is always better than too little as you can always tip some out. Negatives include a larger bottle to store.
2L	Generally too large for a water bottle but plausible for a hydration bladder where the water can curve to the shape of your body.

Total Storage

Total storage is the total amount of water you're aiming at carrying. Depending on where you live, how fit you are, how far between refill points, how much you sweat etc, depends on how much water you will need to carry. Below is a list of storage factors that should be considered when choosing a bottle. Below are the factors you should consider when deciding how much water you'll need for your EDC, BOB or INCH bags.

Location	In warmer countries you will consume more water than someone in colder locations.
Bodily Needs	Each person is different and you may use up water faster or slower than someone else by means of sweating etc.
Availability	How accessible water is in your region determines how much you need to stockpile before reaching another water source.
Company	Depending on how many people are in your party you may have to carry your children's water for them.

Storage Location
Water can be stored wherever you please, however inside a pack will keep it cleaner and safer. Storing water on the exterior of a pack can increase the noise you make, unbalance you and make you more visible. It will make it easier to drink though. Water will be constantly sourced on your journey so keep it easily accessible at all times so you can stay hydrated easily.

Colour

The colour of a bottle can have a range of effects, so choose carefully. For more gear colour effects see the LIGHT section.

Black	Absorbs heat better when exposed to sunlight and thus can reach higher temperatures to kill bacteria.
White	Reflects light and keeps the bottle cooler than all other colours.
Clear	Lets sunlight and UV rays through the bottle to kill contaminants.
Bright Colours	Draws the eye easily especially in outback areas where there's only greens, blacks and browns. Avoid if you can.

Weight

If weight is important to you, try to choose thinner containers or flexible storage containers. Solid bottles such as Nalgene ones are very heavy duty and even perhaps needlessly heavy over lighter counterparts. A reasonable aim for the weight of each water bottle is between 28-56g (1-2 oz).

Bottle Mouth

There are a huge array of cap designs that prevent spilling liquid to stopping it coming open when bounced around. This section will cover the prominent ones.

Regular Mouth	A small mouth on the bottle to make drinking easier, however cleaning inside becomes harder.

Wide Mouth	Bottles that have a large opening for faster filling, emptying and sometimes allow connection with a purifier. However it may be spilt easily when going over bumps.
Lid Lock	Some bottles have a latch that keeps the lid on tightly so it won't break open.

Fittings

Bottle fittings are extensions that can be bought to alter the features of it.

Sipper Lid	A lid which converts a wide mouth Nalgene bottle into a regular mouth bottle to make drinking easier.
Pillid	Nalgene has third party lid sections that can be screwed onto their bottles to store items such as purification tablets.

Tips

- Transparent plastic bottles can be used for SODIS to purify the water if left in the sun.
- Ensure the type of plastic is suitable for the long term storage of water and won't leak chemicals over time.
- Volume markings make rationing and measuring water much easier which is particularly useful for freeze dried meals.
- You can find combinations of bottles and cups where the cup fits snugly over the end to conserve space.
- Never buy aluminium bottles for putting over a fire as it can melt.
- Go for stainless steel or titanium. See the MATERIALS section for details of metal melting points.
- Metal bottles should NOT have any form of plastic coating on the inside of the bottle.
- Keep in mind the colour of your bottle if you're trying to stay stealthy.
- Bottles that contain a purification system or a filter can eliminate the need for another piece of kit.

Brands

These are some of the most respected and recommended water bottle brands.

Nalgene	Nalgene bottles are wide mouth bottles, made of Tritan which is virtually unbreakable and there are a few "mods" that can be added to bottles for extra features such as a pillid and sipper mouthpiece. These bottles are quite heavy though and cannot boil water.
Camelbak	
Klean Kanteen	Makers of high quality stainless steel bottles, but ensure you pick a non-insulated one.
Keith Titanium	They make titanium cookware, canteens and bottles. They are quite expensive.
Pathfinder	
Stanley	
Unbranded	Generally unbranded bottles will suffice as long as the material is of good quality. Ensure it won't leak or is easily punctured or broken.

Cost

Water bottles come in fairly cheap at $5-20. Hydration bladders are much more expensive costing between $30-$100.

Water Storage

Zip Lock Bag Useful Item 4/5 Tin, EDC, GH, BOB	An ultra compact water storage option which is also effective at SODIS. These bags have multiple uses from storing gear inside to make them waterproof, lighting fires with them, and storing and purifying water.	**Uses** • Waterproofing Gear • Holding Water • Tablet Purification • Solar Purification	**Top Brands** • Pack4Life • Kraft • Generic Ebay Brands
Condom Useful Item 3/5 Tin, EDC, GH, BOB	Used for backup water storage containers and are so compact they can fit into pocket survival kits. Make sure the condom is unlubricated and unpowdered to avoid water contamination. Generally these are one use only and can be tied off to store water for a later date. With use they will stretch slowly until they become unusable or leak. To purify water with a condom, first fill it with about 1L of water and then add a purification tablet then tie it off and leave it for the designated time. You can also use them for their designated purpose - sex if you feel like you won't be needing it as a water container in the future.	**Uses** • Temporary Bucket • Holding Water • Purifying Water • Protecting Limbs • Slingshot Material • Sex	**Cost** Condoms can be picked up for a few dollars for a packet of 20 or so.

Water Filter

Water Filter Essential Item 5/5 EDC, GH, BOB, INCH	Used to filter particulate and organisms from water for immediate use or storage. Useful if you need a quick supply of water if there's no time for boiling or you're on the move bugging out, otherwise boiling is probably better as it's infinitely re-usable and a filter will clog over time. You can back-wash filters but you'll need to use clean water on hand already filtered or boiled and filtered through a piece of smooth to remove particulate. For more information see the WATER section.

Filter Type	**Gravity Filter** A filter which uses gravity as the driving force by hanging two bags or using barrels.	**Pump Filter** Required to be pumped by hand to purify water from the source.	**Bottle Filter** A filter in the cap of a bottle which removes contaminants as you drink. Allows you to scoop up water and keep moving quickly.	**Straw Filter** Powered by sucking through the straw and requires you to be at the source while you drink.	**UV Purifier** Purifies low turbidity water by waving a UV light around to kill the contaminants.	

Filter Life	The filters life is measured in litres (or gallons) pumped and assumes it's regularly maintained during its life. Generally the advertised life of a filter isn't accurate so you should always have a backup in the situation it fails or becomes blocked.
Flow Rate	How fast you can purify water whether by pumping or gravity. A flow rate of 1L/min is average for all types of filters with some reaching up to 2L a minute. The flow rate often slows over time as the filter becomes blocked.
Weight	The weight of the entire setup including bottles, bags and cleaning equipment if included. A weight between 141-283g (5-10oz) is typical for a filter.
Brands	**Top Brands** ● Sawyer ● Platypus ● Lifestraw ● MSR ● Katadyn ● Steripen
Cost	The cost of a filter can vary wildly based on what type of filter you're looking for. The typical range can be from $25 for a decent cheap filter like the sawyer mini to $300 for the MSR Guardian.

Water Purification

Water Purification Tablets Essential Item 5/5 Tin, EDC, GH, BOB, INCH	Tablets or additives that kill bacteria, viruses and protozoa in water. Generally it's 1 tablet to 1 litre of water with a killing time that ranges from 30m for most bacteria and viruses to 4 hours for cryptosporidium. These take up such little space and are so light that it's easy to throw a sheet into a BOB. Just ensure you renew them then they are about to expire. See the WATER section for more information on any of the purification methods below.

Types (Powder / Crystals)

Potassium Permanganate (Condy's Crystals)	It can be used to purify water, treat infections and fungal infections.	**Top Brands** ● Gold Cross	**Shelf Life** Forever if stored properly	
Calcium Hypochlorite (65%+)	Purifies water by creating a bleach solution.	**Top Brands** ● N/A	**Shelf Life** Around 10 years if stored in an airtight container.	Found in some supermarkets in the pool cleaning aisle in white plastic tubs. This is an oxidiser and can therefore be a hazard to your health. Never breathe in the fumes. Store away from heat and light or it could combust. Airtight containers may require "breathing" every so often as it will consume the oxygen in it and cause a vacuum.
Iodine (Tetraglycine Hydroperiodide)	Purifies water when dissolved and left for 30m-4h.	**Top Brands** ● Potable Pure ● Coghlans		

Types (Tablets)

Sodium Dichloroisocyanurate (Chlorine)	Purifies water when dissolved and left for 30m-4h.	**Top Brands** ● Katadyn ● Aquatabs ● Potable Aqua	**Shelf Life** Between 2-4 years depending on storage methods	The most common type of chlorine tablet and often found for cheap in camping stores.
Chlorine Dioxide (Chlorine)	Purifies water when dissolved and left for 30m-4h.	**Top Brands** ● Lifesystems ● CleanOxide	**Shelf Life** About 10 Years if stored properly	A harder to find chlorine tablet which has a longer life than Sodium Dichloroisocyanurate.

Types (Liquids)

Bleach (Unscented)	Purifies water when dissolved and left for 30m-4h.	**Top Brands** ● N/A	**Shelf Life** Approximately 1 year from manufacture or a few weeks after the expiry date on the bottle.	Ensure it's unscented or you could poison yourself when drunk.
Hydrogen Peroxide	Purifies water when dissolved and left for 30m-4h.	**Top Brands** ● Gold Cross ● Sanofi	**Shelf Life** Around 1 year, or a week or two after the expiry date.	
Colloidal Silver	Silver is a known antibacterial therefore colloidal silver will slowly purify water over time.	**Top Brands** ● Fulhealth (or make some yourself)		

Flocculation

Flocculation	Flocculation refers to the process by which fine particulates are caused to clump together into a floc. The floc may then float to the top of the liquid (creaming), settle to the bottom of the liquid (sedimentation).	**Top Brands** ● Chlor-Floc	**Shelf Life** 4 year shelf life	There's commonly 30 packets per a box. See the WATER section for more information.

Emergency Water

Emergency Water Conditional Item 2/5 GH, BOB, Ext	Emergency water is commonly a small foiled packet of potable water which should be used when there are no other options available. They have saved people's lives in the past and are small and light enough to put one or two inside your pack for emergencies. They are only rated 2/5 because they're expensive and aren't as useful as carrying a few purification tablets or a filter. They are more for stockpiling in houses, boats and caches.				**Shelf Life** Water never expires if stored correctly, although some of the chemicals of the bag could leech into the water over time.
Types	Generally all emergency water comes in foil packets but there are some other styles.	**Foil Packet** The foil packets are flexible tri-laminate pouches and are torn in a corner when needed. They are generally 125ml (4.22floz).	**Cans** Your typical 354ml (12floz) soda can but containing water instead. Opened the same way as sodas.		
Brands	Common brands of emergency water are as follows.	**Mayday** Yellow and black hazard style pattern foil containers. 125ml (4.22floz) each, 5 year shelf life.	**S.O.S** 125ml (4.22floz) each, 5 year shelf life.	**Datrex** 125ml (4.22floz) each, white bag with blue writing. 5 year shelf life.	**Blue Can** 354ml (12floz) each can.

4 Food

This section helps you choose the food related items in your kits.

Canned Food

Canned Food Conditional Item 3/5 GH, BOB, INCH, Ext	The most common survival food that comes to mind. Often very heavy due to the water it contains therefore it's not recommended to put into backpacks. Canned food typically lasts forever if kept at a cool temperature, this excludes a few types of ingredients such as tomatoes which can cause the can to bulge over time. Cans often require a can opener or knife to get it open unless it has a ring pull seal. Canned food is self-contained and simply requires heating before eating. The can is reusable when you're done for a multitude of purposes. If water is limited in the environment eating canned food is ideal as it will provide you with some liquids.				**Shelf Life** Never expires if stored correctly and there's no rust on the seams.
Food Types	The following are the types of food that can be found in cans. Buy the foods you like and that you'll eat as well as ones that give you the calories you need.	**Meals** Meals which contain a few different ingredients such as meat, veges and sauce.	**Soup** Various soups such as pea and ham, tomato and potato.	**Fish** Fish and fish products like sardines, salmon and tuna.	**Fruit** Any type of fruits like apples, pears and blueberries.
Food Types	**Veges** Canned vegetables such as peas, carrots and potatoes.	**Sweets** Desserts or sweets such as condensed milk.	**Drinks** You can get some canned drinks such as fruit juice, coffee and tea.		
Can Variations	These are some canned food variations that may affect your purchasing decisions.	**Ring Pull** Some cans have a ring pull mechanism making it easier to open, however if they rust around the indent they are much more likely to spoil.	**Shape** Cans come in all shapes and sizes and cylinders are very inefficient when storing food due to the wasted space.		
Brands	Brands don't generally matter when buying canned food, just buy the ones you like the taste of.				
Weight	The heaviest of all the foods combining a metal can with the weight of watery food. You should try to avoid carrying canned food if you're backpacking due to it simply being a waste of weight. Canned food should be used in circumstances where you need to bug out fast and stay on your feet or you don't have the ability to boil water.				
Waste	The resulting products from eating a can is the can itself and the lid and possibly the label. The can could be reused in multiple other ways but the lid isn't much use. An empty can weighs up to 28g (1oz) and isn't compressed easily which can be annoying when trying to fit it back into your pack. Unless the can is cleaned thoroughly it will attract animals in search for food such as bears.				
Cost	A very cheap source of food coming in at about a dollar or two per can. Ensure any cans you buy are dent and rust free.				

Freeze Dried Food

Freeze Dried Food Conditional Item 4/5 BOB, INCH, Ext	Great tasting, lightweight food which only requires boiling water and about 10 minutes till it's ready. Canned food contains the water it needs inside it therefore it's much heavier then it's freeze dried and MRE counterparts. I would recommend Mountain House as their food has been guaranteed to a 30 year shelf life. Competing brands don't often contain oxygen absorbers which greatly increases shelf life. For more information see the FOOD section.	**Shelf Life** Depends on the brand, but most last 5 years minimum with Mountain House lasing up to 30 years.

Food Types

The following are the types of freeze dried food you can buy. As always you should buy the foods you like and that you'll eat as well as giving you the calories you need.

Meals	Freeze dried meals such as spaghetti bolognese, chilli mac and chicken nachos.
Soup	Powdered soups such as pea and ham, tomato and potato.
Fruit	Freeze dried sliced fruit.
Veges	Freeze dried vegetables like as peas, carrots and potatoes.
Dessert	Packaged desserts like freeze dried ice cream and cheesecake.
Drinks	Powdered and freeze dried drinks like coffee, tea and smoothies.

Heating / Eating

These are a few ways you can cook and eat your freeze dried food (FDF).

Boiling Water	The most common way to heat FDF is to add boiling water to it and letting it sit.
Flameless Heater	To use a flameless heater bag just add the water and put it inside the heater bag. You can also buy foil pouches to retain more heat as it cooks.
Flame Heating	Simply add both the package contents and water to a bowl and heat over a flame.
Eat Cold	You don't even need to heat the food to be able to eat it if you so desire.
Eat Dehydrated	You could eat FDF without adding water in an emergency and don't have time to stop. Only do this if you're on the run and have enough water. You shouldn't eat food when you're low on water.

Brands	**Top Brands** ● Mountain House ● Back Country Cuisine ● Outdoor Gourmet ● Wise ● Campers Pantry ● Outdoor Gourmet				
Weight	The lightest option for camping food if you have water on hand to reconstitute it.				
Waste	When you're done with the food you have the packet left over which might be useful for transporting water with. Unlike the left over can, this package can be compressed down to a small size to transport back home afterwards. Some packs have oxygen absorbers inside the pack to help it last longer, but they generate more waste.				
Cost	The most expensive option for survival foods which can cost between $10-20 a packet.				

MREs

MREs **Conditional Item** 3/5 **GH, BOB, INCH, Ext**	An MRE or "Meal Ready to Eat" is a military ration that contains everything required for a days worth of food in one package. They contain water and are therefore bulkier and heavier than freeze-dried foods. They often contain two meals, a breakfast, jams, jellies, coffee sachet, sugar, energy bars and more.	**Shelf Life** Generally they have a 10 year shelf life which is good but doesn't quite compare with the 30+ years of some freeze dried food.	**Convenience** Most of it is done for you with MRE's, all you need to do is heat it up and eat it. It also comes with a lot of extra packets to make it taste perfect.

Food Types	Generally MRE's have a limited selection of food types which cover the basic food types and food allergies. MRE's often contain plenty of additional snacks to eat throughout the day as well as useful items like matches. Food types generally consist of curry, meatballs and beef stews.									
Brands	**Top Brands** ● Russian MRE's ● US Surplus MREs ● Hungerbuster ● Ameriqual									
Weight	**Weight** Because MRE's contain everything required to eat them, including water they weigh quite a bit.	**Size** MRE's are quite bulky and thick as they contain a lot of different food packets.								
Waste	MRE's generate a huge amount of waste in the form of empty packets and plastic containers. It will be quite annoying to carry these back with you in your pack assuming you follow the Leave No Trace methodology.									
Cost	MRE's are hard to get a hold of, especially ones which have a very distant expiry date. Due to their elusiveness they may cost a fair bit to get a hold of. Cost ranges from $15 to $30.									

Rations

GEAR | Descriptions | Gear | Food | Rations

Rations Conditional Item 3/5 GH, BOB, INCH, Ext	A bar packed with energy and nutrition designed to last up to 10 years for use while bugging out to prevent the need to cook. Not to be confused with energy bars which are designed to only give you a boost of energy before a race, event or run and have a much shorter lifespan. They can come in different sizes typically - 400 calorie, 1200 calorie, 2400 calorie and 3600 calorie. Ensure the package has a vacuum prior to opening or it may be spoiled.								**Shelf Life** Can last between 5-10 years.	
Food Types										
Brands	**Top Brands** ● Mayday ● Datrex ● ER ● Grizzly Gear ● Mainstay ● S.O.S.									
Weight	Rations can be quite heavy as they are packed into a solid 'brick' of nutrition. Generally they are vacuum packed so they save as much space as possible while preventing oxygen and light from spoiling them as quickly. They do however contain small amounts of moisture and therefore aren't as light as if they were freeze-dried, and some are designed to help prevent you from becoming dehydrated.									
Waste	Probably the food type that has the least waste for the calories and the plastic can also be compressed into the smallest size when you're finished eating.									
Cost	Ration bars are generally pretty cheap coming in at $5 - $15 per bar depending on size and calories.									

Energy Bars

Energy Bars Useful Item 2/5 EDC, GH, BOB, INCH	Energy bars will fill your stomach and give you an energy boost when you need it most, but doesn't have much nutritional value.				**Shelf Life** Generally have shelf lives of around 1-2 years depending on the ingredients.

Types

Energy Bar Types	**Organic Bars** These are energy bars that focus largely on providing energy in as natural a method as possible. Organic bars reject artificial sweeteners and inserted protein, preferring to have a compact load of simple ingredients.	**Meal Replacement Bars** These are designed more for dieting and weight loss rather than a quick burst of energy during hiking or backpacking. They are meant to provide the complete nutrition of a lunch or breakfast and to fill you up.	**Protein Bars** Some energy bars, such as protein bars, are designed to help you gain muscle mass. These bars attempt to cram as much protein as possible for recovery from strenuous workouts or backpacking trips with high-mile days.	**Endurance Bars** Endurance bars are primarily designed to be eaten before a long workout. They typically have a higher proportion of carbohydrates to provide complex, non-sugary energy that is digested over a long period of time.	**Activity Bars** Similar to endurance bars, activity bars focus on prolonging energy. However, they tend to focus on all-day outdoor activities that require both energy and some meal-replacement nutritional features. Clif Bar is perhaps the most prevalent bar in this category.
Food Types	Today you can find a wide range of energy bars in supermarkets, so finding one you like the taste of and provides you with a boost of energy will be easy.		**Types** ● Nut Bars ● Power Gels ● Jelly/Lolly Style Bars ● GORP Bars		
Brands	**Top Brands** ● Clif Bars ● Bloks Bars ● Bear Valley Pemmican ● ProBar ● PowerBar Triple Threat ● Larabar ● Hammer Bar				
Weight	These are often fairly light and sometimes come in sections which can be pulled apart to eat it over the day. They usually weigh between 10g-100g.				
Waste	Bars have a fairly small amount of packaging around them but it can add up quickly. Waste should always be taken with you in the wild so consider how you will dispose of it beforehand.				
Cost	Very cheap bars which can be bought in most any shop today for $2-$5.				

Utensils

Utensils Essential Item 5/5 GH, BOB, INCH	An eating utensil is essential in a BOB for keeping your hands clean and allowing easier transferral of food to your mouth. You should only need one spork coupled with your primary knife to complete any basic kitchen tasks required in the campsite.	**Utensils** ● Fork ● Knife ● Spoon ● Spork ● Serrated Knife ● Chopsticks ● Toothpick ● Skewer	

Types

GEAR | Gear | Descriptions | Food | Utensils

Types of eating utensils.

Fork The most common eating utensil today allowing easy pickup of solid foods.	**Serrated Knife** An additional knife shouldn't be necessary to your primary, but a redundancy is always useful.	**Spoon** A spoon for scooping up and eating liquids and liquid-like foods.	**Spork** A spork combines the usefulness of a fork and a spoon at a slight efficiency cost to each utensil.	**Chopsticks** Chopsticks can be used instead of a fork if you're adept at using one. They can also suit many other camping tasks.	**Toothpick** You can pick up small chunks of food with this utensil as well as clean your teeth when done.
Skewer Similar to chopsticks but designed to be pushed through meats and cooked over a fire.					

Materials

Utensils can come in many different materials each with their own benefits.

Plastic Most camping plastics are typically unbreakable and can withstand fairly high temperatures. Not to be used over open flames.	**Stainless Steel** Probably the most trusted type of metal which has been used for decades as the metal of choice. It can be quite heavy though.	**Aluminium** A lightweight metal which has corrosion resistance and is often found in cutlery.	**Titanium** A lightweight and strong metal with great corrosion resistance. However it is often expensive.		

Build

Some utensils have a certain build style which can greatly affect the use of the product.

Folding Cutlery Packs down to a smaller size, however its lock may snap out while in use sending your food flying.	**Locking System** Some sets of cutlery have a locking system so they don't jangle when in your pack.	**Carabineer Holes** Some items may have holes which you can thread your carabineer through to secure it better.	**Long Handle** Very useful in combination with freeze dried foods which have deep bags.	**Double Ended** You may come across a double ended utensil such as a spoon with a fork at the other end.	**Multi-Use** Some products may have a secondary tool built into a primary tool such as a knife section built into the side of a fork.

Weight / Size

Generally the weight of an eating utensil is miniscule coming in at under 28g (1oz). The size however may be a bit too big to fit inside a self contained cooking kit especially chopsticks.

Cost

Often very cheap coming in between $1 for the plastic type and $20 for a titanium cutlery set of 3.

Brands

Keith Titanium A great brand for titanium cookware which is ultralight and well made.	**lightmyfire** A brand which sells a few nifty lightweight plastic cutlery products which they say can't break.	**Sea to Summit** Great quality cutlery with a focus on light weight.	**Jetboil** Slightly bulkier and heavier cutlery but works well.	**Toaks** A good quality camping manufacturer who makes cutlery, pots and pans.	**Ebay** There's plenty of unbranded copies on eBay which are likely to last as long as the branded ones albeit slightly bulkier or heavier.

Can Opener

Can Opener Conditional Item 3/5 BOB, INCH	A quality rustproof can opener is required if you have canned food or are planning to run into canned food on your journey. You should use a manual can opener with as few moving parts as possible to help prevent it breaking. The P-38 is the smallest and lightest can opener available, however it takes some skill to use.	**Types** • Solid Metal • Twist Type • Automatic

Cooking Pot

Cooking Pot Essential Item 5/5 BOB, INCH	A cooking pot, pan or canteen cup is vital to cook food and boil water in. Make sure it's not aluminium and that it will fit everything you want to cook inside. It should hold at least 500ml. Try to combine the pot, canteen, spork, stove, fuel and scrubber together to save space by ensuring they all fit inside the pot. The more pots that fit snugly inside or around your primary pot allows you to have more utensils while only slightly increasing space used.

Metals	**Aluminium** Lightweight but could melt if placed in a fire directly but fine if you will be cooking over a gas stove.	**Stainless Steel** Very strong and won't corrode but fairly heavy.	**Titanium** A lightweight metal just as strong as stainless steel.	**Cast Iron** Extremely heavy but will last a lifetime.	

GEAR	Gear	Food	Cooking Pot					
				Features	**Hanger** Look for pots with a metal hanger so you can hold it above a fire.	**Handles** Use a pot that has handles to protect yourself from burns. Some handles have a sheath to protect your hands more.	**Lid** A lid will assist in cooking food quicker.	**Spout** A spout can prove to be useful when boiling water and makes it easy to pour into bottles.
				Considerations	**Fuel** Matching your pot size to your fuel canister will make the most of the space.	**Cup** Try to find a cup that fits snugly outside your pot. It won't take any extra space and it can be used for drinks.	**Base Size** Make sure your pot is large enough to fit on your stove securely.	**Volume** Ensure the pot is big enough to boil water in for your dehydrated meals and that it will fit the entirety of your canned meal.
				Weight / Size	Generally metal pots are fairly lightweight, especially if they are made of aluminium or titanium. The size of the pot doesn't matter too much as long as you can store items inside it such as the fuel, stove, spork and cleaning items.			
				Cost	Cost can range from a few dollars up to $100 for the well known brands with many features. The lighter the metal, generally the higher the cost.			
				Brands	**Top Brands** • Jetboil • Keith • Triangia • 360 Degrees • MSR			

Scrubber

GEAR	Gear	Food	Scrubber	
				Scrubber **Useful Item** 3/5 **BOB, INCH**	The easiest way to clean a pot in the wilderness. You should cut the handle off as they can usually weight more then the scrubber. Ensure the bristles don't fall out over time with use and that it cleans well. Never use metal bristles as they are prone to falling out and ending up in food. There aren't any *best* brands, as good scrubbers can be found for $1 almost anywhere. Give the bristles a pull and see if they will fall out with some effort. If you don't want the extra weight you can always use a rag or a piece of clothing. Snow and leaves may also work to clean pots and utensils in certain situations.

Stove

GEAR	Descriptions	Food	Stove			
				Stove **Essential Item** 5/5 **BOB, INCH**	A stove for cooking meals and boiling water with. Unless you want to light a fire every time you want to cook or boil I recommend a portable stove. There are a range of choices each with its benefits and shortfalls. For more information on stoves see the COOKING section.	**Top Gas Stove Brands** • MSR • Coleman • Soto • Jetboil • Gasmate • Companion

Stove Types

GEAR	Descriptions	Food	Stove						
				Gas Stoves Gas stoves are the fastest way to boil water but require gas canisters which will eventually expire leaving the stove useless. **Requires: Gas Canisters**	**Alcohol Stove** An alcohol stove requires you to bring alcohol or other burnable material with you but can still be used as a tiny wood stove if you need. **Requires:** Alcohol	**Petroleum Stoves** Use petrol or kerosene under pressure to generate a flame. They require a lot of maintenance and aren't often recommended. **Requires:** Petrol (Gas)	**Chemical Stove** Small folding stoves which use flammable solids such as hexamine as fuel. **Requires:** Solid Fuel	**Wood Stove** A wood stove will allow you to burn any material on the go including hexamine tablets and will last the longest time. **Requires:** Wood	**Candle Stove** Stoves which use candles to heat up food. These are difficult and slow to cook with. **Requires:** Candles
GEAR	Descriptions	Food	Stove	**Solar Stoves** Any stoves which use the power of the sun to heat and cook food. **Requires:** Sunlight	**Flameless Stoves** Flameless heater bags which when exposed to oxygen, heat up immensely and can cook or reheat food. They are one use only. **Requires:** Nothing Extra	**Electric Stoves** Stoves which use electricity to heat coils. **Requires:** Electricity			

Fuel

GEAR	Gear	Food	Fuel			
				Fuel **Conditional Item** 3/5 **BOB, INCH**	If you have any type of stove you'll need some sort of fuel to burn. This can either be solid, liquid or gas. Solid fuel can be found as wood in the environment and thus makes your pack lighter. You can also bring hexamine tablets which efficiently burn with almost no smoke or smell. Liquid fuel can be quite heavy if you pack a lot of it and it may degrade slowly over time. It's possible to distil more at home but otherwise you're out. Gas fuel can be the most efficient and cleanest to burn of the three but can't be made at home. However it's very cheap, doesn't expire and comes in various sized canisters. There are also different mixes of gases used for different environments. For more information see the FUEL section.	**Gas Brands** • MSR • Jetboil • Coleman • Soto • Primus • Gasmate

Solid Fuels

GEAR	Gear	Food	Fuel						
				Size As you use the fuel it will free up more and more space.	**Weight** Fairly light to transport.	**Efficiency** Moderate efficiency as it's difficult to get the heat desired as it burns down.	**Ease of Use** Just light and put it under a pot or pan.	**Portability** Simple to transport but some may need to be vacuum packed.	**Hazards** Little to no hazards.

GEAR Descriptions Food Fuel

Problems Often requires a flame to light it. Hard to extinguish and use elsewhere if you're done cooking.	**Cost** Very cheap to buy.				

Liquid Fuels

Size Unlike solid fuels you won't gain more space as you use the fuel up.	**Weight** Very heavy to transport.	**Efficiency** Hard to tailor the flame to your requirements as it's either lit or unlit.	**Ease of Use** More difficult to use than solid or gas fuels.	**Portability** Difficult to transport and may leak over your equipment.	**Hazards** Could leak in your pack rendering it all flammable.
Problems Spillable unlike the other fuel types.	**Cost** Slightly more costly than gas or solid fuels.				

Gas Fuels

Size You're left with a canister until the gas is all used up and you can discard it.	**Weight** Moderately heavy to transport.	**Efficiency** Very efficient fuel providing a high amount of heat.	**Ease of Use** Just attach a stove and light.	**Portability** Easy to transport by throwing into a pack.	**Hazards** Could explode if heated over 50°C.
Problems Won't work in freezing conditions. Canister must be warmed up first.	**Cost** Moderately priced depending on the type of fuel.				

For more information see the FUEL section.

Multivitamin

Multivitamin Conditional Item 3/5 BOB, INCH	Replenishes vitamin levels if you're unable to get the recommended doses of everything or you're living off pre-processed foods. Ensure you get the highest quality brand and check the expiration dates every 6 months to ensure they still safe to consume. Typically you will only need to take one tablet every 3-5 days to keep your vitamin levels up. They are so small and worth the effort to throw a few into a BOB in case you ever need them. They may also help cure some diseases such as scurvy due to a lack of specific vitamins when SHTF.	**Top Brands** ● Blackmore's ● Cenovis ● Nature's Own ● Berocca

5 Shelter

This section helps you choose the shelter related items in your kits.

Shelters

Tarp Essential Item 5/5 BOB, INCH	A shelter building material, blanket, poncho or weather shield which can be set up into multiple form factors. There are many different types of tarps ranging from poly to canvas which all provide a different level of protection and all weight differently.	**Common Types** ● Poly Tarps ● Canvas Tarps ● Heavy Duty Tarps ● Vinyl Tarps ● Mesh Tarps ● Cuben Fiber ● Tyvek

Tarp Types

Poly Tarp	A lightweight tarp which is moderately heavy and has fair puncture resistance.
Canvas Tarp	A heavy tarp which is extremely puncture resistant.
Heavy Duty Tarp	A heavy tarp which is very puncture resistant.
Vinyl Tarp	Vinyl Tarps offer long-lasting, superior protection against issues such as rips, punctures, abrasion, liquids, mildew, oil, grease, acid, and wind.
Mesh Tarp	A heavy woven tarp with tiny holes which helps keep grass alive underneath.
Cuben Fiber	Light, yet expensive material which is puncture resistant.
Tyvek	Ultralight house wrap material with puncture resistant properties. Great for groundsheets. Crinkly to lie on when new which may give away your position.

Tent / Swag / Bivy Essential Item 4/5 BOB, INCH	The biggest item you will generally have to carry with you, but it will protect you from nearly everything outside its walls. Each form of shelter such as a tent, swag, bivvy and a hammock each has different benefits such as size, strength, durability, versatility and materials. See the SHELTER section for more information on choosing a shelter.

Tent Brands

Sleeping Bag

Sleeping Bag Essential Item 5/5 GH, BOB, INCH	A sleeping bag is essential in cold environments as they will keep you warm via insulation and protected from the environment outside. They often contain either duck down, feathers, cotton, wool or modern synthetic materials to keep you warm. There's a lot of various cold weather ratings they range from so you should pick one depending on the minimum temperature of the environment you're planning on camping / bugging out in.

Types

The shape of the sleeping bag when looked at from above.

Rectangle A typical rectangular shape which allows a lot of room for movement.	**Rounded** A rounded bag is the middle of the lot which cuts down a bit on weight and size while keeping a fair bit of room for movement.	**Mummy** A mummy shaped bag tapers off from the broader top to a thinner base for the feet to save weight and size.			

Weather Rating

Upper Limit The highest air temperature at which an average man can sleep comfortably.	**Comfort** The lowest air temperature at which an average woman can sleep comfortably.	**Lower Limit** The lowest air temperature at which an average man can sleep comfortably.			

Materials

These are the most common materials found in and on sleeping bags.

Down (Filling)	A down sleeping bag will provide the most insulation, especially goose down. It takes up very little room when compressed and fluffs up nicely once unrolled. Good down usually has a fill rating of about 500 to 800 inches per ounce. Down sleeping bags are very soft and have a great warmth-to-weight ratio. Down sleeping bags, however, are not the best for wet or humid environments as down will not insulate when wet.
Synthetic (Filling)	Synthetic-fill sleeping bags were designed to combine the qualities of down with better insulation qualities when the sleeping bag becomes wet. Although synthetic insulations don't compress as well as down insulation, they are machine washable and dryable. For summer camping and hiking, synthetic-fill sleeping bags are ideal.
Nylon / Polyester / Taffeta (Liner)	These soft, smooth fabrics are the most popular sleeping-bag lining fabrics. They are breathable and comfortable, and they don't heat up as much as others when you're lying in the same spot for a while. Less expensive sleeping bags will use nylon or polyester linings, while taffeta is the highest quality of the three fabrics.
Fleece (Liner)	Fleece and other brushed linings help you feel warmer when the temperature starts to dip. They feel very soft on the skin, but because fleece traps heat, they could be uncomfortable when you're sleeping in the same spot for a long period of time. Fleece and brushed linings are generally seen in rectangular sleeping bags where you'll have more room to shift positions.
Silk (Liner)	Silk is soft, supple and breathable, and it won't overheat from trapping body warmth. Silk is often seen in very expensive mummy-style down sleeping bags. It tears more easily than other liners and is hard to repair, which can be a problem in a down sleeping bag.
Flannel / Cotton (Liner)	These fabrics are most often seen in rectangular sleeping bags. They are natural materials that are breathable, durable and lightweight. They are easy to clean and repair. Cotton and flannel both trap moisture and should be reserved for campouts in moderate to dry environments.
Nylon, Polyester, Taffeta (Shell)	These are the most common materials used for mummy sleeping bags. They are the least durable of the synthetic materials and are best for car camping or general walk-in camping. Nylon, polyester and taffeta are low cost and extremely breathable fabrics. Use these for late spring, summer and early fall camping because temperatures will be moderate. The sleeping bags need to be water-proofed for damper conditions.
Ripstop (Shell)	Ripstop is nylon or polyester that has heavier threads woven into the material. The heavier threads reinforce the shell, making it stronger and more resistant to both tears and moisture, while still remaining breathable. Ripstop is great for three-season camping where conditions won't be too damp.
DryClime, Microfiber, Gossamer Micro (Shell)	These are very tightly woven materials that are strong and moisture-resistant. They are softer than Ripstop, though, because they lack the heavier threads sewn into the material. Sleeping bags made of these fabrics are a great choice for three-season camping or even four-season camping, provided you're not camping in snow caves and your winter camping has ideal conditions.
DryLoft (Shell)	This fabric has water-resistant abilities, but it is very breathable, making it very comfortable. It won't trap any moisture inside. You'll stay warm and dry on the inside and leave the wet and dampness on the outside of the sleeping bag. Look for DryLoft if four-season camping, backcountry camping or canoe camping is what you plan to do.

Weight / Size

A sleeping bag is one of the "Big Three" items in your BOB, therefore to keep things lightweight it's recommended to aim for 1kg.

Cost

You can pick up a sleeping bag for $15 all the way up to $500 depending on the material and insulation rating.

GEAR | Descriptions | Gear | Shelter | Sleeping | Mattress

Brands

Top Brands • Sea to Summit • Marmot • Sierra Designs • Coleman • Teton					

Mattress

Mattress Essential Item 5/5 GH, BOB, INCH	Vital in any environment as the cold ground will sap all the warmth from your body to equalize the temperature. Quite a few different designs of mattresses are on the market today with different benefits, sizes and shape. Choosing the right one may be quite a challenge with so many options.	**Types** • Foam Mattress • Air Mattress • Self-Inflating • Closed-Cell Foam	**Best Brands** • Klymit • Therm-a-Rest • Rei • Coleman • Sea to Summit • Exped

Types

Air Mattress A mattress which only uses air for inflation to keep it as light weight and small as possible. You can blow it up with your mouth or a pump.	**Self-Inflating** A self inflating mat starts to expand automatically when spread out due to a compressible piece of foam inside.	**Foam Mattress** A flat foam pad which generally can't be compressed. They may also be known as yoga mats.	**Closed-Cell Foam** Made up of cells that are completely closed. The cells are pressed together, so air and moisture are unable to get inside the foam. Because of this, closed cell foam is much more rigid and stable than open cell foam.		

Overall Shape

The shape of the mattress when looked at from above.

Rectangle A typical rectangular shape which allows a lot of room for movement.	**Rounded** A rounded mattress which cuts down a bit on weight and size while keeping a fair bit of room for movement.	**Rectangle** A typical rectangular shape which allows a lot of room for movement.	**Rounded** A rounded mattress which cuts down a bit on weight and size while keeping a fair bit of room for movement.		

Comfort Shape

The contours and shape of individual cells or the air.

Flat The mattress is the same thickness the whole way across. This generally applies to foam, self-inflating and closed cell mattresses.	**Air Strips** Some air mattresses may have air strips either going horizontally or vertically from one edge to the other.	**"V" Pattern** Air cells in the shape of the letter V over the length of the mattress.	**Checkerboard Pattern** A pattern mimicking a checkerboard with high and low areas of air.		

Materials

Most mattresses use a composite plastic with ripstop capabilities. Modern mattresses are quite highly tear and puncture resistant but pay attention to how thick the outer material is.

Thickness

The thicker the mattress, the more protected you will be from the cold ground which can be a killer in any climate. Mattresses can range from 0.5cm in height all the way to 10cm+ (when inflated) to provide a cushy nights sleep. See the insulation row below for information on the R-Value rating which can help decide in what thickness to buy.

Insulation

R-Value R-Value is a sleeping pad's ability to insulate its user from the ground. This insulation is measured on a scale from 0 to 6. The higher the R-value, the warmer it will be.	Some manufacturers, don't use R-values. They opt instead to simply specify a temperature range their pads are suited for. An important thing to remember is R-Value is not an independently verified value. One brands R-Value 2.5 pad may differ from another manufactures.	**R-Value Range** **°C = °F = R-Value** 16°C = 60°F = 0.5 10°C = 50°F = 1.0 4°C =40°F = 1.5 -1°C = 30°F = 2.0 -7°C = 20°F = 2.5 -12°C = 10°F = 3.0	**R-Value Range** **°C = °F = R-Value** -18°C = 0°F = 3.5 -23°C = -10°F = 4.0 -29°C = -20°F = 4.5 -34°C = -30°F = 5.0 -40°C = -40°F = 5.5 -45°C = -50°F = 6.0

Weight

Weight is an important aspect of bugging out, so naturally you will want to find a mattress that won't hurt your back while carrying it. Air mattresses are the lightest and therefore the best option when backpacking, also their comfort may leave something to be desired especially for side sleepers.

Compressed Size

When backpacking you want the smallest possible form factor so you can save room for other equipment. The following cells detail the size that each types packs down to. Foam and closed-cell mattresses can only be rolled up and very slightly compressed with compression straps if you have them, so they aren't recommended for backpacking. Self-inflating mattresses can be deflated up until a point where the pressure of the sponge trying to re-inflate will be too great to compress it any further. Air mattresses are often chosen because they can be deflated to the size of a 1L water bottle. You can find ones that come even smaller but they sacrifice durability for size.

GEAR | Gear | Shelter | Mattress

Cost

Generally the larger, the more elaborate and lighter the mattress, the higher the price. Prices can range from $50 to over $300 (AUD) so have a budget in mind.

Brands

The market for camping mattresses has expanded greatly lately and so have the manufacturers.	**Top Mattress Brands** ● Therm-a-Rest ● Klymit ● Exped ● Coleman ● Sea to Summit

Blanket

Blanket **Conditional Item** 3/5 **BOB, INCH**	Only really essential in cold environments, but deadly if you forget one and you need it. Try to buy a wool blanket as they provide the most warmth overall but are a little bulkier and heavier than alternatives. There's not really a best brand to buy as long as you're getting nearly 100% pure material.	**Types** ● Down ● Bamboo ● Silk ● Wool ● Synthetic ● Linen ● Cotton

Materials

These are common blanket materials.

Down Blanket (Lightweight)	A down blanket or down throw is thinner and lighter than a down comforter. The spaces between the down clusters in a blanket trap warm air, keeping you warm without added weight.
Synthetic (Lightweight – Midweight)	Synthetic fibres such as polyester, nylon, and acrylic tend to be ultra-soft. Electric blankets are usually made with synthetic materials.
Bamboo (Lightweight)	Luxuriously soft and lightweight, bamboo fabric is similar to modal, with its smooth hand and flowing drape. Called rayon from bamboo, these fabrics are known for their soft, comfortable, and highly absorbent properties.
Linen (Midweight)	Linen is hypoallergenic, moisture-wicking and adjusts to your body temperature to stay cool in the summer and warm in the winter. Linen becomes softer with every wash.
Wool & Cashmere (Midweight – Heavyweight)	Wool blankets tend to be heavier and warmer than other fabrics. Wool fibres come from the fleece of lambs, sheep, goats, camels, llamas, alpacas and vicunas. Wool from sheep is the most common. Softer, more luxurious wool comes from Cashmere goats, Angora goats and Merino sheep. The spaces between the fibres in a fuzzy or napped blanket trap warm air, keeping you warmer.
Cotton (Lightweight – Midweight)	Cotton blankets can vary in weight and texture, making them a year-round bedding staple. Unlike synthetic fibres, cotton fibres breathe naturally and are absorbent. Cotton will wick moisture away from the skin and leave a layer of warm, dry air. If allergies are a concern, cotton is an excellent choice since it can be washed in hot water.
Silk (Midweight)	Known for its strength, softness and warmth, silk blankets offer the ultimate in luxury. Silk also has natural anti-fungal and anti-microbial properties. Silk blankets should be dry cleaned.

Size

Throw	Twin	Full	Queen	King	
127 x 177cm (50" x 70")	183 x 228cm (72" x 90")	203 x 228cm (80" x 90")	228 x 228cm (90" x 90")	274 x 228cm (108" x 90")	

Cost

Generally quite cheap but can range between $5 to $100.

Brands

Brands don't generally matter when buying blankets as so many manufacturers make them and provide almost identical warmth.

Groundsheet

Groundsheet **Important Item** 5/5 **GH, BOB, INCH**	A fairly essential piece of kit to help protect the tent, swag or bivy against punctures. The sheet can be any range of thickness from 0.5mm all the way to 3mm thick. Try to get a piece that will hold your shelter without excess being visible to save weight and space in your pack. The sheet has a variety of other uses such as rainwater collection, reflecting heat and used as a roof over your shelter if required therefore the term "Groundsheet" is a bit restrictive for all the functions it can provide.

Types

Tarpaulin	These are versatile, multi-purpose tarpaulins made from woven polyethylene (often with a laminated coating) that come in various sizes, thicknesses, and colors. They are widely available at hardware and camping stores. **Materials:** Polyethylene (PE). **Purpose:** Can be used as a basic groundsheet under a tent (though you need to ensure it's tucked under the tent edges to prevent water pooling), as a rain fly, sun shade, gear cover, or emergency shelter. **Advantages:** Very affordable, widely available, waterproof, durable for their cost, versatile. **Disadvantages:** Can be bulky and heavy, noisy when crinkled, don't breathe, water can pool on them if not correctly sized or pitched, can get very hot in the sun.

GEAR Descriptions Gear Shelter Groundsheet

Tent Footprints	These are groundsheets specifically designed to match the exact dimensions and shape of a particular tent model. They are typically cut slightly smaller than the tent's floor to prevent water from pooling between the footprint and the tent in rainy conditions. **Materials:** Often made from durable, lightweight coated nylon (e.g., ripstop nylon with a PU or silicone coating), polyester, or sometimes more premium ultralight materials like Dyneema Composite Fabric (DCF). **Purpose:** To add an extra layer of protection to the tent's floor from abrasion, punctures (from rocks, twigs), and moisture, thereby prolonging the life of the tent. They also help keep the bottom of the tent clean. **Advantages:** Perfect fit, lightweight, often comes with attachment points that align with the tent, minimal bulk. **Disadvantages:** Can be more expensive than generic tarps, only usable with the specific tent model it's designed for.
Mesh Groundsheets	These are woven mesh mats that allow dirt, sand, and water to fall through, keeping the top surface cleaner. They are popular for caravanning, under awnings, or in sandy environments. **Materials:** Heavy-duty shade cloth material, PVC-coated mesh, or patented multi-weave fabrics (like C-Gear Multimats). **Purpose:** To provide a clean, breathable, and sand-filtering surface for living areas outside the tent (e.g., under an awning), or as a protective layer under swags or tents in certain conditions. **Advantages:** Easy to clean, sand and dirt fall through, non-absorbent, breathable, won't rot or mold, good for protecting grass underneath in some campsites. **Disadvantages:** Not waterproof, do not provide a barrier against moisture from the ground, can be slippery when wet (especially the multi-weave types), more expensive than basic tarps.
Canvas Groundsheets	Traditional, heavy-duty groundsheets made from woven cotton canvas, often treated for water resistance. They are typically thick and robust. **Materials:** Cotton canvas (sometimes polycotton blends). **Purpose:** Offer excellent protection against rough ground, punctures, and provide insulation. Commonly used under traditional canvas tents, swags, or as heavy-duty covers. **Advantages:** Very durable and long-lasting, breathable, waterproof (when properly treated/weathered), offer good insulation, mildew resistant if cared for. **Disadvantages:** Very heavy and bulky, expensive, can be hard to clean and stain easily, require more maintenance.
Ultralight Groundsheets	These are extremely lightweight and compact materials often used as DIY footprints or purchased as minimalist options. **Materials:** ● Tyvek: A spun-bonded olefin material (like house wrap), known for being lightweight, strong, puncture-resistant, and breathable. It can be a bit crinkly initially but softens with use. ● Polycryo (Polyethylene Film): A very thin, clear plastic film (like window insulation shrink wrap). It is exceptionally lightweight and waterproof. ● Dyneema Composite Fabric (DCF / formerly Cuben Fiber): The lightest and strongest material for its weight, completely waterproof, but also the most expensive. **Purpose:** To provide a minimal protective barrier under ultralight tents or bivvy bags, reducing pack weight. **Advantages:** Extremely lightweight, pack down incredibly small, waterproof (except for Tyvek which is breathable), durable for their weight (especially Tyvek and DCF). **Disadvantages:** Can be less durable than heavier options against sharp objects (especially polycryo), expensive (DCF), Tyvek can be crinkly/noisy, polycryo can be slippery and hard to manage in wind.

Weight / Size					

Cost

Heat Reflector

Heat Reflector **Conditional Item** 3/5 **BOB, INCH**	A pad made of a heat reflective material such as aluminium used to bounce heat back while sleeping or used as a fire reflector. Keeping warm is typically one of the most important survival rules as you can die in 3 hours without shelter in freezing conditions. It can also be used to reflect heat away from yourself in summer if tied to a frame between you and the sun, which should be more effective than an ordinary roof. Pads can range from the cheap medical thermal blankets to a heavy duty one which can sustain more damage and last longer. For more information see the SHELTER section. A groundsheet can be used as a less effective reflector if you don't want to carry one of each.	**Other Uses** ● Heat Reflector ● Heat Retainer ● Solar Cooking ● Signalling Device

6 Clothing

Clothing is required to cover any weather, season or time of day that you may need to get home in. Clothing can be used as a makeshift water filter, shoelaces can be used as paracord and it all keeps you warm. Every country is different and it may be very hot or cold wherever you are, therefore pack for your local climate.	**Typical Clothing** ● Shirt ● Shorts ● Underwear ● Socks ● Shoes	**Other Clothing** ● Warm Weather Gear ● Poncho ● Quick Dry Clothes ● Hiking Boots ● Heavy Duty Gloves

GEAR | Descriptions | Gear | Clothing

Beneficial Clothing

These are the types of clothing that would be beneficial in a survival situation.

Moisture Absorbing	Clothing that absorbs and dissipates moisture created from sweat.
Quick Drying	Clothes that dry rapidly when they become wet.
Sun Protection	Clothing that has an SPF rating to reduce sun damage to the skin.
Insect protection	Insect repellent and pesticide clothing that helps prevent you from being bitten.
Protective Clothing	Thick and heavy clothing with defensive properties to protect from various elements.
Tactical Clothing	Black clothing designed to blend into the night.
Camouflage Clothing	Camo clothing to help you blend into the local environment.

Long Sleeve Shirt & Pants

Long Sleeve Shirt & Pants Essential Item 5/5 EDC, GH, BOB, INCH	A long sleeve shirt and full length pants are important in addition to the clothes you were originally wearing to swap out from. They can keep you warm and give you a level of protection from bugs, insects, ticks and leeches. These can take up a decent amount of space and weight in your BOB but if you have to drop one set of clothes, remove the short sleeve.	**Best Brands** • Fjallraven • The North Face • Arc'teryx • Kathmandu

Short Sleeve Shirt & Pants

Short Sleeve Shirt & Pants Conditional Item 3/5 EDC, GH, BOB, INCH	In addition to the long sleeve, a short sleeve can be a life saver in hot conditions and be made of a lighter material. You can easily cut long clothes to become shorter but it's much harder to lengthen short clothes.	**Best Brands** • Fjallraven • The North Face • Arc'teryx • Kathmandu

Underwear

Underwear Essential Item 5/5 EDC, GH, BOB, INCH	Having some spare underwear is vital to be able to wash the other pair and helps establish a basic level of hygiene. It's better to pick a type you're comfortable with rather than the "best" type made of kevlar or something.	**Types** • Briefs • Boxers • Quick Drying

Socks

Socks Essential Item 5/5 EDC, GH, BOB, INCH	Your feet will be hit hard during a bug out situation and the last thing you need is damp or wet feet which can cause disease and bacteria. A second or even third pair or socks will go a long way and keep fungal infections at bay. The relief of changing to a fresh pair of socks after a long day of hiking is such a morale booster as well.	**Types** • Cotton Socks • Wool Socks • Bamboo Socks • Waterproof Socks

Jacket

Jacket Conditional Item 4/5 GH, BOB, INCH	Vital in cold weather situations, look for ones with down filled sections and full body coverage. A waterproof one would be beneficial but only if you don't already have a rain poncho.

Hat

GEAR
Gear
Clothing
Wide Brim Hat

Hat
Important Item
4/5
EDC, GH, BOB, INCH

Used to keep the sun off you and prevent your skin from burning. A hat with a strap will keep it fixed on your head in strong winds or prevent the need to hold it. Hats are vital in warmer climates such as Australia, India, Mexico and all those around the equator.

Gloves

Gloves
Useful Item
4/5
EDC, GH, BOB, INCH

There will likely be a lot of heavy log lifting and splinters will be a real possibility without a good set of gloves. Find a pair that's designed for heavy use which go up past your wrist a little for maximum protection. They're also great for protecting your hands from freezing as well as providing a basic level of sanitary protection. If you want to use your mobile with gloves, be sure to pick a type that has touchscreen capabilities or the fingerless type.

Rain Poncho

Rain Poncho
Important Item
4/5
GH, BOB, INCH

An important piece of clothing to reduce the amount of rain that reaches you. Wet clothes can be horrible especially when times are already tough and it could cause fungal diseases. A full length poncho would be ideal to shed as much rain as possible. Ensure the hood extends a little further to prevent getting rain on your face. A secondary waterproof jacket would be beneficial underneath as there's bound to be stray drops that get through the gaps.

Shemagh

Shemagh
Important Item
4/5
GH, BOB, INCH

Used for camouflage, covering your face from air particles and removing water sediment. Buying a green or camo shemagh will allow you to blend in to a degree if you're wanting to stay hidden. You can use it as a pillow, insulation layer, handkerchief, foraging container, towel, tourniquet, water filter, sling and washcloth.

Eyewear

Glasses
Conditional Item
5/5
EDC, GH, BOB, INCH

If you wear glasses this is an essential item as you don't want to end up being unable to see if you accidentally break your only pair. If the frame breaks you can always use some small pieces of duct tape to repair it, however if the glass breaks you're stuck. Because of this it's a good idea to bring just the glass as a third backup so you can make your own frame with sticks and tape in an emergency.

Sunglasses
Useful Item
4/5
EDC, GH, BOB, INCH

Helps prevent glare, strong sunlight as well as snow blindness. There are a few additional features you can add to sunglasses today including polarising, glare reduction, different tints and various light reduction ranges.

Protective Glasses
Useful Item
3/5
BOB, INCH

Heavy duty glasses made for protection against sandstorms, snowstorms, dust storms, virus protection etc. These are similar to a gas mask but instead of covering your whole face, they just protect your eyes.

Beanie

Beanie
Conditional Item
3/5
BOB, INCH

Keeps your head warm and camouflages your silhouette. A cold head will make nights tougher as you lose a lot of your heat through your head.

Belt

GEAR | Descriptions | Gear | Clothing | Belt

Belt Useful Item 4/5 EDC, GH, BOB, INCH	Keeps your pants up and provides room for molle attachments and other gear. You can also buy some made from paracord which can be utilized in an emergency situation.

Shoes

Shoes Essential Item 5/5 EDC, GH, BOB, INCH	Essential piece of gear preventing foot injury and making it easier to hike across tough terrain. The ideal shoes should be hiking boots with high sides that reach fairly high up your leg to reduce the number of injuries you're likely to get. Steel caps and soles provide a lot of extra protection but will be a huge weight gain and make hiking a lot harder.

Thermals

Thermals Conditional Item 4/5 GH, BOB, INCH	Generally used by sports athletes and swimmers but can come in handy in snowy conditions when the temperature drops near freezing. Can be rather heavy clothing and underutilized in summer but it's worth its weight to keep you alive in the other months.

7 Fire

This section helps you choose the fire related items in your kits.

Fire Starter

Fire Starter Essential Item 5/5 Tin, EDC, GH, BOB, INCH	For igniting tinder to create a fire with. Some may be more difficult to light then others, so use what you're comfortable with. NOTE: Have at least two ways at minimum to start a fire. For more information see the FIRE section.	**Examples** • Matches • Flint & Striker • Magnifying Glass • Lighter	**Fire Uses** • Warmth • Cooking • Boiling • Sterilizing	**Best Brands** • BIC • Zippo • Z-Plus
Lighter	A self-contained lighter mechanism capable of producing a steady flame. Generally the EDC lighter is an easy to use lighter which generates a solid flame.		**Uses** • Fire lighting	**Recommended** • BIC Lighter • Zippo Lighter • Matches

See the FIRE section for more information on fire starters.

Tinder

Tinder Conditional Item 4/5 Tin, EDC, GH, BOB, INCH	Tinder is a combustible material easily burned to help start a fire when the weather isn't on your side. The amount of tinder you need to pack is difficult to determine as your environment affects it heavily. It's generally used if there's none naturally available or the weather is poor. It should be stored in a weatherproof container to prevent it becoming damp. For more information see the FIRE section.		**Recommended Tinders** • Shaved Magnesium • Alcohol • Fat Wood • Char cloth • Lint
A small amount of tinder can be used to ignite a spark and fuel a larger fire. Kindling on the other hand can only be lit from a flame next to it for about 2 seconds and should not be brought in any of your bags.		**Uses** • Fire lighting	**Types** • Shoelace • Fatwood • Magnesium

See the FIRE and FUEL sections for more information on tinders.

Candle

Candle Useful Item 3/5 Tin, EDC, GH, BOB, INCH	A small candle can be used for lighting other parts of a fire, keeping a flame alive for longer or camp lighting. Larger candles are best suited as a lighting source but ensure they aren't likely to fall over and ignite nearby gear. Citronella candles "can" repel bugs and mosquitoes within a small radius which could come in handy over regular candles but from experience there's not too much of a difference between that and regular candles. Candles about 1 inch (2.5cm) are the most optimum for burning as they reduce wasted wax and have the longest burn time. For more information see the FIRE section.

8 Medical

This section helps you choose the medical related items in your kits.

First Aid Kit

First Aid Kit Essential Item 5/5 Tin*, EDC*, GH*, BOB, INCH	An essential item as you will certainly get some form of injury during the disaster from a minor cut to a sting, or a broken bone. Include the typical items in a first aid kit or buy a pre-packaged one from the shops. See the section below for a list of recommended items in this kit. *It's not possible for a whole first aid kit to fit inside a survival tin, EDC bag or Get Home bag, but some components of the kit can, such as Band-Aids and sutures.

Trauma Kit

Trauma Kit Essential Item 5/5 EDC*, GH*, BOB, INCH	Used for major and life threatening injuries which are also bound to occur at some point in the future. See the trauma section below for a list of recommended items in this kit. *It's not possible for a whole trauma kit to fit inside an EDC bag or Get Home bag, but some components of the kit can, such as Band-Aids, sutures and surgical blades.

Dental Kit

Dental Kit Useful Item 3/5 BOB, INCH	Tooth problems can inflict real pain depending on the problem. This kit should relieve some of the pain and provide a solution. See further below for a list of recommended items in this kit.

Insect Repellent

Insect Repellent Important Item 3/5 GH, BOB, INCH	Insects can be a real nuisance when bugging out, not to mention their ability to transmit diseases and this will provide some protection during the worst periods.

Survival Blanket

Survival Blanket Useful Item 4/5 GH, BOB, INCH	Can be used as an emergency shelter to hop into in extreme conditions, under you as a heat reflector while you sleep or it can reflect heat from a fire back towards you. They generally take up an extremely small size but unfortunately can't be re-compressed back down to that size so you either have to make space for it or discard it. They can sound like a bag of chips when you're moving it around, so be warned that it can give away your position.

Masks

Face Mask Useful Item 4/5 BOB, INCH	A mask to cover your face while treating the wounded, or for those who are sick.
Gas Mask Important Item 4/5 BOB, INCH	An important piece of kit in any preppers bag. You don't know what disaster may have happened and a gas mask can reduce dust, volcanic ash and viruses that reach you. Get one that either fits over your whole face or just your nose and make sure the filters fit it and you have a variety for multiple scenarios. Have enough backup filters for about a week in case it takes you longer then you think to reach your destination, or if they become clogged fast. Full face fitting masks are recommended over nose masks but a beard can leave a slight gap in it thus allowing minor amounts of particulate in. Carry a razor to reduce this risk.

Snake/Spider Bite Kit

GEAR | Descriptions | Medical | Snake/Spider

Snake/Spider Bite Kit Conditional Item 3/5 BOB, INCH	A kit that slows the spread of venom around your body long enough to hopefully let your liver process the toxins in smaller quantities. It may include a venom extractor to pull out some of the venom from the wound. Some countries may not have any venomous creatures and so this is a conditional item based on locale. Prevention is always the best method, so if you don't have one of these kits you should be extra careful where you tread and stick your hands.	**Often Includes** ● 2+ Bandages ● 1 Razor ● Alcohol Wipes ● 1 Venom Extractor ● 1 Medical Guide	**Best Brands** ● Sawyer Extractor

Medical | Potassium

Potassium Permanganate

Potassium Permanganate Important Item 4/5 Tin, BOB, INCH	Multiple uses from wound treatment, fungal treatment and water purification. The most versatile medication you will encounter with multiple uses in different fields. Can also be combined with glycerine to produce fire.

GEAR | Gear | Medication

9 Medication

This section helps you choose the medication related items in your kits.

Descriptions | Medication | Medications

Medications

Antibiotics Essential Item 5/5 BOB, INCH	Treats bacterial infections which are life threatening when ignored. Be sure they are kept in a cool, dark environment to extend their life as long as possible. Doctors can prescribe antibiotics if you explain why you want them and your concerns for the situation of the world. Examples: Penicillin, Amoxicillin, Doxycycline, Cephalexin, Ciprofloxacin, Clindamycin, Metronidazole, Azithromycin.
Intestinal Sedative Important Item 4/5 Tin, EDC, GH, BOB, INCH	Settles the stomach and prevents diarrhoea for a few hours. Examples: Loperamide (Imodium), Diphenoxylate (Lomotil), Bismuth, Codeine, Cholestyramine (Questran).
Analgesic Essential Item 5/5 Tin, EDC, GH, BOB, INCH	Reduces the amount of pain felt. Examples: Panadol, Asprin, Nurofen, Codeine, Acetaminophen (Tylenol), Naproxen (Aleve), Diazepam (Valium).
Antihistamines Conditional Item 4/5 Tin, EDC, GH, BOB, INCH	Treats allergy symptoms. This is a conditional item and it's recommended you bring a few if you're prone to allergies. Examples: Polaramine, Benadryl.
Antihelmetics Conditional Item 3/5 BOB, INCH	Anthelmintics or antihelminthics are a group of antiparasitic drugs that expel parasitic worms (helminths) and other internal parasites from the body by either stunning or killing them and without causing significant damage to the host. These are most useful in countries with subpar standards of hygiene but can also be useful to take if you suspect a worm. Examples: Mebendazole, Albendazole, Praziquantel.
Personal Medication Essential Item 5/5 EDC, GH, BOB, INCH	Medication specific to you to keep an affliction at bay. Examples include an inhaler for asthma, an insulin pen for diabetics and an epi-pen if for allergies.
Anti-Malaria Tablets Conditional Item 3/5 Tin, EDC, GH, BOB, INCH	Prevents malaria in regions where it's prevalent.

10 First Aid Kit

This section helps you choose the first aid related items in your kits.

Kit Items

Alcohol Prep Pads Essential Item 5/5 Tin, GH, BOB, INCH, Ext	For cleaning bacteria and debris from wounds, it kills any viruses and bacteria it comes in contact with and it can be used as tinder which will catch any spark. You should have at minimum 5 of these pads in any kit.
Tweezers / Needles Essential Item 4/5 GH, BOB, INCH, Ext	For removing ticks and splinters. These are generally tiny and lightweight and can fit into any kit.
Gauze Bandages Essential Item 5/5 GH, BOB, INCH, Ext	Wraps the wound up to protect it and let it heal.
Band-Aids Essential Item 5/5 Tin, GH, BOB, INCH, Ext	To place over minor wounds and letting them heal.
Moleskin Pads Important Item 4/5 GH, BOB, INCH, Ext	Prevents friction points in shoes and shields blisters.
Eye Wash Useful Item 2/5 BOB, INCH, Ext	Washes foreign objects from the eye or washes out debris from wounds.
Surgical Tape Useful Item 4/5 GH, BOB, INCH, Ext	To wrap around bandages to hold them in place. This is only required if you have non-stick bandages in your kit.
Super Glue Useful Item 3/5 GH, BOB, INCH, Ext	For closing up smaller wounds but may burn the skin. You can purchase tiny 1ml bottles of super glue which are ideal for skin application purposes or repairing small devices with minimum wastage.
Triangle Sling Useful Item 4/5 BOB, INCH, Ext	For binding up a limb to prevent further injury after a break.

11 Trauma Kit

This section helps you choose the trauma related items in your kits.

Trauma Kit Items

Stethoscope Important Item 3/5 BOB, INCH, Ext	For checking the heart rate of a patient. This item should only be included in a dedicated medical kit if you have one.
Blood Pressure Cuff Useful Item 2/5 BOB, INCH, Ext	To check the blood pressure of a patient.
Tourniquet Essential Item 5/5 BOB, INCH, Ext	To temporarily stop the flow of blood.
Splints / Bandages Important Item 3/5 BOB, INCH, Ext	For holding broken bones in place. SAM splits are recommended due to their ability to be rolled up lengthways easily when not in use but once you bend it along the width, it forms a rigid structure allowing it to hold the bone. It can also be cut with scissors into any length, shape or size that is required. You could always save space and use sticks or nearby materials instead of a custom made splint, however it won't be as comfortable.
Israeli Dressing Important Item 4/5 BOB, INCH, Ext	A bandage used on large wounds to absorb blood, hold them tight and provide a non stick bandage. They come in sterile bags which have had the air removed and are straight-forward to open and apply to wounds. There are a variety of sizes they come in so having a few different types on hand is ideal to choose the right one for the type of wound.
Quick Clot Powder Important Item 4/5 BOB, INCH, Ext	To clot wounds quickly if bleeding won't stop. The granules should be tipped into any openly bleeding wound and held until the bleeding slows or stops. These have expiry dates so be sure to refresh them once they are getting to their end of their life.
Nasopharyngeal Airway Useful Item 3/5 BOB, INCH, Ext	A nasopharyngeal airway is used to keep an airway open - generally long enough for other drugs to work.
Suture / Staple Kit Important Item 3/5 BOB, INCH, Ext	For fixing up larger skin breaks. Staples should be used on the head whereas sutures should be used on any malleable skin which is broken.
Gloves / Sanitizer Important Item 4/5 BOB, INCH, Ext	To prevent the spread of bacteria into the patient. Sanitizer could be isopropyl alcohol, alcohol wipes, Dettol etc.
Defibrillator Useful Item 2/5 INCH, Ext	To restart the heart if it's stopped. Make sure you know how to use it if you have one. These are quite bulky and heavy and are therefore only really recommended to have in a car or external location. It will also be a problem to recharge it in a SHTF environment. They are however, extremely valuable if you need to use one to save a life.

Numbing Agents Useful Item 4/5 BOB, INCH, Ext	To reduce localized pain if required. Some numbing agents are just wipes which are used directly on the skin and others which are injected and require refrigeration at certain temperatures.

12 Dental Kit

A dental kit isn't required for the minor bags, but can get pretty important in a long term off grid situation.

Dental Kit Items

Dental Mirrors Important Item 4/5 INCH, Ext	For looking around the teeth.
Tooth Filler Useful Item 4/5 INCH, Ext	Filler material for teeth.
Dental Picks Useful Item 2/5 INCH, Ext	For scraping the teeth.
Forceps Important Item 3/5 INCH, Ext	For grabbing and pulling out teeth.
Tweezers Important Item 4/5 INCH, Ext	For grabbing and pulling out small items. A pair of these should be in your first aid kit anyway.
Cotton Balls Useful Item 3/5 INCH, Ext	For holding the gums away from the teeth. They can also be used as tinder.
Dental Wax Useful Item 2/5 INCH, Ext	Relief from braces and other in-mouth metal devices.
Surgical Gloves Important Item 4/5 INCH, Ext	Keeps the hands clean and free of bacteria. A few pairs of these should also be in the trauma kit.
Toothache Reliever Important Item 3/5 INCH, Ext	Relieves the pain of toothaches. A good choice is 'Oil of Cloves' or 'Clove Oil', which is obtainable from any chemist.

13 Hygiene

Hygiene is an important category to have, since it prevents disease and injury.

Tablet Napkins

Tablet Napkins Useful Item 2/5 GH, BOB	Compact and versatile for cleaning messes or yourself. A more permanent towel and washer is recommended for INCH bags and external locations. They can be used as toilet paper if wet slightly.

Hand Sanitizer

Hand Sanitizer Useful Item 4/5 GH, BOB, INCH	Isopropyl, hand cleaner fluid or wet wipes are ideal. Can also be used for fire lighting.

Soap

Soap Important Item 4/5 GH, BOB, INCH	Either a small bar of soap or wafer-thin one use soap strips.

Small Mirror

Small Mirror Essential Item 5/5 Tin, GH, BOB, INCH	A mirror can be used for self observation for hygiene or medical purposes. It can also be used to bounce light to a target area to signal them. Reflected at aircraft, this mirror can prove life saving to show where you're located. A mirror can reflect light over 10km's (6.2mi) and only requires a single flash for someone to notice. Look for the unbreakable, ultralight compact ones which take up next to no room and weight. It's recommended to buy one with an aiming hole in the middle to make it easier to hit your target, however this makes it annoying when you're using it to look at yourself.

Microfibre Towel

Microfibre Towel Useful Item 4/5 BOB, INCH	Pack a small one to dry off easily after bathing or getting wet. In an emergency it could also be used as toilet paper if you're fine with rinsing it thoroughly and sterilizing it after each use.

Toilet Paper

Toilet Paper Useful Item 2/5 GH, BOB, INCH	The travel kind to save space. It's recommended to have biodegradable toilet paper so you can just bury it once its used.

Toothbrush & Paste

Toothbrush & Paste Useful Item 3/5 BOB, INCH	For cleaning teeth to prevent dental issues.

Personal Necessities

Personal Necessities Conditional Item 5/5 **EDC, GH, BOB, INCH**	These are conditional items such as tampons which make life much easier. Tampons can also be used as tinder and wound care if needed.

14 Tools

This covers the basic tools everyone needs in their kits.

Knife

Knife Essential Item 5/5 **EDC, GH, BOB, INCH**	Arguably the most important item in your BOB. A knife can perform a limitless number of tasks from gutting fish to sparking flint. The most versatile piece of equipment with an infinite number of uses. A few types of knives can be worn around the neck or strapped to the leg and still remain invisible to others, you don't want to be considered a threat. A lollipop could be carried around as a makeshift weapon when held tight in a fist.	**Uses** ● Cutting ● Skinning ● Opening ● Defence ● Shaving ● Whittling ● Reflecting	**Weapons** ● Knife ● Pocket Knife ● Gun ● Lollipop	**Best Brands** ● Smith & Wesson ● Schrade ● Ka-Bar ● Gerber ● CRKT

Types

Fixed Blade A knife with a blade which doesn't move constructed from a solid piece of metal.	**Folding-Assist Open** A knife that folds away and can be opened but must be done manually unlike a switchblade.	**Switchblade** A knife which flicks open at the press of a button.	**Throwing** A small and lightweight knife designed for throwing.		

Tang

Full Tang The steel extends from the tip all the way through the handle to the base.	**Skeletonized Tang** The tang has been cut out to save weight at the cost of strength and durability.	**Partial Tang** A tang which doesn't extend to the end of the handle, but partially through it.	**Narrowing Tang** A tang which slowly tapers down inside the handle.	**Stick Tang** A thin but long tang which runs most of the length of the handle.	

Tang Styles

Scaled The handle has two pieces fastened to each side of the tang with rivets.	**Encapsulated** The handle is moulded around the tang.	**Extended** The tang extends beyond the butt, usually functioning as a hammer surface.	**Stick** The tang is much narrower than the blade to cut weight.	**Hidden** The rivets and edges of the tang are hidden.	**Skeletonized** The tang metal is hollowed out, to cut weight and often to make a storage compartment.
Tapered The tang is tapered from blade to butt to gradually reduce the size, thickness, and weight.	**Push** The tang is inserted (pushed) into the handle and then fastened.				

Blade Styles

Plain Edge A continuous, smooth, sharpened cutting edge without any serrations.	**Serrated** Features a saw-like edge with a series of "teeth" or scallops.	**Combination Edge** The blade is sharpened on both sides, tapering to a central point, allowing it to cut on both the push and pull strokes.	**Double-Edged** A knife with two cutting edges. Do not use for batoning wood.		

Blade Length

2 Inch For intricate detail work and fine tasks.	**3 Inch** Leatherman knife size. Great for everyday carry.	**4 Inch** Versatile for general utility and outdoor tasks.	**5 Inch** The minimum size to baton wood.	**6 Inch** A good medium for a survival knife size.	**7 Inch** Superior reach for combat and heavy cutting.
8 Inch For heavy-duty chopping and large game.	**9 Inch** Great leverage for significant bushcraft tasks.	**10 Inch** Ultimate reach and power for extreme chopping.			

Blade Thickness

<1mm Ideal for skin incisions and medical use.	**1mm** Best used for very fine work such as medical purposes.	**2mm** Still quite a fine blade, best used for medical purposes, cutting rope and whittling.	**3mm** Solid for chopping smaller pieces of wood. The smallest size required for batoning wood.	**4mm (5/32")** Good for chopping all kinds of wood and will last quite a long time.	**5mm** An average thickness survival blade which should last decades with moderate use.

GEAR Gear Tools Knife

6mm Getting on the heavier side with less benefits over the thinner blades. Good for INCH bags.	**7mm** A heavy duty blade which should last decades with heavy use.	**8mm** One of the thickest and heaviest blades you can buy and likely the most durable.			

GEAR Tools Knife

Handle Material

Wood Classic feel, aesthetic warmth, natural grip.	**Plastic** Lightweight, durable, inexpensive, low maintenance.	**Rubberised** Excellent grip, shock absorption, comfortable, non-slip.	**Metal** Extremely durable, strong, hygienic, elegant look.	**Coated Leather** Good grip, comfortable, classic look, durable.	

Edge

Plain / Straight A smooth cutting, which isn't necessarily "straight" as it usually has curves, especially a belly.	**Partially Serrated** A portion of the knife blade near the handle may have serrations or scallops.	**Serrated** Serrations on the knife. Serrations can cut fibrous materials like ropes and straps, which are difficult for a straight edge.			

GEAR Descriptions Tools Knife

Blade Point

Straight-Back The back of the knife is straight.	**Drop-Point** This point features a gradual and convex curve that drops from the spine to the point. It's probably the most common design for survival knives because of its strength and ease of sheathing.	**Clip-Point** The reverse of the drop point, where the curve is concave from the spine to point like metal was 'clipped' out of the blade. This is a common design for survival blades.	**Tanto-Point** Points of this kind have many variations but all feature one or more straight edges to the point. The design is optimized for fighting and tactical uses.	**Spear-Point** Like the name says, designed for spearing, with symmetrical convex curves from spine and belly. Since spearing is just one of dozens survival knife uses, this point is specialized.	**Trailing-Point** A trailing point knife is a knife that has a back edge that curves upward. The "trailing point" is named for the point which trails higher than the generalized axis of the spine of the knife blade.

GEAR Gear Tools Knife

Features

Clip A clip allowing attachment to a belt, backpack or similar.	**Lanyard Hole** A hole allowing it to be tied to something with cord.				

Butt / Pommel

The pommel is the same as the butt of the knife. Most of the time, the butt is the generic name for the end of the handle, while a pommel is a specific piece – either part of the tang or an end cap – that reinforces the butt so it can be used for striking or hammering. In survival knives, a pommel is common, as it adds the 'hammer' functionality, even if it is limited.

GEAR Tools Knife

Sheath Material

Plastic A low quality material which is waterproof but may not last long.	**Nylon** o	**Leather** If the leather is of high quality it will last a lifetime.	**Zytel** o		

GEAR Descriptions Tools Knife

Blade Grinds

Centerline Grind A blade grind resembling that of a double-edged knife in which the top and bottom bevels meet in the center of the blade's width. Only the bottom edge is sharpened and the spine of the knife is left unsharpened to create a swedge.	**False Edge** A sharpened secondary edge on the spine of a blade near the point. If unsharpened, it is called a swedge.	**Flat Saber Grind** A blade ground with flat bevels that extend from the centerline of the blade to the cutting edge. This grind maintains full thickness through a larger portion of the blade for increased strength.	**Full Flat Grind** A blade ground with flat bevels that extend from the spine all the way to the cutting edge. This grind reduces drag during cutting and decreases overall weight.	**Hamaguri (Appleseed)** Japanese for "clam" or "clamshell," it describes a blade ground with convex radiused bevels. Also called an Appleseed or Moran grind, it is often produced by grinding on a slack grinding belt.	**Hollow Grind** A blade with bevels that are ground with a concave radius. The bevels may extend the full width of the blade (full hollow grind) or only a portion of its width.
Single-Bevel Grind Also called a chisel grind, this describes a blade that is beveled on only one side. It may be flat or hollow ground.	**Swedge** An unsharpened bevel on the spine of a blade near the point. If it were sharpened it would be considered a false edge. A swedge reduces blade weight, enhances balance, and improves penetration.	**Zero Grind** A grind similar to a full-flat grind but without the secondary bevel at the cutting edge. The plane of the bevel continues to create the cutting edge.	**Zero Saber Grind** zerosabergrind (Scandinavian or "Scandi" grind) Similar to a flat-ground saber, but without a secondary bevel at the cutting edge. The plane of the bevel continues to create the cutting edge.		

GEAR Gear Tools Knife

GEAR Tools Knife

Properties of Knife Steel

Hardness	Hardness is the ability to resist deforming when subject to stress and applied forces. Hardness in knife steels is directly correlated to strength and is generally measured using the Rockwell C scale (aka "HRC").
Toughness	Toughness is the ability to resist damage like cracks or chips when subject to impact or "sudden loads". Chipping is a knife's worst enemy and never easy to fix. There are a number of different ways to measure toughness (i.e. Charpy, Izod) thus it's less standardized than hardness when it comes to knives. In general, the harder the steel the less tough it's likely to be.

Wear Resistance	Wear resistance is the steel's ability to withstand damage from both abrasive and adhesive wear. Abrasive wear occurs when harder particles pass over a softer surface. Adhesive wear occurs when debris is dislodged from one surface and attaches to the other. Wear resistance generally correlates with the steel's hardness but is also heavily influenced by the specific chemistry of the steel. In steels of equal hardness, the steel with larger carbides (think microscopic, hard, wear resistant particles) will typically resist wear better. However, carbides can become brittle and crack, thus decreasing toughness.
Corrosion Resistance	Corrosion resistance is the ability to resist corrosion such as rust caused by external elements like humidity, moisture and salt. Note that a high resistance to corrosion does involve a sacrifice in the overall edge performance.
Edge Retention	Edge Retention represents how long the blade will retain its sharpness when subject to periods of use. It's what everyone talks about these days but unfortunately the measurement of edge retention lacks any defined set of standards and so much of the data is subjective. Edge retention is a combination of wear resistance and an edge that resists deformation.
Knife Steel Categories	
Carbon	Generally made for rough use where toughness and durability is important. Common in survival knives and machetes. They take a sharp edge and are relatively easy to re-sharpen. The trade-off is being more prone to corrosion given the low chromium content. The most popular carbon knife steel is 1095.
Tool Steel	Primarily hard steel alloys used in cutting tools. Some popular tool steels in this group include D2, O1 and Crucible's CPM series (i.e. CPM 3V) plus more advanced high speed steels like M4.
Stainless Steel	Basically carbon steel with added chromium to resist corrosion and other elements which increase performance levels but usually at the expense of inferior toughness. Easily the most popular category today for EDC knives and includes the 400, 154CM, AUS, VG, CTS, MoV, Sandvik and Crucible SxxV series of steels. Note that to qualify as a true stainless steel there must be at least 13% chromium.
Specific Knife Steels	
1095	This is the most popular 10-series standard carbon steel (about 1% carbon) with low corrosion resistance and average edge retention properties. Why would you want 1095 steel? The appeal here is 1095 is a tough steel that's resistant to chipping, it's easy to sharpen, takes a crazy sharp edge and is inexpensive to produce. This makes it desirable for larger heavy duty fixed blades and survival knives which are going to be subject to more abuse than your typical EDC. Many manufacturers will coat their 1095 knives to delay the onset of any corrosion but a simple oil treatment will do the trick.
CPM S110V	Quite simply the ultimate in wear resistance and edge retention in 'mainstream' knife production. Still relatively rare in the marketplace and arguably indistinguishable from CPM-S90V outside of the laboratory, but the fact remains that nothing holds an edge like Crucible's CPM-S110V. It's costly, a bitch for knifemakers to work with and sharpening can drive you nuts but a CPM-S110V blade will hold up for a ridiculous amount of time.
CPM M4	A high performance tool steel which excels at toughness and arguably holds and edge better than any other carbon steel. Like all CPM steels, CPM M4 is created using Crucible's patented Crucible Particle Metallurgy process, which provides an extremely homogeneous, stable and grindable product compared to the traditional processes. CPM M4 provides superbly balances levels of abrasion resistance and toughness through high doses of molybdenum (hence the "M"), vanadium and tungsten together with reasonably high levels of carbon. It can be hardened to around 62-64 HRC but note M4 is a carbon steel is not considered stainless with relatively low levels of chromium. So, while this is one of the best steels around for cutting, it has to be properly cared for and may develop a patina over time. Some manufacturers have resorted to coatings which do help but note they won't last forever. Easy to sharpen? Ah, no.
440C	Once considered the high-end in US knife steels, 440C is a good all-round steel that has now been overshadowed by many of the newer super-steels on the block. This is a stainless steel commonly used on many mass-manufactured pocket knives and represents a solid affordable all-round choice. It's reasonably tough and wear resistant but it really excels at stain resistance. Holds an edge better than it's 400-series counterpart 420HC but at the expense of some corrosion resistance. The 440C blades can be sharpened relatively easily. It has the highest levels of carbon and chromium in this group.
1084	An excellent balance between hardness and toughness, making them ideal for creating resilient knives with superior edge retention. It will only rust if you leave it wet.
420HC	Generally considered the king of the 420 steels, 420HC is similar to 420 steel but with increased levels of carbon (HC stands for High Carbon) which makes the steel harder. Still considered a lower-mid range steel but the more competent manufacturers (e.g. Buck) can really bring out the best in this affordable steel using quality heat treatments. That results in better edge retention and resistance to corrosion. In fact, this is one of the most corrosion resistant steels out there, despite it's low cost. You'll find it mostly on budget blades (< $50) and multi-tools. Many leatherman knives use this steel.
AUS8	In the world of stainless steel, AUS 8 offers a great compromise between quality and price. It can take an incredibly sharp edge. It won't hold that edge as well as something like 154CM because it's a lot softer, but that also makes it tough enough to be a good working knife, and it will almost always make a knife more affordable than if you used any other decent quality stainless steel. If you're putting an AUS-8 blade under consistently heavy use, you will spend a fair bit of time maintaining the edge, but all that sharpening will be done with a lot less effort than VG-10 or AUS-10, and it usually makes a knife cheap enough that a chipped edge doesn't really feel like a huge loss.
D2	D2 steel is a tool steel often referred to as "semi-stainless" as it falls just short of the required amount of chromium (13%) to qualify as full stainless yet it still provides a good amount of resistance to corrosion. On the flip side D2 steel is much harder than other steels in this category such as 154CM or ATS-34 and as a result holds its edge a little better. That said, it's not as tough as many other steels and exponentially tougher to sharpen. In fact, you really need to be a master-sharpener to get a fine edge on D2.
5160	Alloy Steel 5160, or AISI 5160, is a high carbon and chromium steel. Users benefit from its outstanding toughness, ductility, and fatigue resistance. Although 5160 is a high-quality steel for knives, it isn't commonly used in shorter blades. Instead, you're more likely to see it in survival knives and swords due to its flexible yet durable qualities. With its high carbon and chromium alloy, 5160 is the steel of choice for sword manufacturers due to its high impact resistance. The biggest drawback to 5160 as a popular knife making steel is its lower edge retention, but this very down side is what makes it appropriate for survival knives. If you're out in the bush and don't have access to a regular knife sharpener, you can get decent results using a rock. A 5160 spring steel knife is also great for camping and other outdoor activities because it can handle tasks such as batoning and wood chopping without breaking or chipping.
Weight	

Ranges from 3oz - 16oz. Make sure to buy one you're happy with the weight of, as you may be carrying it on your belt, necklace or backpack. As a knife is one of the most versatile items you'll carry, you should never skimp on it. A hefty knife will provide it's weight in gold even if it's a few extra ounces.

Cost

You can expect to pay from $100-$700 USD for a quality knife which will last as long as you. Stay away from the cheap and nasty ones and do your research before purchasing. With that said, there are some decent quality 'cheap' knives that will suit the purpose of bushcraft for a while.

Multitool

Multitool
Important Item
3/5
EDC, GH, BOB, INCH

Used for fixing gear, making repairs and as a secondary knife. Generally the additional tools only come in handy in suburban areas or if you have a bike or other small machinery.

Best Brands
- Leatherman
- Gerber
- SOG

A handy tool comprised of multiple useful tools which cover a range of common scenarios. Ensure it contains all the tools you're likely to use and excludes the ones you will never need. Buy a lightweight one if you're trying to shed weight. If you're bugging out via bike you might as well get a bike specific multitool with every tool you may need for a breakdown.

Uses
- Knife
- Bottle Opener
- File
- Pliers
- Saw
- Screwdriver
- Carabineer

Tools

Weight

The weight can vary substantially from about 96g to over 300g for one of the highest end multitools so pick one with only what you will use and no more.

Cost

For a Leatherman you can pick the Skeletool up for $80 USD and the highest end one for about $250.

Wire Saw

Wire Saw
Useful Item
2/5
BOB, INCH

A wire saw is best utilized in the smaller kits where a folding saw won't fit. They can generally cut through trees and branches up to 5cm (2 in) thick. Some types have a chainsaw blade instead of a wire which can help cut faster but requires more strength to pull. The wire saw is tiny and extremely light so it could be worth throwing one in your BOB if you'll use it.

Folding Saw

Folding Saw
Essential Item
3/5
BOB, INCH

A folding saw is a typical woodworking saw that folds into the handle to save space and protect the blade. They are much easier to cut wood with than wire saws and can generally be sharpened. They come in a wide range of sizes to fit into different bags - but generally go into INCH bags and not BOBs.

Best Brands
- Silky Bigboy
- Bahco

Hatchet

Hatchet
Important Item
4/5
INCH, Ext

Hatchets can primarily be used to cut trees for shelter building and hammering pegs among some other minor uses. They are much heavier than hatchets and wire saws but can last longer without needing to be sharpened and aren't as likely to break as with the wire and blade of the other two. These should only be carried in INCH bags in general but you decide based on your requirements and Bug Out Route.

Best Brands
- Estwing
- Fiskars
- Husqvarna

Folding Shovel

Folding Shovel
Important Item
3/5
BOB, INCH

For digging holes to dispose waste or to assist in shelter building. A shovel will always come in handy at some point when you're working with the earth. It's basically essential if you're never coming home so you can dig latrines, do gardening, dig for food and even cook on.

Best Brands
- SOG
- IUNIO
- Gerber

GEAR | Descriptions | Light & Power | Gear

15 Light & Power

Any light and power needs you should have.

Headlamp

Headlamp Essential Item 4/5 GH, BOB, INCH	The only option for a hands free light so you can still perform tasks like cooking. The batteries should last the entire 3 day (Bug Out) trip home if used wisely. For INCH bags you will want a couple of spare batteries and a way to recharge them such as solar or a hand crank generator. Light is essential and can deter enemies, provide visibility and signal others. A modest brightness is around 700 lumens which should provide ample visibility when hiking at night, as they get brighter you drain the batteries quicker and sometimes you only need a weak light. Look for a headlamp with a 1 lumen mode to save batteries if you just want to read in your tent.	**Headlamp** • 700+ Lumens • Headband Attachment • Brightness Settings • Different Colours	**Best Brands** • Olight • CREE • LED Lenser

You may want to think about getting a headlamp with multiple colours to use in different situations. An example being that red light can maintain your night vision better than other colours whereas green light is better to use to remain undetected in forest situations.
For more information on torches see the LIGHT section.

Keychain Torch

Keychain Torch Useful Item 3/5 EDC, GH, BOB, INCH	A small backup LED light for finding bag contents and lighting your way if your headlamp dies. Try to find a torch which uses a common battery type such as AAA or AA which are easier to replace if yours die or don't recharge well anymore. Look for something between 80-200 lumens like the i3E EOS from Olight.	**Best Brands** • Olight • Finware • Maglite • Energizer
Torch	Valuable in dark areas and for use at night. For more information on torches see the LIGHT section.	**Uses** • Lighting • Glass Breaking • Deterring Animals • Signalling

Glowstick

Glowstick Useful Item 4/5 GH, BOB, INCH	Temporary instant light if required and better for stealth work than torches. You can buy glowsticks in any colour required including infrared. Glowsticks can be cooled down to extend the duration of the light at the cost of brightness and heat them up to speed up the reaction, making them brighter. Glowsticks are wind and water proof allowing them to be used during rain, storms and underwater and are therefore prized during natural disasters.	**Activation** To use a glowstick, bend the tube until the inner glass vial breaks and then shake a few times to mix the compounds.	**Brightest Colours** 1. Green 2. Yellow 3. Orange 4. Red 5. Blue 6. Pink 7. Purple 8. White

For more information on glowsticks, see the LIGHT section.

Batteries

Batteries Conditional Item 4/5 GH, BOB, INCH	Batteries in one form to power all electronics like GPS and radio. For more information see the ELECTRICITY section.	**Common Batteries** • AAA • AA • C • D • 18650 • 9v	**Best Brands** • Olight • Eneloop • Energizer • Duracell

See the ELECTRICITY section for more information on batteries.

Battery Charger

Battery Charger Conditional Item 3/5 BOB, INCH	A charger for the batteries (above) to convert sunlight into electricity so you can continue to use your electronics.

Power Bank

Power Bank Important Item 4/5 GH, BOB, INCH	A useful device when you need some information from your phone or you have to make a call and your phone is dead. The need to keep updated with what's happening is vital and if the communications grid is still up you can use the internet to find out how the disaster is unfolding - but only if you have power.	**Size** Look for a power bank that's 10,000+ mAh	**Best Brands** • Anker • MI • Jackery

For more information on batteries, see the ELECTRICITY section.

Solar Panel

GEAR | Gear | Light & Power | Solar Panel

Solar Panel Useful Item 3/5 BOB, INCH	To recharge the power bank and phone. May be combined with the power bank. One of the easiest ways to gather electricity, simply put it in direct sunlight and let it charge a battery bank. This item should generally only be in an INCH bag or be located at your final bug-out location. If you will be living off the grid from a backpack it's recommended to have one to help charge your mobile and other electronics.	**Best Brands** • Anker • Rockpals • ACOPOWER • RAVPower

Types	
Regulator	Generally a portable solar panel will contain a regulator, but for those panels which just come with a positive and negative lead, this will be an additional purchase you need to make. You have to choose the regulator carefully to exceed the panel's maximum volt and amperage outputs.
Wattage	A 15W solar panel is the minimum wattage you should have to charge a modern smart phone in full sunlight. However I recommend a 50W minimum to charge a smart phone even in cloudy situations. A 120W panel is recommended as a minimum for a small group of people but won't fit into a backpack.
Maintenance	Solar panels don't require much maintenance. You should wipe it down every week or so to help it gather the maximum light possible. If you want the most efficient panels you can get it's also recommended to aim the panel directly at the sun every 4 hours or so to track it across the sky.
Weight	
Cost	

Crank Charger

Crank Charger Conditional Item 3/5 BOB, INCH	If the sky is cloudy for multiple days in a row, you can use a crank charger to power your electronics. You have to be actively turning the handle to generate electricity which will tire you out quite quickly as opposed to a solar panel where you just need to place it in the sun.	**Best Brands** • HUABAN • Kaito • RunningSnail

16 Communication

This section covers the communication devices you should have in your bag.
For more information on Mobile Phones, Apps and the best prepper mobile devices, see the COMMUNICATION section.

Mobile Phone

Mobile Phone Essential Item 5/5 EDC	A multipurpose device to find location, play games, play music, read information and more. As useful as they might be - they still might give away your location if you're being tracked by the government.	**Best Brands** • Samsung • Apple • Asus • HTC
	Almost everyone has one and uses it daily, great for pictures, information and maps. You may be able to be tracked via your phone even if the grid is down so keep it secure. You can keep some cash inside your phone case for emergencies.	**Uses** • Maps • Entertainment • Communication • Note taking
Accessories	It's wise to have some sort of protective casing around the phone or waterproofing if it isn't already.	**Accessories** • Case / Cover • Waterproof Bag • Charger Cable • Wall Plug • Screen Protector • Earphones
Comms	Communication is vital in this day and age, however this feature will be useless without a working grid. There are some apps that allow text and call communications over a wifi and bluetooth hotspot however you need to be in a relatively close proximity.	
Music	One of the most widespread use of phones is the ability to play any music you want - provided it's on the device in SHTF. Ensure you have a set of earphones and you can listen to whatever you load the device up with.	
Internet Access	Currently you have the world at your fingertips and access to any knowledge on the internet. When this goes down however all this will be lost. Download any information you need and get the books and apps you need before you realize there's no internet.	
Navigation	Phones with a connection to the GPS servers can pinpoint your location and provide you with your location if you have a map app. The app works offline however you will need to download the maps of your region so you can use them when the grid is down.	**Topographic Apps** • Alpine Quest • Backcountry Navigator • AndNav • Maverick • OruxMaps • Osmdroid • TrekBuddy

Apps	Try not to update any apps if they currently work just fine, but if you do ensure you test it thoroughly.	**Useful App Types** ● Informational ● Instructional ● Entertainment
Entertainment	Keeping occupied is vital when bugging out and there's nothing to do, a mobile can solve most of those problems as long as you have the games downloaded beforehand.	**Entertainment Types** ● Music ● Games ● Reading Books

Whistle

Whistle Essential Item 4/5 GH, BOB, INCH	Used signal for help if you are lost or want to attract attention. Whistles can be finger sized all the way up to large spiral shapes to maximize the sound of the whistle. Some whistles have finger holes to allow for more pitches.

Radios

Radio Essential Item 5/5 GH, BOB, INCH	Listen in to emergency broadcast stations and get weather updates. A radio with NOAA weather and shortwave is ideal to get news from a greater distance and even outside your country. Some phones come with a built-in FM radio which can eliminate the need to have a second device. Radios these days can be extremely tiny and fit in the palm of your hand, although you shouldn't expect any more than FM radio from them.	**Best Brands** ● Tecsun ● Panasonic ● Sangean ● Kaito
Scanner Useful Item 2/5 GH, BOB, INCH	A scanner radio which has more functions than a conventional radio. In addition to listening to AM and FM stations they can tune into short wave, aviation, police, ambulance, NOAA etc. This may not be needed unless you're dedicated to getting regular updates to the weather or want to listen to the police or aviation broadcasts. For more information, see the COMMUNICATIONS section.	**Best Brands** ● Baofeng ● Uniden

Transmitting

Two Way Radio Conditional Item 4/5 EDC, GH, BOB, INCH	Lets you chat with your team or other people in close proximity. Extremely useful when the mobile networks and internet are down and you have to separate from the members of your party. For information on using a Two Way Radio, see the COMMUNICATIONS section.	**Best Brands** ● ICOM ● Baofeng ● Uniden ● Midland ● Arcshell

555nm 50mw Laser

555nm 50mw Laser Conditional Item 3/5 EDC, GH, BOB, INCH	A strong laser to produce a bright visible beam for location at night or deterrence of adversaries and animals. 555nm green light is the most visible wavelength. 532nm is the most common green coloured laser. This can be a very small unit if custom built, or easily usable in a laser pen form. 50mw lasers won't harm the eyes unless directly shone into them, so never aim directly at people or planes. When SHTF you will want the laser to be on as little as possible to avoid unwanted attention, therefore only use short bursts. The beam will travel over about 10km's horizontally, but will only be visible a few km's if shone vertically. Don't forget the batteries, and it's recommended that you remove the batteries if it won't be used for long periods.

17 Weapons

The weapons you should have in your kit.

Defensive Weapon

Defensive Spray Conditional Item 4/5 EDC, GH, BOB, INCH	Capsicum or other form of deterrent spray for people and animals.

GEAR | Descriptions | Weapons | Defensive Weapons

Taser Useful Item 2/5 EDC, GH, BOB, INCH	A non lethal weapon if you don't want to kill the individual but instead only make a get-away. Useful in the city or until you get out of the suburbs. May be difficult to recharge.

Primary Weapon

Primary Weapon Essential Item 5/5 BOB, INCH	This is generally a rifle of some sort but it could also be a handgun, bow, crossbow, sword, air rifle etc. See the WEAPONS and OFFENCE sections for more information.
Rifle	For defending yourself from people or animals.
Bow / Crossbow	An almost silent alternative to a gun for hunting or defence.
Sword / Machete	A close range option for defence or hacking through undergrowth.

Secondary Weapon

Handgun Conditional Item 4/5 EDC, GH, BOB, INCH	For hunting animals or people and defending yourself.
Slingshot / Sling Conditional Item 2/5 GH, BOB, INCH	For hunting wild game and defending yourself.
Knife	Refer to the tools section above for the rating of knives.

Ammo

Ammo Conditional Item 5/5 EDC, GH, BOB, INCH	Essential if you have a gun or other primary weapon which requires it, unless you make your own.
Arrows Conditional Item 3/5 GH, BOB, INCH	Required if you have a bow, unless you fletch your own from natural materials.
Bolts Conditional Item 3/5 GH, BOB, INCH	Required if you have a crossbow, unless you fletch your own from natural materials.
Ball Bearings Conditional Item 2/5 GH, BOB, INCH	Some ball bearings for shooting from a slingshot. These could be fishing sinkers instead to provide dual-uses. Generally though, rocks should be used instead of both of these due to their availability in the environment.

18 Tactical

Any tactical gear to keep you stealthy.

GEAR GEAR GEAR GEAR GEAR GEAR GEAR
Descriptions Gear Descriptions Gear
Tactical Monocular /

Monocular / Binoculars

Monocular / Binoculars Optional Item 3/5 GH, BOB, INCH	For observing people, locations and animals from afar. Some situations will call for scouting and you will have a huge advantage if you see threats before they see you. This could also be a scope on a rifle instead of an additional monocular.	**Best Brands** • Bushnell • Nikon • Wingspan • Skygenius

Tactical Face Paint

Face Paint

Face Paint Conditional Item 1/5 GH, BOB, INCH	Camouflages any exposed skin to provide additional stealth. This is a conditional item and may only be needed in certain situations but particularly when you don't want to be observed by other humans or animals. If stealth is of the utmost importance you should also have a camo net to conceal your shelter.

Tactical Camo Net

Camo Net

Camo Net Useful Item 1/5 GH, BOB, INCH	Material used to cover colourful objects and prevent glint. They are perfect for blending your shelter into the surrounds if you don't wish to be seen. Ensure you have the correct coloured net to match your environment and season.

19 Morale

Gear which will keep your morale up.

Morale Family Pictures

Family Pictures

Family Pictures Useful Item 5/5 EDC, GH, BOB	To show people if you've lost a family member or to remind you of the good times.

Morale Alcohol / Cigar

Alcohol / Cigar

Alcohol / Cigar Optional Item 3/5 GH, BOB, INCH	Something to look forward to and will keep you going, however they are not recommended due to the mental impairment they offer once consumed.

Morale Games

Games

Games Useful Item 3/5 GH, BOB, INCH	A pack of cards, music or a mobile game can go a long way to restore morale.

Morale Religion

Religious Items

Religious Items Conditional Item 4/5 EDC, GH, BOB, INCH	If you adhere to a religion take a physical or digital Bible to save weight and stay grounded in your faith.

ptions

GEAR Descriptions

20 Navigation

Equipment which will help you navigate.

Plans

Plans Essential Item 5/5 EDC, GH, BOB, INCH	These are your bug out or bug-in plans either on a mobile device or a printed format so you can easily access them.

Local Maps

Local Maps Essential Item 5/5 GH, BOB, INCH	Maps of the local topography to assist in navigation and bugging out. Ensure you have enough maps to cover the entirety of any bug-out plans including extra terrain around it in case you have to change your plans. You should have both digital maps and physical maps in case something happens to one such as an EMP which kills your mobile devices.

Compass

Compass Essential Item 5/5 GH, BOB, INCH	To guide you in the right direction if your GPS fails. Be sure you know how to use your compass or you could get extremely lost.	**Best Brands** • Silva • Eyeskey • SUUNTO

Handheld GPS

Handheld GPS Useful Item 3/5 GH, BOB, INCH	A primary location device to help navigate if the satellites still work. A mobile phone also works as a GPS device if you have the correct apps and maps downloaded.	**Best Brands** • Garmin

Altimeter

Altimeter Conditional Item 3/5 GH, BOB, INCH	To find your altitude to help boiling water and crossing terrain in high elevation areas. An altimeter can also help in determining altitude sickness. Some phones can provide this functionality via apps to save additional weight.	**Best Brands** • Garmin • Sun Company

21 Misc

All other equipment which isn't covered by another topic is included here.

Cash

Cash Essential Item 5/5 EDC, GH, BOB, INCH	If you require to barter and cash is still valued. The grid may still be up when you return to civilization and you could hire a taxi home and buy a cheeseburger.

Barter Coins

Barter Coins Important Item 3/5 BOB, INCH, Ext	Gold and Silver will work well to trade for things you need. Be sure you know how to verify gold and silver coins from fakes.

Notepad & Pen

Notepad & Pen Important Item 4/5 BOB, INCH	Writing notes like plant locations, things to do or past experiences.	**Best Brands** ● Rite in the Rain
Notebook	Use this for taking notes, numbers and other information you require stored.	**Uses** ● Note taking ● Drawing ● Games ● Origami
Pen	For writing on the notepad or your skin if required.	**Uses** ● Writing ● Stabbing

Snare Wire

Snare Wire Important Item 3/5 INCH	To trap animals without using fishing line which will break. Set and forget. (But not forever)

Paracord / Rope

Paracord / Rope Essential Item 5/5 EDC, GH, BOB, INCH	Vital to keep - from shelter building to rappelling and even fire starting. Have at least 30 metres (100ft) of cordage. If you cut paracord, use a small flame to bind the ends so they don't unravel.

Duct Tape

Duct Tape Important Item 4/5 GH, BOB, INCH	A strong backup to paracord for construction, restraining or repairs.

Garbage Bag

Garbage Bag Essential Item 5/5 GH, BOB, INCH	For water gathering, a solar still, a makeshift shelter and for storage.

Sewing Kit

Sewing Kit Useful Item 3/5 INCH	To repair your tent and clothes. See further below for the recommended contents of the sewing kit.

Fishing Kit

Fishing Kit Useful Item 3/5 INCH	A bit of line, sinkers and hooks, and maybe an automatic fishing reel. See below for the recommended contents of the fishing kit.

Latex Tubing

Latex Tubing Useful Item 4/5 BOB, INCH	To use as a tourniquet, slingshot elastic, bowstring or piping.

Hand Warmer

Hand Warmer Conditional Item 2/5 GH, BOB, INCH	Extremely useful in cold environments when bugging out to warm the body and hands. The adhesive ones can be applied to the chest to prevent your core temperature from dropping too low. They generally last about 4 hours for the majority of the heat release and take 15 minutes to warm up once opened.

Documentation

Documentation Essential Item 5/5 EDC, GH, BOB, INCH	Documents may be vital in SHTF scenarios for crossing borders, proving your identity or at the very worst, corpse identification. Most of the listed documents are one sheet and very light however they are the type of things you don't want to fold to make it more compact. Generally you will want to carry the originals on you as they are useless if left at home where anyone can find and use it.

Prepper Plan	A detailed plan of your actions, bug out route and secret codes if SHTF. Generally you will have other people in your bug out plan and this document will remind them what to do if the worst does happen so they know what they're doing when disaster strikes. There should be a lot of redundancies in the plan for the most plausible scenarios and disasters. For more information see the PREPAREDNESS section.			
Birth Certificate	The second most important documentation piece can prove your existence and birthplace generally recognised worldwide. Take the original one and fold it very neatly so it fits into your pack better.			
Passport	Probably the most vital piece of documentation which should always be carried. This will allow you to cross borders if you need to flee the country and there's still a form of government and border protection. Not as necessary in un-bordered countries such as Australia but still important to carry.			
Marriage Certificate	Proof that you're married to someone. Some countries prohibit intercourse between unmarried individuals which could become a problem without this certificate.			
Immunization Records	To keep track of what diseases you're immunized against. If you're injured you can look back over when you had your last shot to determine your risk of infection and proceed from there. It will help you make better decisions about using your rare antibiotics which will likely be highly sought after when SHTF.			
Drivers Licence	As a form of ID that includes a picture and it's compact size makes it a useful one for identifying yourself.			
Important Numbers	Some additional numbers you should keep on hand in case you require them.	**Other Numbers** • Social Security Number • Tax File Number	**Bank Account Details** • BSB • Account Number • Account Name • Bank phone no.	**Family and Friends Details** • Name • Address • Phone Number

Flash Drive

Flash Drive Essential Item 5/5 EDC, GH, BOB, INCH	With survival guides, books, important documents and entertainment. Used for storage of important documents, maps, prepping tips and music. Takes up no space and is incredibly light. Ensure you have tested that the USB is compatible with your phone or that you have an adapter for it. Test the utilities used to open the PDF's, Maps and Contact List. Once tested on your phone be sure not to update the applications automatically or manually as this could end the compatibility of your USB or Micro SD card. The best storage to size and weight option is the microSD cards where you can now get 400gb in a form factor the size of your thumb, however always store the information in multiple places in case it fails. Digital storage can fail so its recommended that you have an exact copy of the drive on a spare located somewhere else in your BOB as well as on your phone.

GEAR | Gear | Misc | Flash Drive

USB Drive / Micro SD	Recommended Brands • SanDisk • Samsung • Corsair	Recommended Sizes • 32Gb • 64Gb • 128Gb • 256Gb Any larger and the risk of losing the data is too great, unless you have redundancies.	Important Files (Encrypted) • Passport Information • Medical Information • Birth Certificate • Medicare Details • List of Contact No's. • "Return to" Lost Info	Prepper Files • TPE Spreadsheet • Your Bug-Out Plan • BOB/INCH Bag Contents • Local Maps (PNG, JPG) • Local Digital Topo Maps • Survival Books	Entertainment Files • Novels • Movies • Music • Podcasts (eg. TSP) • Pics of Family & Friends	

GEAR | Descriptions | Misc | Credit Card

Credit Card

Credit Card Essential Item 5/5 EDC, GH, BOB, INCH	So you can purchase things since the grid may still be up.

GEAR | Gear | Misc | Backpack

Backpack

Backpack Essential Item 5/5 N/A	A way to hold and organize all your items. Choose one that's inconspicuous and not too large. Camo backpacks will draw too much attention to yourself if you're attempting to bug out.

GEAR | Misc | Metal Straw

Metal Straw

Metal Straw Useful Item 3/5 BOB, INCH	Used to drink from recently boiled water and to blow on fires.

GEAR | Descriptions | Misc | Wallet / Purse

Wallet / Purse

Wallet / Purse Important Item 3/5 EDC, GH, BOB, INCH	Used to carry ID, money, notes etc.	
Wallet	Wallets house your credit and other discount cards, money and sometimes coins.	**Uses** • Daily Transactions • Holding Cards • Holding Coins • Holding Cash • Metal Survival Cards
Purse	The female form of a wallet however it generally contains a lot more space for beauty and hygiene products.	**Uses** • Daily Transactions • Holding Cards • Holding Coins • Holding Cash • Metal Survival Cards • Hygiene Products • Beauty Products

GEAR | Gear | Misc | Keys

Keys

Keys Essential Item 4/5 EDC, GH, BOB, INCH	For unlocking your house, car, safe, shed and anything at your bug out location.

GEAR Descriptions Misc Keys

Keys / Keyring	For unlocking your house and car - typically something everyone has at least one of. Generally people have a few extra items on their keyring from toys to flashlights which can come in useful.	**Uses** ● Unlocking House ● Unlocking Car ● Unlocking Storage ● Other Locks	**Useful Attachments** ● Mini Torch ● Mini Knife ● USB Drive ● Carabineer / Clip ● Bottle Opener ● Pill Bottle ● Mini Lighter

Watch

GEAR Gear Misc Watch

Watch **Important Item** 4/5 **EDC, GH, BOB, INCH**	For telling the time and finding north with. A solar powered watch can recharge itself when it comes into contact with the sun and will often last up to 10 years before the battery fails.	**Best Brands** ● Casio ● Timex

Features

The importance of keeping time is a valuable tool in any society, including SHTF. However these days watches do so much more then tell time.	**Features** ● Luminous Hands/Digits ● Water Resistance ● Alarm ● Solar ● Calendar ● Chronograph	**Features** ● Light ● Compass ● Altimeter ● Barometer ● Thermometer ● Tachymeter	**Features** ● Annual Calendar ● Perpetual Calendar ● Leap Year ● Time Zones ● Moon Phase ● Heart Rate Monitor	**Features** ● Power Reserve Indicator ● Tourbillon ● Foudroyante

Watch Types

Analog Watch
Can use for finding north using the hands and the sun. More sensitive to heat and shocks. Slightly less accurate than digital watches.

Digital Watch
Uses slightly less power than analog watches. A more robust and weather proof watch type. More difficult and less accurate to find north with.

Smart Watch
Smart watches use the most power and a lot of features will be unavailable during SHTF. It's not recommended to have this watch type due to all the negatives in a survival situation. The watch may give away your position when alarms go off or other notifications.

Watch Complication Descriptions

Power Source Battery Solar & Battery Auto Wind Manual Wind	**Luminous Hands/Digits** Use this to reduce the amount of power consumed instead of a button press light.	**Water Resistance** 30M - Splash Resistant 50M - Shower Resistant 100M - Swim Resistant 300M - Dive Resistant **100M+ Recommended**	**Alarm** Excellent for reminding you to do something - although may give away your position in SHTF.	**Solar** Excellent for SHTF when you won't be able to find replacement batteries.	**Calendar** Keeping track of the day and date will be important to remember birthdays and keep morale up.
Chronograph Useful for timing relatively short intervals or the speed of grabbing your BOB.	**Light** May give away your position at night but worthwhile to have in survival situations.	**Compass** A great redundancy to have in case your primary compass breaks or fails.	**Altimeter** Displays the altitude you are at, useful for water boiling and oxygen requirements.	**Barometer** Measures atmospheric pressure and is useful for determining short term weather patterns.	**Thermometer** Useful if you need to know the ambient temperature.
Tachymeter Used for measuring the speed of objects between known distances.	**Annual Calendar** A calendar that only needs updating once a year in February to account for leap years.	**Perpetual Calendar** A calendar that never requires updating and is always accurate.	**Time Zones** Lets you find the time in different parts of the world.	**Moon Phase** Shows you the moon phase if you don't want to look up.	**Heart Rate Monitor** For measuring heart rate during exercise or at rest.
Power Reserve Indicator Displays how much power is left in the watch.	**Tourbillon** Counters the effects of gravity by mounting the escapement and balance wheel in a rotating cage, negating gravity when the timepiece is stuck in a certain position.	**Foudroyante** A sub-dial indicating fractions of a second. This complication is also known as the flying seconds hand.			

Band Type

Jewellery

GEAR Descriptions Misc Jewellery

Jewellery **Optional Item** 1/5 **EDC, GH, BOB, INCH**	Any jewellery on or in your body. A watch is considered jewellery but it's included below due having additional features. Each of these can have a unique use in a survival situation, from being a conductor to bartering. You can buy paracord jewellery such as a wristband, belt or keychain which often has other built in survival items like flint.	**Common Jewellery** ● Necklace ● Rings ● Piercings ● Bangle ● Earrings ● Rings

GEAR
Gear
Descriptions
Sewing Kit

22 Sewing Kit

The items which you should include in your sewing kit.

Scissors

Scissors	
Scissors Useful Item 2/5 BOB, INCH	For cutting cloth, cord, rope and thread. Look for a small pair of folding ones. You can also use a knife to cut thread but it won't be as clean and could be hard to thread through a needle. Some multitools have a pair of scissors on them.

Needles

Needles	
Needles Essential Item 5/5 BOB, INCH	For sewing with. Choose a variety of lengths and thicknesses. Try to keep them in a solid container where they can't be lost or poke through fabric. Needles can also be used for medical purposes when a probe is needed. They could also be turned into a rudimentary compass if you have a magnet.

Pins

Pins	
Pins Important Item 4/5 BOB, INCH	Get the type of pins with a spherical coloured end. Can be used for temporarily holding cloth, clothes or shelters together.

Thread

Thread	
Thread Important Item 4/5 BOB, INCH	To sew with. White, Black, Olive, Green and Brown recommended. To save space, fill bobbins instead of packing the whole roll of thread.

Buttons / Zipper

Buttons / Zipper	
Buttons / Zipper Useful Item 2/5 BOB, INCH	For attaching missing buttons or broken zippers to clothes.

Patches

Patches	
Patches Useful Item 3/5 BOB, INCH	To patch up ripped clothing and tents.

Elastic Strips

GEAR Descriptions Gear Sewing Kit Elastic Strips

Elastic Strips
Useful Item
3/5
BOB, INCH

To re-do the elastic if it breaks.

Safety Pins

Safety Pins
Useful Item
4/5
BOB, INCH

To hold two pieces of fabric together.

Thimble

Thimble
Useful Item
2/5
BOB, INCH

To prevent sewing injuries. Even a pinprick can get infected in a SHTF situation where there's little sanitisation.

Measuring Tape

Measuring Tape
Useful Item
3/5
BOB, INCH

To measure fabric.

Seam Ripper

Seam Ripper
Useful Item
2/5
BOB, INCH

For scavenging other materials to reuse or repairing clothing.

23 Fishing Kit

The items which you should include in your fishing kit. Generally a fishing kit is only needed in an INCH bag.

Strong Fishing Line

Strong Fishing Line
Essential Item
5/5
BOB, INCH

To attach hooks and sinkers to. Can also be used as backup cordage.

Hooks

Hooks
Important Item
4/5
INCH

For catching fish.

Sinkers / Floaters

Sinkers / Floaters Conditional Item 2/5 INCH	Various types to drop the line deep in the ocean or to keep it on the surface. You could use sticks and rocks instead to save a bit of weight if desired.

Yoyo Reel

Yoyo Reel Useful Item 4/5 INCH	Set and forget and hopefully you'll have fish by the end of the day. A highly recommended item which should make acquiring food much easier with almost no effort.

Retractable Fishing Rod

Retractable Fishing Rod Conditional Item 2/5 INCH	For regular fishing. Sticks will also work as a rod but be prepared for them to break.

Lures

Lures Conditional Item 2/5 INCH	For attracting fish, can include mini glowsticks and fish shaped lures.

Fishing Net

Fishing Net Useful Item 4/5 INCH	For pulling in fish and catching them in rivers. Make sure the net is strong and won't break if it gets caught on rocks and sticks.

5 Specialist Gear

This section is gear exclusively for specific climates or locations but is certainly essential in those locations.

Mountain Gear

Specific gear used for mountaineering.

Climbing Ropes Conditional Item 4/5 Specialist Gear	Ropes used for ascending or descending steep drops that mountainous terrain offers. Some ropes may not be retrievable once used and it's recommended you bring more length than you think you need. See the KNOTS section for more on types of ropes.
Hiking Boots Conditional Item 4/5 Specialist Gear	Choose footwear appropriate for the terrain (ankle support for rocky terrain, lighter shoes for well-maintained trails). Ensure they are broken in and ideally waterproof. Don't forget your hiking socks which should be moisture-wicking (wool or synthetic) to prevent blisters. Carry an extra pair as well.

Moisture-Wicking Clothes
Conditional Item
4/5
Specialist Gear

Worn next to the skin, they pull sweat away from your body to keep you dry. Crucial for comfort and preventing hypothermia when you sweat. (Avoid cotton – it absorbs moisture and stays wet). Materials: Merino wool, synthetic blends.

Gaiters
Conditional Item
4/5
Specialist Gear

These are fabric sleeves that go over your boots and lower pants. They keep out debris pebbles, dirt, snow and moisture, and can protect from scratches in overgrown trails.

Sunglasses
Conditional Item
4/5
Specialist Gear

Protects eyes from harsh glare and UV radiation. Essential for eye health and comfort, especially on bright days or with snow cover.

Trekking Poles
Conditional Item
4/5
Specialist Gear

Improve balance, reduce strain on knees (especially downhill), and provide stability on uneven or slippery terrain. Highly recommended for mountain hiking.

Cave Gear

Specific gear used for spelunking.

Powerful Headlamp
Conditional Item
4/5
Specialist Gear

Your BOB is likely going to contain a torch, but a headlamp will allow handsfree light. This should be a decently powerful headlamp to illuminate at least 30m ahead. Choose a model where the batteries can be instantly replaced, and be sure to bring plenty of spares. One with plenty of lighting options (low, medium, bright, strobe, red light, etc) will allow you to adapt to the changing conditions.

Secondary Headlamp
Conditional Item
4/5
Specialist Gear

A second headlamp in case the first fails. This will also allow you to have light while you replace the batteries in the other one.

Caving Helmet
Conditional Item
4/5
Specialist Gear

Hard-shell, durable, designed for caving, with secure clips for headlamps. Head protection from falls, falling rocks, and bumps in confined spaces.

Caving Harness
Conditional Item
4/5
Specialist Gear

Robust, simple, no padding (padding absorbs water and gets heavy), designed for comfort during long hangs. Connects you to ropes for ascending and descending.

Ascenders
Conditional Item
4/5
Specialist Gear

Mechanical devices for gripping a rope and allowing upward movement. Usually a chest ascender (Croll) and a handled ascender (Jumar/Basic). For climbing ropes out of pits.

Descenders
Conditional Item
4/5
Specialist Gear

Friction device for controlled rope descent (e.g., Petzl Stop, Rack). For safely lowering yourself into vertical shafts.

Cowstails
Conditional Item
4/5
Specialist Gear

Dynamic or semi-static rope lanyards, often one long and one short, attached to the harness. For clipping into safety points, passing knots on rope, and maintaining connection to the system.

Carabiners
Conditional Item
4/5
Specialist Gear

Locking carabiners (screw-gate or auto-locking) of various shapes (HMS, D-shape). Minimum 6-8 per person. Essential connectors for all parts of the SRT system.

Foot Loop / Etrier Conditional Item 4/5 Specialist Gear	Webbing loop attached to ascender for foot placement during ascent. Provides leverage for climbing ropes.
Climbing Ropes Conditional Item 4/5 Specialist Gear	Ropes used for ascending or descending steep drops that mountainous terrain offers. Some ropes may not be retrievable once used and it's recommended you bring more length than you think you need. Choose low-stretch static ropes specifically rated for caving/SRT. Lengths determined by cave depth.See the KNOTS section for more on types of ropes.
Drill & Bolt Kit Conditional Item 4/5 Specialist Gear	For installing or replacing anchors in the cave roof/walls.
Rope Protectors Conditional Item 4/5 Specialist Gear	Durable material placed at rope edges. Prevents rope abrasion against sharp rocks.
Undersuit/Thermal Conditional Item 4/5 Specialist Gear	Wicking material (fleece, polypropylene, wool) that retains warmth when wet. Avoid cotton. Caving environments are cold and wet. Keeps you warm and prevents hypothermia.
Caving Overalls/Suit Conditional Item 4/5 Specialist Gear	Durable, abrasion-resistant material (e.g., Cordura, PVC-coated nylon), often padded at knees/elbows. Protects skin and undersuit from abrasion, dirt, and water.
Neoprene Socks Conditional Item 4/5 Specialist Gear	Thick neoprene to provide insulation when wet. Keeps feet warm in cold, wet conditions.
Sturdy Caving Boots Conditional Item 4/5 Specialist Gear	Excellent grip (Vibram soles recommended), good ankle support, durable, drainable. Rubber wellingtons are common for wet caves. Navigating slippery, uneven, and often muddy terrain.
Gloves Conditional Item 4/5 Specialist Gear	Durable, grippy, and abrasion-resistant (e.g., gardening gloves with rubberized palms, specialized caving gloves). Protects hands from rope burn, sharp rocks, and cold.
Trash Bags Conditional Item 4/5 Specialist Gear	To remove waste from the cave.
Oxygen Meter Conditional Item 4/5 Specialist Gear	Deep inside caves there may be lower levels of oxygen, or it could be non-existent which is why an oxygen meter is essential.
Cave Radios Conditional Item 4/5 Specialist Gear	Specialized cave radios (e.g., Heyphone) for surface-to-underground communication.

GEAR Specialist Gear Cave

Spare Lights
Conditional Item
5/5
Specialist Gear

If the cave you will be entering is deep and doesn't have natural holes allowing light in you'll need a consistent way to produce your own light including a ton of spare batteries and various charging mechanisms. This particularly applies if you will be living inside a cave, however if so you might want to consider setting up a solar panel on the outside with cables leading in. If you're deep in a cave you may want to ensure you choose a light that doesn't consume oxygen like a torch or glowstick over a flame.

Snow Gear

Specific gear used for arctic and snowy climates.

Show Shoes
Conditional Item
4/5
Specialist Gear

Show shoes are important if you know you'll be walking on freshly fallen snow.

Show Shovels
Conditional Item
4/5
Specialist Gear

At least one sturdy snow shovel. Consider different types: a regular push shovel for clearing paths and a smaller, more robust shovel for breaking up ice or heavier snow. Ergonomic handles can reduce back strain.

Ice Melt / Rock Salt
Conditional Item
4/5
Specialist Gear

Chemical pellets (sodium chloride, calcium chloride, magnesium chloride) or sand/grit. These prevent ice formation and melts existing ice on walkways, steps, and driveways, preventing slips and falls. Be mindful of pet-safe options.

Ice Scrapers
Conditional Item
4/5
Specialist Gear

Handheld tools with a blade for scraping ice off surfaces. For clearing ice from vehicle windows, steps, and small patches of pavement.

Gumboots
Conditional Item
4/5
Specialist Gear

Helps prevent your feet from getting damp from the snow.

Roof Rake
Conditional Item
4/5
Specialist Gear

A long-handled tool with a wide head for pulling snow off rooftops. Prevents "ice dams" (where melting snow refreezes at the eaves, causing water to back up under shingles and into your home) and reduces heavy snow load on the roof.

Thermal Gear
Conditional Item
5/5
Specialist Gear

Used for very cold climates such as the polar regions or anywhere where the temperature drops extremely low.

Sunglasses
Conditional Item
5/5
Specialist Gear

Used to prevent snow blindness.

Desert Gear

Specific gear used for desert environments.

Multiple Water Bottles
Conditional Item
5/5
Specialist Gear

You're going to need a lot of water in the desert. If you are unable to find another water source by the time you're half out, you will need to go back to refill. So even though it's a burden, you will need as much as you can reliably carry without being overburdened. Include a couple of flexible ones to save on weight and space - but be gentle with them.

Solar Still Materials
Conditional Item
5/5
Specialist Gear

Plastic sheeting, a small container, and tubing. (Knowledge of how to construct and operate is essential, yield is typically low).

Wide Hat Conditional Item 5/5 Specialist Gear	A wide brimmed hat will help keep the sun off you. White is recommended to reflect more of the sun.
Electrolyte Drinks Conditional Item 2/5 Specialist Gear	These drinks can quickly and effectively replace any lost minerals and keep you hydrated for longer.
Face Wrap Conditional Item 4/5 Specialist Gear	A face wrap or shemagh will further protect your body from the sun and any sandstorms that come your way. I recommend one that's white if you're in the desert to help reflect the sun.
Sunglasses Conditional Item 5/5 Specialist Gear	Protects your eyes from the sun. But ones that wrap around your face to help protect your eyes from sand particles the wind kicks up.
Sunscreen Conditional Item 4/5 Specialist Gear	Helps prevent sunburn and resulting skin cancer by protecting your skin. This isn't as necessary if you're covered by loose-fitting white clothes covering most of your visible skin.
Lip Balm Conditional Item 4/5 Specialist Gear	Prevents cracked and sunburnt lips.
Shovel Conditional Item 2/5 Specialist Gear	For digging in sand (to get unstuck, find cooler ground, bury waste, or construct a simple shelter).
Portable Shelter Conditional Item 2/5 Specialist Gear	A portable shelter can be pitched in the sand and used as a reprieve from the sun when needed. It's not essential but you will probably wish you had one at least once. A tarp will also work to give you a reprieve from the sun.
Breathable Footwear Conditional Item 5/5 Specialist Gear	Hiking boots or shoes with good ankle support: Protect from rough terrain, rocks, and potential bites (snakes, scorpions). Good ventilation is key.
Moisture Wicking Socks Conditional Item 5/5 Specialist Gear	Wool or synthetic: Several pairs to prevent blisters and manage sweat.
Warm Clothes Conditional Item 5/5 Specialist Gear	Deserts can drop below freezing at night depending on the country and warm clothes are extremely important to pack. This includes: a down jacket, gloves, a beanie and a warm sleeping bag. You may not want the warm sleeping bag if you're considering only moving at night and sleeping during the day.
Vehicle Recovery Gear Conditional Item 5/5 Specialist Gear	If traveling by vehicle, essential for getting unstuck: sand ladders/traction boards, tow strap, high-lift jack, tire repair kit, air compressor (12V).

Jungle Gear

Specific gear used for jungle survival.

Machete Conditional Item 5/5 Specialist Gear	Perfect for slashing your way through thick undergrowth and vines if required.
Full Length Clothes Conditional Item 5/5 Specialist Gear	These will help protect you from sharp sticks and undergrowth as well as provide a barrier from mosquitos, ticks and leeches.
Dry Bags Conditional Item 5/5 Specialist Gear	Essential for keeping critical items (clothing, sleeping bag, electronics, first aid kit, fire starters) completely dry inside your pack.
Bag Rain Cover Conditional Item 5/5 Specialist Gear	Keeps the rain off your backpack.
Hammock Conditional Item 5/5 Specialist Gear	Elevates you off the wet, bug-infested, and potentially snake-ridden ground. The bug net is also helpful for protection against mosquitoes (malaria, dengue, Zika) and other biting insects.
Bug Spray Conditional Item 5/5 Specialist Gear	Permethrin spray (for clothing/gear) and strong insect repellent (DEET/Picaridin).
Head Net Conditional Item 5/5 Specialist Gear	A small and light item which will prove invaluable in a region where flies and mosquitos are thick in the air.
Mosquito Net Conditional Item 5/5 Specialist Gear	A small and light item which will prove invaluable in a region where flies and mosquitos are thick in the air. It will let you sleep more comfortably without having to keep slapping yourself. It attaches to the top of the tent and covers you while you sleep and acts as a secondaary barrier for flying and biting insects which happen to make it into your tent. In some regions, mosquitoes have diseases which you certainly don't want in a disaster scenario.
Wide Hat Conditional Item 5/5 Specialist Gear	For sun protection, and keeping rain off your face.
Anti-fungal Cream Conditional Item 5/5 Specialist Gear	To prevent the proliferation of fungal infections exacerbated by the damp.
Malaria Tablets Conditional Item 5/5 Specialist Gear	Essential in regions where malaria is prevalent. Some of the most common types are: Chloroquine (Aralen), Doxycycline (Vibramycin, Oracea, Adoxa, Atridox), Quinine (Qualaquin), Mefloquine (Lariam), Atovaquone/proguanil (Malarone), Artemether/lumefantrine (Coartem), and Primaquine phosphate (Primaquine).
Tick Remover Conditional Item 5/5 Specialist Gear	To remove ticks.

Sea Gear

Specific gear used for living on or near the sea.

GEAR | Specialist Gear | Sea Gear

Rash Vest Conditional Item 5/5 Specialist Gear	The primary defense against jellyfish stings (including Irukandji and Box Jellyfish in tropical waters). While not 100% impenetrable, they significantly reduce exposed skin. They also provide excellent sun protection.
Vinegar Conditional Item 5/5 Specialist Gear	Essential in regions where jellyfish are prominent as it inactivates the stinging cells that haven't fired. It is also useful to clean rust off metal due to living so close to the ocean air.
Reef Shoes Conditional Item 5/5 Specialist Gear	Protect feet from sharp objects (broken shells, coral), stonefish, stingrays, and other creatures camouflaged on the seafloor. Essential when wading or swimming in rocky, reefy, or murky areas. Shuffling your feet when walking in sandy shallows can also help scare off stingrays, preventing you from stepping directly on them.
Snorkeling Gear Conditional Item 5/5 Specialist Gear	Allows you to see what's in the water around you, helping you identify potential threats and avoid them.
Insect Repellent Conditional Item 5/5 Specialist Gear	Protects against mosquitoes and sandflies, which can be prevalent near beaches, especially around dawn and dusk, or in vegetated areas. Look for repellents containing DEET, Picaridin, or oil of lemon eucalyptus for effective protection.

Medical Specialist Gear

GEAR | Specialist Gear | Medical Gear

Specialised gear and larger equipment used by medical professionals. These would generally need a dedicated exam room to be used in. All equipment needs to be robust, easily repairable, and have readily available spare parts. Skilled personnel are essential. Many of these items require specialized training to use effectively and safely.

Exam Table Conditional Item 3/5 Specialist Gear	Provides a stable and adjustable surface for examining patients. Look for a sturdy, manually adjustable table (height, backrest).
Procedure Chair Conditional Item 3/5 Specialist Gear	For minor procedures, phlebotomy, or patient positioning.
Operating Room Table Conditional Item 3/5 Specialist Gear	For surgical procedures. A sturdy, adjustable table is essential.
Portable X-Ray Machine Conditional Item 3/5 Specialist Gear	For diagnosing fractures, pneumonia, and other conditions. Some portable X-ray units have battery or hand-crank power options, though image quality may be limited. This is a very complex and specialized piece of equipment.
Ultrasound Machine Conditional Item 3/5 Specialist Gear	For imaging internal organs, assessing pregnancies, and guiding procedures. Portable ultrasound machines with battery power are available, though image quality will be lower than a full-size unit.
Autoclave Conditional Item 3/5 Specialist Gear	For sterilizing surgical instruments. Pressure cookers can be adapted for this purpose, but proper training is crucial.

Microscope Conditional Item 3/5 Specialist Gear	For examining blood smears, urine samples, and other specimens. A basic optical microscope is necessary.
Centrifuge Conditional Item 3/5 Specialist Gear	For separating blood components. A hand-crank centrifuge is a better choice in a grid-down scenario.
Oxygen Concentrator Conditional Item 3/5 Specialist Gear	Provides supplemental oxygen. Some models can run on batteries or solar power.
Nebulizer Conditional Item 3/5 Specialist Gear	For delivering inhaled medications. Some portable nebulizers are battery-powered.
Suction Machine Conditional Item 3/5 Specialist Gear	For clearing airway obstructions. Hand-operated suction devices are available.
Surgical Lights Conditional Item 3/5 Specialist Gear	For illumination during procedures. LED lights are energy-efficient and can run on batteries.
Cautery Unit Conditional Item 3/5 Specialist Gear	For controlling bleeding during surgery. Battery-powered units exist but are less common.
Ambu Bag Conditional Item 3/5 Specialist Gear	For manual ventilation. This is a crucial item, also listed previously.
Spinal Board & Cervical Collars Conditional Item 3/5 Specialist Gear	For immobilizing patients with suspected spinal injuries.
Stretcher Conditional Item 3/5 Specialist Gear	For transporting patients.
Medication Storage Conditional Item 3/5 Specialist Gear	Maintaining the stability of medications (especially temperature-sensitive ones like insulin) is critical.
Basic Laboratory Items Conditional Item 3/5 Specialist Gear	For basic testing. This includes: Microscopes (mentioned above), Test tubes, beakers, and other glassware, Bunsen burner (for heating, if fuel is available), Manual cell counter, Simple scales

Generator Conditional Item 3/5 Specialist Gear	To provide electricity for essential equipment. Requires fuel, which may be scarce.

Pandemic Gear

Gear which should be possessed in a pandemic situation.

Plastic Sheeting Conditional Item 3/5 Specialist Gear	Used to cordon off rooms to isolate potential viruses.
Duct Tape Conditional Item 3/5 Specialist Gear	Used to fix the plastic sheeting to the walls and doors. It can also be used to seal gaps in windows and doors.
Disposable Coveralls Conditional Item 3/5 Specialist Gear	Full-body protective suits designed to protect against splashes, particulates, and some chemical/biological agents. Provides full-body barrier protection for tasks involving higher risk of contamination (e.g., caring for a severely ill person, decontamination). They can be hot, difficult to don/doff without contaminating oneself, and single-use.
Boot Covers Conditional Item 3/5 Specialist Gear	Disposable or reusable shoe covers for entry/exit points, or dedicated "dirty" footwear for specific high-risk areas. Prevents tracking pathogens into clean areas of the home.
Decontamination Sprayers Conditional Item 3/5 Specialist Gear	Battery-operated or manual sprayer for applying disinfectants over larger surfaces or for personal decontamination. Efficiently applies disinfectants for large-scale cleaning of surfaces or for decontaminating PPE.
UV-C Sterilization Lamps Conditional Item 3/5 Specialist Gear	Ultraviolet germicidal irradiation devices. Can be used to disinfect surfaces or potentially decontaminate certain PPE (like N95s) if manufacturer guidelines allow. Dangerous if used improperly (can cause skin burns, eye damage). Requires careful adherence to safety protocols.
Oxygen Concentrator Conditional Item 3/5 Specialist Gear	Generates concentrated oxygen from ambient air, or pre-filled oxygen tanks. For individuals with pre-existing respiratory conditions, or to support someone experiencing severe respiratory distress. Requires a prescription for oxygen tanks and knowledge of flow rates.
Powered Air-Purifying Respirators Conditional Item 3/5 Specialist Gear	PAPRs are a battery-operated unit that filters ambient air and delivers it through a hose to a loose-fitting hood or tight-fitting mask. Filters are typically P100 (99.97% filtration of airborne particles).
Humidifier Conditional Item 3/5 Specialist Gear	Can help keep nasal passages moist, which may aid in filtering out pathogens, and alleviate coughs/sore throats when sick.
Biohazard Bin Conditional Item 3/5 Specialist Gear	For segregating and safely storing potentially infectious waste. Why Advanced: Critical for infection control, especially when caring for sick individuals.

6 Household Gear

GEAR Household Gear

This section contains a list of gear to stockpile if you have a homestead and space isn't an issue for you. It's better to have it and not need it - then need it and not have it. It's sorted by room, but you don't have to store the items for that room IN that room. For those where quantities aren't included, just store as many as is reasonable that you will use. Think of this list as a worst case scenario where everything goes down and there's no manufacturing anymore. I got the idea for this section from SouthernPrepper1 who is essentially stocking up his homestead enough to be considered a small hardware shop where he is able to grab whatever he needs, or barter that which others need.

Kitchen

Items found in the kitchen which you will likely need multiple of during a grid-down situation.

Kitchen

- Trash Bags - Lots of different sizes, and include ones which are biodegradable.
- Sanitiser Sprays & Wipes, Washing Gloves
- Pots & Pans in various sizes and metals.
- Kitchen Cooking Utensils (Forks, Knives, Spoons, Graters, Cutting Boards, Scales, Timers)
- Cooking Gas - If you use a gas stove not reliant on an external gas tank
- Spare Electrical Appliances (Scales, Beaters, Toasters, Air Fryers, Microwaves)
- Spare Water Filters & Filter Replacement Parts
- Lighters & Matches
- Fire Extinguishers & Fire Blankets
- Disposable Plates and Cutlery
- Plastic Containers & Chinese Containers - For storage of pretty much anything you need.
- Canning Equipment (Jars, Lids, Pressure Cookers, etc)

Kitchen

- Cookbooks
- Bottled Water
- Mylar Bags - To store foods in.
- Knives, both kitchen knives and survival knives
-
-
-
-
-
-
-
-

Bedroom

The items which are normally stored in the bedroom which you will need.

Bedroom

- Clothing to last each person 10+ years. Account for aging and a decrease in people's sizes as many will lose weight in a survival situation.
- Blankets, Sleeping Bags, Linen & Sheets
- AM/FM/Shortwave Radios and earphones to use them quietly
- Portable Fans
- Curtains & Curtain Rods
- Device Charger Cables, Spare Phone Batteries
- Battery Chargers
- Batteries - Every type you use, but specifically ones that are for commonly used items in disasters like headlamps.
- Electronic Devices - Phones, Tablets, Speakers and anything else you could barter or use yourself.
- Guns, Lots of Guns, and enough ammunition for a small army.
- USBs & Hard Drive - Fill them with prepper information.
- Glasses Backups - The last thing you need in a disaster is broken glasses and no replacement.

Bathroom & Toilet

Any items you need stored up that are related to the bathroom or toilet.

Bathroom

- Bath & Tile Cleaning Products
- Soap, Handwash, Shampoo
- Toothbrushes & Toothpaste
- Brooms & Mops
- Insecticides & Vermin Control
- Common Medicines (See the Home Clinic section below for more)
- Spare Taps, Tap Washers, Toilet Seals, Flusher Replacement Parts
- Toilet Cleaners, Sprays and Scrubbers
- Toilet Paper, Razors
- Urine Collector - Used to separate the urine from the faeces to make disposal easier
- Medications, Prescriptions & Vitamins
-

Nursery

These are the items you will need if you are raising a baby. There are more detailed explanations of some of the items below in the "Baby Gear" section. See the Baby Safety section in DEFENCE for more tips on keeping them safe at home.

Nursery

- A Nappy Bag to contain all the essential items
- Clothes: Onesies, Bodysuits, Footed Pajamas, Pants, Shirts, Singlets, Sleep Suit, Hats, Shoes
- Nappies or Reusable Nappies (See below for a detailed calculation for quantity)
- Lots of scented nappy bags
- Educational Materials & School Books
- Baby Wipes
- Baby-Proofing Equipment (Gates, Corners, Safety Plugs, Drawer Lockers)
- Crib/Cot/Bassinet and Mattress
- Swaddle Cloths
- Towling/Burp Cloths
- Baby Monitor
- Change Mat

- Dummies (Pacifiers)
- Formula & Glass Bottles for feeding. Include extra teat sizes as they grow up.
- Breast Pump, Milk Storage Bottles, Breast Pads
- Bibs
- Rash Cream
- Play Mat (Waterproof is ideal)
- Bathtub, wash clothes, baby soap, towels
- Nail clippers/scissors,
- Nasal Aspirator
- Car Seat
- Plenty of Toys & Children's Books to give them as they develop, including bath toys
- Ensure your medical kit accounts for baby and child specific items. (Infant Paracetamol, small band-aids etc)

- Baby Bouncer
- Stroller/Pram with extra accessories as needed (Rain cover, cup holder, spare parts, etc)
- Portable Cot to use if travelling
- Baby Carrier/Sling
- Doorway Gates/Playpen
-
-

Baby Gear

This section is focused on providing a complete list of items a baby needs growing up. You may be surprised by how many nappies and other items they can go through. Keep in mind that every baby is different and the nappy sizes may shift up or down based on their weight and how fast they grow.

Nappies

How many nappies you're likely going to need to raise a baby from birth until they are completely toilet trained. This only counts disposable nappies, you can work out how many reuseable nappies you will need from the below numbers.

Baby Stage	Baby Weight	Approx Age	Nappy Sizes	Total Nappies Needed	Notes
Preemie	< 3Kg	Before Due Date	P3 size for babies less than 500g. P2 size for babies less than 1,000g. P1 size for babies less than 1,800g. 0	Depends how early they are born. Best to have a box of P1's and 0's if you have the money and the space.	Not applicable to all babies, but it could add up to 10 weeks worth of items onto the list. Additionally, a lot of specialist gear may be required based on how early they arrive.
Newborn	< 5 Kg	0-3 Months	0 or 1	**8-12 Per Day = 720-1,080 Nappies**	
Infant	3-8 Kg	1-6 Months	2	**6-9 Per Day = 540-810 Nappies**	
Crawler	6-11 Kg	4-12 Months	3	**5-7 Per Day = 900-1,260 Nappies**	
Toddler	9-14 Kg	6-24 Months	4	**4-6 Per Day = 1,440-2,160 Nappies**	
Walker	12-18 Kg	1-3 Years	5	**4-5 Per Day = 1,440-1,800 Nappies**	
Junior	16+ Kg	2+ Years	6		
Extra Large	17+ Kg	3+ Years	7	Depends how long they need more nappies	Some kids need more time to toilet train.
			TOTAL DISPOSABLE NAPPIES	**5,000 to 7,000+**	This covers every nappy they will ever need.

Above is a summarised list of the total nappies above to make it easy to see at a glance how many you approximately need.

Formula

Below is a table of how much formula a baby will need if they are entirely fed with it from birth. Formula (or breastmilk) remains the main source of nutrition until at least 12 months of age, even after solids are introduced. Most babies will not exceed 960 mL (32 ounces) of formula in a 24-hour period. Remember that every baby is different. Your baby may eat more or less than these averages. Always feed on demand and watch for your baby's hunger and fullness cues. A 900g tub would then yield approximately 900 g×7 mL/g=6300 mL or 6.3 litres of prepared formula.

To use the table:
1. Find your baby's current weight in the first column.
2. Look across to see the recommended formula intake per kilogram and the estimated total daily amount.
3. Divide the total daily amount by the average number of feeds for your baby's age/weight to get an idea of how much to prepare per bottle.
4. Adjust based on your baby's cues. If they're regularly finishing bottles and still rooting, offer a little more. If they're leaving a lot, offer a little less.

Example
If your baby weighs 5 kg, they likely need around 5 kg×150 mL/kg/day=750 mL of formula per day.
If they feed 7 times a day, each bottle would be about 750 mL/7 feeds≈107 mL. You might prepare 120 mL bottles.

Baby Weight & Stage	Approx Age	Formula Per kg of Body Weight (mL/kg/day)	Est. Total Daily Formula (mL)	Average Feed Size	Est. Daily Formula Powder Needed (g)	Monthly Formula Powder Needed (g)	Monthly Tubs Needed (900g tub ≈ 6.3L)	Cumulative Tubs Needed	Notes
Newborn 0-4 Kg	Birth - 1 Month	100-150	100 - 600 (avg. 350)	8-12 ml	14 - 86 (avg. 50)	1500	1.7	1.7	Starting very small, increasing rapidly
Newborn 4-5 Kg	1-2 Months	150	600 - 750 (avg. 675)	6-10 ml	86 - 107 (avg. 96)	2880	3.2	4.9	

Infant 5-6 Kg	2-3 Months	150	750 - 900 (avg. 825)	6-8 ml	107 - 129 (avg. 118)	3540	3.9	8.8	
Infant 6-7 Kg	3-4 Months	120-150	720 - 900 (avg. 810)	5-7 ml	103 - 129 (avg. 116)	3480	3.9	12.7	
Crawler 8-9 Kg	4-6 Months	120	840 - 960 (avg. 900)	5-7 ml	120 - 137 (avg. 129)	7740 (2 mths)	8.6 (2 mths)	21.3	
Crawler 9-10+ Kg	6-9 Months	90-120	720 - 950 (avg. 835)	4-6 ml	103 - 136 (avg. 119)	10710 (3 mths)	11.9 (3 mths)	33.2	Formula decreasing as solids increase
Toddler 9-10+ Kg	9-12 Months	75-100	700 - 900 (avg. 800)	3-4 ml	100 - 129 (avg. 114)	10260 (3 mths)	11.4 (3 mths)	44.6	Significant solids intake

After 12 months, babies normally transition to cow's milk, but they can stay on formula as well.

Clothing

Below is a list of clothes needed for babies up until they are about 4 years old.

Newborn 0-3 Months	• Bodysuits (short-sleeve): 5-7 (base layer for warmth or standalone in warm weather) • Bodysuits (long-sleeve): 5-7 (for cooler weather or layering) • One-piece Sleepers/Footed Rompers: 7-10 (easy for sleeping and general wear; choose zip-up for convenience) • Footed Pants/Leggings: 3-5 (great for layering over bodysuits) • Hats (soft cotton): 2-3 (for warmth, especially post-bath or in cool temps) • Socks/Booties: 5-7 pairs (keep tiny feet warm) • Light Jackets/Cardigans: 2-3 (for layering in cooler rooms or outdoors) • Swaddles/Sleep Sacks: 3-5 (for safe sleep)
Baby (3-12 Months)	• Bodysuits/T-shirts (short-sleeve): 7-10 • Bodysuits/Long-sleeve Tops: 5-7 • Pants/Leggings/Soft Jeans: 5-7 pairs (durable for crawling) • Shorts/Capris: 3-5 pairs (for warmer weather) • Dresses/Skirts (for girls): 3-5 (often come with matching bloomers) • One-piece Sleepers/Pajamas: 5-7 • Light Sweaters/Hoodies/Cardigans: 2-3 (for layering) • Outerwear (light jacket/coat): 1-2 (depending on climate) • Socks: 7-10 pairs • Hats (sun/warmth): 1-2 each (season-appropriate) • Swimwear (optional): 1-2 sets (if applicable)
Toddler (1-2 Years)	• T-shirts/Tops (short-sleeve): 7-10 • Long-sleeve Tops/Sweaters: 5-7 • Pants/Jeans/Track Pants: 7-10 pairs (easy for movement, potentially toilet training) • Shorts/Capris: 5-7 pairs • Dresses/Skirts: 5-7 • Underwear/Training Pants: 7-10+ (if toilet training; you'll need many extra changes) • Pajamas: 4-5 sets • Mid-weight Jacket/Coat: 1-2 (for warmth) • Rain Jacket/Windbreaker: 1 • Socks: 7-10 pairs • Hats (sun/warmth): 1-2 each • Swimwear: 1-2 sets • Shoes: Sneakers/walking shoes (2 pairs), sandals/water shoes (1 pair), winter boots (if applicable, 1 pair)
Preschooler (2-4 Years)	• T-shirts/Tops (short-sleeve): 7-10 • Long-sleeve Tops/Sweaters: 5-7 • Pants/Jeans/Track Pants: 7-10 pairs (durable for play) • Shorts/Capris: 5-7 pairs • Dresses/Skirts: 5-7 • Underwear: 7-10+ pairs • Pajamas: 4-5 sets • Mid-weight Jacket/Coat: 1-2 • Rain Jacket/Windbreaker: 1 • Socks: 7-10 pairs • Hats (sun/warmth): 1-2 each • Swimwear: 1-2 sets • Shoes: Sneakers (2 pairs), sandals/water shoes (1 pair), dressier shoes (1 pair), winter boots (if applicable, 1 pair)

Total Estimated Garments (Excluding Burp Cloths/Bibs): Approximately 200-280+ items over the 4-year period, representing the flow of clothing in and out of your child's wardrobe due to growth. This doesn't mean you have 200 items in the closet at once, but rather the cumulative number of unique items you would purchase or receive across all the sizes your child will wear in these categories. Remember, this is a substantial investment. Many parents rely on gifts, hand-me-downs, and second-hand stores to manage costs and reduce waste.

School Room

This room is used for younger kids to play in from about 4 to 12 and also covers the items that kids will need over the years, including schooling materials.

Study

This room is used for schooling, study and research and covers the time period of teenagers to adults.

- Pens, Pencils, Permanent Markers.
- Printing Paper, Lined Paper, Grid Paper
- Sticky Tapes, Glue
- Paper Tools (Rulers, Compasses, Protractors, Erasers, Hole Punches, Clipboards)
- Stickers and coloured stickers (Useful for prep identification and documenting gear)
- Whiteboards and Markers
- Books - As many as you can store on as many prepper related topics you can think of.
- Sewing Machine & lots of Thread & Fabrics
- Cash & Precious Metals (In a safe) - Preferably in coins to be able to barter easily.

Laundry

The laundry and everything you should stock in it.

- Washing Powders/Tablets, Laundry Soap, Bleach
- Hot Water System Spare Parts
- Pet Beds, Toys, Kitty Litter
- Dustpan/Brushes & Mops
- Insect Repellant
- Scrubbing Board - For washing clothes manually
- Manual Washing Machine
- 3/4" and 1" Laundry Hose Replacements
- Cleaning Scrubbing Brushes & Plungers

Living Room

The living room, where the family can play together and stay entertained.

- Novels for all ages to keep the family entertained
- Physical DVD's - To keep you entertained in the event the internet goes down.
- Board Games - To keep the family entertained if there's no electricity.
- Candles or LED Lanterns
- Cushions and Blankets
- Bibles

Home Clinic

These are items you would need to run a small doctor's office and pharmacy all in one in your self-sufficient home.

Basic Equipment

- An Extensive Medical Library
- Headlamps & Batteries
- Antibacterial Soap/Hand Sanitizers and Antiseptic/Alcohol Wipes
- Gauze Pads (Plenty of types and sizes)
- Non-Stick Gauze
- Triangular Bandages (A few, as these can be washed)
- Safety Pins (All Sizes)
- Israeli Bandages (Choose a few sizes)
- Band-Aids (Lots of different shapes and sizes)
- Absorbent Pads in multiple sizes
- Medical Tape - To tape down absorbent pads
- Duct Tape (For holding broken limbs)
- Tourniquets
- Moleskin / Skin Blister kit
- Reusable Cold Packs/Heat Packs
- Cotton Eye Pads, Patches
- Cotton Swabs & Cotton Balls
- Disposable Gloves
- Face Masks
- Bandage Scissors
- Tweezers (Various Shapes and Tips)
- Magnifying Glass
- Headlamp or Penlight
- Kelly Clamps

• Sutures & Needle Holder	• 2.5% Lidocaine cream
• Scalpels (Buy a variety of tips)	• Panadol/Ibuprofen/Aspirin
• Hemostatic Agents	• Benadryl / Claritin
• Saline Solution (Wound Wash)	• Imodium
• Survival Sheet/Solar Blanket - To keep the injured warm	• Pepto-Bismol
• Thermometers - Have at least a contactless and an in-ear one	• Essential Oils (Lavender, Peppermint, Eucalyptus, Clove, Oregano, etc)
• Antiseptic Solutions (Dettol, Betadine, Isopropyl Alcohol)	• Oral Rehydration Packs
• Herbal Teas, Tinctures and Salves	• Water Purification Filter or Tablets
• Antibiotic Ointment	• Silvadene Cream
• Sunscreen & Lip Balms	• Oral Antibiotics
• Insect Repellent (Deet is preferred)	•
• 1% Hydrocortisone Cream	•
• Neck Collar	
• Eye cups, eye wash	
• Ammonia inhalants	
• Slings and Splints	
• Irrigation Syringes	
• Emergency Obstetric Kit	
• Cidex Solution	
• Lidocaine	
• Epinephrine (Epi-Pen)	
• Terconazole cream (antifungal)	
• Wart removal cream/ointment/solution	
• Hemorrhoid cream/ointment	

Medications

This is a list of recommended medications for a home clinic set up to serve about 100 people over 3 years.

• Paracetamol (Panadol, Dymadon, Tylenol) - 1,000 units	• Metronidazole (Flagyl, Metronex) - 150 units
• Ibuprofen (Nurofen, Brufen, Advil) - 500 units	• Trimethoprim/Sulfamethoxazole (Bactrim, Septrin) - 100 units
• Acetylsalicylic Acid (Aspirin, Aspro, Disprin) - 200 units	• Doxycycline (Doryx, Vibramycin, Doxy-Caps) - 100 units
• Codeine (Panadeine Forte, Nurofen Plus) - 100 units	• Ceftriaxone (Rocephin) - 50 units
• Morphine Sulfate (MS Contin, Kapanol, Sevredol) - 50 units	• Aciclovir (Zovirax, Lovir) - 50 units
• Naloxone (Narcan) - 10 units	• Fluconazole (Diflucan, Candis) - 20 units
• Lidocaine (Xylocaine, Lignocaine) - 50 units	• Clotrimazole (Topical Cream) (Canesten, Clomazol) - 10 units
• Lidocaine (Topical) (Xylocaine Viscous, LMX 4) - 10 units	• Albendazole/Mebendazole (Zentel, Vermox) - 50 units
• Amoxicillin (Amoxil, Moxacin) - 300 units	• Permethrin (Topical Cream) (Lyclear, Kwellada) - 5 units
• Amoxicillin + Clavulanic Acid (Augmentin, Amox-Clav) - 150 units	• Tetanus Toxoid Vaccine (Adacel, Boostrix) - 50 doses
• Azithromycin (Zithromax, Aziclar) - 100 units	• Tetanus Immunoglobulin (Tetagam P, HyperTET) - 5 doses
• Ciprofloxacin (Cipro, Ciproxin) - 150 units	• Salbutamol (Albuterol) Inhaler (Ventolin, Asmol) - 20 units
• Salbutamol (Nebulizer Solution) (Ventolin Nebules) - 10 units	• Atenolol (Tenormin, Noten) - 50 units
• Prednisolone (Predsone, Panafcort) - 50 units	• Glyceryl Trinitrate (GTN) (Anginine, Nitrolingual) - 50 units
• Dexamethasone (Dexmethsone, Oradexon) - 20 units	• Furosemide (Lasix, Urex) - 50 units
• Oral Rehydration Salts (Hydralyte, Gastrolyte) - 500 sachets	• Aspirin (Low Dose) (Cartia, Astrix) - 100 units
• Loperamide (Imodium, Gastro-Stop) - 50 units	• Insulin (Mixed Types) (Novolin, Humulin, Levemir, Novorapid) - 50 vials
• Bisacodyl (Dulcolax, Lax-Tabs) - 20 units	• Metformin (Diaformin, Glucophage) - 100 units
• Aluminium or Magnexium Hydroxide (Mylanta, Gaviscon) - 20 units	• Glucose (Oral) (Dextrose tabs, Glucogel) - 20 units
• Omeprazole (Losec, Nexium, Somac) - 50 units	• Glucagon (GlucaGen) - 2 units
• Ondansetron (Zofran, Nausetrol) - 20 units	• Levothyroxine (Eutroxsig, Oroxine, Synthroid) - 50 units
• Amlodipine (Norvasc, Amlo) - 100 units	• Hydrocortisone (Oral/Injectable) (Solu-Cortef, Cortef) - 20 units
• Enalapril (Renitec, Vasotec) - 100 units	• Diazepam (Oral) (Valium, Antenex) - 50 units
• Hydrochlorothiazide (Dithiazide, Hydrodiuril) - 50 units	• Diazepam (Rectal Gel/Injectable) (Stesolid, Valium) - 5 units
• Phenobarbitone (Phenobarb) - 20 units	• Chloramphenicol Eye Drops/Ointment (Chlorsig, Chemicetina) - 5 units
• Fluoxetine (Prozac, Lovan, Zactin) - 50 units	• Artificial Tears (Refresh, Systane, Hylo-Forte) - 5 units
• Haloperidol (Serenace, Haldol) - 10 units	• Combined Oral Contraceptives (Levlen, Yaz, Microgynon) - 30 cycles
• Chlorphenamine (Chlorpheniramine) (Piriton, Allerest) - 50 units	• Progestogen-only Pills (Microlut, Noriday, Cerazette) - 10 cycles
• Loratadine/Cetirizine (Claratyne, Zyrtec, Telfast) - 50 units	• Emergency Contraception (Levonorgestrel) (Postinor-1, EllaOne) - 5 units
• Epinephrine (Adrenaline) (Adrenaline Chloride, EpiPen - Note: EpiPen is an auto-injector, this refers to the ampoule) - 20 units	• Oxytocin (Syntocinon) - 5 units
• Povidone-iodine Solution (Betadine, Povidone) - 2 units	• Ferrous Sulphate (Ferro-grad C, Fefol) - 50 units
• Chlorhexidine Solution (Surgi-Prep, Hibiclens) - 2 units	• Folic Acid (Folacin, Megafol) - 20 units
• Hydrocortisone Cream (1%) (Hydrozole, DermAid) - 10 units	• Sodium Chloride 0.9% IV (Normal Saline) (Saline IV) - 100 units
• Mupirocin Ointment (Bactroban) - 5 units	• Glucose 5% IV (Dextrose 5%) (Dextrose IV) - 50 units
• Emollient Cream (e.g., Paraffin-based) (QV Cream, Sorbolene) - 5 units	• Multivitamin supplements (Centrum, Swisse, Blackmores) - 50 units
	• Activated Charcoal (Charcodote, Actidose) - 5 units

Clinic Equipment

• Treatment Table	• Sterile Drapes
• Portable Bed	• Air Splints
• Plaster of Paris Cast Kits	• SAM Splints
• Naso-oropharyngeal Airway Tubes	• Scrub Suits
• Nasal Airways	• IV equipment (Saline, Tubes, Syringes, Needles, Paper Tape, IV Stands)
• Resuscitation Bag	• Folding Stretchers
• Endotracheal Tube/Laryngoscope	• Towels
• Portable Defibrillator	• Bulb Syringes
• Blood Pressure Cuff (Manual and Automatic)	• Moveable Medical Light
• Stethoscopes	• Assorted Clamps
• Otoscope and Ophthalmoscope	• Emergency Obstetric Kit
• Pregnancy Test Kits	• Obstetric Forceps

• Uterine Sound & Uterine Dilators
• Bone saw (for amputations)
• Chest decompression kits and drains
• Penrose Drains
• Foley Catheters
• Urine Bags
• Enema Kit
• Nasogastric Tubes
• Pressure Cooker, Autoclaver or Ultrasonic Cleaner (For Sterilization)
•
•
•

Dental Equipment

• Cotton Pellets and Rolls
• Dental Mirror, Dental pick, Toothpicks
• Dental Floss
• Clove Bud Oil
• Zinc Oxide
• Commercial Dental Dits
• Needle Holder
• Extraction Equipment
•
•
•
•

Basement

The room where you store all of the supplies in these sections as well as other misc items that need to be kept cool.

• As much long life food as possible. (Stored on pallets off the concrete)
• Water Barrels (Immovable) (Stored on pallets off the concrete)
• Water Jugs with Bungs & Taps (Portable ones)
• Water Filters & filtration parts.
• Battery Backups / Power Stations.
• Backup Off-Grid Electrical (Inverters, Cabling, DC Converters, Switches)
• Alcohol for drinking, medical use, tincture-making and barter
•
•
•
•
•

Garage

Any items in the garage that you should have stocked up.

• Fasteners (Screws, Bolts, Nails, Glue, Duct Tape) Store as many types and sizes you can.
• Household Electrical (Light Bulbs, Wires, Circuit Breakers, Outlets, Switches, Power Boards, Extension Leads)
• Hand Tools (Spanners, Socket Sets, Screwdrivers, Pliers, Clamps, Chisels, Saws, Measuring Tools, Hammers, Mallets, Hex Sets, Staple Gun, Glue Gun)
• Power Tools (Drills, Grinders, Blowers, Multitools, Power Saws, Planers, Routers, Sanders)
• Electrical Tools (Multimeter, Crimpers, Cable Cutters, Soldering Iron, Solder)
• Safety Equipment (Ear Muffs, Protective Glasses, Face Masks, Hard Hats, First Aid Kits, Gas Masks, Gloves, Boots, Coveralls, Roof-Climbing Safety)
• Wood Fittings (Cabinet Fittings, Latches, Knobs, Handles)
• Generators (Petrol, Diesel or Battery)
• Vehicle Maintenance Equipment (Jack Stands, Oil Pan, Oil, Car Batteries, Coolant, Cleaning Sprays, Rags)
• Welding Equipment
• Plumbing Spares (Toilet Seals, Tap Washers)
• Masonry, Plastering Tools & Cement

• Tie-Downs, Ropes, Paracord
• Camping Water Heaters
• Mattresses (Inflatable or Regular)
• Tents & Tent Pegs, Shadecloths, Gazebos, Tarps, Umbrellas - To use as shelters or water collection objects.
• BBQ's, Lighters & Outdoor Ovens (Include lots of fuel for these)
• Passive Home Defence (Barb Wire, Locks, Tripwires, Fake Cameras, Lights, Motion Sensors, Dogs?)
• Pre-cut wooden boards to put over the windows in emergencies
• Pre-cut wooden dowel pieces to bar the windows
• Replacement Fly-Screen
• Lots of garage shelving
• TONS of plastic tubs to store all of this gear - Ones where you can access the gear from the side rather than unstacking it each time
• Knives

Shed

Gear stored in the shed which can be used for household repairs and DIY.

- Misc Pieces of Metal - Useful for projects.
- Misc Pieces of Wood - Also useful for projects, but you never know when you need a certain piece of wood for repairs.
- Fuel Cans - For use with your Bug-Out Vehicle (BOV), or generator.
- Outdoor Woodworking Tools - Axes, Hatchets, Saws.
- Mechanic Tools - To repair your cars with.
- Spare BOV Parts - So you can fix it yourself if something breaks. (Don't forget to download the how-to videos)
- Spare components for household electronics for repairs - Computer, Vacuum, Fan, Fridge, Freezer, Generator, etc
- Backup Transport - Bicycles, Scooters, Motorbikes, etc.
- Garden Tools - Rake, Hoe, Shovel, Pruners, Lawn Mower.
- Garden Hoses, attachments and fittings including hoses and fittings for water tanks.
- Gardening - Pots, Soil, Seeds, Fertilizer, Mulch, Potting Mix, Netting.
- External Household Spares (PVC Piping, Gutter Lengths, Bricks)

- Work Benches, Saw Horses, Tool Chests
- Spare Antennas for the TV, HAM and Radio Communication
- Roofing Insulation
- Ladders
- Spare Window Glass & tools to cut it to size
- Fences and Gate sections - Used as replacements
- BBQ's and Outdoor Cooking
- Various Types of Wire
- Coolers & Eskies
- Pool Shock (Calcium Hypochlorite)
- Plasterboard
-

Outside

Any items you can store outside which you should have on a homestead.

- Tinder/Twigs/Branches (Anything smaller than firewood to help get it started)
- Firewood (As much wood as you can store if you use it frequently)
- Water Tanks (As many tanks as you can have)
- Backup Solar Panels
- Spare Gas Cylinders (Protected from the sun)
- Spare Land for Waste Disposal
- Spare Land for a Toilet-Pit or Sewage Treatment Plant (If you don't already have a composting toilet and are reliant on the sewage lines)
- Bricks to use for future projects - Such as building an oven, walls, garden beds or even a granny-flat.
- Spare fencing to replace any which becomes damaged.
- Pallets & Spare Wood - Great for various projects and construction.
-
-

7 External Gear

This section is for gear not found in your bags or on your person, but is still required in most preparedness situations such as transportation and larger items. For additional information on vehicle types and what can be found in them, take a look at the TRANSPORT and LOCATIONS categories.

Backpack

The backpack isn't inside the BOB but is still essential to have. See the GEAR > Backpacks section above for more information.

Hiking Frame

A hiking frame is a type of trailer which holds your gear as you hike across tough terrain. It has one wheel which makes contact with the ground and another curved handle which you can either hold manually or attach to a belt clip keeping your hands free. An example of a hiking frame is the monowalker. They are basically essential if you're planning on bugging out on foot but it's also useful to have one in your car to make seamless transitions between the two transport types.

Car / Van / SUV / 4WD

Any type of car is the likeliest method of transport people will use when bugging out, as most people own at least one and have the knowledge to drive it. They all have their advantages and disadvantages such as a car getting great mileage in the suburbs and cities and the 4WD being able to go off-road.

Motorbike

Motorbikes are great bug out vehicles for individuals wanting to go fast and have the ability to avoid most traffic. They have the drawbacks of not being able to carry many supplies and being very loud in most cases which can draw unwanted attention.

Bicycle

GE Bicy

External Gear

A bicycle is another common bug-out transport method suitable for escaping under the radar as they can go off-road and fit through much smaller gaps than a car can. Although most of them come at the cost of requiring the rider to be fit and healthy unless it's an electric model. Another drawback is that they won't fit anywhere near as much gear as a car, but they have the ability to add a small bike trailer on the back and saddle bags to the sides.

Campervan / Tiny House

Campervans and tiny houses are great ways to continue your current lifestyle in any location you choose. The ability to move an entire house on demand takes a powerful engine but gives you all the comforts of home as you bug out, either to an alternative destination or to set up your home in a more secure location.

Bus

GEAR External Gear Bus

A bus can be a great transport method for larger families or combined families if you're all going to the same destination. It would also work well if you have a huge amount of gear to take with you, allowing you to basically take your entire stockpile of food with you. As seen on doomsday preppers you can also use them as a defensive wall if parked correctly or if you have multiple buses at your disposal.

Trailer

Trailer

Trailers can greatly expand your storage space when bugging out in a land vehicle. They can come in a multitude of sizes to suit your needs and allow you to carry more than you normally would. They can also be disconnected in a hurry and abandoned if they're slowing you down or putting you at risk such as on icy slopes. They can also be modified to allow you to sleep inside them if required.

Boat

GEAR External Gear Boat

As the only way to travel across water, boats can be both a blessing and a curse depending on what type of boat it is and how big the body of water is. If you have a boat docked at any point in your bug out plan there's always the chance that it may be damaged, looted or gone when you arrive to sail away. Because of this it's best to tow the boat behind a car to the waters edge so you're certain that you have a mode of transport when you bug out.

Helicopter

Plane

GEAR External Gear Plane

The ultimate way to travel quickly across both land and water. Planes can be expensive to buy, time consuming to learn and sometimes tough to pilot in a disaster, but once those barriers are out of the way they can get you wherever you need to be - fast, as long as there's a landing strip. However they come at the cost of safety, if for some reason your runway of choice has obstacles on it or you become a shooting target to those below.

Survival

How to survive in the wilderness and foreign climates

“The history of the world, my sweet,
is who gets eaten and who gets to eat."
Sweeney Todd

Introduction

Survival skills are techniques that a person may use in order to sustain life in any type of natural environment. These techniques are meant to provide basic necessities for human life which include water, food, and shelter. The skills also support proper knowledge and interactions with animals and plants to promote the sustainability of life over a period of time. Survival skills are often associated with the need to survive in a disaster situation but should be learned prior.

Purpose	The aim of SURVIVAL is to help the reader stay alive in any climate, scenario or location they may find themselves in. Whether it's surviving on a desert island after a plane crash, surviving in a log cabin in the alps or surviving in a major city after the country has torn itself apart.
Lost?	● For identifying, collecting and purifying naturally occurring water, see the WATER section. ● For surviving specific disasters, see the NATURAL DISASTERS section. ● If you want to know how to identify plants and in particular, edible ones, see the PLANTS section. ● For information on catching wild food, see the HUNTING and FISHING sections. ● If you're looking for survival tips after a plane crash, see the PERSONAL DISASTERS section. ● For information on the different climates around the globe, see the GEOGRAPHY section.

Contents

1 Killers

Death is the permanent cessation of all biological functions that sustain a living organism. Phenomena which commonly bring about death include aging, physiological or organ failure, predation, poisoning, malnutrition, disease, suicide, homicide, asphyxia, drowning, severe burns, drug intoxication, starvation, dehydration, electrocution, intense heat or cold, radiation toxicity, warfare attacks such as bombings, as well as explosions and accidents or major trauma resulting in fatal injury. The remains of a living organism begin to decompose shortly after death. It is an inevitable process eventually occurring in all living organisms. This is certainly a morbid start to this section, but an essential one to know if you're trying to survive as long as possible.

As of the early 21st century, over 150,000 humans die each day.

Death, particularly of humans, has commonly been considered a sad or unpleasant occasion, due to the affection for the deceased and the termination of social and familial bonds. Other concerns include fear of death, necrophobia, anxiety, sorrow, grief, emotional pain, depression, sympathy, compassion, solitude, or saudade. Many cultures and religions have the idea of an afterlife, and also hold the idea of judgement and reward for good deeds or punishment for sin.

Common Deaths

The following is a list of the causes of human deaths worldwide for different years arranged by their associated mortality rates. In 2002, there were about 57 million deaths. In 2005 about 58 million people died. In 2010 52.8 million people died. In 2016, the WHO recorded 56.7 million deaths with the leading cause of death as cardiovascular disease causing more than 17 million deaths (about 31% of the total) as shown in the chart to the side.

Below are the most common reasons for death in today's world. Survival includes these just as much as out of the ordinary events such as SHTF. The statistics below are from 2014[n].

Cardiovascular Disease 17,650,000 Deaths/year	**Cancers** 8,930,000 Deaths/year	**Respiratory Disease** 3,540,000 Deaths/year	**Diabetes/Blood & Endocrine Disease** 3,190,000 Deaths/year
Dementia 2,530,000 Deaths/year	**Lower Respiratory Infections** 2,380,000 Deaths/year	**Neonatal Deaths** 1,730,000 Deaths/year	**Diarrheal Diseases** 1,660,000 Deaths/year
Road Incidents 1,340,000 Deaths/year	**Liver Disease** 1,260,000 Deaths/year	**Tuberculosis** 1,210,000 Deaths/year	**Kidney Disease** 1,190,000 Deaths/year
Digestive Disease 1,090,000 Deaths/year	**HIV/AIDS** 1,030,000 Deaths/year	**Suicide** 810,000 Deaths/year	**Malaria** 710,000 Deaths/year
Homicide 390,000 Deaths/year	**Nutritional Deficiencies** 370,000 Deaths/year	**Meningitis** 320,000 Deaths/year	**Protein-energy Malnutrition** 310,000 Deaths/year
Drowning 230,000 Deaths/year	**Maternal Deaths** 210,000 Deaths/year	**Parkinson's Disease** 170,000 Deaths/year	**Alcohol Disorder** 160,000 Deaths/year
Intestinal Infections Diseases 140,000 Deaths/year	**Drug Disorders** 130,000 Deaths/year	**Hepatitis** 130,000 Deaths/year	**Fire** 130,000 Deaths/year
Conflict 120,000 Deaths/year	**Heat-releated Deaths (Hot/Cold)** 50,000 Deaths/year	**Terrorism** 30,000 Deaths/year	**Natural Disasters** 10,000 Deaths/year

Life Expectancy

Life expectancy is a statistical measure of the average time an organism is expected to live, based on the year of its birth, its current age, and other demographic factors including gender. The most commonly used measure is life expectancy at birth (LEB), which can be defined in two ways. Cohort LEB is the mean length of life of an actual birth cohort (all individuals born in a given year) and can be computed only for cohorts born many decades ago so that all their members have died. Period LEB is the mean length of life of a hypothetical cohort assumed to be exposed, from birth through death, to the mortality rates observed at a given year.

The longest verified lifespan for any human is that of Frenchwoman Jeanne Calment, who is claimed to have lived to age 122 years, 164 days, between 21 February 1875 and 4 August 1997, which however is disputed. This is referred to as the "maximum life span," which is the upper boundary of life, the maximum number of years any human is known to have lived.

This is a chart of the average life expectancy in every country of the world, as of 2015.

Unusual Deaths

This is a list of unusual deaths, to entertain, but also to point out the fragility of life.

● A poodle named Cachy, fell from 13 floors and fatally hit 75-year-old Marta Espina, killing both instantly. In the course of the events, 46-year-old Edith Sola, who came to see the incident, was fatally hit by a bus. An unidentified man, who witnessed Edith's death, had a heart attack and also died on his way to the hospital.
● An entire football team of 11 in Eastern Kasai, Democratic Republic of the Congo, were fatally struck by lightning while playing. The other team left unharmed.
● Three people died of carbon dioxide suffocation and drowning when 25 kg of dry ice was thrown into an indoors swimming pool at a sauna party in Moscow to create a layer of thick white fog over water surface, which, inadvertently, displaced oxygen.
● Hoong Leong, 37, was struck in the shoulder by a falling gas cylinder whilst walking home during stormy conditions. Leong survived the initial impact but went into cardiac arrest and died upon arrival at hospital.
● Sergio Millán, 59, was alone in his apartment in Torreforta, Tarragona, Spain when an explosion in a petrochemical plant 3 kilometers away launched a one-ton iron plate into the apartment above him, which caused the ceiling to collapse, killing him.
● Elena "Lena" Struthers-Gardner, 60, was carrying a mason-jar style drinking glass with a screw-top lid in her kitchen when she collapsed. The 10-inch stainless steel straw entered her left eye socket and pierced her brain.

● Salvator Disi, 62, was decapitated while using a power cart to jump start a helicopter in Hernando County, Florida. The unexpected up-and-down motion of the helicopter caused the rotor blades to strike Disi.
● Jennifer Riordan, 43, a passenger aboard Southwest Airlines Flight 1380, died after debris from an engine failure struck and destroyed the window she was sitting next to. She was partially blown out through the window, but was pulled back into the aircraft and was given CPR until an emergency landing was made. She died upon arrival at hospital with her cause of death determined to be blunt trauma to the head, neck and torso.
● 16-year-old high-school student Kyle Plush died after becoming trapped in his Honda Odyssey. Attempting to reach his tennis equipment, Plush leaned over the third row of seats into the trunk. When the row of seats "squashed his chest", Plush became pinned and later died. During the incident, the teen called 9-1-1 twice, by using Apple iPhone's Siri voice-activation. Responding to the 9-1-1 calls, police were not able to find Plush; he was eventually discovered in the vehicle by his father about six hours later.
● Rajesh Maru, 32, died at Nair Hospital in Mumbai after carrying a metal oxygen tank into a room housing an MRI scanner; the machine's magnetic field pulled Maru in, pinning his hand and breaching the tank, releasing liquid oxygen. An autopsy showed that Maru died instantly from pneumothorax brought on by exposure to very high levels of leaked oxygen.

● Elizabeth Isherwood, 60, walked naked into an airing cupboard at the villa she was renting and shut the door. When she tried to leave, part of the door handle broke off in her hand. She dug into the wall in an attempt to escape, but struck and burst a pipe, which sprayed water into the cupboard and caused her eventual death by hypothermia. She was found several days later. Why she had shut herself in the cupboard in the first place remained a mystery.
● Rebecca Burger, 33, died after a pressurized canister of whipped cream exploded and struck her in the chest. The injury caused Burger to go into cardiac arrest.
● Debra Bedard, 58, died after falling from a golf cart onto shards of wine glasses that had broken in her hands.
● Elisa Lam, from Vancouver, British Columbia, was missing for several weeks before being found dead in a large water tank on the roof of the Cecil Hotel in Los Angeles, after guests complained about the taste of the water.
● Peng Fan, a chef in Foshan, China, was bitten by a cobra's severed head, which he had cut off 20 minutes earlier while preparing a soup.
● Robert Dreyer, 89, drowned on his birthday after crashing his car into a fire hydrant. Dreyer successfully stepped out of his car, but was swallowed by a sinkhole likely created as a result of the destruction of the fire hydrant and subsequent water pressure.

● Charlie Holt, 5, was killed at the Sun Dial Restaurant, a rotating restaurant at the top of Westin Peachtree Plaza Hotel in Atlanta, Georgia; his head was caught in a small space between the rotating and non-rotating sections.
● On 21 November 2016, a powerful southerly change in Melbourne, Australia, resulted in the death of 10 asthmatic people who succumbed to respiratory failure. This was due to a stark wind (60 km/hour) that distributed ryegrass pollen into the moist air, rupturing them into very fine specks, particles small enough to enter people's lungs.
● Michael Scaglione died after smashing his golf club against a golf cart. The head broke off and impaled him in the throat, severing his jugular vein.
● Allan Pinkerton, the founder of the Pinkerton Detective Agency, was in Chicago, Illinois when he tripped on the pavement and severely bit on his tongue. His tongue became infected with gangrene, ultimately leading to his death.
● Isadora Duncan, broke her neck when her long scarf caught on the wheel of a car in which she was a passenger.
● Caleb Schwab, 10, was decapitated when he was ejected from his raft on Verrückt, a 168-foot-tall (51 m) water slide.
● Lottie Michelle Belk, 55, was fatally stabbed in the chest by a beach umbrella blown by a strong wind. Wind speeds at the time reached 20–25 miles per hour (32–40 km/h).

● V. Kamaraj, a 40-year-old Indian bus driver, was claimed by local Indian newspapers to have been killed by a meteorite which left a two-foot (61 cm) crater.
● Stephen Whinfrey, 50, became trapped and asphyxiated when rabbiting near Doncaster, England, after his head became stuck down a rabbit hole.
● Ravi Subramanian, an Air India technician, was sucked into an aircraft's jet engines.
● Charmayne Maxwell, died after falling backward while holding a wine glass. During the fall the wine glass shattered on the ground behind Maxwell's head, and the shards pierced her neck, causing profuse bleeding.
● Peter Biaksangzuala, an Indian association football player from Mizoram state, died after sustaining spinal cord injuries while awkwardly landing a somersault celebrating a goal.
● Frank Hayes, a 35-year-old jockey of Elmont, New York won his first and only race when he was dead. Riding a horse, Sweet Kiss, Frank suffered a fatal heart attack mid-race and collapsed on the horse. Sweet Kiss managed to still win with Frank Hayes' body on it, meaning he technically won.
● Garry Hoy, a lawyer in Toronto, fell to his death from the 24th floor of the Toronto-Dominion Centre while demonstrating to a group of visitors that the building's windows were "unbreakable." Hoy threw himself against the window, which did not break but popped out of its frame.

- Christophe de Margerie, an oil executive, was killed when his corporate jet collided with a snowplow reportedly driven by a drunk driver.
- Miguel Martinez, 14, from Lubbock, Texas, was impaled through the chest by the horn of a bull statue while playing hide-and-seek at night.
- Denver Lee St. Clair was asphyxiated by an "atomic wedgie" administered by his stepson during a fight. After St. Clair had been knocked unconscious, the elastic band from his torn underwear was pulled over his head and stretched around his neck, strangling him.
- João Maria de Souza, 45, was crushed in his bed by a cow falling through the roof of his home in Caratinga, Minas Gerais in Southeast Brazil. The cow had climbed on top of the house from a steep hillside behind it. Both the cow and de Souza's wife (who had been in bed next to him) were unharmed.
- An unnamed Belarusian fisherman, 60, bled to death after being bitten by a beaver which he had tried to grab in order to have his picture taken with it.
- A seven-year-old girl died after being struck by a stone thrown by an elephant from its enclosure at the zoo at Rabat, Morocco.
- Roger Mirro was crushed by a trash compactor while looking through a dumpster for his phone.
- 88-year-old Ilda Vitor Maciel died in a Brazilian hospital in Barra Mansa (south of state of Rio de Janeiro), as a result of nursing technicians injecting soup through her IV drip instead of her feeding tube.

- Erica Marshall, a 28-year-old British veterinarian in Ocala, Florida, died when the horse she was treating in a hyperbaric oxygen chamber kicked the wall, released a spark from its horseshoes which triggered an explosion.
- Jimmy Ferrozzo, died while engaging in sexual intercourse with his girlfriend Theresa Hill on a grand piano that was lowered from the ceiling by a hydraulic motor. Ferrozzo accidentally activated the lifting mechanism which pinned him against the ceiling leading to his suffocation. Hill survived the accident.
- Edward Archbold, 32, of West Palm Beach, Florida, choked on "arthropod body parts" during a cockroach-eating contest.
- Mike Edwards, 62, died when a large round bale of hay rolled down a hill and collided with the van he was driving.
- Muraka Jenny Vearncombe, 42, was decapitated by a piece of a metal pipe flung by a tractor-pulled lawnmower as she walked to work in Townsville, Australia.
- A 14-year-old boy from Jiaozhou, Shandong, China was killed when the pneumatic cylinder in his office chair exploded.
- Larry Ely Murillo-Moncada, a 25-year-old supermarket employee from Council Bluffs, Iowa, is believed to have fallen into the 18-inch gap between a cooler and a wall and become trapped. His body was not discovered for almost ten years, when the cooler was finally moved.

- A 43-year-old Irish mother of four died of an allergic reaction after having sex with a German Shepherd dog.
- Humberto Hernandez, a 24-year-old Oakland, California resident, was killed after being struck in the face by an airborne fire hydrant while walking. A passing car had struck the fire hydrant and the water pressure shot the hydrant at Hernandez with enough force to kill him.
- Steve Irwin was a world-renowned Australian wildlife expert died from blood loss after being pierced in the heart by a startled short-tail stingray's barb while filming in shallow water in the Great Barrier Reef during a lull in filming for Ocean's Deadliest.
- Michael Kosanovich, 21, was crushed to death by a 2002 Lexus IS300s automobile after its owner started it by remote control. The car rolled forward, and he was pinned between two vehicles.
- Truls Hellevik, a Norwegian diver, was explosively dismembered in a diving bell accident at the North Sea. Hellevik was exposed to an eight-atmosphere change in air pressure which instantaneously forced his body through a 60-centimetre-diameter (24 in) opening. Three other divers were also killed in the accident.
- Kenneth Pinyan died from injuries caused by anal sex with a stallion.
- Sam Ballard, 29, died from angiostrongyliasis (infection by a roundworm) after eating a garden slug as a dare eight years earlier.

- John Hutcherson drove home drunk with his friend Francis Brohm hanging out the passenger window. Hutcherson ran off the road and sideswiped a telephone-pole support wire, decapitating Brohm. Hutcherson continued the final 12 miles to his Atlanta, GA home, parked in the driveway and then went to bed. A neighbor found the headless body in the truck the next morning.
- Phillip Quinn, 24, from Kent, Washington, was killed when a lava lamp he was heating on a stove exploded and a shard pierced his heart.
- Hitoshi Nikaidoh, a doctor in Houston, Texas, was decapitated after his head was trapped in the doors of an elevator at his workplace.
- Brian Douglas Wells from Erie, Pennsylvania, was killed by an explosive collar around his neck, as part of a bank-robbery scheme.
- Michael Colombini, 6, died during an MRI scan at a New York-area hospital, after an oxygen tank was magnetically pulled into the machine and fractured his skull.
- Bliss Scott, 7, died after touching an African snail, from which she contracted meningo-encephalitis caused by Angiostrongylus cantonensis.
- Jonathan Capewell, 16, died from a heart attack brought on by the buildup of butane and propane in the blood after excessive use of deodorant sprays.
- William Snyder, a 13-year-old, died in San Francisco, California, when a circus clown swung him around by his heels.

- After watching the "Kung Fu Kapers" episode of The Goodies, Alex Mitchell laughed continuously for 25 minutes and then fell dead on his sofa from heart failure.
- Brandon Lee, 28-year-old film actor, martial artist, and son of Bruce Lee, was accidentally shot to death by co-star Michael Massee while filming a scene for The Crow, as the result of an improperly-loaded prop gun.
- Yulia Sharkom, 21, was trying to grab her 2-year-old daughter from her car through the half-open front seat window in Belarus when her neck was jammed by the window after her daughter pressed the automatic switch. She died eight days later, having suffered asphyxia leading to brain damage.
- Henry Taylor, a pall bearer at Kensal Green Cemetery in London, tripped over a stone and stumbled as he was carrying a coffin. The other pall bearers let go of the coffin and it fell on top of Taylor, crushing him to death in front of all the mourners. The widow of the man in the coffin reportedly "nearly went into hysterics".

2 Stressors

These are common stresses which can affect you in a survival situation.

Physiological Stressors

In a survival situation, individuals face a complex interplay of physical and psychological demands that act as significant stressors. These stressors can severely impact decision-making, physical performance, and overall well-being.

Hunger & Thirst

The fundamental lack of food and water creates intense physiological stress. Dehydration can quickly lead to fatigue, dizziness, impaired cognitive function, and eventually organ failure. Starvation causes weakness, metabolic changes, and a severe reduction in energy and mental acuity. Prolonged hunger can lead to "hanger," affecting mood and judgment.

Sleep Deprivation

The inability to get adequate, restorative sleep due to fear, discomfort, or the need for vigilance significantly impairs cognitive abilities, including decision-making, problem-solving, memory, and concentration. It also negatively affects physical coordination, mood regulation, and can lead to hallucinations in extreme cases.

Extreme Temperatures

Exposure to severe cold (hypothermia) or extreme heat (hyperthermia) directly stresses the body, requiring immense energy to maintain core temperature. This can lead to exhaustion, confusion, and loss of consciousness.

Injury and Illness

Physical injuries, no matter how minor, cause pain, limit mobility, and drain energy. Illnesses, often exacerbated by exposure, poor hygiene, and nutritional deficiencies, further weaken the body and distract the mind.

Fatigue and Exhaustion

The cumulative effect of physical exertion, lack of rest, and the physiological demands of survival can lead to profound fatigue, making even simple tasks overwhelming and increasing the risk of accidents.

Psychological Stressors

Fear and Anxiety

The constant threat of danger (animals, harsh environment, unknown future) triggers the "fight, flight, or freeze" response, leading to heightened anxiety, panic attacks, and impaired rational thinking.

Uncertainty and Lack of Control

Not knowing when rescue will come, where the next meal will be, or if help is available creates immense psychological distress and can lead to feelings of helplessness and hopelessness.

Isolation and Loneliness

Being alone for extended periods can lead to profound psychological effects, including depression, hallucinations, and a loss of will to survive. Even with others, a breakdown in group dynamics can add stress.

Decision-Making Pressure

Every choice in a survival situation can have life-or-death consequences. The constant need to make critical decisions under extreme duress, often with incomplete information, is a major source of stress.

Boredom and Monotony

While it might seem counterintuitive, periods of inactivity or repetitive tasks can lead to boredom, which can erode morale, focus, and mental resilience.

Loss of Hope/Despair

When all efforts seem to fail and the situation appears insurmountable, individuals can experience profound despair, leading to a loss of motivation and the will to continue.

Guilt or Responsibility

If others are involved, feelings of guilt over perceived failures or an overwhelming sense of responsibility for their safety can be immense stressors.

3 Resource Priority

This is an ordered list of what your priorities should be when in a survival situation. Each of them is explained in more detail below.

Positive Mental Attitude	As attested by those who have survived wilderness emergencies, a positive mental attitude may be the most essential element in survival.
First Aid	If an injury is life threatening, such as rapid loss of blood, first aid becomes the most important thing to do.
Shelter	Extreme weather conditions such as extreme heat or cold make finding or building a shelter of high importance. At such times even painful but minor injuries must wait until shelter is available. This is even more urgent if night is approaching.
Fire	Often, along with shelter, you will need a fire for warmth and signalling. Fuel should be secured and the fire started before dark.

Signalling	Signalling. When you have taken the first steps in dealing with the emergency, you will need to prepare rescue signals.
Water	Water. Under all circumstances, water is essential. You can live only a few days without it. Finding water is even more urgent when the weather is hot and dry.
Food	A person can live several weeks without food; it does not rate high as a survival priority.
Companionship	Humans are made to have company. Going without another person, or another form of life can literally send someone insane over a long period.

Positive Mental Attitude

Positive Mental Attitude (PMA) is the philosophy that having an optimistic disposition in every situation in one's life attracts positive changes and increases achievement. By keeping optimistic you can combat the 3 Seconds Without Hope rule whereby with no hope you will surely die. Being focused on survival and knowing you can succeed is the biggest advantage you will have over everybody else in a disaster who will see the situation as hopeless. If you aren't in a positive state of mind yet there's no point going any further down the list until you're dedicated to surviving. If you're reading this, you're obviously alive and that's the only prerequisite you need. You're here for a reason and you're survived everything up until now so don't quit!

For more information on your mental state see the POPULATION > Psychology section.

First Aid

Healing your body is the next step required. If you're injured in any way be sure to take care of it immediately as it could get infected.

For more information on first aid and medical related issues, see either the MEDICAL, MEDICATION, ILLNESS, INJURY, EMOTIONAL or NATURAL REMEDIES sections.

Shelter

Start to look for or construct a shelter if one isn't readily available, this should be done as a top priority if there's extreme adverse weather such as a hurricane, blizzard or sandstorm occurring.

For more information on shelters, shelter building and house repairs, see the SHELTER section.

Fire

A fire will restore morale and keep you warm as well as letting you cook food and boil water. Fire is often a prerequisite for water which requires boiling if there's no filters available. Fire is often a prerequisite for signalling for help by using the smoke and flames to catch people's attention.

For more information on fires and signalling see the FIRE and COMMUNICATION sections.

Water

A source of water is next to accomplish. Be sure it's free from pathogens and you have enough to sustain your body's needs with some spare.

For more information on water, see the WATER section.

Signalling

Set up a signal fire nearby and have your campfire on standby to light it if you hear or see a plane or boat.

For more information on signalling see the COMMUNICATION section.

Food

Another requirement is food. Ensure you can forage or hunt for food in your location to sustain your body. You should always have adequate water before thinking about food or eating it as it takes quite a lot of water to process it.

For information on finding food and cooking food, see the FOOD, COOKING, RECIPES, HUNTING, FISHING, PLANTS, and ANIMALS sections.

Companionship

4 Documentation

During any survival situation you should keep a record of all events, particularly discoveries of edible plants and other nearby resources. Keep a track of what day it is for morale and remember small things like birthdays to keep your spirits high. It's also useful to create a map of the local landscape to help you plan for the future and potential future disasters such as flooding.

Documenting can stave away boredom and loneliness and keep your mind occupied. Research the surrounds of your area thoroughly and learn what plants can be used for food, water and medicine. Know what predators are in the area and how to keep them at bay.

Documenting

Here you will find tips on what to document and how to document them properly so you can refer back to your notes and understand any valuable information you have noted during your surviving period.

Pre-Planning for Documentation

Gather Basic Tools:
- Writing Utensils: Waterproof pens, pencils.
- Notebook/Paper: Waterproof paper (Rite in the Rain is excellent), durable notebook, or a logbook.
- Digital Devices: Charged smartphone, camera, voice recorder. Consider spare batteries, power banks, and solar chargers.
- Secure Storage: Waterproof bag/container for documentation tools and collected data.
- Makeshift Book: Rocks, Inner Bark & Leaves can all make useful writing surfaces, with Charcoal, plant juices or soot being ink replacements.

Establish a System:
- Decide on a format (e.g., chronological journal, specific forms).
- Consider establishing codes or abbreviations for common events or observations to save time.

What to Document

Date and Time
- Always begin each entry with the precise date and time. This is fundamental for chronological understanding. If you aren't sure of the date, you could note the date you believe it to be on the first entry and put down "Day 2, 3.. etc" for the remainer.

Location
- Specific Address/GPS Coordinates: As exact as possible.
- Relative Location: If GPS is unavailable, landmarks, distances from known points, terrain features.
- Changes in Location: Note every move, including direction, distance, and reason for movement.

Environmental Conditions
- Weather: Temperature (estimated or actual), precipitation (rain, snow, hail), wind (direction, strength), cloud cover, sunlight conditions.
- Terrain: Condition of ground (wet, dry, muddy), accessibility, hazards (fallen trees, landslides, floods).
- Natural Hazards: Fires, floods, storms, earthquakes, wildlife encounters.

Personal Status
- Physical Health: Injuries (type, severity, treatment), symptoms of illness, fatigue levels, hydration status (water intake), hunger (food intake).
- Mental/Emotional State: Mood, stress levels, clarity of thought, any signs of panic or despair, morale.
- Vitals (if monitored): Heart rate, respiratory rate.
- Clothing/Gear Status: Condition, any damage or loss.

Actions Taken
- Decisions Made: What decisions were made and why (e.g., "Decided to move east due to rising water").
- Tasks Performed: Building shelter, purifying water, foraging, signaling, administering first aid, maintaining equipment, attempting communication.
- Resources Used: What resources were consumed (food, water, fuel, medical supplies).
- Failures/Challenges: What didn't work and why.

Observations
- Sensory Details: Sights, sounds, smells (e.g., "saw smoke to the west," "heard distant sirens," "smelled burning plastic").
- Signs of Life/Activity: Human (footprints, distant lights, aircraft, rescue efforts), animal (wildlife, domestic animals), vegetation changes.
- Damage/Impacts: To infrastructure, natural environment, property.
- Resource Availability: Potential water sources, edible plants, shelter materials.

Communication Attempts
- Method: Radio, phone, satellite phone, signaling (fires, mirrors).
- Time: When attempts were made.
- Outcome: Success/failure, content of communication.
- Contacts: Who was contacted.

Group Dynamics
- Number of People: Initially and any changes.
- Names/Roles: Of individuals.
- Individual Status: Health and morale of others.
- Interactions: Conflicts, cooperation, leadership.

How to Document

Maintain a Chronological Journal/Log
- Regular, timestamped entries are crucial. Even short notes are better than nothing.
- Be consistent, even when tired or stressed.
- Use a simple, clear writing style.
- If using paper, number pages for easy reference.

Photographs and Videos
- Capture Context: Don't just focus on damage; show scale, location, and the general environment.
- Timestamp: Ensure your camera/phone is set to the correct date and time.
- Variety: Take wide shots, close-ups, and sequential photos showing progression.
- Selfies (for personal status): Can be useful for documenting physical changes or injuries.
- Video: Can capture movement, sounds, and a more dynamic sense of the situation. Narrate if possible.

Voice Recordings
- If writing is difficult (e.g., in the dark, cold, or injured), use a voice recorder or smartphone.
- State date, time, and your location at the beginning of each recording.
- Speak clearly and concisely.

Maps and Sketches
- If possible, mark your route, hazards, resource locations, and significant observations on a map.
- Simple sketches can convey information about shelter construction, injuries, or unknown objects more effectively than words alone.

Be Objective and Factual
- Stick to observations and actions. While emotions are valid, try to keep documentation factual for later analysis.
- Avoid assumptions or speculation. Note what you see and do.

Secure and Back Up Data
- Protect physical notes from water, fire, and loss.
- If using digital devices, consider how you will power them and if you can transfer data to a more secure, off-site storage method (e.g., cloud storage, external hard drive) when possible.

Planning

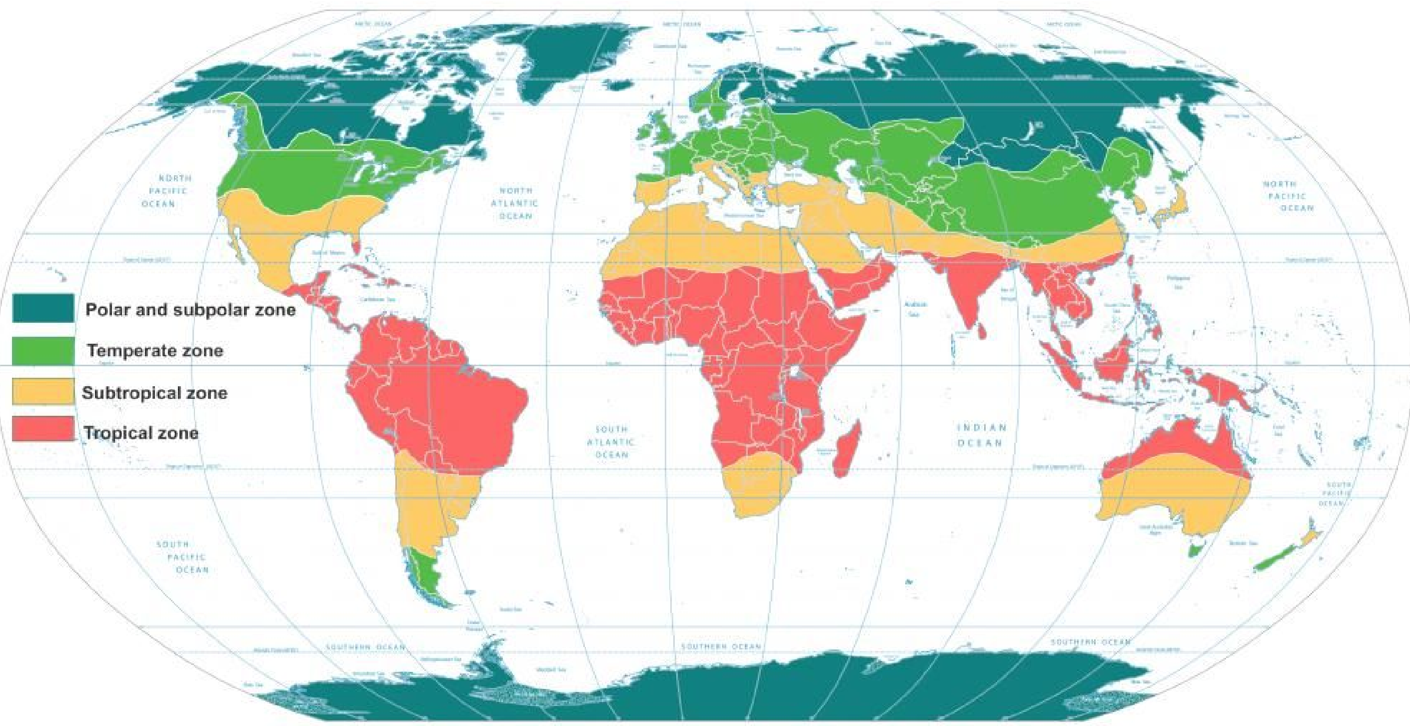
This section details how you can best plan for wilderness survival if you know you'll be in a certain area when disaster strikes.

Entry Phase The entry into the operation field.	**Objectives** The objectives to complete during the mission.	**Recovery** The plan for evacuation and returning home.	**Contingency Plans** Backup plans in case things take a turn or don't work out.		

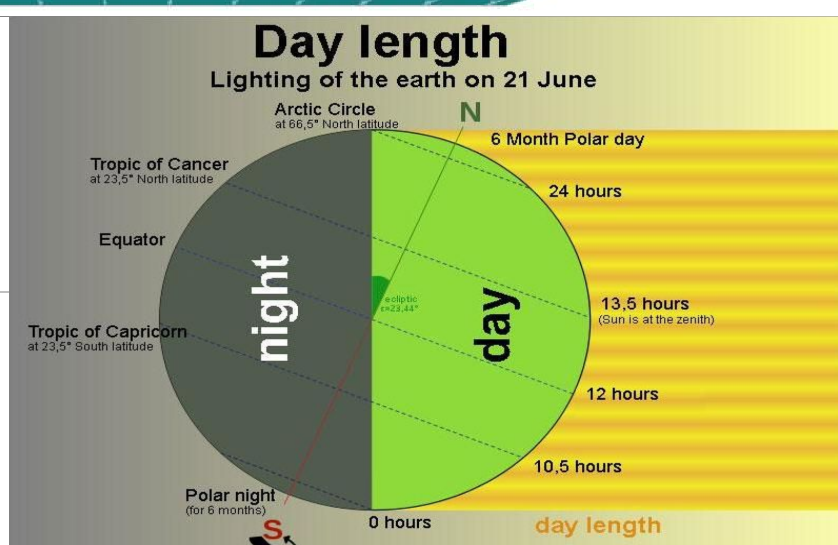
5 Climate

Climate refers to the average weather conditions in a particular region over a long period, typically 30 years or more. It encompasses patterns of temperature, precipitation, humidity, wind, and other atmospheric phenomena. Unlike weather, which describes day-to-day atmospheric conditions, climate represents the expected range and variability of these conditions over an extended timeframe.

Climate Zones



Legend
- **Dark Green**: Polar and Subpolar Zones
- **Green:** Temperate Zones
- **Orange:** Subtropical Zones
- **Red:** Tropical Zones



Tropical Zone

Tropical Zone

Tropical Zone 0°–23.5°	In the regions between the equator and the tropics (equatorial region), the solar radiation reaches the ground nearly vertically at noontime during almost the entire year. Thereby, it is very warm in these regions. Through high temperatures, more water evaporates and the air is often moist. The resulting frequent and dense cloud cover reduces the effect of solar radiation on ground temperature.			
Area Around the equator, from 23.5° further north to 23.5° southern latitude	**Sun Path** Sun at the zenith (90°) at least once per year, never lower than 43°	**Average Temperature** >20 to 30°C (68 to 86°F)	**Minimal Temperature** 0°C (32°F) (no frost) **Maximal Temperature** Up to 40°C (104°F) (seldom more)	**Climate** Humid - warm. Often precipitation (humid), sometimes (short) drought. "Day time" instead of "season climate" (daily changes in temperature are bigger than the annual changes of daily averages).
Day Length 10 to 13.5 hours	**Precipitation** Rain - will be defined by trade winds and its seasonal shift		**Vegetation** Evergreen forests, savannah	**Properties** More than 40% of Earth's population live in the tropics, with an increasing tendency

Subtropical Zone

Subtropical Zone 23.5°–40°	The subtropics receive the highest radiation in summer, since the Sun's angle at noon is almost vertical to the Earth, whilst the cloud cover is relatively thin. These regions receive less moisture (see trade winds), what increases the effect of radiation. Therefore, most of the deserts in the world are situated in this zone. In winter, the radiation in these regions decreases significantly, and it can temporarily be very cool and moist.			
Area Between the tropical zone and the temperate zone (25° to 40° North and South latitude)	**Sun Path** 90 to 27° above the horizon, according to place and season	**Average Temperature** >20 to 35°C (68 to 95°F)	**Minimal Temperature** -5°C (23°F) **Maximal Temperature** +66°C (150.8°F) (Libya, Iran)	**Climate** Tropic summer, non-tropic winter
Day Length 9 to 15 hours	**Precipitation** Dry, winter humidity and always wet areas		**Vegetation** Semi-deciduous or evergreen forests, hardwood forests with winter rain, savannah, pasture land, semi-desert, warm temperate moist forests, nemoral deciduous forests.	**Properties** Extreme heat, strong precipitation and drought in some areas

Temperate Zone

Temperate Zone 40°–60°	In the temperate zone, the solar radiation arrives with a smaller angle, and the average temperatures here are much cooler than in the subtropics. The seasons and day length differ significantly in the course of a year. The climate is characterised by less frequent extremes, a more regular distribution of the precipitation over the year and a longer vegetation period - therefore the name "temperate".			
Area Between the cold zone and the subtropical zone (40° to 60°)	**Sun Path** Maximum 73°, minimum 0° (at Arctic Circle)	**Average Temperature** Between 0 and 20°C (32 to 68°F)	**Minimal Temperature** -40°C (-40°F) **Maximal Temperature** +40°C (104°F)	**Climate** Warm and cold temperate
Day Length 4 to 16 hours 8 to 12 hours at 50°N	**Precipitation** From 300 to 2000 mm, average 800 mm		**Vegetation** Deciduous forests, warm temperate forests, savannah	**Properties** Extreme temperature and precipitation is rare

Cold Zone

Cold Zone 60°–90°	The polar areas between 60° latitude and the poles receive less heat through solar radiation, since the Sun has a very flat angle toward the ground. Because of the changes of the Earth axis angle to the Sun, the day length varies most in this zone. In the summer, polar days occur. Vegetation is only possible during a few months per year and even then is often sparse. The conditions for life in these regions are very hard.			
Area 60° to 90° North and South latitude	**Sun Path** 53° above the horizon (polar day) to under the horizon (polar night)	**Average Temperature** -47 to 0°C (-52.6 to 32°F)	**Minimal Temperature** -89°C (-128.2°F) (Antarctica) **Maximal Temperature** +25°C (77°F) (Tundra)	**Climate** Ice climate (average temperature of the warmest month below 0°C (32°F)), and tundra climate (average temperature of the warmest month between 0 and 10°C (32°F and 50°F)
Day Length 0 to 24 hours (polar night respectively polar day)	**Precipitation** Variable, mostly in the form of snow		**Vegetation** Polar area: scarce Tundra: moss, lichens, grass, boreal forest with conifer wood	**Properties** Hostile to life, polar lights

Earth's Climate

Details on the different climates on planet earth.

Polar Regions

The polar regions are the coldest areas on Earth, located at the planet's northernmost and southernmost extremities. Defined generally by the Arctic and Antarctic Circles (approximately 66.5 degrees North and South latitude), these regions experience extreme variations in daylight, including periods of 24-hour darkness in winter and 24-hour daylight in summer, due to the Earth's axial tilt.

Characterized by incredibly low temperatures, substantial ice and snow cover, and unique ecosystems, the polar regions play a critical role in regulating global climate by reflecting solar radiation back into space.

Ice Sheet

an ice sheet is a massive, continental-scale body of glacial ice that covers a large land area, typically exceeding 50,000 square kilometers (about 19,000 square miles). These vast ice masses are formed by the accumulation and compression of snow over thousands of years.

Polar Desert

A polar desert is a type of cold desert found in the Earth's polar regions, primarily the Arctic and Antarctic. Despite being covered in vast amounts of ice and snow, they are considered deserts due to extremely low precipitation.

Tundra

Tundra is a distinct biome characterized by its treeless landscape, a direct result of extremely cold temperatures, strong winds, and a permanently frozen layer of subsoil known as permafrost. While the surface soil thaws briefly during the short, cool summers, this shallow thaw is insufficient for deep-rooted trees to establish. Instead, the vegetation consists primarily of low-growing plants like mosses, lichens, sedges, and dwarf shrubs, all adapted to the harsh conditions.

Despite often being covered in snow, tundra regions receive very little annual precipitation, sometimes earning them the moniker "cold deserts." These conditions create a unique environment found predominantly in the far Northern Hemisphere as Arctic tundra, encircling the pole, and also at high altitudes on mountains worldwide, known as alpine tundra.

Arctic Tundra

Found in the far Northern Hemisphere, circling the North Pole and extending south to the taiga (boreal forest).

Alpine Tundra

Located on high mountains around the world, above the treeline where temperatures are too low for trees to grow.

Northern Coniferous Forest

The Northern Coniferous Forest, also widely known as the Boreal Forest or Taiga, is the largest terrestrial biome on Earth, forming a vast, circumpolar belt across the high northern latitudes of North America, Europe, and Asia. This biome is characterized by its long, cold, and often snowy winters, coupled with short, cool, and moist summers. The dominant vegetation consists of coniferous evergreen trees like spruce, fir, and pine, which are uniquely adapted to these harsh conditions.

Their needle-like leaves, often coated in wax, help reduce water loss and allow them to photosynthesize even in cooler temperatures, giving them a head start on growth in spring compared to deciduous trees.

Beneath the dense canopy of these conical trees, which allows snow to easily slide off their branches, the forest floor typically has a thin, acidic, and nutrient-poor soil layer. This is due to the slow decomposition of conifer needles in the cold climate and the leaching of nutrients by acidic precipitation. Despite the limited biodiversity compared to warmer biomes, the Northern Coniferous Forest supports a variety of cold-adapted wildlife, including moose, bears, wolves, lynx, and various bird species, many of which migrate or adapt to the long winters through hibernation or specialized diets. This immense forest plays a crucial role in global carbon cycling, storing vast amounts of carbon, particularly in its extensive peatlands and slow-decomposing organic matter.

Taiga

Taiga, also known as boreal forest or snow forest, is a biome characterized by coniferous forests consisting mostly of pines, spruces and larches.

Deciduous Forest

A deciduous forest is a type of biome characterized by trees that seasonally shed all of their leaves, typically in autumn. The word "deciduous" itself comes from Latin, meaning "to fall off." This shedding of leaves is an adaptation to conserve water and energy during colder winter months or dry seasons when photosynthesis is less efficient or impossible.

Before dropping, the leaves of these trees often change color to vibrant reds, oranges, yellows, and browns, creating the spectacular displays associated with autumn in many parts of the world.

These forests are predominantly found in temperate regions across the middle latitudes, including large areas of eastern North America, western Europe, and northeastern Asia. They thrive in climates with four distinct seasons: warm, wet summers ideal for growth, and cold winters during which the trees enter a dormant state. The decomposition of the annually shed leaves enriches the soil with nutrients, making the ground in deciduous forests typically fertile. This nutrient-rich soil, combined with moderate precipitation distributed throughout the year, supports a diverse array of plant and animal life that have adapted to the seasonal changes, with many animals hibernating or migrating during the colder months.

Temperate Broadleaf Forest

Temperate broadleaf and mixed forest is a temperate climate terrestrial biome, with broadleaf tree ecoregions, and with conifer and broadleaf tree mixed coniferous forest ecoregions.

Temperate Grassland

Temperate grasslands are a major terrestrial biome characterized by vast open spaces dominated by grasses, with very few trees or large shrubs. These ecosystems are typically found in mid-latitude regions across continents, far from the moderating influence of oceans.

They experience distinct seasonal changes, with hot summers and cold winters, often with significant temperature fluctuations both seasonally and even within a single day. Rainfall is moderate, generally ranging from 250 to 900 millimeters (10 to 35 inches) annually, which is sufficient to support grasses but not enough for widespread tree growth.

The absence of trees in temperate grasslands is also maintained by factors like seasonal droughts, occasional natural fires (often ignited by lightning), and grazing by large native herbivores. The soil in these regions is typically deep, dark, and exceptionally fertile due to the extensive, densely branched root systems of the grasses. When these roots die and decompose, they contribute a rich layer of organic matter (humus) to the soil, making temperate grasslands some of the most productive agricultural lands in the world. Examples of temperate grasslands include the prairies of North America, the steppes of Eurasia, the pampas of South America, and the veld of South Africa.

Dry Steppe

The Dry Steppe is a particular type of grassland biome that represents a transition zone between the more humid temperate grasslands and true deserts. It's characterized by a semi-arid climate, meaning it's too dry to support forests but not quite dry enough to be a full desert. Key features of a dry steppe include very low annual precipitation, typically less than 250-400 millimeters (10-16 inches), which falls erratically throughout the year. This limited rainfall results in shorter, sparser grasses compared to the taller, denser vegetation found in more humid temperate grasslands like prairies. Trees are generally absent except along watercourses.

Dry steppes experience significant temperature extremes, with hot summers and cold winters, often with large diurnal (daily) temperature swings. The soils are often less fertile than those of the wetter grasslands and are more prone to erosion due to less continuous vegetation cover. Examples include parts of Central Asia (the traditional "steppe" regions), the Patagonian steppe in Argentina, and the fringes of many subtropical deserts.

Temperate Steppe

Temperate Steppe is a type of grassland biome found in the Earth's mid-latitudes, characterized by a semi-arid continental climate. This means it experiences distinct seasons with hot summers and cold winters, often with significant temperature fluctuations throughout the day. While it receives more precipitation than a true desert, it's not enough to support the growth of large forests, leading to a landscape dominated by grasses and scattered shrubs. The amount of rainfall, which typically ranges from 250 to 500 millimeters (10 to 20 inches) annually, determines the density and height of the grass cover.

Compared to other temperate grasslands like the North American prairies, which tend to be more humid and support taller grasses, the temperate steppe generally features shorter, sparser grasses. This is partly due to lower and more erratic rainfall. The soils of temperate steppes, though often rich in organic matter from decaying grass roots, can be less fertile and more prone to erosion than those of wetter grasslands. These vast, treeless plains are found in continental interiors, such as the expansive Eurasian Steppe, parts of the Great Plains in North America, and the Patagonian steppe in South America, supporting a variety of grazing animals and resilient plant life adapted to the dry, windy conditions.

Mediterranean Regions

A Mediterranean Region is defined by a specific type of climate known as a Mediterranean climate, which is characterized by hot, dry summers and mild, wet winters. This distinct seasonal pattern is a key defining feature, as most other regions with warm summers receive their highest precipitation during those hotter months.

These regions are typically found in the mid-latitudes, roughly between 30° and 45° North and South of the equator, and almost exclusively on the western coasts of continents. The name originates from the Mediterranean Basin, where this climate is most widespread, but it also occurs in other scattered locations globally, including parts of California, central Chile, the southwestern tip of South Africa, and parts of southern and southwestern Australia.

The vegetation in these regions is highly adapted to the unique rainfall pattern, often featuring evergreen shrubs and small trees with leathery leaves, deep root systems, and adaptations to frequent wildfires.

Mediterranean Vegetation

Mediterranean vegetation, any scrubby, dense vegetation composed of broad-leaved evergreen shrubs, bushes, and small trees usually less than 2.5 m (about 8 feet) tall and growing in regions lying between 30° and 40° north and south latitudes.

Tropical Forests

Tropical forests are expansive forested regions found in the Earth's tropical zones, primarily located between the Tropic of Cancer and the Tropic of Capricorn, which are roughly 23.5 degrees north and south of the equator. These biomes are characterized by consistently warm temperatures throughout the year, typically ranging between 20°C (68°F) and 29°C (85°F), with very little seasonal variation. They also receive significant amounts of annual rainfall, making them incredibly humid environments.

This combination of consistent warmth and abundant moisture fosters an astonishing level of biodiversity, housing an immense variety of plant and animal species, often accounting for a disproportionately large percentage of the world's total species despite covering a relatively small portion of the Earth's land surface.

While often synonymous with "rainforests," the term "tropical forests" actually encompasses a broader range of forest types based on their specific rainfall patterns. Tropical rainforests are the most well-known, experiencing high rainfall year-round with no distinct dry season. Other types include seasonal tropical forests (also known as tropical moist deciduous forests or monsoon forests), which have a pronounced wet and dry season, with trees shedding their leaves during the drier periods.

There are also tropical dry forests, which experience an even longer and more intense dry season, leading to more drought-adapted vegetation, and specialized types like cloud forests (found at higher altitudes with persistent mist and fog) and mangrove forests (found in coastal, brackish water environments). Despite their incredible ecological importance as carbon sinks and biodiversity hotspots, tropical forests worldwide face significant threats from deforestation, agricultural expansion, and climate change.

Tropical Rainforest

Tropical rainforests are the most biodiverse and lush type of tropical forest, characterized by consistently high temperatures and very abundant rainfall throughout the year, with no distinct dry season. They are primarily located in a band around the Earth's equator, between the Tropic of Cancer and the Tropic of Capricorn. This continuous warmth and moisture create ideal conditions for incredibly dense and tall vegetation, dominated by broad-leaved evergreen trees that form multiple layers, including an emergent layer of towering trees, a dense canopy that blocks much of the sunlight, an understory, and a relatively clear forest floor.

Despite their incredible richness in plant and animal species – housing an estimated 50% or more of the world's total biodiversity – the soils in tropical rainforests are often surprisingly poor in nutrients. This is because the high rainfall rapidly leaches nutrients away, and the incredibly fast decomposition rates mean that nutrients are quickly taken up by the dense plant life rather than being stored in the soil. The rapid cycling of nutrients, coupled with the consistent warm and wet conditions, makes tropical rainforests incredibly productive ecosystems, playing a vital role in global climate regulation and the water cycle.

Subtropical Rainforest

A Subtropical Rainforest is a type of dense, evergreen forest found in regions that transition between tropical and temperate climates. It shares many characteristics with true tropical rainforests, but it's typically located further from the equator, generally between 23.5° and 35° north and south latitude. This geographical position means that while they still experience consistently warm temperatures and high humidity year-round, they may have a slightly cooler average temperature than tropical rainforests, and can sometimes exhibit more seasonal variation, including a less pronounced but still present dry season or occasional cooler periods.

In terms of flora and fauna, subtropical rainforests are incredibly biodiverse, though perhaps slightly less so than their tropical counterparts. They feature a multi-layered canopy of tall, broad-leaved evergreen trees, many of which exhibit buttressing (flared bases for support) similar to tropical species. Large woody vines (lianas) and abundant epiphytes (plants that grow on other plants, like orchids and ferns) are also common. These forests typically thrive on fertile soils, often derived from basalt or alluvium, and require substantial annual rainfall, generally exceeding 1300mm. Significant examples of subtropical rainforests are found in regions like eastern Australia, the southeastern United States, and parts of southern China and Brazil.

Subtropical Dry Forest

A Subtropical Dry Forest is a type of forest biome that occupies a transitional zone between the more humid subtropical rainforests and drier grasslands or deserts. Unlike rainforests that receive consistent rainfall, subtropical dry forests are defined by a distinct seasonality in their precipitation, experiencing hot, rainy summers and long, pronounced dry seasons. While temperatures remain warm to hot year-round, the extended periods of drought are the key environmental factor shaping these ecosystems.

The vegetation in subtropical dry forests is highly adapted to cope with these dry periods. While many species are deciduous, shedding their leaves during the dry season to conserve water (similar to temperate deciduous forests but driven by drought, not cold), some are evergreen, featuring adaptations like thick, leathery leaves or waxy coatings to minimize water loss. The canopy is generally lower and less dense than in rainforests, and the presence of thorny shrubs and succulents can be common. These forests support a diverse range of wildlife that also exhibit adaptations to the dry conditions, such as seasonal migrations or estivation (a state of animal dormancy, similar to hibernation, characterized by inactivity and a lowered metabolic rate, that occurs in response to high temperatures and arid conditions). You can find examples of subtropical dry forests in regions like parts of Queensland and New South Wales in Australia (often referred to as "dry rainforests" or "dry vine thickets"), Mexico, South America, and Africa.

Monsoon Forest

A Monsoon Forest, also known as a tropical deciduous forest or tropical seasonal forest, is a type of forest biome characterized by its distinct wet and dry seasons, a result of the powerful influence of monsoon winds. Unlike tropical rainforests that receive high rainfall year-round, monsoon forests experience a hot, very rainy summer (the monsoon season) followed by a long, pronounced dry season. This dramatic shift in precipitation dictates the life cycle of the vegetation.

During the wet season, the forest is lush and green, with trees in full leaf, often appearing similar to a rainforest. However, as the dry season approaches, most trees adapt by shedding their leaves to conserve precious water, a process that can lead to the forest looking quite barren and open. The trees in these forests are generally not as tall or dense as those in rainforests, and the undergrowth can vary from sparse during the dry season to quite thick during the wet. These forests are found in tropical regions where monsoon circulation is a dominant climatic factor, including parts of South and Southeast Asia, northern Australia, Africa, and Central and South America. They play a vital ecological role, supporting diverse wildlife adapted to the seasonal changes.

Montane Forest

A Montane Forest is a type of forest ecosystem found at higher elevations in mountainous regions around the world. The term "montane" literally means "of or inhabiting mountains." These forests exist in a distinct altitudinal zone, typically above lowland forests and below the treeline (where the forest gives way to alpine tundra or bare rock). The specific elevation range varies greatly depending on latitude and local climate; for instance, montane forests in tropical regions will be found at much higher altitudes than those in temperate or boreal zones.

The climate of a montane forest is generally cooler and often wetter than that of the surrounding lowlands due to increased elevation. This cooler temperature, combined with frequent cloud cover, mist, and higher precipitation (often including snow), creates a unique environment. The vegetation of montane forests is highly diverse, ranging from coniferous trees (like pines, firs, and spruces) in temperate and boreal mountains to broadleaf evergreen species in tropical montane regions. Trees often exhibit adaptations to the cooler temperatures, strong winds, and shallower, rockier soils, sometimes appearing stunted or gnarled at higher elevations. The presence of mosses, lichens, and epiphytes (plants growing on other plants) is often abundant, especially in "cloud forests," which are a specific type of montane forest perpetually shrouded in mist. These forests are vital for biodiversity, watershed protection, and carbon sequestration.

Savannah

A savanna (also spelled savannah) is a type of grassland biome characterized by vast open spaces dominated by grasses, but unlike temperate grasslands, they have scattered trees and shrubs that are widely spaced, preventing a closed canopy from forming. The defining feature of savannas is their distinct seasonal climate, with a hot, rainy summer followed by a long, pronounced dry season. This seasonal rainfall pattern, along with factors like frequent natural fires and the grazing of large herbivores, prevents the widespread growth of dense forests, allowing grasses to thrive.

Savannas are most extensively found in tropical and subtropical regions, particularly across large parts of Africa (famous for its iconic wildlife like lions, elephants, and giraffes), South America, Australia, and parts of Asia.

The specific types of trees and grasses vary by region, but common adaptations include deep root systems to access water during dry periods, thick bark to resist fires, and deciduous habits (shedding leaves) during the dry season. Savannas are crucial ecosystems for global biodiversity and play a significant role in carbon cycling, acting as a transitional zone between lush tropical rainforests and arid deserts.

Grass Savannah

A Grass Savanna is a specific type of savanna biome that is predominantly characterized by its extensive grass cover, with trees and shrubs being either completely absent or extremely sparse and widely scattered. While all savannas feature grasses as a dominant vegetation component, a "grass savanna" emphasizes the minimal presence of woody plants. This open landscape is maintained by a combination of factors, including a distinct wet and dry season (where the dry season often leads to natural fires), low and often erratic rainfall that discourages widespread tree growth, and the intensive grazing pressure from large herbivores.

These environments are typically found in tropical and subtropical regions, acting as a transition zone between true grasslands and areas with more tree cover. The grasses, which are often tall and coarse, are well-adapted to the seasonal changes, growing rapidly during the wet season and often dying back or turning brown during the dry season to conserve water. The deep root systems of these grasses enable them to survive droughts and recover quickly after fires, which are a natural and important part of maintaining the grass-dominated landscape by clearing out woody seedlings.

Tree Savannah

A Tree Savanna is a specific type of savanna biome that features a more prominent presence of trees compared to a pure "grass savanna," though the trees are still widely scattered and do not form a closed canopy like in a forest. This open woodland-grassland structure allows ample sunlight to reach the ground, supporting a continuous layer of grasses and other herbaceous plants. The density of trees in a tree savanna can vary significantly, but generally, their spacing is sufficient to prevent them from completely shading out the understory.

Like all savannas, tree savannas are characterized by a distinct seasonal climate with hot, rainy summers and prolonged dry seasons. The trees present in these ecosystems are highly adapted to these conditions, often exhibiting features like deep taproots to access groundwater during droughts, thick bark to resist frequent fires, and deciduous habits where they shed their leaves during the dry season to conserve moisture. Common tree species vary by region, but examples include acacia and baobab trees in Africa, and various eucalyptus species in Australia. The balance between trees and grasses in a tree savanna is maintained by a complex interplay of factors including rainfall patterns, soil conditions, frequency of fires (which can suppress tree growth), and the grazing activities of large herbivores.

Desert

A desert is an extremely arid land area characterized by very low precipitation, typically receiving less than 250 millimeters (10 inches) of rain per year. This severe lack of available moisture is the defining feature, making water the most limiting factor for life. As a result, deserts support only sparse vegetation, with plants and animals exhibiting specialized adaptations to survive the harsh, dry conditions.

Despite the common image of hot, sandy landscapes, deserts can occur in various forms and temperatures. While many are indeed hot with significant daily temperature swings (very hot days and cold nights), "cold deserts" or "polar deserts" also exist in high latitudes, where precipitation is similarly low but temperatures are consistently freezing.

The lack of dense vegetation in deserts exposes the land surface to significant weathering processes by wind and occasional, intense flash floods, often leading to distinctive landforms such as sand dunes, stony plains, and exposed bedrock.

Arid Desert

An arid desert is essentially a desert that is specifically defined by its extreme dryness. The term "arid" itself means very dry and lacking in rainfall. So, when we talk about an arid desert, we are emphasizing the primary characteristic that makes it a desert: its severe lack of precipitation.

These environments receive less than 250 millimeters (10 inches) of rain annually, and often much less, sometimes experiencing years with virtually no rainfall at all. The high temperatures common in many arid deserts, combined with strong winds, lead to very high evaporation rates, meaning any moisture that does fall quickly evaporates. This combination of minimal rainfall and high evaporation results in landscapes that are often barren or have very sparse vegetation, with plants and animals that possess remarkable adaptations to survive the extremely dry conditions. The arid zone covers a significant portion of the Earth's land area, including many of the world's most famous deserts like the Sahara, the Arabian Desert, and a large portion of Australia's interior.

Semiarid Desert

A Semiarid Desert is a transitional biome that lies on the fringes of true arid deserts. The key distinction is that while still very dry, it receives slightly more precipitation than an arid desert, typically between 250 and 500 millimeters (10 to 20 inches) annually. This increased, though still limited, rainfall allows for a greater density of vegetation compared to arid deserts.

The landscape of a semiarid desert is generally dominated by sparse grasslands, often featuring short, scattered grasses, and a greater presence of drought-resistant shrubs and small, thorny trees. The climate is characterized by hot summers and cool to cold winters, with significant daily temperature swings. While less harsh than an arid desert, water scarcity is still a defining challenge, and the vegetation and animal life are highly adapted to survive prolonged dry periods, sometimes punctuated by unpredictable rainfall. Examples include parts of the Great Basin in North America, the Australian Outback surrounding the central deserts, and the fringes of the Sahara and Arabian deserts.

Xeric Shrubland

A Xeric Shrubland is a type of biome characterized by its dry (xeric comes from the Greek word for "dry") conditions and the dominance of woody-stemmed shrubs and hardy plants. It's often found in areas that are too dry for forests but not quite as extreme as true deserts, serving as a transitional zone. These regions receive very low annual rainfall, typically less than 250 millimeters (10 inches) on average, though it can sometimes reach up to 500 millimeters in marginal areas. What truly defines them is that evaporation usually exceeds the amount of precipitation, leading to a persistent moisture deficit.

The vegetation in xeric shrublands is highly adapted to conserve water and withstand prolonged drought. Plants often have small, leathery, or waxy leaves to reduce water loss, deep root systems to tap into scarce groundwater, or are succulents that store water in their tissues, like cacti. Examples of common plants include creosote bush, sagebrush, and various thorny shrubs.

While many xeric shrublands experience hot days and cold nights due to the lack of insulating humidity, their temperature variability can range from hot year-round to regions that become quite cold in winter (like parts of the Gobi Desert). These biomes are found across various continents, including significant areas of Australia (such as the Carnarvon xeric shrublands in Western Australia and parts of the Central Ranges), North America, Africa, and Asia, and are critical for a diverse array of specially adapted animal life.

Ocean

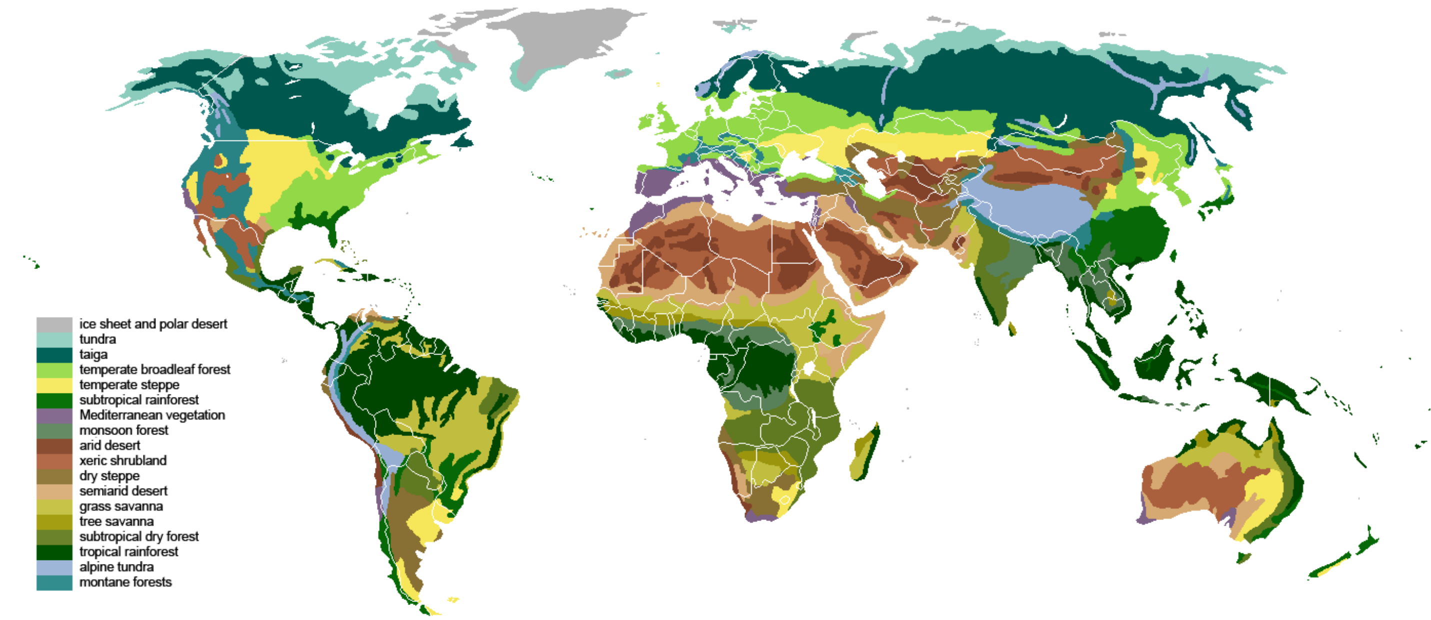
The ocean refers to the vast, continuous body of salt water that covers approximately 71% of Earth's surface. It is the largest reservoir of water on the planet, holding about 97% of all Earth's water. While often divided into five major oceans (Pacific, Atlantic, Indian, Southern/Antarctic, and Arctic) for geographical convenience, these are all interconnected and water flows freely between them, effectively forming one global ocean.

The ocean plays a critical role in regulating Earth's climate and weather patterns due to its immense capacity to absorb, store, and transport heat and carbon dioxide. Its waters are constantly in motion through currents, waves, and tides, influenced by factors like temperature, salinity, winds, and gravitational forces from the Moon and Sun.

The ocean is also an incredibly diverse habitat, supporting the vast majority of Earth's animal and protist life, and is fundamental to the planet's oxygen production through microscopic marine plants called phytoplankton.

Vegetation

Below is a map of the world showing the corresponding vegetation types per region.



6 Landforms

Landforms are the various types of land you will encounter throughout the world. Some are useful for survival purposes such as setting up a tent and others are good for observation points. This can be used as a guide for identifying landforms and helping choose where you should bug out to with examples of advantages, disadvantages and hazards at each location. The survival rating is a score from 1-5 which rates how ideal the landform is as a permanent Bug-Out Location (BOL).

Subheadings

1. Mountainous	2. Continental Plain	3. Fluvial	4. Glacial
5. Oceanic and Coastal	6. Volcanic	7. Aeolian	8. Artificial

1 Mountainous

Table Butte

Table Butte 2/5 A dangerous and hard to reach location with few resources yet fair protection.	A table is a butte, flank of a mountain, or mountain, that has a flat top.	**Advantages** • Line of Sight • Hard to Spot by Ground • Flat Area • Natural Protection • Fair Animal Protection	**Disadvantages** • Easily Spotted by Air • Hard to Reach • Hard to Escape • Little/No Water • Mostly Rock • Little Vegetation

Survival Perspective
A table butte may be a naturally protective location for a campsite but its height means that it's not likely to have any water on it which means climbing up and down the steep faces over and over. It will provide a fantastic lookout point from the top for threats and make it easier to find natural resources while making other tasks difficult. If you select this site for a camp, pitch at least 30m from an edge in case an entire shelf breaks off and falls.

Hazards
• Falling Off
• Eroding Cliffs
• Strong Winds
• Slippery When Wet

Flat

Flat 3/5 Good location for pitching, could flood during rain, few trees make shelter building difficult.	A flat is a relatively level surface of land within a region of greater relief, such as hills or mountains.	**Advantages** • Flat • Plenty of Wildlife • Soft Grasses • Soft Ground • Typically Water Nearby	**Disadvantages** • Easily Spotted • Hard to Escape • Few Trees

Survival Perspective
A flat would be a fairly good location to set up a camp site due to the flat, level ground with a lot of flora and fauna nearby as well as water sources. There may or may not be many trees for cover so choose a spot wisely and ensure that it's not likely to be flooded out.

Hazards
• Possible Flood Plain
• Large Wild Animals

Hill

Hill 4/5 Good location safe from floodwater and has a great line of sight. Ensure there's water nearby.	A hill is a landform that extends above the surrounding terrain. It often has a distinct summit.	**Advantages** • Line of Sight • Flood Resistant	**Disadvantages** • Sloped Ground • Tough Climb

A hill is one of the best choices for setting up a camp, but ensure you're not right at the top or right at the bottom to avoid being detected as easily. Choose an area that's as flat as possible with fewer trees nearby which could fall.

Hazards
- Wild Animals

Mountain

Mountain
4/5
A high location away from other people. Can be very cold and lacks some resources higher up. Avalanche risk.

A mountain is a large landform that stretches above the surrounding land in a limited area, usually in the form of a peak. A mountain is generally steeper than a hill.

Advantages
- Extreme Line of Sight
- Flood Resistant

Disadvantages
- Tough Climb
- Little Fauna
- Little Flora
- Snow Coverage
- Little Water
- Foggy / Cloudy

If you choose to bug out to a mountain, ensure that it has a selection of flora and fauna on it as well as a means to get water easily. Due to the height of the mountain it may be difficult to find a flat piece of ground or find water. You don't want to have to walk up and down a mountain repeatedly to retrieve resources. It may be beneficial to camp above 3.6kms (12,000ft) to prevent a lot of people reaching this area due to altitude sickness. Only young, fit people are likely to encounter you and be able to tolerate the cold.

Hazards
- Avalanches
- Landslides
- Cold
- Slippery
- Altitude Sickness

Mountain Range

Mountain Range
4/5
The best location to conceal yourself from others. Has a lot of resources and pools of water are common.

A mountain range or hill range is a series of mountains or hills ranged in a line and connected by high ground.

Advantages
- Easily Concealed
- Water Pockets
- Flood Resistant

Disadvantages
- Tough Terrain
- Low-ish Line of Sight

A mountain range is a great camping spot away from civilization and tucked away from view. It can have its own rivers and lakes from which to source water. Generally ranges are also home to a variety of flora and fauna which can be hunted. The height means it's cooler near the top which is ideal for hotter environments. Typically there's no settlements or people living on mountain ranges due to the difficulty in putting roads through them and getting resources there. If you head deep into a mountain range you're not likely to meet anyone else if it's far enough away from any major cities.

Hazards
- Avalanches
- Landslides
- Cold
- Slippery
- Altitude Sickness

Plateau

Plateau
1/5
Extremely difficult to reach and very exposed on the top, few resources and often no water.

A plateau is an area of a highland, usually consisting of relatively flat terrain that is raised significantly above the surrounding area, often with one or more sides with steep slopes.

Advantages
- Line of Sight
- Protection from Wildlife
- Protection from Humans

Disadvantages
- Easily Spotted by Air
- Difficult to Climb
- Hard to Escape
- Little/No Water
- Exposed to Wind
- Mostly Rock
- Little Vegetation

Plateau's are a very challenging terrain to reach the top of as they are almost vertical rock surfaces. Camping at the top isn't recommended as there's little resources, no protection from the elements and it's almost entirely rock. However if you do make it to the top and set up camp you will have the ultimate protection from animal predators and humans.

Hazards
- Falling
- Slipping
- Collapsing Pillars
- Rockslide

Ridge

Ridge
3/5
A rocky location with sloped ground which may prove difficult to set up a shelter.

A ridge or mountain ridge are geological features consisting of a chain of mountains or hills that form a continuous elevated crest for some distance. The sides of the ridge slope away from narrow top on either side.

Advantages
- Line of Sight

Disadvantages
- Steep Climb
- Difficult Hike
- Non Flat Ground

Camping on a ridge would be a challenging task but worth it if you can find some flat enough ground. You will have a fantastic line of sight and be well concealed if there's enough vegetation. Water may be difficult to source when you're up high and there's likely to be quite a variety of wildlife nearby.

Hazards
- Slipping
- Falling Rocks
- Landslide
- Avalanches
- Altitude Sickness

Valley

Valley
4/5
A beautiful location hidden from sight with plenty of water and resources.

A valley is a low area between hills or mountains often with a river running through it. In geology, a valley or dale is a depression that is longer than it is wide.

Advantages
- Water
- Flora
- Fauna
- Concealed
- Hunting

Disadvantages
- Low Visibility

Valleys provide shelter from storms, wind and a variety of other natural phenomenon and often have a river flowing through them. If there's no river, water can be obtained by digging at the lowest points until it flows into the hole. Wild animals are likely to be a big risk here, especially those large enough to tear you apart. The ample water will draw them all here.

Hazards
- Floods
- Flash Floods
- Avalanches
- Landslides
- Falling Rocks
- Wild Animals

2 Continental Plain

Ice Sheet

Ice Sheet 1/5 Extremely cold and barren environment with no flora and very little fauna.	An ice sheet is a mass of glacier ice that covers surrounding terrain and is greater than 50,000 km2 (19,000 sq mi).	**Advantages** ● Far From Civilization	**Disadvantages** ● Impossible to Sustain Life ● Little Flora ● Little Fauna ● Lifeless Landscape ● Nothing to Do ● 6 Months Day/Night

Only added to include everything, if you tried living here in a SHTF scenario and are planning to catch your own food you're likely to run out very quickly. This location may work as a hideout if you brought a shipload of food and other resources then stored it away, or just lived off the ship. This method would be particularly useful if the rest of the world was involved in a global war.	**Hazards** ● Freezing ● Avalanches

Plain

Plain 3/5 Open flat plains great for surviving on and great for farming. Watch out for flooding.	A plain is a flat, sweeping landmass that generally does not change much in elevation. Plains occur as lowlands along the bottoms of valleys or on the doorsteps of mountains, as coastal plains, and as plateaus or uplands.	**Advantages** ● Nearby Mountain Lookout ● Line of Sight ● Soft Grass ● Crop Planting	**Disadvantages** ● Easily Visible ● Few Trees

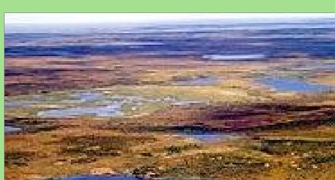
Grasslands would be a fairly good location for a campsite as there's not many risks of disasters provided you're far enough away from mountains. The mountain will provide a great lookout point and can work as an escape point if flooding does occur in the plains. The land would be soft and fertile, perfect for planting large amounts of crops.	**Hazards** ● Flooding ● Avalanche

Steppe

Steppe 2/5 Few trees and shrubs around so you're easily visible. May be difficult to shelter build and have fires without wood.	A steppe is an ecoregion in the montane grasslands and shrublands and temperate grasslands, savannahs and shrublands biomes, characterized by grassland plains without trees apart from those near rivers and lakes.	**Advantages** ● Line of Sight ● Soft Grass ● Crop Planting	**Disadvantages** ● No Trees ● You're Easily Visible ● No Protection

A steppe may provide a suitable camping/BOL but you will be easily visible from quite a distance due to the plain terrain. There might be quite a hike for any form of resources such as wood, food and water. You will also be exposed to any weather even that may arise.	**Hazards** ● Wildlife

Tundra



Tundra 1/5 Extremely cold and barren environment which takes special training to survive in.	Tundra is a type of biome where the tree growth is hindered by low temperatures and short growing seasons.	**Advantages** ● Few People	**Disadvantages** ● Few Animals ● Polar Bears

The tundra environment would be a difficult one to survive in for long periods due to the shortage of resources like flora and fauna. Wood would be hard to obtain to keep warm with and it's tough for anything to grow in this cold environment.	**Hazards** ● Extreme Cold

3 Fluvial

Alluvial Fan

Alluvial Fan 3/5 plenty of rocks which can be used to build a shelter. Never build near the rocks. Fair amount of trees and resources.	An alluvial fan is a fan- or cone-shaped deposit of sediment crossed and built up by streams. If a fan is built up by debris flows it is properly called a debris cone or colluvial fan.	**Advantages** ● Construction Material	**Disadvantages** ● Obvious from Satellite ● Rocky Ground ● Few Trees Under Fan

An alluvial fan is a strange terrain form based on rocks but could be beneficial during construction projects. Don't set up camp on the fan as the sediment is placed there by a strong water flow, but somewhere nearby on higher ground so you can still use the rocks in your house.	**Hazards** ● Flash Flooding

Beach

Beach 4/5 A nice location with lots of resources such as fish and trees. Don't build on the sand. Fairly exposed to bad weather.	A beach is a landform alongside a body of water which consists of loose particles. The particles composing a beach are typically made from rock, such as sand, gravel, beach, pebbles, or cobblestones.	**Advantages** ● Scenic ● Water ● Visible from Air (Rescue)	**Disadvantages** ● Sand Construction ● Very Windy ● Rusts Metal Faster ● Visible from Air (Combat) ● Water Desalination Req.

Possibly everyone's ideal bug out scenario where you sit on the sand drinking coconuts. The sand would make it difficult to build a permanent shelter but heading inland a bit more can provide better protection. A private beach would be best, especially one which is surrounded by steep hills and rocks similar to the picture. If you're near large oceans you need to be mindful that earthquakes can trigger large tsunami's which can wipe out your shelter within hours.

Hazards
- Tsunamis
- High Tide
- Storm Surge
- Cyclones/Hurricanes

Canyon

Canyon
2/5
A barren landscape with nearly sheer drops and few trees. Little water and has a risk of flash floods.

A canyon or gorge is a deep cleft between escarpments or cliffs resulting from weathering and the erosive activity of a river over geologic timescales.

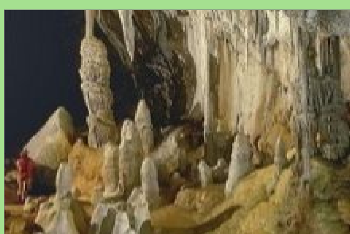
Advantages
- Shelter
- Hideaway
- Hidden from View

Disadvantages
- Difficult Climb
- Rocky Terrain
- Few Trees
- Few Animals
- Few Escape Points
- Possibly Strong Winds

Never camp in the depression of a canyon as they are formed by erosion and rivers but look for higher ground overlooking it. Generally canyons are barren landscapes but occasionally they can be lush and vibrant. You may have a hard time acquiring food and water in this landscape due to being quite barren.

Hazards
- Flash Flooding
- Flooding
- Erosion
- Falling Rocks
- Slipping

Cave



Cave
5/5
Excellent location, choose one deep enough which isn't prone to flooding. Ensure no animal has made their home inside it. May contain water and sheer drops.

A cave is a hollow place in the ground, specifically a natural underground space large enough for a human to enter.

Advantages
- Pre-Made Shelter
- Hidden from Everything
- Keeping Dry

Disadvantages
- Possibly Few Exits
- Fire Smoke Build-up

Caves are probably one of the best landforms to camp in depending on the type of cave. Some can be a few metres deep and others can be huge complexes. Be careful to scout the cave completely before setting up inside one and look out for signs that something already lives inside it. Caves can be extremely deep and can often have vertical cliffs inside them. If they go on endlessly, block off a section and use it as a shelter. Make a map of the internals of a cave so you don't get lost inside and document any important features there are such as running water and other entrances. Be especially sure you check the strength of the cave so it doesn't collapse on top of you while you're inside. You can also reinforce the ceiling by building wooden structures inside. Be especially sure that a cave near sea level won't flood at high tide and that there's always at least one exit at all times - unless you don't mind being cut off for a few hours a day.

Hazards
- Flooding
- Flash Flooding
- Falling Rocks
- Collapsing Walls
- Wild Animals
- Becoming Lost
- Steep Cliffs

Cliff

Cliff
3/5
Cliffs make great lookouts and provide nice protection on one side, but you are fairly exposed.

A cliff is a vertical, or nearly vertical, rock exposure.

Advantages
- Line of Sight
- Flank Protection

Disadvantages
- Windy

Cliffs aren't recommended for camping/survival locations, although they will protect your flank and give you a great view over the edge. Don't camp too close to the edge in case of landslides.

Hazards
- Falling
- Erosion
- Landslides

Floodplain

Floodplain
2/5
You should never camp on a known floodplain as you could get washed away. Even one-nighters are risky if there's rain nearby.

A floodplain is an area of land adjacent to a stream or river which stretches from the banks of its channel to the base of the enclosing valley walls, and which experiences flooding during periods of high discharge.

Advantages
- Easy Water Access
- Lots of Wildlife

Disadvantages
- Mosquitoes/Bugs
- Wild Animals

You should never camp in the lower flat areas beside a river as they could easily flood in times of heavy rain. Instead you should look for an area of higher ground near the river, but even this may not be high enough in times of extreme rainfall.

Hazards
- Flooding
- Flash Flooding
- Crocodiles

Lake

Lake
5/5
A great location with ample resources, food and water.

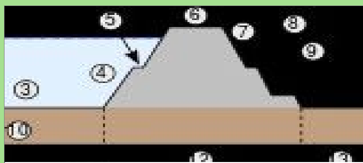
A lake is an area filled with water, localized in a basin, that is surrounded by land, apart from any river or other outlet that serves to feed or drain the lake.

Advantages
- Easy Water Access
- Abundant Wildlife
- Bathing
- Fishing

Disadvantages
- May Freeze in Winter
- Mosquitoes/Bugs

Camping/surviving beside a lake is a commonly chosen location but it's best to be at least 100m (328ft) from the water's edge. Lakes allow unlimited water collection and often sport a bounty of animals, trees and edibles nearby too. They are great for bathing in if the temperature is warm and can be crossed easily by boat.	**Hazards** • Flooding • Crocodiles • Flooding

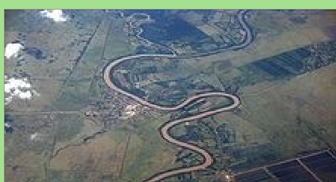
Levee



Levee 3/5 A fairly safe landform to camp on flooding wise and will provide water. You are fairly exposed however.	A levee dike, dyke, embankment, floodbank or stopbank is an elongated naturally occurring ridge or artificially constructed fill or wall, which regulates water levels.	**Advantages** • Ability for Dam • Water Access • Ample Wildlife	**Disadvantages** • May Breakdown

Don't camp on the lower sides of a levee as they could flood in times of great rainfall. The embankment could also break and flood the other low side. Camping at the top of the ridge should protect you from the water but you will be exposed to the elements and a line of sight from others.	**Hazards** • Flooding

Meander



Meander 3/5 Good water source, but be careful from flooding. More difficult to use a boat on.	A meander is one of a series of regular sinuous curves, bends, loops, turns, or windings in the channel of a river, stream, or other watercourse.	**Advantages** • Water Source • Fishing	**Disadvantages** • Longer Sailing Distance

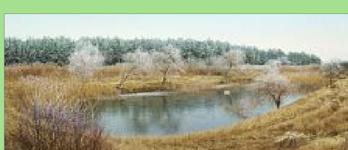
Choosing a BOL along a meander can be a good location if it's sufficiently high to avoid flooding of the river should it occur. However if it does flood you will likely be trapped on your newfound island until the water subsides.	**Hazards** • Flooding • Flash Flooding

Oasis

Oasis 2/5 Attracts a lot of animals but you may run out if the oasis is small. Few resources for building with.	An oasis is an isolated area in a desert, typically surrounding a spring or similar water source, such as a pond or small lake.	**Advantages** • Water • Animals • Aquatic Life	**Disadvantages** • Surrounding Desert • Obvious Hideaway • Very Hot (Day) • Very Cold (Night) • Wild Animals • Few Building Materials

An oasis may sound like a perfect place to bug out to however it's certainly an obvious location if you're running from someone in particular. There's a limited number of trees which will make shelter construction and firewood risky to do, often at the cost of natural shade and sometimes edible fruit trees. There may not be many natural food options fishing and hunting wise but the local animals are sure to gather to this spot for their water requirements. It will be difficult to leave this location due to the surrounding desert and the lack of other water sources.	**Hazards** • Hypothermia • Hyperthermia • Wild Animals

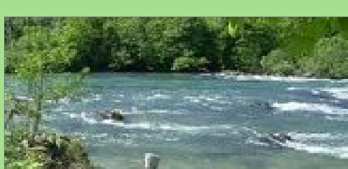
Pond



Pond 4/5 Pond water requires more filtration but also attracts a lot of wild animals.	A pond is a body of standing water, either natural or artificial, that is usually smaller than a lake.	**Advantages** • Water • Aquatic Life • Drinking Hole	**Disadvantages** • Easily Fished Out • Stagnant Water

Camping near a pond will give you sufficient water but if you're fishing from it, you may run out of fish fairly quickly depending on the size of it. Animals should be plenty around this area which will come to drink in the mornings and afternoons.	**Hazards** • Flood Risk • Mosquitoes • Bacteria/Pollution

Rapids



Rapids 4/5 A fast flowing river makes it easy to flee and often sports a variety of fish and healthy trees.	Rapids are sections of a river where the river bed has a relatively steep slope.	**Advantages** • Quick Getaways • Water • Washing	**Disadvantages** • Can't Swim • No Boats • Little Aquatic Life • Harder to Hear

A fast flowing river provides almost identical benefits of a regular river (below) including a water source and food. Rapids can provide the unique tool of a fast escape if you need one and have a boat on standby, but should only be attempted if desperate. Before attempting a getaway you should know what lies ahead in the river, whether it's large rocks, a lake or a waterfall.	**Hazards** • Flood Risk • Being Washed Away

River

River

	**River** 4/5 The most optimum location to camp but ensure it's wide enough so it doesn't dry up in summer. Camp high in case it floods.	A river is a natural flowing watercourse, usually freshwater, flowing towards an ocean, sea, lake or another river.	**Advantages** ● Fresh Flowing Water ● Aquatic Life ● Washing	**Disadvantages** ● Wet Crossing
A river can provide a constant source of clean water to drink from and wash with as well as fish. The water is constantly renewed and refreshed unlike a lake so there's less of a worry of contamination. Ensure you set up camp at least 100m (328ft) from the river and preferably uphill slightly to avoid the threat of flooding.				**Hazards** ● Predators ● Flooding

River Mouth

	**River Mouth** 3/5 A mix of fresh and saltwater making it a requirement to desalinate, upriver is a better option.	A river mouth is the part of a river where the river flows into another river, a lake, a reservoir, a sea, or an ocean.	**Advantages** ● Fresh and Saltwater ● Access to Salt ● Flowing Water	**Disadvantages** ● Contaminated Freshwater
A river mouth is another location similar to a river (above) but with the added benefit of having the ocean or another river nearby as additional water sources. It's best not to choose a location on the corner of the intersection as it's likely to flood in heavy rains but if it's considerably above the ground level then it should be safe.				**Hazards** ● Predators ● Flooding

River Valley

	**River Valley** 4/5 Often very rocky and sometimes creates underwater rivers. Camp up higher.	A valley formed by flowing water, called fluvial valley or river valley, is usually V-shaped.	**Advantages** ● Concealed ● Flowing Water ● Rocky Floor ● Fishing	**Disadvantages** ● Low Line of Sight
Again this is similar to a river but pressed further into the landscape and may sometimes flow in and out of small caves and underground. It's recommended not to camp close to the river depression as the water is likely to reach a high level when it rains a lot. Watch out for water marks showing where the water level has previously reached. These marks include grasses on high branches, bent trees and grasses at a high tide level.				**Hazards** ● Flooding ● Flash Floods ● Wildlife

Strait

	**Strait** 3/5 Great for boats and fishing in and often has a variety of resources.	A strait is a naturally formed, narrow, typically navigable waterway that connects two larger bodies of water. Most commonly it is a channel of water that lies between two land masses.	**Advantages** ● Fishing ● Boating	**Disadvantages** ● Hard to Cross ● Easily Spotted
Similar to lakes and beaches where you have access to a lot of water but the difference is to reach the other landmass you will have to cross the water. Great location if you have a ship or a bunch of ships to protect them from incline weather.				**Hazards** ● Threats on the Land ● Dangerous Sea Life

Swamp

	**Swamp** 2/5 A difficult location to survive in, footwear will be constantly wet, lots of bugs.	A swamp is a wetland that is forested. Many swamps occur along large rivers where they are critically dependent upon natural water level fluctuations.	**Advantages** ● Hard to be spotted ● Ample Wood	**Disadvantages** ● Thick Vegetation ● Wet Boots ● Viral/Bacterial Water ● Lack of Land
A swamp will shelter you well from those seeking to find you but you will have a lot of natural threats to deal with such as water being everywhere and having damp and cold feet. Any shelter you construct will likely have to be above ground to avoid the water, either in the trees or between trees such as a hammock. It's only recommended to set up in a swamp if it's your last option, but it can be done successfully, it will just be challenging to survive in.				**Hazards** ● Mosquitoes/Bugs ● Hidden Crocodiles ● Trench foot

Waterfall

	**Waterfall** 4/5 Waterfalls sport a water source and a free shower however the sound may draw people to it.	A waterfall is a place where water flows over a vertical drop or a series of steep drops in the course of a stream or river.	**Advantages** ● Shower/Bathing ● Camouflages Noise	**Disadvantages** ● Harder to Hear ● May Draw People

You have 3 options of where to camp near a waterfall, the top, the bottom or inside it (if applicable), each has its own benefits and risks involved. Camping at the top keeps one side of your camp safe from people and predators and reduces the noise of the water significantly. Camping at the bottom lets you have waterfall showers to get clean and it masks some of the noise you make. Camping inside the waterfall is probably the best option combining a cave with a waterfall to provide a secure shelter, hidden from sight and a masking noise.	**Hazards** • Slipping • Flooding • Falling Rocks

4 Glacial

Arête

	Arête 3/5 A high location which may have water in the valleys and often has lots of resources. Ground is rocky rarely flat.	An arête is a narrow ridge of rock which separates two valleys.	**Advantages** • Line of Sight • One Sided Wind Shield	**Disadvantages** • Not Flat • Often Rocky • May be in Clouds
An arête could make a fine shelter if you can find some land flat enough and ensuring that the terrain goes high enough above the valleys to avoid floodwaters if they occur. If a flood occurs you might become cut off from the mainland until the water subsides which could take up to a few days depending on how deep the valleys are.				**Hazards** • Falling • Slipping • Rockslide

Cirque

	Cirque 3/5 Provides a level of shelter and elemental protection but may flood easily.	A cirque is an amphitheatre-like valley formed by glacial erosion.	**Advantages** • Weather Protection • Hidden • Water Deposit	**Disadvantages** • Rocky • Few Trees
These can provide you with some great elemental protection but are often prone to flooding due to their low set nature. They are very rocky and it may be a challenge to find enough trees to use for firewood or shelter building.				**Hazards** • Flooding

Esker

	Esker 2/5 An often barren landscape with few resources.	An esker or eschar is a long, winding ridge of stratified sand and gravel, examples of which occur in glaciated and formerly glaciated regions of Europe and North America.	**Advantages** • Navigational Mark • Wind Wall	**Disadvantages** • Obvious Location • Easily Spotted • Cold • Barren Landscape
A fairly barren environment caused by glaciers with limited trees and flora nearby. These landforms aren't likely to house many fauna due to the lack of water nearby too.				**Hazards** • Glaciers

Fjord

	Fjord 3/5 A scenic location but tricky to climb repeatedly to retrieve resources. Often rocky.	A fjord or fiord is a long, narrow inlet with steep sides or cliffs, created by a glacier.	**Advantages** • Concealed Entry • Line of Sight	**Disadvantages** • Few Disembark Points • Lots of Climbing
A fjord is certainly a breathtaking landform but not very ideal when you need to fetch water and other resources by going up and down a cliff multiple times a day. If you can find some kind of cave on the side of a fjord that would be a great location to use, and you can then design a pulley system to fetch watch when you need it.				**Hazards** • Falling Rocks • Erosion

Glacier

	Glacier 1/5 Glaciers are constantly moving so your shelter will likely fall apart or slide into an ocean.	A glacier is a persistent body of dense ice that is constantly moving under its own weight; it forms where the accumulation of snow exceeds its ablation (melting and sublimation) over many years, often centuries.	**Advantages** • Changing Landscape • No People	**Disadvantages** • Unsafe for Shelter • Cold
You should never build a shelter on a glacier as the slow moving ice will thwart any attempt to complete an upright structure and because over time it won't be where you built it since glaciers can move on average 30m (98ft) per day.				**Hazards** • Shelter May Move • Destroys Shelter

Tunnel Valley

	Tunnel Valley 3/5 Often very cold but offers some shielding from the weather.	A tunnel valley is a large, long, U-shaped valley originally cut under the glacial ice near the margin of continental ice sheets such as that now covering Antarctica and formerly covering portions of all continents during past glacial ages.	**Advantages** ● Shielded ● Lookout Points	**Disadvantages** ● Very Cold
Glaciers which have filled with vegetation are the ideal choices as there are also tunnel valleys without trees.				**Hazards** ● Glaciers ● Avalanches

5 Oceanic and Coastal

Atoll

	Atoll 3/5 Isolated from others and may be difficult to reach but it could sport a great variety of resources and food. The atoll may be very small sometimes and survival will be hard.	An atoll sometimes called a coral atoll, is a ring-shaped coral reef including a coral rim that encircles a lagoon partially or completely.	**Advantages** ● Fishing ● Swimming ● Secluded	**Disadvantages** ● Little Land ● Hard to Reach ● Rusts Metal Faster ● Water Desalination Req.
An atoll would be quite a unique experience to bug out to but may be difficult getting there and sustaining yourself for long periods. You are very likely to be alone permanently and have a large variety of seafood all to yourself. However there are often poisonous sea creatures. Depending on the thickness of the atoll there may be few trees to use and running out of wood and other resources is something to keep in mind.				**Hazards** ● Sea Predators ● Poisonous Creatures

Bay

	Bay 4/5 A semi protected landform from LOS, tsunamis and strong winds and makes a good location for boating.	A bay is a recessed, coastal body of water that directly connects to a larger main body of water, such as an ocean, a lake, or another bay.	**Advantages** ● Aquatic Life ● Fishing ● Sheltered Water	**Disadvantages** ● Very Windy ● Rusts Metal Faster ● Water Desalination Req.
A bay is similar to a beach for bugging out to but it provides a greater level of protection from large waves from open waters. It may be easier to fish in a bay due to a higher level of underwater sand versus a regular beach.				**Hazards** ● Sea Predators

Cape

	Cape 4/5 Uninhabited capes are a great choice for survival with water on all sides for fishing and often ample resources.	In geography, a cape is a headland or a promontory of large size extending into a body of water, usually the sea.	**Advantages** ● Secluded ● Water ● Fishing	**Disadvantages** ● Long Distance ● Salty Air ● Very Windy ● Rusts Metal Faster ● Water Desalination Req.
Camping at the end of a cape could be a nice secluded area and provide a similar experience to an island - but connected to the mainland. You would have great views of the surrounding ocean and have a lot of opportunity to catch sea life. The risks include high tide which could cut you off from the mainland and tsunami's which are guaranteed to be deadly.				**Hazards** ● Tsunamis ● High Tide ● Storm Surge

Channel

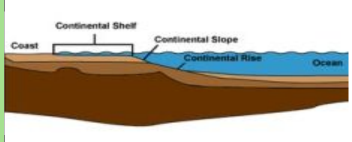
	Channel 3/5 A fairly shallow river great for fishing in, but you risk it flooding in downpours.	A channel is a type of landform consisting of the outline of a path of relatively shallow and narrow body of fluid, most commonly the confine of a river, river delta or strait.	**Advantages** ● Fresh Water ● Aquatic Life ● Walk Across Easily	**Disadvantages** ● Few Large Fish
A channel is great for fishing in but may contain dangerous animals such as crocodiles. There's a risk of flooding due to the shallow nature of the channel.				**Hazards** ● Predators ● Flooding

Coast

	Coast 4/5 The coast is a great place to get both good resources and allow fishing.	A coastline or a seashore is the area where land meets the sea or ocean, or a line that forms the boundary between the land and the ocean or a lake.	**Advantages** ● Fishing ● Salt	**Disadvantages** ● Windy ● Cold ● Rusts Metal Faster ● Water Desalination Req.

A great place to bug out to with a variety of resources and the ability to fish from. It allows fast travel by a boat if desired as well.	**Hazards** • Tsunamis • Tropical Storms

Continental Shelf



Continental Shelf			
Continental Shelf 3/5 A coastal shelf makes fishing easier and allows wading out to nearby islands.	The continental shelf is an underwater landmass which extends from a continent, resulting in an area of relatively shallow water known as a shelf sea.	**Advantages** • Hand Fishing • Degrades Tsunami's	**Disadvantages** • Tidal Change • Windy • Rusts Metal Faster • Water Desalination Req.

A landmass which could be perfect for fishing on due to the fairly shallow shelf. It will also cause any tsunami's to lose their power very fast.	**Hazards** • Flooding • Predators

Coral Reef

Coral Reef			
Coral Reef 2/5 Excellent place for your choice of seafood and it's easy to obtain.	Coral reefs are diverse underwater ecosystems held together by calcium carbonate structures secreted by corals.	**Advantages** • Abundant Food	**Disadvantages** • Underwater • Requires Swimming Skills • Requires Diving Skills

A coral reef can provide you with an abundance of fish if you have the skills to catch them.	**Hazards** • Poisonous Creatures • Sharks

Estuary

Estuary			
Estuary 3/5 Lots of water to choose from but may flood in times of downpour.	An estuary is a partially enclosed coastal body of brackish water with one or more rivers or streams flowing into it, and with a free connection to the open sea.	**Advantages** • Hand Fishing	**Disadvantages** • Brackish Water • Water Desalination Req.

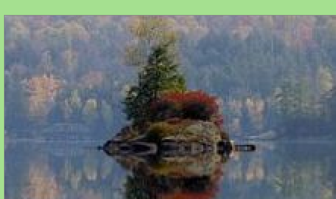
An estuary will trap fish that swim into it during high tide which can be caught easier during low tide.	**Hazards** • Predators

High Island

High Island			
High Island 1/5 Very formidable landmass with little flora or fauna and a chance of eruption.	In geology a high island or volcanic island is an island of volcanic origin.	**Advantages** • Being Alone • Line of Sight • No People	**Disadvantages** • Hard to Reach • Few/No Trees • Few/No Fauna • Very Rocky • Very Windy • Water Desalination Req.

A volcanic island isn't an optimum place to survive on due to the lack of flora and fauna and the need to desalinate all the water you drink.	**Hazards** • Sharp Rocks

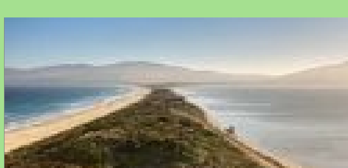
Island



Island			
Island 5/5 Assuming the island is big enough and doesn't have anyone else on it and has the required resources to survive.	An island or isle is any piece of sub-continental land that is surrounded by water.	**Advantages** • No People • Water • Fishing • Line of Sight	**Disadvantages** • Hard to Reach • No/Little Food • Open to the Elements

One of the most ideal locations to bug out to, a private island can provide you with ample resources such as food, water and protection from predators and people.	**Hazards** •

Isthmus



Isthmus			
Isthmus 2/5 You will easily be found by other people moving from one landmass to the other.	An isthmus is a narrow piece of land connecting two larger areas across an expanse of water by which they are otherwise separated.	**Advantages** • Water • Fishing • Line of Sight	**Disadvantages** • Easily Spotted • People Crossing

Not an optimal place for a survival camp due to the fact it's often very thin and people will be driven along it and are very likely to find your camp.	**Hazards** • Tsunami • Floods

Lagoon

Lagoon

Lagoon
4/5
A personal swimming hole with lots of resources nearby and it's easy to catch fish.

A lagoon is a shallow body of water separated from a larger body of water by barrier islands or reefs.

Advantages
- Fishing

Disadvantages
- Tide Variable

A lagoon is similar to an estuary but sealed off from a large body of water which should make fishing much easier as well as the water being shallower.

Hazards
- Predators

Peninsula

Peninsula
4/5
Fairly secure location for survival with the ocean and other resources nearby.

A peninsula is a piece of land surrounded by water on the majority of its border, while being connected to a mainland from which it extends.

Advantages
- Water
- Fishing

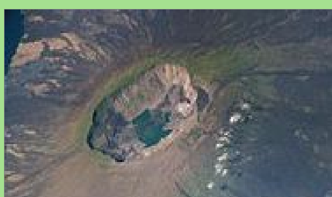
Disadvantages
- One Escape Route

Another fairly good piece of land to survive on, especially if you can seal off the only link to it so you can have the whole place to yourself. Peninsula's can range from very small to huge and often provide a high level of security. There is only one exit however, unless you have a boat.

Hazards
- Tsunami

6 Volcanic

Caldera



Caldera
5/5
Perfect, shielded location with ample water, flora, supplies and often far from people.

A caldera is a large cauldron-like depression that forms following the evacuation of a magma chamber/reservoir.

Advantages
- Environment Protection
- Water
- Few/No People

Disadvantages
- Obvious Position
- High Altitude
- Flooding

This would be an optimum place for a camp but you just have to ensure that it's not going to erupt while you're living in it. You're highly protected from most weather events if you set up camp within the lip of the volcano and have amazing views and line of sight to protect yourself from enemies. Make sure that it's not likely for the entire caldera to fill up with water during heavy rainfall. You can also make an artificial drainage channel to prevent this.

Hazards
- Eruptions
- Flooding
- Rockslides

Crater Lake

Crater Lake
4/5
A nice location with ample resources but at a risk of flooding and other people.

A crater lake is a lake that forms in a volcanic crater or caldera, such as a maar; less commonly and with lower association to the term a lake may form in an impact crater caused by a meteorite, or in the crater left by an artificial explosion caused by humans.

Advantages
- Environment Protection
- Water

Disadvantages
- Obvious Position
- High Altitude

Basically the same as a caldera but usually found at lower altitudes and created by meteors or artificial explosions. You lose a bit of an advantage from a caldera due to the fact a crater lake is often pushed into the ground and not situated on a mountain which makes it more prone to flooding.

Hazards
- Flooding
- Other People

Geyser

Geyser
2/5
May provide warmth and water at a risk of volcanic activity.

A geyser is a spring characterized by intermittent discharge of water ejected turbulently and accompanied by steam.

Advantages
- Warm/Hot Water/Springs
- Hard Water
- Hot Shower

Disadvantages
- May not Shoot

As spectacular geysers are they aren't an ideal location for bugging out to as the geological events occurring below the ground could become unstable very quickly.

Hazards
- Burns
- Eruptions
- Earthquakes

Lava Dome

Lava Dome
1/5
Very few resources and difficult to pitch a shelter on.

In volcanology, a lava dome or volcanic dome is a roughly circular mound-shaped protrusion resulting from the slow extrusion of viscous lava from a volcano.

Advantages
- Line of Sight

Disadvantages
- No Flora
- Rocky Land

Basically a rock with very little resources nearby. It is also difficult to climb and there's nothing of value on this landform.

Hazards
- Eruptions
- Falling Rocks

Lava Field

	**Lava Field** 1/5 Very little resources and difficult to build on and exposure to the elements.	A lava field, also called a lava plain or lava bed, is a large expanse of nearly flat-lying lava flows.	**Advantages** • Line of Sight	**Disadvantages** • Easily Spotted • Rocky Land • Little Water • Little Flora • Little Fauna
A flat, nearly lifeless field with little vegetation and even less animal life.				**Hazards** • Fresh Lava

Lava Plateau

	**Lava Plateau** 1/5 Very little resources and difficult to build on and exposure to the elements.	Lava plateaus are formed by highly fluid (runny) basaltic lava during numerous successive eruptions through numerous vents without violent explosions (quiet eruptions).	**Advantages** • Generally Flat • Line of Sight	**Disadvantages** • Little Flora • Little Fauna • Rocky Land • Little Water
A flat, nearly lifeless field with little vegetation and devoid of animal life. The lava may have made strange shapes and could offer a cave to dwell in.				**Hazards** • Eruptions

Volcanic Crater

	**Volcanic Crater** 2/5 Susceptible to flooding and has little flora.	A volcanic crater is a roughly circular depression in the ground caused by volcanic activity.	**Advantages** • Hidden Well • Environment Protection	**Disadvantages** • Little Flora • Rocky Land
Very rocky and has a potential to fill up with water in downpours. There isn't much vegetation nearby and little animal life.				**Hazards** • Eruptions • Flooding

Volcano

	**Volcano** 1/5 Too risky to permanently camp on and few resources nearby.	A volcano is a rupture in the crust of a planetary-mass object, such as Earth, that allows hot lava, volcanic ash, and gases to escape from a magma chamber below the surface.	**Advantages** •	**Disadvantages** • Rocky Land
Danger of eruption and a lifeless terrain consisting of rocks and hardened lava.				**Hazards** • Eruptions

Wall Rock

	**Wall Rock** 2/5 Provides some protection at a risk but few resources nearby overall.	Wall rock is the rock that constitutes the wall of an area undergoing geologic activity.	**Advantages** • Wind Protection	**Disadvantages** • Rain Off-pour • Erosion
The rock wall could provide some degree of protection but rocks could also fall from the top if you camp at the sides of it. Dwelling on top of this structure is dangerous.				**Hazards** • Falling Rocks

7 Aeolian

Desert

	**Desert** 2/5 A difficult landscape to survive in but few people will be around and there's often water if dug for.	A desert is a barren area of landscape where little precipitation occurs and consequently living conditions are hostile for plant and animal life.	**Advantages** • Secluded • Line of Sight	**Disadvantages** • Little Water • Little Flora • Little Fauna • Temperature Extremes
A dry, hot and often flat landscape consisting of rocks, sand or dirt. Water is hard to find but there's often plant life nearby.				**Hazards** • Hyperthermia • Hypothermia

Dry Lake

Dry Lake 2/5 A dry lake which may contain salts and water if dug down, few resources nearby and temperature extremes.	A dry lake is either a basin or depression that formerly contained a standing surface water body, which disappeared when evaporation processes exceeded recharge.	**Advantages** • Line of Sight	**Disadvantages** • Deep Water • Little Flora • Temperature Extremes
A lake which has dried up and is extremely flat and desolate with little flora and fauna.			**Hazards** • Flash Flood

Dune

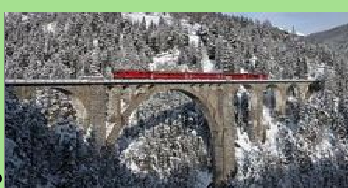
Dune 1/5 Better off surviving at a low point in a desert where water is more likely.	In physical geography, a dune is a hill of loose sand built by aeolian processes (wind) or the flow of water.	**Advantages** • Line of Sight	**Disadvantages** • Windy • Little Ground Strength • Little Water • Little Flora • Little Fauna • Temperature Extremes
It's never a good idea to build a shelter on sand, especially a mountain of sand which changes shape often.			**Hazards** • Sand Avalanche • Sand in the Air

8 Artificial

Artificial Island

Artificial Island 3/5 This island is likely to be heavily populated and you may have to travel to the mainland for resources.	An artificial island or man-made island is an island that has been constructed by people rather than formed by natural means.	**Advantages** • Water Source • Buildings	**Disadvantages** • Population
An artificial island created to house people on. There's likely to be structures on it already but be careful that it doesn't flood.			**Hazards** • Flooding

Bridge



Bridge 2/5 Fairly risky to camp on due to being exposed and make certain there won't be any trains/cars coming across.	A bridge is a structure built to span physical obstacles without closing the way underneath such as a body of water, valley, or road, for the purpose of providing passage over the obstacle.	**Advantages** • Crossing Point • Easy to Defend	**Disadvantages** • 2 Access Points • Easy to Spot • Elemental Exposure
A bridge could be a solid location for a shelter provided it's protected from the elements by a mountain and been well built. Wider bridges are better for shelters and offer more space. There's generally only 2 points of access to bridges making it easier to defend, although resources will need to be hauled up to them.			**Hazards** • Vehicles / Transport • Falling • Bridge Failure • Transport Crossing

Building

Building 5/5 Choose a building far from other people as this is typically the only risk facing this location.	A building, or edifice, is a structure with a roof and walls standing more or less permanently in one place, such as a house or factory.	**Advantages** • Weather Shelter	**Disadvantages** • Built Up Area
A building is the most common dwelling today, choose one that's secluded and has a lot of resources nearby naturally.			**Hazards** • Other People

Canal (Man-Made)

Canal 2/5 Canals are likely to be in larger cities and therefore dangerous to camp near.	Canals, or navigations, are human-made channels, or artificial waterways, for water conveyance, or to service water transport vehicles.	**Advantages** • Ample Water	**Disadvantages** • Often in Cities
Canals which are man made are very likely to be built up and therefore can be dangerous to live near.			**Hazards** • Other People

Dam

Dam

Dam
4/5
May be a hotspot for people to head to, but can provide unlimited water and electricity if maintained.

A dam is a barrier that stops or restricts the flow of water or underground streams.

Advantages
- Ample Water
- Electricity
- Strong Structure

Disadvantages
- Easily Spottable

Dams are a very solid structure which should be easy to defend from their edges although you could be ambushed with no escape point. They are likely to be targeted by enemy planes and ships so only head there once you're sure the war has left your area.

Hazards
- Flooding
- Dam Breaking
- Water Overflow

Ditch

Ditch
2/5
Ample water with the ability to transport it distances but may dry up or flood in heavy rain.

A ditch is a small to moderate depression created to channel water.

Advantages
- Water Transportation
- Water

Disadvantages
- Vehicle Barrier

A ditch is a simple channel which is built to transport water along particularly in farmland and to villages without water. Ditches may overflow if there's sufficient rain so always have that in mind. You could also create your own diversion to a campsite if you require - as blocking it completely might alert someone to your presence.

Hazards
- Flooding

Land Reclamation

Land Reclamation
2/5
Often highly built up and sometimes prone to flooding.

Land reclamation, usually known as reclamation, and also known as land fill (not to be confused with a landfill), is the process of creating new land from ocean, riverbeds, or lake beds.

Advantages
- At Sea Level

Disadvantages
- High Population
- Difficult to Escape

Reclaimed land is often built upon due to needing more land for various reasons.

Hazards
- Flooding
- Tsunami Risk

Polder

Polder
3/5
Would be perfect for farmland and water but prone to flooding.

A polder is a low-lying tract of land enclosed by dikes (levees) that form an artificial hydrological entity, meaning it has no connection with outside water other than through manually operated devices.

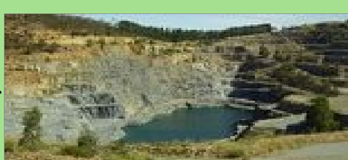
Advantages
- Ample Water
- Water Control
- Farming

Disadvantages
- Damp Ground

This would make a fair shelter location but enemies could destroy the levee and allow water to rush in if it's high enough. You could also generate electricity from the levee if there's somewhere the water can flow on to, or be used as.

Hazards
- Flooding

Quarry



Quarry
2/5
Few resources and may flood but provides some elemental protection.

A quarry is a place from which dimension stone, rock, construction aggregate, riprap, sand, gravel, or slate has been excavated from the ground.

Advantages
- Useful Rocks
- Wind Shelter

Disadvantages
- Low Line of Sight

A fairly barren location with few trees and wildlife. There's often a small lake at the bottom due to rain and water seepage.

Hazards
- Flooding

Reservoir

Reservoir
4/5
Provides ample water and there's often wood nearby, should make a good shelter location.

A large artificial lake used as a source of water supply.

Advantages
- Ample Water
- Good Line of Sight

Disadvantages
-

An artificial lake would provide a great source of water and will often have plenty of wildlife and resources such as trees nearby.

Hazards
- Flooding

Road

	**Road** 2/5 Abandoned roads could provide a fair location for a shelter but people may travel along the road and find you. Hard to fix down shelters.	A road is a thoroughfare, route, or way on land between two places that has been paved or otherwise improved to allow travel by foot or some form of conveyance, including a motor vehicle, cart, bicycle, or horse.	**Advantages** ● Easy Movement ● Generally Flat	**Disadvantages** ● High Population Area ● May be Blocked ● Hard to Affix Shelter
Roads are a risky shelter location as people often travel them either on food or in a vehicle. It's very difficult to set up a shelter on concrete, but at least it's flat and free of debris.				**Hazards** ● Traffic

Tunnel

	**Tunnel** 5/5 A tunnel could provide an excellent shelter from all forms of weather and a defence against people if the ends are blocked.	A tunnel is an underground passageway, dug through the surrounding soil/earth/rock and enclosed except for entrance and exit, commonly at each end.	**Advantages** ● Weather Shelter ● Easy Movement ● Bomb Shelter	**Disadvantages** ● Little Line of Sight ● Few Escapes ● Dark ● Possible Blockages ● No Solar Use
If setting up in a tunnel, make sure you know how it's drained and keep those systems operational. Don't use generators or you could be suffocated inside. The perfect tunnel would be one that has one end higher than the other or is an **inverted** "U" shape to allow water and air to flow through. Never choose a tunnel in a "U" shape that goes under the ground level. Tunnels will be very dark even during the day depending on their length so you will need some form of lighting it using lights or mirrors to bounce the light around. The biggest bonus for tunnels is their few entrances and the ability to resist gunfire, missiles and other forms of weapons, so they are the best choice in a war scenario.				**Hazards** ● Flooding ● Carbon Monoxide

7 Water Survival

This section describes how to survive on the ocean and how to properly cross bodies of water while heeding the dangers.

Swimming

Swimming is the self-propulsion of a person through water or other liquid, such as saltwater or freshwater environments, usually for recreation, sport, exercise, or survival. Swimmers achieve locomotion by coordinating limb and body movements to achieve hydrodynamic thrust that results in directional motion. Newborns can instinctively hold their breath underwater and exhibit rudimentary swimming movements as part of a survival reflex. Swimming requires endurance, skill, and efficient techniques to maximize speed and minimize energy consumption.

Treading Water

The swimmer is in the water head up and feet down. Different kicks, such as the whip kick or eggbeater kick, and hand movements (Sculling) are used to stay afloat. This is useful to keep the head out of the water for a better view or to catch an object as for example in water polo. In addition, treading water is used in training by competitive swimmers in order to build up the strength of the kick; butterfly or scissors kick are most common when training vertically.

Non-swimmers often splash and kick in an effort to stay above the surface but their lack of technique along with shortness of breath and the panic factor make for a very ineffective method of treading water. They will usually tire quickly and not be able to stay above the surface very long.

Experienced swimmers use a variety of techniques to stay above the surface. These techniques often involve sculling, flutter kick, and other unofficial techniques of staying above the surface.

Whip Kick / Frog Kick: Consists of two phases: bringing the feet into position for the thrust phase and the insweep phase. From the initial position with the legs stretched out backward, the feet are moved together towards the posterior, while the knees stay together. The knees should not sink too low, as this increases the drag. Then the feet point outward in preparation for the thrust phase. In the thrust phase, the legs are moved elliptically back to the initial position. During this movement, the knees are kept together. The legs move slower while bringing the legs into position for the thrust phase, and move very fast during the thrust phase.

Eggbeater Kick: The swimmer's back must be straight, knees bent so that the thighs are parallel to the surface of the water, and lower legs perpendicular to the surface.

The left foot makes a clockwise motion while the right leg makes a counterclockwise motion towards the axis of the body, in a similar manner to operating the pedals on a bicycle. The legs should never meet as when one foot is on the inside of the motion, the other should be on the outside. The arms are not involved directly in this kick. The most critical aspect to having an effective eggbeater kick is flexibility. A very good hip motion range is needed to achieve a good eggbeater kick.

Sculling: This is a figure 8 movement of the hands for forward motion or upward lift. Used in surf lifesaving, water polo, synchronized swimming and treading water.

Survival Floating / Drownproofing

Drownproofing is a method for surviving in water disaster scenarios without sinking or drowning. Lying on the prone (face down in water) with minimal leg movement, and staying afloat with the natural buoyancy. Lift the head to breathe only then return to floating again. This style is only to stay afloat and to rest. This is also known as dead man float and drownproofing.

In Drownproofing terminology, the great majority of people are "floaters". That is to say that, with the lungs fully inflated (or say at total lung capacity), they have slightly less specific gravity than water and will not start to sink until they exhale. An average floater has 3–4 lb (1.4–1.8 kg) of positive buoyancy in fresh water. "Sinkers" can also benefit from a modified technique, but will find it more difficult to learn and will probably need specialised coaching.

In the Drownproofing survival technique, the subject floats in a relaxed, near-vertical posture, with the top of the head just above the surface. Using the arms or legs to exert a downward pressure, the subject raises himself sufficiently so that the mouth is above the surface and a breath is taken, before dropping back into the relaxed float. This is done several times a minute (typically between 5 and 10), depending upon the needs of the individual. It is important to keep the lungs fully inflated for the maximum possible time and to exhale and inhale rapidly when a breath is taken. The technique is easy to learn and does not require arduous training or a high standard of physical fitness. With practice, it is possible to remain afloat in this way for a long time with minimal effort. Lanoue taught his students to perform the technique with hands and feet tied, thus demonstrating that it is possible to survive even when injured or otherwise disabled.

Back Floating

Similar to the survival floating, except on the back.

Front Crawl

The fastest style for swimming on the surface. Done while face down. The arms alternate while the legs perform a flutter kick.

Flutter Kick: Flutter kicks are a four-count exercise. Starting position is lying flat on the back with the feet and head approximately 6 inches (15 cm) off the ground. Hands are under the buttocks to support the lower back. Count one: raise the left leg to a 45-degree angle, keeping the right leg stationary. Count two: raise the right leg off the ground to a 45-degree angle while, at the same time, moving the left leg to the starting position. Counts three and four are repetitions of the same movements. Legs must be locked, with toes pointing away from the body.

Trudgen

The trudgen is similar to the front crawl, except that it is paired with a scissors kick, similar to that used in the sidestroke.

Scissors Kick: A scissor kick occurs when the legs are asymmetrical and the knees are apart. The legs move simultaneously but in different directions, like the blades of scissors.

Butterfly Stroke

Performed face down in the water. The legs perform a dolphin kick while the arms move symetrically in a forward circle at the same time. The butterfly stroke boasts a higher peak velocity than the front crawl, owing to the synchronous propulsion generated by the simultaneous pull/push of both arms and legs.

Dolphin Kick: The dolphin kick is named for its resemblance to the motions made by a swimming dolphin. It is typically used in competitive swimming immediately after a swimmer enters the water or after turns. The swimmer performs the kick by moving both legs together, vertically, which sends a wave through the swimmer's body, propelling them forward. The shoulders rise with a strong up and medium down kick, then lower with a strong down and up kick. A fluid undulation connects the motion. The feet are pressed together to avoid loss of water pressure. The feet naturally point downwards, give thrust downwards, move up the feet, and press down the head.

Breaststroke

Performed face down in the water without rotating the torso. The arms stay in the water and move synchronously, while the legs perform a whip kick (which is sometimes called a breaststroke kick). It is possible to keep the head elevated out of the water throughout the stroke, although the head usually dips in and out.

Whip Kick / Frog Kick: Consists of two phases: bringing the feet into position for the thrust phase and the insweep phase. From the initial position with the legs stretched out backward, the feet are moved together towards the posterior, while the knees stay together. The knees should not sink too low, as this increases the drag. Then the feet point outward in preparation for the thrust phase. In the thrust phase, the legs are moved elliptically back to the initial position. During this movement, the knees are kept together. The legs move slower while bringing the legs into position for the thrust phase, and move very fast during the thrust phase.

Backstroke

Done while lying on the back. One arm reaches behind the head with a fingertip entry while the other arm is by the side. The legs perform a flutter kick. In backstroke, the arms contribute most of the forward movement. The arm stroke consists of two main parts: the power phase (consisting of three separate parts) and the recovery. The arms alternate so that one arm is always underwater while the other arm is recovering. One complete arm turn is considered one cycle. From the initial position, one arm sinks slightly under water and turns the palm outward to start the catch phase (first part of the power phase). The hand enters downward (pinkie finger first) then pulling out at a 45-degree angle, catching the water.

During the power phase the hand follows a semi-circular path from the catch to the side of the hip. The palm is always facing away from the swimming direction, while remaining straight as an extension of the arm, and the elbow always points downward towards the bottom of the pool. This is done so that both the arms and the elbow can push the maximum amount of water back in order to push the body forward. At the height of the shoulders, the upper and lower arms should have their maximum angle of about 90 degrees. This is called the Mid-Pull of the power phase.

The Mid-Pull phase consists of pushing the palm of the hand as far down as possible with the fingers pointing upward. Again, the goal is to push the body forward against the water. At the very end of the Mid-Pull, the palm flaps down for a last push forward down to a depth of 45 cm, creating the finish of the power phase. Besides pushing the body forward, this also helps with the rolling back to the other side as part of the body movement. During the power phase, the fingers of the hand can be slightly apart, as this will increase the resistance of the hand in the water due to turbulence.

To prepare for the recovery phase, the hand is rotated so that the palms point towards the legs and the thumb side points upwards. At the beginning of the recovery phase of the one arm, the other arm begins its power phase. The recovering arm is moved in a semicircle straight over the shoulders to the front. During this recovery, the palm rotates so that the small finger enters the water first, allowing for the least amount of resistance, and the palms point outward. After a short gliding phase, the cycle repeats with the preparation for the next power phase.

Sidestroke

The sidestroke is a swimming stroke, so named because the swimmer lies on one's side with asymmetric arm and leg motion. It is helpful as a lifesaving technique and is often used for long-distance swimming. The sidestroke allows the swimmer increased endurance because instead of working both arms and legs simultaneously in the same way, the side stroke uses them simultaneously but differently. A swimmer tired of exercising one side can turn over and use the other, the change of action helping the limbs to recover.

On the side, pull the water as if with a rope with arms going out and stopping in the middle while ensuring that the strokes are most hydrodynamic when moving towards the desired location, and pushing the most water when moving away from the location. In addition, the legs are performing a scissors kick, which is like whip kick, but sideways.

Dog Paddle

The dog paddle or doggy paddle is a simple swimming style. It is characterized by the swimmer lying on their chest and moving their hands and legs alternately in a manner reminiscent of how dogs and other quadrupedal mammals swim. It is effectively a "trot" in water, instead of land. It is often the first swimming stroke used by young children when they are learning to swim. The dog paddle has also been taught as a military swimming stroke when a silent stroke is needed - since neither arms or legs break the surface.

Face over water and paddling with alternate hands, often with the nose and mouth above the water. This stroke can be used in reverse to propel the body feet first.

Snorkeling

Snorkeling is the practice of swimming face down on or through a body of water while breathing the ambient air through a shaped tube called a snorkel, usually with swimming goggles or a diving mask, and swimfins. In cooler waters, a wetsuit may also be worn. The snorkel may be an independent item or integrated with the mask. The use of this equipment allows the snorkeler to observe the underwater environment for extended periods with relatively little effort, and to breathe while face-down at the surface.

Snorkel: A snorkel is a device used for breathing air from above the surface when the wearer's head is facing downwards in the water with the mouth and the nose submerged. It may be either separate or integrated into a swimming or diving mask. The integrated version is only suitable for surface snorkeling, while the separate device may also be used for underwater activities such as spearfishing, freediving, finswimming, underwater hockey, underwater rugby and for surface breathing with scuba equipment. A swimmer's snorkel is a tube bent into a shape often resembling the letter "L" or "J", fitted with a mouthpiece at the lower end and constructed of light metal, rubber or plastic.

Diving

Underwater diving, as a human activity, is the practice of descending below the water's surface to interact with the environment. It is also often referred to as diving, an ambiguous term with several possible meanings, depending on context. Immersion in water and exposure to high ambient pressure have physiological effects that limit the depths and duration possible in ambient pressure diving. Humans are not physiologically and anatomically well-adapted to the environmental conditions of diving, and various equipment has been developed to extend the depth and duration of human dives, and allow different types of work to be done.

In ambient pressure diving, the diver is directly exposed to the pressure of the surrounding water. The ambient pressure diver may dive on breath-hold (freediving) or use breathing apparatus for scuba diving or surface-supplied diving, and the saturation diving technique reduces the risk of decompression sickness (DCS) after long-duration deep dives. Atmospheric diving suits (ADS) may be used to isolate the diver from high ambient pressure. Crewed submersibles can extend depth range to full ocean depth, and remotely controlled or robotic machines can reduce risk to humans.

Freediving

Freediving, free-diving, free diving, breath-hold diving, or skin diving, is a mode of underwater diving that relies on breath-holding until resurfacing rather than the use of breathing apparatus such as scuba gear. Besides the limits of breath-hold, immersion in water and exposure to high ambient pressure also have physiological effects that limit the depths and duration possible in freediving.

Scuba Diving

Scuba diving is a mode of underwater diving whereby divers use breathing equipment that is completely independent of a surface breathing gas supply, and therefore has a limited but variable endurance. The word scuba is an acronym for "Self-Contained Underwater Breathing Apparatus" and was coined by Christian J. Lambertsen in a patent submitted in 1952. Scuba divers carry their own source of breathing gas, usually compressed air, affording them greater independence and movement than surface-supplied divers, and more time underwater than freedivers. Although the use of compressed air is common, other gas blends are also used.

Open-circuit scuba systems discharge the breathing gas into the environment as it is exhaled and consist of one or more diving cylinders containing breathing gas at high pressure which is supplied to the diver at ambient pressure through a diving regulator. They may include additional cylinders for range extension, decompression gas or emergency breathing gas.

Closed-circuit or semi-closed circuit rebreather scuba systems allow recycling of exhaled gases. The volume of gas used is reduced compared to that of open-circuit, making longer dives feasible. Rebreathers extend the time spent underwater compared to open-circuit for the same metabolic gas consumption. They produce fewer bubbles and less noise than open-circuit scuba, which makes them attractive to covert military divers to avoid detection, scientific divers to avoid disturbing marine animals, and media divers to avoid bubble interference.

River Crossing

Different ways to cross a body of moving water safely.

Dangers

There are many dangers around crossing rivers, some of which may not be very obvious at first.

Water Speed	The water speed plays a huge factor in the danger of crossing the river, and geneally the one people think of the most. Further down in the River Crossing section, under Raft Crossing is the internationally accepted rating system for rafting on rapids. It will give you a scale of how dangerous a river is to try and cross.
River Width	The wider the river, generally, the more dangerous it will be. However when rivers widen, they often lose some depth.
Water Depth	The water depth, combined with its speed are two of the greatest factors in determining its safety. You want to look for a crossing point where the depth is generally unchanged.
Water Temperature	If the water is colder, it will make it more difficult to cross due to the 'shock' of freezing or cold water on your body.
Water Clarity	The muddier the water, the harder it will be to see threats under its surface.
Noise	Rapids can drown out your voice easily, so if you're with a team, use hand signals you all agree on before you begin.

SURVIVAL | Water Survival | River Crossing | Dangers

Moving Hazards	In deep, rapid flowing water, there may be debris such as logs being carried downstream which will likely knock you off your feet. Some flowing water can carry along boulders along the floor of the river.
Fixed Hazards	There could be fixed hazards under the surface of the water such as a chasm, tree roots, very sharp rocks or even sheared parts of metal man-made structures.
Tree Entrapment	Trees lying across the river surface with their branches hanging down form a natural sieve which can easily entrap a swimmer. If you cannot avoid floating towards a strainer or tree you must change position from the white water float position to a head first position. From this position a front crawl stroke can be used to assist the swimmer to propel themselves up and over the tree. This can be a difficult manoeuvre especially if the tree has a large trunk. As an absolute last resort if the swimmer cannot get up and over the tree, they must plan to dive underneath head first, timing their breathing and attempting to pull themselves through the branches. When participating in any recreational activity on rivers where trees are a factor participants must plan on scouting around corners before entering the water especially after floods.
Foot Entrapment	Foot Entrapment is a very common drowning scenario and is usually caused by swimmers finding themselves in relatively shallow moving water and attempting to stand up. In this situation it is very easy to wedge a foot between two large rocks especially if the swimmer is wearing hiking boots. The force of the current will carry their body forward forcing their head under the water. Once entrapment of this type occurs it is difficult if not virtually impossible for a victim to escape unaided. Rescuers must try and reach the victim without putting themselves at risk. This can be done by either shallow water crossing up fo the victim or as a last resort swimming down. The intention being to reach the victim and keep their head above water until extrication can be achieved.
Wildlife	The most dangerous wildlife you need to watch out for during crossings would be alligators, crocodiles, piranhas, jellyfish, bears, hippos and potentially sharks if you're a little upstream from the ocean. Keep in mind that crocodiles can hold their breath up to 8 hours and typically stay submerged for over 1 hour at a time. Alligators typically need to take a breath every 20 up to 45 minutes but can hold their breath many hours. See the 'Sea Threats' section below for more on wildlife dangers.

Crossing Basics

● Take the time to study the water and alternative routes before crossing.
● Have multiple points of contact at all times.
● Know your entry and exit points to the water.
● Don't fight the current, use it to help you cross by moving diagonally across it.
● Use mutual support if you are part of a team crossing.
● Avoid wearing baggy clothes.
● Swim if you fall in.
● Anticipate what could go wrong in the crossing and have a contingency plan for each event.

Crossing Point

Anticipate what would happen if someone is swept away. Choose a place where the water leads into easier conditions such as a calm pool or shallower water. Ensure you know the layout of the river and down the river a few hundred metres before you attempt to cross. Analyse the threats mentioned above at different point along the river and choose the safest location from them all.

Wading Across

When the current is strong, but still safe enough to cross, face upstream and shuffle across the river sideways. By crossing at a shallow diagonal angle, you can reduce the risk of being pushed backward and slipping on an unseen obstacle. Move one foot at a time. Do not cross your legs. Make small careful steps. Work your way sideways and slightly upstream using the full strength of your legs to keep yourself secure. Keep two points of contact securely pressed into the ground at all times. Make sure that each foot is firmly planted before you make your next move.

Pack Floating
Used where crossing is deep and the river is clear of debris and the current is not a problem. Hold the pack in front with one hand and use your other hand (with the aid of your legs) to propel your pack and yourself towards the bank. The contents of pack should be water-proofed before any pack float. Everyone pack floating should be able to swim.

If You Fall In
Your backpack will quickly become a waterlogged anchor that may rotate on top of you and pin you down. If this happens, save yourself by ditching your pack if you need to. Otherwise lean back on pack and face downstream and push down on pack straps to keep the pack on your back. Keep your feet in a running position and head diagonally towards the bank. Remove the pack only if you lose control of it and/or it pushes you under.

Unbuckle your pack before you start your crossing so that you can quickly jettison it if you're panicked during the crossing. It may be a good idea to keep the most essential items on your belt in case this happens. Only you can determine your essentials, but these are most likely to be a communication device, a knife, a water bottle and a tarp.

If You Are Swept Away without your Backpack
Point your feet downstream and ensure you are on your back. You want to look where you're going and use your feet to protect yourself from impacts. Protect your head and face as you go. Swim quickly to shore and away from hazards.

Pole Crossing

In most situations, you want to use one or two trekking poles or sturdy sticks. Lean into your pole(s) and lean into the current. It's debatable and situation dependent whether you want to use one or two poles. If the current is moving your poles around, you might find that you need both hands to manage a single pole. But if a single pole breaks or moves, you don't have the security of the second pole. It can be a good idea to remove your trekking pole basket to reduce drag.

SURVIVAL Water Survival River Crossing Pole Crossing

- Hold the pole diagonally across the body.
- Have your body parallel to the direction of river flow.
- Pole positioned upstream and moved through the water.
- Pole dimensions approximately 2 metres x 6cm.
- Pack straps loosened and waist band undone.
- Maximum depth of water approximately thigh deep.
- Lean on pole using it as a '3rd' leg as you move your feet forward.
- Move diagonally across and slightly downstream in an 'arc' fashion.
- Used for individual crossings.
- Lacks strength of mutual support methods.
- Suitable for rivers with reasonably smooth bottoms and no hazards down stream.
- Always wear footwear.

Long Pole Crossing (Group)

This is a group crossing technique where every member holds onto a long pole or tree branch and crosses.

- The group should be parallel to direction of the river flow.
- Strongest person on the upstream end, they also control the movement of the group.
- Second strongest person on the downstream end.
- Pack straps loosened. Waist belt undone.
- Upstream arm over and downstream arm under the pole. Everyone's arms should be linked together.
- The maximum water depth should be up to waist height.
- The pole diameter should be around 6-7 cm.
- The group should move diagonally across and slightly downstream.
- Used by groups of 3-6 people where river conditions are too dangerous for individual crossing.
- Very strong and stable method.
- Retreat backwards if conditions are too difficult. Do not turn around.
- Always wear footwear.

Mutual Support Crossing (Group)

A method for groups to use when crossing strong rivers when a long pole isn't available.

- Strongest person on the upstream end.
- Upstream person slightly forward.
- Second strongest person at downstream end.
- Link your arms at the elbow.
- The group should be parallel to the current.
- The maximum river depth approximately should be about thigh deep.
- Pack straps loosened and waist band undone.
- Used by groups of 3-5 people.
- Suitable for rivers with uneven beds.
- Groups move as a single unit.
- Always wear footwear.

Rope Crossing

Disclaimer
Ropes are often poorly used by backpackers crossing creeks. They can pin you down, strangle you and kill you in a multitude of ways. Don't even think about it unless you're a swiftwater expert. Make sure that nobody is ever tied into a rope and that the rope is never tied around the thrower if used to rescue someone in the water. A knife must be carried in an accessible position by the person controlling the rope in order to cut a trapped person free if this becomes necessary.

Carrying floating ropes is a major advantage in any river crossing, provided they are used with care and the group have practised in a safe environment beforehand. A rope throw bag is nylon bag with two ends - one end is a fixed size where the floating rope comes out and the other end has a drawstring to aid in the rope coming out when it's thrown. The small end of the bag has the rope with a loop tied into it so it can't be pulled back into the bag which is also threaded through a closed-cell foam pad to aid in flotation and a washer on either side of the foam. This is the end that the individual in distress grabs. Through the middle of the bag is the rest of the wound rope, with the other end coming out of the bag and is held by the rescuer or tied to a sturdy object.

Crossing with Injured

If there is an injured person in the party, it is best to stay and wait for help to arrive. But if the situation arises where an evacuation is required, the following two methods work well:

Mutual Support Using a Pole

This method is the same as the pole crossing except that the group will form two parallel lines behind the leader. The leader moves into the water, facing upstream with the pole out in front in both hands and the bottom end pushed into the river bed about a metre upstream. The rest of the team lines up in two parallel lines behind the leader. The pair directly behind the leader use their outside arm to pull down (not back) on the leaders shoulders or pack straps if wearing a pack and link their inside arms across each other's shoulders and so forth down the line.

It will depend on how many members in the party as to where the biggest and strongest members will be placed. They can either link inside arms with the patient sitting on their arms or sit the patient on a pole carried between them. The load can also be shared between two pairs in this manner with the pair in front supporting the legs. The patient if conscious can relieve some of the load by wrapping their arms around either shoulder of the main carriers. The load bearers are placed in the middle of the line and the rest of the party closes up to form mutual support.

Carrying a Stretcher

If the patient is seriously injured or too heavy for the above method, a stretcher can be made out of poles or rope. The stretcher is placed down the centre of the two lines and lifted with the inside arms of the rescuers. Each person in the line grasps the outside shoulder of the person directly in front with their outside arm as in the method above. The group closes up to gain mutual support and moves as a team under the instructions of the leader.

Never tie a person into a stretcher when crossing water in case the people carrying slip and fall. The patient if tied in would have no chance of survival unless rescued immediately. Do not place a patient face down in a stretcher or allow their head to go under the water. If the patient is strapped in, remove all ties before reaching the rivers edge and pack them safely away. Re-strap the patient only when the party is safely on the opposite shore. Carrying a patient on a stretcher successfully across a river will take some practice and will generally require a large group.

In all group crossing methods the person at the front of the line calls the commands and in the case of a large group will need to call loudly and clearly.

Swimming Across

When the river is too deep to walk and there is no other option such as walking down to the nearest bridge or waiting for the river to drop, the party may be able to cross by swimming. This does however carry a considerable risk factor especially if some of the party are not strong swimmers. It is the responsibility of the leader to always be aware of the capabilities of all members in the group.

Swimming, Using a Pack as a Float

This method is for strong swimmers only, as each person swims separately and therefore does not have any support from the rest of the party. Most swimmers will need a clear run and if there is any current a long run out so a careful choice of the crossing place is necessary. The swimmer wades out into the river facing upstream with the pack in front floating on the water. As long as it has been well packed, with all items secured inside a water proof bag, the pack will have considerable buoyancy.

As the water becomes deeper, the pack can be used like a kick board either held out in front or by pushing it under the chest area to keep the upper body slighily raised out of the water. The arms and legs are used for propulsion as one would when swimming and an attempt must always be made to stay facing upstream angling towards the far bank.

If the party has a rescue throw bag the strongest swimmer can swim across first and assist the other members by throwing a rope out as soon as they get close. Once the person swimming receives the rope they then roll over onto their backs into the white water float position with the pack downstream. Taking the rope over the opposite shoulder will pendulum them to shore.

Recovery of Swimmers

There is always a possibility that something can go wrong during a crossing, but as long as the crossing place is chosen carefully this need not lead to disaster. The main problem that will occur is people getting swept off their feet. When this happens the pack becomes a lifejacket. The swimmer assumes the white water float position leaning back on the pack, with their head upstream and body turned slightly towards the direction of travel. Kicking with the legs and using the arms in a backstroke motion provides a more than adequate means of propulsion. The swimmer must wait until safely eddied out before any attempt is made to stand up. With the modern camlock waist belts keeping them cinched tight will stop the pack riding up allowing hands to stay free for swimming. Older style packs will generally have to be taken off and used as flotation devices.

Team River Crossing

If you have multiple people crossing a river, you can use these techniques.

Mutual Support Method / Human Chain / Line Abreast

This is one of the most common and effective methods for groups of 3-6 people.

Formation: Group members stand in a line parallel to the river flow, facing slightly upstream.
Positioning: The strongest and tallest person should be positioned at the upstream end, as they break the force of the current for those downstream. The second strongest person is often at the downstream end.
Linking: Individuals link arms, grasp each other's pack straps, or hold onto each other's hip belts. The goal is to create a solid, interlinked unit that moves together.
Movement: The group moves as one unit, taking small, shuffling steps. They move diagonally across the river, slightly downstream with the current, rather than trying to go straight across. This minimizes resistance and uses the current's force to assist the crossing.
Communication: Constant communication within the group is vital to coordinate steps and react to changes in the riverbed or current.

Human Tripod / Triangle Formation

This technique is particularly effective for groups of three.

Formation: Three individuals form a triangle, interlocking arms or holding onto each other's shoulders, with the strongest person at the apex facing slightly upstream into the current.
Movement: The group moves in unison, taking coordinated small steps. The triangular formation provides excellent stability, distributing the force of the water across multiple points of contact.

Advantages: This method offers good all-around stability and allows for a 360-degree awareness of surroundings.

Line Astern / Strongest Person Leading

This method involves people lining up one behind the other, facing upstream into the current.

Formation: Group members stand in a line, one behind the other, each holding onto the pack or waist of the person in front. The strongest person leads from the front, breaking the current.
Movement: The leader coordinates the movement, often a sideways "crab walk," while the rest of the group follows, maintaining the connection.
Advantages: This can be effective in narrower channels or where the current is very strong, as the leader bears the brunt of the force.

Group Rope Technique

This technique is used for larger groups or when conditions are particularly challenging, requiring specialized equipment and skills.

Deployment: A strong swimmer or a pair of strong swimmers (preferably with swift water rescue training) crosses the river first, taking a rope with them.
Anchoring: The rope is securely anchored on both sides of the river (using sturdy trees or rock formations and appropriate knots like a bowline or figure-eight follow-through).
Crossing: The remaining group members then cross one at a time, or sometimes in small groups, using the rope as a handrail and a stabilizing aid. Packs can be attached to the rope with carabiners to be pulled across.
Safety: This method requires careful planning, proper knot-tying, and strong anchoring points. Downstream safety (with a throw bag and rescue personnel) should be considered.

Ocean Crossing

SURVIVAL | Water Survival | Ocean Crossing

How to cross the ocean in a boat or ship. It's assumed that the journey will take quite some time without the ability to stop for additional resources. See the TRANSPORT > Sea > Liveaboard section for more information on living on a boat.

Considerations

Food	
Water	
Waste	
Power	
Medical	
Communication	
Passports	If the grid is still up, or is up in another country, you are going to need a passport to get your into the other country successfully.

Dangers

There are a few dangers and consideration to take into account when crossing the ocean.

Storms	
Animals	

Rafting

Rafting and whitewater rafting are recreational outdoor activities which use an inflatable raft to navigate a river or other body of water. This is often done on whitewater or different degrees of rough water.

Rapids Categorization

Below is the internationally accepted rating system for rafting on rapids. It will give you a scale of how dangerous it is to try and cross.

Class I	Moving water with a few ripples and small waves. Few or no obstructions.
Class II	Rapids with smaller waves, clear channels that are obvious without scouting. Some maneuvering might be required.
Class III	Rapids with high, irregular waves. Narrow passages that often require precise manoeuvring. (This is the one that's a whole lot of fun)
Class IV	Long, difficult rapids with constricted passages that often require complex maneuvering in turbulent water. The course may be hard to determine and scouting is often necessary.
Class V	Extremely difficult, long, and very violent rapids with highly congested routes, which should be scouted from shore. Rescue conditions are difficult, and there is a significant hazard to life in the event of a mishap. Expert paddlers only.
Class VI	The difficulties of Class V carried to the extreme. Nearly impossible and very dangerous. For teams of experts only. Involves risk of life. Class VI rapids are not commercially raftable.

Marine Hazards

These are threats you may come across or have to consider when swimming in water or floating in a boat. Threats range from sharp rocks to deadly sea creatures.

Storms

See the NATURAL DISASTERS section for more on storms.

Waves

Wind waves or wind-generated waves, are water surface waves that occur on the free surface of bodies of water. They result from the wind blowing over an area of fluid surface. Waves in the oceans can travel thousands of miles before reaching land. Wind waves on Earth range in size from small ripples, to waves over 100 ft (30 m) high, being limited by wind speed, duration, affected area and water depth.

When directly generated and affected by local waters, a wind wave system is called a wind sea (or wind waves). Wind waves will travel in a great circle route after being generated - curving slightly left in the southern hemisphere and slightly right in the northern hemisphere. After moving out of the area of fetch, wind waves are called swells and can travel thousands of miles. A noteworthy example of this are waves generated south of Tasmania during heavy winds that will travel to southern California producing desirable surfing conditions. More generally, a swell consists of wind-generated waves that are not significantly affected by the local wind at that time. They have been generated elsewhere or some time ago. Wind waves in the ocean are called ocean surface waves.

Wind waves have a certain amount of randomness: subsequent waves differ in height, duration, and shape with limited predictability. They can be described as a stochastic process, in combination with the physics governing their generation, growth, propagation, and decay—as well as governing the interdependence between flow quantities such as: the water surface movements, flow velocities and water pressure. The key statistics of wind waves (both seas and swells) in evolving sea states can be predicted with wind wave models.

Although waves are usually considered in the water seas of Earth, the hydrocarbon seas of Titan may also have wind-driven waves.

Rogue Wave

Rogue waves (also known as freak waves, monster waves, episodic waves, killer waves, extreme waves, sneaker waves, and abnormal waves) are unusually large, unexpected and suddenly appearing surface waves that can be extremely dangerous, even to large ships such as ocean liners.

Rogue waves present considerable danger for several reasons: they are rare, are unpredictable, may appear suddenly or without warning, and can impact with tremendous force. A 12-metre (39 ft) wave in the usual "linear" wave model would have a breaking pressure of 6 metric tons per square metre (t/m2) (59 kPa; 8.5 psi). Although modern ships are designed to tolerate a breaking wave of 15 t/m2 (150 kPa; 21 psi), a rogue wave can dwarf both of these figures with a breaking pressure of 100 t/m2 (0.98 MPa; 140 psi).

In oceanography, rogue waves are more precisely defined as waves whose height is more than twice the significant wave height (Hs or SWH), which is itself defined as the mean of the largest third of waves in a wave record. Therefore, rogue waves are not necessarily the biggest waves found on the water; they are, rather, unusually large waves for a given sea state. Rogue waves seem not to have a single distinct cause, but occur where physical factors such as high winds and strong currents cause waves to merge to create a single exceptionally large wave.

Rogue waves can occur in media other than water. They appear to be ubiquitous in nature and have also been reported in liquid helium, in nonlinear optics and in microwave cavities. Recent research has focused on optical rogue waves which facilitate the study of the phenomenon in the laboratory. A 2015 paper studied the wave behaviour around a rogue wave, including optical, and the Draupner wave, and concluded that "rogue events do not necessarily appear without a warning, but are often preceded by a short phase of relative order". A 2012 study confirmed the existence of oceanic rogue holes, the inverse of rogue waves, where the depth of the hole can reach more than twice the significant wave height.

Rocks

Rocks can be dangerous to any form of boat or swimmer as they can shred through wood or metals given enough speed. Rocks or other water obstructions should always be watched for.

Icebergs

Very similar to rocks, however these can constantly move and may come towards you if the wind favours them. It may be deceptive but one did sink the supposedly unsinkable titanic.

Sandbank

Sandbanks, especially when they are submerged or partially hidden, can cause boats to ground, leading to damage, delays, and potentially dangerous situations. They are not static and can shift and change shape due to tides, currents, and weather conditions, making navigation challenging and potentially dangerous. When wind and tide combine, shallow sandbanks can create breaking water, which can be dangerous for boats, especially smaller ones, to navigate. Sandbanks can act as obstacles, narrowing channels and forcing boats to take unpredictable routes, increasing the risk of collisions or grounding. If a boat grounds on a sandbank, it can become difficult to maneuver or free, potentially leading to loss of control and further damage.

Creatures

See the ANIMALS section for more dangerous sea creatures and information on how to treat animal attacks.

Jellyfish

Jellyfish stings can cause pain and other health problems, and some species, like the box jellyfish and Irukandji, can be life-threatening, potentially leading to conditions like Irukandji syndrome with symptoms including severe pain, muscle cramps, and heart problems.

Crocodile & Alligator

Crocodiles are potentially dangerous to humans. People should never take unnecessary risks in crocodile habitat. Saltwater crocodiles inhabit both saltwater and freshwater habitats.

Some of the ways to stay safe in areas that may have saltwater crocodiles include:
• Never swim in water where crocodiles may live even if there is no warning sign. Only swim in designated safe swimming areas.
• Follow all crocodile warning signs - they are there for your safety and protection.
• Always keep a watch for crocodiles. They will see you before you see them.
• Never provoke, harass or interfere with crocodiles, even small ones.
• Never feed crocodiles - it is illegal and dangerous.
• Be extra vigilant around water at night and during the breeding season from September to April (Australia).
• Avoid approaching the edge of the water and don't paddle or wade at the edge of the water.
• Stay well back from any crocodile slide marks. Crocodiles may be close by and may approach people and boats.
• The smaller the boat, the greater the risk.
• Always stand a minimum of five metres from the water's edge when fishing.
• Be especially vigilant when launching or retrieving your boat in saltwater crocodile habitat.

• Do not lean over the edge of a boat or stand on logs overhanging water.
• Never dangle your arms or legs over the side of a boat. If you fall out of a boat, get out of the water as quickly as possible.
• Camp at least 2 metres above the high water mark and at least 50 metres from the water's edge. Avoid places where native animals and domestic stock drink.
• Avoid returning regularly to the same spot at the water's edge to fill your bucket.
• Dispose of food scraps, fish offal and other waste properly and away from your campsite.
• Never leave food scraps, fish frames or bait at your campsite. Always check that previous campers have not left these behind.
• Never prepare food, wash dishes or pursue any other activities near the water's edge or adjacent sloping banks. Instead, fill up your bucket and move away from the edge of the water before you start any tasks.

Stingray

Octopus

8 Desert Survival

This section focuses on how to survive in hot climates.

Desert Tips

● Take it slow – The last thing you need to worry about is passing out in the middle of the desert, so take it easy, rest lots, and drink a ton of water. If you need to sit down often, that's fine! Go at your own pace and enjoy the hike.
● Bring a friend – Because the desert is such a hostile environment, it's not a good idea to go alone. Invite a friend, or better yet, a group of people. There's both safety and fun in numbers.
● Don't bring your dog – A ton of hikers love hitting the trails with their four-legged friends, but the desert is not a safe place for your pup. The hot sand can be severely damaging to the pads of their paws, and it just means extra water for you to drag along.
● Bring your phone, but turn it off – Extreme heat causes most phones to malfunction and drain the battery a lot faster than usual. Save your battery just in case you need your phone and keep it off until that happens. If you need your phone on, bring a backup battery.
● Do NOT eat the cacti – This is a huge myth – eating the insides of a cactus will not quench your thirst. It will very likely make you sick to your stomach, which will dehydrate you faster.

● Take advantage of shade when you get it – There's not much shade in the desert, so when you come across it, take a break. This will help conserve energy, water, and keep your health in a good place.
● Have an emergency plan in place – Do not, under any circumstances, hike into the desert without telling anyone of your plan. This is as easy as contacting a friend and telling them where you'll be hiking, when you should be back by, and when to assume you've gone missing. Finding lost hikers in the desert is like finding a needle in a haystack, so make it easy and have a plan.

Water Requirements

All the body's fluids make up one large body fluid pool. Losses of fluid from any one source is reflected in the levels of all the body's other fluids: e.g. profuse sweating will ultimately result in decreased blood volume. If a patient loses enough fluid through any manner-bleeding, sweating, vomiting, or diarrhoea-the end result is the same: dehydration and, potentially, volume shock. Adequate fluid is also critically important in hot environments to help our body thermo regulate. Dehydration is always easier to prevent than it is to treat. So it is important to ensure that all members of your group replace their regular fluid losses by drinking adequate amounts of water.

Your body absorbs fluids best when you drink frequently and in small amounts rather than drinking large amounts at one time. It also helps with fluid absorption if you drink while eating. A pinch of salt and sugar in the water will do if no food is available. Very dilute mixtures of sports drinks like Gatorade (add just enough to taste) work well for this purpose. Don't depend on feeling thirsty to tell you when to drink. Thirst is a late response of the body to fluid depletion. Once you feel thirsty, you are already low on fluids. The best indicator of proper fluid levels is urine output and colour. You, and all the people in your group should strive to be "copious and clear." Ample urine that is light coloured to clear shows that the body has plenty of fluid. Dark urine means that the body is low on water, and is trying to conserve its supply by hoarding fluid which means that urine becomes more concentrated (darker).

Season	Fluids / Day	Explanation
Fall / Spring	1.8-2.8L (0.47-0.73gal)	This is what an average person will need on a daily basis in general temperate conditions.
Hot Weather	2.8-3.7L (0.73-1gal)	In hot and humid weather you are losing additional fluid through sweating which must be replaced.
Winter	2.8-3.7L (0.73-1gal)	In the winter time you are losing moisture through evaporation to the dry air and especially through respiration. Dry air entering the lungs heats up and is exhaled saturated with moisture.
All Seasons	1.8L (0.47gal)	At high altitude the body looses more fluid. Increase your fluid intake if you are travelling at high altitudes (over 8,000 feet/2,438 meters)

Body Regulation

Fluids & Salts
Another factor in overall fluid balance is the replacement of salts lost to sweat. In most cases the salts found in normal food consumption is adequate for salt replacement. In the event of severe dehydration, a solution of ½ teaspoon salt and ½ teaspoon of baking soda per quart/litre of water can be used to replace lost fluid and salt. Use lukewarm fluids. Discontinue the fluids if the person becomes nauseated or vomits. Restart fluids as soon as the person can tolerate it.

Thermoregulation
The body has a number of mechanisms to properly maintain its optimal core temperature of 98.6° F (37° C). Above 105° F (40° C) many body enzymes become denatured and chemical reactions cannot take place leading to death. Below 98.6° F (37° C) chemical reactions slow down with various complications which can lead to death. Understanding thermoregulation is important to understanding Heat Illnesses and Cold Injuries.

Body Core Regulation
- **Vasodilation:** Increases surface blood flow which increases heat loss (when ambient temperature is less that body temperature).
- **Vasoconstriction:** Decreases blood flow to periphery, decreases heat loss.
- **Sweating:** Cools body through evaporative cooling.
- **Shivering:** Generates heat through increase in chemical reactions required for muscle activity. Visible shivering can maximally increase surface heat production by 500%. However, this is limited to a few hours because of depletion of muscle glucose and the onset of fatigue.
- **Activity:** Increasing/Decreasing Activity will cause corresponding increases in heat production and decreases in heat production.
- **Behavioural Responses:** Putting on or taking off layers of clothing will result in thermoregulation.

Heat Challenge

In hot weather, especially with humidity, you can lose a great deal of body fluid through exercise. This can lead to a variety of heat related illnesses including Heat Exhaustion and Heat Stroke. Heat Challenge is a combination of a number of external heat factors. Balanced against this Heat Challenge is your body's methods of Heat Loss (passive and active). When Heat Challenge is greater than Heat Loss, you are at risk for a heat-related injury. In order to reduce the risk you need to either decrease the Heat Challenge or increase your Heat Loss. Fluids are a central part of exercising in a Heat Challenge.

Heat Challenge
(Negative Factors)
- Temperature
- Exercise
- Humidity
- Body Wetness from sweating
- Wind

Passive Heat Loss
(Positive Factors)
- Body Size/shape - your surface to volume ratio effects how quickly you lose heat.
- Insulation - type of clothing layers
- Body Fat - amount of body fat also effects how quickly you lose heat
- Shell/Core Response - allows the body shell to act as a thermal barrier

Active Heat Loss
(Positive Factors)
- Radiant Heat from the body
- Sweating which causes heat loss through evaporation. Amount of sweating is limited by your fluid levels and level of fitness.

Heat Index

This chart provides guidelines for assessing the potential severity of heat stress. Individual reactions to heat will vary. Heat illnesses can occur at lower temperature than indicated on this chart. Exposure to full sunshine can increase values up to 8.3°C (15°F).

Temperature / Humidity	21°C (70°F)	24°C (75°F)	27°C (80°F)	29°C (85°F)	32°C (90°F)	35°C (95°F)	38°C (100°F)	41°C (105°F)	43°C (110°F)	46°C (115°F)	49°C (120°F)
0%	18°C (64°F)	20°C (69°F)	23°C (73°F)	26°C (78°F)	28°C (83°F)	31°C (87°F)	33°C (91°F)	35°C (95°F)	37°C (99°F)	39°C (103°F)	42°C (107°F)
10%	18°C (65°F)	21°C (70°F)	24°C (75°F)	27°C (80°F)	29°C (85°F)	33°C (90°F)	35°C (95°F)	38°C (100°F)	41°C (105°F)	44°C (111°F)	47°C (116°F)
20%	19°C (66°F)	22°C (72°F)	25°C (77°F)	28°C (82°F)	30°C (87°F)	33°C (93°F)	37°C (99°F)	41°C (105°F)	44°C (112°F)	49°C (120°F)	54°C (130°F)
30%	19°C (67°F)	23°C (73°F)	26°C (78°F)	29°C (84°F)	33°C (90°F)	36°C (96°F)	40°C (104°F)	45°C (113°F)	51°C (123°F)	57°C (135°F)	64°C (148°F)
40%	20°C (68°F)	23°C (74°F)	26°C (79°F)	30°C (86°F)	34°C (93°F)	38°C (101°F)	43°C (110°F)	56°C (123°F)	58°C (137°F)	66°C (151°F)	
50%	20°C (69°F)	24°C (75°F)	27°C (81°F)	31°C (88°F)	36°C (96°F)	42°C (107°F)	49°C (120°F)	57°C (135°F)	66°C (150°F)		
60%	21°C (70°F)	24°C (76°F)	28°C (82°F)	33°C (90°F)	38°C (100°F)	46°C (114°F)	56°C (132°F)	65°C (149°F)			
70%	21°C (70°F)	25°C (77°F)	29°C (85°F)	34°C (93°F)	41°C (106°F)	51°C (124°F)	62°C (144°F)				
80%	22°C (71°F)	26°C (78°F)	30°C (86°F)	36°C (97°F)	45°C (113°F)	58°C (136°F)					
90%	22°C (71°F)	26°C (79°F)	31°C (88°F)	39°C (102°F)	50°C (122°F)						
100%	22°C (72°F)	27°C (80°F)	33°C (91°F)	42°C (108°F)							

Apparent Temperature	32-40°C (90-104°F)	31-54°C (105-130°F)	Over 54°C (130°F)
Heat-stress risk with physical activity and/or prolonged exposure.	Heat Cramps / Exhaustion possible.	Heat Cramps / Exhaustion likely. Heat Stroke possible.	Heat Stroke very likely.

Heat Illnesses

Heat Cramps

Heat cramps are a form of muscle cramp brought on by exertion and insufficient salt.

Treatment
Replace salt and fluid and stretch the muscle. Kneading and pounding the muscle is less effective than stretching and probably contributes to residual soreness.

Heat Syncope

Heat Syncope (fainting) is a mild form of heat illness which results from physical exertion in a hot environment. In an effort to increase heat loss, the skin blood vessels dilate to such an extent that blood flow to the brain is reduced, resulting in symptoms of faintness, dizziness, headache, increased pulse rate, restlessness, nausea, vomiting, and possibly even a brief loss of consciousness. Inadequate fluid replacement which leads to dehydration contributes significantly to this problem.

Treatment
Heat Syncope should be treated as fainting. The person should lie or sit down, preferably in the shade or in a cool environment. Elevate the feet and give fluids, particularly those containing salt (commercial "rehydration" mix or ½ teaspoon salt and ½ teaspoon baking soda per quart/0.9 litre). The patient should not engage in vigorous activity for at least the rest of that day. Only after they have completely restored their body fluids and salt and have a normal urinary output should exercise in a hot environment be resumed (and then cautiously).

Heat Exhaustion

This occurs when fluid losses from sweating and respiration are greater than internal fluid reserves (volume depletion). Heat Exhaustion is really a form of volume shock. The lack of fluid causes the body to constrict blood vessels especially in the periphery (arms and legs). To understand Heat Exhaustion think of a car with a radiator leak pulling a trailer up a mountain pass. There is not enough fluid in the system to cool off the engine so the car overheats. Adding fluid solves the problem.

Symptoms of Heat Exhaustion
- Sweating
- Skin - Pale, clammy (from peripheral vasoconstriction)
- Pulse - Increased
- Respirations - Increased
- Temperature - normal or slightly elevated
- Urine Output - Decreased
- Patient feels weak, dizzy, thirsty, "sick," anxious
- Nausea and vomiting (from decreased circulation in the stomach)

Treatment

Victims of Heat Exhaustion must be properly re-hydrated and must be very careful about resuming physical activity (it is best to see a physician before doing so). Treatment is as described above for Heat Syncope, but the person should be more conservative about resuming physical activity to give the body a chance to recover. Have the person rest (lying down) in the shade. Replace fluid with a water/salt solution (commercial "rehydration" mix or ½ teaspoon salt and ½ teaspoon baking soda per quart/0.9 litre). Drink slowly, drinking too much, too fast very often causes nausea and vomiting. Evacuation usually is not necessary, however, Heat Exhaustion can become Heat Stroke if not properly treated. A victim of Heat Exhaustion should have be closely monitored to make sure that their temperature does not go above 39° C (103° F). If it does so, treat the person for Heat Stroke.

Heat Stroke (Hyperthermia)

Heat Stroke is one of the few life threatening medical emergencies. A victim can die within minutes if not properly treated. Heat Stroke is caused by an increase in the body's core temperature. Core temperatures over 105° (41° C) can lead to death. The rate of onset of Heat Stroke depends on the individual's fluid status. To understand Heat Stroke, think of that same car pulling a trailer up a mountain pass on a hot day. This time the radiator has plenty of fluid, but the heat challenge of the engine combined with the external temperature is too much. The engine can't great rid of the heat fast enough and the engine overheats. There are two types of Heat Stroke-fluid depleted (slow onset) and fluid intact (fast onset).

- Fluid depleted - The person has Heat Exhaustion due to fluid loss from sweating and/or inadequate fluid replacement, but continues to function in a heat challenge situation. Ultimately, the lack of fluid has minimized the body's active heat loss capabilities to such an extent that the internal core temperature begins to rise. Example: a runner on a hot day with limited water.
- Fluid intact (fast onset) - The person is under an extreme heat challenge. The heat challenge overwhelms the body's active heat loss mechanisms even though the fluid level is sufficient. Example: a runner pushing hard on a 40° C (104° F) day.

Symptoms

- The key to identifying Heat Stroke is hot skin. Some victims may have hot, dry skin, others may have hot, wet skin because they have just moved from Heat Exhaustion to Heat Stroke.
- Peripheral vasoconstriction (skin gets pale)
- Pulse Rate - increased
- Respiratory Rate - increased
- Urine Output - decreased
- Temperature - increased (over 105°F / 41°C)
- Skin - may be wet or dry, flushed
- AVPU - Severe changes in mental status and motor/sensory changes, then the person may become comatose, possibility of seizures.
- Pupils - may be dilated and unresponsive to light

- Efforts to reduce body temperature must begin immediately. Move the patient to a cooler spot or shade the victim. Remove clothing. Pour water on the extremities and fan the person to increase air circulation and evaporation. Or cover the extremities with cool wet cloths and fan the patient. Immersion in cool (not cold) water is also useful. During cooling the extremities should be massaged vigorously to help propel the cooled blood back into the core.
- After the temperature has been reduced to 39°C (102°F), active cooling should be reduced to avoid hypothermia (shivering produces more heat). The patient must be monitored closely to make sure that temperature does not begin to go up again.
- Volume replacement - the victim will probably need fluid regardless of the type of onset.
- Basic life support, CPR if needed.
- Afterwards there can be serious medical problems. Prepare to evacuate your patient.

For more information on heat related illnesses, see the INJURY > Environmental section.

9 Arctic Survival

This section focuses on how to survive in cold climates.

Cold Water Survival

Cold water is estimated to be around and under the temperature of 21°C (70°F). However, this will vary in each case due to the specific circumstances and physical condition of the person involved. Many of the fatal boating accidents occur in the "out-of-season" months when the water is cold. What happens to the body when suddenly plunged into cold water? The first hazards to contend with are panic and shock. The initial shock can place severe strain on the body, producing instant cardiac arrest, as happened to a 15 year old scout in the month of March in Pennsylvania several years ago. Survivors of cold water accidents have reported the breath driven from them on first impact with the water. Should your face be in the water during that first involuntary gasp for breath, it may well be water rather than air. Total disorientation may occur after cold water immersion.

Persons have reported "thrashing helplessly in the water" for thirty seconds or more until they were able to get their bearings. Immersion in cold water can quickly numb the extremities to the point of uselessness. Cold hands cannot fasten the straps of a lifejacket, grasp a thrown rescue line, or hold onto an over-turned boat. Within minutes, severe pain clouds rational thought. And, finally, hypothermia (exposure) sets in, and without rescue and proper first aid treatment, unconsciousness and death. Normal body temperature of course, is 37°C (98.6°F) Shivering and the sensation of cold can begin when the body temperature lowers to approximately 36°C (96.5°F). Amnesia can begin to set in at approximately 34°C (94°F), unconsciousness at 30°C (86°F) and death at approximately 26°C (79°F).

How to Survive
Cold water robs the body's heat 32 times faster than cold air. If you should fall into the water, all efforts should be given to getting out of the water by the fastest means possible. Persons boating in the cold water months should be thoroughly skilled in rescue and self-rescue techniques. Most accidents involve small boats which with practice, can be righted and re-entered. Most boats, even filled with water, will support the weight of its occupants. If the boat has capsized and cannot be made right, climb on top of it. Physical exercise such as swimming causes the body to lose heat at a much faster rate than remaining still in the water. Blood is pumped to the extremities and quickly cooled. Few people can swim a mile in fifty degree water. Should you find yourself in cold water and are not able to get out, you will be faced with a critical choice - to adopt a defensive posture in the water to conserve heat and wait for rescue, or attempt to swim to safety. Should you find yourself in the water, avoid panic. Air trapped in clothing can provide buoyancy as long as you remain still in the water. Swimming or treading water will greatly increase heat loss and can shorten survival time by more than 50%. The major body heat loss areas are the head, neck, armpits, chest and groin. If you are not alone, huddle together or in a group facing each other to maintain body heat.

Preparation
Proper preparation is essential when boating on cold water. Make sure your boat and equipment are in first class condition. Check the weather forecast before leaving for your event. Always tell someone where you are going and when you expect to return. Dress in several layers of light clothing. Next to a diver's wet suit, wool clothing offers the best protection. Always wear a personal flotation device (PFD) when boating.

Treatment
Treatment for hypothermia depends on the condition of the person. Mild hypothermia victims who show only symptoms of shivering and are capable of rational conversation may only require removal of wet clothes and replacement with dry clothes or blankets. In more severe cases where the victim is semi-conscious, immediate steps must be taken to begin the rewarming process. Get the person out of the water and into a warm environment. Remove the clothing only if it can be done with a minimum of movement of the victim's body. Do not massage the extremities. Lay the semi-conscious person face up, with the head slightly lowered, unless vomiting occurs. The head down position allows more blood to flow to the brain. If advanced rescue equipment is available it can be administered by those trained in its use. Warm humidified oxygen should be administered by face mask. Immediately attempt to rewarm the victims body core. If available, place the person in a bath of hot water at a temperature of 105-110°F. It is important that the victim's arms and legs be kept out of the water to prevent "after-drop". After-drop occurs when the cold blood from the limbs is forced back into the body resulting in further lowering of the core temperature. After-drop can be fatal. If a tub is not available, apply hot, wet towels or blankets to the victim's head, neck, chest, groin, and abdomen. Do not warm the arms or legs. If nothing else is available, a rescuer may use their own body heat to warm a hypothermia victim. Never give alcohol to a hypothermia victim.

Facts

Most persons recovered in cold water "near" drowning cases show the typical symptoms of death:
- Cyanotic (blue) skin coloration
- No detectable breathing
- No apparent pulse or heartbeat
- Pupils fully dilated (opened)

These symptoms, it was discovered, did not always mean the victim was dead. They were, on the other hand, the body's way of increasing its chances of survival through what scientists call the mammalian diving reflex. This reflex is most evident in marine mammals such as whales, seals or porpoises. In the diving reflex, blood is diverted away from the arms and legs to circulate (at the rate of only 6-8 beats per minute, in some cases) between the heart, brain and lungs. Marine mammals have developed this ability to the point where they can remain under water for extended periods of time (over 30 minutes in some species) without brain or body damage. Humans experience the diving reflex, but it is not as pronounced as in other mammals. The factors which enhance the diving reflex in humans are:

- Water temperature - less than 21°C (70°F) or colder, the more profound the response and perhaps the more protective to the brain
- Age - the younger the victim, the more active the reflex
- Facial immersion - the pathways necessary for stimulating this series of responses seem to emanate from facial cold water stimulation.

The diving reflex is a protective mechanism for humans in cold water immersions, but it may confuse the rescuer into thinking the victim is dead. Resuscitative efforts for these victims should be started immediately utilizing CPR in accordance with your training.

Cold Water Survival Time

The following is a table comparing the water temperature to the amount of time symptoms set in and the expected survival time.

Water Temperature	Exhaustion or Unconsciousness in:	Expected Survival Time
21–27°C (70–80°F)	3–12 hours	3 hours – indefinitely
16–21°C (60–70°F)	2–7 hours	2–40 hours
10–16°C (50–60°F)	1–2 hours	1–6 hours
4–10°C (40–50°F)	30–60 minutes	1–3 hours
0–4°C (32.5–40°F)	15–30 minutes	30–90 minutes
<0°C (<32°F)	Under 15 minutes	Under 15–45 minutes

Cold Weather Injuries

Heat Loss

These are the ways in which heat can be lost from your body.

Radiation	Loss of heat to the environment due to the temperature gradient (this occurs only as long as the ambient temperature is below 98.6). Factors important in radiant heat loss are the surface area and the temperature gradient.
Conduction	Through direct contact between objects, molecular transference of heat energy. Water conducts heat away from the body 25 times faster than air because it has a greater density (therefore a greater heat capacity). Stay dry = stay alive! Steel conducts heat away faster than water. Example: Generally conductive heat loss accounts for only about 2% of overall loss. However, with wet clothes the loss is increased five times.
Convection	Is a process of conduction where one of the objects is in motion. Molecules against the surface are heated, move away, and are replaced by new molecules which are also heated. The rate of convective heat loss depends on the density of the moving substance (water convection occurs more quickly than air convection) and the velocity of the moving substance.
Evaporation	Heat loss from converting water from a liquid to a gas. (Perspiration - evaporation of water to remove excess heat)
Perspiration (General)	It is important to recognize the strong connection between fluid levels, fluid loss, and heat loss. As body moisture is lost through the various evaporative processes the overall circulating volume is reduced which can lead to dehydration. This decrease in fluid level makes the body more susceptible to hypothermia and other cold injuries.
Perspiration (Sweating)	Body response to remove excess heat Insensible Perspiration - body sweats to maintain humidity level of 70% next to skin - particularly in a cold, dry environment you can lose a great deal of moisture this way Respiration - air is heated as it enters the lungs and is exhaled with an extremely high moisture content
Wind Chill	Is an example of the effects of air convection, the wind chill table gives a reading of the amount of heat lost to the environment relative to a still air temperature.

Cold Response

Cold Challenge - (negative factors) ● Temperature ● Wet (rain, sweat, water) ● Wind (blowing, moving, e.g. biking) Total = Cold Challenge	**Heat Retention - (positive factors)** ● Size/shape (Eskimo vs. Masai) ● Insulation (layering/type) ● Fat (as insulation) ● Shell/core (shunt blood to core) shell acts as a thermal barrier Total = Heat Retention	**Heat Production - (positive factors)** ● Exercise, shivering Limited by: ○ Fitness ○ Fuel stores (glycogen) ○ Fluid status (efficient exercise) ○ Food intake (kindling, sticks, logs)

Core Temperature
- Heat is both required and produced at the cellular level. The environment acts as either a heating or a cooling force on the body. The body must be able to generate heat, retain heat, and discharge heat depending on the body activity and ambient external temperature.
- Body temperature is a measure of the metabolism - the general level of chemical activity within the body.
- The hypothalamus is the major centre of the brain for regulating body temperature. It is sensitive to blood temperature changes of as little as 0.5°C and also reacts to nerve impulses received from nerve endings in the skin.
- The optimum temperature for chemical reactions to take place in the body is 37°C (98.6°F). Above 105 F many body enzymes become denatured and chemical reactions cannot take place leading to death. Below 98.6°F chemical reactions slow down with various complications which can lead to death.
- Core = the internal body organs, particularly the heart, lungs, and brain.
- Core temperature is the temperature that is essential to the overall metabolic rate of the body. The temperature of the periphery is not critical.

Core Temperature Regulation

How the body regulates core temperature.

1	Vasodilation - increases surface blood flow, increases heat loss (when ambient temperature is less that body temperature). Maximal vasodilation can increase cutaneous blood flow to 3000 ml/minute (average flow is 300-500 ml/minute).
2	Vasoconstriction - decreases blood flow to periphery, decreases heat loss. Maximal vasoconstriction can decrease cutaneous blood flow to 30 ml/minute.
3	Sweating - cools body through evaporative cooling.
4	Shivering - generates heat through increase in chemical reactions required for muscle activity. Visible shivering can maximally increase surface heat production by 500%. However, this is limited to a few hours because of depletion of muscle glucose and the onset of fatigue.
5	Increasing/Decreasing Activity will cause corresponding increases in heat production and decreases in heat production.
6	Behavioural Responses - putting on or taking off layers of clothing will result in heat regulation

Hypothermia

1. Hypothermia - "a decrease in the core body temperature to a level at which normal muscular and cerebral functions are impaired."	**2.** Conditions Leading to Hypothermia ● Cold temperatures ● Improper clothing and equipment ● Wetness ● Fatigue, exhaustion ● Dehydration ● Poor food intake ● No knowledge of hypothermia ● Alcohol intake - causes vasodilation leading to increased heat loss	**3.** What are "hypothermia" temperatures ● Below freezing ● 40° - Ex. Shenandoah's, wind and rain ● 60° - Ex. Rayanna and hurricane ● Any temperature less than 98.6° can be linked to hypothermia

Hypothermia Symptoms

Basic Hypothermia	Watch for the "Umbles" - stumbles, mumbles, fumbles, and grumbles which show changes in motor coordination and levels of consciousness.
Mild Hypothermia	**Core temperature 35.5-37°C (96-98.6°F)** ● Shivering - not under voluntary control ● Can't do complex motor functions (ice climbing or skiing) can still walk & talk ● Vasoconstriction to periphery

Moderate Hypothermia	**Core temperature 33.8-35°C (93-95°F)** ● Dazed consciousness ● Loss of fine motor coordination - particularly in hands - can't zip up parka, due to restricted peripheral blood flow ● Slurred speech ● Violent shivering ● Irrational behaviour - Paradoxical Undressing - person starts to take off clothing, unaware s/he is cold ● "I don't care attitude" - flattened affect
Severe Hypothermia	**Core temperature 30-33.3°C (86-92°F) and below (immediately life threatening)** ● Shivering occurs in waves, violent then pause, pauses get longer until shivering finally ceases - because the heat output from burning glycogen in the muscles is not sufficient to counteract the continually dropping core temperature, the body shuts down on shivering to conserve glucose ● Person falls to the ground, can't walk, curls up into a fetal position to conserve heat ● Muscle rigidity develops - because peripheral blood flow is reduced and due to lactic acid and CO_2 build-up in the muscles ● Skin is pale ● Pupils dilate ● Pulse rate decreases ● At 32°C (90°F) the body tries to move into hibernation, shutting down all peripheral blood flow and reducing breathing rate and heart rate. ● At 30°C (86°F) the body is in a state of "metabolic icebox." The person looks dead but is still alive.
Hypothermia Death	● Breathing becomes erratic and very shallow ● Semi-conscious ● Cardiac arrhythmias develop, any sudden shock may set off Ventricular Fibrillation ● Heart stops, death

Assessment
- If shivering can be stopped voluntarily = mild hypothermia
- Ask the person a question that requires higher reasoning in the brain (count backwards from 100 by 9's). If the person is hypothermic, they won't be able to do it. (Note: there are also other conditions such as altitude sickness that can also cause the same condition)
- If shivering cannot be stopped voluntarily = moderate - severe hypothermia
- If you can't get a radial pulse at the wrist it indicates a core temp below 90-86°F
- The person may be curled up in a fetal position. Try to open their arm up from the fetal position, if it curls back up, the person is alive. Dead muscles won't contract only live muscles.

For more information on cold related illnesses, see the INJURY > Environmental section.

10 Urban Survival

Survival in the suburbs, particularly in times of turmoil is a completely different beast to surviving on say, a desert island where your priorities and threats are completely different. This section aims to get you prepared for any situation which may arise where you are at a high risk of dying in the cities or suburbs.

Urban Survival

When the grid is up, one can survive in major population centres without a lot of issues. The biggest issue will be sheltering from unsavoury weather such as the cold, storms and flooding, parti

Street Smarts

Obtaining Food

Urban Threats

These are the threats you may encounter in an urban environment.

Crime

Competition

Competition of limited resources.

Limited Resources

In cities, food is trucked in from the farms which lay on the outskirts or another part of the country entirely which makes obtaining it difficult when a disaster strikes a city.

Food Removal

Have you noticed that cities and most suburbs almost never have plants which grow food in them?

Homeless Survival

You will generally only find long-term homeless individuals in the cities or suburbs, since out in the more remote places you generally have more liberty to build your own home. Even if you don't have the skills, country folk are often more hospitable and will take in those in need. This section aims to help you survive as a homeless individual if you are in a densely populated area.

11 Search & Rescue

This section will either help you to perform a search and rescue, or help you to avoid being found if that's your goal.

Search and Rescue (SAR) is the search for and provision of lifesaving assistance to people in distress and imminent danger of loss of life. SAR arrangements are intended to complement other emergency services (police, fire, ambulance) in circumstances where those services are unable to operate effectively. Depending upon the extent and complexity of the incident and on the available staff and facilities, SAR may take many forms in response to a distress situation. Unless the action is indivisible from that of safeguarding life, a SAR operation does not, however, include salvage or the saving of property.

Subheadings

1 Rescuer Training

The importance of thorough training for all personnel employed on SAR missions cannot be overemphasised. Failure of a single link in the often complex chain of action required in SAR missions can compromise the success of the operation, resulting in loss of lives of SAR personnel, lives of those that might otherwise have been saved and/or loss of valuable resources. The purpose of training is to meet SAR system objectives by developing SAR specialists. Since considerable experience and judgement are needed to handle SAR situations, necessary skills require significant time to master. Training can be expensive but contributes to operational effectiveness. Quality of performance will match the quality of training. This is the training and skills that rescuers should have before attempting search and rescue:

Land SAR Training	Search and Rescue (SAR) training.
Search and Rescue Crew Training	SAR Authorities should coordinate SAR exercises in conjunction with search and rescue crews to ensure practice is maintained in techniques employed in SAR operations.
Dropmaster and Dispatchers	The dispatch of survival stores and equipment from an aircraft to survivors on land or over water is an exacting task, which, if not performed well, can nullify or seriously delay the rescue effort and may endanger the aircraft and its crew.
Air Observer Training	Major SAR operations require a considerable number of observers who may be drawn from various organisations.
Aviation Search and Rescue Units (SRU)	Accordingly, operators are given training in one or more of the following aspects of SAR operations: ● Visual search procedures/techniques; ● Airborne location of distress beacons using aural homing techniques; ● Airborne location of distress beacons using DF equipment; ● On ground location of localised distress beacons; ● Operation of electronic sensor systems in SAR operations; ● Aerial delivery of supplies/equipment overland and/or over water; and ● Helicopter rescue techniques.
First Aid Training	All personnel involved in SAR need to be trained in basis first aid. JRCC, ADF and State/Territory have first aid training capabilities, via the Ambulance Services. While all personnel should have a basic first aid knowledge, at least one member of each search team should be qualified to a higher level of training, Senior First Aid or First Response First Aid. Regular training needs to be carried out to instill confidence in the delivery of first aid in remote situations.
Map Reading and Navigation	● Training is to be in accordance with the established map/chart reading plans for each State/Territory. The World Geodetic System (WGS) is a standard for use in cartography, geodesy, and navigation worldwide. It is the reference coordinate system used by the Global Positioning System (GPS). WGS standardises the Earth as a spheroid with its accompanying coordinate framework. The Australian Geodetic Datum (AGD), both the 1966 and 1984 versions, has been replaced by Geocentric Datum of Australia (GDA94). ● Training in map/chart usage is to be based on a combination of manual/historical methods and electronic methods to ensure an all-round capability.
Radio Operating Procedures	Training is to be in accordance with established standards within the JRCC, ADF and State/Territory and the Australian Emergency Manual—Communications
Field Craft	Field craft is a broad subject which is difficult to define in its entirety. It is a series of practical skills which can only be taught in the field. The aspects of field craft which are important to the searcher are: ● Searching ground by eye; ● Judging distance; ● Basic tracking; and ● Living in the bush.
Observation Skills	Observation is the skill of looking for clues and may be required to be conducted by day or night. The principles of clue recognition and interpretation are shown as Appendix E-13 to this Manual.

Observation Skills-Day

The ability to 'see' rather than just look, may need to be taught when operating in the unfamiliar bush environment, and observing changes and noting details are skills which must be developed in most people. To understand why things are seen, it must be explained that several factors are involved which aid this process:
- Shape—regular shapes do not occur in nature.
- Shine—rarely do natural things shine.
- Shadow—unusual shadows will often reveal what may appear to be hidden.
- Movement—immediately attracts the eye.
- Colour—differences to the natural background are obvious to the trained eye.
- Spacing—regular spacing does not occur in nature.

Observation Skills-Night

Due to the physical characteristics of the eye, if an observer looks directly at a small or dim object at night, it may not be seen. To optimise night vision objects should be observed 'off centre':
- Off Centre (Averted Vision): To achieve 'off centre' vision, the eye should be 'aimed off' from the object about a fist's width at arm's length. Only by experiment can the searcher find out which direction is most suitable for their aim off i.e. above, below or to one side of the object. It is important that the searcher resist the temptation to look directly at the object.
- Scanning: Scanning is the short, abrupt movement of the eye over or around an area of observation or an object that is being kept in view. It is used in conjunction with off centre vision in order to gain the maximum use of the eyes at night. Therefore, the observer should move their visual axis every 4–10 seconds. Night scanning differs from day-time scanning. Should the daytime technique of looking from left to right in overlapping parallel bands from near to far be used, then nothing would be seen.
- Starring: It is important to realise that when staring at a stationary light or prominent object in an otherwise black scene, the object may start moving. This happens because the eye has no bearing on which to check the exact position. This can be prevented by 'placing' the object against something else such as a finger at arm's length.
- Confidence: In order to gain confidence in the ability to see under low light levels, the correct use must be made of the eyes. Objects seen at night tend to be fuzzy and hazy around their extremities. Through practice, an observer must learn to recognise objects at night and how they differ from their day-time appearance. Once a searcher is familiar with the techniques of seeing at night, the confidence necessary for night operations will quickly follow.

Protection of Night Vision: Any bright light will spoil night vision. It is important that the searcher instinctively closes, or covers one eye when faced with any light at night. In addition they should:
  - Avoid looking at any bright light unnecessarily;
  - Shield the eyes with their hand from flares, spotlights or headlights (by so doing it's possible to see objects moving beyond the lights and it protects night vision);
  - Avoid waving torches about as not everybody will be quick enough to close their eyes in order to avoid being dazzled;
  - Put one hand over the glass when using torches to map read, and use the fingers to limit both the area illuminated and the brightness of the light (keep one eye shut and the time spent on reading the map to a minimum); and
  - Use of coloured filters on torches will assist in maintaining night vision although similar coloured markings on maps cannot be seen.

Team and Individual Skills

Each individual search team member must receive training in:
- Map/chart reading and navigation;
- Radio operating procedures;
- Basic first aid;
- Field craft/seamanship;
- Observation; and
- Search techniques.

Searchers

All persons involved in searches need specific skills, attributes, equipment and both physical and mental capabilities:
- Personal Equipment - Each searcher must be self-sufficient in personal equipment. Such equipment should be capable of being carried on the person, in pockets or on a belt. The carriage of excess equipment should be avoided as searchers must remain highly mobile. Suggested items include:
  - Clothing and footwear appropriate to the weather and the environment;
  - Appropriate headgear;
  - Filled water bottles, snacks and nibbles;
  - Pocket knife, whistle, notebook and pen;
  - Compass and map (if required);
  - Sun cream, insect repellent etc.; and
  - Minor personal first aid items.
- Attitude - Must be psychologically prepared for both the rigours of the search operation and for the possibility of locating a seriously injured or deceased person.
- Readiness—A readiness for the search including:
  - Commitment to the task;
  - Time commitment for the entire search rather than small segments of it;
  - Discipline and teamwork; and
  - Acceptance of hardships.
- Fitness—Searchers must be sufficiently fit to cope with the physical demands for the search activity.

Search Team Leaders/ On-Scene Commanders

Desirable Qualities: Searches involve people, therefore it is essential that the STL/OSC has the knowledge, experience and personality to effectively lead and control the team. They must be an effective manager, must be aware of the capabilities of the team, have an understanding of each member's limitations and have their general well-being in mind. There is a need for adequate rest, food and shelter during operations and the STL/OSC must ensure that this is provided.

The attributes of a STL/OSC include:
- Leadership skills;
- Dedication;
- Knowledge; and
- Flexibility.

The main skills for a STL/OSC are as follows:
- Orders - The ability to give clear, concise and detailed orders;
- Map/chart Reading and Navigation - The ability to read a map/chart and navigate in a variety of environmental conditions;
- Use of Radios - Use a radio, pass messages and use the terrain to best effect;
- Casualty Handling - They must have a sound knowledge of first aid and casualty handling procedures;
- Fieldcraft/seamanship - Must be skilled in living, navigating and operating in the field or at sea as appropriate; and
- Search Techniques - Must be competent in the implementation of all appropriate search techniques.

2 Distress and Emergency Signals

There are many signals that can be used to indicate a distress or other emergency. These emergency signals may be made by radio, satellite, telephone, texting, internet (email, social media, etc.). RADAR (e.g. transponders), flags, pyrotechnics, flashing lights, smoke, sounds, shapes and ground panels.

Emergency Signals

Marine Radio Alarm Signal	With the full implementation of the Global Maritime Distress and Safety System (GMDSS) in February 1999 the automatic alarm devices used on 2182 kHz are no longer required. However, some maritime communication stations may still use the voice alarm signal consisting of two sinusoidal audio frequency tones, one of 2200 Hz and the other of 1300 Hz, producing a distinct warbling sound to draw attention to a distress broadcast. Merchant shipping complying with the SOLAS Convention now guard the Digital Selective Calling (DSC) distress frequencies.
RTF Distress Signal	The distress signal “MAYDAY” is used to indicate that a craft or person is threatened by grave and imminent danger and requires immediate assistance. It has precedence over all other communications. The distress message is preceded by the word MAYDAY spoken three times.
RTF Urgency Signal	The urgency signal “PAN PAN” is used to indicate that the calling station has a very urgent message to transmit covering the safety of a ship, aircraft or person. It has precedence over all other communications, except distress traffic. The urgency message is preceded by the words 'PAN PAN' spoken three times.
RTF Safety Signal	The safety signal “SECURITÉ” indicates that the station is about to transmit a message concerning the safety of navigation or providing an important meteorological warning. The safety message is preceded by the word 'SECURITÉ' spoken three times. All stations hearing a distress, urgency or safety signal shall not make any transmissions that might interfere with those signals and be ready to copy any message that follows.
Radiotelephony Distress/Emergency Frequencies	The following frequencies have been designated as distress or emergency frequencies.

Radio Telephone	**DSC**	**NBDP**			
2182	2187.5	2174.5			
4125	4207.5	4177.5			
6215	6312	6268			
8291	8414.5	8376.5			
12 290*	12 577.0	12 520.0			
16 420*	16 804.5	16 695.0			
VHF: Ch. 16	VHF: Ch. 70	VHF not used			

Note: None of the MF/HF DSC or NBDP frequencies are used when calling. The AMSA HF DSC network monitors DSC in the 4 – 16 MHz bands.

* The frequencies 12 290 kHz and 16 420 kHz be used only for distress, urgency and safety communications, and safety-related calling limited to that, to and from rescue coordination centres.

2182 kHz	The international MF voice distress frequency primarily for ship-to-ship communications, the upper side band 2182 kHz is used for follow-on communications after an initial DSC distress alert on 2187.5 kHz for GMDSS shipping. In Australia, some Limited Coast Radio Stations operated by Volunteer Marine Rescue (VMR) Groups around the coast advertise the monitoring of the 2182 frequency. Contact the local VMR Unit to ascertain its monitoring of 2182. The two-tone alarm may still be used on 2182 kHz to draw attention but auto alarms are no longer a part of the Radio Regulations.
4125, 6215, 8291, 12290 and 16420 kHz	These frequencies have been authorised for common use by ships and coast stations using the HF frequencies for upper sideband radiotelephony on a simplex basis for calling, reply and safety purposes. The frequencies quoted are the carrier frequencies. The State and Territory Coast Radio Stations monitor the distress and safety frequencies in the 4, 6 and 8 kHz bands.
121.5 MHz	The international aeronautical emergency frequency for aircraft and those aeronautical stations primarily concerned with the safety and regularity of flight and having equipment in the 118-136 MHz VHF band. Ships fitted with the capability are authorised to communicate on this frequency with aircraft for safety purposes.
156.8 MHz (Marine VHF Channel 16)	The international distress, safety and calling frequency for radiotelephony stations of the maritime mobile service, when using frequencies in the Marine VHF bands 156 to 174 MHz. State and Territory limited coast radio stations, port authorities, merchant ships, fishing craft and pleasure craft use VHF Ch. 16. Merchant ships maintain a continuous bridge listening watch on VHF channel 16 to the maximum extent practicable when at sea; and is monitored in all active marine rescue bases. 156.3 MHz (Marine VHF Channel 6) is used for coordination at the scene of an incident
243 MHz	243 MHz is the international military aeronautical emergency frequency.
Safety Frequencies	The following table indicates Safety frequencies in use in Australia.

156.375 MHz	VHF FM RTF (Marine channel 67)	Marine safety: Australia only (supplementary to Channel 16 and used to broadcast weather and warnings from State/Territory limited coast stations)
27.88 MHz (Channel 88)	HF (Marine) RTF	27 MHz band, pleasure craft safety frequency (in Australia) 27.88 MHz has been overtaken in popularity by VHF 16 by the general public.
2524 kHz	MF (Marine) RTF	Pleasure boat safety, volunteer SAR organisations (in Australia)

Global Maritime Distress and Safety System (GMDSS)	Ships subject to the Safety of Life at Sea (SOLAS) Convention are obliged to be outfitted with certain communications equipment to participate in the Global Maritime Distress and a Safety System (GMDSS). Fishing vessels and small craft around Australia, if carrying compatible GMDSS equipment can also participate.

Ships operating under GMDSS requirements in the Australian SRR can be expected to carry:
- MF DSC;
- VHF radiotelephone (Channels 6, 13, 16 and 67);
- VHF DSC (Channel 70);
- Inmarsat-C or HF DSC;
- An AIS-SART or RADAR SART; and
- An EPIRB.

Daylight Emergency Signalling Devices

Mirrors	Reflective mirrors (heliographs), used by survivors to reflect the sun's rays towards a SAR unit, are an effective daylight device. Mirrors have been detected as far away as 80 kilometres (45 miles) and from as high as 10,000 feet, although the average distance is about 18 kilometres (10 miles). Fluorescent material (known as retro-reflective tape) that reflects a large percentage of sunlight is usually sewn on one side of lifesaving craft coverings and has been detected as far away as 9 kilometres (5 miles) with an average of 6 kilometres (3.5 miles).

Fluorescent Sea Dye Marker	This stains the water a green or red colour, has been sighted as far away as 18 Kilometres (10 miles), with an average of 5 kilometres (3 miles). However, sea dye is not visible when searching up-sun because of surface glare.
Orange Smoke	Orange smoke generating signals have been sighted as far away as 20 kilometres (12 miles) with an average of 14 kilometres (8 miles). Smoke signals are most effective in calm wind conditions and open terrain. The effectiveness of smoke signals decreases rapidly with an increase of wind speed above 15 knots (25 kph).
Flares	Pyrotechnic flares may be used in daylight; however their detectable range is only about 10 per cent of the night-time range.

Night-time Emergency Signalling Devices

Fires	On land, fires are arguably the most effective night time signal that survivors may use. Fires have been sighted as far as 90 kilometres (50 miles) away, with the average range varying with the size of the fire, the absence of other light sources on the earth's surface, the terrain and Height of Eye of the search asset.
Flashing Strobe Lights	Flashing strobe lights are an effective compact night signalling device available for individual survivors. Strobe lights have been sighted as far as 35 kilometres (20 miles) away with an average of 6 kilometres (3.5 miles).
Incandescent Lights	Incandescent lights that are used on some individual lifejackets have a much smaller detectable range than strobe lights, generally about 1 kilometre (0.5 mile).
Flares, Star shells and Rockets	Flares, star shells and rockets have been detected as far away as 60 kilometres (35 miles), with an average of 45 kilometres (25 miles) from the air.
Night Vision Goggles	With the use of Night Vision Goggles (NVG) objects emitting small amounts of light such as mobile telephone screens are able to be seen from great distances. There is no need for a telephone signal, it is the lit screen that is being detected. Larger light sources such as fires, torches, and strobe lights can be viewed from considerably farther. E-Flares and some LED strobe lights have been identified as being invisible on NVG due to the frequencies used. Searchers must be aware of this.

RADAR/IFF/SSR

The basic equipment consists of an interrogator and a transponder. The interrogator, which is usually incorporated into air search RADAR systems, transmits electronic challenges, and if any replies are received will display them on the Radarscope. The transponder, which is usually installed in aircraft, ships and boats, is triggered into operation by the interrogator's challenge and transmits a series of pulses. The reply is displayed as small bars slightly beyond the RADAR target of the transponderequipped craft. Since interrogators usually use the same antenna as the air search RADAR, replies are only received as the search RADAR beam sweeps across the transponder-equipped craft. In addition, transponder replies will be detected at much greater ranges than the RADAR return from the craft itself.

Secondary Surveillance RADAR (SSR) is the name used to describe similar equipment in use by Airservices Australia and civil aircraft. Military mode 3 is the same as civil mode A and thus the systems are compatible for air traffic control and emergency purposes. Military mode 3, code 7700 and civil mode A, code 7700 transmits an emergency signal and, unless amplified by additional information, will be considered as a distress signal.

Radio and Distress Beacons

In addition to the obvious uses of standard radio for transmitting emergency signals and messages, there are a variety of types of emergency equipment designed for use by survivors or carried in the vessel's wheelhouse. These include:
- Hand held VHF transmitters found in life rafts;
- 406 MHz distress beacons (GMDSS approved); An AIS-SART; and
- 9 GHz SAR Transponders.

Satellites

The COSPAS-SARSAT system uses three search and rescue satellite constellations: LEOSAR, GEOSAR and MEOSAR. Each LEOSAR satellite makes a complete orbit of the earth around the poles in about 100 – 105 minutes. The satellite views a "swath" of the earth of approximately 4000 km wide as it circles the globe, giving an instantaneous "field of view" about the size of a continent. When viewed from the earth, the satellite crosses the sky in about 15 minutes, depending on the maximum elevation angle of the particular pass.

LEOSAR satellites are not equally spaced and hence do not pass over a particular place at regular intervals. In view of this, pass schedules are computed for each LUT every day. On average a satellite will pass over continental Australia every 90 minutes but, because of the irregularity of passes, there could be up to five (5) hours between passes.

The current GEOSAR constellation is composed of satellites provided by the USA, India, Russia and Europe. These satellites provide continuous global coverage for 406 MHz beacons with the exception of the Polar Regions. As the GEOSAR satellites appear stationary from Earth, if the direct line of sight from the beacon to the GEOSAR satellite is blocked (for example, by terrain such as a mountain, called shadowing), the beacon will not be detected by the GEOSAR satellite.

The MEOSAR satellites consist of satellites provided by the United States, the Russian Federation and the European Union. The full MEOSAR constellation will have about 72 satellites. These MEOSAR satellites orbit the Earth at altitudes between 19,000 and 24,000 km, a range considered as a medium-altitude Earth orbit. The footprint of a MEOSAR satellite is between 12000 and 13000 km and the satellites provide continuous global coverage of the Earth. These satellites send the beacon message back to earth where it is detected by a MEOLUT (MEOSAR Local User Terminal).

With sufficient information, the MEOLUT will generate a location for the distress beacon. The beacon activation information is forwarded to a Mission Control Centre (MCC) and then to the relevant Rescue Coordination Centre (RCC) which responds to the beacon activation. The MEOSAR system will detect beacons in almost real-time (i.e. within 5 minutes). If the beacon is detected by three or more MEOSAR satellites, then the location of the beacon will be determined as well. When the full constellation of MEOSAR satellites is in operation, this will mean location will be determined within 10 minutes, 95 percent of the time.

Beacon Detection

A LUT tracking LEOSAR satellites is known as a LEOLUT. A LEOLUT generates the position of a distress beacon using Doppler shift, which is caused by the relative movement between a satellite and a beacon. As a satellite approaches a beacon there is an apparent rise in the beacon frequency and as the satellite moves away the frequency appears to fall. When a satellite is at its closest point to a beacon the received frequency is the same as the transmitted frequency (the point of inflection) and provides the "Time of Closest Approach" (TCA).

This method of calculation produces two possible positions for each beacon (labelled A and B), either side of the satellite's ground track; one is the true position and the other is its mirror image. The ambiguity is due to the equipment only being able to determine the distance between a satellite and a beacon and not the direction. Position ambiguity is subsequently resolved by using other independent location data (for example; an encoded location or data from another LEOSAR satellite pass).

A LUT tracking MEOSAR satellites is known as a MEOLUT. A MEOLUT generates the position of a distress beacon using DOA (Difference of Arrival) processing. Upon receiving a transmission (a beacon burst) from a 406 MHz distress beacon via a MEOSAR satellite, a MEOLUT will generally measure two key values: the Time of Arrival (TOA) and the Frequency of Arrival (FOA). Assuming reception of a beacon transmission through at least three distinct MEOSAR satellites, MEOLUT processing can provide a two-dimensional (longitude and latitude) beacon location using a combination of time difference of arrival (TDOA) and frequency difference of arrival (FDOA) computations. The location computed by a MEOLUT is known as a difference of arrival (DOA) location. Three-dimensional locations (i.e., with the addition of a computed altitude) are possible when the beacon burst is relayed to a MEOLUT via four or more MEOSAR satellites.

Beacons

There are three types of COSPAS-SARSAT distress beacons:
- Emergency Locator Transmitters (ELT) used by aviators (generally larger devices mounted in the tail of an aircraft);
- Emergency Position Indicating Radio Beacons (EPIRB) used by mariners (waterproof and required to float upright); and
- Personal Locator Beacons (PLB) used on land (initially not required to be waterproof or buoyant but new generation ones are becoming so.).

A distress beacon with GNSS (Global Navigation Satellite System, also known as a GPS) capability is able to transmit an encoded location as part of its beacon message. There are two mechanisms used to derive the GNSS location: either the distress beacon has an internal GNSS receiver or the distress beacon receives the GNSS data from an external device that connects to the beacon. Due to the popularity of the GPS system, the encoded location is often known as the GPS location of the beacon. Aviators and mariners often carry PLBs as personal back up devices to ELTs and EPIRBs.

Because 406 MHz beacons transmit an extremely stable frequency, positions calculated by the LUT usually fall within a radius of 5km from the actual beacon position. All 406 MHz beacons sold in the Australian region are required to transmit on a side frequency of 121.5 MHz to facilitate homing.

406 MHz beacons use digital technology that allows an identifier to be sent when the beacon is activated. This identifier correlates to a registration database held at the JRCC and allows additional information to be gained about the target. 406 MHz beacons should be coded with a country code and registered in the country that maintains the database for that country code. It is therefore important that all Australian 406 MHz beacons are registered with JRCC Australia.

Other Distress Alerting Devices

SPOT Personal Satellite Messenger device (SPOT)	The SPOT device and its associated service originate from a USA company called SPOT LLC. SPOT is primarily a tracking device which can also send preformatted messages indicating that a person is safe or that they require non-emergency assistance. In addition the user is able to alert an Alerting Post that they are in distress. SPOT LLC has contracted for the provision of 24-hour emergency monitoring and response to SPOT users through the International Emergency Response Coordination Centre (IERCC), an Alerting Post located in the United States of America. These devices operate on cellular or satellite telephone networks and are therefore vulnerable to coverage limitations. The devices offer a range of functions which may be more attractive to a hiker or bushwalker than a COSPAS-SARSAT approved device but there are limitations to the devices that could hamper a search and rescue effort.
AIS-SART	The AIS-SART derives position and time synchronization from a built in GNSS receiver and transmits its position with an update rate of one (1) minute. Every minute the position is sent as a series of eight (8) equal position reports, this is to maintain a high probability that at least one of the position reports is sent on the highest point of a wave.
Maritime Survivor Locating Systems. VHF DSC Maritime Survivor Locating Devices (MSLD)	The VHF DSC MSLD, such as the Mobilarm Crewsafe series of beacons, transmit a MAYDAY using a synthesised voice on VHF Channel 16 and a distress alert on DSC (VHF Channel 70) immediately a man overboard incident occurs (or when the unit is manually activated), this is repeated once the MSLD obtains a GPS position (within 1 minute) and is updated every 5 minutes for the first 30 minutes, and then every 10 minutes for the life of the battery (24 hrs.). The MSLD includes the MMSI for identification; some MSLD may also transmit on AIS and a 121.5 MHz homing signal.
Thuraya Satellite Devices	The Thuraya Telecommunications Company ("Thuraya") runs and operates the Thuraya Satellite Network to provide telecommunications products and services in the coverage area of the Thuraya Satellite System. Thuraya devices have the capability to a provide distress alerting function to subscribers. The Thuraya subscriber will initiate an emergency call by pressing and holding a "special button" or activating a special function on the Thuraya device. The device will then obtain a GPS fix and send the location and event request via the Thuraya satellite system.

Merchant Shipping and GMDSS

Communications between merchant vessels in distress and SAR organisations are achieved by a satellite and radio watch system known as the Global Maritime Distress and Safety System (GMDSS). The GMDSS enables a distress alert to be transmitted and received automatically over short and long distances. The system allows SAR authorities as well as shipping in the vicinity of the distress to be rapidly alerted so that a coordinated search and rescue operation can be commenced with the minimum of delay.

Additionally the GMDSS provides for urgency and safety communications, and the dissemination of Maritime Safety Information (MSI). Certain fishing vessels and other marine craft may also carry GMDSS equipment. GMDSS equipped vessels perform the following functions wherever they operate:
- Transmit ship-to-shore distress alerts by two independent means;
- Receive shore-to-ship alerts (usually relayed by International RCCs);
- Transmit and receive;
- Ship-to-shore alerts;
- SAR coordinating communications;
- On-scene communications;
- Locating signals;
- Maritime safety information;
- General radio communications to and from shore; and
- Bridge to bridge communications.

Limited Coast Radio Stations (Australia)

In Australia, Limited Coast Radio Stations (LCRS) are located in nine locations: Sydney, Gladstone, Cairns, Darwin, Port Hedland, Fremantle, Adelaide, Melbourne and Hobart and maintain a continuous radio watch by monitoring the following distress frequencies:
- 4125, 6215, and 8291 kHz with 8176 kHz used to broadcast weather and warnings at regular times;
- 156.8 MHz (VHF CH16). Channel 16 is monitored in various other locations in each State/Territory;
- Channel 67 is used to broadcast weather and warnings

Ship Stations

SURVIVAL Search & Rescue Distress and Emergency Signals Ship Stations

There are three distinct categories of vessels to be catered for by the marine SAR system; these are:
- Deep sea vessels (SOLAS);
- Fishing vessels; and
- Pleasure craft.

Most deep-sea vessels will carry communications equipment compatible with the GMDSS. Other vessels, most of which use satellite communications, may extend this coverage. A continuous bridge listening watch is kept on VHF Ch16, as far as is practicable. Vessel Tracking System (VTS) is utilised by most states/territories to monitor the location of SOLAS vessels with the reef systems and other locations posing heavy traffic or environmental concerns.

Fishing Vessels
Some fishing vessels will carry GMDSS equipment; however the majority of fishing vessels carry a variety of radio equipment and do not maintain regular watches. Frequencies allocated to fishing vessels are normally not compatible with large ships. Some fishing vessel operators are members of cooperatives and their normal procedure whilst fishing is to maintain daily radio schedules with the cooperative base station. AFMA and some State Fisheries Authorities use Vessel Monitoring Systems (VMS) utilising Inmarsat-C polling to track fishing vessels in their fisheries for regulatory reasons. These authorities may be able to assist an RCC in contacting or locating fishing vessels.

Pleasure Craft
These craft are under state control and hence the regulations concerning the carriage of radio and other SAR equipment vary from state to state, and within the state, depending upon the type and size of craft and its area of operations. There is a general acceptance by the boating community of the need to carry some type of radio. The 27 MHz marine radio is a popular choice. 27.88 MHz has been designated as the primary distress, safety and calling frequency, with 27.86 MHz as the secondary. These frequencies are often referred to as channels 88 and 86 respectively and care must be taken not to confuse them with the VHF Marine FM frequencies that are always referred to as channels. VHF Marine FM radio is increasingly being used by pleasure craft.

3 Communication

SURVIVAL Search & Rescue Communication

Frequencies
The most common methods of radio communications are listed below:

HF (High Frequency)	HF operates in the band 3 to 30 MHZ. In addition to ground waves, sky wave operation is possible which vastly increases the range. This type of transmission relies on 'bouncing' radio waves from a layer of ionised gases 150 km above the earth's surface and back down to ground. Considerable distances can be achieved using HF. However, the system tends to be noisy and requires large aerial installations and some degree of expertise to operate. It would normally be used only as a rear link back to a search headquarters;
VHF (Very High Frequency)	VHF operates in the band 30–300 MHZ. This type of transmission is commonly used by mobile radio fleets and gives reliable communications over a distance of 20– 30 km. It is primarily 'line of sight' transmissions. This means that hills or major obstacles may impede reliable communications and the base site should always be as high as possible. difficulty may be experienced at times by searchers losing communications. If this happens, operators should be aware that a small change in location or moving to a high point may assist in regaining contact. This applies equally to UHF.
UHF (Ultra High Frequency)	UHF operates in the band 300– 3000 MHZ. This method is strictly 'line of sight' and in flat or open terrain, to increase its range, it requires repeater stations on some high point to relay messages and therefore requires some degree of technical expertise to install.

Radios in General
UHF CB style radios provide the best balance between portability and communications. Not only searchers and headquarter bases should be provided with UHF radios but their carriage and usage by persons travelling in the more remote areas of Australia should be encouraged.
- A vehicle mounted radio attached to an external antenna will provide the best coverage although a hand-held device will also work, albeit with a limited range. Spare batteries should always be carried if the radio is not hard wired.
- UHF Channel 9 or 40 have been identified as "listening channels". Once a call has been established, users can move to a clear channel.
- UFH Channel 5 is a designated emergency channel, while this is Duplex it is also an emergency Simplex channel and there are no duplex repeaters on this channel in the bush.
- UHF Channel 11 is a dedicated Australian calling frequency which after establishing contact users move to another channel.
- While the above channels are dedicated, a search asset with a scanning radio will detect a missing person calling on any channel within range. Modern scanning radios cover all 40-80 channels every 4 seconds, ensuring that not active channel is missed.

Attention must be given to the state of the batteries in portable sets and spare batteries should always be available. Batteries should not be left in sets which will not be used for any length of time. It is recognised that most radio failures are caused by a lack of care and knowledge on the part of operators, rather than deficiencies within the sets themselves.

Loss of communications: During search operations it is likely that situations will arise where radio communications are less than 100% effective. Teams should be briefed as to their actions in case of a loss of communications. These actions may include backtracking to their last point of communication, problem solving, using other forms of communication, relaying through other stations, non-use of Distress Devices – 'no news is good news', or carrying on with an assigned task – 'be at this spot at this time'.

Ground to Air Communications: Aircraft operate on aviation transport group frequencies allocated by Australian Communications Authority and can be contacted through the airport control tower, but radios are available which can contact aircraft on a special frequency. Prior arrangement with the aircraft pilot is necessary to work on this channel as the aircraft normally listens out on tower frequencies. Another alternative is to place on board the aircraft a portable radio on the same frequency as is being used by the search teams.

Procedures and Practices
To achieve efficiency, standard radio procedure should be used. Although two- way conversations will be needed, messages should be written for reference at a future time. It may also be necessary to refer to past actions or decisions and this makes necessary the keeping of a written record. Search Team Leaders should carry a note book to record messages.

Other Methods of Communications
Mobile telephones: The rapid expansion of the mobile telephone network throughout Australia has provided the SAR coordinator with another option for SAR communications, although it must be noted that they do not work in all locations. A number of considerations must be taken into account by the SMC when considering mobile telephones as a communications method:
- The use of a radio net should always be the first option,
- The extent of the networks and coverage at the search location
- The availability and type of mobile telephones at the search location
- The battery life and ability to recharge those mobile telephones available
- The ability to send and receive spoken words, text messages and photographs.
- Mobile telephones may be considered as a secondary communication method, and when direct and private contact is to be made between the SMC and teams.

- The use of text messages may be more successful than verbal communications. Text messages require less signal strength and will be received when a mobile telephone comes within range even if it is some time since it was originally sent.

Other methods of communicating, which can be used but require some degree of prior planning are:
- Control of Contact or Close Search - Whistles, loud hailers, and simple voice orders. (To contact both single and multiple teams).
- Location of Search Teams or Finds - Smoke, light (fire), signalling mirrors.
- Recall signals - Whistles, sirens, gun shots, pyrotechnic rockets.
- The General Public - Commercial radio stations for supplying information and instructions to the public.
- Mobile Communications - For relay points.
- Field Signals - Searchers may be required to use field hand signals or audible sounds to communicate within or between teams. Recognised audible signals are:
  - One short blast at irregular intervals - searchers looking for a missing person and as an acknowledgment of a distress signal;
  - Three short blasts together, regularly spaced—distress signal; and
  - Four short blasts together, regularly spaced—which is recall signal.

4 Information

When the SAR system first becomes aware of an actual or potential emergency, the information collected and the initial action taken are often critical to a successful SAR operation. It must be assumed that in each incident there are survivors who will need assistance and whose chances of survival are reduced by the passage of time. The success of a SAR operation depends on the speed with which the operation is planned and carried out. Information must be gathered and evaluated to determine the nature of the distress, the appropriate emergency phase, and what action should be taken. Prompt receipt of all available information by the RCC is necessary for thorough evaluation, immediate decision on the best course of action and a timely activation of SAR assets to make it possible to achieve the following:
- Locate, support and rescue persons in distress in the shortest possible time.
- Use any contribution survivors may still be able to make towards their own rescue while they are still capable of doing so.

Experience has shown that the chances for survival of injured persons decrease by as much as 80% during the first 24 hours, and those for uninjured persons diminish rapidly after the first three days. Following an accident, even uninjured persons who are apparently able-bodied and capable of rational thought are often unable to accomplish simple tasks and are known to have hindered, delayed or even prevented their own rescue.

Several factors will influence the extent and manner of an initial SAR response. In general these are the:
- Extent and reliability of information about the location of the missing persons
- Availability of aircraft, marine assets and land parties for searching;
- Prior, actual and forecast weather conditions;
- Times of daylight/darkness;
- Nature of terrain/sea conditions;
- Availability of survival supplies and supply dropping teams; and
- Time delay in notification.

Air, Marine or Land Incident Information

The following information, or as much of it as is required to address an emergency situation, should be obtained from the craft or the individual reporting the actual or potential emergency situation or incident. As many of the items should be obtained as circumstances permit.

- Name, address, and telephone number or contact point of person reporting.
- Distressed craft (name/type/callsign/registration) or identification.
- Position of emergency (latitude/longitude or bearing/distance) from a known point or the last reported position and the next reporting position).
- Nature of emergency (fire, collision, person overboard, disabled, overdue, crash or missing hiker etc.).
- Date/time of emergency occurrence and the Date/time of notification.
- For aircraft, altitude, attitude, heading, speed and endurance.
- Craft description (size, type, markings, hull, colour of cabin, deck, rigging, fuselage colour, tail colour, wingtip colour, unusual features).
- Details of persons on board, persons involved (POB) including number of people involved, ages, state of health, injuries, and intentions.
- Date, time and departure point, planned route, speed, ETA and destination.
- Radio frequencies currently in use monitored or scheduled.
- Emergency radio equipment and frequencies, EPIRB, ELT, or flares.
- Actual weather/sea conditions.
- Local action being taken or assistance required.
- Owner/agent of distressed craft and contact method.
- Possible route deviations.
- Navigation capabilities.
- Survival equipment including quantity of food/water and signaling devices.
- Mobile phone numbers of any person.

Missing Person

- Personal details (Name, DOB, address, telephone numbers, employment, social status, married);
- Physical features (Description, fitness, ability, past history);
- State of health (physical and mental);
- Medication (taken, carried or left behind) (what are the effects of this?);
- Psychological issues (Happiness, depression, family trouble, financial trouble, legal trouble)
- Dress (Wearing now and what taken? Is it suitable for the conditions?);
- Food/water (Any? Sufficient? Will last how long?);
- Handedness, (Left or right);
- Any means of transport (Where is it? Public transport?);
- Time last seen (Intentions, intended routes, previous routes?); and
- Any other information considered relevant.

Such information may well dictate the urgency of the search. If, for example, the person has a history of going missing, it may suggest a policy of wait and see.

Objects/Evidence

When conducting a search for an object such as aircraft, vessel, vehicle, or any other article it will be necessary to gain a complete description of the object. This should include:
- Description;
- Make;
- Model;
- Colour;
- Size;
- Weight;
- Registration number;
- Markings; and
- Safety aspects/danger.

Where an object is unlikely to be readily identifiable, the requirement for detail is increased. If possible, a model, photograph, or drawing should be obtained. Particular emphasis should be on safety factors if the object is likely to offer a hazard to the finder. An example would be the hazards associated with modern aircraft.

5 Emergency Phases

Emergency phases are based on the level of concern for the safety of persons, vessels or aircraft. Upon initial notification the notified SAR authority or ATS unit classifies the SAR incident as being in one of the three following emergency phases:
- Uncertainty Phase (INCERFA).
- Alert Phase (ALERFA).
- Distress Phase (DETRESFA).

The emergency phase may be reclassified by the SMC as the situation develops. The current emergency phase should be used in all communications about the SAR incident as a means of informing all interested parties of the current level of concern for the safety of persons or craft which may be in need of assistance.

Maritime search and rescue in Australia is based on the GMDSS and although there are three forms of messages from a ship to the SAR authority, there is no mention of emergency phases in GMDSS documentation or IAMSAR Volume 3, the SAR manual carried by ships. Emergency phases should be used internally among maritime SAR authorities to indicate the level of concern and as criteria for escalating a SAR action. An uncertainty phase relates to a safety broadcast, the alert phase to an urgency broadcast and a distress phase to the distress broadcast.

Uncertainty Phase

The uncertainty phase is assigned any time doubt/uncertainty exists as to the safety of an aircraft, vessel or person because of knowledge of possible difficulties, or because of lack of information concerning progress or position. The keyword is DOUBT. This does not mean that the SMC has doubt that a SAR situation exists, more that there is doubt about the level of safety of those involved.

An Uncertainty Phase is said to exist when there is knowledge of a situation that may need to be monitored, or to have more information gathered, but that does not require dispatching of resources. When there is doubt about the safety of persons, vessel or aircraft, the situation should be investigated and information gathered. For aircraft, an INCERFA is declared when:
- No communication has been received from an aircraft within a period of fifteen (15) minutes after the time a communication should have been received, or from the time an unsuccessful attempt to establish communication with such aircraft was first made, whichever is the earlier.
- An aircraft fails to report departure from a Mandatory Broadcast Zone (MBZ) or non-standard Common Traffic Advisory Frequency (CTAF) area after a call notifying readiness to taxi or take-off or after an airborne call from within a MBZ or CTAF area, within five (5) minutes after estimate for the boundary.
- An aircraft fails to arrive within 15 minutes of the last estimated time of arrival last notified to or estimated by ATS units; whichever is the later, except when no doubt exists as to the safety of the aircraft and its occupants

For persons, vessels or aircraft, an Uncertainty Phase is declared where the persons, vessels or aircraft have:
- Been reported overdue at the intended destination;
- Failed to make an expected position safety report; or
- There has been no immediate request for assistance received but the possibility exists that a situation could escalate.

Alert Phase

The alert phase is assigned any time apprehension exists for the safety of persons, vessels or aircraft because of definite information that serious difficulty exists which does not amount to a distress or because of a continued lack of information concerning progress or position. The key word is APPREHENSION.

An Alert Phase exists when persons, vessels or aircraft are having some difficulty and may need assistance, but are not in immediate danger. Apprehension is usually associated with the Alert Phase, but there is no known threat requiring immediate action. SRUs may be dispatched or other SAR assets diverted to provide assistance if it is believed that conditions might worsen or that SAR assets might not be available or able to provide assistance if conditions did worsen at a later time.

For a SAR involving an overdue target, the Alert Phase is declared when apprehension exists as to the safety of an aircraft/vessel or persons. Apprehension exists due to the lack of progress or positions of persons, vehicles or aircraft or inability to confirm safety in a suitable timeframe. At the Alert Phase, coordinators should begin or continue communications searches, land searches and in some cases tasking of vessels/aircraft to high probability locations. Vessels in the area may be asked to maintain a sharp lookout, report all sightings and render assistance if needed.

An Alert Phase is declared when:
- Following the Uncertainty Phase, subsequent attempts to establish communication with persons, vessels or aircraft have failed or inquiries to other relevant sources have failed to reveal any news.
- An aircraft has been cleared to land and fails to land within five (5) minutes of the estimated time of landing and communication has not been re-established with the aircraft.
- Information has been received which indicates that the operating efficiency of the aircraft, ship or other craft has been impaired but not to the extent that a forced landing or distress situation is likely, except when evidence exists that would allay apprehension as to the safety of that craft and its occupants.
- An aircraft is known or believed to be the subject of unlawful interference.

Distress Phase

The distress phase is assigned whenever immediate assistance is required by persons, vessels or aircraft threatened by grave or imminent danger or because of continued lack or information concerning progress or position. The key words are GRAVE or IMMINENT DANGER and IMMEDIATE ASSISTANCE.

The Distress Phase exists when there is reasonable certainty that the targets are in imminent danger and require immediate assistance. For SAR incidents involving an overdue target, a distress exists when communications searches and other forms of investigation have not succeeded in locating the target or revising its ETA so that it is no longer considered overdue. If there is sufficient concern for the safety of a target and the persons aboard to justify search operations, the incident should be classified as being in the Distress Phase. For aircraft, a Distress Phase is declared when:
● Following the Alert Phase, the further unsuccessful attempts to establish communication with the aircraft and more widespread unsuccessful inquiries point to the probability that the aircraft is in distress.
● The fuel on board is considered to be exhausted, or to be insufficient to enable the aircraft to reach safety.
● Information is received which indicates that the operating efficiency of the aircraft has been impaired to the extent that a forced landing is likely.
● Information is received or it is reasonably certain that the aircraft is about to make or has made a forced landing, except when there is reasonable certainty that the aircraft and its occupants do not require immediate assistance.
● A report is received that a radio distress beacon has been activated or other visual distress signals have been observed.

For ships, other craft or people, a Distress Phase is declared when:
● Positive information is received that a ship or other craft or people are in danger and need immediate assistance; or
● Information is received which indicates that the operating efficiency of the ship or other craft has been impaired to the extent that a distress situation is likely.

6 Uncertainty Phase Procedures

● Verify the information received, considering the need to extend inquiries to:
○ Landing areas including the aerodrome of departure and other locations close to the route where a subject aircraft might have landed
○ Aircraft, including the subject aircraft, known to be on the same route, in the same area or within communication range, by way of ATS units, or radio contacts calling or listening out, including monitoring emergency frequencies.
○ Vessels known to be on the same route, in the same area or within communication range, by way of VMS, VTS, Coastal radio stations or vessel broadcasts.
○ Persons known to be on the same route, in the same area or within communication range, by way of electronic/social media (television, radio, Facebook, mass texting, etc.) and/or speaking to persons located within the search area.
○ Family, friends, operator of the aircraft, marinas, etc.

● When no flight plan has been filed, or in the case of ships or other craft, no information is available on the intentions of the captain, attempt to obtain information from which the route and departure, flight and arrival times of the aircraft, ship or other craft may be determined.
● Establish close liaison with alerting units to ensure that the following occurs:
○ New information, (e.g.: obtained through widespread communication checks, requests to the public, review of weather factors, etc.) will be made immediately available for evaluation, plotting, decision making etc.
● Plot the route of the subject craft, making use of all available intelligence.
● Conduct a communications search. (More information below)

● Determine actual weather conditions along the route and at the destination.
● Record all incoming information and progress reports, details of action as described below, subsequent developments and decisions.

Communication Search

The communication search can be conducted by the following two primary methods:
● Attempting to communicate with the person, vessel or aircraft by all means of electronic communications through various paths.
● Determining the target craft's most probable location by:
○ Making inquiries at aerodromes (including the aerodrome of departure) and other locations where an aircraft might have landed or at locations where a ship or other craft might have stopped or called (including the point or port of departure).
○ Contacting other appropriate sources including persons who may have knowledge of the intentions of the pilot in command or ship's captain.
○ Using electronic methods to track mobile telephones, leave text or voice mail messages or utilise electronic/social media (television for witnesses, radio, Facebook or similar).

When the communications search or other information received indicates that the person, vessel or aircraft is not in distress, the SAR authority will close the incident and immediately inform the operating agency, the reporting source and any alerted authorities, centres, or services. However, if apprehension regarding the safety of the person, vessel or aircraft and its occupants continues, the Uncertainty Phase should progress to the Alert Phase.

7 Distress Phase Procedures

When a distress phase has been declared by a SAR authority or transferred by Airservices, another RCC or SAR authority, the SAR authority should:
● Initiate or continue any appropriate actions normally performed during the Uncertainty and Alert Phases.
● Ensure an SMC has been appointed and that all interested parties have been informed of the incident.
● Examine the detailed plans of operation for the conduct of SAR operations in the area.
● Determine the availability of SAR assets to conduct SAR operations and attempt to obtain more assets if a need for them is anticipated.
● Estimate the position of the target, estimate the degree of uncertainty of this position and determine the extent of the area to be searched and if a significant search effort is anticipated, use search planning techniques to maximise the chances of finding the survivors.
● Develop a search action plan or rescue plan as appropriate for the conduct of the SAR operation and communicate the plan to the appropriate authorities.

● Initiate action, activating SAR assets as appropriate such as:
○ Search assets may be dispatched from their bases in accordance with the search plan.
○ Aircraft and vessels may be diverted in-flight or en-route.
○ Whenever practicable, aircraft dispatched early should carry droppable supplies (suitable for the environment in which the incident is occurring) unless these aircraft are unsuitable for dropping and/or an unacceptable delay would result to their departure on account of loading.
○ In the latter case, droppable supplies should be loaded on a suitable aircraft as soon as possible.
● Amend the plan as the operation develops.
● Notify the State of registry of the target craft, if applicable.
● Notify JRCC Australia, ADF, State or Territory Police, Maritime Authorities, ATSB and/or CASA, Media as appropriate.
● At an early stage, request aircraft, vessels, coastal radio stations and other relevant services to:
○ Maintain a listening watch for transmissions from the target, by voice, survival radio equipment and from an emergency beacon (ELT/EPIRB/PLB);
○ Assist the target as far as practicable if found; and
○ Inform the RCC of any developments.
● Maintain close liaison with the following:
○ Appropriate agencies for onward transmission to the target (if possible) and for traffic coordination.
○ Other RCCs along the planned route of the target as well as those whose SRRs are within the target's maximum radius of action as determined from its last known position (i.e. the possibility area), ensuring that any information they receive regarding the incident is conveyed to the coordinating RCC.
● Inform community groups by way of radio and television broadcasts requesting sighting and hearing reports and any other intelligence regarding the whereabouts of the subject craft using established procedures for contacting designated personnel at broadcasting stations and specifying messages in precise form.

8 Intelligence Gathering and Assessment

Information relating to a missing craft may be gathered from a variety of sources, in particular from the owner or operator, Airservices and general maintenance records and from the public at large. Careful and accurate assessment of intelligence and information is a vital part of search action and may be instrumental in modifying probability areas, reprioritising search activities and adopting revised search strategies.

Type of Information

● Missing target (aircraft, vessel, and person). As much information as possible regarding the target(s) needs to be obtained.
● Objects: When conducting a search for an object such as aircraft, vessel, vehicle, or any other article, it will be necessary to gain a complete description of the object.
● Weather: It is of vital importance to gain knowledge of weather conditions that have or are likely to prevail in the area of search prior to, during and in the immediate future. In extremes, this will indicate the possible time frame for any involved person's survival.

● Area of Search: The success of an operation will depend to a large extent upon accurate prior knowledge of the area/locality to be covered. It will be necessary to have knowledge of:
- ○ General sea conditions and topography;
- ○ Known problem areas;
- ○ Hazards and terrain;
- ○ Sea state/foliage/ground cover; and
- ○ Rendezvous points

Therefore it is desirable that a field reconnaissance be carried out as early as possible.

● Resources. These resources are basically in two groups:
1. Personnel. Information should include:
   - ○ Number available;
   - ○ Experienced/inexperienced;
   - ○ Capability and response considerations
   - ○ Time available; and
   - ○ Special requirements (e.g. mountain rescue).
2. Equipment. This may include:
   - ○ Vehicles;
   - ○ Vessels (Inshore and off shore);
   - ○ Aircraft (Drones)
   - ○ Radios;
   - ○ Electronic aids (Tracking devices, mobile telephone locators, etc.);
   - ○ Maps, charts and plotting equipment; and
   - ○ Special equipment

Availability and access of information

Having detailed the type of information required, there are three factors to consider:
● Where can the information be obtained?
● How may the information be accessed (e.g. medical records)?
● How much is enough?

Sources of Information

● About Missing Persons (whether from vessel, aircraft or missing): Sources of quality information may include:
- ○ Family;
- ○ Friends;
- ○ School;
- ○ Employer;
- ○ Family doctor;
- ○ Last known contact;
- ○ Hospitals/medical centres;
- ○ Public transport companies;
- ○ Social media; and
- ○ Mobile telephone tracking.

● About the Weather: Sources may include:
- ○ Bureau of Meteorology;
- ○ Local knowledge;
- ○ Local records;
- ○ Experience;
- ○ Electronic sources and archives; and
- ○ Reconnaissance teams.

● About the Area: Sources may include:
- ○ Maps (topographic, parish, forestry);
- ○ Charts (RAN, RN, etc.);
- ○ Electronic (Google maps, Google Earth, satellite images);
- ○ Sketches;
- ○ Local knowledge;
- ○ Aerial photographs; and
- ○ Reconnaissance.

● About Resources: Sources may include:
- ○ Police;
- ○ Emergency services;
- ○ Volunteer services (SES, Coast Guard, Volunteer Marine Rescue);
- ○ Bushwalking club;
- ○ Defence services;
- ○ General aviation;
- ○ Community facilities/organisations; and
- ○ Media.

Evaluating Information: The SMC must consider the traits of the missing person, vessel or aircraft, together with the merit of all available information, to predict the person's possible movement, or to reduce the area of probability. Because total required information will not be available prior to commencing a search, information gathering and evaluation will be continuous throughout an operation. On evaluating the information the SMC will need to make some judgment of the urgency or severity of the situation and whether to take any action of not.

Search Information Phases

The phases for gathering search information include the following:

Pre-Search Phase (Collection, collation, evaluation): In the period between raising the alarm and the actual beginning of the search, as much relevant information as possible needs to be acquired and evaluated. The assessment of information is described earlier in this chapter and this may determine that an alarm has been raised prematurely and the search should be delayed or cancelled, or it may reinforce the sense of urgency due to factors such as:

- Missing person's physical or mental condition (experience, capability, preparedness);
- Vessel, vehicle or aircraft mechanical condition
- Weather conditions; or
- Sea conditions or terrain in the area.

Briefing Phase (Dissemination) - The decision to mount a search has been made and search assets are being prepared to commence the operation. Pilots, masters, and team leaders are required to attend a briefing at which orders will be given regarding the conduct of the search. Details that need to be covered are:

- Briefing needs to be in the SMEAC format, standard among SAR assets;
- Information relevant to the missing target;
- The area to be searched;
- The recommended search pattern;
- The command and communications system; and
- Any special instructions

All this information must be clearly and fully understood by the participants. The omission of a single item of information may lead to an unsuccessful search conclusion.

Search Operations Phase - In the conduct of the operation, the search assets must constantly seek and provide further relevant information. This may be provided in the form of:

- Location of physical clues;
- Information from persons in the area;
- Interpretation of topographical factors; and
- General experience.

Debriefing Phase (Collection, collation, evaluation, dissemination)—As search assets return to the RCC, pilots, masters and team leaders need to be debriefed. Care needs to be taken that all relevant information is gathered and then re-evaluated as the situation develops. This information will then be distributed to assets still searching or before new assets are deployed.

Interviewing Witnesses

Care must be taken in the selection of a person to interview witnesses. Consideration should be given to the use of specially trained officers, e.g. a police officer with SAR training.

When interviewing witnesses, the following points should be kept in mind:

- The interview should be conducted as soon as practicable after the event. Many people forget important facts quickly and are influenced by other opinions, press reports.
- The interviewer should know the subject, be aware of the details reported previously, and have questions prepared in advance to clarify points on which further information is required.
- After identifying himself, the interviewer should explain the purpose of the Interview clearly.
- Persons being interviewed should be asked to give a personal account of events without coercion or suggestion. They may then be asked questions designed to solicit other facts.
- When possible, statements should be tested by related occurrences, e.g. the distance of the craft from the observer by weather phenomena such as visibility and cloud base; the time of observation by the extent of daylight, position of the sun or radio program.
- If witnesses are not clear about particular aspects, they may be left to consider the incident further and be given opportunity to contact you should additional information subsequently come to mind.

Urgency of Response

Evaluating incidents to determine the urgency and the extent of required SAR response, or the termination of response is a function requiring information, judgement and experience. In emergency situations requiring immediate assistance, the action taken must be accomplished quickly and positively. Where uncertainty exists, evaluation is usually more difficult and time consuming because of the many factors involved.

Perhaps the most difficult task the SMC undertakes is the evaluation of these factors. They usually become apparent between the time the incident is reported and the execution of the search. This is a time when speed and reliability will be most important, however it is also a time when incident reports may be incomplete or confused. The most serious limitation is time. When persons are injured or are subjected to adverse climatic or water conditions, the chances of survival decrease rapidly.

Time limitation also may be dictated by the number of hours left for a daylight search, although the SMC should not arbitrarily rule out night search, especially in unpopulated areas, over the ocean, and over flat terrain or deserts. The facilities available to conduct a search may be limited by lack of available personnel and search assets. The SMC must be aware of availability of SAR facilities within their region. Terrain, weather and oceanographic conditions can affect all areas in SAR planning and operations.

Search visibility, aircraft limitations, search effectiveness, safety of flight and time available to complete the search are some of the factors that will affect search capability. Whenever practicable, pertinent data should be plotted on a chart to aid in evaluating related factors. Normally the SMC determines the urgency and extent of SAR services required for an incident. A rapid but systematic approach is essential since prompt response to emergency incidents is the essence of the SAR system.

General Time Factors

The probability of finding survivors and their chances of survival diminish with each minute after an incident occurs. Prompt positive action is required so that no life will be lost or jeopardised through wasted or misdirected effort. Individual incidents will vary with local conditions such as terrain, climatic conditions, ability and endurance of survivors, emergency equipment available and SAR units available to the SAR system. In the case of seriously injured survivors or survivors in a hostile environment, the reaction time of the SAR system must be measured in minutes. Critically injured survivors of any accident usually die within the first 24 hours if not given emergency medical care.

For survivors not equipped with any type of detection aids daylight visual search is usually the only search method available to the SMC. If darkness were approaching this would be another limiting factor for the SMC to consider.

If it is known or suspected that the survivors have detection aids such as pyrotechnic flares or other night signalling devices or can display other lights, night searches should always be conducted. Night searches, visual and electronic are particularly effective at sea, over sparsely populated areas, flat terrain and deserts. Night aural and visual search should be considered.

Modern electronic detection methods may be effective in locating targets. The capability of these devices should be discussed with the operators of the equipment. Consideration should be given to the use of Night Vision Googles (NVG) or Forward Looking Infra-Red Radar (FLIR) particularly when searching from the air.

First and Last Search Light

First and last search light describes the optimal times that searching should commence and cease taking into account the angle of the sun and the limiting factors caused by a low sun on searchers. First search light is 45 minutes after sunrise and last search light is 45 minutes before sunset. These times allow for the sun to either rise above the horizon sufficiently for searching towards the east, or to be sufficiently above the horizon for searching towards the west. In mountainous or built up areas these times may vary due to darkness extending for lengthier periods.

Given the urgency and circumstances a SMC may choose to utilise these times to conduct searches. Civil twilight is that period of time when the sun is 6° (24 minutes) below the horizon, either before sunrise or after sunset. This time can be utilised by aircraft to travel to their respective search area, but originally related to when a star sighting could be taken from an aircraft. Nautical twilight is that period when the sun is 12° (48 minutes) below the horizon, either before sunrise or after sunset. This time can be utilised by vessels to travel to their respective search area but originally related to when a star sighting could be taken from a ship.

Weather/Oceanographic Factors

It is of vital importance to gain knowledge of weather conditions that have or are likely to prevail in the area of search prior to, during and in the immediate future. In extremes, this will indicate the possible time frame for the missing person's survival. Adverse weather prevailing in or approaching an area where survivors are located may also limit the time available to conduct a SAR operation. Not only are survivors of an incident more difficult to detect under adverse weather conditions, but also SAR units themselves operate at lower efficiency due to conditions and higher stresses on the search personnel.

Accurate knowledge of weather conditions and the prudent judgment based on it will enhance the likelihood of a successful mission. Knowledge of the prevailing weather conditions will also play an important role in the safety of the search units. If weather will not allow for a search operation to be mounted without endangering additional lives, the search effort should be deferred or suspended. If weather is currently good but forecast to deteriorate in a short time, more rapid action is required and detailed planning may suffer due to the time available. If weather is good and forecast to remain so, more extensive planning may be accomplished.

Wind, visibility and cloud cover influences the search track spacing. Therefore, the better the weather information, the more realistic will be the derived track spacing. Maintaining accurate search patterns is difficult in adverse weather. Aerial units are particularly vulnerable. For this reason the patterns selected should allow for more precise navigational accuracy. Safety may sometimes be prejudiced by actual weather conditions, which must, therefore, be monitored continuously by the SMC.

Low cloud base and restricted visibility are particularly hazardous during searches that cover large areas where many aircraft are employed. Should air search be conducted under adverse weather conditions that deteriorate below the required flight conditions, then air search may have to be suspended. In situations where survivors are adrift in regions of high velocity water current, searches should be mounted without delay. The probability of locating survivors is high during the early stages of survival craft drift as the drift factor allowed for in search calculations will be of reasonable accuracy over a short time period.

When missions involve overdue craft, the weather situation should be evaluated to determine what effect it may have had upon the craft's operating capabilities and/or the actions of the craft's operator prior to SAR system activation. To obtain an overall weather picture an attempt should be made to complete the following questionnaire:

- What was the weather at the departure point, destination and along the planned track at the time the overdue craft should have been in those areas? If no established weather facilities are available, the information should be obtained from local reliable sources in the areas concerned, such as police or marine volunteers, if possible.
- What was the enroute and forecast weather briefing given to the crew of the missing craft, and what was the operator's reaction to the weather briefing?
- What was the weather in the area where the missing craft is presumed to be and if the time of emergency is known, what were the actual weather conditions at the craft's estimated position?
- Were there any marked changes in wind or sea currents that might have resulted in navigation errors?
- Were there any areas of low ceiling, poor visibility, precipitation, thunderstorms, frontal activity, turbulence, icing, that may have caused the craft to attempt circumnavigation, or that could have exceeded either the crafts or operator's capability?
- Were there any areas of marked pressure changes that may have caused aircraft altimeter errors?

Terrain Factors

Terrain may be a major factor in evaluating an incident. Terrain may dictate the type of search pattern required, and may limit the selection of search aircraft that can be used. Aircraft that are highly manoeuvrable and will be effective at moderately high altitudes may be required in rugged mountain areas. High performance or large transport aircraft may be unusable in confined areas and helicopters may not be able to operate in the thin air and turbulence associated with mountains and contour searches. Terrain may also limit the time available for search. For example low-level searches in mountain areas are normally limited to daylight only, often restricted by increased shadows due to deep valleys and high mountains.

The type of survival kit carried by the distressed craft and the equipment, such as the type of hoist device used by available helicopters will also be influencing factors. Dense foliage may hamper both visual and electronic searches and require increased numbers of aircraft and closer search track spacing. Man-made additions to the terrain such as power-lines, towers and bridges must also be considered when planning search areas and the altitudes of search aircraft. The type of rescue team used after the distress site has been located is also dependent upon terrain. When there is doubt about survivors or the area is inaccessible, time is a factor. Should other help not be readily available, airdrops or parachutists may be required. Before deploying parachutists, the ability for them to land, to be resupplied and recovered must be considered.

Survival Equipment Factors

The amount and type of survival and signalling equipment available to the survivor will influence not only the urgency of the SAR system's response, but also the methods and procedures employed in various SAR stages. The SMC may concurrently conduct a high level electronic search and a visual search. The SMC must use their common sense, good judgment and background experience to evaluate the appropriate response for taking advantage of the survivor's capability to signal and survive.

Risks v Gain Factors

SAR assets are responsible for taking whatever action they can to save life at any time and place where their facilities are available and can be effectively used. Nevertheless, there may be a point beyond which SAR services are not expected and cannot be justified. Known and inherent risk must be carefully weighed against the mission's chances for success and the gains to be realised. SAR personnel and equipment shall not be placed at risk, nor the mission attempted, unless lives are known to be at stake and the chances for saving lives are within the capability of the personnel and equipment available. All reasonable action shall be taken to locate distressed personnel, determine their status and bring about their rescue. Prolonged SAR operations after all probability of survival has been exhausted are uneconomical and not warranted. The decision to conduct such operations must be based on probability of detection.

Studies have shown that the period within 12 to 24 hours of a distress incident is the most critical for recovery of survivors. The best chance of successful recovery occurs during this time period. Within 48 hours, chances are still good, but after that time the chance of successful recovery decreases rapidly.

9 Search Planning and Evaluation

The wellbeing of survivors is critically dependent on early location and support. It is vital that as soon as possible after becoming aware of an incident, SAR authorities quickly implement procedures for a rapid search of the most likely area of distress. In general, the initial SAR response requires ready application of simple procedures to quickly cover the most likely area of distress. The search area described will be of rudimentary construction, e.g. a circle, square or rectangle depending on the nature of the target.

The stage 1 search area (equivalent to a Reflex search on land) will be of sufficient proportions to cover all reasonable alternative tracks of the target and will incorporate areas highlighted by intelligence information. This strategy precedes the more complex calculations that will give rise to a more precise area which, failing the success of stage one search will form the basis for a formally planned and executed action at a later time. The stage one search may be undertaken in relatively short time and allow ready allocation and briefing of the few necessary resources.

All of the basic search theory concepts are described in this chapter. Practical examples are provided for each concept, showing how it may be applied to the search-planning problem. These examples require only basic arithmetic skills and an understanding of the basic probability concepts encountered in everyday life. Although search planning may be perceived to be complex, each step is relatively simple.

Aviation and Marine Search Planning Steps

Search planning involves the following steps:

- Evaluating the situation, including the results of any previous searching (This may include incidents that have occurred in that location in the past and search efforts on previous days);
- Estimating the distress incident location and probable error of that location;
- Estimating the survivors' post-distress movements and probable error of that estimate;
- Using these results to estimate the most probable location (datum) of survivors and the uncertainty (probable error of position) about that location;
- Determining the best way to use the available search assets so the chances of finding the survivors are maximised (optimal search effort allocation);
- Defining search sub-areas and search patterns for assignment to specific search assets; and
- Providing a search plan that includes a current description of the situation, search target description(s), specific search responsibilities to search assets, on-scene coordination instructions and search asset reporting requirements.

These steps are repeated until either the survivors are located or evaluation of the situation shows that further searching would be futile. While the JRCC and the ADF generally cease search efforts upon the Time Frame for Survival (TFFS) being reached, police have obligations under jurisdictional Coroner's Acts to continue searching for, and recovering, deceased persons that were previously the subject of a SAR operation.

Estimating the Distress Incident Location

The first step in search planning is to determine the limits of the area containing all possible survivor locations. This is usually done by determining the maximum distance survivors could have travelled (by aircraft, vessel, vehicle or on foot), or survivors in the water might have drifted, between the time of their last known position (LKP) or splash point (SP), and the known or assumed time that search assets can reach the commence search point, by drawing a circle with a radius equal to that distance around the LKP (S/T/D calculation) or SP. Knowing the extreme limits of possible locations allows the search planner to determine where to seek further information related to the missing craft or people and whether any incoming intelligence might apply to the incident.

This initially may result in a very large search area that may be too large to search with the available resources. Therefore, the next step is to develop one or more scenario/s or sets of known facts plus some carefully considered assumptions, describing what may have happened to the survivors since they were last known to be safe. Each scenario must be consistent with the known facts of the case, have a high likelihood of being true and allow the search planner to establish a corresponding geographic reference or datum for the survivors' most probable position (MPP). Three possible situations may exist with respect to the location of a distress incident when it is reported.

Approximate Position Known	The incident may have been witnessed: reported as a navigational fix by another craft or the craft in distress; or computed by the SMC as a dead reckoning position from a previously reported and reliable position of the craft in distress (manually or electronically).
Approximate Track Known	The craft in distress may have filed a trip or voyage plan prior to departure that included the intended track or route but the craft's actual position along the track is unknown. A single line of position, such as a flare sighting or DF, should be treated the same as a track known situation.
Approximate Area Known	When neither the position nor the intended track is known, at least an area that the craft in distress was probably within can usually be determined. The SMC should try to reduce this area to an area of high probability that can be used as the initial search area or, if the area is small enough for adequate searching with available assets, use it.

Search Response Stages

A search typically involves three stages:

- Stage 1 - Immediate response. An initial visual and/or electronic search along the missing target's planned route.
- Stage 2 - Nominated area either side of track. Normally a search conducted in an area 10 nautical miles either side of track but this can be varied depending on circumstances.
- Stage 3 - Mathematically derived area. An expanded search of a probability area calculated using the navigational tolerances of the missing and search craft, allowing for drift if applicable and the application of a safety factor.

Stage 1 and 2 searches can be run concurrently. By way of example, if a distress incident occurs at the end of daylight or during the night, when the first visual search cannot be undertaken until the following day, then it may be appropriate to conduct both stages simultaneously. Note that an essential part of any search stage will be the establishment of a rescue plan, coordination with the Police and consideration of the early dropping of SAR datum buoys. Some emergency situations will suggest a still more spontaneous reaction. Where a target reports encountering a distress situation, the location is reasonably well known and there are other assets of opportunity in the near vicinity, it may be possible to divert an asset to the area or intercept the distressed target's track with instructions to undertake a track crawl search along the known route.

If circumstances allow, the diverted asset may be instructed to proceed parallel to the distressed targets track at an appropriate off-set distance to one side and to return at the same off-set distance on a reciprocal heading on the other side of the targets track. Such a procedure can provide coverage of the distressed target's track and the most likely lateral area either side of it. Whether this is practicable will be dependent on such factors as endurance of the diverted craft, its suitability for the task, weather, daylight and terrain. The pertinent factors should be discussed with the crew of the diverted craft prior to tasking

Factors Affecting the Search Response Plan

There is a wide spectrum of factors that may influence the extent and manner of an initial SAR response. To summarise some of the more important ones:
● Extent and reliability of information about the location of the distressed craft and its occupants;
● Availability of aircraft, marine craft and land parties for searching;
● Actual and forecast weather conditions;
● Times of daylight/darkness;
● Nature of terrain; and
● Availability of survival supplies and rescue assets

Initial Search Procedures

When the distress position is not known with certainty, the procedure most frequently used first is to search along the intended track of the missing target. If not already completed, inspection of possible landing places should continue. It may be necessary to allocate one or more aircraft to the task of examining those possible landing areas that have not been inspected during the landing site and communications checks. The size of the area to be considered for this purpose will be at the discretion of the SMC, however, they should be guided in determining final limits to landing site checks by the size of the probability area, modified by any pertinent intelligence information.

Unless it is positively determined that the missing target does not have an emergency beacon, information should be obtained from the JRCC on the satellite pass schedule and an aircraft should be quickly allocated to an electronic search. It may be possible to arrange for an electronic search to be flown either before or after some other task but it should be noted that it is not practicable for an aircraft to be tasked for a combined electronic and visual search. All aircraft on visual searches however, as on other tasks, should be briefed to keep a listening watch on 121.5 MHz and 406.0 MHz, but the maintenance of a listening watch will be supplementary to the primary task. Likewise, an aircraft assigned to an electronic search should be briefed to keep a general look out for visual signals if possible.

Maximum Search Effort

When a situation of actual distress is either known or strongly suspected to exist, the time available for search will usually be limited. A maximum search effort must be completed within this time. Quite often a large search area is also involved, further compounding the SMC's problems. The following method has proved successful in approaching this situation:
● Determine a search area that gives a high POD of successfully finding the search object;
● Use a track spacing equal to sweep width (C = 1.0, or no lower than 0.5);
● Decide the time by which the search must be completed (available light, first and last search light, electronic searching);
● Select the number of SAR asset hours required to complete one search of the area within the allocated time (refer to the ATNPS formula);
● Dispatch sufficient SAR assets to complete one search of the area within the allocated time; and
● If unsuccessful, expand and/or repeat in accordance with the repeated expansion concept.

Do not re-orientate the search or change SAR unit assignments whilst on task if it can be avoided.

Once a large-scale search is ordered and SAR assets are dispatched, reorientation of the search area for that particular search is both difficult and wasteful. Planning should therefore be thorough and then adhered to. The SMC must also resist the temptation to re-deploy assets whenever new intelligence or doubtful hearing or sighting reports are received.

New intelligence should be evaluated with the possibility that the information needs immediate action. Additional assets should be dispatched to investigate leads that come to light after the assigned assets have commenced searching. This will prevent unsearched areas and maintain the momentum of the search. It is almost impossible to resume a search in an area after that asset has been diverted to another search area. Holes in searches create doubt and reduce the overall POD.

Search Sequence

There is no single sequence of search types, search patterns, etc. which can be suggested as standard procedures. The matrix in the table below shows one search sequence employing various factors and search parameters. Such a sequence could be used where large areas must be searched initially and search assets are limited. Each incident will require its own specific sequence and parameters should be recalculated for each search. Searching both a land and marine environment with aircraft provides the most rapid response and greatest chance of survival.

In instances where aircraft are unavailable or in insufficient numbers then a vessel search will become necessary in a marine incident. A vessel search may be limited initially to a trackline search to provide a maximum POD. Vessel visual, electronic, wreckage and beacon searches are limited by the height of eye (Hoe) of searchers and the sea conditions at the time.

Search No	Type	Period	Target	Speed (Kt)	Track Spacing (NM)	Altitude AGL/ AMSL (FT)
Initial	Track line	Day/Night	Active target	100/200	5	Below 5000
1	Electronic Beacons	Day/ Night	Electronic	150/500	20	High as practicable
2	Visual (aids)	Night	Fires, flares, torch, etc.	100/150	10	1500-3000
3	Visual (aids)	Day	Mirrors, dye, smoke, etc.	100/150	10	1500-2000
4	Visual (rafts)	Day	Life rafts	100/150	1.5	300-1500
5	Visual (wreckage)	Day	Wreckage, survivors	75/130	0.5	200-2000

The most effective search, by far, is an electronic search for a beacon. Electronic searches cover larger areas very rapidly with a high POD. After a beacon search, and given that it is known that the survivors from a maritime incident have distress flares, the next most effective detection aids are luminous types used at night.

The SMC therefore plans to use a search unit on a night track line search during the first darkness period following the ditching. This pattern is also expanded laterally, but at a track spacing of 20 miles. Since the survivors will be in better physical and mental condition during the early stages of their ordeal, the SMC takes advantage of this by deploying a night search at the first opportunity. This minimises the possibility of the detection aids being lost prior to their use, or of the survivors becoming too weak to use them effectively.

The third most effective group of detection aids are the daylight aids such as mirrors, smoke and sea dye marker. The first daylight visual search is therefore based on this group of detection aids. A larger area can be covered initially by using 10-mile track spacing. In addition, the SMC is taking advantage of the probable better physical and mental condition of the survivors, in the same manner as when the early night search for the luminous detection aids was commenced.

If in a maritime incident, the electronic search, the night visual search and the day visual search for detection aids are unsuccessful; the SMC must next plan to search for life rafts. Just as the SMC assumed that the survivors were able to use their beacon, luminous detection aids and daylight detection aids in previous searches, he now assumes that the survivors were able to board their life rafts after ditching or abandoning their vessel. Therefore the SMC uses slower aircraft at close track spacing to search visually for life rafts.

If these raft searches were also unsuccessful, the SMC must then use extremely small track spacing and search for survivors in the water, wreckage and debris. From the second search on, the SMC should have also directed that all SAR assets maintain RADAR search, where RADAR is available, even though the search was planned on the more tangible effective detection aids available to the survivors.

Determination of Search Areas

The possibility area is the area in which a missing craft could be located. Usually the area is too big to be considered the search area but knowledge of its extent and boundaries may be of use when assessing intelligence information, in particular sighting or hearing reports.

The possibility area is displayed as a circle drawn around the last known position (LKP) of the target. The radius of this circle should equal the endurance at the time of the LKP expressed in terms of distance and taking into account wind velocity for aircraft or drift for vessels. It is assumed that the target may have proceeded in any direction until its fuel was exhausted.

The possibility area may be determined by:
● For aircraft, drawing a wind vector downwind from the LKP to a scale representing a distance equal to the wind speed multiplied by the known or estimated remaining fuel endurance time, while for vessels, drawing the drift for the time period since the LKP; then
● Drawing a circle from the end of the wind vector or drift, of a radius (using the same scale) representing a distance equal to the aircraft TAS or vessel speed multiplied by the known or estimated remaining fuel endurance.

Figure 3-1 shows the possibility area for an aircraft with a last known position of A. Position B is the aircraft's datum once the wind vector has been applied. The circle is derived using a radius, centred on B, of the aircrafts remaining endurance, which in this example is 150 NM.

Where: A = LKP, TAS = 100kt, W/V +180/15 (Wind vector is 180°T (Blowing from the south) at 15kts), Endurance remaining at A = 90 minutes. Therefore A-B = 22.5 NM (15kt winds x 90mins endurance (1.5hrs) and radius B-C = 150 NM (100kt speed x 90mins endurance (1.5hrs)).

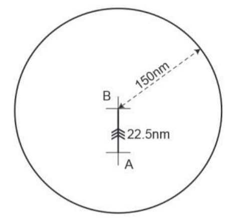

Figure 3-1 Possibility Area

The probability area is the area in which a missing craft and/or survivors are most likely to be found, taking into account possible errors in the navigation of the missing craft and of the search asset, together with an allowance for any water movement (should the incident occur on or over water) and a safety factor. When the position of an incident is reported by a witness, or reported as a navigational fix determined by RADAR or another craft or by the distressed craft itself, or calculated by the RCC in the form of DR position, the probability area is enclosed by a circle of probability centred on that position, taking into account the applicable above mentioned factors.

In the case of a downed aircraft, joining lines 10 NM either side of the aircraft's known, planned or suspected route will normally form the initial probability area for an aircraft search. The 10 NM may be adjusted to allow for the type of flight, e.g. a transiting helicopter may be 5 NM either side of track where as a turbo prop or jet aircraft may be 15 NM or more. This is referred to as a Stage 2 search.

When Stage 1 and Stage 2 search actions fail to locate the target, the probability area should be determined by drawing circles of probability around the last known position, the first missed report position, and any turning points along the planned track.

Tangents to the circles then enclose the intervening area. This is referred to as a Stage 3 search and is shown in Figure 3.3. Planning for the Stage 3 search should commence when it is apparent the target cannot be located by the Stage 2 search.

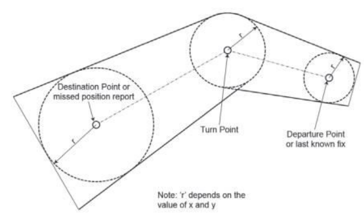

Figure 3-3: Stage 3 Search Area (Mathematically Derived)

Search Radius

This is defined as the radius of a circle, centred at the most probable position of the target at any given time (the Datum), equal in length to the Total Probable Error of Position (E) in nautical miles, increased by a safety factor. For successive searches of the probability area the safety factor is increased progressively. The safety factors applied to the Total Probable Error of Position to obtain a Search Radius (R) are shown in Table 3-2.

Search Effort	Safety Factor						
Initial Probability Area	1.1						
First Expansion	1.6						
Second Expansion	2.0						
Third Expansion	2.3						
Final Expansion	2.5						

Drift Error for Waterborne Targets
Over land, the Datum is the last known position; however when survivors are known or thought to be in or on the water an allowance must be made for movement of the water resulting from the effects of wind and current. The degree of displacement of the Datum from the last known position assumes increasing importance with the passing of time, and MUST be allowed for in search planning. This displacement is a function of:
● The average sea current;
● The average wind current; and
● Leeway

Sea Current
Tidal and local geographic features may affect sea currents near the coast. When areas near the coast are to be searched, the water movement for the area should be discussed more fully with local experts.

Tidal Streams
Tides are caused by the gravitational pull of the moon and sun, modified by the depth and shape of the sea basin along the coastal areas. Currents in coastal waters are usually affected by tides, changing in predictable velocity as the state of the tide changes. In some locations tidal streams are of the reversing type, abruptly changing direction 180 degrees at about the time of high and low water. In other places the direction will change in small increments so as to create a constant rotary movement. Variations of these tidal effects may also be found.

The exact effect of the tide on currents in any specific area may be found by consulting tide tables or local charts. Local knowledge is again of great value in dealing with movements of tidal streams. While the changes in direction of tidal streams have a tendency to nullify the cumulative effect, they must nevertheless be considered in computing drift for the following reasons:
- Often, with reversing streams, the effect in one direction is greater than in the other so that, over a period of time, the resultant effect is more in one direction than in the other; and
- Even over short periods of time the flow of tidal streams will cause significant changes in the probable position of a search object.

River Current
River current will affect SAR incidents that occur in offshore areas near river mouths. Tidal streams affect the river current speeds near the mouths of the rivers. In large rivers this affect may be noticed several kilometres upstream from the mouth. Published current tables often give values which are combinations of tidal and river flow effects. These are among areas where reversing streams will be greater in one direction that the other. On the other hand, river current affects both total current and sea current at its mouth. Some major rivers extend their influence quite significantly off shore. Seasonal variations in water volume and velocity should be considered.

Longshore Current
Longshore currents are caused by incoming swells striking the shore at an angle. Longshore current information must be obtained from direct observation or local knowledge.

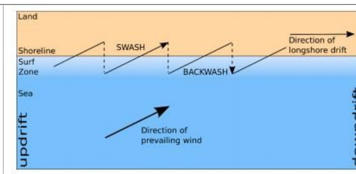

Figure 3-8 Longshore Currents

Swell/Wave Current
In calm conditions, swells and waves may affect rafts and other small marine search targets. The effect is similar to leeway in that the raft is being moved through the water. However swell/wave current speed is so small, under 0.1 knot, that the drift force is usually ignored in determining general search areas. It is useful however for determining probable direction of target movement in some cases.

Surf Current
Surf current is only considered for incidents occurring in coastal surf areas. It is more of a rescue or salvage factor than a search planning factor. Surf currents will move a drifting object after it enters the surf zone. If no longshore current is present, the surf current will move the object towards the shore perpendicular to the line of breakers. If a long shore current is present, the object will be displaced in the direction of the long shore current.

Rip Current
Rip current is a special type of surf current. It is a narrow band of current flowing seaward through the surf line as a result of the long shore current building up a large volume of water along the beach line, and then bursting through the incoming surf on its way back to sea. Rip currents are only a few metres wide through the surf line, but they fan out and slow down when in smoother water. Rip currents occur when longshore currents are present, and in places where some form of bottom trough, bottom rise or shoreline feature assists in deflecting the long shore current build up in a seaward direction.

Local Wind Current
Local wind current is the current generated by wind acting on the surface of the water. The current changes with variations of the wind pattern. Near the coast, wind current can be affected by various factors and consideration should be given to omitting the wind current vector from search areas close to the coast. Offshore, consideration should also be given to omitting the wind current vector, if it is considered to be an area of consistent winds.

The velocity of a wind current is calculated from:
- Wind data for the 48 hours preceding splash time;
- Actual and forecast winds between splash time and Datum time; and
- The application of coefficients taken from tables held in RCCs.

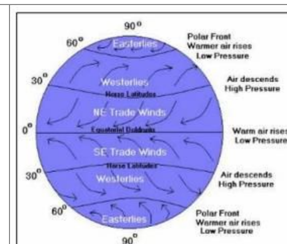

Figure 3-9 Wind Direction and Speed

Wind current is calculated for 6-hour periods, the periods being coincident with the meteorological synoptic periods. The current for any given synoptic period is the cumulative effect of the wind in the area for the 48 hours prior to the end of the synoptic period being considered. The direction and speed coefficients obtained from the tables allow for the effect of Coriolis, and the reversal of wind direction, to express the result as 'SET'.

Leeway
Leeway is the movement of a search object caused by it being pushed through the water by local winds blowing against its exposed surfaces. A boat, raft or any other type of marine craft has a certain proportion of its hull and superstructure exposed above the surface of the water at all times. This exposed area is blown against by local winds, which in turn have the effect of pushing the marine craft through the water.

The more surface area the wind has to blow against, the greater will be the wind's effect on drift. If the silhouette of a boat were projected onto a flat plane, which was perpendicular to the wind direction, the area enclosed by the silhouette would be called the exposed flat-plane area. As the boat's heading changes relative to the wind, its flat-plane area also changes, usually becoming least when the boat is heading directly into the wind or downwind.

The pushing force of the wind is countered by the water drag on the underwater hull. The drag varies with the volume, shape, depth and orientation of the underwater hull. When a marine craft is parallel to the wind direction the least amount of underwater drag will exist since the craft will be pushed through the water in the direction its hull is designed to move.

Almost the same conditions exist when the boat is pointed directly into the wind and is being pushed backwards through the water longitudinally. When the boat's heading is perpendicular to the local wind, however, the greatest amount of underwater drag will exist since the boat must now be pushed sideways through the water. Between these extremes the amount of underwater drag will vary depending on the heading of the boat.

Datum Plot

The bearing and distance of a Datum from its associated Last known position is found by combining four vectors as shown in Figure 3-10:

- The sea current;
- The wind current; and
- Two leeway vectors, one each for left and right divergence.

The value of the vectors may change with time; therefore it is necessary to calculate a mean value for each vector for the period between splash time and datum time. All calculations are related to meteorological synoptic periods, or part thereof.

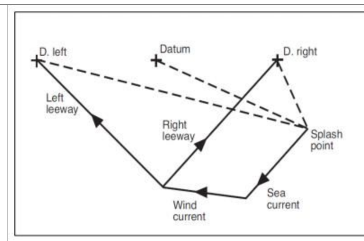

Figure 3-10 Datum Plot

The objective being to calculate the movement attributable to each factor during the period under consideration, with a vector summation for the whole period and then to combine the individual effects to establish a most probable position for the target. When the most probable position has been established, an allowance is made for possible errors, which is then combined with the navigation error allowances in the Total Probable Error (E) of Position formula.

Land Search Planning

Land SAR is the operational coordination and management of a search and rescue response for the following situations:

- A person/vehicle/vessel or aircraft reported missing in a land environment.
- A person/vehicle/vessel or aircraft reported overdue as a result of either scheduled contact time or a planned excursion in a land environment.
- A request from another SAR authority to assist in a land based SAR incident
- Evidentiary and crime searching in a land based environment

It is important for the SMC to make an assessment of the facts of the situation relating to the missing person, as soon as possible after receiving significant information. These assessments may prevent any of the following errors being made:

- A search operation too slowly implemented due to a poor appreciation of the missing person's life and death situation.
- A search operation which is terminated prematurely because it is falsely assumed that the missing person could not have survived.
- A search operation which is conducted in too small or large a search area because of a lack of knowledge related to the missing person's mobility.

Unless each search is considered in detail and likely problems identified, the result could be:

- Loss of life
- An ineffective search
- An aggravation of the situation
- Bad publicity
- A loss of community credibility for the SAR Authority and/or searchers
- A loss of organisation or individual morale
- Any combination of the above

Before any SAR incident can be prosecuted the SMC must have situational awareness in relation to the incident. Without this the SMC is blindfolded and will be making decisions that are not based on the actualities of the incident. If the SMC is in unfamiliar terrain then any time spent gaining situational awareness, either through a drive around, a fly over or at the least, a study of a topographical map, is never wasted.

Definition: The accepted definition of situational awareness is 'The perception of the elements in the environment within a volume of space and time, the comprehension of their meaning and the projection of their status in the near future.'

The first part is recognising all the small components that make up the SAR scenario at that particular time and location. As the scenario develops these small components will change, making them only valid for a short period. These small components may include:

- Weather
- Missing person/vehicle/vessel or aircraft
- Terrain/topography
- Incident location
- Daylight/darkness
- Resources available
- Lead times for resources
- Coordination activities

The second part is understanding what each of these small components means. Examples of this are as follows:

- Weather – What impact will the immediate weather have on the search, the searchers, the missing person/vehicle/vessel or aircraft, visibility, specialised clothing and food requirements?
- Missing person/vehicle/vessel or aircraft – What is the description of the target, changes that may occur as a result of the incident causes (Crash, overturned, fire), difficult of finding the target, location of the target, safety and/or danger features.
- Terrain/topography – how will this impact on the search, searchers, search area determination, person/vehicle/vessel or aircraft, resource requirements, time, funnel points, barriers.
- Incident location – transport to and from scene, travel from FSH to search areas, lead time, specialist transport/search techniques, resource availability.
- Daylight/darkness – search time available, travel time, search visibility

- Resources available – type and number, suitability, availability, lead time, specialist resources.
- Lead times for resources – time to scene, time on scene, resupply
- Coordination activities – availability of trained coordination staff, incident command system, availability of maps, electronic aids, printers, communication systems

Search planning involves the following steps:

- Evaluating the situation, including the results of any previous searching;
- Identifying the Last Known Position (LKP) of the MP and any error associated with that location;
- Estimating the MP's post LKP movements and any associated error of that estimate;
- Using these results to estimate the most probable location or route of the MP and the uncertainty about that location;
- Determining the best way to use the available search assets so the chances of finding the MP are maximized (optimal search effort allocation);
- Defining search sub-areas and search patterns for assignment to specific search assets; and
- Providing a search plan that includes a current description of the situation, search object description(s), specific search responsibilities to search assets, on-scene coordination instructions and search asset reporting requirements.

Scenario-Based Assessment

Scenario-Based Assessment

Scenario-based searching assesses the reasons for the loss of an object or the disappearance of a person and can be used alone or in conjunction with an appreciation. Consideration is given to all factors that may assist or impede the discovery of the missing person or object. A search strategy is developed from this in the eight stage process as described below.

This method presents a better alternative to speculative searching as it is based on a full evaluation of all information available. It also allows for the consideration of multiple scenarios and ensures that the most appropriate assets available are used. If more than one scenario emerges, action must be prioritised according to the relevant merits of each scenario and the resources available.

The eight stage process, SCENARIO, is a mnemonic designed to ensure that all of the objectives are achieved when searching for any type of object.
S - Specify person or item sought
C - Confirm last location
E - Establish circumstances of disappearance
N - Note factors influencing discovery
A - Analyse possible strategies
R - Raise search strategies
I - Identify priority search
O - Ongoing reassessment

Search Urgency Assessment (SUA)

A Search Urgency Form will be completed as soon as possible to establish the seriousness of the incident to determine the appropriate response.

There are eleven categories to be assessed:
● Number of MP's in group;
● Age;
● Medical conditions;
● Intent
● Cognitive capacity
● Experience profile
● Physical condition;

● Clothing;
● Equipment;
● Experience;
● Weather; and
● Terrain and hazards

Each of the eleven categories are individually assessed in line with information received. Each category is then assigned a number depending upon the situation (e.g. Section 1 relates to the number of missing persons. If there is only one then a number 1 is assigned to that section; if there are two MP's then a 2 is assigned etc.)

After the completion of the assessment the assigned numbers are added to determine the overall seriousness of the incident. The appropriate responses are:
● 11-17 Immediate response
● 18-27 Measured response
● 28-42 Conduct further inquiries and re-evaluate the situation
Also, if there is a number 1 assigned to any of the categories then an immediate response is required.

Terrain Factors

Terrain may be a major factor in evaluating an incident. Terrain may dictate the type of search pattern required, and may limit the selection of search assets that can be used. Terrain may also limit the time available for search. For example low-level searches in mountain areas are normally limited to daylight only. Equipment, such as the type of hoist device used by available helicopters will also be influencing factors. Dense foliage may hamper both visual and electronic searches and require increased numbers of aircraft and closer search track spacing.

Man-made additions to the terrain such as power-lines, towers and bridges must also be considered when planning search areas and the altitudes of search aircraft. The type of rescue team used after the distress site has been located is also dependent upon terrain. When there is doubt about survivors or the area is inaccessible, time is a factor. Should other help not be readily available, search teams may need to be winched into the search area. Before deploying assets under these conditions, the ability for them to land, to be re-supplied and recovered must be considered.

Environments

Rainforest

All rainforests have a crown cover of 80 per cent or more and so are classified as closed forests. Rainforests comprise a significant proportion of Australia's closed forest, but only 2.6 per cent of the total area of native forests. Rainforest ground-covers are often sparse due to the low levels of light under the dense canopies. Understoreys are varied depending on the kind of rainforest. Some are characterised by vines or ferns. Mosses and other epiphytes are often a feature of rainforests.

Vine forests are a kind of rainforest characterised by the presence of significant vines growing on the trees. They are largely confined to the tropics and sub-tropics. Rainforest with a significant cover of ferns and mosses are concentrated in the temperate zones and at high altitudes in the tropics. There are many types of rainforest, varying mainly with rainfall and latitude.

Be aware that lost person in rainforest conditions may exhibit any or all of the following:
● Failure to make shelter;
● May be hidden in the buttress roots of many rain forest fig varieties;
● Discard their equipment;
● Disorientated – walking any direction;
● Tend to walk down hill (depending on level of experience – experienced walkers may try to access high areas to resolve their position or to gain telephone service);
● Following a path of least resistance;
● Cold Temperate areas – may exhibit characteristics of Alpine areas.

Rainforest Resources considerations:
● Experienced Search Teams – with local knowledge and the ability to navigate within a featureless environment;
● National Park Rangers – or local rangers;
● Police Mounted Units, Search and Rescue Mounted Units;
● Aviation support – consider limitations;
● Tracker dogs, may be valuable first up but will otherwise be easily distracted by the many rain forest smells;
● Motorcycles/bicycles- search and rescue trained.

Alpine Environment

Alpine areas relate to high mountainous areas which are subject to extreme environment changes involving rain, snow, hail and strong winds. Alpine search teams differ from normal ground search teams mainly due to the different weather, altitude and hazards they must face and the different variety equipment and skills they use to overcome and travel in these hazardous conditions. Due to these hazardous conditions an Alpine searcher should be a trained SAR member skilled in
movement over snow & alpine survival skills able to move efficiently, skillfully and with safety in winter or sub winter conditions through terrain at low or high altitudes.

This member must be of a high fitness level, able to cope with the physical and mental demands required to move efficiently in this changing environment. All alpine SAR members must able to work as a team member and prepared and equipped for overnight survival when necessary. These guidelines are intended to differentiate Alpine searchers from normal searchers to allow for the selection of teams to handle situations that are specific to their expertise and training.

The following considerations should be taken into account:
● Equipment - Alpine equipment is very specialized to deal with extreme temperatures and conditions. All equipment should be suitable for the conditions and be checked by a team leader before entering an alpine environment. Poor equipment can put searchers lives in danger.
● Alpine searchers - Due to extreme conditions and change environment only trained alpine searchers should be used in the field on an alpine search. When entering remote areas a team should be no less than four members who are self-sufficient for overnight.
● Time frame for Survival In Alpine environment it is critical that immediate actions be taken to reduce the likely risk of exposure to hypothermia of the missing person/s.
● Medical training - Due to difficult access and remoteness of an alpine search, Paramedics or equivalent medical expertise in search teams or readily available to render assistance.
● Search techniques and search patterns – A search manager should utilize local knowledge of Alpine SAR members and/or ski patrol to assist in search tactics due to alpine mobility issues of search teams and lost persons.
● Restrictions in mobility of search teams and lost persons. Allow for greater time periods in the travel of distances.
● Makeup, search technique and search patterns used by searchers.
● Avalanche risks - A search manager should use only trained avalanche specialist in declaring search areas safe and when leading search teams in specialized searching using probes and avalanche receivers.

Hypothermia is the lowering of a body's core temperature and is the most common condition missing persons will suffer from in an alpine environment. A search manager and team leaders should be aware that lost person in alpine conditions may exhibit any or all of the following:
● Failure to make shelter
● Discard their equipment
● Disrobing of clothing
● Failure to respond to searchers
● Following a path of least resistance

This should be considered when clothing or equipment is located by search teams. The majority of missing persons in alpine environments wear high visibility clothing and equipment. Due to changing weather conditions they become disorientated, misjudge distances and become benighted.

Alpine Resources considerations:
● Overland snow/all-terrain vehicles
● Ski patrols
● Alpine horse riders and bush walkers from volunteer rescue agencies
● Aviation support
● Thermal imaging / night vision
● Avalanche specialists
● Mountain trained members in mountaineering, steep, snow and ice techniques
● GPS – carried by search teams
● Medical staff on standby.

Arid Environment

Australia is the world's driest inhabited continent. Over 70% of the continent receives between 100mm and 350mm of rainfall per year, classifying it as semi-arid or arid. Desert regions are found mostly in central and Western Australia, which makes up approximately 18% of the mainland. All of Australia's deserts are classed as subtropical deserts, given their location between the latitudes of 20 degrees and 30 degrees south of the Equator.

They are hot deserts, which means they have little rainfall and extreme temperatures, often reaching over 50°C. Humidity averages at between 10 and 20 percent. Searing day time temperatures, cold nights and lack of surface water are just a few of the challenges facing travellers in the desert. Desert surfaces are not always sandy; some consist of stones or 'gibbers' and have no sand at all.

In desert conditions, because of the extremes of temperature, both hyperthermia and hypothermia can affect the missing person. The amount of water carried and the methods which it is used by the missing person can have a critical effect on survival times. During the initial action stage an assessment of the target needs to be made in relation to their possible actions while the search is being conducted.

Persons who are level headed and remain in a sheltered or shady location will survive for much longer periods than a person who is attempting to self-help by walking throughout the day. The general rule is for a target to remain with their vehicle if lost as it is far easier to find a larger object such as a vehicle than a smaller target such as a person.

Historically most targets will spend a small percentage of time with their vehicle and then decide to walk off in search of help. In areas that are familiar to the target this may be a successful strategy, but in most instances it results in death. It is unusual for the SMC to be the first person on the scene of a SAR incident. Vital clues as to the direction, speed and condition of the target can be gathered from observations of their footprints or other markings in the immediate vicinity of a vehicle.

Consideration should be given by the SMC to brief all teams about the possible destruction of clues around vehicles. When the target's vehicle is located one team member should approach it from the hardest surface possible to ascertain if there are persons inside or if notes or other information has been left. The area in the vicinity of the vehicle should then be thoroughly inspected for footprints and other marks and the direction in which they are going. Further planning can then be made on the information obtained. If there are no obvious signs left at the vehicle, then this would be used as a possible LKP with search planning concentrated on that point.

In featureless country it is almost impossible to navigate accurately without extensive equipment. A target will often aim to walk a straight path but in reality will wander. The handedness of the target will provide a clue the direction of the wanderings. Right handed persons will tend to walk in circles veering off to the left, with left handed persons going in right hand circles. Mental condition will also play a significant part in the survival of the target. There are many stories of the explorers surviving tremendously difficult conditions without water for days.

Historically this has been attributed to the harder living conditions and tougher life styles of those explorers. With the increased pampering of people today the physical ability to survive in harsh desert conditions has diminished. The mental state will have a large effect on a target's survival. Those with a 'no give up' attitude may have better odds of survival that a person with no will power.

Be aware that lost persons in arid conditions may exhibit any or all of the following:
● May shelter in or under their vehicle;
● May dig themselves in under the sand, if experienced;
● May discard their equipment;
● May become disorientated – walking any direction;
● May sleep by day and walk by night, if experienced;
● Following a path of least resistance; and
● May seek out river beds and ranges in search for water.

The following resource considerations should be made:
● The use of indigenous trackers or visual trackers;
● Making air search a priority;
● The use of trail bikes and helicopters;
● Use of helicopters for transport of searchers and logistics supplies;
● Hardening experienced Search Teams to the environment; and
● The use of ground teams to recover the missing person once located, unless a helicopter has access.

Mountain Environment

Although Australia is considered the flattest of the world's continents it does contain some significant mountain areas with respect to SAR. Whilst about 10% of the country may be considered mountainous due to the elevation, a much smaller proportion contains areas of high relief that create substantial SAR issues. Due to the fact that many of Australia's mountain areas are National or Wilderness Parks they are often in close proximity too many of Australia's largest population centres.

Access: Many mountain areas are in wilderness or National parks. As such access into these areas is often limited. Resources in terms of searchers often have to trek great distances to reach their allotted search areas. Air support may not be available due to weather conditions, terrain or vegetation. Additional human resources may be needed to move equipment.

Communications: Many of the mountain areas are not serviced by regular communication networks. It is important to liaise with emergency services that may be able to provide additional portable sites to improve forward net coverage. Even with additional radio communications, there will be no guarantee of continuous coverage. It means that briefings and operational instructions to Team leaders must be absolutely and thoroughly conveyed.

Containment: It is almost impossible to contain an area in mountainous terrain to keep the target within it. The importance of continually monitoring trails, significant points, log books or known 'trap points' where persons could move through is essential.

TFFS: In mountainous areas the targets are often adventurous, with activities such as bush walking, canyoning, trekking, rafting, abseiling and climbing. Often the report of a missing person will not be received until the person is well overdue. With many adventurous activities extending over many days, time becomes critical as injury or misadventure may well have occurred earlier in the activity. Therefore the missing person or group may well be approaching their TFFS by the time emergency services are notified. Search strategies that emphasise fast and reconnaissance methods are indicated.

LPB: Persons who venture into mountainous areas are often motivated and aim to achieve a task. Ascertaining as much data as possible regarding the MP will enable the SMC to determine the likely characteristics of the person. Often these persons are trail orientated and will seek water and/or shelter if injured.

Vertical Rescue: Where called to search areas of high relief for missing people it is advisable to ensure that emergency services with skills in Vertical Rescue are placed on Alert or called to be part of the search so as not to delay the arrival of these trained operators should they be subsequently be needed.

Training: High levels of fitness and resourcefulness are needed as Mountain search crews may well be deployed not only in difficult terrain but over protracted days without opportunity of relief in often poor or changeable weather. Excellent navigation and map reading skills are required in any search team. The ability to effectively use GPS technology should also be considered as a skill within each search team.

● Contain any search area as quickly as possible. This can be done by using FAST and reconnaissance strategies in deploying teams to tracks, LKP, intended destination, lookouts, major camp grounds or known 'trap points' where a person or persons must pass through. These would be the initial high probability areas.
● Many mountainous area and lookouts contain logbooks or visitors' books. It is imperative that these are checked as soon as possible in an effort to narrow down the search area.
● Set up a forward net communication as soon as possible.
● Postpone a general search strategy until there is clear evidence or a definite clue to the missing person's whereabouts (e.g. Found backpack, clothing, footprints etc.) Be flexible about search team sizes, e.g. A team of 2 where communications is excellent across most of the area being searched, a team of 3 where communications is intermittent and a team of 4 where communications is poor or marginal.

● A search team of 3 is a very flexible team size as this size can strike a good balance between rapid movement and deployment and team security. A team of 3 can search in a Single File, Track Sweep, Point and Flank and Purposeful Meandering.
● Use the 'call and listen' techniques. Note that in calling from a ridgeline, the sound will not travel down the sides of a ridge or spur, sound will only travel out to the facing slopes. It is important to therefore call out from opposite ridges into a valley.

● Caves and Mines: Enthusiasts are now delving deeper and further underground into increasingly more difficult areas of caves or abandoned mines. Caves and older mines pose many problems to both the caver and potential rescuers, including narrow constrictions, vertical shafts, water at varying levels, risk of collapse and rock falls, bad air and almost complete darkness. Search and rescue in these environments should only be undertaken by trained specialists. There are several spelunking groups in the southern states and most of the underground mines have mine rescue specialists that could be called upon in an emergency.

Urban Searching

Land searches in urban areas are often required for targets such as those intending suicide and those with dementia or similar ailments. The general strategy employed for urban search is similar to that of the rural or 'bush' search, but the problems encountered are different. Urban search problems include:
● Greater number of places of concealment;
● Complicated search areas;
● Greater number of property owners; and
● Distinguishing between the missing person and the local population. It is vital to have a good description and preferably, a current photograph of the missing person or object

Urban Search Strategies: Urban search and rescue should not be confused with USAR which is the locating and rescuing of persons trapped inside fallen buildings such as in an earthquake. This task normally falls to the respective Fire and Rescue Authorities. Urban land searches will usually progress through the stages of:

- Reconnaissance;
- General search; and
- Building/contact search.

Though the stages are similar to that of a rural search, variations to some of the methods and techniques are required.
Urban Search - Major Complex: In the case of a major complex, e.g. a large hospital, each of these stages would be included within the boundaries of the complex. If the lost person is not found, then a new search area surrounding the complex is determined.

Urban Search Area Segmentation: The same segmentation principles apply as for rural search operations. Boundaries will generally be defined by artificial features, such as roads, drainage channels, railway lines and major complexes (industry, commerce, government). Some natural features which may form boundaries include rivers, shorelines and nature strips. Where roads are used as boundaries between search segments, the boundary would normally follow the centre line of the road.

Urban Environment - Reconnaissance Search: The reconnaissance stage requires small search teams to carry out a quick check of specific areas of high probability within the area of possibility. Areas which should be checked during the reconnaissance stage:

- Locations that are familiar to the lost person, e.g. current or previous residence, the home of friends and family, church, hotel, even if assurances are given that these areas have been checked.
- Hazardous areas e.g. construction sites, quarries, rooms/buildings that are rarely used (locked or unlocked).

Urban Environment -General Search: A general search stage is carried out in an area of probability, checking for signs or indications of the missing person. A check of such places as public buildings e.g. public toilets, railway station and other shelters, such as store and plant rooms or a large building, large culverts and beneath bridges, should be carried out. A special check of hazardous areas, including railway tracks, banks of rivers, lakes, swimming pools, drains, dams and construction sites where the missing person could be trapped or injured, should be made.

Urban Environment - Building/Contact Search: Building search as it implies, requires the systematic searching of each and every corridor, room and possible place of concealment within a building. Several buildings may be contained within one property, therefore requiring a systematic search of the property surrounding the buildings. Always gain permission to search property or seek police assistance. Building searches in large complexes, such as a hospital or shopping centre, present a different problem. Divide these buildings into sectors by wings or, in the case of a multi-story building, by floors. Appoint a separate team leader for each of these sectors and, where possible, have a member of the staff who occupy the building (with knowledge of the building) accompany the team leader.

The team leader must progressively report those areas searched and list those areas not searched, ensure that they are searched, later.

Urban Environment, Conclusion: Don't be misled by thoughts or statements such as 'there wouldn't be anyone in there', or information like 'I've already searched that building'. If you have the responsibility to search an area, then you make sure that you or those for whom you are responsible cover the whole area.

Telephone Triangulation

With most people now carrying mobile telephones the potential for telephone triangulation by the various telephone carriers can reduce SAR efforts dramatically. During the information gathering stages it should be canvassed as to whether the MP has a mobile telephone with them. Something as simple as making a telephone call, sending a text message or leaving a voice message may resolve a SAR incident. If these methods do not produce results, contact with the service provided can often produce a location or direction from a mobile telephone tower.

The individual State/Territory methods in contacting service providers will differ, as will any charges that are made by these providers. If the MP is in an urban area and their telephone is on, a triangulation can be reasonably successful within a small space of time. A large number of mobile telephone towers in an area can produce a very defined search area, whereas a small number or only one tower will produce a much larger search area, such as a bearing and distance from a particular tower. MP's lost in rural, mountainous or remote areas may have little mobile reception, with an associated small chance of triangulation. Mobile telephones with dead batteries will not be of much use. A triangulation should be requested as part of the initial intelligence gathering.

Reflex Search

Reflex tasking can be likened to a bicycle wheel with the hub situated on the LKP or IPP. The spokes represent the various routes, tracks, trails or directions that could have been taken by the MP. The tyre represents the limit of the reflex search which is recommended at 300-50m.

The reflectors represent places of high probability within this reflex area. These could include huts, track junctions, hazards, lookouts, cliffs and water courses. A reflex task requires minimal planning and it used as a first response search. The first SRU on scene can be tasked while the SMC is on route.

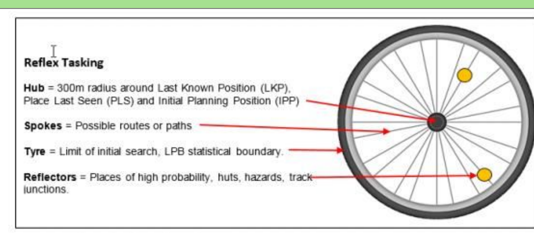

Figure 3 - 31 Bicycle method for Reflex Tasking

Formal Search

There are four strategies in determining the formal search area in a land environment:

- Theoretical (How far could the MP have travelled in the time period)
- Statistical (Using Lost Person Behaviour, what is the statistical distance the MP could be located within)
- Subjective/Decision Points (Using the terrain to determine likely search areas)
- Deductive (Looking closely at the facts, clues and assumptions)

Each of the methods are laid over each other to give a very accurate representation of the situation, and if done correctly will serve to reduce the search area to the highest probable locations.

Theoretical Search Strategy (Naismith's Rule)
The first step in land search planning is to determine the limits of the area containing all possible MP locations. This is usually done by determining the maximum distance the MP's could have travelled between the time of their last known position (LKP) and the known or assumed time the SAR incident occurred. By utilising Naismith's Rule a general indication of the maximum distance that could be travelled by the MP will be obtained. Using this as the radius a circle can then be drawn around the LKP, which will indicate the maximum distance the MP will have walked from the LKP. This method only works when it is known that the MP does not have access to other forms of transport. Knowing the extreme limits of possible locations allows the SMC to determine where to seek further information related to the MP's and whether an incoming report might apply to the incident. However, systematic search of such a large area is normally not practical.

Time missing: This time is calculated from when the MP was last seen (Time last seen TLS), not the time they were reported missing or the time they were due back. If there is no definite time last seen this may have to be estimated, on similar lines to estimating the IPP if a LKP is not viable. Commencing this calculation from TLS is done because an incident may have occurred at any time between when they started their activity and the planned return time.

Naismith's Rule: In gauging the speed of travel, Naismith's Rule describes the distance a person may travel per hour over flat terrain and was devised in 1892.
- 5 km/hour - Easy going over open country.
- 3 km/hour - Easy scrambling over rocky ground.
- 1–1.5 km/hour - Difficult going through thick scrub, heavy sand or snow.

Where a person is missing for extended periods or is likely to traverse hilly country, the possible search radius will need to be reduced due to fatigue and slower travel. For each 500 metres of ascent or 1000 metres of descent over the estimated distance travelled, reduced the possible search radius by the equivalent of one hour travel. For every 5 hours the person is missing, reduce the possible search radius by the equivalent of one hour travel for fatigue. The calculation for the possible distance travelled by the MP is relatively simple to perform. Appendix E-6 and E-7 expands on Naismith's Rule and provides further information.

Example: A 3 year old MP has been missing 13 hours in the Lamington NP. The intended route suggests medium conditions or easy scrambling (3kph) with a 500m ascent and a 500m descent.

13hrs missing -
- 1. Calculate any fatigue by dividing the time missing by 5 and ignore any remainders. (13÷5=2 3/5 = 2hrs) 13hrs – 2hrs = 11hrs
- 2. Calculate any ascent Rule is for every 500m of climbing one hour of travel time is taken off: 500m = 1hr. 11hrs – 1hr = 10hrs
- 3. Calculate any descent Rule is for every 1000m of going downhill one hour of travel time is taken off, therefore 500m would be the equivalent of 0.5hrs being taken off the total: 500m = 0.5hrs. 10hrs - .5hr = 9.5hrs.
- 4. Calculate distance travelled: 9.5hrs x 3kph = 28.5km

It is very unlikely that a 6 year old child will have walked 28.5km however, this is an indication of the maximum distance it could be possible to walk in the time frame. Without using Naismith's Rule, this calculation would have been 13hrs x 3kph = 39km. The area encompassed by a 39km radius circle is vastly larger, almost double, that of a 28.5km circle.

This initial calculation provides the SMC with a possible distance that the MP could have travelled in the time since they were last seen. It does not provide a direction or take into account any other factors, including age or behaviour, at this stage. This area is much too large to search adequately, being approximately 2550km². Being a theoretical distance it is highly probable that this distance would not be walked in a straight line but that the MP would wander somewhat and cover a shorter linear distance from LKP.

Statistical Strategy (Lost Person Behaviour)

Lost Person Behaviour: This method relies on Lost Person Behaviour (LPB) to determine the distance that the MP may have travelled from the LKP. By analysing the behaviour of past lost persons in similar situations, it may be possible to 'predict' what the subject now being sought might do, where he/she might go or where he/she might be. This concept is a search planning tool, dealing with generalities, and not absolutes. Lost person behaviour studies provide the SMC with two important items:
- Behaviour traits of lost persons by category.
- Distances travelled by specific categories of lost person

General Categories of Lost Persons: The following are the commonly used categories of lost persons:
- Children 1 to 3 years
- Children 4 to 6 years
- Children 7 to 12 years
- Adolescent Youth 13 to 15 years
- Mental Development Problems.
- Despondent
- Psychological problems
- Bushwalkers
- Dementia/Alzheimer's
- Climbers
- Hunters
- Prospectors
- Children with ADD, ADHD, Asperger's and Autism

Specific factors of LPB that may affect search planning:
- State of Health: The physical health of the lost person will have a direct impact on their ability to selfhelp and formulate rational decisions. Recent illnesses, poor fitness, disease, lack of adequate nutrition and lack of sleep will restrict a person's ability to cope with situations such as being lost in an unfamiliar environment. Increased physical stress will result in fatigue and exhaustion setting in, reducing the ability to think clearly. Good physical health may be an indication of an ability to withstand the rigors of being lost.
- Past Experiences: Studies have shown that persons who often challenge themselves in new ways or expand their comfort zones will be more adaptable to adverse situations, such as being lost. Gathering evidence of past experiences will provide an insight as to the missing person's ability to cope with challenging or stressful situations. A person who rarely does or tries anything new is more likely to be helpless and a liability when lost.

- Physiological effects of the environment: While it is acknowledged that extremes of heat and cold will have a detrimental effect on a missing person, a combination of normal temperatures with rain and/or wind will quickly have adverse effects on a missing person. Wind and wet chill can quickly lower the core body temperature, and will cause a person to seek shelter which will limit their detectability by searchers. Hypothermia has been identified as a leading cause in death and accidents in the outdoors from a search and rescue perspective. Persons suffering from either hypothermia or hyperthermia become irrational and lose the ability to help themselves. Altitude exacerbates any effects of these debilitating conditions.

Fear Factors
- An aspect that is often overlooked with respect to missing persons is general fear. Fear can be categorised as five basic types; fear of being alone, fear of the dark, fear of animals, fear of suffering and fear of death. A SMC must take these fears into account when planning a SAR mission, not just from a lost person point of view but also from a searcher viewpoint.
- Fear of being alone: In Australia this could also be termed fear of the bush. While some people choose the isolation of the bush the average person finds it haunting. The bush, and this term covers everything from the central deserts, coastal rain forests, snowy alps, eucalypt, brigalow and gidyea forests and northern swamps, is a very harsh and difficult place to survive adequately. Most of the continent has very little surface water and native foods are difficult to safely identify.

- Fear of the dark: Most humans have a primeval fear of the dark. This coupled with the noisy nocturnal activities of most native animals makes the bush darkness a stressful place to be. Compounding this is the general loss of our most important sense, sight. Without being able to see objects in the darkness our imagination can often conjure up images that can cause the strongest to be afraid. This sensation is not confined to lost persons, as it also has an effect on searchers. Those searchers on the extremes of any line search will eventually creep closer to the centre because of this fear of the dark, hence a 100m wide search initially will eventually diminish to cover a much smaller area. It is amazing how a small amount of light, from a torch or fire, can alleviate this fear.
- Fear of animals: Although Australia has no known predatory animals that actively prey on humans there is an irrational fear of being in the bush alone. Most native animals are nocturnal and their nightly activity can unnerve people and preclude a good night sleep.

- Fear of suffering: The spectre of survival can cause an often rational fear of suffering in lost persons. Australia is an extremely harsh continent, not designed to support lost persons. The possibility of dehydration, starvation, hypo- and hyperthermia, illness and injury are all real possibilities, and there are many examples of each throughout our history. The thought of the lingering agony of each situation can create a very real fear among some lost persons.
- Fear of death: The fear of a lingering death can haunt many people, particularly when they consider the many things yet to do; leaving loved ones behind, tying up loose ends and the hereafter. In some instances the fear of death can actually hasten it.

Biological Cycles

- These cycles have been recognised in the medical world for many years and do have some application to search and rescue. Most humans go through a cycle of highs and lows which can vary from periods as short as a day to periods of months.
- Female biological cycles are relatively easy to map and generally fall in line with their menstruation cycle.
- Males have similar but less detectable cycles. Studies have shown that married males will generally mirror their female partner's cycles.
- A person at the high point of a cycle may see being lost as a challenge to be met head on. These
people will attempt to self-help and have a greater chance of survival in adverse conditions. Conversely, a person at a low point of a cycle may have little energy to assist themselves and may succumb to conditions more quickly.

Behaviour while Lost

- The recognition of being lost occurs at different stages for people. It may be the slow awareness that it is taking far longer to reach a destination than was calculated or the instant realisation that what was once familiar territory is now not. A lost person can go one of two ways; sit tight and quietly reflect the situation and work out a solution or to hasten their pace as the destination 'could just be over the next hill'. This second situation can then also go in two directions; the realisation that they are getting further into unknown territory and sit down to reflect the situation or to increase their pace and run to avoid the fear of the bush, which now appears to be closing in around them. In other words they are panicking.
- Those persons who take the time to ponder may identify their location and self-help to safety. If this is not possible they will often form a shelter and wait for rescue.

- Those who are compelled to continue in a blind rush often find themselves injured in locations often far removed from their original intended track and therefore take longer to locate and rescue. It is worth considering that these people may often attempt to travel up hill to either locate a path or orientate themselves to their environment before fatigue, despair and/or depression takes over and they tend downwards on the path of least resistance. These people will often take risks beyond their capability and as a result suffer more injuries than would normally be expected.
- In both the above circumstances shock will be suffered by the lost person. This will manifest itself in many different ways depending on the person's mental strength, from simply forgetting incidents that have occurred to failing to seek shelter from rain or snow.

The trauma of being lost may also have the following effects on a lost person:

- Not seeking shelter. Many persons do not make an adequate shelter nor build a fire for warmth. With hypothermia and hyperthermia being very prevalent, particularly in desert, mountainous and urban areas, this is a vital necessity and will extend a person's chances of survival. Survivor questioning has often elicited the assumption that it is not worth the effort of making a shelter even if it will limit heat loss and provide a measure of mental comfort.
- Discarding equipment: Many persons discard their equipment without thought for using it to survive. While it is true that most lost persons are not prepared for the conditions as they only expected to be out for a few hours, there have been many instances of people being extremely well prepared and failing to use the items that had with them, particularly tents and fire making apparatus. Discarding clothing and backpacks is common and may be contributed to the shock of being lost.

- Discarding clothing: Many persons discard their clothing while wandering in the bush. This may because of overheating in warm areas, but soon becomes regrettable as the sun sets and the temperature cools down. While understandable in hotter areas it also happens during the early stages of hypothermia in colder areas. The net benefit of discarding clothing is that the lost person succumbs sooner.
- Sense of abandonment: Often with the shock of being lost is the sense of abandonment, the feeling that nobody is looking for them. Throughout Australia a search mission will be commenced once the alarm has been raised by a concerned party. If the SMC has an itinerary and LKP then the task of locating the MP is much easier. If there is no itinerary, no LKP and the MP has not been seen for some time then the task is that much harder.

- Clothing: Self-helping and responsiveness is a big factor in determining what type of search to opt for. A MP wearing bright clothing and actively seeking assistance will be easily located when compared to a small child dressed in dark clothing hiding in the undergrowth for shelter. Children are often taught 'stranger danger' and are reluctant to approach a stranger in these circumstances. MP suffering shock or other mental issues may make no attempt to draw attention to themselves even if they see a searcher, motor vehicle or helicopter.
- Navigation aids: Ignoring aids such as tracks, paths and fences is a common problem associated with MP's suffering shock. Common sense dictates that if a MP locates one of the above it will lead to a main road, gate or house where help can be obtained. On many occasions a MP will cross a track, path or fence, often without realising it, only to be further lost in an area outside a high probability search area.

10 Air Search

Once the optimal search area has been determined, a systematic search for the search object should be planned. Before a search operation takes place, the search planner should provide a detailed search action plan to all involved, specifying when, where and how individual search assets are to conduct their search operations. Coordination instructions, communications frequency assignments, reporting requirements, and any other details required for the safe, efficient and effective conduct of the search must also be included in the search action plan.

Many of the general factors involved in aerial and maritime search have similarities in their prosecution and planning and are considered together in this manual. Once the search area has been determined, a systematic search for the target should be planned. Factors such as the weather conditions, time available for search, aircraft and vessel speed, search altitude, sighting range and height of eye, size of target, etc., should be taken into account. These factors are related but some may be more important than others. In planning a search operation, the SMC should endeavour to meet the requirements of the more important factors while satisfying the requirements of the others as far as practicable.

Search Area coverage is the systematic search of selected areas of land, or water, to ensure the optimum probability of detection of the object being sought. The factors affecting detection capability have been reduced to four inter-related expressions. The terms and their symbols are:

- Sweep Width (W)
- Track spacing (S)
- Coverage Factor (C)
- Probability of Detection (POD)

The type and number of available search assets will be a factor in determining search area coverage. More time will be required to search a large area thoroughly when there are limited numbers of search assets available unless the distance between successive sweeps of the area is increased. This is not desirable since it would reduce the probability of detection of the target. It may, therefore, be necessary to seek additional search assets from other sources. It is usually preferable to cover a search area from the beginning with an adequate number of search assets.

Visual Search Patterns (Marine and Aviation)

There are six main groups of search patterns:

- Track line;
- Parallel track (search legs are aligned with the major axis of an individual search area);
- Creeping line (search legs are aligned parallel with the minor axis of an individual search area);
- Expanding square;
- Sector;
- Contour

Track Line Search	This procedure is normally employed when an aircraft or vessel has disappeared without a trace. It is based on the assumption that the target has crashed, made a forced landing or ditched on or near the intended route and will be easily seen, or that there are survivors capable of signalling their position by a flashing lamp or other means. It consists of a rapid and reasonably thorough search on either side of the intended route of the target, normally at a height of 1000 to 2000 ft. during day or at 2000 to 3000 ft. at night. A track line pattern is often used as an initial reaction to a distress situation, the second, intensive phase being introduced on the failure of the track line search.	 Figure 4-6 Track Line Search where aircraft is returning back along track
Parallel Track Pattern	Parallel track search patterns can be used for searches involving one or a group of search assets and are the simplest patterns available. The pilot/coxswain of a search vessel steers straight courses or search legs, each leg being one track spacing from the other. Parallel track patterns are normally used when: ● The search area is large and the terrain is relatively level, e.g. desert and maritime areas; ● Uniform coverage is required; and ● The location of the target is not known with any precision	 Figure 4-4 Vessel trackline search
Creeping Line Pattern	These are the same type of searches but the legs are parallel to the short side of the search area. These patterns would be used when there is a stronger probability of the craft in distress being closer to one end of the search area. The SMC should be aware of the drift rate to ensure that the target is not drifting through the search area faster than the search assets are capable of searching. The search unit begins the pattern at the end of the search area where the target is most likely to be. These patterns can also be used both in single and multi-unit searches.	
Expanding Square Search	This procedure begins at the reported position or most probable location and expands outwards in concentric squares. It is a very precise pattern and requires accurate navigation. It may be advisable for vessels, especially when searching for a person in the water with either an expanding square search (SS) to use dead reckoning (DR) navigation rather than more accurate navigational methods. DR navigation will minimize pattern distortion relative to the search object since it will automatically account for the currents affecting the search object's drift during the search.	 Figure 4-8 Expanding Square Search Pattern
Sector Search	This pattern may be employed when the position of distress is known within close limits and the area to be searched is not extensive. It is simple to execute, is likely to provide greater navigational accuracy than a square search and, because the track spacing is very small near the centre, it ensures a high probability of detection in the area where the target is most likely to be located.	 Figure 4-9 Sector Search Pattern - Aircraft
Contour Search (Requires Aircraft)	Contour search is used to examine mountain slopes and valleys when sharp changes in elevation make other types of search impractical. The procedure requires that the search aircraft be flown at a selected contour level adjacent to the side of steep terrain, starting at the highest selected level. The search is started above the highest peak with the search aircraft completely circling the mountain at that level. Then the search aircraft descends a planned vertical distance while making an orbit in the direction opposite to the search (forming a figure eight), then it makes another circuit of the mountain, and so on. If the mountain cannot be circled, successive sweeps at the same intervals should be flown along its side.	 Figure 4-11 Contour Search Pattern

Search Considerations

Night Time Multi-Unit Searches
Extreme care should be taken during multi-asset searches to maintain the observers' night vision whilst working in close proximity to search lights. The operators of searchlights should always remain aware of this concern and direct the search light from a bearing right ahead to a bearing of approximately 45° to port or starboard. For small targets such as a person in the water, search asset track spacing must be adjusted so that the beams of the searchlights maintain a good overlap at all times.

Drift Compensation
In maritime areas where there is a high drift rate, care must be taken to ensure the target does not drift out of a SAR asset's area. This problem occurs when the rate of creep of the SAR asset is less than the rate of drift of the target. When this condition exists some methods of resolving the problem are to:
- Align the SAR assets search legs with the drift vector;
- Use shorter legs for the SAR unit to increase the rate of creep; and
- Increase the SAR asset's speed.

Irregularly Shaped Areas
The foregoing method of allocating aircraft assumes a regularly shaped search area. At times it is more practical to define search area boundaries by geographical features. In these situations, it is frequently impossible to set out geometrically aligned, regularly spaced search tracks. Pilots should be briefed to make every effort to conform to the standard patterns but it may be necessary, at times, to leave the execution of the search pattern to the discretion of the pilots

Search by Infrared (IR) Devices

Infrared (IR) devices such as IR TV cameras or Forward Looking Infrared (FLIR) are passive detection systems used to detect thermal radiation. They operate on the principle of detecting temperature differences to produce a video picture. Therefore, IR devices may detect survivors by their body heat. IR devices are normally preferred for night use. Search height should normally be 200 to 500 ft. for small targets such as persons in the water, and up to a maximum of approximately 1,500 ft. for larger targets or those having a larger heat signature. The track spacing can be based on consultation with the operating crew and taking into consideration the effective detection range as provided by the manufacturer.

Night Vision Goggles

Use of night vision goggles (NVGs) can be effective in search carried out by various types of search units.
The following factors may influence the effectiveness of NVGs for searching:
- NVG quality;
- Crew training and experience;
- Environmental conditions, visibility, moonlight, cloud coverage, rain;
- Level and glare effects of ambient light, natural and artificial;
- SAR asset speed;
- Height of the observer above the surface;
- Surface conditions (like snow), and sea state;
- Size, illumination, and reflectivity of the search object. The presence of reflective tape greatly enhances detectability; and
- Types of survival equipment or light sources used by the survivors.

Glare should be minimised as much as possible within the facility where the NVG users are stationed. This may involve opening or removing windows where practicable. Also proper scanning techniques are important for reducing the adverse effects of moonlight or artificial light sources like, lighthouses, offshore rigs, ships, navigation and strobe lights.

Visible moonlight can significantly improve detection of unlighted search objects when using NVGs. Search object light sources, like strobe or similar lights, mobile telephone screens or even cigarettes, can greatly improve detection even in poor visibility conditions. Recent studies have found that certain LED lights, because of the frequencies they emit on, are invisible to NVG. RCC staff should be aware that sweep width needs to be discussed with the crew conducting the mission and modified according to the conditions encountered in the search area.

11 Land Search

Searching for people lost on land.

Search Dog Capabilities

Search dogs can be trained in a range of different ways to respond to different conditions and circumstances. Understanding these differences, including the benefits and limitations, will assist in determining the most effective search dog capability to be utilised. Search dog capabilities are categorised into 6 main groups indicated in the table below:

Type	Description	Uses
Air Scenting Area Search	Work off lead and use airborne scent. They are normally nondiscriminate and will detect any human scent and other relevant scents to home in on their subject.	• Considered to be the most efficient tool for search controllers • Can efficiently search large areas • Can search difficult, steep terrain more easily than humans • Can easily integrate into a search area • Not bounded by time constraints • Can catalogue the smell of team members • Can search buildings that have collapsed or otherwise damaged • Will detect live and deceased people on land and underwater • Best used in less populated areas such as bush land and rural areas • Able to locate people who are actively hiding, deceased bodies, deliberately concealed bodies and submerged bodies • 'Live find' trained
Ground Disturbance Tracking	Working on lead, this category follows a subject's footsteps by utilising ground scent.	• Most effective when a short period of time has passed (preferably 1-2 hours) • Requires the search area to be uncontaminated where there has been no other recent foot traffic • 'Live find' trained
Scent Specific Tracking	By working on a harness and long lead, this category is trained to detect human scent on the ground. After smelling a scent article/source from the missing person they will search around the last known position to determine the path the missing person walked in order to find them.	• Scent discriminating by following the scent trail of a specific individual • Can be used to rapidly establish direction of travel where a scent source or article of the missing person is available • Requires an uncontaminated scent article/source of the subject • Handlers prefer to obtain the scent article themselves • People in the area are not to interfere with a scent specific tracking dog • There is no time constraint. 24 hours on any surface is within their capability and 48 hours or more if the conditions are suitable • 'Live find' trained
Cadaver/Human Remains Detection (HRD)	Work off lead and search for the presence of deceased persons or human remains that may be on the surface, buried, or hanging.	• Used in missing persons response, cold cases, mass graves, disaster responses including fires, floods, earthquakes etc.
Water Search	Predominantly Cadaver/HRD trained dogs that are trained to work along the shoreline or from a boat, to search for the presence of human remains in salt or fresh water.	• Can work in rivers, lakes, dams, or the ocean • Dogs are trained to alert and their handlers who then take a GPS reading to mark location • Important that they work closely with Police dive teams on the scene to pinpoint location for divers • 'Live find' trained
Avalanche	Search avalanche and heavy snow conditions for the presence of persons buried.	• Rapid activation of teams is essential • Pre-developed MOUs and activation protocols should be in place to optimise response • 'Live find' trained
Urban Search and Rescue (USAR)	Search collapsed structures and debris piles from man-made or natural disasters for the presence of live victims.	• Work off lead without a collar • Used to working at distance from their handlers • Particularly valuable in areas that are too difficult or dangerous to send humans • 'Live find' trained

SURVIVAL | Search & | Land Search | Search Dog Capa

Explanatory Terms

● 'Live find' Dogs - The term 'live find' dog is used for dogs that have been trained to find missing people that are still alive. However, most 'live find' dogs will also be able to find deceased people. All search dogs have been trained as 'live find' dogs, with the exception of Cadaver/HRD Dogs which have been trained specifically to focus on deceased persons.

● 'Scent picture' - All matter gives off scent to some degree which enables Search dogs to utilise their superior sense of smell as their primary search tool. They are able to do this by following a 'scent picture' that is made up of a combination of minute particles that tend to fall to the ground at varying distances from the source.

Composite scents consist of natural and artificial scent. The scent picture will vary with each individual, depending on ethnicity, diet and habits. Other contributing scents may include body odour, hair oil, toothpaste, equipment, footwear and those scents released from brushing and breaking of vegetation and the crushing of small insects.

Water

Methods of finding, purifying and storing water

*"Nothing is softer or more flexible than water,
yet nothing can resist it."*
Lao Tzu

Introduction

Water is essential for almost all forms of life on the planet without which we could not sustain ourselves due to the sheer amount we lose daily without realising. It's something that we all take for granted. We turn on the faucet and there it is, plentiful, clean, drinkable and seemingly endless. Without such a simple way to acquire water many people would panic out of sheer thirst and drink contaminated water from a stream, lake or worse yet - the ocean.

With an atmospheric temperature of 20°C (68°F) the average adult requires 2 to 3 litres (quarts) of water daily. The following section will inform you on multiple ways to acquire water and how to sterilize it to properly kill any viruses or pathogens that may be in it.

Purpose	The aim of WATER is to provide foundational knowledge on finding, harvest and purifying naturally occurring water until it's ready for human consumption. It also outlines how you can protect electronics from water and expounds on how the flow of water around the planet occurs by means of the ocean, rips, tides and waves.
Lost?	● For information on swimming and crossing bodies of water, see the SURVIVAL > Water Survival section. ● For ships, sailing and living on boats, see the TRANSPORT section. ● For tsunamis and flooding, see the NATURAL DISASTERS section. ● For dam failures, see the MAN-MADE DISASTERS section.

Contents

1 Types of Water

Here you can find a description of all the different types of water you may encounter, from distilled to bore water.

The distribution of water on the Earth's surface is extremely uneven. Only 3% of water on the surface is fresh; the remaining 97% resides in the ocean. Of freshwater, 69% resides in glaciers, 30% underground, and less than 1% is located in lakes, rivers, and swamps. Looked at another way, only one percent of the water on the Earth's surface is usable by humans, and 99% of the usable quantity is situated underground.

Water Distribution
- Ocean Water (96.5%)
- Ice and Snow (1.76%)
- Groundwater (1.69%)
- Lakes (0.013%)
- Atmosphere (0.00093%)
- Swamps (0.00083%)
- Rivers (0.00015%)
- Biological Water (0.000081%)

Tap Water	Water from a faucet, may or may not be suitable for drinking depending on country.	**May be Safe to Drink**
Mineral Water	Water that naturally contains minerals and is obtained from underground sources. No further minerals added and cannot be treated before packaging.	**Safe to Drink**
Spring Water	Rainwater leaking from the surface as a spring or puddle. Not passed through a community water system but is suitable for drinking.	**May be Safe to Drink**
Well Water	A well is an excavation or structure created in the ground by digging, driving, or drilling to access liquid resources, usually water. The oldest and most common kind of well is a water well, to access groundwater in underground aquifers.	**Requires Treatment**
Purified Water	Water which has been treated at a water plant removing bacteria, contaminants and dissolved solids.	**Safe to Drink**
Distilled Water	Demineralised water has been treated to remove all the minerals and salt via reverse osmosis. It's not recommended for drinking over long periods of time as it can cause mineral deficiencies.	**Safe to Drink (For a Limited Time)**
Sparkling Water	Water which has undergone carbonation (the addition of carbon dioxide) to make it fizzy. It may be spring water, purified water or spring water.	**Safe to Drink**
Bore Water	Bore water is groundwater that has been accessed by drilling a bore into underground aquifers (water storages) and pumping to the surface. Aquifers may contain chemicals and micro-organisms that are potentially harmful. Some of these chemicals are naturally occurring (such as those present in soils and rocks) while others are a result of contamination.	**Requires Treatment**
Drinking Water (Potable Water)	Drinking water, also known as potable water, is water that is safe to drink or to use for food preparation. The amount of drinking water required to maintain good health varies, and depends on physical activity level, age, health-related issues, and environmental conditions.	**Safe to Drink**

2 Water Loss

This section is about any form of water loss, from natural evaporation to water lost as sweat.

Bodily Water Loss

These are the different methods in which water can be lost from the body.

Exhaling Water Vapour	Water is lost from your body through breathing. Depending on the humidity level of the air, we lose about 300-500ml (0.3-0.5 quarts) of fluid a day through breathing.
Perspiration	You can lose up to 1.9L (2 quarts) of water per hour while exercising. Your body temperature rises about 3°C when engaged in physical activity. Sweating is your body's natural cooling system by releasing H2O in the form of perspiration.
Urine	We lose water through urination. A person typically loses 1.5 litres of water a day through urine. If your water intake is high then your kidneys produce larger amounts of water to help maintain a balance.
Bowels	Water keeps the food you eat moving through your intestines which also need water to help keep stools soft and easy to pass. All faeces contain water, causing water loss during a bowel movement. A person typically loses about 6% of their water through faeces.
Diet	Diets containing heavily processed foods could lead to water loss in your body. Heavily processed foods lack the moisture of fresh foods. Meat proteins pull water from the body to aid in digestion. Less moisture in your foods may be causing your body to pull more water from its water supply.

Water Loss Modifiers

The following list will multiply any water loss you are experiencing, so try to minimise their impact.

Heat Exposure	When an individual is exposed to very high temperatures, water lost in sweat can be increased to as much as 3.5 quarts an hour. Water loss at this increased rate can deplete the body fluids in a short time.
Exercise	Physical activity increases the loss of water by: ● The increased respiration rate causes increased water loss by evaporation through the lungs. ● The increased body heat causes excessive sweating.
Cold Exposure	As the temperature decreases, the amount of water vapour in the air also decreases. Therefore, breathing cold air results in increased water loss by evaporation from the lungs.
High Altitude	At high altitudes, increased water loss by evaporation through the lungs occurs not only as a result of breathing cooler air but also as a result of the increased respiratory efforts required.
Burns	After extensive burns, the outermost layer of skin is destroyed. When this layer is gone, there is no longer a barrier to water loss by diffusion, and the rate of water loss in this manner can increase up to 5 quarts a day.

Illness	Severe vomiting or prolonged diarrhoea can leas to serious water depletion.

Natural Water Loss

This covers any form of natural forms of water loss such as evaporation.

Evaporation	Water naturally evaporates over time but can really add up when you have large quantities of it.
Freezing	When water freezes it becomes ice. Ice is unusable in it's current form but can easily be turned back into water again by applying a low, steady heat.
Steam	Water can be lost in the form of steam. This occurs when the water reaches its boiling point. It's difficult to capture and turn steam back into water so try to keep it below boiling point.

Water Conservation

Some tips on conserving both bodily water and natural water.

Conserving Water
- Avoid exertion, rest
- Keep cool, stay in shade
- Don't lie on heated surfaces
- Don't eat, or eat as little as possible
- Don't drink alcohol which requires fluid to break down
- Don't talk and breathe through the nose, not the mouth
- Drink in small sips, even if you have an ample supply

Conserving Household Water
- Flush the toilet once a day for liquids and solids every use
- Fill a bucket for washing hands and add antibacterial elements
- Wash your clothes manually in a scrubber bag
- Use disposable cutlery and eating utensils to prevent washing up
- Take sponge baths instead of showers and especially baths
- Utilise rain, lakes or rivers for showers

Rationing Water
Try to ration water in any survival situation unless you have large amounts of it readily available. Don't drink more water than is necessary in your current situation if water is limited. Extra water will only come out as urine in a few hours and oversaturation doesn't have many additional benefits. Do not ration a limited amount of water and only take sips if you're very thirsty. It's better used early on to keep your mind and body strong so you can search for more.

3 Water Acquisition

Acquiring water is a vital skill in survival situations and should be one of the top priorities after medical needs. The section below will describe how to find water in different environments.

Minimum Water Intake
You need about 2L (64oz) of water per day to stay alive. This depends heavily on how much you are moving and the environment you're in. Find a suitable source of water that won't dry up over time such as a lake or spring.

Locating Water

The below are some tips on finding bodies of water using nature.

Animals	Animals require water regularly, grazing ones are never far from water as they drink at dawn and dusk.
Birds	Birds are never far from water. When they fly straight and low they are heading for water. They fly from tree to tree when returning from water - resting frequently.
Insects	Bees only fly 6.5km (4mi) from their hives at most. Flies keep within 90m (295ft) of water.
Valleys	Look in valley bottoms where water naturally drains. If none look for patches of green vegetation and dig.
Stream Beds	Dig in gullies and dry stream beds. Go deep enough and you should find water spilling in from the sides.
Mountains	In mountains look for water trapped in crevices.
Coast	On the coast dig above the high water line or look for lush vegetation in cliff faults - there may be a spring.
Warnings	Be wary of pools with no green vegetation around or contains animal bones. Watch out for mineral build-ups around the edges of lakes which indicate alkaline conditions. In the desert lakes with no outlets become very salty - distil to drink.

Polar Water Tips
Ice will yield more water per given volume than snow and requires less heat to do so. If the sun is shining, snow or ice may be placed on a dark surface to melt. If snow must be used for drinking water, use the snow closest to the ground. This snow is packed tighter and will produce more water. To melt snow, add it a little at a time to a pot over a fire preventing burning out the bottom of the container through insulation and airspace. All arctic water should be purified by some means. In the summer surface water may be discoloured but is drinkable when purified. You can use body heat to melt ice and snow using a waterproof container and placed between clothing layers. Do not place it directly next to the skin. Do not ingest unmelted snow or ice as it will lower the body's temperature, inducing dehydration and causing minor cold injury to lips and mouth.

Tundra Water Tips
The tundra is usually a wet place because the low temperatures cause evaporation of water to be slow. Much of the arctic has rain and fog in the summers, and water gathers in bogs and ponds.

Northern Coniferous Forest Water Tips
- Follow animal tracks (they could lead you to a water source).
- Look for lush green plants (a sign that water can be close by).
- Keep moving until you find water.
- Listen for running water.
- Look for low-lying areas or valleys (water always flows downhill).
- Collect rainwater and dew.
- Melt snow or ice. Do not eat frozen snow and ice, which will lower your body temperature and lead to dehydration.

Deciduous Forest Water Tips
Collecting rainwater is the safest way to obtain drinking water. You can use all the containers you have and strategically place them in areas to catch rain water. If you have a tarp you can tie it to trees creating a catch that drains into a container. You can also collect water that plants release through transpiration. You can also collect drinking water from snow and ice.

Temperate Grassland Water Tips
There's little rainfall in the temperate grasslands so your best bet would be to look for valleys or pools of water.

Mediterranean Regions Water Tips
The Mediterranean region is one of the most water-scarce regions in the world, however there are often plenty of rivers flowing into it to be found.

Tropical Forests Water Tips
Water is abundant in tropical forests such as in large vines which can be cut at the bottom and a nick higher up to allow the water to trickle out. You can also head to lower ground to find either a river or puddles of water. There's often a lost of dew on low-lying plants in the morning, so grab some cloth and gently wipe over safe plants and squeeze it into a container before filtering it.

Savanna Water Tips
Dehydration is a serious threat out in the open if you are unexpectedly isolated. High daytime temperatures can cause you to lose body fluids rapidly and become dehydrated. Rain is an infrequent event on the savanna, but if it rains while you are stranded, try to catch as much rainwater as possible with whatever containers you have at your disposal. If there has been recent rain, rocky outcrops are a good place to find fresh water in shallow depressions on the rocks.

A smart strategy to look for water is to find some higher ground to get an elevated view of your surroundings. Scan the landscape for clumps of trees or a line of trees across the plains, which could indicate a watercourse. If there is water in the stream or river, you can use it for drinking, but it would be better to boil it first. Always check for crocodiles and hippos in any body of water. Animals move to and from water sources to drink in the savanna, so following animal trails heading downhill could lead to water.

Standing pools of water are usually unsafe to drink because of bacteria and parasite contamination. Dig in the sand a little way from the water's edge to access water filtered through the sand. This water should be clean enough to drink, but boiling it first would be the best option. In dry river beds, look for the lowest points of the watercourse and dig into the sand in the river bed to find water. A favorable location is the inside of any bends in the watercourse, where the water flows the slowest and has a chance to seep into the sandy river bed. Once you feel the sand in the hole becoming moist, dig a little deeper and wait for the water to filter into the hole.

Plants can be a good source of water if you know where to look and which plants to use. But this option can be unsafe if you use the wrong plants. An accessible plant source of water is the baobab tree, which is distinctive in shape on the African plains. These trees capture rainwater in crevices in the tree's crown and can be a valuable resource if you are desperate for water.

Desert Water Tips
Sufficient water to last until the next water hole is reached should be on hand. Be prepared to backtrack if you cannot find your next source. Look for water before your supply is exhausted. Water canteens should be transported in such as way that they cannot be damaged or the seams split. You can drink 2.1L (2.2 quarts) of water at a time. The body sweats this amount in two hours. To maximise your water intake drink slowly and in sips. Drink as much as you can, rest and slowly drink again. Repeat this a few times until your body is saturated. To conserve water, do not travel in the heat of the day but only in the early morning, late evening or on a moonlit night. Set up a sheltered rest area for the day. The optimum drinking water temperature is between 10° - 15°C (50 - 59°F). To cool water, it can be wrapped in a wet cloth which will cause cooling when the water evaporates. Palm trees will grow where the water table is closest to the surface. Dig for water at the low point between dunes.

Ocean Water Tips
Collect rainwater in any available containers and store for future use. Collect dew on metal surfaces on foggy days. Use a Solar Still to distil the seawater. Use a desalter kit if there are no other options available.

Water Sources

Rain	Collect with a tarp and store for 7 days max without filtering. Can drink immediately.
Snow	Melt snow gradually and keep adding more to the liquid so you don't burn the bottom of the pot. It's 10% water depending on the type and isn't as efficient to collect as rain or hail. If the snow is fresh it doesn't typically require boiling.
Hail	Melt hail gradually and keep adding more to the liquid. Hail is 100% water and contains pathogens so boiling is essential.
Rivers	Filter the pathogens, viruses and particulate out. Always filter no matter how clear it looks.
Ocean	Desalinate - boil the water and recondense in a container. The average salinity of Earth's oceans is about 35 grams of salt per kilogram of sea water (3.5% salt). Most of this salt was released from volcanic activity or extracted from cool igneous rocks.
Lakes	Filter pathogens, viruses and particulate out. Ensure there's no green algae around the edges or carcasses nearby.

Evapotranspiration (Water Transpiration Bag)	Shake leaves to remove bugs. Place transparent bags over some of the fresh leaves on a medium tree or large shrub and tie at ends with a clean rock in the corner and a tube with a tap if available to prevent opening the bag. Do not use for more than three days consistently. Ensure the plant isn't toxic. Provides 3.7L/bag a day. Water may taste bitter.
Plant Condensation	Dig a shallow hole next to a plant with many leaves. Place a plastic bag over the plant and have its side slope to the lowest point which is in the hole. Tie or tighten the opening of the bag around the base of the plant. The plant will collect water with its root system. It should work for a few days as long as the plant isn't too exposed to the sun as it will be killed by overheating.
Vegetation Bag	Cut foliage from trees or herbaceous plants, sealing it in a large clear plastic bag and allow it to heat in the sun to extract the fluids contained within. The bag should be filled with about 1 cubic yard of foliage, sealed and exposed to the sun. The average yield is 320ml/bag in a 5 hour day. The water can be bitter to taste caused by leaf breakdown in the water. Use a taste test prior to consumption to test for toxins.
Dew Collection	Use clothing to mop up morning dew and wring into a cup. Dew and condensation settles on cold surfaces. These surfaces can be pieces of metal, grass, smooth rocks. Dew will evaporate at sunrise.
Fog Harvesting	Mesh netting made of nylon or polyethylene - AKA shade netting. Placed in a location with common fog on a mountain. The altitude should be 2/3rds of the stratocumulus cloud's thickness above the base - around 400-1000m. Mountain fog is denser then coastal fog. Harvests about 50L per day per m.
Atmospheric Water Generator	An atmospheric water generator (AWG) is a device that extracts water from humid ambient air. Water vapour in the air is condensed by cooling the air below its dew point, exposing the air to desiccants, or pressurizing the air. Unlike a dehumidifier, an AWG is designed to render the water potable.
Animals	In an emergency you can filter fresh animal blood for viruses and treat it for bacteria - only if you were the one to kill it. The eyes can be sucked for water as well. Large fish have a drinkable fluid along their spines. Gut the fish and keeping it flat remove the backbone being careful not to spill the liquid. In Aus desert frogs that burrow in the ground can be dug up and squeezed for their water.
Plants	Plants trap water in cavities. Shake old bamboo to find it and cut each notch to retrieve. Vines can store water but ensure sap isn't poisonous. Cut a deep notch high up and then close to the ground letting it drain, then work your way up.
Roots	Water Tree, Desert Oak, Bloodwood have roots near the surface. Pry them up and cut in 30cm lengths. Remove the bark and suck out the moisture or shave to a pulp and squeeze over mouth.
Cacti	Water is stored in the fruit and bodies but some are poisonous. Prickly pears are moisture laden in the fruit and 'ears'.
Vines	Slice the vine high up to prevent water capillary action and slice the bottom off. Water should slowly flow out. Avoid the liquid if it's cloudy, milky or has a bitter or sour taste. Do not touch the vine with your mouth. If the flow stops, cut another nick in the opposite end to drinking.
Green Bamboo	Water may be trapped within sections of bamboo. Shake it to determine if there's water inside by listening for sloshing. Cut two 45° notches on the same side and pry the piece away. Ensure the inside walls are clean and white and the water will be safe. If there are brown or black spots or any discolouration the water should be purified first.
Moss	Moss in tropical forests can be wrung of its water into your mouth.
Soil & Sand	In a muddy or damp area dig a hole one to two feet. Allow water to seep into the hole. Purify this to drink. Wet sand can be put in a piece of cloth which is then pressed or wrung to force the water out. The water will be cloudy for both methods but if left - will settle or can be filtered through a fine cloth.
Coast Water	Along coasts, water may be found by digging beach wells. Locate the wells behind the first or second pressure ridge. Wells can be dug 3-5 feet deep and should be lined with driftwood to prevent stirring up sand when procuring the water. The average well may take as long as 2 hours to produce 4 to 5 gallons of water.
Solar Still	Dig a hole 90cm across and 60cm deep in a moist area and cover with plastic sheet held by rocks then place a container in the centre. Ensure area receives lots of sunlight. Add a tube to drink from.
Sandy Beach & Salty Lakes	Along sandy beaches or salty desert lakes, dig a hole in a sand depression 30m (100ft) from the shore. Filtered water will gradually seep into the hole.
Dry Rivers	Follow a dry river bed and because of the rock structure or composition a stream might emerge. Dig a pit if the soil is moist. Follow the riverbed to the source. There might still be a trickle of water or humid soil. Dry meandering stream beds might have water deposits just below the surface at outside bends. Dig in these bends for water.
Groundwater	Groundwater is part of precipitation that seeps down through the soil until it reaches impervious rock. If the water can not find any area to flow into it saturates the area above the rock with water. It then slowly moves underground, generally at a downward angle and may eventually seep into streams, lakes and oceans. Dig deep into the earth at a low point to reveal. Filtering may be required.
Sinkholes	Sinkholes are common where the rock below the land surface is limestone, carbonate rock, salt beds, or rocks that can naturally be dissolved by ground water circulating through them. As the rock dissolves, spaces and caverns develop underground. Sinkholes are dramatic because the land usually stays intact for a while until the underground spaces get too big. If there is not enough support for the land above the spaces then a sudden collapse of the land surface can occur.
Rocky Ground	In rocky ground, look for springs and seepages.
Limestone and Lava	Limestone and lava rocks will have more and larger springs than any other rocks. Most lava rocks contain millions of bubble holes; ground water may seep through them.
Lava Flows	Look for springs along the walls of valleys that cross a lava flow.
Clay	Water moves slowly through clay, but many clays contain strips of sand which may yield springs. Look for a wet place on the surface of clay bluffs and try digging it out.
Granite	Most common rocks, like granite contain water only in irregular cracks. A crack in a rock with a bird dung around the outside may indicate a water source that can be reached by a piece of surgical house used as a straw or siphon.
Tree Spile	Requires: Drill, Bit, Mallet, taps, vinyl tube, bucket, bleach. Number of taps per tree by diameter: 12" - 1 Tap, 18" - 2 taps, 24+ - 3 taps. Drill a 12mm hole up at an angle up into the tree 5cm deep and insert spile tapping it gently. Connect the tube and run it to the bucket. Sap will collect slowly over days. Store in a cool place. Sap most likely Jul-Early Sep.

WATER
Water Acquisition
Water Sources

Cliffs	Find water at the leeward base (the steep side of the dune opposite the direction of the wind) of large dunes or at a very low spot between dunes.
Iceberg Water	Composed of freshwater and can be used as a source of drinking water.
Old Sea Ice	A bluish or blackish ice which shatters easily and generally has rounded corners. It's almost salt free.
New Sea Ice	Is milky or gray coloured with sharp edges and angles. This type of ice will not shatter or break easily. Snow and ice may be saturated with salt from blowing spray; if it tastes salty select a different source.
Urine	Drinking urine straight is not recommended but possible. Consume within 6 hours after urinating. Using a solar still, distillation or reverse osmosis membrane, generates pure drinking water. Boiling, water filters and purifying tablets kill bacteria but leave the waste products, but it's drinkable. Urine is 95% water, 2.5% is urea and 2.5% hormones, enzymes and salts.

Urban

Urban Water Sources

Household Water Sources

WATER
Water Acquisition
Urban Water Sources
Household Water Sources

Tap	As long as there's water pressure you can get water from the tap. However this supply will run out quickly if SHTF. Use the lowest tap in your home to get every drop.
Hot Water System	A limited supply of water which can be utilised. Can give you from 125L-315L.
Fridge & Freezer	Use water melted from the freezer to purify.
Hoses	There could be residual water in outdoor hoses which you can collect and filter if required. Uncoil, lift one end and collect the water coming out.
Toilet Water	You can use the water in the tank (not the bowl) to purify. Drinking from the bowl only if desperate and you have sufficiently strong purification.
Air Conditioners	If you have a water collection tray you can use this water to distil to provide drinking water. Note: The trays are typically home to a host of various bacteria, protozoa and possibly viruses.
Fish Tank Water	If you use a strong filter (0.02 microns or less) you can filter and drink tank water. Freshwater is much easier to purify as saltwater requires distillation or desalination.
Drains	Drains will hold water for a long period of time. However it will require extreme purification methods.
Cars	You can get water from the wiper fluid container on cars which have been abandoned, but filter it prior to use.

Suburban Water Sources

WATER
Water Acquisition
Urban Water Sources
Suburban Water Sources

Park Taps	Using a sillcock key you can turn on these taps and drain them. Some taps may have a typical handle or a lever style tap.
Water Towers	Hold large amounts of water, typically found on hills to increase the water pressure but may be difficult to access due to fences and proprietary water keys.
Fire Hydrants	Fire hydrants are very difficult to open due to having a pentagonal socket. **Signage** ● H = Potable Water ● RH = Recycled Non Potable ● P = Pathway (Location) ● R = Roadway (Location)
Wells	

Retrieving Water

WATER

Retrieving Water
Sillcock Keys

Sillcock Keys

The taps - known as "Anti Vandal Taps" are used in parks, water treatment plants and other government run areas to prevent water theft. This water can be accessed by using a special key on the top of the tap to turn it on. The keys are called "Sillcock Keys" in America and "Vandal Proof Keys" generally everywhere else. A special type of key used for recycled water is called an "Anti Vandal Recycled Water Key". There a multitude of key types which should be covered in the next cells but it helps to have the four-way key for opening multiple types of taps.

Key Shape	Used For
Rectangle with convex short ends	Generally on the 4-way keys.
Reverse Cog-shaped teeth with flat sections on upper and lower areas	Generally on the 4-way keys.
Zig-Zagged Teeth	Generally on the 4-way keys. I've seen a few of these in parks, some are marked as recycled water.
Fire Hydrant Wrench Hexagonal	Allows the opening of fire hydrants for use of the water.
Square	These are rarely seen, but it seems harder to get this type of key as they aren't included in the general 4-way keys.
Zig-Zagged Circular Teeth with flat base and pointed teeth	A mid-way key shape between the cog and the zig-zagged shape. Generally on the 4-way keys.

Pumps

Water

Pumps are used for transporting water either horizontally or vertically. They are useful for moving volumes of water over a distance or retrieving it from wells. The two main categories of water pumps are: Centrifugal pumps, and Positive Displacement Pumps.

Positive Displacement Pumps	Positive displacement pumps work by delivering a fixed amount of water through mechanical contraction and expansion of a flexible diaphragm. While such pumps are relatively efficient, there is the drawback that they need a very small clearance between the rotating pump and the unit's outer edge. Hence, rotation might be carried out at a slow speed. In cases when higher speeds are necessary, the liquids might erode and consequently reduce the pump's overall efficiency. **Typical Uses** Positive displacement water pumps are commonly used as they are very efficient. This is mainly because they remove air from the lines and consequently, eliminate the need for bleeding. These pumps are ideal for liquids that have a high viscosity and where sensitive solids might be present.
Rotary Displacement Pumps	Rotary displacement pumps include gear pumps, screw pumps, hollow disk pumps, rotary vane pumps and vibratory pumps. All of these are considerably efficient as they are able to manipulate highly viscous fluids which typically have higher flow rates. **Typical Uses** Such pumps are most commonly used to circulate lubricating oil in mechanical equipment. They are also used to provide pressure for hydraulic operating systems.
Dynamic Pumps	Dynamic, or rotodynamic pumps, are velocity pumps which add kinetic energy to the fluid to raise its flow velocity. As a result, the higher energy is transformed into pressure, until the velocity decreases as it nears the discharge line. **Typical Uses** Dynamic pumps are used for water supply, to pump crude oil as well as in the food industry. They are also commonly used in the chemical industry, and various commercial applications.
Centrifugal Pumps	A centrifugal water pump makes use of a rotating impeller in order to move the water within. Then it pressurises the discharge flow. There are different types of centrifugal water pumps, including standard models and submersible models. At times these kinds of pumps need recirculating liquid in order to prevent overheating problems which can be caused by low flows. It is also important to prime or fill the pump with the pumped fluid in order to help it work properly. **Typical Uses** These pumps work well when thin liquids need to be handled. As a result, practically all kinds of liquids, even those with low viscosity can be pumped with centrifugal pumps. They offer very high flow rates too. Centrifugal pumps are used in various kinds of water system applications, especially for agricultural purposes. Such pumps will typically move water from a dam or bore, direct it to the pipes for storage or to use it for irrigation. These pumps are also used for dewatering and in pumping sewage and construction-related applications. They are commonly used to pump water supplies in buildings, and to pump water from domestic wells. Such pumps are also used to boost the pressure in the water intake lines. Most centrifugal pumps are compatible with pneumatic systems too.
Axial & Radial Centrifugal Pumps	Radial centrifugal pumps pressurise the pumped flow and move it outwards through downstream piping. Axial pumps provide fluid motion by means of a lifting force caused by the impeller vanes. **Typical Uses** Such pumps are typically used in diverse commercial, industrial and domestic settings. These include the provision of water supply in residential areas, sewage disposal, in chemical, food and beverage manufacturing, as well as in oil and gas industrial operations.
Reciprocating Pumps	Reciprocating pumps fall under the positive displacement pumps category. They have an expanding cavity on the suction side, and a decreasing cavity on the discharge side. The water pump will work by filling the cavity and displacing the fluid. This is done alternately and with each cycle a constant volume is carried out. **Typical Uses** Reciprocating pumps are commonly used to pump high viscosity fluids, such as oils, resins and paints. They are ideal in applications where high pressure output is required. Such pumps are generally self-priming and since they have the advantage of not being affected by pressure levels, they are ideal in applications where the supply is irregular.
Submersible Pumps	Submersible pumps, as the name itself implies, will be submerged in the fluid. They operate by using the principle of electric submersible pumping. By lowering the flow pressure, the pressure at the bottom is also decreased. **Typical Uses** Such pumps can be quite expensive since they might require the use of special electricity cables, and the electric usage is generally considerably higher. They are used in deep wells such as oil wells, and in applications where the motor is able to operate under high pressures and temperatures. They are also suited to dealing with groundwater flooding in basements to keep properties dry, using sump pumps that sit inside a pit.
Peristaltic Pumps	A peristaltic pump is sometimes also referred to as a hose pump or a tube pump. This type of pump works by applying positive displacement principles, whereby the fluid is supplied in the tubing by rotating rollers. Then it is squeezed in a soft tube, and as the roller passes through it, it expands and forms a vacuum. This enables the fluid to enter. These rollers rotate either directly or by a motor, and there is no need for valves in such pumps. Such pumps have the advantages of being self-priming and ideal for flow regulation. They are tolerant to contamination with particles. **Typical Uses** These kinds of pumps are ideal in cases where viscous and corrosive fluids are being handled. This is because the only piece of the pump which comes into contact with the liquid is the tubing. These pumps are relatively maintenance free.
Diaphragm Pumps	A diaphragm pump, or membrane pump is another type of positive displacement pump. The diaphragm is either made from rubber, thermoplastic or Teflon. Its reciprocating action combined with the proper valves on the sides will pump the liquid. There are three main types whereby: The diaphragm is sealed with one front in the liquid being pumped, and the other in air, or in hydraulic liquid. This diaphragm is flexible, so the volume of the pump chamber can increase or decrease as required. There is a set of non-return valves which block the reverse flow. Electro-mechanical movement is carried out, and the system flexes the diaphragm, which has one head open for air. One or more unsealed diaphragms are employed to pump on both heads. When the volume of a chamber is increased, the pressure will diminish and as a result the fluid will make its way in the chamber. This will later rise so that the fluid is driven out. The cycle ends when the diaphragm moves up. **Typical Uses** Such pumps are generally used when chemicals such as acids, bleach and caustics are involved. They are also used to move abrasive fluids such as concrete. These pumps are also commonly found in the aircraft and automobile industries.

Wells

Wells are dug to hopefully provide a reliable and ample supply of water.

Dug Wells	Made with a pick and a shovel if the ground is soft and the water table is shallow. They are often lined with stones to prevent them from collapsing. They cannot be dug much deeper than the water table because it keeps filling up with water. During the dry season or a drought the water table will fall and the depth of the well can be increased.
Driven Wells	Built by driving a small diameter pipe into soft earth, such as sand or gravel. A screen is usually attached to the bottom of the pipe to filter out sand and other particles. They can only tap shallow water, and because the source of the water is so close to the surface, contamination from surface pollutants can occur.
Drilled Wells	Most modern wells are drilled. Drill rigs are often mounted on big trucks. Drilled wells can be drilled more than 1,000 feet deep. Often a pump is placed at the bottom to push water up from the surface.

Other Water

Bottled Water
Water stored in a bottle for consumption. Some bottles may leach chemicals into the water when heated. Water jug dispensers can also be found in some households. The jugs are generally 19L (5 gal).

Canned Water
More sustainable than bottled water and won't leach chemicals into the water. Some manufacturers started to use Nitrogen flush to remove air and bacteria from their cans to prolong shelf life to 30 years or longer, making the water suitable for long term storage. May have resealable lids or the common ring pull lid system.

Water Pouches Water Pouches are small flexible pouches of clean drinking water which you cut open to drink from. They generally hold 125ml each and have expiry dates of around 5 years. They aren't practical for anything but consumption and are often fairly expensive. Pouches are considered more durable, freeze resistant, impact resistant and heat resistant then water bottles thus giving them a unique purpose.	**Known Brands** • Datrex • Mainstay • Mayday • SOS Emergency	**Expiry** Chemicals may leak into the water over its lifetime and may be contaminated after it's expired. It's recommended to boil the water when expired. It will generally last 5 years.

4 Water Purification

This sections covers how to turn potentially dangerous water into drinking water.

In general there are 3 stages to producing drinking water from any type of water.

1. Remove Sediment	Filter out unwanted matter in the water such as dirt and sand. This makes it easier to kill pathogens.
2. Kill/Remove Pathogens	Remove the risk of pathogens by either killing them or removing them from the water. The first step can be combined with this step sometimes.
3. Remove Odour/Flavour	Remove/correct any natural bad taste lingering in the water or resulting from additives in the previous step.

Water Purification Overview

This section is a tabular description of each purification method to assist with choosing the best way to purify water. Each of the following purification methods are expanded in more detail in the sections below. Bugout convenience is how easy the purification is to accomplish on the go and how easy it is to store, use and repair. The scores signify the convenience of using this technique in a survival or bug-out situation. For more information on any of the techniques below, head to the section below entitled "Purification".

Note the difference between **Kills** and **Removes** as it could be important. "Improves" and "Reduces" are used for a slightly less effectiveness than "Removes" or "Kills" respectively.

Filter Type	Convenience Score	Effects & Requirements	Treatment Time & Effectivity	Lifespan & Maintenance
Makeshift Water Filter A custom filter built in the field from sand, cloth, rocks and moss.	**Makeshift Water Filter** **3/5** Easy filter to build and use in the field, but won't filter pathogens.	**Effects** • Removes Larger Particulate **Requires** • Plastic Body • Filterable Materials	**Treatment Time (1L)** 2 Minutes **Not Effective On** • Viruses • Chemicals	**Effective Lifespan** Infinite **Maintenance Required** Wash thoroughly prior to first use. May become clogged over time.
Manufactured Filters Any form of manufactured water filter.	**Manufactured Filters** **5/5** Very easy to use and maintain. Slowly blocks with age.	**Effects** • Removes Protozoa • Removes Bacteria • Removes Viruses* **Requires** • A Filter • Clean Water Container	**Treatment Time (1L)** 2 Minutes **Not Effective On** • Viruses* • Chemicals • Salts	**Effective Lifespan** 50L-1,000L Clogs as it ages **Maintenance Required** Occasional back flushing when it becomes clogged. *Only some models remove viruses.
Bank Filtration Water is filtered naturally through a bank to remove contaminants.	**Bank Filtration** **3/5** If you're near the ocean a bank should be common. Be 100% sure the water is consumable.	**Effects** • Lowers Turbidity **Requires** • A suitable bank • Digging Utensil	**Treatment Time (1L)** o **Not Effective On** • Viruses	**Effective Lifespan** o **Maintenance Required** o

Tap Filters Filters that fit over household faucets.	**Tap Filters** **2/5** Can only be used with taps. Large and Bulky.	**Effects** • Removes Protozoa • Removes Bacteria • Removes Chlorine • Removes Lead • Removes Asbestos • Removes Odours **Requires** • Tap Filter • Grid Water • Tap Pressure	**Treatment Time (1L)** 1 Minute **Not Effective On** • Viruses • Chemicals • Salts	**Effective Lifespan** 50L-1,000L Clogs as it ages **Maintenance Required** Occasional back flushing when it becomes clogged.
Carbon Filtering Putting water through carbon removes particulate and bad taste but leaves the bacteria and viruses.	**Carbon Filtering** **3/5** Only removes particulate and bad taste.	**Effects** • Removes Larger Particulate • Removes Bad Taste **Requires** • Carbon	**Treatment Time (1L)** 2 Minutes **Not Effective On** •	**Effective Lifespan** o **Maintenance Required** o
Activated Charcoal Charcoal with a large surface area for holding contaminants.	**Activated Charcoal** **3/5** Only removes particulate and bad taste.	**Effects** • Removes Larger Particulate • Removes Bad Taste **Requires** • Activated Charcoal	**Treatment Time (1L)** 2 Minutes **Not Effective On** •	**Effective Lifespan** o **Maintenance Required** o
Hand Filtering (Straining) Filtering water through a piece of fine clothing folded over at least 8 times.	**Hand Filtering (Straining)** **3/5** Only removes particulate. Very easy to use.	**Effects** • Reduces Protozoa • Reduces Bacteria • Reduces Turbidity **Requires** • Large Cloth or Material	**Treatment Time (1L)** 2 Minutes **Not Effective On** • Viruses • Chemicals • Salts	**Effective Lifespan** o **Maintenance Required** Rinsing out of the straining material.
Slow Sand Filter A filter using sand and a biofilm layer to kill microorganisms.	**Slow Sand Filter** **2/5** Takes a long time to set up but provides ample clean water. Removes most contaminants. Lots of maintenance and space required. Lots of resources required to build.	**Effects** • Removes Protozoa • Removes Bacteria • Removes Viruses • Removes Turbidity • Removes Heavy Metals • Improves Odour, Taste • Reduces Iron • Reduces Manganese • Reduces Arsenic **Requires** • Lots of Space	**Treatment Time (1L)** o **Not Effective On** • Salts • Fluoride • Chemicals	**Effective Lifespan** Infinite **Maintenance Required** Have to maintain the biofilm layer to keep the filter running.
Rapid Sand Filter Rapid sand filtration is a purely physical drinking water purification method. Rapid sand filters (RSF) provide rapid and efficient removal of relatively large suspended particles.	**Rapid Sand Filter** **2/5** Takes a long time to set up but provides ample clean water. Removes most contaminants. Lots of maintenance and space required. Lots of resources required to build.	**Effects** • Removes Turbidity **Requires** • Lots of Space	**Treatment Time (1L)** 4k-12k Litres per Hour **Not Effective On** • Bacteria • Viruses • Fluoride • Arsenic • Salts	**Effective Lifespan** o **Maintenance Required** • Frequent Cleaning • Skilled Supervision • High Energy Input • Backwashing
Biosand Filter Biosand filters remove pathogens and suspended solids from water using biological and physical processes that take place in a sand column covered with a biofilm.	**Biosand Filter** **2/5** Takes a long time to set up but provides ample clean water. Removes most contaminants. Lots of maintenance and space required. Lots of resources required to build.	**Effects** • Removes Protozoa • Removes Bacteria • Removes Turbidity • Removes Colour • Removes Odour • Removes Iron **Requires** •	**Treatment Time (30L)** 1 Hour **Not Effective On** • Dissolved Compounds • Viruses	**Effective Lifespan** Has a Long Life **Maintenance Required** • Requires Constant Use
Sedimentation Sedimentation is the process of settling or being deposited as a sediment.	**Sedimentation** **2/5** Only clumps particulate together for removal.	**Effects** • Reduces Sediment • Reduces Turbidity • Reduces Viruses • Reduces Bacteria • Reduces Protozoa **Requires** • Sediment Chemicals	**Treatment Time (1L)** o **Not Effective On** • Most Things • Chemicals	**Effective Lifespan** One Time Use **Maintenance Required** • Careful PH control
Coagulation Coagulates the sediment so it falls out of suspension for easy removal.	**Coagulation** **2/5** Only clumps particulate together for removal.	**Effects** • Clumps Sediment • Reduces Turbidity • Reduces of Protozoa • Reduces of Bacteria • Reduces of Viruses **Requires** • Coagulants	**Treatment Time (1L)** 5 Minutes **Not Effective On** • Most Things • Chemicals	**Effective Lifespan** o **Maintenance Required** o
Boiling Boil water at high temperatures to kill pathogens.	**Boiling** **5/5** The most convenient way to purify water in the field.	**Effects** • Kills Protozoa • Kills Bacteria • Kills Viruses **Requires** • Fire • Metal Pot	**Treatment Time (1L)** 5 Minutes **Not Effective On** • Turbidity • Chemicals • Taste • Smell • Colour	**Effective Lifespan** Infinite **Maintenance Required** • None

Solar Pasteurisation The heating of water to levels over 65°C (149°F) and under boiling can kill all pathogens over a longer period of time.	**Solar Pasteurisation** **3/5** Similar to SODIS and boiling but uses less energy. Harder to confirm organisms are dead.	**Effects** ● Kills Protozoa ● Kills Bacteria ● Kills Viruses **Requires** ● Heat Source ● Unmeltable Container	**Treatment Time (1L)** 6 Minutes **Not Effective On** ● Turbidity ● Chemicals	**Effective Lifespan** Infinite **Maintenance Required** ● None
Distillation Collection of the steam from boiling water recondensed back into a liquid.	**Distillation** **4/5** Guarantees water purity but takes a long time and special equipment.	**Effects** ● Removes Turbidity ● Removes Protozoa ● Removes Bacteria ● Removes Viruses ● Removes Salts ● Removes Sugars **Requires** ● Fire ● Condensation Tubing ● Funnel Section ● Boiling Container ● Collection Container	**Treatment Time (1L)** 30 Minutes **Not Effective On** ● None?	**Effective Lifespan** Infinite **Maintenance Required** ● None
Chlorination Add chlorine to water and mix to kill pathogens.	**Chlorination** **5/5** Very easy to purify water. Must to wait some time for it to work. Tiny tablets.	**Effects** ● Kills Protozoa ● Kills Bacteria ● Kills Viruses **Requires** ● Chlorine (Such as:) ○ Sodium Hypochlorite ○ Calcium Hypochlorite ○ Electrolytic Purification	**Treatment Time (1L)** 30m for Bacteria / Protozoa or 4h for Cryptosporidium **Not Effective On** ● Turbidity ● Chemicals	**Effective Lifespan** ○ **Maintenance Required** None
Electrolytic Water Purifier Generates chlorine from salty water to kill pathogens. (WATA) (Sodium Hypochlorite)	**Electrolytic Water Purifier** **4/5** Generates chlorine with salt easily and quick to use. Batteries Required.	**Effects** ● Kills Protozoa ● Kills Bacteria ● Reduces Viruses **Requires** ● Salt ● Chlorine Generator	**Treatment Time (1L)** 1 Minute Initial 30m or 4h Chlorination **Not Effective On** ● Cryptosporidium ● Turbidity ● Chemicals ● Taste ● Smell ● Odour	**Effective Lifespan** Infinite **Maintenance Required** Keeping the batteries charged.
UV Light Shining of a light into clear water to kill pathogens.	**UV Light** **3/5** Often requires additional filtration methods. Batteries required.	**Effects** ● Kills Protozoa ● Kills Bacteria ● Kills Viruses **Requires** ● UV Purifier	**Treatment Time (1L)** 2 Minutes **Not Effective On** ● Turbidity ● Chemicals ● Taste ● Odour	**Effective Lifespan** About 5,000 hours until the LED dies. **Maintenance Required** Keeping the batteries charged.
SODIS (Solar Disinfection) The use of the sun's UV rays to kill contaminants in water.	**SODIS** **3/5** Easy to access materials but takes a long time to purify.	**Effects** ● Kills Protozoa ● Kills Bacteria ● Kills Viruses **Requires** ● Full Sunlight for 8h	**Treatment Time (1L)** ● 6 Hours ● 2 Days (If Cloudy) **Not Effective On** ● Chemicals	**Effective Lifespan** Infinite **Maintenance Required** None
Copper / Silver Ionization / Electrolysis Metals with antimicrobial properties that kills pathogens slowly.	**Copper/Silver Ionization / Electrolysis** **2/5** Infinite reusability but slow and hard to tell when the water is drinkable.	**Effects** ● Kills Protozoa ● Kills Bacteria ● Kills Viruses **Requires** ● Specific Metals	**Treatment Time (1L)** 2 Days **Not Effective On** ●	**Effective Lifespan** ○ **Maintenance Required** None
Colloidal Silver An antibacterial solution of silver that kills pathogens.	**Colloidal Silver** **2/5** Hard to obtain colloidal silver and use to treat water effectively.	**Effects** ● Kills Protozoa ● Kills Bacteria ● Kills Viruses **Requires** ● Silver ● Electricity Source ● Colloidal Generator	**Treatment Time (1L)** 4 Hours **Not Effective On** ●	**Effective Lifespan** ○ **Maintenance Required** Generation of colloidal silver solution
Ceramic Candle Filter A vertical gravity fed ceramic filter which purifies water.	**Ceramic Candle Filter** **3/5** Large and bulky but simple to use.	**Effects** ● Removes Protozoa ● Removes Bacteria ● Removes Most Viruses **Requires** ● Filtration Device	**Treatment Time (1L)** 2 Minutes **Not Effective On** ●	**Effective Lifespan** ○ **Maintenance Required** Scrubbing the filter clean
Membrane Filtration A simple membrane which filters out contaminants.	**Membrane Filtration** **4/5** Generally compact, portable and easy to use.	**Effects** ● Removes Protozoa ● Removes Bacteria ● Removes Some Viruses **Requires** ● Membrane Filter	**Treatment Time (1L)** 2 Minutes **Not Effective On** ●	**Effective Lifespan** ○ **Maintenance Required** ○

Reverse Osmosis An extremely fine filter membrane that removes most contaminants.	**Reverse Osmosis** **3/5** Removes virtually every contaminant but requires maintenance and parts are large and hard to get.	**Effects** • Removes Protozoa • Removes Bacteria • Removes Viruses • Removes Salts • Removes Sugars • Removes Chemicals • Removes Pesticides • Removes Synth Dyes • Removes Heavy Metals • Removes Pharma Drugs **Requires** • RO Filter • Water Pressure	**Treatment Time (1L)** 30 Seconds **Not Effective On** •	**Effective Lifespan** ○ **Maintenance Required** Replacement of the old filters when they wear down.
Hydrogen Peroxide Mix hydrogen peroxide to kill pathogens.	**Hydrogen Peroxide** **2/5** ○	**Effects** • **Requires** • Hydrogen Peroxide • Mixing Container	**Treatment Time (1L)** ○ **Not Effective On** •	**Effective Lifespan** ○ **Maintenance Required** ○
Ozonation The use of ozone gas molecules to kill contaminants.	**Ozonation** **2/5** Requires complex resources and electricity to use.	**Effects** • Removes Protozoa • Removes Bacteria • Removes Viruses • Adds Bad Taste • Adds Bad Odour **Requires** • Ozone Generator	**Treatment Time (1L)** ○ **Not Effective On** •	**Effective Lifespan** ○ **Maintenance Required** ○
Adsorption over Metal-Organic Frameworks (MOFs) Adsorption processes with porous materials. (e.g. zeolites, activated carbon, silica gel, metal-organic frameworks)	**Adsorption over Metal-Organic Frameworks (MOFs)** **1/5** Extremely difficult to accomplish off-grid due to resources needed.	**Effects** • Removes small neutral contaminants • Removes Boron • Heavy Metals • Removes Salt **Requires** •	**Treatment Time (1L)** ○ **Not Effective On** •	**Effective Lifespan** ○ **Maintenance Required** ○
Solar Desalination Solar desalination is a technique to produce water with a low salt concentration from sea-water or brine using solar energy.	**Solar Desalination** **1/5** Extremely difficult to accomplish off-grid due to resources needed.	**Effects** • Removes Salt **Requires** •	**Treatment Time (1L)** ○ **Not Effective On** •	**Effective Lifespan** ○ **Maintenance Required** ○
Electrodialysis Desalination Electrodialysis reversal desalination (EDR), is a water desalination process in which electricity is applied to electrodes to pull naturally occurring dissolved salts through an ion exchange membrane to separate the water from the salts.	**Electrodialysis Desalination** **1/5** Extremely difficult to accomplish off-grid due to resources needed.	**Effects** • Removes Salt **Requires** •	**Treatment Time (1L)** ○ **Not Effective On** •	**Effective Lifespan** ○ **Maintenance Required** ○
Ion Exchange Ion exchange is a water treatment process commonly used for water softening or demineralization, but it also is used to remove other substances from the water in processes such as dealkalization, deionization, and disinfection.	**Ion Exchange** **1/5** Extremely difficult to accomplish off-grid due to resources needed.	**Effects** • Removes Salt • Removes Nitrate • Removes Fluoride • Removes Sulphate • Removes Arsenic **Requires** •	**Treatment Time (1L)** ○ **Not Effective On** •	**Effective Lifespan** ○ **Maintenance Required** ○
Geothermal Desalination Geothermal desalination is a process under development for the production of fresh water using heat energy.	**Geothermal Desalination** **1/5** Not yet a functioning way to purify water.	**Effects** • Removes Salt **Requires** •	**Treatment Time (1L)** ○ **Not Effective On** •	**Effective Lifespan** ○ **Maintenance Required** ○
Freezing Desalination Freeze-thaw desalination uses freezing to remove fresh water from salt water.	**Freezing Desalination** **1/5** Extremely difficult to accomplish off-grid due to resources needed.	**Effects** • Removes Salt **Requires** •	**Treatment Time (1L)** ○ **Not Effective On** •	**Effective Lifespan** ○ **Maintenance Required** ○
Advanced Oxidation Processes Advanced oxidation processes (AOPs), in a broad sense, are a set of chemical treatment procedures designed to remove organic (and sometimes inorganic) materials in water and wastewater by oxidation through reactions with hydroxyl radicals.	**Advanced Oxidation Processes** **1/5** Extremely difficult to accomplish off-grid due to resources needed.	**Effects** • Removes Salt **Requires** •	**Treatment Time (1L)** ○ **Not Effective On** •	**Effective Lifespan** ○ **Maintenance Required** ○

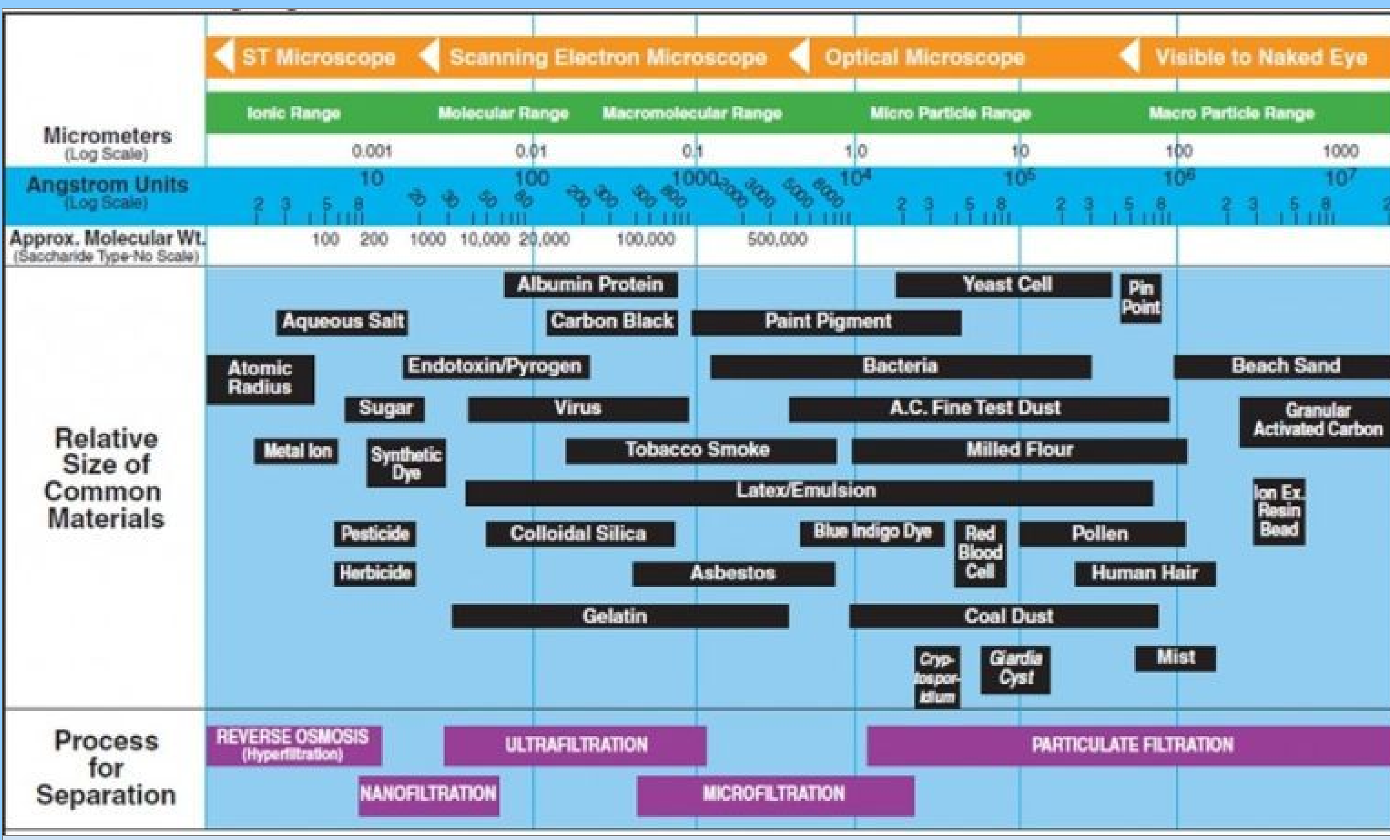
Filter Membrane Size

The table below shows the sizes of various materials that are filtered from water and the type of membane required to filter them out.

Name	Filters	Filtration Material

10,000 Micron Filter (1cm)	Filters anything larger plus: • Leaves • Sticks • Plastics (wrappers, caps etc.)	• Large Insects (Beetles, etc)	• Stones in a handmade filter
1,000 Micron Filter (1mm)	Filters anything larger plus: • Bugs • Insects		• Sand in a handmade filter • Fly Screen
100 Micron Filter (0.1mm)	Filters anything larger plus: • Sand • Dust Mites • Food Scraps		• Loose Clothing (folded over a few times)
10 Micron Filter (0.01mm) (10,000nm)	Filters anything larger plus: • Hair (Thin end first) • Rust • Dust	• Pollen • Fine Sand • Plant Spores • White Blood Cells	• Tightly Knit Clothing (folded over) • Activated Charcoal
1 Micron Filter (1,000nm)	Filters anything larger plus: • Protozoan Cysts • Giardia • Cryptosporidium	• Red Blood Cells • Mould • Coffee • Cement Dust	• All Manufactured Filters (Lifestraw, Katadyn, MSR)
0.1 Micron Filter (100nm)	Filters anything larger plus: • Bacteria • Clay	• Paint Pigment • Asbestos • Radioactive Fallout	• Most Manufactured Filters (Sawyer Mini, Katadyn Pocket)
0.01 Micron Filter (10nm)	Filters anything larger plus: • Atmospheric Dust • Colloidal Silica	• Natural Smoke	• Specific Manufactured Filters (MSR Guardian)
0.001 Micron Filter (1nm)	Filters anything larger plus: • Viruses • Pesticides • Synthetic Dye		• Reverse Osmosis
0.00001 Micron Filter (0.01nm)	Filters anything larger plus • Hydrogen Atoms • Helium Atoms		• None Known

Filter Size Table



Size of Objects in Microns (μm)

Filter Size Table

Anthrax: 1-5	**Clay:** 0.1-50	**Lead Dust:** 0.1-0.7	**Salt:** 0.0003-0.002
Antiperspirant: 6-10	**Coal Dust:** 1-100	**Liquid Droplets:** 0.5-5	**Skin Flakes:** 0.5-10
Asbestos: 0.7-90	**Copier Toner:** 0.5-15	**Mist:** 70-350	**Natural Smoke:** 0.01-0.1
Car Emissions: 1-150	**Corn Starch:** 0.1-0.8	**Mould:** 3-12	**Spider Web:** 2-3
Colloidal Silver: 0.001-0.01	**Dust Mites:** 100-300	**Mould Spores:** 10-30	**Plant Spores:** 3-100
Bacteria: 0.3-60	**Eye of a Needle:** 1,230	**Oxygen:** 0.0005	**Starches:** 3-100
Beach Sand: 100-10,000	**Fertilizer:** 10-1,000	**Paint Pigments:** 0.1-5	**Sugars:** 0.0008-0.005
Water Molecule: 0.000275	**Fibre Insulation:** 1-1,000	**Pesticides:** 0.001	**Textile Fibres:** 10-1,000
Bromine: 0.1-0.7	**Glass Wool:** 1,000	**Pollen:** 10-1,000	**Viruses:** 0.005-0.3
Burning Wood: 0.2-3	**Hair:** 40-300	**Radioactive Fallout:** 0.1-10	**Atmospheric Dust:** 0.001-30
Carbon Dioxide: 0.00065	**Household Dust:** 0.05-100	**Red Blood Cells:** 5-10	**Synthetic Dye:** 0.001-0.005
Cement Dust: 3-100	**Iron Dust:** 4-20	**Sawdust:** 30-600	**Water Molecule:** 0.000275

Filters vs Purifiers

This is the difference between water filters and water purifiers.

Water Filter	A water filter is a porous substance such as activated carbon which removes sediment and unwanted substances such as harmful chemicals and toxins from our water. Although filters are valuable, by themselves they are generally inadequate for turning municipal or well water into healthy drinking water. A filter improves taste and odour and reduces the level of many chemical contaminants in drinking water.
Water Purifier	A water purifier is defined as a system that removes 90-95% of all contaminants in water. There are three recognized purifier technologies known today: reverse-osmosis, deionization, and distillation. Because of their powerful capabilities, purifiers must form the foundation of any drinking water system to have a chance at creating truly pure water.

Membrane Classifications

These are the different classifications of water filter membranes. These are useful when purchasing a filter and you don't understand the terms used.

Microfiltration (MF) **Pore Size: ~0.1µm** **(±0.05-5)**	● High effectiveness in removing protozoa ● Moderate effectiveness in removing bacteria ● Not effective in removing viruses ● Not effective in removing chemicals
Ultrafiltration (UF) **Pore Size: ~0.01µm** **(±0.001-0.05)**	● Very high effectiveness in removing protozoa ● Very high effectiveness in removing bacteria ● Moderate effectiveness in removing viruses ● Low effectiveness in removing chemicals.
Nanofiltration (NF) **Pore Size: ~0.001µm** **(±0.008-0.01)**	● Very high effectiveness in removing protozoa ● Very high effectiveness in removing bacteria ● Very high effectiveness in removing viruses ● Moderate effectiveness in removing chemicals.
Reverse Osmosis (RO) **Pore Size: ~0.0001µm**	● Very high effectiveness in removing protozoa (for example, Cryptosporidium, Giardia); ● Very high effectiveness in removing bacteria. ● Very high effectiveness in removing viruses ● Removes common chemical contaminants (metal ions, aqueous salts), including sodium, chloride, copper, chromium, and lead; may reduce arsenic, fluoride, radium, sulphate, calcium, magnesium, potassium, nitrate, and phosphorous.

Micron Ratings

The micron Absolute, Nominal and Mean Filter ratings can vary significantly in purchased water filters. Knowing which you are buying will give you the best quality.

Absolute Micron Rating (International Rating)	The absolute rating, or cut-off point of a filter refers to the diameter of the largest spherical glass particle normally expressed in micrometres (mm), which will pass through the filter under laboratory conditions. It represents the pore opening size of the filter medium. Theoretically filter media with an exact and consistent pore size or opening has an exact absolute rating.
Nominal Micron Rating (US Rating)	The nominal rating refers to a filter capable of cutting off a nominated minimum percentage by weight of solid particles of a specific contaminant (usually glass beads) greater than a stated micron size normally expressed in micrometres (mm). I.e. 90% of 10 micron.
Mean Filter Rating	The mean filter rating refers to the measurement of the average pore size of a filter element. It establishes the particle size above which the filter starts to be effective. It is determined by the bubble point test and it is more meaningful than a nominal rating and in case of filter elements with varying pore size, more realistic than an absolute rating.

Water Filter Pore Size in Microns

Following is a list of popular water filters and their 'claimed' micron rating. The actual rating may differ due to the testing methods stated above.	**3 Micron Filters** ● Aquamira Frontier **0.2 Micron Filters** ● Lifestraw ● Katadyn Pocket ● Lifestraw Family ● MSR Trailshot ● MSR Miniworks EX ● Katadyn Hiker ● Katadyn Hiker PRO	**0.2 Micron Filters (cont)** ● Katadyn Vario ● Katadyn Expedition ● Katadyn BeFree ● Platypus GravityWorks ● MSR Sweetwater ● Black Berkey ● MSR HyperFlow ● MSR AutoFlow Gravity	**0.1 Micron Filters** ● Sawyer Filter ● Sawyer Squeeze ● MSR Miniworks ● Survival Hax Filter ● First Need XL ● Miniwell Filter ● Berkey Ceramic ● Versa Flow	**0.05 Micron Filters** ● Survivor Filter **0.02 Micron Filters** ● Etekcity Portable ● MSR Guardian **0.01 Micron Filters** ● AquaPura Premium ● Survivor Filter PRO ● Etekcity 1500L	

Water Filter Testing

You can test a water filters provided micron rating without specialist equipment at home using typical household items. Each material will be dissolved in water and will allow a certain filter type to remove it or not. The following are the items and the micron size that filters them out.
(Ordered Smallest to Largest) This was developed by myself (Fluidic Ice) but hasn't been tested yet so use at your own discretion.

Filter Method	Particle Size	Description	Filters

Salt	0.0003-0.002	Mix salt with pure water until fully diluted. Filter the mixture and if you can't taste salt at the end the filter is smaller than 0.0003-0.002 microns.	All Viruses +
Sugar	0.0008-0.005	Mix sugar with pure water until fully diluted. Filter the mixture and if you can't taste sugar at the end the filter is smaller than 0.0008 - 0.005 microns.	All Viruses +
Synthetic Dye	0.001-0.005	Mix a synthetic dye with pure water until fully diluted. Filter the mixture and if it isn't coloured at the end the filter is smaller than 0.001-0.005 microns.	All Viruses +
Colloidal Silver	0.001-0.01	Filter colloidal silver and if you can't taste the mixture at the end the filter is smaller than 0.001-0.01 microns.	Most Viruses +
Corn Starch	0.1-0.8	Mix corn starch with pure water until fully diluted. Filter the mixture and if you can't taste corn starch at the end the filter is smaller than 0.1-0.8 microns.	Most Bacteria +

Purification Methods

A study by Rob Reed using brass jugs showed a major reduction of bacteria with containers made of brass. "In brass vessels, the live E. coli levels fell and after 48 hours they were at undetectable levels." Brass sheds copper particles into the water that kill the bacteria. The levels of the metal in the water is less then the daily recommended dose.

Oligodynamic Effect (Copper)

Oligodynamic Effect
The oligodynamic effect is a biocidal effect of metals, especially heavy metals, that occurs even in low concentrations. Brass doorknobs and silverware both exhibit this effect to an extent. The oligodynamic effect was discovered in 1893 as a toxic effect of metal ions on living cells, algae, moulds, spores, fungi, viruses, prokaryotic, and eukaryotic microorganisms, even in relatively low concentrations. This antimicrobial effect is shown by ions of copper as well as mercury, silver, iron, lead, zinc, bismuth, gold, and aluminium. In 1973, researchers at Battelle Columbus Laboratories conducted a comprehensive literature, technology and patent search that traced the history of understanding the "bacteriostatic and sanitizing properties of copper and copper alloy surfaces", which demonstrated that copper, in very small quantities, has the power to control a wide range of moulds, fungi, algae and harmful microbes.

Copper Inhibits
Actinomucor elegans, Aspergillus niger, Bacterium linens, Bacillus megaterium, Bacillus subtilis, Brevibacterium erythrogenes, Candida utilis, Penicillium chrysogenum, Rhizopus niveus, Saccharomyces mandshuricus, and Saccharomyces cerevisiae in concentrations above 10 g/L. Candida utilis (formerly, Torulopsis utilis) is completely inhibited at 0.04 g/L copper concentrations. Tubercle bacillus is inhibited by copper as simple cations or complex anions in concentrations from 0.02 to 0.2 g/L. Achromobacter fischeri and Photobacterium phosphoreum growth is inhibited by metallic copper. Paramecium caudatum cell division is reduced by copper plates placed on Petri dish covers containing infusoria and nutrient media. Poliovirus is inactivated within 10 minutes of exposure to copper with ascorbic acid. A subsequent paper probed some of copper's antimicrobial mechanisms and cited no fewer than 120 investigations into the efficacy of copper's action on microbes. The authors noted that the antimicrobial mechanisms are very complex and take place in many ways, both inside cells and in the interstitial spaces between cells. The 3-dimensional structure of proteins can be altered by copper, so that the proteins can no longer perform their normal functions. The result is inactivation of bacteria or viruses. Copper may disrupt enzyme structures, and functions by binding to sulphur- or carboxylate-containing groups and amino groups of proteins.

Copper facilitates deleterious activity in superoxide radicals. Repeated redox reactions on site-specific macromolecules generate HO radicals, thereby causing "multiple hit damage" at target sites. Copper can interact with lipids, causing their peroxidation and opening holes in the cell membranes, thereby compromising the integrity of cells. This can cause leakage of essential solutes, which in turn, can have a desiccating effect. Copper damages the respiratory chain in Escherichia coli cells. and is associated with impaired cellular metabolism. Faster corrosion correlates with faster inactivation of microorganisms. This may be due to increased availability of cupric ion, Cu^{2+}, which is believed to be responsible for the antimicrobial action.

In inactivation experiments on the flu strain, H1N1, which is nearly identical to the H5N1 avian strain and the 2009 H1N1 (swine flu) strain, researchers hypothesized that copper's antimicrobial action probably attacks the overall structure of the virus and therefore has a broad-spectrum effect. Microbes require copper-containing enzymes to drive certain vital chemical reactions. Excess copper, however, can affect proteins and enzymes in microbes, thereby inhibiting their activities. Researchers believe that excess copper has the potential to disrupt cell function both inside cells and in the interstitial spaces between cells, probably acting on the cells' outer envelope.

Efficacy on Copper Surfaces
Recent studies have shown that copper alloy surfaces kill E. coli O157:H7. Over 99.9% of E. coli microbes are killed after just 1–2 hours on copper. On stainless steel surfaces, the microbes can survive for weeks. Results of E. coli O157:H7 destruction on an alloy containing 99.9% copper (C11000) demonstrate that this pathogen is rapidly and almost completely killed (over 99.9% kill rate) within ninety minutes at room temperature (20°C, 68°F).

At chill temperatures (4°C, 39.2°F), over 99.9% of E. coli O157:H7 are killed within 270 minutes. E. coli O157:H7 destruction on several copper alloys containing 99%–100% copper (including C10200, C11000, C18080, and C19700) at room temperature begins within minutes.

At chilled temperatures, the inactivation process takes about an hour longer. No significant reduction in the amount of viable E. coli O157:H7 occurs on stainless steel after 270 minutes. Studies have been conducted to examine the E. coli O157:H7 bactericidal efficacies on 25 different copper alloys to identify those alloys that provide the best combination of antimicrobial activity, corrosion/oxidation resistance, and fabrication properties. Copper's antibacterial effect was found to be intrinsic in all of the copper alloys tested.

As in previous studies, no antibacterial properties were observed on stainless steel (UNS S30400). Also, in confirmation with earlier studies the rate of drop-off of E. coli O157:H7 on the copper alloys is faster at room temperature than at chill temperature. For the most part, the bacterial kill rate of copper alloys increased with increasing copper content of the alloy. This is further evidence of copper's intrinsic antibacterial properties.

Oligodynamic Effect (Brass, Bronze, Copper-Nickel Alloys)

Efficacy on Brass, Bronze, Copper-Nickel Alloys
Brasses, which were frequently used for doorknobs and push plates in decades past, also demonstrate bactericidal efficacies, but within a somewhat longer time frame than pure copper. All nine brasses tested were almost completely bactericidal (over 99.9% kill rate) at 20°C (68°F) within 60–270 minutes. Many brasses were almost completely bactericidal at 4°C (39.2°F) within 180–360 minutes. The rate of total microbial death on four bronzes varied from within 50–270 minutes at 20°C (68°F), and from 180 to 270 minutes at 4°C (39.2°F).

The kill rate of E. coli O157 on copper-nickel alloys increased with increasing copper content. Zero bacterial counts at room temperature were achieved after 105–360 minutes for five of the six alloys. Despite not achieving a complete kill, alloy C71500 achieved a 4-log drop within the six-hour test, representing a 99.99% reduction in the number of live organisms.

Oligodynamic Effect (Stainless Steel)

WATER
Water Purification
Purification Methods
Oligodynamic Effect

Efficacy on Stainless Steel
Unlike copper alloys, stainless steel (S30400) does not exhibit any degree of bactericidal properties. This material, which is one of the most common touch surface materials in the healthcare industry, allows toxic E. coli O157:H7 to remain viable for weeks. Near-zero bacterial counts are not observed even after 28 days of investigation. Epifluorescence photographs have demonstrated that E. coli O157:H7 is almost completely killed on copper alloy C10200 after just 90 minutes at 20°C (68°F); whereas a substantial number of pathogens remain on stainless steel S30400. Copper alloys kill more than 99.9% of MRSA within two hours. Subsequent research conducted at the University of Southampton (UK) compared the antimicrobial efficacies of copper and several non-copper proprietary coating products to kill MRSA.

At 20°C (68°F), the drop-off in MRSA organisms on copper alloy C11000 is dramatic and almost complete (over 99.9% kill rate) within 75 minutes. Stainless steel S30400 did not exhibit any antimicrobial efficacy. After incubation for one hour on copper, active influenza A virus particles were reduced by 75%. After six hours, the particles were reduced on copper by 99.999%. Influenza A virus was found to survive in large numbers on stainless steel.

Oligodynamic Effect (Silver)

The metabolism of bacteria is adversely affected by silver ions at concentrations of 0.01–0.1 mg/L. Therefore, even less soluble silver compounds, such as silver chloride, also act as bactericides or germicides, but not the much less soluble silver sulphide. In the presence of atmospheric oxygen, metallic silver also has a bactericidal effect due to the formation of silver oxide, which is soluble enough to cause it. Bactericidal concentrations are reduced rapidly by adding colloidal silver, which has a high surface area. Even objects with a solid silver surface (e.g., table silver, silver coins, or silver foil) have a bactericidal effect.

Silver drinking vessels were carried by military commanders on expeditions for protection against disease. It was once common to place silver foil or even silver coins on wounds for the same reason. Silver sulfadiazine is used as an antiseptic ointment for extensive burns. An equilibrium dispersion of colloidal silver with dissolved silver ions can be used to purify drinking water at sea. Silver is incorporated into medical implants and devices such as catheters.

Surfacine (silver iodide) is a relatively new antimicrobial for application to surfaces. Silver-impregnated wound dressings have proven especially useful against antibiotic-resistant bacteria. Silver nitrate is used as a haemostatic, antiseptic and astringent. At one time, many states required that the eyes of newborns be treated with a few drops of silver nitrate to guard against an infection of the eyes called gonorrhoeal neonatal ophthalmia, which the infants might have contracted as they passed through the birth canal.

Silver ions are increasingly incorporated into many hard surfaces, such as plastics and steel, as a way to control microbial growth on items such as toilet seats, stethoscopes, and even refrigerator doors. Among the newer products being sold are plastic food containers infused with silver nanoparticles, which are intended to keep food fresher, and silver-infused athletic shirts and socks, which claim to minimize odours.

Purification By Effect

This section groups purification methods with the same effect together so you can quickly find which one you need to achieve the desired results such as needing to remove the salt from water or only the viruses from water. Some purification methods are mentioned more than once which fit into multiple categories such as distillation in Kills/Filters Contaminants and desalination.

Filters Particulate Only

These are types of water purification methods which removes the particulate only while leaving the viruses and bacteria.

DIY Water Filter	● Cloth ● Rocks ● Coarse Sand ● Fine Sand ● Charcoal ● Moss ● Sphagnum ● Cheesecloth ● Fine Cloth
Water Filter	All manufactured water filters almost entirely eliminate particulate in water.
Carbon Filtering	Heat dense wood/cloth in a pot without access to oxygen until black and crumbly. Charcoal removes contaminants and impurities using chemical adsorption. Removes chlorine, sediment, volatile organic compounds, taste and odour from water. Not effective at removing minerals, salts, and dissolved inorganic compounds.
Activated Charcoal	Powder charcoal, 25% (weight) solution of Calcium Chloride to water, add charcoal to make paste, spread paste, bake at 107°C (224.6°F) for 30m. 454g of activated charcoal contains a surface area of approximately 404k m2.
Hand Filtering	Pour water into an alternative container through a piece of fine fabric folded over about 8 times to catch particles.
Rapid Sand Filter (RSF)	Filters particulate from water.
Sedimentation	Leave water for 2 hours until particles drop to the bottom of the container. Over 1-2 days of settling will remove larger microbes such as some parasites, and some microbes. Viruses and bacteria will not be removed as they are too small.
Coagulation	Clumps sediment together which then drop out of suspension. Add coagulants to the water to quicken the sedimentation process. Coagulants: Aluminium sulphate, polyaluminium chloride (liquid alum) and ferric sulphate. Natural Coagulants: Prickly Pear Cactus, Moringa seeds, broad beans, fava beans.

Kills/Filters Contaminants

These are types of water purification which kills the viruses and bacteria only while leaving particulate such as dirt in the water.

Boiling	Altitudes under 2km - 1 Minute Rolling Boil. Altitudes over 2km - boil for 3 minutes. Prevent recontamination by ensuring flames engulf the whole bottle and threads before pouring it out.
Distillation	Boil water in a pot with a cold convex lid to collect the moisture into a container below. Has a ratio of 200:1 - 450:1 to create one litre.
Solar Pasteurisation	Heating water to 65°C (149°F) for 6 minutes, or to a higher temperature for a shorter time, will kill all germs, viruses, and parasites. Above 50°C (122°F), time decreases at roughly a factor of 10 for every 10°C (50°F) increase in pasteurisation temperature. Viruses appear the hardest to kill and essentially set the boundary for acceptable time-temperature processes.

Chlorination	Chlorine kills viruses and bacteria in water. 30m for most bacteria, 4 hours for Cryptosporidium. Types: ● Chlorine ● Iodine ● Chlorine Dioxide ● Calcium Hypochlorite (70%) ● Bleach (6%) Some chlorine formulations can be used for cleaning wounds.
UV Light	Ensure water isn't too turbid and use the UV light for 1 minute every litre for 0 NTU. If water is turbid stir the light around.
SODIS	<50% cloud - 6 hours. >50% cloud - 2 days. Temp >50°C (122°F) - 60 min. Temp >60°C (140°F) - 1 min. Use bottles less then 5cm wide. Use reflective surface to maximise light. Requires less then 30 NTU water. Shake a 3/4 bottle to oxygenate it prior to placing then fill the rest and do not touch it again.
Copper / Silver Ionization / Electrolysis	Colloidal Silver and Copper act as antimicrobials and slowly ionize the water and purify it. They destroy biofilms slowly.
Electrolytic Water Purifier	Creates chlorine (Sodium Hypochlorite) from a brine solution. (Salty water) Mix the solution into the water to be purified. Potable Aqua - Pure Use any semi pure non-salty water. Generates from 1-20L. 1L - 20s, 10L - 3m. Reduces all bacteria and viruses by 99.99%. Lasts 60k Litres. 150L per charge. 1h Solar Charge = 2L. 30m mixture time for bacteria and viruses, 4h for crypto. 37g salt storage. 2.22kg's for 60k L. Can use any type of sodium chloride, food grade recommended.

Filters Particulate & Kills/Filters Contaminants

These purification techniques remove both the particulate and the bacteria and viruses from water, leaving potable water.

Reverse Osmosis	Removes most contaminants by filtering through a semi permeable membrane. 0.0001 micron filter size, Does not filter chlorine, radon, pesticides, benzene, toluene and trihalomethanes. Filters out salt. Requires a lot of filter replacement and maintenance.
Water Purification: Adsorption over Metal-Organic Frameworks	Experimental Prototypes Only.
Slow Sand Filter (SSF)	Removes turbidity and pathogenic organisms. High reliability and low lifecycle costs. Biological process vs RSF. Removes sediment and biologically filters via the biofilm. Microbes are sourced from water source and establish within a few days (3 weeks for full community). The predatory bacteria feed on water-borne microbes passing through the filter. Requires Filter Chamber, Reservoir and pipes. Order: Water inlet flows to the top of the SSF leaving 1-1.5m water on top, Schmutzdecke / microbial community, Sand bed - 0.6-1.2m deep, 50cm gravel, drainage layer and pipes last. The total height of the filter is between 2.5-4m. Requires slow filter time at 0.1-0.3 m3/h per 1sq m. Water remains several hours prior to being filtered. Water requires pressure (or weight) to push it through the sand. No bacteria present at the outlet. Turbidity < 1 NTU = 90-99% bacteria and viruses. Highly effective for: Bacteria, Protozoa, Viruses, Turbidity, Heavy Metals (Zn, Cu, Cd, Pb), Somewhat effective for: Odour, Taste, Iron, Manganese, Organic Matter, Arsenic. Not effective for: Salt, Fluoride, Chemicals. Chlorination may be used as a final treatment step to kill remaining bacteria. Flow rate = 0.1-0.3 m/h for microorganism nutrients and oxygen. Organism build up may occur and clog filter - so scrape the top layer off.
Biosand Filter	0.9m tall cylinder and 61cm wide. Filled with: water (10%), washed sand (70%), gravel (20%). Water 5cm deep adjusted from outlet pipe coming from the bottom then U turns at the top allowing the biofilm layer. Diffusion layer avoids disruption of biofilm layer maturing in 20-30 days. Kills pathogens via: Mechanical Trapping (Sieve), Adsorption (Pathogens become attached to each other), Predation (Pathogens absorbed by microorganisms) and Natural Death (Not enough food or oxygen for the pathogens). Removes: Bacteria 87-98%, Viruses 70-90%, Protozoa > 99%, Turbidity 85%, Iron 90-95%.
Ozone Water Filter	Infuses incoming water with highly reactive ozone molecules. Starts with an ozone generator chamber where a high intensity UV light is used to break the bonds of oxygen molecules and create the unstable ozone molecule. The ozone air is forced into through the generator chamber into the recycling tank. Once the ozone enters the water it oxidizes biological components including almost all bacteria and viruses. It also bonds with many dissolved minerals, causing them to precipitate to the bottom of standing water. Ozone has been found to effectively remove 99% of all biological pathogens including Giardia and Cryptosporidium. It also is effective at removing iron and manganese as well as freeing up chlorine to kill even more microbes if used in a multiple step system. The ozone has a half-life of only a few minutes, so after it has purified the water any remaining molecules break down into standard oxygen. This creates an environment that highly oxygenates the water.

Desalination

These purification techniques remove salt in the water and can be used for purifying seawater.

Distillation	Distillation, the process involving the conversion of a liquid into vapor that is subsequently condensed back to liquid form.
Solar Desalination	Solar desalination is a technique that harnesses solar energy to convert saline water into fresh water, making it suitable for human consumption and irrigation.
Reverse Osmosis	Reverse Osmosis uses membranes to remove salt and impurities from seawater. RO is efficient, scalable, and can save energy with the right systems. Cleaning seawater before using RO improves filter performance, and energy-saving measures can reduce power usage by 30-40%, making RO a great choice for obtaining freshwater from the sea.
Electrodialysis Desalination	Electrodialysis is a versatile technology that employs membranes and electricity to remove salt from seawater, but its applications go beyond producing drinking water. It can also be utilized to extract salt, de-salt soy sauce, and recover valuable substances from salt-containing wastewater. In essence, it offers various practical uses beyond just purifying drinking water.
Ion Exchange Desalination	Ion exchange is a water treatment method where one or more undesirable ionic contaminants are removed from water by exchange with another non-objectionable, or less objectionable ionic substance.
Geothermal Desalination	Geothermal desalination refers to the process of using geothermal energy to power the process of converting salt water to fresh water.
Freezing Desalination	Freezing desalination is a water treatment process that uses controlled freezing to remove dissolved salts and impurities from saline water like seawater or brackish groundwater. It works by cooling the feedwater below its freezing point, causing pure water molecules to crystallize into ice crystals while expelling contaminants. These ice crystals then separate from the resulting concentrated brine solution and get washed and melted to produce fresh water.

Removes Bad Taste/Odour

These filtration materials remove bad taste and odours from water.

WATER | Water Purification | Purification Methods | Purification

Charcoal/Carbon	Tap water can contain artificial, organic pollutants such as pharmaceuticals, herbicides, pesticides, lead, uranium, or mercury that can affect your health even in low amounts. Placing a charcoal stick in your water removes these toxins because charcoal filters have large porous surfaces that attract, and hold contaminates to the inside. Carbon filters contain an alkaline effect that helps soften and give your water a pleasant taste.
Activated Charcoal	Activated charcoal is a black powder that's odorless. Chlorinated tap water can taste bitter and unpleasant but activated charcoal works to bond with sodium hypochlorite (a chlorine compound) within its structure, thus improving the quality and taste of water. Activated charcoal is different to regular charcoal by how much material it 'absorbs' due to having more pores to trap materials.

Filtering Info

Bacteria / Virus Sizes Giardia: 8-12 microns Cryptospor: 4-6 microns Bacteria: 0.2-4 microns Viruses: 0.004-0.1 microns	**Filter Sizes** Guardian: 0.02 Microns Sawyer: 0.1 Microns Miniwell: 0.1 Microns RO: 0.0001 Microns	**Water Pollutants** **(Micron Size which stops the Particles)** **10 Micron** - Rust, Pollen, Fine Sand, Plant Spores **1 Micron** - Protozoan Cysts **0.1 Micron** - Bacteria **0.01 Micron** - Asbestos, Colloidal Silica **0.001 Micron** - Viruses, Synthetic Dyes **0.0001 Micron** - Dissolved Solids, Radioactive Substances, Heavy Metals, Pharmaceutical Drugs	**Cloth Filter** Using clothing or a cloth can remove fine particulate from water sources but leaves the smaller bacteria and viruses intact.

Water Additives

These are compounds that can be added to water to help clean, purify or kill pathogens present.

Potassium Permanganate (KMnO4)
Expiry: Never
Mix 3-4 crystals per Litre of water until light pink (background colour) and wait 2 hours before drinking. Store solution and crystals out of sunlight and in a cool place.

AKA: Condy's Crystals

Calcium Hypochlorite
Expiry: 10 Years
Mix 1g (70%+) into a 1L solution with water, then use to treat 100L as a 1:100 ratio, filtering the sediment out. Wait 1 hour before drinking or 2h if below 15°C (59°F) or water is cloudy. A faint chlorine odour should be present. Store chlorine solution in a sealed container out of direct sunlight and discard after 2 weeks. Corrosive at pH (14-16) - Therefore can't be used on wounds. May require sodium bicarbonate to decrease alkalinity.

Water/Wound Disinfection: 1g/L (1000ppm or 0.1%)
General Disinfection:
- Clean - 1g/L - 0.1%
- Med. Clean - 2g/L - 0.2%
- Dirty - 5g/L - 0.5%
- Blood - 10g/L - 1%

Bleach
Expiry: 1.5 Years
Use two drops per litre, only unscented bleach.

Chlorine
Expiry: 5y.
Each 1.67g tablet of NaCC releases 1g chlorine - in 1L (0.1% solution or 1000ppm) pH of 6-7 and therefore can be used for cleaning wounds.

Tablet Formulations
Sodium Dichloroisocyanurate (NaDCC, sodium troclosene)

Water Treatment
1g/200L (Unless pre-packaged)

Troclosene Sodium (Chlorine) Expiry: 2 Years One tablet/L if clear, wait 30m before drinking or 4h for cryptosporidium. Two tablets if high turbidity. AKA: Sodium Dichloroisocyanurate	**Chlorine Disinfection** **Water/Wound Disinfection** 1g/L (1000ppm or 0.1%) **General Disinfection** ● Clean - 1g/L - 0.1% ● Med. Clean - 2g/L - 0.2% ● Dirty - 5g/L - 0.5% ● Blood - 10g/L - 1%	**Sodium Dichloroisocyanurate** **(Troclosene Sodium)** Used in most of the water purification tablets manufactured today. Some may contain silver. **Use:** 1 Tablet in 1L **Expiry:** 10 Years **Storage:** Cool, dark, dry area **Brands:** Aquatabs.
Chlorine Dioxide Expiry: Forever < 24°C (75.2°F) Most effective treatment. One tablet per litre, wait 30m before drinking or 4h for cryptosporidium.	**Chlorine Dioxide** Used in a few brands of water purification tablets. **Use:** 1 Tablet in 1L **Expiry:** Infinite if kept cool **Storage:** Cool, dark, dry area **Brands:** Katadyn Micropur MP1, Lifesystems, Potable Aqua. Created by mixing 28% sodium chlorite solution with an acid such as citrus juice. AKA: MMS	

Iodine
Expiry: 7 Years
Treat water with two drops per litre. Avoid using for extended periods.
AKA: Tetraglycine Hydroperiodide

Iodine can come in liquid, powder or granular forms. Not to be confused with iodide which is used to saturate the thyroid gland during radiation.

Colloidal Silver
Expiry: 10 Years ~ 20-29°C (68°F-84.2°F) in a dark glass jar.
Colloidal Silver is simply silver ions and microscopic silver particles produced by electrolysis and suspended in distilled water. It is a mineral supplement that may provide support for your body's natural immune system. It should not be confused with old style silver medicines that contained chemically or mechanically powdered silver. This modern form of Colloidal silver can be made at home using distilled water that costs just a few dollars for 4 litres.

Using Colloidal Silver
.05 microns to .0008. 1ppm = 1mg Silver.
Combine with Hydrogen Peroxide for more effectiveness. 100 drops a day of 15 ppm CS is safe.
Use 50ml/L to treat water. CS can be used in place of chlorine when storing water to keep it biologically safe.
Treats Irrible Bowel Syndrome (IBS). Colloidal Silver is an Antibacterial, Antifungal and Antiviral.

Hydrogen Peroxide (H_2O_2)
Expiry: 1y Unopened, 1m opened.
1-2ppm (1-2mg/L - 11drops/L) stir and leave for 10m. When injected into water, hydrogen peroxide releases a large amount of dissolved oxygen which has a strong oxidizing effect, destroying odors and oxidizing iron and other contaminants. Hydrogen peroxide does not add chemical by-products into the water, only oxygen and water.

Calcium Hydroxide (Slaked Lime)
Expiry: 10+ Years if stored correctly away from carbon dioxide and moisture.
One significant application of calcium hydroxide is as a flocculant, in water and sewage treatment. It forms a fluffy charged solid that aids in the removal of smaller particles from water, resulting in a clearer product. This application is enabled by the low cost and low toxicity of calcium hydroxide. It is also used in fresh-water treatment for raising the pH of the water so that pipes will not corrode where the base water is acidic, because it is self-regulating and does not raise the pH too much. It's an odorless white powder.

Aluminium Sulphate
Expiry: Legal shelf life is 5 years.
Sedimentation agent for turbid water. Flocculation creates flocs of a higher density by agglomerating fine particles in suspension in the water.

Treatment Plant Set-up

Centralised drinking water treatment plants treat large amounts of water from many households in one single spot and consequently most often require more operation and maintenance and the construction of a water distribution system. Semi-centralised drinking water treatment plants are middle-scaled units e.g. on community level. These systems are most often designed to remove several types of contaminants from anthropogenic or natural origin: suspended and dissolved solids, ions (metals, fluorine, phosphates, nitrates), organic compounds (organic micropollutants, natural organic matter), and microorganisms (bacteria, viruses).

As there is no water treatment method able to remove all these contaminants in one step semi-centralised and centralised treatment often needs multistep plants, which combine several techniques to purify water. Here a general overview of plant set-up for drinking water production is given.

Summary	**Working Principle** Combines several processes (e.g. aeration, coagulation-flocculation, filtration, disinfection) to remove a wide variety of contaminants present in water.	**Capacity/Adequacy** Sophisticated combination of water treatment processes. Skilled labour required to guarantee the performance of each process.	**Performance** Efficient for all kinds of water when treatment plants are adequately designed and set up.	**Costs** Relatively high implementation and operation costs because of high inputs of labour, chemicals and electricity.	**Self-Help Compatibility** The incoming water and treated water quality has to be monitored to optimise each step of the plant.
	O&M Continuous operation and maintenance staff is required.	**Reliability** Highly reliable if the treatment plant is well maintained.	**Main Strength** Very efficient for any kind of water.	**Main Weakness** The whole system has to be controlled on a regular basis to be efficient, hence the system is sophisticated and requires skilled labour, energy, technical equipment and chemicals.	

Advantages	• Very efficient and reliable for purifying water	• Can be adapted to any kind of water	• Relatively low cost for drinking water production	
Disadvantages	• Skilled labour, technical equipment, electricity and chemicals required to design and operate the plant	• Plant has to be continuously controlled and maintained	• High initial investment costs to build infrastructure	

Introduction
Drinking water treatment plants involve several consecutive processes, which remove solids, organic and inorganic pollutants, some metals and pathogenic microorganisms. The treatment plant set-up should be designed to take into account the quality of water being treated. In general, water treatment can be divided into: primary treatment to remove solids; secondary treatment to remove organic compounds as well as nitrogen and phosphorous; and tertiary treatment for disinfection. Different sizes of treatment plants exist like centralised plants for big cities requiring a developed distribution system and semi-centralised plants adapted to provide drinking water to smaller communities at the point of use (POU).

Treatment Plants
There is no precise method for treating surface water because of the various qualities of water that exists. Groundwater typically requires less treatment than water from lakes, rivers and the sea. Nevertheless, a series of conventional processes can be identified; they are presented in the figures below. In general the treatment of fresh water involves the following key steps:

Step 1	**Primary Steps** Aeration: The water is mixed to liberate dissolved gases and to suspend particles in the water column. Sometimes a pre-oxidation step is also performed at this stage. Coagulation-Flocculation: In this step coagulants are added to remove the suspended particles (clay, organic material, metals, microorganisms), which stick to the coagulants forming heavy particles. Sedimentation: The heavy particles (flocs) settle to the bottom leading to clear water.

Step 2	**Secondary Step** Filtration: The water is run through a series of filters, which trap and remove particles still remaining in the water column. Typically, slow or rapid sand filtration and more recently membranes or reverse osmosis are used to accomplish this task. Due to growing concerns regarding micro-pollutants, additional treatments such as advanced oxidation processes, activated carbon adsorption alone or combined with ozonation or H2O2 are sometimes used to remove these trace organic compounds.
Step 3	**Tertiary Step** Disinfection: The water is now largely free of particles, organics and microorganism and is now treated to destroy any remaining disease-causing pathogens. This is commonly done with chlorination, ozonation, hydrogen peroxide, or UV radiation (similar to the point of use UV tubes). The water is then sent to the pumping station for distribution to homes and businesses. Chlorination is the most widely used disinfection method because it permits maintaining residual chlorine at a level efficient enough to guarantee the absence of microorganism until the water has reached its point of use. When drinking water is produced from the sea, the water is desalinated by electrolysis or membranes such as reverse osmosis or by a solar process desalination.

Operation and Maintenance
Drinking water treatment plant operation and maintenance includes the following tasks:

- Operate and adjust equipment controls to purify and clarify water.
- Inspect equipment and monitor operating conditions, meters, and gauges to determine load requirements and detect malfunctions.
- Add chemicals, such as ammonia, chlorine, and lime, to purify and disinfect water and other chemicals, such as ferric chloride, peroxide, and polymers, to enhance water treatment.
- Collect and test water samples, using test equipment.
- Record operational and laboratory data, observations of processes, and meter and gauge readings on specified forms.
- Clean and maintain tanks, basins and filter beds, using hand tools and power tools.
- Maintain, repair, and lubricate equipment, using hand tools and power tools.

Many of these tasks can be automated in modern treatment plants but trained operators and engineers are still required to control and maintain the system. Moreover, operation of the treatments also requires a significant amount of chemicals, which might not be available in little industrialised or remote areas. Required energy input is significant. In Switzerland, required energy input for treatment and distribution of drinking water, including abstraction, is relatively low (around 0.4kWh/m3) due to the excellent quality of groundwater. In case of polluted or seawater treatment in semi-centralised plants, the required input is higher (around 1-2 kWh/m3). Smaller drinking water treatment plants may be installed at semi-centralised level or point of use in order to minimise energy requirements for distribution.

Average Costs
The cost of high quality municipal drinking water including transport is between less than 1 $/m3 in the US and more than 2 $/m3 in Denmark and Germany. The cost of drinking water from semi-centralised treatment plants operating in developing countries depends on water source quality and capacity. In the case of seawater and polluted sources it is typically around 1-2 $/m3. An important initial investment is required to build the treatment plant, which should be designed properly taking into account water composition to minimise the costs.

Applicability
Centralised drinking water treatment plants are useful when water is supplied from a source containing natural or anthropogenic contaminants such as lakes, rivers, seas or groundwater. Many different types of raw water can be purified in treatment plants as processes are designed for each case considering water quality and desired capacity. The treatment plants need to be maintained by skilled labour to regularly control water quality and optimise processes. Smaller drinking water treatment plants may be installed at semi-centralised level or point of use in order to minimise energy requirements for distribution.

5 Purification Methods

This is a more detailed explanation of the purification methods in the section above. Keep in mind that you may have to combine two methods to make water drinkable as some only do half the job.

Subheadings

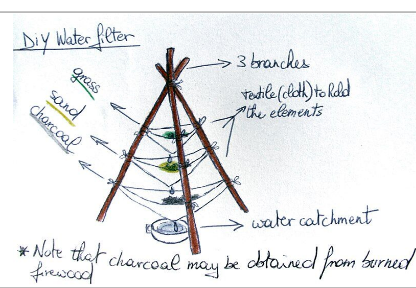
1 Makeshift Filter

A crude water filter made from easily obtainable materials such as rocks, sand and cloth. These are your best bet when there is no other way to purify water or you're in a survival situation.

Materials Needed
- Plastic Bottle
- Knife/Scissors
- Tiny Rocks/Gravel
- Coarse Sand
- Fine Sand
- Charcoal Dust
- Fine Cloth/Coffee Filter

Assembly
1. Cut the base off of the container
2. Wrap and tie the fine cloth over the nozzle of the bottle.
3. Fill the bottle in layers of materials, starting with the charcoal, fine sand, then coarse sand and finally the rocks.
4. The bottle should be basically full and split evenly into the different fillings.
5. Add another piece of cloth over the top of the bottle so it's capped at both ends.
6. Filter a few litres through the filter to flush anything remaining out.
7. The filter is ready and should remove most particulate.



The filtered water will still need to be sterilized to kill pathogens. The picture is an example of a similar method of filtration using sticks and cloth.

2 Manufactured Filters

Portable water purification devices are self-contained, easily transported units used to purify water from untreated sources (such as rivers, lakes, and wells) for drinking purposes. Their main function is to eliminate pathogens, and often also of suspended solids and some unpalatable or toxic compounds. These units provide an autonomous supply of drinking water to people without access to clean water supply services, including inhabitants of developing countries and disaster areas, military personnel, campers, hikers, and workers in wilderness, and survivalists. See Filter Membrane Size for more information on filters.

Household Purifiers

These are some common household purification systems.

Big Berkey Water Filter	Filters water through a charcoal medium and drips into the chambers below to generate safe drinking water. Sizes range from 1.5Gal (5.6L) to 6Gal (22.7L) with varying flow rates from 2.75G/h (10L) to 26G/h (98L). Some filters have 1 charcoal filter with up to 8 for the largest. For more information on these types of filters, have a look at #22 below titles "Ceramic Candle Filter".
Non-Electric Distiller	Excellent water purifier that works over a gas stove, campfire or electric hotplate. Produces about 3.2 quarts (3L) of 100% steam distilled water in 1.2 hours using 8900 Btu/hr gas burner or 2600 watt electric burner. Waterwise 1600 distiller model.
Berkefeld Water Filter	Similar to the Big Berkey but uses ceramic filters.
LMS Water Purification	A commercial and large water filter used by governments and emergency agencies during disasters which are usually mounted on the back of a ute or a skid for easy trailer transport. It generates about 4,000L of drinking water per hour.

3 Boiling

Boiling is the rapid vaporization of a liquid, which occurs when a liquid is heated to its boiling point, the temperature at which the vapour pressure of the liquid is equal to the pressure exerted on the liquid by the surrounding atmosphere. There are two main types of boiling: nucleate boiling where small bubbles of vapour form at discrete points, and critical heat flux boiling where the boiling surface is heated above a certain critical temperature and a film of vapour forms on the surface. Transition boiling is an intermediate, unstable form of boiling with elements of both types. The boiling point of water is 100°C (212°F) but is lower with the decreased atmospheric pressure found at higher altitudes. Boiling water is used as a method of making it potable by killing microbes that may be present. The sensitivity of different micro-organisms to heat varies, but if water is held at 70°C (158°F) for ten minutes, many organisms are killed, but some are more resistant to heat and require one minute at the boiling point of water.

Boiling Water

As a method of disinfecting water, bringing it to its boiling point at 100 °C (212 °F), is the oldest and most effective way since it does not affect the taste, it is effective despite contaminants or particles present in it, and is a single step process which eliminates most microbes responsible for causing intestine related diseases. Water's boiling point rests at around 100 °C (212 °F), when at an elevation of 0. In places having a proper water purification system, it is recommended only as an emergency treatment method or for obtaining potable water in the wilderness or in rural areas, as it cannot remove chemical toxins or impurities.

The elimination of micro-organisms by boiling follows first-order kinetics—at high temperatures, it is achieved in less time and at lower temperatures, in more time. The heat sensitivity of micro-organisms varies, at 70 °C (158 °F), Giardia species (causes Giardiasis) can take ten minutes for complete inactivation, most intestine affecting microbes and E. coli (gastroenteritis) take less than a minute; at boiling point, Vibrio cholerae (cholera) takes ten seconds and hepatitis A virus (causes the symptom of jaundice), one minute.

Boiling does not ensure the elimination of all micro-organisms; the bacterial spores Clostridium can survive at 100 °C (212 °F) but are not water-borne or intestine affecting. Thus for human health, complete sterilization of water is not required. The traditional advice of boiling water for ten minutes is mainly for additional safety, since microbes start getting eliminated at temperatures greater than 60 °C (140 °F) and bringing it to its boiling point is also a useful indication that can be seen without the help of a thermometer, and by this time, the water is disinfected. Though the boiling point decreases with increasing altitude, it is not enough to affect the disinfecting process.

Summary

Boiling drinking water with fuel is the oldest and most commonly practiced household water treatment method. The water needs to be heated until the appearance of the first big bubbles to ensure that it is pathogen free. Many organizations recommend boiling both for water treatment in developing countries and to provide safe drinking water in emergency situations throughout the world - though it is quite laborious and uses a lot of energy. Boiling only kills pathogens and does not remove turbidity or chemical pollution (e.g. arsenic) from drinking water. So prior to boiling, water can be purified by settling or filtration method.

Advantages	• Effectively kills most pathogens.	• Easy, simple and widely accepted method of disinfection (particularly in tea-consuming cultures)	• Biogas cooking stoves can be used for the cooking stove (e.g. biogas linked toilet)		
Disadvantages	• Can be costly due to fuel consumptions	• Use of traditional fuel (firewood, kerosene/gas) contributes to deforestation and indoor air pollution	• Potential user taste objections • Time consuming	• Does not remove turbidity, chemicals, taste, smell, colour	• Water needs to cool down before use unless it's used for hot drinks
	• Risk of injuries (especially when children are around)				

Boiling

Boiling is oldest and most effective household drinking water treatment. It is promoted in both developing countries where water is routinely of uncertain microbial quality and in developed countries when conventional water treatment fails or water supplies are interrupted as a result of disasters or other emergencies. 21.2% of the population in South-east Asia report boiling their water before drinking it. The WHO recommends bringing water to a rolling boil as an indication that a disinfection temperature has been achieved. If practised correctly, boiling is one of the most effective water treatment methods to kill or deactivate all classes of waterborne pathogens, including bacterial spores and protozoan cysts that have shown resistance to chemical disinfection and viruses that are too small to be mechanically removed by microfiltration. Heating water to even 55°C (131°F) has been shown to kill or inactivate most pathogenic bacteria, viruses, helminths and protozoa that are commonly water borne. A clean container should be used for the boiling and after boiling, water should be stored in a clean and covered container, and handled carefully (no utensils should be brought in contact with the water, thus water needs to be poured in another clean recipient for consumption) to minimise the recontamination. Despite its effectiveness and simplicity, boiling has the disadvantage to require affordable and sufficient fuel to have properly boiled water for a regular drinking purpose, and is quite labour intensive.

Effectiveness		
If the boiling point is reached, boiling is effective in killing bacteria, viruses, protozoa, helminths and most pathogens from drinking water. Incomplete inactivation of pathogens in boiled water is attributed to users not heating the water to the boiling point and/or recontamination of boiled water in storage. Boiling does not remove turbidity, chemicals (e.g. arsenic), taste, smell or colour from water. Therefore, settling or even filtration (by cloth or slow sand or biosand filter) is often needed prior to boiling.	**Bacteria** Lab: 100% **Viruses** Lab: 100%	**Protozoa** Lab: 100% **Helminths** Lab: 100%

Applicability
Chemical pollution such as arsenic is not removed by boiling. Also water with high amounts iron (with reddish colour), calcium or chlorine is not suitable for boiling. White scales may deposit in container bottom after boiling if calcium is high in waters. In such case, the container should be washed properly after every use. Boiled water tastes flat and people may not like that. Thus, boiled water can be chilled in freezer or cooled down to room temperature to have good taste. Boiling is suitable where enough fuel sources (e.g. wood, kerosene, electricity, gas, charcoal etc.) are locally available all the time in affordable cost. Especially in densely populated areas, boiling with fuel wood is not appropriate to the overexploitation of the wood resources and the subsequent environmental damage such as desertification and soil erosion. Boiled water may cause burn injuries if not handled properly. Long term exposure in fire or stove smoke of the person boiling the water may cause associated respiratory diseases. For this indoor cooking space should be made well ventilated.

4 Tap Filters

Tap filters are filters that can be fitted directly onto a faucet. They are easy to handle and quite effective since they remove pathogens (e.g. Cryptosporidium and Giardia), contaminants (e.g. chlorine, lead, asbestos), sediments and bad odours. The user can turn the filter on and off by switching a small handle. Most often, these filters are based on activated carbon (see also adsorption). The filter medium should be changed frequently (following providers' requirements) to ensure its effectiveness. Costs vary between $20 and $40 USD (depending on country and provider). The filters should not be used without assessing their performance and the water quality to treat.

5 Carbon Filtering

Carbon filtering is a method of filtering that uses a bed of activated carbon to remove contaminants and impurities, using chemical adsorption. Each particle, or granule, of carbon provides a large surface area, or pore structure, allowing contaminants the maximum possible exposure to the active sites within the filter media. One gram of activated carbon has a surface area in excess of 3,000 m2 (32,000 sq ft). Activated carbon works via a process called adsorption, whereby pollutant molecules in the fluid to be treated are trapped inside the pore structure of the carbon substrate. Carbon filtering is commonly used for water purification, air filtering and industrial gas processing, for example the removal of siloxanes and hydrogen sulphide from biogas. Active charcoal carbon filters are most effective at removing chlorine, particles such as sediment, volatile organic compounds (VOCs), taste and odour from water. They are not effective at removing minerals, salts, and dissolved inorganic substances. Typical particle sizes that can be removed by carbon filters range from 0.5 to 50 micrometres. The particle size will be used as part of the filter description. The efficacy of a carbon filter is also based upon the flow rate regulation. When the water is allowed to flow through the filter at a slower rate, the contaminants are exposed to the filter media for a longer amount of time.

Activated Carbon Filtering
Activated carbon filters normally have a pre-filter to remove sediments and avoid damage of the carbon unit. They are well suited to sediment and particulate removal as well as the reduction of chlorine, chlorine disinfection bi-products, a wide range of volatile organic compounds, and other contaminants responsible for bad tastes and odours. The filter system WH3, for example, is a good choice for well water, lake water, stream water, and municipal (city) water treatment applications. These filter systems are expensive (up to 200 US$ and more) and require periodic maintenance (change of filter components).

6 Activated Charcoal / Carbon

Activated carbon filtration is a commonly used technology based on the adsorption of contaminants onto the surface of a filter. This method is effective in removing certain organics (such as unwanted taste and odours, micropollutants), chlorine, fluorine or radon from drinking water or wastewater. However, it is not effective for microbial contaminants, metals, nitrates and other inorganic contaminants. The adsorption efficiency depends on the nature of activated carbon used, the water composition, and operating parameters. There are many types of activated carbon filters that can be designed for household, community and industry requirements. Activated carbon filters are relatively easy to install but require energy and skilled labour and can have high costs due to regular replacement of the filter material.

Overview	**Working Principle** The pollutants are removed from water through adsorption on the surface of the activated carbon. Use at the POE or POU (e.g. advanced filters).	**Capacity/Adequacy** Simple technique using abundant raw material (e.g. petroleum coke, bituminous coal, lignite, wood products, coconut shell or peanut shell). Skilled labour required at least occasionally.	**Performance** Efficient for pollutant having high affinity with activated carbon surface (non-polar compounds).	**Costs** Relatively low operation costs.	**Self-Help Compatibility** Initial analysis of water is required to choose proper adsorbent (type of activated carbon).
	O&M Regular replacement or regeneration of carbon cartridge.	**Reliability** Reliable if the water composition is taken into account when choosing the type of activated carbon used as filter material.	**Main Strength** Activated carbon can be produced relatively easily everywhere in the world.	**Main Weakness** Filter has to be replaced on a regular basis.	

Advantages	• Easy to install and maintain	• Can be used at the point-of-entry (semi-centralised drinking water treatment plants, wastewater treatment plants) or at the point-of-use (household / community filters)	• Efficient to remove certain organics, chlorine, radon	• Based on materials available everywhere	
Disadvantages	• Filter has to be replaced regularly	• Skilled labour required, at least occasionally	• Water analysis is required to choose the most adapted type of activated carbon	• Contaminants are separated from water but not destroyed	

Introduction
The use of carbon in the form of charcoal has been used since antiquity for many applications. In Hindu documents dating from 450 BC charcoal filters are mentioned for the treatment of water. Charred wood, bones and coconut charcoals were used during the 18th and 19th century by the sugar industry for decolourising solutions. Activated carbon is a material prepared in such a way that it exhibits a high degree of porosity and an extended surface area. During water filtration through activated carbon, contaminants adhere to the surface of these carbon granules or become trapped in the small pores of the activated carbon. This process is called adsorption. Activated carbon filters are efficient to remove certain organics (such as unwanted taste and odours, micropollutants), chlorine, fluorine or radon, from drinking water or wastewater. However, it is not effective for microbial contaminants, metals, nitrates and other inorganic contaminants. Activated carbon filtration is commonly used in centralised treatment plants and at household level, to produce drinking water and in industries to treat effluents. It is also an upcoming treatment applied for the removal of micropollutants both in drinking water production and for the purification of treated wastewater before disposal.

Treatment Principles
There are two basic types of water filters: particulate filters and adsorptive/reactive filters. Particulate filters exclude particles by size, and adsorptive/reactive filters contain a material (medium) that either adsorbs or reacts with a contaminant in water. The principles of adsorptive activated carbon filtration are the same as those of any other adsorption material. The contaminant is attracted to and held (adsorbed) on the surface of the carbon particles. The characteristics of the carbon material (particle and pore size, surface area, surface chemistry, etc.) influence the efficiency of adsorption. The characteristics of the chemical contaminant are also important. Compounds that are less water-soluble are more likely to be adsorbed to a solid. A second characteristic is the affinity that a given contaminant has with the carbon surface. This affinity depends on the charge and is higher for molecules possessing less charge. If several compounds are present in the water, strong absorbers will attach to the carbon in greater quantity than those with weak adsorbing ability.

Preparation
The medium for an activated carbon filter is typically petroleum coke, bituminous coal, lignite, wood products, coconut shell or peanut shell. The carbon medium is “activated” by subjecting it to stream (a gas like water, argon or nitrogen) and high temperature (800-1000°C) usually without oxygen. In some cases, the carbon may also undergo an acidic wash or be coated with a compound to enhance the removal of specific contaminants. The activation produces carbon with many pores and a high specific surface area. It is then crushed to produce a granular or pulverised carbon product.

Use
Activated carbon units are commonly used to remove organics (odours, micropollutants) from drinking water at centralised and decentralised level. At centralised level, they are generally part of one of the last steps, before the water is fed into the water distribution network. At decentralised level, activated carbon filtration units can either be point-of-use (POU) or point-of-entry (POE) treatment. A POE device is recommended for the treatment of radon and volatile organic compounds because these contaminants can easily vaporise from water in showers or washing machines and expose users to health hazards. POU devices are useful for the removal of lead and chlorine. The structure of POU devices can either be in-line, line-bypass faucet mounted (see also advanced filters) or pour-through (similar to the design of ceramic candles, colloidal silver or biosand filters). Activated carbon filters can also be used as a tertiary treatment in wastewater treatment plants to remove micropollutants from municipal effluents or recalcitrant contaminants from industrial effluents.

Combination
Activated carbon is often used as pre-treatment to protect other water treatment units such as reverse osmosis membranes and ion exchange resins from possible damage due to oxidation or organic fouling. The combination of ozonation with activated carbon is a very efficient technique for eliminating organic matter including micropollutants. Besides, the lifetime of activated carbon filters is extended drastically when used in combination with ozone, deceasing operation costs substantially.

Cost
Installation costs are moderate but additional technical equipment is required. Operating costs are usually limited to filter replacement. Depending on the type and concentration of the contaminant being removed, some carbon filters may require special hazardous waste handling and disposal, which can be costly.

Operation
Carbon filters are relatively easy to install and maintain but skilled labour is required at least occasionally for monitoring the removal performance over time of both POU and POE equipment. Activated carbon filters have a limited lifetime. After long-term use, their surfaces are saturated with adsorbed pollutants and no further purification occurs. The filter material therefore has to be replaced at regular intervals, according to manufacturer's instructions. Replacement intervals should be calculated based on the average daily water use through the filter and the amount of contaminant being removed. Cartridge disposal depends on usage. A carbon cartridge can be backwashed and then reused or discarded if non-toxics have been adsorbed.

Applicability
Activated carbon filters are widely used to produce drinking water at household and community level (to remove certain organics, chlorine or radon from drinking water) and to treat industrial or municipal wastewaters. It is not efficient for disinfection and nitrates removal. Adsorption on activated carbon is a simple technology based on materials such as fossil fuels (petroleum coke, lignite...) and even agricultural waste (e.g. coconut shell, wood, etc.). To choose the most applicable type of activated carbon for a given application it is important to analyse the composition of the influent water previously. The carbon filter has to be replaced or regenerated regularly to remain efficient. Activated carbon can also be used as a pre-treatment to protect other water treatment units.

7 Hand Filtering (Straining)

Straining is a very simple method of filtration. In this process, water is poured through a piece of cloth which has been folded a few times, which removes some of the suspended silt and solids and destroys some pathogens. After straining, water may not be perfectly safe for drinking but it can be a drinking water improvement step for people with no other treatment options. It is very important to use a clean cloth, as a dirty cloth may introduce additional pollutants into the water.

Advantages	• Simple, low cost and easy technique	• Consumes little time	• Reduces turbidity from drinking water	• Known to reduce the risk of cholera if used correctly	• No particular equipment needed
Disadvantages	• Requires extra washing of sari after use	• Not completely effective for removal of bacteria	• Not effective for removal of viruses and chemical		

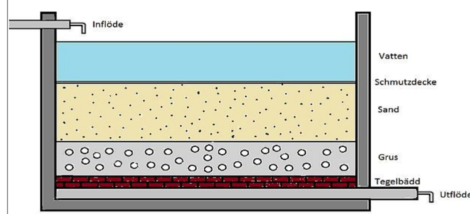
Effectiveness
Straining water through a piece of clean cloth is an extremely simple, low- resource method and widely used for household water treatment. Cloth filters have been used in many cultures for centuries. Typically in South Asia, a sari or saree (a strip of unstitched cloth ranging from four to nine meters in length that is draped over the body of women (it is also a traditional garment) is folded 7 to 8 times and used as a filter. In laboratory experiments using electron microscopy, it was found that an inexpensive sari cloth, folded four to eight times provides a filter of about 20 µm mesh size, was small enough to remove all zooplankton, most phytoplankton, all Vibrio Choleraeattached to the plankton and other particulates larger than 20 µm. The risk of cholera is therefore reduced of about 50%. Water is poured through the folded sari cloth and collected in a pot underneath. The efficiency of straining depends on the weave of the cloth and the number of times it has been folded. Specific monofilament filter cloths are very efficient where guinea worm disease is prevalent. Such cloths remove organisms known as copepods, which act as intermediate hosts for the guinea-worm larvae. Dracunculiasis, more commonly known as guinea worm disease, is caused by drinking water hosting a parasite called Dracunculus medinensis.

Very Effective ● Helminths ● Protozoa	**Fairly Effective** ● Turbidity ● Bacteria ● Taste ● Colour ● Smell	**Not Effective** ● Viruses ● Chemicals	In a laboratory experiments, it was found that an old sari cloth made up of cotton is most effective in removing V. Cholerae. After several launderings, threads of an old sari become soft and loose, reducing the pore size compared to a new sari cloth. Cloth filters do not remove chemical contaminants or dissolved compounds from water. After straining, additional treatment methods can further improve the safety of drinking water.

Applicability
Though the water collected from cloth filter is not perfectly safe, it is a drinking water improvement step for people with limited options. This procedure can be used as the first stage of treatment. Then water can be treated through available methods like sand filtering (see also biosand filter) or treated further with disinfection methods such as SODIS, boiling, chlorination and others. Both cotton and nylon cloths are suitable for filtration. It is very important to use clean and dry cloth, as a dirty cloth may introduce additional pollutants or pathogens into the water.

8 Slow Sand Filter

Slow sand filters are used in water purification for treating raw water to produce a potable product. They are typically 1 to 2 metres deep, can be rectangular or cylindrical in cross section and are used primarily to treat surface water. The length and breadth of the tanks are determined by the flow rate desired by the filters, which typically have a loading rate of 200 to 400 litres per hour per square metre (or 0.2 to 0.4 cubic metres per square metre per hour). Slow sand filters differ from all other filters used to treat drinking water in that they work by using a complex biological film that grows naturally on the surface of the sand. The sand itself does not perform any filtration function but simply acts as a substrate. Although they are often preferred technology in many developing countries because of their low energy requirements and robust performance, they are also used to treat water in some developed countries. Slow sand filters now are also being tested for pathogen control of nutrient solutions in hydroponic systems.



A Slow Sand Filter Example

Method of Operation
Slow sand filters work through the formation of a gelatinous layer (or biofilm) called the hypogeal layer or Schmutzdecke in the top few millimetres of the fine sand layer. The Schmutzdecke is formed in the first 10–20 days of operation and consists of bacteria, fungi, protozoa, rotifera and a range of aquatic insect larvae. As an epigeal biofilm ages, more algae tend to develop and larger aquatic organisms may be present including some bryozoa, snails and Annelid worms.

The surface biofilm is the layer that provides the effective purification in potable water treatment, the underlying sand providing the support medium for this biological treatment layer. As water passes through the hypogeal layer, particles of foreign matter are trapped in the mucilaginous matrix and soluble organic material is adsorbed. The contaminants are metabolised by the bacteria, fungi and protozoa. The water produced from an exemplary slow sand filter is of excellent quality with 90-99% bacterial cell count reduction.

Slow sand filters slowly lose their performance as the biofilm thickens and thereby reduces the rate of flow through the filter. Eventually, it is necessary to refurbish the filter. Two methods are commonly used to do this. In the first, the top few millimetres of fine sand is scraped off to expose a new layer of clean sand. Water is then decanted back into the filter and re-circulated for a few hours to allow a new biofilm to develop. The filter is then filled to full volume and brought back into service.

The second method, sometimes called wet harrowing, involves lowering the water level to just above the hypogeal layer, stirring the sand; thus precipitating any solids held in that layer and allowing the remaining water to wash through the sand. The filter column is then filled to full capacity and brought back into service. Wet harrowing can allow the filter to be brought back into service more quickly.

Features
● Unlike other filtration methods, slow sand filters use biological processes to clean the water, and are non-pressurized systems. Slow sand filters do not require chemicals or electricity to operate.
● Cleaning is traditionally done by use of a mechanical scraper, which is usually driven into the filter bed once the bed has been dried out. However, some slow sand filter operators use a method called "wet harrowing", where the sand is scraped while still under water, and the water used for cleaning is drained to waste.
● For municipal systems there usually is a certain degree of redundancy, since it is desirable for the maximum required throughput of water to be achievable with one or more beds out of service.
● Slow sand filters require relatively low turbidity levels to operate efficiently. In summer conditions with high microbial activity and in conditions when the raw water is turbid, blinding of the filters due to bioclogging occurs more quickly and pre-treatment is recommended.
● Unlike other water filtration technologies that produce water on demand, slow sand filters produce water at a slow, constant flow rate and are usually used in conjunction with a storage tank for peak usage. This slow rate is necessary for healthy development of the biological processes in the filter.

While many municipal water treatment works will have 12 or more beds in use at any one time, smaller communities or households may only have one or two filter beds. In the base of each bed is a series of herringbone drains that are covered with a layer of pebbles which in turn is covered with coarse gravel. Further layers of sand are placed on top followed by a thick layer of fine sand. The whole depth of filter material may be over 1 metre in depth, the majority of which will be fine sand material. On top of the sand bed sits a supernatant layer of unpurified water.

As they require little or no mechanical power, chemicals or replaceable parts, and they require minimal operator training and only periodic maintenance, they are often an appropriate technology for poor and isolated areas. Slow sand filters, due to their simple design, may be created DIY. DIY-slow sand filters have been used in Afghanistan and other countries to aid the poor. Slow sand filters are recognized by the World Health Organization, Oxfam, and the United States Environmental Protection Agency as being superior technology for the treatment of surface water sources.

According to the World Health Organization, "Under suitable circumstances, slow sand filtration may be not only the cheapest and simplest but also the most efficient method of water treatment." Due to the low filtration rate, slow sand filters require extensive land area for a large municipal system. Many municipal systems in the U.S. initially used slow sand filters, but as cities have grown they subsequently installed rapid sand filters, due to increased demand for drinking water.

Summary
Slow sand filtration is a type of centralised or semi-centralised water purification system. A well-designed and properly maintained slow sand filter (SSF) effectively removes turbidity and pathogenic organisms through various biological, physical and chemical processes in a single treatment step. Only under the prevalence of a significantly high degree of turbidity or algae-contamination, pre-treatment measures (e.g. sedimentation) become necessary. Slow sand filtration systems are characterised by a high reliability and rather low lifecycle costs.

Moreover, neither construction nor operation and maintenance require more than basic skills. Hence, slow sand filtration is a promising filtration method for small to medium-sized, rural communities with a fairly good quality of the initial surface water source. As stated by the WHO, slow sand filtration provides a simple but highly effective and considerably cheap tool that can contribute to a sustainable water management system.

Advantages	● Very effective removal of bacteria, viruses, protozoa, turbidity and heavy metals in contaminated fresh water	● Simplicity of design and high self-help compatibility: construction, operation and maintenance only require basic skills and knowledge and minimal effort	● If constructed with gravity flow only, no (electrical) pumps required	● High reliability and ability to withstand fluctuations in water quality	● Easy to install in rural, semi-urban and remote areas, Simplicity of design and operation
	● Local materials can be used for construction	● No necessity for the application of chemicals	● Long lifespan (estimated >10 years)		
Disadvantages	● Minimal quality and constant flow of fresh water required: turbidity (<10-20 NTU) and low algae contamination. Otherwise, pre-treatment may be necessary	● Cold temperatures lower the efficiency of the process due to a decrease in biological activity	● Very regular maintenance essential; some basic equipment or ready-made test kits required to monitor some physical and chemical parameters	● Possible need for changes in attitude (belief that water that flows through a green and slimy filter is safe to drink without the application of chemicals), Chemical compounds (e.g. fluorine) are not removed	● Natural organic matter and other DBPs precursors not removed (may be formed if chlorine is applied for final disinfection)
	● May require electricity	● Loss of productivity during the relatively long filter skimming and ripening periods	● Requirement of a large land area, large quantities of filter media and manual labour for cleaning, Low filtration rate		

Introduction

Slow sand filtration has been an effective water treatment process for preventing the spread of gastrointestinal diseases for over 150 years, having been used first in Great Britain and later in other European countries. SFFs are still used in London and were relatively common in Western Europe until recently and are still common elsewhere in the world.

The move away from slow sand filtration in industrialised countries has largely been a function of rising land prices and labour costs, which increased the cost of SSF produced water. Where this is not the case, SSFs still represent a cost-effective method for water treatment. Since these conditions prevail in many developing countries, it is a very promising technique for water purification and, therefore, the development of a sustainable water system.

Design Principles

The basic principle of the process is very simple. Contaminated freshwater flows through a layer of sand, where it not only gets physically filtered but biologically treated. Hereby, both sediments and pathogens are removed. This process is based on the ability of organisms to remove pathogens. In this context, it is important to distinguish slow and rapid sand filtration.

The difference between the two is not simply a matter of the filtration speed, but of the underlying concept of the treatment process. Slow sand filtration is essentially a biological process whereas rapid sand filtration is a physical treatment process (WHO n.y.). To learn more about rapid sand filtration have a look at the factsheet: rapid sand filtration.

Although the physical removal of sediments is an important part of the purification process, the relevant aspect is the biological filtration. The top layers of the sand become biologically active by the establishment of a microbial community on the top layer of the sand substrate, also referred to as 'schmutzdecke'. These microbes usually come from the source water and establish a community within a matter of a few days. The fine sand and slow filtration rate facilitate the establishment of this microbial community.

The majority of the community are predatory bacteria that feed on water-borne microbes passing through the filter. Hence, the underlying principle of the SSF is equivalent to the bio-sand filtration. While the former is applied to semi-centralised water treatment, the latter mainly serves household purposes.

Structure

As the process itself, the basic structure is very elementary. Essentially, only the filter chamber, a type of reservoir and pipes are required. The filter chamber can either be constructed as an open or as a closed box. Depending on climatic and other factors, the one or the other is more reasonable (e.g. cold climate requires a closed box since low temperatures decrease the performance of the process).

Once a SSF facility is built, only clean sand is required for occasional replacement. The sand layers are put in gradually according to their grain sizes: rather coarse grains at the bottom and fine grains at the top. The sand-bed is usually covered with one meter of supernatant water.

As the process of biological filtration requires a fair amount of time in order to purify the water sufficiently, SSFs usually operate at slow flow rates between 0.1 – 0.3 m3/h per square metre of surface. The water thus remains in the space above the medium for several hours and larger particles are allowed to separate and settle (see also sedimentation).

It then passes through the sand-bed where it goes through a number of purification processes. The water requires some kind of physical pressure in order to pass the drag created by the sand layers. In terms of construction, two different types are feasible. The pressure can be built up either by pumps or gravity. While pump systems need some type of engine and a more elaborate construction, gravity systems work without any highly technological means.

Health Aspects

Slow sand filtration is an extremely efficient method for removing microbial contamination and will usually have no indicator bacteria present at the outlet. SSFs are also effective in removing protozoa and viruses. If the effluent turbidity is below 1.0 nephelometric turbidity units (NTU), a 90 to 99% reduction in bacteria and viruses is achieved. Yet, slow sand filtration is generally not effective for the majority of chemicals.

However, it can be argued that chemical standards for drinking water are of secondary concern in water supply subject to severe bacterial contamination. Although SSFs are very effective for the removal of microbiological pathogens, disinfectants (e.g. chlorination) are often used in treatment facilities as a step subsequent to the SSF unit.

Firstly for the purpose of inactivating any remaining bacteria as the final unit of treatment, and secondly, for the provision of a residual disinfectant that will remove any bacteria introduced during storage and/or distribution. Chlorine is generally added after the filter unit in order to not affect the biological process.

If the water contains high amounts of natural organic matter (NOMs), e.g. surface waters in tropical regions, chlorination should be avoided due to the risk of the formation of disinfection by-products (DBPs). When attacked by chlorine radicals, NOMs form trihalomethane (THM) and other organic DBPs, which are known to be carcinogenic.

Effectiveness	**Highly Effective** ● Bacteria ● Protozoa ● Viruses ● Turbidity ● Heavy Metals	**Fairly Effective** ● Odour ● Taste ● Iron ● Manganese ● Organic Matter ● Arsenic	**Not Effective** ● Salts ● Fluoride ● Trihalomethane Precursors ● Most Chemicals		

Construction
A SSF consists of a box, often made of concrete in which a bed of sand is placed over a layer of gravel and perforated pipes. These pipes collect the treated water. For community use, filter chambers can also be made out of brick or ferro-cement. Recently, also plastic boxes have been used as filter chambers. The simple design of SSFs makes it easy to use local materials and skills in their construction. Due to the simplicity of construction, SSFs can be built by experienced contractors, or by communities with external technical assistance. Basic hydrological equipment like valves and measurement devices become necessary only if the facility is rather large.

Operation / Maintenance
For a SSF to be effective, it must be operated and maintained properly. If topographic circumstances allow the water to flow through gravity during the whole process, no pumps and thus no electricity is required. However, the flow of water must be maintained at a rate between 0.1–0.3 metres per hour. This provides a stable flow of nutrients and oxygen to the microorganisms in the filter and gives them time to treat the water. After several weeks to a few months, the population of microorganisms may get too dense and start to clog the filter.

If flow rates are too low, the filter must be drained and the top layer of the sand scraped off, washed, dried in the sun, and stored. After several scrapings, the cleaned and dried sand is added back to the filter, together with new sand, to make up for losses during washing. Every two months, all the valves must be opened and closed to keep them from becoming stuck, and any leaks in the system must be repaired immediately.

SSFs can be operated and even monitored by communities, provided the caretakers are trained well. It takes a caretaker less than one hour a day to check whether the filter is functioning properly and to adjust flow rates. Several people can clean a filter unit in only one day, but it is important that hygienic measures are observed constantly. If the filter is well-designed and constructed, hardly any repairs of the filter tanks and drainage system will be necessary, although the valves and metal tubing may need occasional attention.

If water test kits are available, water quality can be easily monitored without special training. Nevertheless, a SSF for community use requires considerable organisation for scraping and re-sanding the filter units. A local caretaker will have to be trained. Apart from extra sand, some chlorine and test materials, very few external inputs are needed. With proper external assistance, water organisations can manage their water treatment independently.

Costs
Construction costs strongly depend on local conditions. Since SSFs demand rather large land areas but low input of construction materials, the capital costs primarily consist of wages and costs for land acquisition. The cost of imported materials and equipment may be kept to almost negligible proportions. Therefore, water purification through a SSF is very economical in areas where labour costs are low and land is not a limiting factor. Operational costs are incurred almost solely from the cleaning of the filter beds. No chemicals or other materials are needed for the process. No compressed air, mechanical stirring, or high-pressure water is needed for backwashing. There is thus a saving not only in the provision of plant but also in the cost of fuel or electricity.

9 Rapid Sand Filter

Rapid sand filtration is a purely physical drinking water purification method. Rapid sand filters (RSF) provide rapid and efficient removal of relatively large suspended particles. Two types of RSF are typically used: rapid gravity and rapid pressure sand filters. For the provision of safe drinking water, RSFs require adequate pre-treatment (usually coagulation-flocculation) and post-treatment (usually disinfection with chlorine).

Both construction and operation is cost-intensive. It is a relatively sophisticated process usually requiring power-operated pumps, regular backwashing or cleaning, and flow control of the filter outlet. Rapid sand filtration is common in developed countries for the treatment of large quantities of water where land is a strongly limiting factor, and where material, skilled labour, and continuous energy supply are available.

Overview	**Working Principle** After being pre-treated (coagulation-flocculation), freshwater flows through a sand- and gravel bed. Hereby, particles are removed through a physical filtering process	**Capacity/Adequacy** Large urban areas where land area is limited and chemicals, electricity and skilled labour are easily available	**Self-Help Compatibility** Rather low, highly technical facilities, chemicals and energy required	**Costs** In general, construction, operation and maintenance costs for rapid sand filters are significantly higher than costs for slow sand filters	**Performance** 4'000 – 12'000 litres per hour per square metre of surface; generally only removes solids and suspended particles; requires pre-treatment (coagulation-flocculation) and post-treatment (disinfection)
	O&M Very frequent cleaning (every 24 - 72h) and skilled caretakers required	**Reliability** Highly reliable if properly operated	**Main Strength** Rapid and efficient in removing turbidity	**Main Weakness** Not effective for the removal of bacteria, pre-treatment (e.g. coagulation/flocculation) and final disinfection (e.g. chlorine) are therefore needed	

Advantages	● Highly effective for removal of turbidity (usually < 0.1-1 NTU)	● High filter rate (4'000 – 12'000 litres per hour per square metre of surface), small land requirements	● No limitations regarding initial turbidity levels (if coagulant or flocculant is available and correctly applied)	● Cleaning time (backwashing) only takes several minutes and filters can be put back into operation instantly	
Disadvantages	● Not effective in removing bacteria, viruses, fluoride, arsenic, salts, odour and organic matter (requires pre- and post-treatment)	● High capital, energy input and operational costs	● Frequent cleaning (backwashing) required (every 24-72h)	● Skilled supervision essential (e.g. for flow control and dosage of disinfectant)	● Backwashing water and sludge needs treatment; sewage system or stabilisation ponds required

Introduction
Rapid sand filters evolved at the end of the 19th century in the United States and quickly gained popularity. By the 1920s, they were widely used as a major water purification method, since necessary facilities required less land area compared to slow sand filters. Today, a combination of flocculation and coagulation, sedimentation, filtration and disinfection (e.g. chlorination, ozonation) is the most widely applied water treatment technology for treating large quantities of drinking water in industrialised countries. Rapid sand filtration, in contrast to slow sand filtration, is a purely physical treatment process. As the water flows through several layers of coarse-grained sand and gravel, relatively large particles are held back safely. However, RSFs never provide safe drinking water without adequate pre-treatment and final disinfection. Usually, coagulation and flocculation and chlorination are applied for that purpose.

Treatment Process
The filter chamber is usually made out of reinforced concrete, filled with sand and gravel to the height of 1.5-2 metres. The water is supplied to the top of the sand-bed and filtered as it flows through the layers of graded sand and gravel. A system of perforated pipes on the bottom drains the chamber.

The filter chamber can be constructed as open tanks (rapid gravity filters) or closed tanks (pressure filters). This filtering process is determined by two basic physical principles. First, relatively large suspended particles get stuck between the sand grains as they pass the filter medium (mechanical straining). Second, smaller particles adhere to the surface of the sand grains caused by the effect of the van der Waals forces (physical adsorption).

The major parts of a gravity rapid sand filter
- Chamber: filter tank or filter box
- Filter media (sand)
- Gravel support
- Under drain system
- Wash water troughs

A chemical filter-aid (i.e. coagulant or flocculant) might be added to promote additional adhesion. In the course of these processes, more and more particles accumulate in the filter medium, increasingly causing clogged filters and decreased performance. Initial filtering performance can be re-achieved through a cleaning of the filter bed. This is usually conducted through backwashing: the flow of water is reversed, so that treated water flows backwards through the filter. The sand is re-suspended and the solid matter is separated in the surface water.

Often, air is injected additionally to support the cleaning process (WHO 1996). As soon as most particles are washed out and the backward flowing water is clear, the filter is put back to operation. Clearly, relatively large quantities of sludge are generated through backwashing and require some form of treatment before discharge into the environment.

Health Aspects
Rapid sand filtration is a highly effective method to remove turbidity if it is correctly applied. Equally, solids formed during pre-treatment, i.e. coagulation-flocculation, are filtered. A well-operated RSF reduces turbidity to less than 1 NTN and often less than 0.1 NTU. Regarding the removal of most other contaminants, the RSFs are ineffective. If combined with adequate pre-treatment measures and final disinfection, rapid sand filtration usually produces safe drinking water. Typical treatment performance of rapid sand filters if freshwater has been pre-treated with coagulation-flocculation.

Effectiveness	**Moderately Effective** ● Turbidity ● Iron ● Manganese	**Somewhat Effective** ● Odour ● Taste ● Bacteria ● Organic Matter	**Not Effective** ● Viruses ● Fluoride ● Arsenic ● Salts		

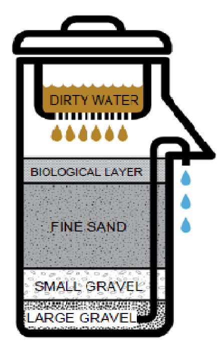
Construction
The construction of a RSF requires the supervision of a competent engineer and highly skilled workers. It involves the construction of reinforced concrete fundaments and walls and many technical installations. Only a very precise realisation guarantees a functioning water treatment. Operation of a rapid sand filter consists of flow control, regular backwashing and cleaning. The period between backwashes depends on the quality of the influent water and normally lies between 24 – 72 hours (UNEP 1998). The cleaning process requires an interruption of the purification process of 5 - 10 minutes per filter bed. Several parallel filter units are required to guarantee constant water supply. The backwash process must be observed carefully; in particular the rate of flow must be controlled to avoid erosion of the filter medium. Periodic repacking of the filter bed may be required at infrequent intervals to ensure efficient operation (UNEP 1998). Operation and maintenance thus requires skilled and highly reliable workers.

Costs
The construction cost of rapid sand filters is determined primarily by the cost of materials such as cement, building sand, gravel, reinforcing steel, filter media, pipes, and valves. However, the cost of land and transport of materials could add substantially to the total cost. The cost of energy required to operate a rapid sand filter and the costs for treatment of generated sludge during backwashing may add significant costs. Although operation is usually conducted automatically, frequent inspection by a well-educated worker is necessary to ensure proper treatment. Maintenance costs will include repairs of the filters and replacement of equipment. In general, construction, operation and maintenance costs for rapid sand filters are significantly higher than costs for slow sand filters.

Applicability
Rapid sand filtration requires very complex technical installations, highly skilled workers for construction and operation as well as large energy inputs. Unless pre-treatment and disinfection is applied, the filtered water is not safe for drinking. Its application is hence reserved for industrialised countries or urban areas where land is a limiting factor. RSF can provide a very efficient method in larger urban water supply systems if preconditions are met. For any other areas, RSFs are usually economically unreasonable.

10 Biosand Filter

A biosand filter (BSF) is a point-of-use water treatment system adapted from traditional slow sand filters. Biosand filters remove pathogens and suspended solids from water using biological and physical processes that take place in a sand column covered with a biofilm. BSFs have been shown to remove heavy metals, turbidity, bacteria, viruses and protozoa.



BSFs also reduce discoloration, odour and unpleasant taste. Studies have shown a correlation between use of BSFs and a decrease in the occurrence of diarrhoea. Because of their effectiveness, ease of use, and lack of recurring costs, biosand filters are often considered appropriate technology in developing countries.

It is estimated that over 200,000 BSFs are in use worldwide. Biosand filters are typically constructed from concrete or plastic. At the top of the filter, a tightly fitted lid prevents contamination and unwanted pests from entering the filter. Below this, the diffuser plate prevents disturbance of the biofilm when water is poured into the filter.

Water then travels through the sand column, which removes pathogens and suspended solids. Below the sand column, a layer of gravel prevents sand from entering the drainage layer and clogging the outlet tube. Below the separating layer is the drainage layer consisting of coarser gravel that prevents clogging near the base of the outlet tube.

Filtration Process
Pathogens and suspended solids are removed by biological and physical processes that take place in the biolayer and the sand layer. These processes include:

Mechanical Trapping	Suspended solids and pathogens are trapped in the spaces between the sand grains.

Predation	Pathogens are consumed by microorganisms in the biolayer.
Adsorption	Pathogens are absorbed into each other and to suspended solids in the water and sand grains.
Natural Death	Pathogens finish their life cycles or die because there is not enough food or oxygen.
Running	The high water level (hydraulic head) in the inlet reservoir zone pushes the water through the diffuser and filter, then decreases as water flows evenly through the sand. The flow rate slows because there is less pressure to force the water through the filter. The inlet water contains dissolved oxygen, nutrients, and contaminants. It provides the oxygen required by the microorganisms in the biofilm. Large suspended particles and pathogens are trapped in the top of the sand and partially plug the pore spaces between the sand grains. This causes the flow rate to decrease. Idle time typically comprises greater than 80% of the daily cycle; during this time, microbial attenuation processes are likely to be significant. Most removal occurs where water is in contact with the biofilm. The processes that occur in the biofilm have not been identified. When the standing water layer reaches the level of the outlet tube, the flow stops. Ideally, this should be high enough to keep the biofilm in the sand layer wet and allow oxygen to diffuse through the standing water to the biolayer. The pause period allows microorganisms in the biolayer to consume the pathogens and nutrients in the water. The rate of flow through the filter is restored as they are consumed. If the pause period is too long, the biolayer will consume all of the pathogens and nutrients and will die, reducing the efficiency of the filter when it is used again. The pause period should be between 1 and 48 hours. Pathogens in the non-biological zone die from a lack of nutrients and oxygen.
Maintenance	Over time, particles accumulate between the filter's sand grains. As more water is poured, a biofilm forms along the top of the diffuser plate. Both of these occurrences cause a decrease in flow rate (clogging and bioclogging). Although slower flow rates generally improve water filtration due to idle time, it may become too slow for the users' convenience. If flow rates fall below 0.1 litres/minute, it is recommended by CAWST to perform maintenance. The "swirl and dump", or wet harrowing cleaning technique, is used to restore flow rate. About 1 US gallon (3.8 L) is poured into the filter before cleaning (assuming the filter is empty). The upper layer of sand is then swirled in a circular motion. Dirty water from the swirling is dumped out and the sand is smoothed out at the top. This process is repeated until flow rate is restored. Cleaning the diffuser plate, outlet tube, lid, and outside surfaces of the filters regularly is also recommended. Long-term sustainability and efficacy of biosand filters depends on education and support from knowledgeable support personnel.

Contaminant Removal

Turbidity	Results for turbidity reductions vary depending on the turbidity of the influent water. Turbid water contains sand, silt and clay. Feed turbidity in one study ranged from 1.86 to 3.9 NTU. In a study water was obtained from sample taps of water treatment plants from three local reservoirs. It poured through a slow sand filter and results showed that turbidity decreased to a mean of 1.45 NTU. In another study using surface water a 93% reduction in turbidity was observed. As the biofilm above the sand ripens, turbidity removal increases. Although biosand filters remove much turbidity, slow sand filters, which have a slower filtration rate, remove more.
Heavy Metals	There is limited research on the removal of heavy metals by biosand filters. In a study conducted in South Africa, the filter removed about 64% of iron and 5% of magnesium.
Bacteria	In laboratory studies, the biosand filter has been found to remove about 98-99% of bacteria. In removal of Escherichia coli it was found that the biosand filter may increase due to biofilm formation over about two months. The removal after this time ranged from 97-99.99% depending on the daily water volume and percent primary effluent added. The addition of primary effluent or waste water facilitates growth of the biofilm which aids bacterial die-off. Research shows that biosand filters in use in the field remove fewer bacteria than ones in a controlled environment. In research conducted in 55 households of Bonao, Dominican Republic, the average E. coli reduction was about 93 percent.
Viruses	Lab tests have shown that while the filters reduce significant quantities of E. coli, they remove significantly fewer viruses because viruses are smaller. In a study using bacteriophages, virus removal ranged between 85% and 95% after 45 days of usage. A recent study has suggested that virus removal increases significantly over time, reaching 99.99% after approximately 150 days.
Protozoa	In one lab test the biosand filter removed more than 99.9% of protozoa. In tests for one type of protozoa, Giardia lamblia, the filter removed 100% over 29 days of use. It removed 99.98% of the oocysts of another protozoa, Cryptosporidium sp., possibly due to their smaller size. This removal was comparable with that of the slow sand filter.

Advantages	• High removal of pathogens	• Removal of turbidity, colour, odour and iron (water tastes and looks good)	• Relatively high flow-rates can be achieved (over 30 L per hour)	• One-time installation with few maintenance requirements and negligible operation costs	• Can be fabricated from locally available materials generating an opportunity for local businesses
	• Long life	• Easy to operate and maintain			
Disadvantages	• Biological layer takes 20 to 30 days to develop to maturity	• Low rate of virus inactivation	• High turbidity (> 50 NTU) will cause filter to clog and requires more maintenance	• Requires that the filter be used on a regular basis	• Cannot remove dissolved compounds
	• Lack of residual protection (risk of re-contamination)	• Can be difficult to move or transport (due to weight)	• Requires that the filter be used on a regular basis		

How it Works
The biosand filter is an innovation on traditional slow sand water filters (which have been used for community water treatment for hundreds of years CAWST 2009), specifically designed for intermittent or household use. The BSFs was developed by Dr. David Manz in the 1990s at University of Calgary, Canada. The filter is simple to use and can be produced locally anywhere in the world because it is built using materials that are readily available. Their capital costs depend on the local material and labour costs. However, they require no consumables and the operating costs are negligible. BSFs consist of a simple container with a lid, enclosing layers of sand and gravel, which traps physically sediments, pathogens and other impurities from the water. A biofilm, which forms as a shallow layer of water, sits atop the sand column and contributes to the elimination of pathogens.

The filter container can be made of concrete, plastic or any other water-proof, rust-proof and non-toxic material. The most widely used version is however the concrete container, approximately 0.9 m tall and with a surface of 0.3 m2 (LANTAGNE et al. 2006). The concrete filter box is cast from a steel mould or made with a pre-fabricated pipe. The container is filled with layers of sieved and washed sand and gravel, also referred to as filter media (CAWST 2009). There is a standing water height of 5 cm above the sand layer, which is maintained by adjusting the height of the outlet pipe. It is this design feature that allows the formation of a biofilm layer and distinguishes the BSF from other slow sand filters, allowing for small-scale construction and intermittent use.

A diffusion layer avoids that water reaches the sand surface too fast, which could disturb the biofilm layer. The filter operation is very simple. Water is poured onto the top of the filter as needed. Then the water will travel slowly through the sand and gravel bed. At the base of the filter the water is collected in a pipe and is drained through plastic piping out of the filter for be collected and stored in a clean water container. Concrete filters have the outlet pipe embedded in the concrete, protecting it against breaks and leaks. The treated water should be collected by the user in a safe storage container placed on a block or stand, so that the container opening is just under the outlet, minimising the risk for recontamination.

Pathogens and suspended solids are removed through a combination of biological and physical processes that take place in the biofilm layer and within the sand layer. These processes include mechanical trapping, predation, adsorption, and natural death.

- Mechanical trapping and sieving: Suspended solids and pathogens are physically trapped in the spaces between the sand grains.
- Adsorption and attachment: Pathogens become attached to each other (and thus more easily sieved), suspended solids in the water, and the sand grains.
- Predation: Pathogens are consumed by other microorganisms in the biological layer. This biological layer matures over one to three weeks, depending on volume of water put through the filter and the amount of nutrients and micro-organisms in the water.
- Natural death: Pathogens finish their life cycle or die because there is not enough food or oxygen for them to survive.

Effectiveness
The biosand Filter is a proven technology, which removes pathogens such as bacteria, protozoa and helminth. BSFs are also somewhat effective for the removal of virus (CAWST 2009). Physical parameters such as turbidity and iron are also eliminated from drinking water.

However, dissolved chemicals (such as organic pesticides or arsenic) are not removed. The treated water generally has an agreeable colour, taste and odour. The table below shows the biosand filter treatment efficiency in removing pathogens, turbidity and iron.

Bacteria
Lab: Up to 96.5%
Field: 87.9 to 98.5%

Viruses
Lab: 70 to >99%
Field: N/A

Protozoa
Lab: >99.9%
Field: N/A

Turbidity
Lab: 95%
Field: 85%

Iron
Lab: N/A
Field: 90-95%

Operation & Maintenance
The flow rate through the filter will slow down over time as the pore openings between the sand grains become clogged. For turbidity levels greater than 50 NTU (Nephelometric Turbidity Units), the water should first be strained through a cloth or sedimented before using the BSF. When the flow rate drops to a level that is inadequate for the household use the filter needs to be cleaned. This is done by a simple 'swirl and dump' procedure performed on the top of the sand, and only takes a few minutes. The swirl and dump process consist in agitating the surface sand, thereby suspending captured material in the standing layer of the water (see cawst.org). The dirty water is than removed and dumped away. The process can be repeated as many times as necessary to regain the desired flow rate. The need for cleaning depends on the amount and quality of water being put through the filter. If the water is relatively clean (turbidity less than 30 NTU), the filter can likely run for several months without this maintenance procedure. When a BSF is used for the first time, there is no biofilm yet. The biological layer typically takes 20 to 30 days to develop to maturity in a new filter depending on inlet water quality and usage (CAWST 2009). Removal efficiency and the subsequent effectiveness of the filter increase throughout this period. After cleaning, a re-establishment of the biological layer takes place, quickly returning removal efficiency to its previous level.

Applicability
BSF are suitable for the treatment of water at household-, school- or community-level. BSF can efficiently and directly treat contaminated surface or ground water since it also removes turbidity and iron. However, it is recommended not to use water with turbidity more than 50 NTU. Further, dissolved chemicals (e.g. organic pesticides or arsenic) are not removed. Chlorinated water should not be poured into this filter as chlorine kills microorganisms presented in biofilm resulting in low pathogen removal performance. Nevertheless, the water can be chlorinated after filtration in order to improve the security for elderly or infant members of the household/community. A BSF should be constructed only by trained technicians. Though the construction and installation look very simple, incorrect filter design and installation can lead to poor filter performance. However, materials are generally locally available and the construction by trained local staff may create opportunities for local business.

11 Sedimentation

Sedimentation is a physical water treatment process using gravity to remove suspended solids from water. Solid particles entrained by the turbulence of moving water may be removed naturally by sedimentation in the still water of lakes and oceans. Settling basins are ponds constructed for the purpose of removing entrained solids by sedimentation. Clarifiers are tanks built with mechanical means for continuous removal of solids being deposited by sedimentation.

Sedimentation is recommended as simple pre-treatment of water prior to application of other purification treatments such as filtration and disinfection methods. It removes undesirable small particulate suspended matters (sand, silt and clay) and some biological contaminants from water under the influence of gravity. The longer the water is sedimented, the more the suspended solids and pathogens will settle to the bottom of the container. Adding special chemicals or some natural coagulants can accelerate sedimentation.

Three common chemicals used are aluminium sulphate, polyaluminium chloride (also known as PAC or liquid alum) and ferric sulphate. 'PUR' is a powder product containing both coagulants and disinfectant. Some native plants like prickly pear cactus, Moringa seeds, broad beans and Fava beans have all been traditionally used as natural coagulant to help sediment water in a number of countries in Africa and Latin America.

Advantages	• Simple and low cost water pre-treatment technology. • Certain contaminants such as lead and barium can be also effectively removed by coagulation	• Coagulants reduce the time required to settle out suspended solids.	• Natural coagulants can sometimes be obtained for free or at a low cost.	• Coagulation can also be effective in removing protozoa, bacteria and viruses, particularly when polyelectrolyte is used. Some bacteria and viruses can attach themselves to the suspended particles in water that cause turbidity. Thus, reducing turbidity levels through coagulation may also improve the quality of water.	
Disadvantages	• If only settling or plain sedimentation is practised, it removes only partially turbidity and some microorganisms	• Maximum effectiveness requires careful control of coagulant dose and pH, and consideration of the quality of the water being treated, as well as mixing	• Costs are variable depending on coagulant; some coagulants like polyelectrolyte are expensive to buy. Effectiveness of coagulants varies from one to another	• Without using coagulants, a long sedimentation time is needed	• Training is required for coagulant dosage, jar testing and frequent monitoring

	● Except with the use of specific coagulants, it is not effective for removing dissolved chemicals from the water	● May be toxic if used improperly	● Natural coagulants are not available in a usable form and need to be prepared		

Sedimentation
The suspended particles in water vary considerably in source, composition, charge, particle size, shape and density. The smaller particles present in water are kept in suspension by the action of physical forces on the particles themselves. One of the forces playing a dominant role in stabilisation results from the surface charge present on the particles. Most solids suspended in water possess a negative charge and since they have the same charge sign, repel each other when they come close together. Therefore they will remain in suspension rather than clump together and settle out of the water. Sedimentation is a simple, low cost pre-treatment technology to reduce settable solids and some microbes from water under the influence of gravity prior to application of other purification methods. It also improves the visual qualities of the water and increases its acceptance by consumers. The longer the water is stored, the more the suspended solids and pathogens will settle to the bottom of the container. Adding chemical or natural coagulants to the water can quicken the sedimentation process. Aluminium sulphate, polyaluminium chloride (also known as PAC or liquid alum) and ferric sulphate are three common types of chemicals used for the coagulation. Some examples of natural coagulants are prickly pear cactus, Moringa seeds, broad beans and Fava beans. Some products like "PUR" contain both coagulants and disinfectant. Coagulants are dosed in solution at a rate determined by raw water quality. After sedimentation, the water should be filtered to further remove suspended materials and pathogens.

Working Mechanism
Much of the suspended material can be removed by simply allowing the water to stand and settle for some time. This retention time (from one hour up to two days, the longer the better) is required to settle particles in the bottom. Storing water for at least one day will also promote the natural die-off of some bacteria. Coagulants enhance sedimentation because they neutralise the surface charge of suspended particles. Particles that cause turbidity (e.g. silt, clay) are generally negatively charged, making it difficult for them to clump together because of electrostatic repulsion.

But chemical coagulant particles are positively charged, and they chemically attracted to negative turbidity particles, neutralising the latter's negative charge and accumulate to form larger particles (flocs), which settle faster. Natural coagulants contain significant quantities of water-soluble proteins, which carry an overall positive charge when in solution. The proteins bind to the predominantly negatively charged particles that cause turbidity and form flocs. The flocs can be settled out or removed by filtration. Bacteria and viruses can attach themselves to the suspended particles in water. Therefore, reducing turbidity levels through coagulation may also improve the microbiological quality of water.

Effectiveness
Plain sedimentation often is effective in reducing water turbidity, but it is not consistently effective in reducing microbial contamination. Storing water for as little as a few hours will sediment the large, dense particles like inorganic sands and silts, large microbes and any other. Overnight or 1-2 days longer settling times will remove larger microbes, including Helminth ova and some parasites, some microbes, such as certain algae, and the larger clay particles. Most viruses and bacteria and fine clay particles are too small to be settled out by simple gravity sedimentation. Sedimentation by using coagulant reduces the time required to settle out suspended solids and is very effective in removing fine particles. Some bacteria and viruses can also attach themselves to suspended particles. Therefore, reducing turbidity level through coagulation may also improve some microbiological quality (bacteria, viruses, protozoa and helminths) of water. The use of Moringa Oleifera seeds for water treatment is efficient in reducing 80% to 99.5% of turbidity accompanied by 90% to 99.99% bacterial reduction.

Bacteria - Lab: >90-99%
Viruses - Lab: >90-99%
Protozoa - Lab: >90-99%
Helminths - Lab: >90-99%
Turbidity - Lab: 80-99.5%

The effectiveness of the coagulants has a complex dependence on the type of coagulant used, the nature of the raw water, being affected by such things as temperature, pH and especially the specific proportions of organic, inorganic and biological particles that constitute the suspended solids as well as mixing. The best approach for determining the treatability of a water source and determining the optimum parameters (most effective coagulant, required dose rates, pH) is by use of a jar tester. Plain sedimentation or settling is not effective for removing dissolved chemicals from the water.

Applicability
Sedimentation is used to remove solids from water. It is suitable for water with high sediment content. It is easy to perform and requires a minimum of materials and skill. It can be done with as little as two or more simple storage vessels such as pots and buckets by manual transfer. Typically, at least two containers are needed to settle water: one to act as the settling vessel and another to be the recipient of the supernatant water after the settling period. Care must be taken to avoid disturbing the sedimented particles when recovering the supernatant water by decanting or other methods. Staffs need to be adequately trained to carry out jar tests to determine coagulant dosage. For better results, the coagulants should be rapidly and thoroughly mixed in water. Coagulants can be expensive to buy (particularly polyelectrolyte) and need accurate dosing equipment to function efficiently. When water is sedimented in vessel, the sediment should be removed and the vessel should be cleaned after each use. More rigorous physical or chemical cleaning is needed to avoid the microbial colonization of the vessel surface. Some communities have opted not to use aluminium based coagulants because of unsubstantiated reports that claim that the aluminium in drinking water poses a risk to public health despite of scientific evidences. Based on the WHO (2008), there is no evidence of health risk. Studies have been carried out to determine the potential risks associated with the use of M. Oleifera seed in water treatment but there is no evidence to suggest any acute or chronic effects on humans, particularly at the low doses required for water treatment.

12 Coagulation (Flocculation)

In water treatment, coagulation flocculation involves the addition of polymers that clump the small, destabilized particles together into larger aggregates so that they can be more easily separated from the water. Coagulation is a chemical process that involves neutralization of charge whereas flocculation is a physical process and does not involve neutralization of charge. The coagulation-flocculation process can be used as a preliminary or intermediary step between other water or wastewater treatment processes like filtration and sedimentation. Iron and aluminium salts are the most widely used coagulants but salts of other metals such as titanium and zirconium have been found to be highly effective as well.

Coagulation is affected by the type of coagulant used, its dose and mass; pH and initial turbidity of the water that is being treated; and properties of the pollutants present. The effectiveness of the coagulation process is also affected by pre-treatments like oxidation. In a colloidal suspension, particles will settle very slowly or not at all because the colloidal particles carry surface electrical charges that mutually repel each other. A coagulant (typically a metallic salt) with the opposite charge is added to the water to overcome the repulsive charge and "destabilize" the suspension. For example, the colloidal particles are negatively charged and alum is added as a coagulant to create positively charged ions. Once the repulsive charges have been neutralized (since opposite charges attract), the van der Waals force will cause the particles to cling together (agglomerate) and form micro floc.

Introduction
Coagulation-flocculation is a chemical water treatment technique typically applied prior to sedimentation and filtration (e.g. rapid sand filtration) to enhance the ability of a treatment process to remove particles. Coagulation is a process used to neutralise charges and form a gelatinous mass to trap (or bridge) particles thus forming a mass large enough to settle or be trapped in the filter. Flocculation is gentle stirring or agitation to encourage the particles thus formed to agglomerate into masses large enough to settle or be filtered from solution.

WATER Purification Methods Coagulation

Overview	Self-Help Compatibility Skilled operators required	Capacity/Adequacy Relatively simple technology	Performance High efficiency in removing charged suspended and dissolved particles	Costs Relatively low cost	Working Principle Suspended particles are destabilised by addition of a clarifying agent leading to the neutralisation of their charges. Particles thus agglomerate (flocs formation) and are able to decant.
	O&M Continuous consumption of chemicals and electricity	Reliability Reliable if operating conditions are optimised taking into account wastewater content	Main Strength Removes solids and improves filtration	Main Weakness Continuous input of chemicals required	

Advantages	• Simplicity and cost-effectiveness	• Separates many kind of particles from water	• Enhances filtration process	• Uses abundant and low cost chemicals	
Disadvantages	• Input of chemicals required	• Qualified personnel required for design (e.g. construction of chambers and dosage of chemicals) and system maintenance	• Transfer of toxic compounds into solid phase and formation of sludge that has to be treated subsequently	• Relatively time consuming process	

Introduction
Dissolved and suspended particles are present in most of natural waters. These suspended materials mostly arise from land erosion, the dissolution of minerals and the decay of vegetation and from several domestic and industrial waste discharges. Such material may include suspended, dissolved organic and/or inorganic matter, as well as several biological organisms, such as bacteria, algae or viruses.

This material has to be removed, as it causes deterioration of water quality by reducing the clarity (e.g. causing turbidity or colour), and eventually carrying pathogenic organisms or toxic compounds, adsorbed on their surfaces. To separate the dissolved and suspended particles from the water coagulation and flocculation processes are used. Coagulation and flocculation is relatively simple and cost-effective, provided that chemicals are available and dosage is adapted to the water composition.

Regardless of the nature of the treated water and the overall applied treatment scheme, coagulation-flocculation is usually included, either as pre-treatment (e.g. before rapid sand filtration) or as post-treatment step after sedimentation (see also centralised water purification plants). Most solids suspended in water possess a negative charge; they consequently repel each other. This repulsion prevents the particles from agglomerating, causing them to remain in suspension.

Coagulation and flocculation occur in successive steps intended to overcome the forces stabilising the suspended particles, allowing particle collision and growth of flocs, which then can be settled and removed (by sedimentation) or filtered out of the water. Coagulation-Flocculation is also a common process to treat industrial and domestic wastewater in order to remove suspended particles from the water.

Coagulation Principles
Coagulation destabilises the particles' charges. Coagulants with charges opposite to those of the suspended solids are added to the water to neutralise the negative charges on dispersed non-settable solids such as clay and organic substances. Once the charge is neutralised, the small-suspended particles are capable of sticking together.

The slightly larger particles formed through this process are called microflocs and are still too small to be visible to the naked eye. A high-energy, rapid-mix to properly disperse the coagulant and promote particle collisions is needed to achieve good coagulation and formation of the microflocs. Over-mixing does not affect coagulation, but insufficient mixing will leave this step incomplete. Proper contact time in the rapid-mix chamber is typically 1 to 3 minutes.

Flocculation
Following coagulation, flocculation, a gentle mixing stage, increases the particle size from submicroscopic microfloc to visible suspended particles. The microflocs are brought into contact with each other through the process of slow mixing. Collisions of the microfloc particles cause them to bond to produce larger, visible flocs. The floc size continues to build through additional collisions and interaction with inorganic polymers formed by the coagulant or with organic polymers added. Macroflocs are formed.

High molecular weight polymers, called coagulant aids, may be added during this step to help bridge, bind, and strengthen the floc, add weight, and increase settling rate. Once the floc has reached its optimum size and strength, the water is ready for the separation process (sedimentation, floatation or filtration). Design contact times for flocculation range from 15 or 20 minutes to an hour or more.

Coagulation Flocculation Separation In water treatment, coagulation and flocculation are practically always applied subsequently before a physical separation. The Coagulation-Flocculation process consists of the following steps:	1. Coagulation-flocculation: The use of chemical reagents to destabilise and increase the size of the particles; mixing; increasing of flog size 2. A physical separation of the solids from the liquid phase. This separation is usually achieved by sedimentation (decantation), flotation or filtration.	The common reagents are: mineral and/or organic coagulants (typically iron and aluminium salt, organic polymers), flocculation additives (activated silica, talcum, activated carbon…), anionic or cationic flocculants and pH control reagents such as acids or bases. Certain heavy metal chelating agents can also be added during the coagulation step.

Jar Test
The jar test is used to identify the most adapted mix of chemical compounds and concentrations for coagulation-flocculation. It is a batch test consisting of using several identical jars containing the same volume and concentration of feed, which are charged simultaneously with six different doses of a potentially effective coagulant. The six jars can be stirred simultaneously at known speeds. The treated feed samples are mixed rapidly and then slowly and then allowed to settle. These three stages are an approximation of the sequences based on the large-scale plants of rapid mix, coagulation flocculation and settling basins. At the end of the settling period, test samples are drawn from the jars and turbidity of supernatant liquid is measured. A plot of turbidity against coagulant dose gives an indication of the optimum dosage (i.e. the minimum amount required to give acceptable clarification).

The criteria thus obtained from a bench jar test are the quality of resultant floc and the clarity of the supernatant liquid after settling. The design of the full-scale plant process is then done based on the bench-scale selection of chemicals and their concentrations. Unfortunately, the jar test suffers from a number of disadvantages, despite its widespread application. It is a batch test, which can be very time-consuming. And the results obtained from a series of jar tests might not correspond to the results obtained on a full-scale plant.

Operation and Maintenance
The operation of coagulators, flocculators and clarifiers requires trained operators. Maintenance work should be undertaken regularly. The key aspects of operation and maintenance of coagulators, flocculators and clarifiers are:
- Chemical stock: There should be a good stock (at least sufficient for one month of operation).
- Plant layout: The flocculator and clarifiers should be located close to one another and water should flow slowly between them so as to not break up the flocs.
- Dosing control: Correct dosing of coagulant chemicals is very important for efficient and effective removal of suspended solids. Samples of raw water should be taken regularly, and tested with a range of coagulant concentrations to determine the optimum dose rate of coagulant. The results should be used to adjust the coagulant dose.
- Flocculation should be achieved by gentle mixing so as to maximise the number of collisions between suspended particles and flocs, without breaking the flocs up through rapid mixing.
- Rapid mixing of the water and coagulant chemicals at the point where the chemicals are added is essential.

During the course of coagulation-flocculation treatment, a substantial amount of sludge coming from the settling process is generated. This sludge can be reused as fertiliser for agriculture when no toxic compounds are present. In the presence of toxic sludge the solid waste has to be treated or disposed of in an environmentally proper manner.

Applicability
Coagulation-flocculation is a conventional pre-treatment method (typically in combination with sedimentation] and rapid sand filtration) used to separate the suspended and dissolved compounds (turbidity) from the water in (semi-)centralised drinking water treatment plants. Many charged species such as suspended mineral, organics, pathogens, and dissolved species such as metal ions, phosphates, fluoride, and radionuclides can be separated by these processes. Chemicals reactants (flocculants and coagulants) concentration must be adjusted properly to the exact composition of the water. The operation of coagulators, flocculators and clarifiers requires trained operators. Maintenance work should be undertaken regularly to guarantee an efficient treatment. Coagulation-flocculation is also often used to remove suspended solids in domestic and industrial wastewater treatment plants.

Determining Coagulant Dose
Jar Test
The dose of the coagulant to be used can be determined via the Jar Test. The jar test involves exposing same volume samples of the water to be treated to different doses of the coagulant and then simultaneously mixing the samples at a constant rapid mixing time. The microfloc formed after coagulation further undergoes flocculation and is allowed to settle. Then the turbidity of the samples is measured and the dose with the lowest turbidity can be said to be optimum.

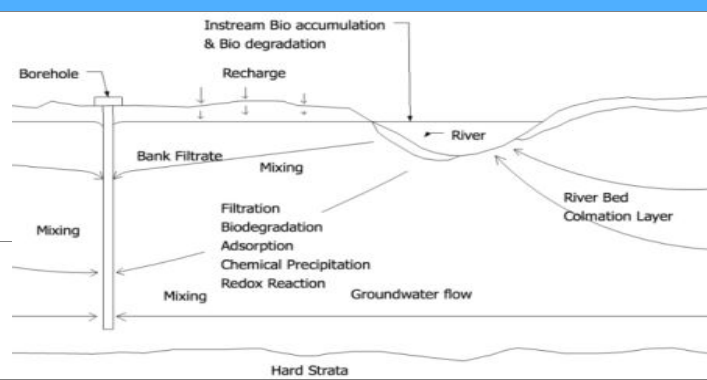
Microscale Dewatering Tests
Despite its widespread use in the performance of so-called "dewatering experiments", the jar test is limited in its usefulness due to several disadvantages. For example, evaluating the performance of prospective coagulants or flocculants requires both significant volumes of water/wastewater samples (litres) and experimental time (hours). This limits the scope of the experiments which can be conducted, including the addition of replicates. Furthermore, the analysis of jar test experiments produces results which are often only semi-quantitative. Coupled with the wide range of chemical coagulants and flocculants that exist, it has been remarked that determining the most appropriate dewatering agent as well as the optimal dose "is widely considered to be more of an 'art' rather than a 'science'". As such, dewatering performance tests such as the jar test lend themselves well to miniaturization.

Limitations
Coagulation itself results in the formation of floc but flocculation is required to help the floc further aggregate and settle. The coagulation-flocculation process itself removes only about 60%-70% of Natural Organic Matter (NOM) and thus, other processes like oxidation, filtration and sedimentation are necessary for complete raw water or wastewater treatment. Coagulant aids (polymers that bridge the colloids together) are also often used to increase the efficiency of the process.

13 Bank Filtration

Bank filtration (BF) is a drinking water pre-treatment step, where river water is induced to percolate in subsurface passage through a river bed and mix with ambient (or natural) groundwater, before being extracted through a pumping well adjacent to the river bed.

It can be applied as first step within a multi-barrier approach in an overall treatment chain where groundwater quantity is insufficient or of poor quality (e.g. geogenic pollution).



Advantages	• Can dampen pollution peaks and buffer extreme climatic conditions (quality and quantity).	• Huge freshwater storage capacity.	• Can reduce costs of supplementary treatment steps.	• Low requirements for skilled labour, chemicals and energy use (depending on purpose of output water).	
Disadvantages	• Prone to clogging/colmation at high levels of suspended solids.	• Permeability can be influenced by high (seasonal) temperature amplitude.	• High organic pollution and high mean temperatures can lead to lowered treatment efficiency.		

Design
During subsurface passage in biologically active soil layers (with aerobic, anaerobic and anoxic milieus), water quality of surface water can be improved before being mixed with groundwater and extracted for use. BF systems involve several physical, chemical and biochemical processes and are particularly known for the efficient reduction/removal (or even elimination) of suspended solids, organic pollutants, microorganisms, heavy metals, nitrogen, toxic algae as well as organic trace compounds (e.g.: pharmaceutical products), salinity or taste- and odour causing compounds. Relying on natural processes, design and treatment capacity (and efficiency) of BF systems strongly depends on local circumstances such as quality and quantity of available river- and ground water, hydraulic residence times of the water in the soil, the porosity of the soil, the hydraulic potential of the aquifer, temperature, pH values and oxygen concentrations as well as underlying redox processes. Depending on the bank filtrate quality, disinfection or even supplementary treatment steps are necessary to achieve drinking water quality. Besides its polishing function, BF also provides huge fresh water storage capacity for buffering extreme climatic conditions and shock loads, but also represents an artificial groundwater recharge technique preventing the overuse of aquifers, saltwater intrusion and land subsidence.

Operation
Basic requirements for the operation of a BF system are the availability of surface water as primary water source and a detailed consideration of the groundwater level in the surroundings of the abstraction well. Water abstraction should not result in adverse effects on the aquifer or the river downstream of the site. Depending on the BF site's characteristics and purpose of the output water, operation of a BF system is easy and only little maintenance is needed. Compared to high-end technologies, requirements for skilled labour and energy & chemical use are very low. However, more requirements may arise in relation to design, operation and maintenance of the water abstraction well. One challenge in relation to well operation is the prevention/handling of colmation of the infiltration path.

Cost
Costs for establishing riverbank filtration systems depend on many factors, including aquifer characteristics, type of well-screen installation, facility design, and distance to the population served. However, costs can be classified as moderate. Using natural treatment processes, BF system can be considered as cost-effective system, which ideally can reduce costs for subsequent treatment steps. Additional costs can arise in dependency of raw-water quality and continuative treatment steps for diverging intended purpose (e.g. drinking water use). Investment costs are costs for the abstraction well (construction, pump, main, control system etc.) as a minimum, as well as costs for groundwater monitoring of BF processes and water quality. Operational costs are primarily costs for pumping electricity for abstraction well operation. For abstraction (and treatment) facilities skilled personal is required.

14 Solar Pasteurisation

Contrary to belief, it is not necessary to boil certain water to make it safe to drink. Heating water to 65°C (149°F) for 6 minutes, or to a higher temperature for a shorter time, will kill all germs, viruses, and parasites. This process is called pasteurisation. Solar pasteurisation has proven to be a very low-cost disinfection method to produce drinking water out of non-turbid fresh water.

However, solar pasteurisation is not that easy to implement and monitor, thus it is not a wide spread method for point-of-use water treatment. Pasteurisation is one of many techniques to disinfect drinking water and is applicable to developing countries. Other techniques such as chlorination, ozonation or operation of wells may be more suitable particularly if a large amount of water is needed.

Conversely, if a relatively small amount of water is needed, pasteurisation systems, like other HWTS methods have the advantage of being able to be scaled down with a corresponding decrease in cost. In other words, if only little money is available, you can use pasteurisation to get a little clean water, perhaps enough for a family, but not a village.

Today, throughout the world, beverages such as milk, fruit juice, beer and wine are disinfected through pasteurisation on an industrial scale. Consumers are familiar with and trust the process of pasteurisation. Apart from water, milk can also be pasteurised at home, a procedure used to make it more durable. In case of milk, pasteurisation is reached when heated above 63°C for 30 minutes.

Solar Pasteurisation
Pasteurisation is the process of disinfecting water by heat or radiation without boiling. Typical water pasteurisation achieves the same effect as boiling, but at a lower temperature (usually 65-75°C/ 149-167°F), over a longer period of time. A simple method of pasteurising water is to put blackened containers with water in a solar cooker. The solar cooker reflects sunlight onto the container, which heats up the content.

The cooker may be an insulated box made of wood, cardboard, plastic, or woven straw, with reflective panels to concentrate sunlight onto the water container. It may also be an arrangement of reflective panels, or a reflective "satellite dish", on which the water pot sits. The box cooker should be frequently repositioned to ensure it is catching all available sunlight (and never in shade). A thermometer or indicator is needed to tell when the required temperature is reached for pasteurisation to monitor the required exposure time of six minutes.

Common devices for monitoring the water temperature use either beeswax, which melts at 62°C (143.6°F), or soybean fat, which melts at 69°C (156.2°F). A simple device known as the Water Pasteurisation Indicator (WAPI) has been developed at the University of California. Water may take one to four hours or more to heat to those temperatures. Heating the water to the pasteurisation temperature rather than the boiling point reduces the energy required by at least 50%.

However, solar pasteurisation is only effective if treated water is protected from post-treatment contamination during storage. The Water Pasteurisation Indicator (WAPI) indicates when water is safe to drink. When the soybean wax inside a small tube melts at about 70°C (158°F), the wax changes from solid (left) to liquid (right) state. An iron ring ensures that the tube is staying in the same position while in the solar cooker.

Advantages	● The system requires no additional inputs (electricity, chemicals or fossil fuels) after installation.	● Simple designs are available at very low cost, and this device may be built with parts available in most countries.	● Anyone can be trained to construct a solar cooker and there are no specific manufacturing hazards.	● Solar pasteurisation boxes can also be used as solar cookers for cooking meals.	● Compared to boiling, the pasteurisation process does not consume wood, charcoal or other biomass as energy supply (environmentally more sustainable) and does not take time and energy for its procurement.
Disadvantages	● Requires sunny weather and does not work during continuous rainfall, on very cloudy days, or under freezing conditions.	● Recontamination is possible after the water has cooled because it contains no residual disinfectant; subsequent safe storage is essential.	● Does not reduce turbidity, odour, taste or colour and does not remove chemical pollutants from water.	● While construction is low-cost, the life-cycle costs (chlorination, sand filters, UV treatment) are relatively high compared to competition.	● Users require a thermometer or pasteurisation indicator device.
	● Users need to keep track of containers to know which ones have been treated and to ensure that they always have treated water (batch process).	● Users may need to wait for water to cool prior to use. Cookers are made from lightweight and easily breakable materials.	● Boiling is sometimes preferred because it provides a visual measure of the water reaching sufficient temperature without requiring a thermometer.		

How it Works
Boiling or heating with fuel is perhaps the oldest means of disinfecting water at the household level and is also one of the most effective. It kills or deactivates all classes of waterborne pathogens, including protozoan cysts that have shown resistance to chemical disinfection and viruses that are too small to be mechanically removed by microfiltration.

As the water heats due to radiation from the sun, the increased temperature will kill or inactivate an important part of commonly waterborne pathogenic bacteria, viruses, helminths, and protozoa at a temperature between 65° and 75°C (149-167°F). But, spores are more resistant to thermal inactivation than vegetative cells; treatment to reduce spores requires a thermal treatment up to boiling point and must ensure sufficient temperature and time.

Furthermore, solar pasteurisation does not improve turbidity, odour, taste, colour or chemical contamination. As temperatures reach 50°C or greater, pathogenic microbes are inactivated. The temperatures which cause approximately a 1-log decrease in viability within 1 min are 55°C for protozoan cysts; 60°C for E. coli, enteric bacteria, and rotavirus; and 65°C for hepatitis A virus (3, 5, 7–9, 16).

When the WAPI wax melts at about 70°C, the cumulative lethal effect is determined by the gradual increase in temperature, often at least 30 min from 50 to 70°C, as well as the gradual cooling once the water is removed. In addition, the water at the bottom of the black jar is often 5 to 10°C cooler than the water at the top of the jar. Microbes in the upper portion will have been inactivated before those in the bottom portion, where the WAPI is located.

Temperature

Pasteurisation time decreases exponentially with increasing temperature. Above 50°C, time decreases at roughly a factor of 10 for every 10°C increase in pasteurisation temperature. Viruses appear the hardest to kill and essentially set the boundary for acceptable time-temperature processes. In rural Kenya, a simple thermo indicator which changes colour at 70°C was applied to show household members when pasteurisation temperature had been reached. This increased the number of households whose drinking water was free of coliforms from 10.7 to 43.1% and significantly reduced the incidence of severe diarrhoea compared to a control group.

Temperature Safety Zone
- 72°C at 6m
- 70°C at 8m
- 68°C at 15m
- 66°C at 25m
- 64°C at 40m

- 100% E.coli killed in 1.5 hours at 60°C
- 100% Viruses killed in 1.5 hours at 70°C
- 100% Protozoa killed in 45 seconds at 70°C

Solar Pasteurisation Devices

Literature distinguishes between batch devices and flow-through solar devices. Batch devices are used to heat water on a home scale with a simple solar cooker. While potentially inexpensive, durability of the solar box needs further investigation. Compared to other energy sources it can save fuel costs, but not labour costs, which are still relatively high. A portable version is the AquaPac, a low cost polyethylene plastic with UV inhibitors added, and air-filled bubble pack sheeting. An example for an enhanced batch device is the solar puddle, which essentially is a puddle in a greenhouse. A combination of (black) plastic sheeting is put in a shallow pit and then filled with water to be pasteurised by the solar heat. On days with good sunshine the required temperature with a water depth of up to 62 mm (2 1/2 inches) can be reached. Another way to pasteurise water is to use flow-through pasteurisation devices. They can be enhanced with a heat exchanger by recycling heat from the outgoing pasteurised water. Flow-through devices have several advantages over the simpler batch processes.

First, potable water becomes available throughout the day as new increments of treated water are added to the clean storage vessel. Second, this type of unit can adapt to variable solar conditions and is an automatic process, also decreasing the likelihood of an accident occurring when transferring water in and out of a batch unit e.g. a solar cooker jar. Flow-through devices can make use of wasted heat like the one generated in traditional clay ovens, so called "chullis". The main drawback of flow-through solar pasteurisation devices is the difficulty of ensuring safe storage, as the water needs to be transferred to a new recipient before consumption. The Solar Pasteuriser with Integral Heat Exchanger (SPIHX) collects and converts solar energy to heat energy to bring water to pasteurisation levels. Once pasteurised, the thermostat valve opens and the water flows through the bottom channel. The middle aluminium sheet facilitates heat exchange between the hot outgoing pasteurised water and cold incoming contaminated water.

Applicability

The solar pasteurisation method is effective to remove bacteria, viruses, protozoa and helminths from raw fresh water. It cannot produce drinking water from raw water with high turbidity and dissolved matter. While the removal capacity has predominantly been proved in laboratory tests, the solar pasteurisation method seems more suitable on household level rather than for producing high quantities of drinking water. Because it relies on solar energy its effectiveness depends on the daily hours of sunshine in the area of application. Solar pasteurisation might be an option on both, the village and household level. But household usage is more competitive because village-scale alternatives have much lower treatment cost. Existing solar devices have water disinfection costs that are an order of magnitude less than boiling. Solar thermal pasteurisation with existing manufactured devices costs more than the remaining alternatives but is highly effective and lowest in maintenance. Quite some solar pasteurisers that have been developed are an educational tool or curiosity rather than practical methods of producing safe water applicable in developing countries on a large scale.

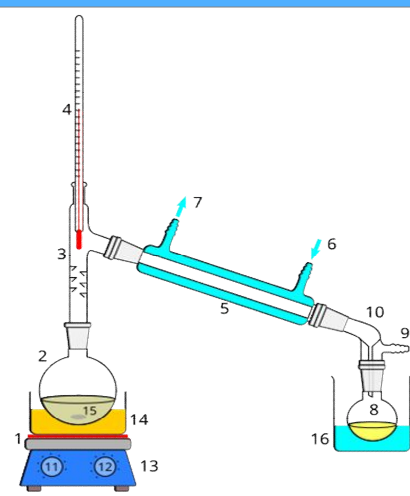
15 Distillation

Distillation is a process that relies on evaporation to purify water. Contaminated water is heated to form steam. Inorganic compounds and large non-volatile organic molecules do not evaporate with the water and are left behind. The steam then cools and condenses to form purified water.

Distillation is most effective in removing inorganic compounds such as metals (iron and lead) and nitrate; hardness (calcium and magnesium); and particulates from a contaminated water supply. The boiling process also kills microorganisms such as bacteria and some viruses.

The effectiveness of distillation in removing organic compounds varies, depending on such chemical characteristics of the organic compound as solubility and boiling point. Organic compounds that boil at temperatures greater than the boiling point of water (some pesticides) can be effectively removed from the water.

Organic compounds that boil at temperatures lower than the boiling point of water (ex., benzene and toluene) will be vaporized along with the water. If these harmful compounds are not removed prior to condensation, they will re-contaminate the purified product.



Laboratory distillation set-up using, without a fractionating column

14: Heating (Oil/sand) bath
15: Stirrer bar/anti-bumping granules
16: Cooling bath.

16 Chlorination

Water disinfection by chlorination was massively introduced in the early twentieth century. It set off a technological revolution in water treatment and complemented the known and used process of filtration. In addition to destroying harmful microorganisms, chlorination also reduces the amount of iron, manganese and hydrogen sulphide in water. Chemical disinfection using chlorine has the benefits of being relatively quick, simple, and cheap and allows a residual amount of chlorine to remain in the water to provide some protection against recontamination.

Advantages	• Simple, inexpensive and reliable technique	• Effectively kills bacteria and viruses	• Provides residual chlorine for some protection against re-contamination	• Widely available in different countries	• Easy to use
Disadvantages	• Requires that users purchase chlorine on a continuous basis and may not affordable by very poor people	• Does not deactivate parasites like Giardia, cryptosporidium and worm eggs	• Taste is unacceptable to some users	• Dose is product specific	• Availability may be restricted in rural and remote areas

	• Requires clear water to be most effective	• Chlorination of water with high organic matter leads to the risk of toxic disinfection by-products formation			

Chlorination
The disinfection of drinking water by adding chlorine is called chlorination. Chlorine was used for the first time in 1850 when John Snow used it in London's water distribution system to combat cholera. Similarly, American cities like Chicago and New Jersey started to use chlorination around 1908, a step which brought a significant decrease in the number of deaths caused by cholera, typhoid, diarrhoea and hepatitis A. Today, chlorination is used to treat most of drinking water in the world since it is easy, inexpensive and reliable. Chlorine is widely available in different countries with different brand and names. Chlorination can be achieved by using liquefied chlorine gas, sodium hypochlorite solution or calcium hypochlorite granules and on-site chlorine generators (e.g. WATA). Chlorine is widely applied for the centralised disinfection of drinking water in municipal water supply systems. International agencies have also been promoting chlorination at household level as effective and simple drinking water treatment option in developing countries. Chlorine as a household level point of use treatment is available either a solution which is added at doses of one to several drops per litre of water to treat, or as tablets, which will dissolve in the treated water. Aside from these commercial products, water can also be treated at the community level by mixing chlorine in water tanks, wells and household vessels.

How it Works
When chlorine is added to water, the chemical element dissolves and forms radicals. These kill pathogens such as bacteria and viruses by breaking the chemical bonds in their molecules or by attacking the cells of the microorganisms. The different radicals and ions formed during chlorination destroy many bacteria and viruses, but also oxidise some organic matter, dissolve colours and destroy chloramines, toxic products derived from ammonia. It takes about 30 minutes to make water safe to drink.

Chlorine Use
The correct amount of chlorine solution must be used. If the concentration of chlorine is inadequate the solution may fail to destroy all the harmful micro-organisms and if in excess, health may be adversely affected. Only an appropriate amount of chlorine can destroy most of harmful micro-organisms and provide a safe amount of residual chlorine. Chlorine that does not combine with other components and remains in the water is called "Free Residual Chlorine" (FRC). FRC makes sure that water which has been treated by chlorination will not get recontaminated when being transported or stored. According to WHO guidelines, the FRC concentration in drinking water should be between 0.2 to 0.5 mg/L.

Effectiveness
Chlorine disinfection of drinking water is limited for the protozoan pathogens (in particular cryptosporidium) and some viruses (WHO 1996). Turbidity can protect microorganisms from disinfection. Further, when the natural organic matter (NOM) of the water is high, this can lead to the formation of disinfection by-products (DBPs) such as halogenated organic molecules, mainly trihalomethanes (THM), some of which are potentially hazardous.

However, the risks to health from these by-products are extremely small in comparison with the risks associated with inadequate disinfection, and disinfection should not be compromised in attempting to control DBPs.

In 1991, the International Agency for Research on Cancer evaluated the carcinogenic potential of chlorinated drinking water. IARC concluded, that "there is inadequate evidence for the carcinogenicity of chlorinated drinking-water in humans".

However, for water containing large amounts of organics, the formation of carcinogenic halogenated disinfection products derived from the organic matter attacked by the chlorine is extremely high – it is therefore recommended to use pre-filtration (e.g. slow sand filtration or bio-sand filtration).

Very Effective

Clear Water
1 Tablet

Turbid Water
2 Tablets

Applicability
Chlorination is very suitable for places where people are directly drinking water from bacterial contaminated water sources but where other contamination (e.g. natural organic matter, arsenic) are not of concern. It is socially acceptable by general public for purifying water because of easy handling, cost effectiveness as well as good removal of microbial organism in drinking water. It is most commonly used for water disinfection during emergencies. However, a constant supply of chlorine must be guaranteed.

17 Electrolytic Purification

Chlorination, which means adding active chlorine (Sodium Hypochlorite) to water, is the most common method used for disinfecting of drinking water. Active chlorine destroys or inactivates most pathogenic microorganisms, including parasites, bacteria and viruses with a very high reliability. The WHO estimates that chlorination is the most secure, effective and economic option. Yet, generally speaking, chlorine is not produced in low-income countries, but imported in the form of tablets or bleach, at relatively high cost. WATA is technology and approach developed by Antenna Foundation which integrates health education with the local production of chlorine by electrolysis (through the WATA device) in a sustainable supply chain, making safe water treatment a profitable activity.

Advantages	• Local production (avoids most storage and transportation problems and environment impacts)	• Generation of income for local communities (e.g. water kiosk)	• Especially suitable for humanitarian response or war-thorn areas, where for example chlorine gas is banned.	• Quality control is possible at every stage of production and use	• Disinfectant can be used for a large range of applications (e.g. disinfecting laboratory equipment, wounds, cleaning latrines, disinfecting surfaces etc.)
	• Solar versions available for autonomous use	• Low Cost	• Easy to use		
Disadvantages	• Reaction time of 30 min required before consumption after treatment	• Education and training for operators are essentials, especially when using Maxi-WATA®	• Only clear water can be used to produce WATA® solution and the solution only effective to treat clean water	• Electricity required (but can be run with solar energy)	• Chlorination can cause the generation of a very low concentration of toxic disinfection by-products (DBPs) in the case of disinfecting water with a high organic matter content
	• Dosage might be more difficult than with tablets	• Chlorine taste and smell			

Electrolytic Water Purifier

To prevent waterborne diseases it is fundamental to deliver safe water at the point of use. The 2017 published Joint Monitoring Programme (JMP) report from WHO and UNICEF shows that recontamination occurs very often between the point of collection and the point of use and thus leads to an increase in waterborne diseases. It is thus fundamental to find a solution to enable populations to address their drinking water problem in a self-sufficient and perennial way. To respond to the need of BoP communities to have access to simple and affordable water treatment methods at the household level, Antenna Foundation has developed a range of WATA devices (Mini-WATA, WATA-Standard, WATA-Plus, Midi-WATA and Maxi-WATA), and control reagents (the WataBlue & WataTest). Until today WATA kits have been used in over 100 countries.

WATA Devices The WATA is a handy, robust device designed specifically for the production of active chlorine through the electrolysis of salted water under conditions in developing countries. The resulting solution can be used for drinking water disinfection (1 Litre of chlorine per 4,000 Litres of contaminated water) since the strong oxidising power of the chlorine will destroy most of the pathogenic germs and the water will be drinkable after 30 minutes.	**Mini-WATA** 1 (g/h) active chlorine 0.5L or active chlorine in 3h **WATA-Standard** 4.8 (g/h) active chlorine 1L of active chlorine in 2h 30m	**WATA-Plus** 22.5 (g/h) active chlorine 15L of active chlorine in 4h **Midi-WATA** 45 (g/h) active chlorine in 4h	**Maxi-WATA** 80 (g/h) active chlorine 60L of active chlorine in 4h 30m

WATA

This sodium hypochlorite solution can also be used as a disinfectant for home use. The WATA® system is extremely adaptable to meeting the disinfectant needs of larger institutions such as health facilities also. Additionally, the sodium hypochlorite solution is similar to Dakin's solution, a neutral disinfectant, and can be used directly for cleaning wounds.

Use of WATA

The device requires only water, salt and electricity to function. It is important to note that clear water is a requirement for both the production process and as an input for the disinfection process. For the production process, highly turbid water will interfere with the electrolysis process and the resulting solution may not be at 6g of active chlorine per litre. If the turbidity (a measure of the suspended solids in the water) of the water to be disinfected exceeds 5 units of turbidity (NTU), it could diminish the treatment's efficiency and not guarantee adequate inactivation of microbes. If highly turbid water is the only source available, the suspended solids need to be removed, for example by (cloth) filtration, sedimentation or flocculation. The WATA is appropriate for urban and rural areas and foster people's autonomy where the technology is implemented. Since the WATA devices need a reliable electricity supply to operate, the Mini-WATA, WATA-Standard and the WATA-Plus are designed to be easily powered with solar energy.

Sodium Hypochlorite Production

The user first prepares salt water at 25g NACl/Litre. The WATA device needs to be immersed in the salt water and connected to a reliable source of electricity. The salt water is converted into sodium hypochlorite solution with a 6 g/L concentration of active chlorine through a process known as electrolysis. Potentially contaminated water can be made potable by adding a small dose of chlorine (5 mL chlorine per 20 L water). Despite the simplicity of operating a WATA device, the production of active chlorine and disinfection of potable water for a community is a responsibility, and thus requires skilled people as operators, specially trained and dedicated for that purpose.

Testing

WataTest and WataBlue reagents are part of the WATA kits and allow the user simple onsite water quality control. WataTest and WataBlue are non-toxic and inexpensive reagents which are used to measure the active chlorine concentration of sodium hypochlorite and free residual chlorine in the water, respectively. Free residual chlorine (FRC) is important because sufficient levels are required to ensure adequate inactivation of microbes and to guarantee the residual effect that chlorine has of preventing the recontamination of water during handling or consumption. Since increasing levels of FRC makes the water taste and smell unappealing, the WHO recommends a level of FRC between 0.2 and 0.5 ppm in order to strike a balance between disinfection and water taste and smell. 0.5 ppm is the level of FRC that the WHO recommends as striking the balance between effective disinfection and acceptability in terms of taste and smell. The WataBlue allows the user to carry out a safe and systematic quality control of the treated drinking water to ensure that this level is reached.

Maintenance

Devices need to be rinsed after each procedure with clean water. If after several uses you notice white marks on the WATA, prepare a solution of 50% white vinegar (or lemon juice) and 50% clean water. For the Mini-WATA and WATA-Standard, leave the device to soak for several hours (overnight for example) and then rinse it with clear water. Never scrub the titanium plates. WATA-Plus, Midi-WATA and Maxi-WATA need to be soaked for at least 24 hours and be completely immersed in the 6 – 10 L solution.

Storage

Properly used, well maintained and carefully stored after each use, WATA devices are designed to operate for 10,000 operating hours, or around 5 years of use. Active chlorine is very sensitive to light. It is therefore very important to store the solution produced with the WATA devices in closed and opaque, non-metallic recipients and label it with the production date. Place the container in a cool place, out of reach of children. Do not expose it to sunlight. The sodium hypochlorite should be used within 24 hours as the concentration of active chlorine will decline if the solution is not stabilized.

Potable Pure Aqua

The Potable Pure Aqua PURE Electrolytic Water Purifier is an example of one of these purifiers which is lightweight, small and can easily be fit into a BOB.

Electrolysis FAQ

- **White Blobs:** Adding too much salt to the brine solution causes white globs to form in the mixture.
- **Colour Change:** If the water is too "hard" it may alter the colour of the water during electrolysis.
- **Electrode Rust:** This is due to not washing the cathode and anode off after use and continual use will add rust to the water.

18 UV Light

The bactericidal effect of concentrated ultraviolet (UV) light is used in many areas and in many set-ups. For drinking water treatment, simple, commercially available UV tubes can be used to kill pathogenic microorganisms in the drinking water. Such UV tube water disinfection devices are an effective, low-cost and simple mean for a very rapid disinfection. They generally consist of a pipe, through which water slowly flows, and in which an UV light bulb is installed, which can be run on electric or solar power. There are many ways to design UV tubes devices and they can be used at household, community or institutional level. Even though very effective, however, chemical or physical pollution (e.g. salinity, heavy metals turbidity) cannot be treated and in opposition to chlorine, there is no residual disinfection effect.

Advantages	• Large quantities of disinfected water can be obtained quickly	• Minimum behaviour change required	• Can be constructed with locally available material	• Highly effective on broad range of pathogens, including E. Coli, Guardia and Cryptosporidium	• No risk for DBP formation (e.g. trihalomethanes)
	• Inactivation independent of pH and temperature	• No transportation, storage or handling of chemicals	• No unpleasant taste or odour (as it can appear for chemical treatments)		
Disadvantages	• Higher cost of equipment when compared with chlorine solution	• Requires regular power source for operation	• Lamp tube needs replacement every 6-12 months	• Some investment for installation is required	• UV lamp needs to be cleaned regularly and handled with care because of their mercury content
	• Only effective for microbial pollution	• No residual disinfection effect and risk of re-growth or recontamination			

UV Light
The bactericidal effect of concentrated ultraviolet (UV) light has been known over many years and is used in many areas and set-ups. The first use of UV light for drinking water disinfection has been reported to be in France in 1910. With the recent development of the UV tube, using locally available components, this technology is now a viable household water treatment method (CAWST 2009).

Facing the challenge that disinfection by-products (DBPs) are formed during chlorination of water containing high organic contents, simple physical instead of chemical disinfection methods, such as UV tubes have gained in interest. A typical UV system provides a flow path surrounding a UV lamp, structured to provide close proximity of the water flow along the length of the UV lamp all by preventing direct contact.

UV Radiation Disinfection Mechanism
The UV tube is basically the same as a commercial fluorescent bulb, except that it lacks the phosphor coating and the glass exterior is replaced by fused quartz. This means the bulb emits mostly UV light. UV light is generally defined to be wavelength of electromagnetic radiation shorter than 400 nm and is further divided into UV-A (315-400nm), UV-B (280-315nm) and UV-C (200-280 nm). UVA and UVB are responsible for sun tanning and sunburning. UVB is partly filtered out by the atmosphere and only a few percent reach the earth surface.

This is good, because UVB light can be directly absorbed by DNA, where it would induce cellular damage. UVC also penetrates cells and damage the DNA, but it is almost entirely filtered out by the ozone layer. The UV tubes used for disinfection do contain the whole spectrum of UV light, including the UVB and UVC. The light, when it reaches microbial cells leads to damage of the genetic material (DNA), rendering them unable to replicate.

The bulbs are suspended inside a larger tube in a covered channel. Water enters at one end and flows through the outlet at the other end. While the water flows through the tube, the UV light emitted from the bulb inactivates the microorganisms. The inactivation is directly related to continuous UV dose and depends on the intensity of the UV light and the duration of UV exposition. The height of the outlet determines the depth of the water in the tube and thus the hydraulic retention time.

In theory, the hydraulic retention time is equal to the exposure time of the microorganisms and should be designed, depending on the bulb intensity, to achieve a sufficiently long contact time for all microorganisms to be inactivated. For the calculations of the HRT, the intensity of the bulb may be adjusted according to the water depth of the farthest point away from the light source as the UV light is attenuated as it penetrates the water.

Effectiveness
UV tubes are effective in inactivating most pathogens, including bacteria, viruses, and cyst forming protozoa such as cryptosporidium (CAWST 2009). Yet, the effectiveness depends strongly on the UV dose. UV tubes are not effective for all pollution other than microbial (chemical and physical pollution) and there is now residual disinfection effect during storage of the treated water. The efficiency of UV light for bacterial inactivation is lowered by the presence of organic matter, iron, sulphites, and nitrites. Turbidity can also interfere with UV radiation, protect microorganisms from inactivation and serve as a food source for re-growth after the disinfection step. Therefore, it is common for UV tubes to incorporate a pre-filtration step, such as a settling unit.

Effective For
• Bacteria
• Viruses
• Protozoa
• Helminth Eggs

Not Effective For
• Turbidity
• Chemicals
• Taste
• Odour
• Colour

Operation
Operation and maintenance of UV tubes is generally low, provided that there is a more or less continuous source of electricity to run the bulb. Once the system is installed, the user needs to make sure that the theoretical flow rate of the water and the corresponding HRT are respected and that the bulb is working correctly. If the bulb becomes dirty, it needs to be taken out and cleaned to maintain the light emission intensity. The systems have generally a long life spam, but bulbs should be replaced at least once every 12 months. During any maintenance activity, however it is important that operators or users protect their skin and eyes from the UV radiation as it is also damaging for human cells.

Applicability
Ultraviolet is being widely used in the water supply systems for disinfection and has a potential to kill most bacteria, viruses, protozoa or helminths. Though, a more or less continuous energy supply is required and the system is not suitable for removing chemical contaminants or turbidity. There is also possibility of re-contamination during distribution or storage of the treated water as there is no residual disinfection effect. However, as it is only a physical treatment, there is low risk for the formation of toxic disinfection by-products (DBP). The UV tubes can be produced with locally available material and be installed at household, community or institutional level, as long as electricity is provided.

19 SODIS (Solar Disinfection)

When microbially polluted water is exposed to solar light in transparent PET bottles, bacteria, virus and some parasites are inactivated by the solar UV-A radiation. 1 to 2 litres of water are filled into clean bottles and exposed to the sun for at least 6 hours if the sky is bright. UV-A radiation is strongly attenuated by clouds; furthermore, turbidity or water depth protects the pathogens from UV-A radiation. Hence the process depends strongly on the local climate, and only low volumes with relatively low turbidity can be treated at a time. SODIS is extremely low-cost and simple and is one of the WHO recommended household level water treatments. However, chemical pollution (e. g. arsenic, fluoride, agricultural residues) cannot be removed by solar disinfection (SODIS).

Advantages	• Improves the microbiological quality of drinking water and therefore health	• Extremely low-cost	• Easy to understand and simple to use	• Relies on locally available resources, plastic bottles and sunlight, a renewable energy source	

Disadvantages	● Does not treat chemical pollution	● Is strongly climate and weather dependent	● Needs large efforts in terms of promotion and information to have an impact	● Requires the availability of PET bottles (or plastic bags)	● Only small volumes can be treated at a time and regardless the simplicity, it is relatively time-consuming to cover the entire water consumption of a household with SODIS

SODIS

Solar Water Disinfection (SODIS) is a simple water treatment technology that can be used at household level. As a point-of-use water purification method, SODIS improves the microbiological quality of drinking water with solar radiation at almost zero investment and maintenance costs. Today, SODIS is one of the recommended household level water treatment technologies by the World Health Organisation (WHO). PET (Polyethylene terephthalat) bottles or plastic bags with a volume of 1 to 2 litres are filled with water of low turbidity and exposed to the sun for a certain time, depending on the local weather conditions. The SODIS reference centre (www.sodis.ch) recommends, that 6 hours are sufficient under bright to 50% cloudy sky, whereas 2 days of exposure are required for 100% cloudy sky. The treatment efficiency can be improved if the plastic bottles are exposed on sunlight-reflecting surfaces such as aluminium- or corrugated iron sheets. During periods of continuous rainfall, SODIS does not perform satisfactorily and rainwater harvesting is recommended during these days.

- Use clean bottles
- Fill bottles
- Close the lid
- Expose to sunlight
- Water can be stored in the bottles

Process

UV-B light (280 to 320 nm) can directly be absorbed by DNA, leading to damage, but only 1% of natural solar light is of this type. Hence, sunlight used during the SODIS process consists mainly of UV-A light (320 to 400 nm), which makes 6% of the total solar light. This light can be absorbed by molecules, which are naturally present in the water. When these molecules (called photosensitizers) have absorbed the energy, they can pass it to the oxygen in the surrounding water, leading to the formation of reactive oxygen species (ROS). ROS include free radicals such as the superoxide anion as well as non-radicals such as hydrogen peroxide. ROS damage the membranes proteins, enhancing the oxidative stress of the cell and accelerating their aging process. But ROS can also lead to some DNA damage, such as single strand breaks and nucleic base modifications, which may be lethal and mutagenic. This type of pathogen inactivation Is called photooxidative stress. Photo- because it is the light which generates ROS, and oxidative stress, because these reactive oxygen species (ROS) lead to stress.

When the water temperature reaches more than 45°C, a synergistic effect of UV-A radiation (optical inactivation) and infrared light (thermal inactivation) is observed. At increased water temperatures, the exposure time needed to disinfect the water is reduced. But during cloudy weather conditions, the solar infrared light is reduced and bottles need to be exposed for 2 days to guarantee that the radiation dose received is sufficient to disinfect the water. In contrast to infrared light (heat), UV-A radiation is only slightly attenuated by clouds. But turbidity in the water reduces the amount of UV radiation that penetrates the water. Therefore, the containers used for SODIS should be relatively flat (i.e. not exceed a depths of 10 cm). Water turbidity can easily be determined: Place the full bottle on a newspaper headline (the letters should have a size of about 1.5 cm) and look through the bottle from top to bottom. Water turbidity is less than 30 NTU if you can read the letters through the water. If not, the water must be filtered first so that SODIS will work.

Suitable Containers

Suitable containers for SODIS are PET or glass bottles. Ordinary window glass is almost opaque to UV light and cannot be used to construct SODIS containers. The use of PVC bottles is not recommended. It is normally marked on the bottle whether it is PET or PVC, however, the labels vary from country to country. PET and PVC bottles are normally marked accordingly. The labels can vary from country to country, though. If the bottles are not marked, you can only tell the difference between the bottles by setting fire to them. PET burns quickly and easily when it is held in a flame. When it is taken out of the flame, the fire goes out slowly, or it may keep burning. The smoke smells sweet. PVC does not burn easily. The material does not burn at all when not in the flame. PVC smoke smells acrid. Heavily scratched or old PET bottle should be replaced regularly as the scratching makes them opaque.

Applicability

SODIS is not a replacement of the access to safe drinking water, as it is required to reach the millennium development goals, but a simple and extremely low cost method to improve the microbial quality of drinking water at household levels. Large volumes cannot be provided with the use of this method. SODIS can be used in both rural areas and urban slums, but PET bottles are generally more available in urban regions. SODIS cannot treat water that is chemically polluted (e.g. arsenic, fluoride or industrial and agricultural organic contaminants). SODIS is very well adapted as a secondary treatment of water coming from an improved source (e.g. well water), which does not meet the microbial quality standards. As SODIS requires a consistently sunny climate and solar irradiation, it is most suited for regions within latitudes of 15°N/ S and 35°N/ S. Turbidity can deteriorate the effect and if the latter is higher than 30 NTU, pre-filtration is required.

As SODIS is extremely low cost, it is adapted for population with little income. However it should not be sold as a method for the poor as this could lower the attractivity of SODIS as people don't like to be labelled as 'poor'. To distribute PET bottles for free will not result in a sustainable application. The integrated promotion together with other household-level drinking water treatments (e.g. chlorination, filtration) to give people the option to make a choice, seems the most promising. It is also recommended to combine SODIS with other interventions to improve the health, sanitation and hygiene situation. This approach allows also working in close collaboration with governmental or other large-scale interventions.

20 Copper/Silver Ionization

Copper-silver ionization is brought about by electrolysis. An electric current is created through copper-silver, causing positively charged copper and silver ions to form. Copper-silver ionization brings us back to basic chemistry: an ion; an electrically charged atom, has a positive charge when it gives up an electron and a negative charge when it takes up an electron. A positively charged ion in called a kation and a negatively charged ion is calles an anion. During ionization, atoms turn into kations or anions. When copper-silver ionization is applied, positively charged copper (Cu^+ and Cu^{2+}) and silver (Ag^+) ions are formed.

The electrodes are placed close together. The water that is disinfected flows past the electrodes. An electric current is created, causing the outer atoms of the electrodes to lose an electron and become positively charged. The larger part of the ions flows away through the water, before reaching the opposite electrode. Generally the amount of silver ions at a copper ion rate of 0.15 to 0.40 ppm lies between 5 and 50 ppb.
The ion concentration is determined by the water flow. The number of ions that is released increases, when electric charges are higher.
When copper ions (Cu^+) dissolve in water, they are oxidized immediately to form Cu^{2+} ions. Copper can be found in the water in free form. It is commonly bond to water particles. Copper (Cu^+) ions are unstable in water, unless a stabilizing ligand is present.

In the United States, several drinking water production companies use copper-silver ionization as an alternative for chlorine disinfection and to prevent the formation of disinfection byproducts. The standard for trihalomethanes was decreased by EPA from 100 to 80 µg/L.
When copper-silver ionization is combined with chlorine disinfection, it is an excellent disinfection mechanism to deactivate viruses and bacteria.

The affectivity of copper-silver disinfection depends on a number of factors:
Firstly, the concentration of copper and silver ions in the water should be sufficient. The required concentration is determined by the water flow, the volume of water in the system, the conductivity of the water and the present concentration of microorganisms.
Secondly, the electrodes should be in good condition. When the water is hard or fouling takes place as a consequence of water hardness and quality, there will be a decrease in electrode release and the additional effect will decrease. By using pure silver and pure copper, the supply of copper and silver ions can be regulated separately. These electrodes suffer from less limestone formation and fouling.
Thirdly, the affectivity of copper-silver ionization depends on the pH value of the water. When pH values are high, copper ions are less effective. When the pH value exceeds 6, insoluble copper complexes will precipitate. When the pH value is 5, copper ions mainly exist as Cu(HCO3)+; when the pH value is 7 as Cu(CO3) and when the pH values is 9 as Cu(CO3)22-.
Fourthly, copper-silver ionization affectivity is determined by the presence of chlorine. Chlorine causes silverchlorine complex formation. When this occurs, silver ions are no longer availbale for disinfection.

Copper-silver ionization can deactivate Legionella bacteria and other microorganisms in slow-running water and still water. Legionella bacteria are very susceptive to copper-silver ionization. Copper-silver ionization also takes care of bio film. Copper remains within the bio film, causing a residual effect. It appears that copper-silver ionization additon causes the number of Legionella bacteria to diminish. After a short period of time, however, the number of Legionella bacteria will rise again because they can also be found in the bio film.

Copper that stays behind in the bio film takes care of these bacteria. When copper and silver ions are added to water constantly, the concentration of Legionella bacteria remains low.
The deactivation rate of copper-silver ionization is lower than that of ozone or UV. A benefit of copper-silver ionization is that ions remain in the water for a long period of time. This causes long-term disinfection and protection from recomtamination. Copper and silver ions remain in the water untill they precipitate or absorb to bacteria or algae, and are removed from water by filtration after that.

Benefits
Copper-silver ionization affectively deactivates Legionella bacteria and bio film and it improves water quality. Copper-silver ionization has a larger residual effect than most other disinfectants. Copper and silver ions remain in the water for a long period of time. Because of its local affectivity, the effect is larger than that of UV. Copper-silver is effective throughout the entire water system, even in dead-end points and parts of the system that contain slow-running water.

Copper-silver use affectivity does not depend on water temperature. When copper-silver is used, less maintenance to the water system is required. Copper-silver is non-corrosive; it causes less strain on the distribution system. Because of a decrease in the use of chemicals, the lids and pumps are not affected. Furthermore, shower heads, tanks and taps are not contaminated. When copper-silver ionization is applied, there are no transport and storage difficulties.

Drawbacks
Copper-silver affectivity depends on the pH value of the water. At a pH value of 9, only one tenth of all Legionella bacteria are removed. When dissolved solid concentrations are high, silver will precipitate. This means silver ions are no longer available for disinfection.
Silver ions easily react with chlorines and nitrates that are present in the water, causing them to no longer be effective.
Some species of microorganisms can become resistant to silver ions. They can remove metal from their systems or convert it to a less toxic product. These microorganisms can become resistant to copper-silver ionization.

Although it is suggested that Legionella bacteria can develop resistance to copper-silver ionization, this disinfectant still appears to be effective for Legionella deactivation. To affectively kill pathogenic microorganisms, copper and silver ions should be present in the entire water system. When the system is used little and the water flow is quite slow, or when there are dead-end points in the system, this can causes problems for disinfection.

21 Colloidal Silver

Colloidal Silver Filters (CSF) are simple household water treatment devices based on a physical treatment, which does not require energy supply. CSFs use a clay candle, pot or disc made of porous ceramic materials similar to traditional ceramic filters. But in CSFs, colloidal silver is used to enhance the inactivation of bacteria and other germs. A filter set consists of two containers: the upper unit holds the ceramic coated with colloidal silver, filtering the water and killing microorganisms, while a lower unit stores the treated water. CSFs remove pathogens and turbidity from drinking water. They can be constructed with locally available material, which can contribute to the development of local commerce.

Advantages	• High removal of bacteria and protozoa; moderate removal of viruses	• Simple to install, operate and maintain	• Local production can create an opportunity small business	• Removes turbidity	• Water tastes and looks good
	• Portable container	• Easy to operate and maintain			
Disadvantages	• Does not removal chemical pollution (e.g. organics, arsenic, fluoride)	• Does not remove all viruses	• Needs to be cleaned regularly especially when using turbid water or water containing iron	• Relatively low flow rate	• Ceramic parts are fragile and are difficult to transport
	• Not applicable for extremely turbid water	• No residual disinfection effect (risk of recontamination)	• Small fissures and cracks may lead to reduced removal of pathogens		

Locally produced ceramics have been used to filter water for hundreds of years. Water is poured into a porous ceramic filter pot or in a pot containing a ceramic candle or disc, filtering the water. The filtered water is collected in another container. The filter removes turbidity and traps and kills pathogens from drinking water (see also ceramic candle filters). To enhance ceramic candle filters, colloidal silver can be added. Colloidal silver helps in pathogen removal and prevents the growth of microorganisms within the filter itself.

These enhanced forms of ceramic filters are called colloidal silver filters (CSF). CSFs were developed at the Central American Industrial Research Institute (ICAITI) in Guatemala in 1981 and are extensively promoted today. Currently, the most widely distributed ceramic filter is the Potters for Peace (PFP) colloidal silver filter, which is shaped like a flowerpot (see also pottersforpeace.org). The filters are designed in particular for simple household use and are a recommended household water treatment and safe storage (HWTS).

They can be produced locally by attending simple technical training. Ceramic filters consist of a set of two containers. The upper unit contains the ceramic unit, which filters the water and the lower unit collects filtered and safe water. A tab device allows the users to withdraw the water for consumption while preventing recontamination by contact with hands or other objects that could bear bacteria. The porous ceramic devices can be either one or two candles, a disc or a pot.

During use, tiny silver particles (colloidal silver) are suspended in the liquid acting as a disinfectant, preventing bacterial growth in the ceramic filter and enhancing inactivation of the bacteria in the filter. The colloidal silver is either added to the clay mixture before firing or impregnated on the fired ceramic pot.

How it Works
Pathogens and suspended material are removed from water through physical processes such as mechanical trapping and adsorption. Colloidal silver breaks down the pathogens' cell walls causing them to die. The filter operation is simple. First, the filter needs to be cleaned with clean water and left aside to dry naturally. Then, the filter units need to be assembled and the upper unit should be filled with water. Then, one has to wait until the water has passed the filter fort he first time. For security, the water filtered for the first time should not be used for consumption. Then, the filter can be refilled and the now filtered water collected in the lower storage unit can is ready to drink. To prevent clogging, water with a high turbidity (levels greater than 50 NTU) should first be strained (through a cloth) or settled before using the filter. The filter pot should be regularly cleaned using a cloth or soft brush to remove any accumulated material. It is recommended that the filter pot, candle or disc be replaced every 1-2 years. Cleaning prevents the formation of a biofilm and protects against fine invisible cracks, which may have developed over time. Any cracks will reduce the effectiveness since water can short-circuit without being filtered through the ceramic pores. However, make sure not to remove all the silver when using a brush for cleaning.

Treatment Efficiency
Candle filters and disc filters normally have a lower contact surface for the water and therefore the filters produce less treated water per day than pot filters. However, the effective treatment rate (or flow rate) depends on the design). A typical pot filter can produce up to 1-3 L/hour while a candle filter produces only 0.1 to 1 L/hour. The effectiveness of ceramic filters at removing bacteria, viruses and protozoa depends on the pore size of the ceramic material and the production quality of the filter unit. Most ceramic filters are effective at removing the majority of the larger protozoan and bacterial organisms and helminths, but not the smaller viral organisms. Laboratory testing has shown that although the majority of the bacteria are removed mechanically through the filter's small pores, colloidal silver is necessary to inactivate almost 100 % of the bacteria. The effectiveness of colloidal silver on viruses is not well known but estimated to be lower due to the smaller size of virus compared or silver particles. Turbidity (solids) is efficiently removed by physical straining (filtration) and also taste, odour and colour of filtered water by CSF is generally improved. Iron is partially removed but other dissolved chemical pollutions are not removed. The effectiveness of CSF colloidal filter has been proven in many studies, where the reduction of diarrhoeal disease incidence among users has been documented. For lack of residual protection, however, it is important for users to be trained on proper operation and maintenance of the ceramic filter and receptacle.

Applicability
CSFs are suitable for households using turbid and contaminated water. However, ceramic filters do not remove arsenic, fluoride, pesticides or other dissolved chemicals. Due to the limited flow rate and storage capacity, CSFs are suitable for households with small families, organisations or school classes. As iron is only partially eliminated, it is recommended to use raw water with little iron only (< 0.3mg/L). Chlorinated water should not be filtered in CSFs. Due to the risk of clogging, water with a turbidity above 50 NTU should be pre-settled or strained to avoid frequent cleaning of the filter.

Creating Colloidal Silver
Distilled water is a fairly good insulator, with a constant voltage connected to silver electrodes in distilled water, the initial current flow is very low because the water has high resistance to electron flow. However, as the silver ions and particles finally do start to accumulate in the water, the resistance in the water drops from the conductive silver building up. The silver comes off the positive electrode as ions (single atoms, missing an electron) carrying a positive electrical charge due to the lack of an electron. As silver particles build up the resistance decreases creating more faster. Silver ions build up and keep gaining size, reflecting yellow light and falling out of suspension. Mechanical stirring solves this problem and uniformity of size is very important. Do not use salt in the reaction. Thicker wire = lower gauge. 14 gauge - 1.63mm, 12 gauge - 2.06mm and 10 gauge - 2.59mm. Thicker gauge silver wires have more surface area and because the size of particles made is directly related to the amount of electrical current per unit area, the thicker gauge wires will make smaller colloidal silver particles for the entire processing run. If you want to skew the range of particle sizes to smaller particles, use 12 and even better, 10 gauge wire, rather than 14 gauge. 1-100nm is a typical size for colloidal silver.

22 Ceramic Candle Filter

Ceramic candle filters (or Berkey Filters) are simple devices made out of clay and used to filter drinking water in order to removes turbidity, suspended materials and pathogens. Removal takes place by physical process such as mechanical trapping and adsorption on the ceramic candles, which have micro-scale pores. Water is poured into the upper of two container and flows through a candle situated in the bottom. Once the water has passed through the candle, it is collected in the lower container. This system both treats the water and provides safe storage until it is used. The filters are easy to assemble and no energy is required. Maintenance includes frequent scrubbing with a brush and proper care during transport and its use. They can be constructed with locally available material, which can contribute to the development of local commerce.

Advantages	• Cheap, simple and easy to use and clean	• Can be constructed with locally available material	• Somewhat effective for the removal of viruses and iron	• Improves taste, smell and colour of water	• Removes pathogens, turbidity and suspended solids
	• Keeps water cold and safe	• Durable, easy to move and transport (except clay pot)			
Disadvantages	• Does not remove all the pathogens	• Does not remove chemical contaminants and colour	• Highly turbid or iron containing water plugs candle pores	• Low flow rate	• Ceramic candle and clay container is not easy to transport due to its fragility and heavy weight
	• Quality control difficult to ensure in local production				

Ceramic Candle Filter
The use of ceramic material for the filtration of drinking water is one of the oldest drinking water treatments. Nowadays, the ceramic candle filters and the colloidal silver filter (see also the colloidal silver filter factsheet) are the most widely used. The devices consist of two compartments, which allow simultaneous treatment and save storage of the drinking water. Candle filters are used in various countries and produced by a range of manufacturers around the globe. Ceramic candle filters basically consist of an upper and a lower container, one or more ceramic candles in between, a tap and a lid. Usually the containers have a diameter of about 30 by 25 cm depth for a treatment capacity of about 8 L and a flow rate of 1-2 L per hour per candle. The ceramic candles are screwed into the base of the upper container. To the lower container is attached a tap that allow to withdraw safe water without risking recontamination. A lid is placed on top of the upper container to prevent contamination. Candles can have very slow flow rates, so it is common to use two or more candles in one filter. The candles are made up of clay and the container can be made from plastic, aluminium, copper, steel or clay material. Though clay containers keep water cold and tasty, due to its fragile nature other materials nowadays replace it.

How It Works
Water is poured into the upper container and flows through the candle and collects in lower container. Turbidity, suspended materials and pathogens are removed from water through mechanical trapping and adsorption in micro-scale pores of ceramic candles. Colloidal silver is sometimes used in candle for more effective pathogen removal.

Operation and Maintenance
Water should be poured slowly into the container, not above the candle as regular water pressure may damage fragile candle. Candle needs to be replaced if any cracks are found: cracks will reduce the effectiveness since water can pass through that crack without being filtered through the ceramic pores. Candle needs regular cleaning, particularly when the flow rate slows down. The candle is cleaned by (slightly) scrubbing the candle surface with a soft scrubber brush or cloth to remove any accumulated dirt. Only clean water (no soap, chlorine or other chemicals!) should be used for cleaning. The candle should not be touched with dirty hands, and not placed on a dirty surface during cleaning. Storage containers, tap and lid should be cleaned on a regular basis using soap and water.

Effectiveness Ceramic candle filters are effective in removing bacteria, protozoa, helminths and turbidity from water. It also removes some viruses and iron and taste, smell and colour of water are improved. The effectiveness of the filter also depends on the production quality, the initial water quality, and the handling practices of users. Highly turbid or iron containing water may plug candle pores easily so that container and candle need to be cleaned more frequently. In this case, the water should be pre-settled before pouring it into filter. It is recommended to use raw water with less iron (<0.3mg/L) and turbidity (<5NTU).	**Bacteria** Lab: >99% Field: >99.95% **Viruses** Lab: >90% Field: N/A **Protozoa** Lab: >100% Field: >100%	**Helminths** Lab: >100% Field: >100% **Turbidity** Lab: 88-97% Field: 97-99%

Production
Candle filters can be manufactured at a local level and contribute to the development of local commerce. Local production process provides financial supports to household and voluntary labours. However, the production of ceramic filters is a lengthy process and a quality control process is required to ensure candle filter's effectiveness. Quality can be affected by variations in clay composition across geographic regions. Variability in weather conditions also makes long-term production planning difficult, and lack of storage can complicate storage of filters. The fragility of ceramic filters can make their transport difficult. A supply chain and market availability for replacement of candles and taps is required. Filters typically come with illustrated instructions in market.

Applicability
Ceramic candle filters are easy to set up and operate, cheap and effective in removing bacteria, protozoa, helminths and turbidity from water. It also removes some viruses and iron and taste, smell and colour of water are improved. But due to the limited flow rate (i.e. 1-2liter/hour) and storage capacity, filters are only suitable for small families, organisations or school classroom. It is suitable where drinking water is little turbid (<5NTU) and contaminated and with little iron (<0.3mg/L). In the case of too high turbidity, water can be presettled. Chlorinated water should not be used in candle filters! Except for clay, filter containers of other materials are easy to transport and handle.

23 Membrane Filtration

Membranes are thin and porous sheets of material able to separate contaminants from water when a driving force is applied. Once considered a viable technology only for desalination, membrane processes are increasingly employed in both drinking water and wastewater treatment for removal of bacteria and other microorganisms, particulate material, micropollutants, and natural organic material, which can impart colour, tastes, and odours to the water and react with disinfectants to form disinfection by-products (DBP). As advancements are made in membrane production and module design, capital and operating costs continue to decline.

Membranes emerged as a viable means of water purification in the 1960s with the development of high performance synthetic membranes. Implementation of membranes for water treatment has progressed using more advanced membranes made from new materials and employed in various configurations. An increasing scarcity in fresh water sources fuelled a push towards alternative resources such as ocean water. Membranes are becoming increasingly popular for production of potable drinking water from ground, surface and seawater sources, as well as for the advanced treatment of wastewater and desalination.

Overview	**Working Principle** Pollutants are separated as water is forced to pass through the membrane.	**Capacity/Adequacy** Simple but high-tech.	**Performance** Excellent separation capacity.	**Costs** Relatively low operation costs.	**Self-Help Compatibility** Process can be automatized but operators required for the control.
	O&M Membranes have to be backwashed on a regular basis to avoid fouling and to increase their lifetime.	**Reliability** Reliable when membranes are maintained properly (backwashing).	**Main Strength** High performance and simple.	**Main Weakness** Membrane fouling, which implies backwashing operation or membrane replacement.	

Advantages	• High performance	• Compact units: less space needed than conventional treatment schemes	• Simple operation	• Membranes available can be used to separate many kinds of contaminants	• Disinfection can be performed without chemicals
Disadvantages	• Membrane fouling	• Production of polluted water (from backwashing)	• Membranes have to be replaced on a regular basis		

Membranes
There are four main types of modules: plate-and-frame, tubular, spiral wound, and hollow fibre. The plate-and-frame module is the simplest configuration, consisting of two end plates, the flat sheet membrane, and spacers. In tubular modules, the membrane is often on the inside of a tube, and the feed solution is pumped through the tube. The most popular module in industry for nanofiltration or reverse osmosis membranes is the spiral wound module. This module has a flat sheet membrane wrapped around a perforated permeate collection tube. The feed flows on one side of the membrane. Permeate is collected on the other side of the membrane and spirals in towards the centre collection tube. Hollow fibre modules used for seawater desalination consist of bundles of hollow fibres in a pressure vessel. They can have a shell-side feed configuration where the feed passes along the outside of the fibres and exits the fibre ends. Hollow fibre modules can also be used in a bore-side feed configuration where the feed is circulated through the fibres. Hollow fibres employed for wastewater treatment and in membrane bioreactors are not always used in pressure vessels. Bundles of fibres can be suspended in the feed solution and the permeate is collected from one end of the fibres.

Water treatment processes employ several types of membranes. They include microfiltration (M-F), ultrafiltration (U-F), reverse osmosis (R-O), and nanofiltration (N-F) membranes. Microfiltration membranes have the largest pore size and typically reject large particles and various microorganisms. Ultrafiltration membranes have smaller pores than microfiltration membranes and therefore, in addition to large particles and microorganisms, they can reject bacteria and soluble macromolecules such as proteins. Reverse osmosis membranes are effectively non-porous and, therefore, exclude particles and even many low molar mass species such as salt ions, organics, etc. Nanofiltration membranes are relatively new and are sometimes called "loose" reverse osmosis membranes. They are porous membranes, but since the pores are on the order of ten angstroms or less, they exhibit performance between that of reverse osmosis and ultrafiltration membranes.

Membrane Materials
Most membranes are synthetic organic polymers (e.g. polysulfone, cellulose acetate). Microfiltration and ultrafiltration membranes are often made from the same materials, but they are prepared under different membrane formation conditions so that different pore sizes are produced. Membranes can also be prepared from inorganic materials such as ceramics or metals. Ceramic membranes are microporous, thermally stable, chemically resistant, and often used for microfiltration. However, disadvantages such as high cost and mechanical fragility have hindered their widespread use. Metallic membranes are often made of stainless steel and can be very finely porous. Their main application is in gas separations, but they can also be used for water filtration at high temperatures or as a membrane support. The current tendency on membrane development is to use nanofunctionalised membranes. Polymer membranes doped with silver nanoparticles to avoid biofouling is an example of such modern membranes.

Membrane Fouling
Membrane fouling is a process where solute or particles deposit onto amembrane surface or into membrane pores in a way that degrades the membrane's performance. It is a major obstacle to the widespread use of this technology. Membrane fouling can cause severe flux decline and affect the quality of the water produced. Severe fouling may require intense chemical cleaning or membrane replacement. This increases the operating costs of a treatment plant. There are various types of pollutants: colloidal (clays, flocs), biological (bacteria, fungi), organic (oils, polyelectrolytes, humics) and scaling (mineral precipitates). Fouling can be divided into reversible and irreversible fouling based on the attachment strength of particles to the membrane surface. Reversible fouling can be removed by a strong shear force of backwashing. Formation of a strong matrix of fouling layer with the solute during a continuous filtration process will result in reversible fouling being transformed into an irreversible fouling layer. Irreversible fouling is the strong attachment of particles, which cannot be removed by physical cleaning.

Operation
Raw water quality must be reviewed frequently and operational parameters of the membrane treatment train should be continually trended and compared to original start up conditions. Pre-treatment efficiencies and post treatment works should also be monitored closely. These tasks can alert operators of pending problems in time for corrective action to occur before production capabilities are impacted. While some changes in the treatment process may not significantly impact plant productivity or finished water quality, they may result in membrane degradation, more frequent cleaning, and generally higher operating costs over time if not properly addressed. When treatment or equipment failures become apparent, it is critical that adequate maintenance resources are made available. As with any industrial facility, routine preventive maintenance activities should be performed prudently as scheduled, while responsiveness to unforeseen repairs also needs to be timely. Unlike other treatment technologies, which produce lower quality product as the raw water quality degrades, membrane systems produce consistent water quality while the systems themselves degrade. Therefore, early detection of raw water changes and making adjustments to the operational parameters to accommodate the changes are the key to successful plant operation. A well-designed plant should include the necessary “tools” and have proper and adequate provisions for conducting routine tests and inspections. Such provisions include a well-equipped laboratory, tools and provisions for testing, and sample points for profiling.

Costs
Membrane filtration systems’ capital costs, on a basis of dollars per volume of installed treatment capacity, do not escalate rapidly as plant size decreases. This factor makes membranes quite attractive for small systems. In addition, for groundwater sources that do not need pre-treatment, membrane technologies are relatively simple to install, and the systems require little more than a feed pump, a cleaning pump, the membrane modules, and some holding tanks.

Applicability
Membrane processes have become more attractive for potable water production and advanced wastewater treatment in recent years due to the increased stringency of regulations, water scarcity, and decreasing costs of membranes. Membrane processes have excellent separation capabilities and show promise for meeting many of the existing and anticipated drinking water standards. Membrane processes are very versatile: for example ultrafiltration and microfiltration are efficient for turbidity suspended particles and microbial removal, nanofiltration and ultrafiltration membranes for organics (e.g. DBP precursors, micropollutants) and viruses separation, and reverse osmosis process for desalination and removal of small size organic contaminants.

24 Reverse Osmosis

Reverse osmosis has become the water purification method of choice for drinking water in many households and bottling plants throughout the world. It is a very efficient method to purify water from even very small molecules. There are many providers of reverse osmosis filter devices but, in general, the treatment stages are the same. It is possible to combine reversed osmosis filters with UV, infrared technology, or ozonation for disinfection (see also UV tubes and ozonation). Most reverse osmosis filters have 4 to 6 filter stages in different combinations.

Stage 1	**5 Micron Sediment Filter:** Removes dirt, rust and sand particles.
Stage 2	**Granular Activated Carbon Filter or Carbon Block Filter:** Takes out 99% of the chlorine and organic chemicals and provides enhanced reduction of taste, odour, and colour.
Stage 3	**1 Micron Sediment Filter:** Provides effective filtration to protect the membrane.
Stage 4	**Reverse Osmosis (RO) Membrane:** A thin film composite (TFC) high quality membrane processes 80 gallons (300 litres) per day. It removes the following hard water contaminants that may be present in the water: lead, cooper, barium, chromium, mercury, sodium, cadmium, fluoride, nitrite, nitrate, and selenium.
Additional Filter Stages	Some systems may use these additional filters below.
Stage 5	**Post Carbon Filter:** Removes objectionable tastes and odours to enhance the quality of drinking water.
Stage 6A	**Deionisation (DI) Filter:** Produces 99.99% pure water by simply attaching this convenient deionisation filter with RO unit. A convenient post RO filtration DI unit (RO/DI unit) provides crucial supplemental filtration to remove most impurities for pure polished product water. Excellent in areas with hard water.
Stage 6B	**Mineral Filter:** This filter improves the qualities of clean water by adding minerals which are necessary for proper human development and health, such as calcium, magnesium, sodium, potassium and others readily found in many natural mineral waters.
Stage 6C	**Ultraviolet Water Steriliser:** Ultraviolet light (UV), a natural part of sunlight is widely accepted as a reliable, efficient & environmentally friendly solution for water disinfection. The UV lamp destroys 99.99% of bacteria and viruses.

Reversed osmosis filter systems might be too expensive for some parts of the world. They also need a power supply (pump) if the water pressure is too low and should not be used for water which is over 45°C (113°F). The filter system should not be frozen and an ideal water pressure should be provided. The three pre-filters should be changed every 6 months depending on water quality.

25 Hydrogen Peroxide

Hydrogen peroxide (H2O2), a colourless water-like liquid, is one of the most versatile, reliable and environmentally friendly oxidising agents. The relative safety and simplicity of its uses has led to the development of a number of applications in water treatment such as odour removal, disinfection or metal removal. Hydrogen peroxide is also used in advanced oxidation processes (AOP) and can be combined with catalysts or other oxidisers to produce reactive oxygen species (ROS) able to attack a wide range of organic compounds and microorganisms. The production of hydrogen peroxide is usually performed at industrial scale but can also be done directly in drinking water (or pre-treated wastewater) by electrolysis.

Overview	**Working Principle** H2O2 s breaks down (spontaneously or with a catalyst) into water producing reactive species that react with microorganisms and pollutants	**Capacity/Adequacy** Relatively high-tech equipment required for "catalysed" H2O2 treatments	**Performance** High efficiency	**Costs** Relatively high operation costs for "catalysed" H2O2 treatments	**Self-Help Compatibility** Engineers are required for the design
	O&M Continuous input of H2O2 required	**Reliability** Reliable if the treatment is designed according to each application	**Main Strength** Very versatile and environmentally compatible oxidising agent	**Main Weakness** Continuous input of H2O2 required	

Advantages	• Destroys toxic organic compounds without pollution transfer to another phase	• Does not produce harmful residues	• Can be combined with catalysts and other oxidisers	• Works for water disinfection (destruction of microorganisms)	• Efficient in treating almost all organic pollutants and in removing some toxic metals
Disadvantages	• Relatively high operation costs due to input of H2O2	• Engineers, additional power and/or chemicals are required for the design of "catalysed" H2O2 treatment systems			

Hydrogen Peroxide
Hydrogen peroxide (H2O2) is a powerful oxidiser that decomposes into an environmental compatible product (water and oxygen). H2O2 is formed under the action of sunlight in natural surface waters due to the presence of natural organic constituents. This mechanism contributes to water purification within the environment. H2O2 is widely used as a bleaching agent for paper and textiles as well as in industrial applications to manufacture or process products. H2O2 can be used for water treatment alone or combined with UV light, a catalyst and/or other oxidants like ozone (see also ozonation). The hydrogen peroxide-based processes are versatile and can treat organics, microbial contamination as well as some inorganic compounds. H2O2-based treatments can be used both for drinking water purification (e.g. to remove bacteria, odour, micropollutants, etc.), and for municipal or industrial wastewater treatment (effluent disinfection, organics degradation, see also advanced oxidation).

Process
The active part of hydrogen peroxide is the peroxide group, which is an oxidant similar to ozone (see ozonation) or chlorine (see chlorination). When dissolved in water, H2O2 spontaneously breaks down into water and oxygen. This decomposition leads to the formation of reactive oxygen species (ROS), which can oxidise certain organics and metal ions and can also kill pathogens. Optimisation of conditions using H2O2 to destroy these pollutants can involve control of pH, temperature and reaction time. No additional additives are required.

"Catalysed" Hydrogen Peroxide
H2O2 can be used in combination with catalysts: UV light and/or other oxidants. The UV light allows the production of an oxidising agent (ROS) called hydroxyl radical (.OH). .OH is one of the strongest oxidants known, much more efficient than hydrogen peroxide alone and is therefore much more efficient in killing microorganisms and degrading organics in water.

H2O2 + UV light --> 2 .OH

Another way of generating hydroxyl radical from H2O2 is the use of a catalyst. The use of iron ions as a catalyst is a common approach and is referred to as Fenton process.

Fe2+ + H2O2 --> Fe3+ + OH- + .OH

This reaction is enhanced by the use of solar light (photo-Fenton).

The addition of both hydrogen peroxide and ozone (peroxone) to wastewater accelerates the decomposition of ozone and enhances the production of hydroxyl radical.

Hydrogen Peroxide Generation
The classical manufacturing process involves the catalytic reaction of Hydrogen (H2) with atmospheric oxygen (O2) to give H2O2. Anthraquinone (Q) is used as a hydrogen carrier. Palladium catalyses the reaction between H2 and Q to create H2Q in solution. Then the solution is oxidised by blowing air producing H2O2 (H2Q + O2 --> H2O2 + Q). Hydrogen peroxide can also be produced directly in wastewater by water electrolysis using electrodes. The required oxygen can be supplied by transfer from the atmosphere.

Cost Considerations
Costs depend on the specifics of the requirement (e.g. H2O2 strength and grade, volume per year, packaging and delivery volumes, and location/proximity to production plant, etc.). For large amounts of technical grade 30% H2O2, the price is roughly a few dollars per kg.

Applicability
The strong oxidising power of H2O2 makes it suitable for the destruction of a variety of pollutants such as bacteria, toxic organic compounds and some metals. The process has many applications in drinking water production: taste and odour control, hydrogen sulphide removal, metal removal, ozone enhancement and disinfection. H2O2has also been used for many years to degrade organics in industrial or municipal wastewater. It can also be used for the disinfection of wastewater treatment plants. When H2O2 is combined with UV light, catalyst or other oxidants, the resulting treatment is more efficient in destroying organics present in high strength wastewaters. When H2O2 is used on its own, the operational costs are limited to input of H2O2. In case of "catalysed" H2O2 treatments, the design is more complex and additional power and/or chemicals input is required.

26 Ozonation

Ozonation (also referred to as ozonisation) is a chemical water treatment technique based on the infusion of ozone into water. Ozone is a gas composed of three oxygen atoms (O3), which is one of the most powerful oxidants. Ozonation is a type of advanced oxidation process, involving the production of very reactive oxygen species able to attack a wide range of organic compounds and all microorganisms. The treatment of water with ozone has a wide range of applications, as it is efficient for disinfection as well as for the degradation of organic and inorganic pollutants. Ozone is produced with the use of energy by subjecting oxygen (O2) to high electric voltage or to UV radiation. The required amounts of ozone can be produced at the point of use but the production requires a lot of energy and is therefore costly. Ozone (O3) has been used in water treatment since the late 19th century. Today it is applied for the disinfection of drinking water, for the removal of effluents from wastewater treatment plants in a process called ozonation (or ozonisation) as well as for the degradation of organic and inorganic pollutants in wastewater (see also advanced oxidation process).

Overview	**Working Principle** Infusion of ozone, a gas produced by subjecting oxygen molecules to high electrical voltage, which reacts with microorganisms and pollutants	**Capacity/Adequacy** High tech equipment required	**Performance** High efficiency	**Costs** Relatively high operation costs	**Self-Help Compatibility** Engineers are required for the design
	O&M Continuous input of electrical power required	**Reliability** Reliable if operating conditions are scaled taking into account wastewater content	**Main Strength** Very efficient and fast method for disinfection and as a AOP	**Main Weakness** Requires complicated equipment as well as large amounts of energy and qualified operators	

Advantages	• Rapidly reacts with bacteria, viruses and protozoa over a wide pH range	• Stronger germicidal properties than chlorination	• No chemicals are added to water	• Also efficient for organics degradation and inorganics removal	• Removes colour, taste and odour
Disadvantages	• Relatively high equipment costs	• Requires large amounts of energy	• Qualified professionals required for design and system maintenance	• Formation of potentially harmful disinfection by-products (DBPs) in the case of brome existence in water	• No residual effect is present in the distribution system
	• Potential fire hazard and toxicity associated with ozone generation				

Disinfection with Ozone
Ozone is an excellent disinfectant and can even be used to inactivate microorganisms such as protozoa, which are very resistant to conventional disinfectants. However, ozone is an unstable gas that transforms to oxygen hence no residual disinfection effect takes place with ozonation.

Degradation of Pollutants
Ozonation is an efficient treatment to reduce the amounts of micropollutants released in the aquatic systems by wastewater treatment plants. Although no residual by-products are generated by ozone itself, some concerns are raised regarding oxidation by-products when water containing both organics and ions, such as bromide, iodide and chlorine ions, are treated with ozonation. A typical ozonation system consists of an ozone generator and a reactor where ozone is bubbled into the water to be treated.

Ozone Effect
The effectiveness of ozone results from its powerful oxidising effect on chemicals and microorganisms caused by the generation of reactive oxygen species during ozone transformation to oxygen. Ozone directly attacks the surface of microorganisms and destroys their cell walls. The cells thus loose their cytoplasm and can no longer reactivate themselves. Ozone can induce an oxidative degradation of many organics and leaves more biodegradable compounds. Besides, ozone can oxidise metallic ions such as Fe(II), Mn(II) or As(III) producing insoluble solid oxides that can be easily separated from water by filtration or sedimentation.

Ozone Production
Because of its relatively short half-life, ozone is generated on-site by an ozone generator. The conventional ways to produce ozone are UV-light and corona-discharge. Ozone generation by corona-discharge is most common nowadays and has many advantages such as longer lifespan of the unit, higher ozone production and higher cost efficiency. Production with UV-light is an option where only small amounts of ozone are required. Other ozone generators that are available involve electrolysis of water and the use of membranes. With this method, the ozone is dissolved in the process water as soon as it is formed resulting in ozonation using minimum equipment.

Technical Aspects
Whilst ozone is the most effective disinfectant overall and is more effective than chlorine in inactivating viral agents, there are significant disadvantages to its use. Ozone does not provide residual protection against recontamination during distribution and as ozone affects biological stability, it may encourage re-growth of bacteria. However, given the concerns about the use of chlorine in many countries because of the formation of toxic disinfection by-products (DBP), the use of ozone is increasingly investigated and the lack of residual may be dealt with by employing regular booster ozonation during distribution.

Cost
The cost of ozone disinfection systems depends on the manufacturer, the site, the capacity of the plant, and the characteristics of the wastewater to be disinfected. Ozonation costs are generally high in comparison to other disinfection techniques. For the removal of micropollutants in wastewater, the additional operation costs for ozonation combined with sand filtration are around 3-4 Swiss cents/m3.

Operation
Ozone generation uses a significant amount of electrical power. Constant attention must thus be given to the system to ensure that power is available. Moreover, ozone should not be released from the system and connections in or surrounding the ozone generator should not be leaking. The operator must monitor the appropriate subunits on a regular basis to ensure that they are not overheated. Therefore, the operator must check for leaks routinely since a very small leak can cause unacceptable ambient ozone concentrations.

Health
There are significant health and safety concerns for operators regarding the production and application of ozone. However, far less is known about ozonation and the effect of ozone on human health. There are also concerns regarding by-product formation during the disinfection of drinking water containing bromide ions.

Applicability
Ozonation has been successfully applied for water disinfection and can kill most bacteria viruses and protozoa. However, there is no residual disinfection effect and ozonation is more expensive than chlorination. Ozonation is a suitable process to degrade organic pollutants (e.g. for micropollutants removal and landfill leachate pre-treatment) and oxidise metallic ions (e.g. iron manganese). Design and construction needs skilled staff and high-tech equipment. Sophisticated generators consuming high-amounts of electricity are required to produce ozone. Although operation and maintenance costs are relatively low, precise monitoring and dosing adjustment of ozone is needed to ensure the efficiency of the treatment.

27 Solar Desalination

Solar desalination is a technique to produce water with a low salt concentration from sea-water or brine using solar energy.

WATER Purification Methods Electrodialysis

28 Electrodialysis Desalination

Electrodialysis is a membrane-based process involving transport of ions through semipermeable membranes using an applied electric field. The applications employing electrodialysis include desalination, table salt production, wine stabilization, whey demineralization, and pickling bath recovery. The process involves an electrodialysis cell in which the feed stream and the permeate stream are separated by polyelectrolyte membranes. Electrodialysis is quite unique among practical desalination processes since it literally desalts the feed source, whereas other processes actually remove pure water. ED is a membrane process utilizing charge-selective membranes and is pressure-based, like RO.

Electrodialysis (ED) was the first commercialized membrane-based desalination technology. It currently serves a relatively small percentage of the drinking water industry having been displaced by the preferential adoption of RO.

29 Ion Exchange

Ion exchange is a water treatment method where one or more undesirable ionic contaminants are removed from water by exchange with another non-objectionable, or less objectionable ionic substance. Both the contaminant and the exchanged substance must be dissolved and have the same type of electrical charge (positive or negative). A typical example of ion exchange is a process called "water softening" aiming to reduce calcium and magnesium content. Nevertheless, ion exchange is also efficient in removing toxic metals from water.

Overview	**Working Principle** Undesirable ionic contaminants are removed from water by exchange with another non-objectionable, or less objectionable ionic substance.	**Capacity/Adequacy** Relatively simple technology.	**Performance** Efficient technology to remove ionic substances from water and to soften water.	**Costs** Relatively low costs.	**Self-Help Compatibility** Monitoring is necessary to manage the regeneration process.
	O&M Ion exchange resin must be regenerated regularly.	**Reliability** Reliable if ion exchange resin regenerated properly.	**Main Strength** Efficient to remove dissolved inorganics.	**Main Weakness** Do not remove particles or bacteria.	

Advantages	• One of the most appropriate technologies to removes dissolved inorganic ions effectively	• Possibility to regenerate resin	• Relatively inexpensive initial capital investment
Disadvantages	• Does not remove effectively bacteria	• High operation costs over long-term	• The process of regenerating the ion exchange beds dumps salt water into the environment (regeneration)

Introduction
In 1850, Thomas and Way performed some of the first scientific research that indicated the existence of an ion exchange process. In their experiment, a solution of ammonium sulphate was passed through soil. The filtrate collected was composed of calcium sulphate instead of ammonium sulphate. The importance of this discovery (in ion exchange terms) was not fully understood until later in that decade, when it was found that this reaction was reversible. Ion exchange was then primary used to soften water. The presence of calcium and/or magnesium in water results in water being considered "hard". Calcium and magnesium ions in water react with heat, metallic plumbing and chemical agents such as detergents to decrease the effectiveness of nearly any cleaning task. Hard water can be softened using an ion exchange softening process. Ion exchange processes can also remove various charged atoms or molecules (ions) such as nitrates, fluoride, sulphates, perchlorate, iron and manganese ions as well as toxic metals (radium, uranium, chromium, etc.) from water. The most typical application of ion exchange is the preparation of high purity water for industrial applications, water softening, recovery or removal of metals in the chemical industry.

Ion Exchange Resins
Synthetic and industrially produced ion exchange resins consist of small, microporous beads that are insoluble in water and organic solvents. The most widely used base-materials are polystyrene and polyacrylate. The diameter of the beads is in the range of 0.3 to 1.3 mm. The beads are composed of around 50% water, which is dispersed in the gel-structured compartments of the material. Since water is dispersed homogenously throughout the bead, water-soluble materials can move freely in and out. To each of the monomer units of the polymer, so called "functional groups" are attached. These functional groups can interact with water-soluble species, especially with ions. Ions are either positively charged (cations) or negatively charged (anions). Since the functional groups are also charged, the interaction between ions and functional groups is exhibited via electrostatic forces. Positively charged functional groups interact with anions and negatively charged functional groups interact with cations. The binding force between the functional group and the attached ion is relatively weak. The exchange can be reversed by another ion passing across the functional group. This process can be repeated continually, with one exchange reaction following another.

Ion Exchange Process
The main component of ion exchange equipment is a microporous exchange resin, which is supersaturated with a loosely held solution. For water softening, this is usually done with sulfonated polystyrene beds that are supersaturated with sodium to cover the bed surface. As water passes through this resin bed, ions attach to the resin beads releasing the loosely held solution into the water. After a time, the beds become saturated and the exchange resin must be regenerated or recharged. To regenerate, the ion exchange resin is flushed with a salt brine solution. The sodium ions in the salt brine solution are exchanged with the ions, which are flushed out with wastewater.

Operation
Maintenance of water softening equipment is somewhat dependent on the type of softener. Some degree of monitoring or managing the regeneration process is generally required. Adequate backwashing of the resin bed is important to ensure the regeneration of the unit. However, regeneration creates wastewater.

Costs
The costs for ion exchange systems are very variable depending on scale and region. Moreover, costs depend on pre-treatment requirements, discharge requirements and utilisation.

Health Aspects
People on restricted sodium diets due to health reasons should account for increased intake through softened water. Drinking and cooking with softened water is often avoided by having a cold water line to the kitchen tap that bypasses the water softener. This provides hard water for drinking cooking and other uses. It is not recommended to repeatedly use softened water for plants, lawns or gardens due to the sodium content.

Applicability
The most common applications of ion exchangers are water softening (remove calcium and magnesium ions), water demineralisation (removal of all ions), and de-alkalisation (removal of bicarbonates). Cation exchange resins can also remove most positively charged ions in water such as iron, lead, radium, barium, aluminium and copper among others. Anionic exchange units can remove nitrate, sulphate, and other negatively charged atoms (called anions). Researchers are developing resins to selectively remove nitrate more efficiently than can currently be done. Ion exchangers are also used to remove or recover metal ions from wastewater in the chemical industry. Some contaminants (such as arsenic, fluoride, lithium ions) are difficult to remove with ion exchange due to a poor selectivity of the resins. Ion exchangers are also used to remove or recover metal ions from wastewater in the chemical industry. Some contaminants (such as arsenic, fluoride, lithium ions) are difficult to remove with ion exchange due to a poor selectivity of the resins.

30 Geothermal Desalination

Geothermal desalination is a process under development for the production of fresh water using heat energy.

31 Freezing Desalination

Freeze-thaw desalination uses freezing to remove fresh water from salt water.

32 Advanced Oxidation Processes

Hazardous organic waste, widely spread in water by industrial, military and domestic sources, is an emerging issue. Advanced Oxidation Processes (AOPs) are efficient methods to remove organic contamination not degradable by means of biological processes. AOPs are a set of processes involving the production of very reactive oxygen species able to destroy a wide range of organic compounds. AOPs are driven by external energy sources such as electric power, ultraviolet radiation (UV) or solar light, so these processes are often more expensive than conventional biological wastewater treatment. Moreover, AOPs can be applied for the disinfection of water, air and for remediation of contaminated soils.

Overview	**Working Principle** Production of reactive oxygen species able to destroy toxic compounds and biologic contamination in water.	**Capacity/Adequacy** High-tech equipment required.	**Performance** High efficiency except for few chemicals	**Costs** High operation costs	**Self-Help Compatibility** Engineers are required for the design
	O&M Generally continuous supply of chemicals (ozone, H2O2…) required	**Reliability** Reliable if operating conditions are scaled taking into account wastewater content	**Main Strength** Destroys almost all organics without pollution transfer to another phase	**Main Weakness** Operation costs	

Advantages	• Destroys toxic organic compounds without pollution transfer to another phase	• Very efficient to treat almost all organic pollutants and remove some toxic metals	• Works also for water disinfection	• Cheap to install	• Adaptable to small scales in developing countries
Disadvantages	• Relatively high operation costs due to chemicals and/or energy input	• Formation of oxidation intermediates potentially toxic	• Engineers are required for the design and often also for operation	• Emerging technologies (still a lot of research is required)	

Introduction
Advanced Oxidation Processes (AOPs) refer to a set of oxidative water treatments that can be used to treat toxic effluents at industrial level, hospitals and wastewater treatment plants. AOPs are successful to transform toxic organic compounds (e.g. drugs, pesticides, endocrine disruptors etc.) into biodegradable substances. AOPs in general are cheap to install but involve high operating costs due to the input of chemicals and energy required. To limit the costs, AOPs are often used as pre-treatment combined with biologic treatment. Advanced oxidation was recently also used as quaternary treatment or a polishing step to remove micro-pollutants from the effluents of municipal wastewater treatment plants and for the disinfection of water. The combination of several AOPs is an efficient way to increase pollutant removal and reduce costs.

Examples of AOPs
Many methods are classified under the broad definition of AOPs. The table shows some of the most studied processes. Advanced oxidation generally uses strong oxidising agents like hydrogen peroxide (H_2O_2) or ozone (O_3), catalysts (iron ions, electrodes, metal oxides) and irradiation (UV light, solar light, ultrasounds) separately or in combination under mild conditions (low temperature and pressure). Among different available AOPs, those driven by light seem to be the most popular technologies for wastewater treatment as shown by the large amount of data available in the literature (STASINAKIS 2008). Solar AOPs are particularly attractive due to the abundance of solar light in regions where water scarcity is high and due to their relatively low costs and high efficiencies.

Dark AOP
- Ozone (O_3)
- Fenton (Fe^{2+} + H_2O_2)
- Electrolysis (electrodes + current)
- Sonolysis (Ultrasounds)

Light Driven AOP
- Photolysis (UV + H_2O_2)
- Photocatalysis (light + catalyst)
- Photo-Fenton (solar light + Fenton)

AOP Mechanism
Advanced oxidation involves several steps schematised in the figure below and explained as follows:

1	Formation of strong oxidants (e.g. hydroxyl radicals).
2	Reaction of these oxidants with organic compounds in the water (KOMMINENI et al. 2008) producing biodegradable intermediates.
3	Reaction of biodegradable intermediates with oxidants referred to as mineralisation (i.e. production of water, carbon dioxide and inorganic salts).

Strategies to Implement AOPs
The costs of AOPs are relatively high and directly related to the efficiency and operational time of the processes. It is therefore worth optimising implementation of AOPs at the right place to limit costs. Several strategies were found to achieve this:
- Simultaneous application of different AOPs promotes the rates of organics oxidation. Typical examples include UV/H_2O_2, UV/H_2O_2/TiO_2, UV/Fenton and Ultrasound/UV/TiO_2, among others. These types of combinations may lead to synergetic effects when treatment efficiencies are greater than the sum of efficiencies that could be achieved by the individual treatments alone.
- Sequential application of various AOPs can treat effluents containing a mixture of organics. This approach is useful when the compounds in the mixture present different levels of reactivity towards different AOPs.
- Application of separation treatment prior to AOP treatment to transfer pollutants to another phase so that they can be treated more easily. Such separation treatment includes stripping, coagulation-flocculation, sedimentation, filtration, adsorption etc.

- AOPs can be applied in pre-treatment stage to enhance biodegradability and to reduce toxicity followed by biological post-treatment. This approach is based on the fact that biological treatment is perhaps less costly and more environmentally friendly than other destructive treatments and that complete mineralisation by AOPs incurs excessive treatment costs.
- AOPs can be installed at different stages of waste (and also drinking) water treatment plants depending on influent composition and desired effluent quality. AOPs can be installed either as tertiary treatment after the biological (secondary) treatment of wastewater, or as pre-treatment stage in order to enhance the biodegradability of trace organic contaminants.

Applicability
AOPs have a wide range of applications such as air (odour elimination, purification), soil (remediation) and water decontamination. In water, these processes have the ability to destroy organic pollutants but they can also be adapted to the removal of inorganic metals. Furthermore AOPs are successful to inactivate bacteria, viruses etc. Different kinds of water are therefore suitable for an AOP treatment: for example industrial wastewater containing toxic compounds can be treated by solar photo-Fenton; surface or ground water can be disinfected by means of improved solar water disinfection by adding H_2O_2 (see also H_2O_2 and SODIS); both bacteria in drinking water plants or micro-pollutants in sewage systems can be degraded using ozonation; Dissolved arsenic can be removed from water by co-precipitation by means of simple methods in presence of iron.

5 Water Storage

Already treated or purified water has to be stored properly to prevent recontamination. Safe storage means keeping your treated water away from sources of contamination, and using a clean and covered container. It also means that drinking from the container should be done in a way that cross-contamination can be avoided. The container should prevent hands, cups and dippers from touching the water, so that the water does not get recontaminated. There are several possibilities to store water. They range from very small covered buckets to large tanks or cisterns. Another possibility is to store water in bottles. Furthermore, the hygienic conditions in a household are crucial. Good hygienic measures include the following.

- Careful storage of household water and regular cleaning of all household water-storage facilities.
- Construction, proper use, and maintenance of latrines.
- Regular hand washing, especially after defecation and before eating, preparing food or handling drinking water.
- Careful storage and preparation of water and food.

Treated water should be stored in plastic, ceramic, or metal containers especially when using treatment options that do not leave residual protection. The following characteristics of containers serve as physical barriers to recontamination.

- A small opening with a lid or cover that discourages users from placing potentially contaminated items such as hands, cups, or ladles into the stored water.
- A spigot or small opening to allow easy and safe access to the water without requiring the insertion of hands or objects into the container.
- A size appropriate for the household water treatment method, with permanently attached instructions for using the treatment method and for cleaning the container.

The following aspects should be considered when planning for safe storage and prevention of recontamination. The water storage container must be covered and only used for treated water.
- Location of storage vessel
- Design of storage vessel
- Removal of water

Containers

Container Types

These are the different plastic types ordered by resin identification code. This code is the number printed onto any plastic items which is surrounded by a recycle icon. They are generally pretty easy to spot and can help identifying what that plastic can be used for.

Plastic Type	Use	Notes & Safety	Water Storage	Food Storage
Plastic #1 - PET Polyethylene Terephthalate (PET)	Water, juice and soft drink bottles	Considered safe but PET can leach metal antimony. The longer it sits on a shelf - the greater the dose present based on factors like sunlight, temperature and pH level.	Shouldn't use for water storage	Safe for food storage
Plastic #2 - HDPE High Density Polyethylene (HDPE)	Milk, water, juice bottles, shampoo containers, cereal liners and grocery bags	Has been found to release estrogenic chemicals which can disrupt hormones and alter cell structure. Can contain the common plastic toxin BPA.	Safe for water storage	Safe for food storage
Plastic #3 - PVC Polyvinyl Chloride (PVC)	Bags for bedding, shrink wrap, deli and meat wrap, plastic toys, plastic flooring, table cloths and medication blister packs	Contains toxins like DEHP which is a plastic softener. Linked to allergies, asthma and autism.	Avoid for water storage	Avoid for food storage
Plastic #4 - LDPE Low Density Polyethylene (LDPE)	Bread bags, newspapers, fresh produce, household garbage, frozen food, paper milk cartons, hot + cold beverage cups	Does not contain BPA but may leach other estrogenic chemicals.	Safe for water storage	Shouldn't use for food storage
Plastic #5 - PP Polypropylene (PP)	Yoghurt containers, plastic ware, deli foods, medications and take-out meals	High heat tolerance making it unlikely to leach chemicals.	Safe for water storage	Safe for food storage
Plastic #6 - PS Polystyrene (PS)	Cups, bowls, take-out containers and meat trays	Known to leach styrene which can damage nervous system and is linked to cancer. Heating PS releases more chemicals faster.	Avoid for water storage	Shouldn't use for food storage

Plastic #7 - Other Other	Sauce bottles, condiment bottles, babies' feeding bottles, infants' drinking cups, reusable water bottles	Usually often contains BPA or BPS which are endocrine disruptors.	Avoid for water storage	Avoid for food storage
Tritan - Nalgene Nalgene Bottles	Water Bottles	Categorized as Plastic #7 Contains no BPS, BPA or estrogen.	Safe for water storage	?

Portable Containers (1-5 Litres)

These are bottles or other containers that are used to transport small quantities of water and can easily fit in a backpack.

Water Bottle	Water bottles can hold any amount of water, but typically from 200ml to 2L. Consider the weight of the bottle when purchasing it as it could add quite a lot of additional weight you don't need. Be sure that the bottle is strong enough to last weeks or months depending on your situation and choose a size based on your location. (Larger for desert areas)
Flexible Water Bottle	Flexible bottles range from 1L to 10L. Flexible water bottles are light bottles that can be folded to a compact size when empty to save pack space.
Water Bladder	Water bladders typically hold between 1-10L of water. Bladders are used in backpacks and often have a sipper function that lets you drink from them while hiking without hands.

Semi-Portable Containers (5-100 Litres)

These containers are larger than bottles and are often bought from camping shops letting you fill them from home. These containers are better for longer trips without access to clean water and can be used for showering as well. Typically they come in either blue or white plastics to make it easier to identify the contents.

Fixed Containers (100+ Litres)

Fixed containers are not easily portable containers (once filled) that contain large amounts of water

Water Tanks	**Rigid Water Container** ○	**PVC Water Holder** ○			

Water Towers

Water towers can be made of concrete or steel and can take various forms. The most suitable form for concrete towers is a cylinder with a curved shaped bottom or with a flat bottom. Steel tanks may have a spherical or dome shaped bottom. The shape chosen is usually a compromise between function, construction and maintenance costs, as well as aesthetics. The lowest water level in the tank is determined according to the pressure requirements in the pipeline. The pressure in the pipelines may vary depending on the type of community and pressure needs of different areas in a city. To keep pumping costs low, water depth in the tank is generally kept small. Due to structural considerations, the depth is kept equal to the diameter.

Storing

Tips on how to store water in containers and how to store the containers.

Water Storage Tips	Containers must not contain BPA and only have been used to store water. Airtight containers prevent bacteria growing. Treat water with chlorine or colloidal silver before storing and again after storage. Check for contamination before drinking stored water. Water becomes flat over time, shake it to reoxygenate it. Ensure a tight seal and that barrels aren't stored on cement which can leak chemicals. Hard containers should resist 5 drop tests full of water from 2m high, flexible containers should resist two drops from 2 metres (6ft) high. Don't use recycled plastics for long term water storage.
Storage Life	

Using Stored Water

These are tips on using water that has been stored for a long time.

- Check the smell of the water. If there's still a slight chlorine smell then it's most likely still good for drinking straight away.
- If there's no smell and it still looks pure, it would be best to put a few purification tablets and stir them in.
- If there is fouling of the water or a bad smell when you open the container, you should re-filter it and add some purification tablets - more than you would in the last step.

In all cases you should shake the water container to 're-oxygenate' it.

6 Water Purity

In many parts of the world, water is not safe enough to drink. There are basic qualitative observations that quickly determine if water is not safe to consume. However, there are also many “invisible” substances that must be tested for professionally to identify the contaminants and to figure out how the specific polluted water can be purified. Testing can be done in the field with portable test kits or mobile laboratories. Water samples can also be collected and sent to a professional laboratory.

Drinking water can come from different sources depending on where we live in the world. Three sources that are used to collect drinking water are: ● Groundwater ● Surface water ● Rainwater	Water is in continuous movement on, above, and below the surface of the earth. As water is recycled through the earth, it picks up many things along its path. Water quality will vary from place to place, with the seasons, and with the various kinds of rock and soil it moves through. For the most part, it is largely natural processes that affect water quality. For instance, water moving through underground rocks and soils may pick up natural contaminants, even with no human activity or pollution in the area. In addition to nature's influence, water is also polluted by human activities, such as open defecation, dumping garbage, poor agricultural practices, and chemical spills at industrial sites. When considering drinking water quality, microbiological contamination is the main concern in most cases since it is responsible for the majority of illnesses and deaths related to drinking unsafe water.

Even though water may be clear, it does not necessarily mean that it is safe for us to drink. It is important for us to judge the safety of water by taking the following three qualities into consideration (see also pathogens and contaminants): **1. Microbiological** – bacteria, viruses, protozoa, and worms **2. Chemical** – minerals, metals and chemicals **3. Physical** – temperature, colour, smell, taste and turbidity	Safe drinking water should have the following microbiological, chemical and physical qualities: ● Free of pathogens ● Low in concentrations of toxic chemicals ● Clear ● Tasteless and colourless (for aesthetic purposes)

Qualitative Observations

The first step to check water quality can be done by very simple observations:

Water Observation	Possible Contaminants
Foamy or Bubbly	Detergents
Black in colour	Manganese, bacterial growth
Brown, yellow or reddish in colour	Iron
Dark brown or yellow in colour	Tannins and pigment from leaves and bark
White deposits or scale	Hardness, dissolved metals
Earthy, fishy, muddy, peaty odour	Organic matter, algae, bacteria
Rotten egg odour	Hydrogen sulphide
Chlorine odour	Chlorine residual from water treatment process
Bitter or metallic taste	pH, zinc, copper

Portable Testing Kits
Analyses for many physical, chemical and microbiological contaminants can be carried out in the field or in a temporary laboratory using specifically designed products that are portable and relatively easy to use. A significant advantage of field analysis is that tests are carried out on fresh samples whose characteristics have not been contaminated or otherwise changed as a result of being stored and transported over long distances. Portable water quality test kits should have the following characteristics:

● Easy to use with simple instructions
● Small and easy to transport
● No restrictions on air transport
● Fast results
● Limited requirement for distilled or deionised water
● Dilution not necessary

● Does not require calibration
● Robust (limited effects from UV light, shock, humidity or temperature)
● Can test several parameters
● Easy to repair or replace
● Limited consumables or consumables are easy to obtain

Inorganic Contaminants

Below is a list of some harmful inorganic contaminants in drinking water and their potential health effects.

Contaminant	MCL (Maximum Contaminant Level)	Potential Health Effects from Long-Term Exposure Above the MCL (Unless specified as short-term)
Antimony	0.006	Increase in blood cholesterol; decrease in blood sugar
Arsenic	0.01	Skin damage or problems with circulatory systems, and may increase the risk of getting cancer
Barium	2	Increase in blood pressure
Beryllium	0.004	Intestinal lesions
Cadmium	0.005	Kidney damage
Chromium (total)	0.1	Allergic dermatitis
Copper	1.3	Short term exposure: gastrointestinal distress
Cyanide (as free cyanide)	0.2	Nerve damage or thyroid problems
Fluoride	4	Decreased IQ and cognitive ability; Bone disease (pain and tenderness of the bones); children may get mottled teeth
Lead	0.015	Infants and children: delays in physical or mental development; children could show slight deficits in attention span and learning abilities
Mercury (inorganic)	0.002	Kidney damage
Nitrate (measured as nitrogen)	10	Infants below the age of six months who drink water containing nitrate in excess of the MCL could become seriously ill and, if untreated, may die. Symptoms include shortness of breath and blue-baby syndrome
Nitrite (measured as nitrogen)	1	Infants below the age of six months who drink water containing nitrite in excess of the MCL could become seriously ill and, if untreated, may die. Symptoms include shortness of breath and blue-baby syndrome
Selenium	0.05	Hair or fingernail loss; numbness in fingers or toes; circulatory problems
Thallium	0.002	Hair loss; changes in blood; kidney, intestine, or liver problems

Water Testing

How to test water for pH, turbidity, chlorine, bacteria, viruses, dissolved compounds etc.

Faecal Coliform Count

Measures the concentration of total coliform bacteria associated with the possible presence of disease causing organisms.

Turbidity Test

Measures the amount of suspended matter in a water supply.

Chlorine and pH Test

Measures the amount of chlorine and pH levels in the water.

Conductivity

By touching the negative and positive leads of a voltmeter that is on in the resistance setting allows you to measure the conductivity of water, a test of its purity. When water conducts electricity, it is made possible by water impurities such as metal and salt.

Materials
- Voltmeter / Multimeter
- Battery
- Wire
- Water Sample

Method
Pour the water into a container. Turn on the voltmeter and connect the battery to the corresponding electrical lead based on which end you've connected. Take note of the voltage. Then place the wire on the positive end of the battery with the voltmeter's negative end on the negative side of the battery. Dip the batteries wire and the positive voltmeter end into the water read the measurement.

Example Measurements
Battery - 1.57v - 100%
Sea Water - 0.6v - 38%
Tap Water - 0.146v - 9.29%
Distilled Water - 0.0059v - 0.37%
Bottled Water - 0.0046v - 0.29% - Very Pure Water

The higher the voltage the less pure the water is. Temperature should also be accounted for in the measurement, as this drastically changes the conductivity.

In standard water (such as tap water) the conductivity result will change by around 2% per °c change. In deionised water the effect of temperature is amplified, and can reach as high as 10% per °c change.

Chemical Tests

Chemical tests such as litmus paper tests which tests the pH of the water.

pH Ranges

Potential Hydrogen
pH or Potential of Hydrogen measures the acidity or basicity of an aqueous solution in moles/L of Hydrogen atoms. Solutions with a pH less then 7 are acidic and solutions with a pH greater then 7 are basic.

Range 0-3
- Battery Acid (-0.2)
- Gastric Fluid (1.2)
- Lemon Juice (2.2)
- Carbonated Drinks (2.5)
- Vinegar (3.0)

Range 3-6
- Orange Juice (3.6)
- Beer (4.3)
- Black Coffee (4.9)
- Pure Rain (5.6)
- Egg Yolk (5.6)

Range 6-9
- Milk (6.6)
- Distilled Water (7)
- Blood (7.4)
- Seawater (8)
- Baking Soda (8.2)

Range 9-12
- Milk of Magnesia (10.6)
- Ammonia (11.4)

Range 12-15
- Bleach (12.7)
- Lye/Caustic Soda (13.6)

Inorganic Materials

A list of the inorganic materials commonly found in water in (MCL/(mg*L-1).

Antimony - 0.0006
Arsenic - 0.01
Barium - 2
Beryllium - 0.004
Cadmium - 0.005

Chromium (total) - 0.1
Copper - 1.3
Cyanide - 0.2
Fluoride - 4
Lead - 0.015

Mercury - 0.002
Nitrate - 10
Nitrile - 10
Selenium - 0.05
Thallium - 0.002

Turbidity

NTU stands for Nephelometric Turbidity Unit. Turbidity is the cloudiness or haziness of a fluid caused by large numbers of individual particles that are generally invisible to the naked eye, similar to smoke in air. The measurement of turbidity is a key test of water quality.

Fluids can contain suspended solid matter consisting of particles of many different sizes. While some suspended material will be large enough and heavy enough to settle rapidly to the bottom of the container if a liquid sample is left to stand (the settable solids), very small particles will settle only very slowly or not at all if the sample is regularly agitated or the particles are colloidal. These small solid particles cause the liquid to appear turbid.

NTU	Level	Description
0-5	**No identifiable matter in the bottle**	Crystal clear water, recommended turbidity level prior to consumption. The only NTU level safe for UV sterilization.
6-24	**Between 10-20% reduced visibility through a standard Nalgene bottle**	Slight Turbidity, drinkable but filtering below 10 NTU is preferred. Boiling highly recommended.
25-50	**Between 20-50% reduced visibility through a standard Nalgene bottle**	Minor Turbidity, drinkable but filtering is preferred. Boiling essential.
50-100	**Between 50-90% reduced visibility through a standard Nalgene bottle**	Some Turbidity, drinkable but filtering is highly preferred. Distillation Preferred.

100-150	**90-100% Opaque liquid in a standard Nalgene bottle**	Fair Turbidity, not drinkable without filtration. Distillation Essential.
150-300	**100% Opaque liquid in a standard Nalgene bottle**	Moderate Turbidity, filtering through a good filter will correct it easily. Boiling not recommended - find alternative water. Distillation Essential.
300-500	**Fingers disappear if hand put in up to wrist**	Moderate Turbidity, filtering through a shirt will reduce it easily. Distillation Essential.
500-1000	**Fingernail disappear if a whole finger is put in**	High Turbidity, recommended filtering through a high quality filter. Distillation Essential.
1000-2000	**Fingernail disappears if immersed up to the first finger joint**	Extreme Turbidity, recommended filtering through a high quality filter. Distillation Essential.
2000+	**Anything disappears almost instantly**	Insane Turbidity, recommended filtering through a high quality filter. Distillation Essential.

Treating Turbid Water

Flocculation / Coagulation
Use Aluminium Sulphate, Ferric Chloride, Gypsum or Poly-Aluminium Chloride as a coagulation agent to drop suspended particles to the bottom. Coagulation will remove about 95.6% of turbidity from the water based on variables. Filtering through a fine medium such as an item of clothing will reduce the turbidity a little.

7 Water Resistance

Information on water resistance and types of waterproofing.

Water Resistance

Water resistance is an important fact to consider when you're going to be immersed in water or walking in rain. It measures the resilience of gear to liquids and how long they can survive immersion. Generally it applies to mobile phones and watches. Watches are often classified by watch manufacturers by their degree of water resistance which, due to the absence of official classification standards, roughly translates to the following (1 metre ≈ 3.29 feet). These vagueries have since been superseded by ISO 22810:2010, in which "any watch on the market sold as water-resistant must satisfy ISO 22810 – regardless of the brand.

Resistance Types

Depth Rating
Terms such as “water resistant to 50 meters” or “water resistant to 200 meters” indicate that the watch can be worn underwater to various depths but it can be misleading. Generally a watch used for water sports and swimming should have at least 100m (10bar) water resistance.

Bar Rating
The bar is a metric unit of pressure, but is not approved as part of the International System of Units (SI). It is defined as exactly equal to 100,000 Pa, which is slightly less than the current average atmospheric pressure on Earth at sea level.

1 Bar Approximately Equals
- 0.987 ATM
- 14.5038 PSI Absolute
- 29.53 inHg
- 750.06 mmHg
- 750.06 Torr
- 1,019.72 centimetres of water (cmH2O).

Atmospheres (ATM)
The ATM of a watch is short for Atmospheres and is a measure of the level of water pressure a watch is designed to withhold. A higher ATM means that a watch can withhold more water pressure, whilst a lower ATM mean that it was designed to withstand less pressure.

Japanese Industrial Standard (JIS)
The Japan Industrial Standards (JIS) for water resistance uses a "0" to "8" scale to define the level of water ingress protection built into each product.

JIS Grade 0	Non-protected
JIS Grade 1	Vertically dripping water shall have no harmful effect (Drip resistant 1)
JIS Grade 2	Dripping water at an angle up to 15 degrees from vertical shall have no harmful effect (Drip resistant 2)
JIS Grade 3	Falling rain at an angle up to 60 degrees from vertical shall have no harmful effect (Rain resistant)
JIS Grade 4	Splashing water from any direction shall have no harmful effect (Splash resistant) ● Protected against solid foreign objects 1.0 mm diameter and greater.
JIS Grade 5	Direct jetting water from any direction shall have no harmful effect (Jet resistant) ● Dust protected. Ingress of dust is not totally prevented, but dust shall not penetrate in a quantity to interfere with satisfactory operation of the apparatus or to impair safety.
JIS Grade 6	Direct jetting water from any direction shall not enter the enclosure (Water tight) ● Dust tight. No ingress of dust.
JIS Grade 7	Water shall not enter the enclosure when it is immersed in water under defined conditions (Immersion resistant)

JIS Grade 8	The equipment is usable for continuous submersion in water under specified pressure (Submersible)

IP Code (Ingress Protection Marking)

Classifies and rates the degree of protection provided against intrusion (body parts such as hands and fingers), dust, accidental contact, and water by mechanical casings and electrical enclosures.

First Digit
Solid particle protection
● The first digit indicates the level of protection that the enclosure provides against access to hazardous parts (e.g., electrical conductors, moving parts) and the ingress of solid foreign objects.

Protects Against
X - No Data
0 - No Protection
1 - Objects >50 mm
2 - Objects >12.5 mm
3 - Objects >2.5 mm
4 - Objects >1 mm
5 - Dust Protected
6 - Dust Tight

Second Digit
Liquid ingress protection
● The second digit indicates the level of protection that the enclosure provides against harmful ingress of water. The ratings for water ingress are not cumulative beyond IPX6. A device which is compliant with IPX7, covering immersion in water, need not be compliant with IPX5 or IPX6, covering exposure to water jets.

Protects Against
X - No Data
0 - No Protection
1 - Dripping water
2 - Dripping water when tilted at 15°
3 - Spraying water
4 - Splashing of water
5 - Water jets
6 - Powerful water jets
6K - Powerful water jets with increased pressure
7 - Immersion, up to 1 m depth
8 - Immersion, 1 m or more depth
9K - Powerful high temperature water jets

Additional Letters
D - Wire
f - Oil resistant
H - High voltage device
M - Device moving during water test
S - Device standing still during water test
W - Weather conditions

North America (NEMA Rating)

In the USA, the National Electrical Manufacturers Association defines NEMA enclosure types in NEMA standard number 250. The following table outlines which IEC 60529 IP code each respective NEMA rating meets. Ratings between the two standards are not directly equivalent: NEMA ratings also require additional product features and tests (such as functionality under icing conditions, enclosures for hazardous areas, knock-outs for cable connections and others) not addressed by IP ratings.

NEMA / IP Code Equivalency
- 1 = IP20
- 2 = IP22
- 3, 3X, 3S, 3SX = IP55
- 3R, 3RX = IP24
- 4, 4X = IP66
- 5 = IP53
- 6 = IP67
- 6P = IP68
- 12, 12K, 13 = IP54

Resistance Equivalency

Water Resistance Rating

Depth Rating	Bar Rating	Atmospheres (ATM)	PSI	Japanese Industrial Standard (JIS)	Suitability	Remarks
Non-Water Resistant	0 Bar	0 Atmospheres	0 PSI	JIS Grade 0	Avoid direct contact with all water.	
Water Resistant (W.R) 10m-30m (32-98ft)	1-3 Bar	~1-3 Atmospheres	14.7-44.1 PSI	JIS Grade 1 JIS Grade 2 JIS Grade 3	Can withstand perspiration, face washing water drops, rain, etc., in daily life, but cannot be used for water-using works, water sports, skin diving, and other types of diving. Do not use it under conditions in which the water pressure changes sharply.	Standing at sea level, your watch is already experiencing 1 atmosphere.
30m (98ft)	3 Bar	~3 Atmospheres	44.1 PSI	JIS Grade 4 JIS Grade 5 JIS Grade 6	Suitable for everyday use. Splash/rain resistant.	Not suitable for showering, bathing, swimming, snorkelling, water related work, fishing, and diving.
50m (164ft)	5 Bar	~5 Atmospheres	73.5 PSI	JIS Grade 7	Suitable for everyday use, showering, bathing, snorkelling, water related work, fishing. Splash/rain resistant.	Not suitable for diving or swimming.
100m (328ft)	10 Bar	~10 Atmospheres	147.0 PSI	JIS Grade 8	Suitable for recreational surfing, snorkelling, sailing and water sports.	Not suitable for diving, it can be taken swimming but it's not recommended.
200m (980ft)	20 Bar	~20 Atmospheres	294 PSI	JIS Grade 8	Suitable for professional marine activity, serious surface water sports and skin diving.	Suitable for skin diving.
300m (984ft)	30 Bar	~30 Atmospheres	441 PSI	JIS Grade 8	Suitable for professional marine activity, serious surface water sports and skin diving.	Suitable for skin diving.
1,000m (3280ft)	100 Bar	~100 Atmospheres	1470 PSI	JIS Grade 8	Suitable for all the above including deep sea diving.	
2,000m (6561ft)	200 Bar	~200 Atmospheres	2940 PSI	JIS Grade 8	Suitable for all the above including deep sea diving.	
Diver's 100 m				JIS Grade 8	Minimum ISO standard (ISO 6425) for scuba diving at depths not suitable for saturation diving.	Diver's 100 m and 150 m watches are generally old(er) watches.
Diver's 200 m or 300 m				JIS Grade 8	Suitable for scuba diving at depths not suitable for saturation diving.	Typical ratings for contemporary diver's watches.
Diver's 300+ m for mixed-gas diving				JIS Grade 8	Suitable for saturation diving (helium enriched environment).	Watches designed for mixed-gas diving will have the DIVER'S WATCH xxx M FOR MIXED-GAS DIVING additional marking to point this out.

ISO 2281

The International Organization for Standardization issued a standard for water-resistant watches which also prohibits the term waterproof to be used with watches, which many countries have adopted. This standard was introduced in 1990 as the ISO 2281:1990 and only designed for watches intended for ordinary daily use and are resistant to water during exercises such as swimming for a short period. They may be used under conditions where water pressure and temperature vary; German Industrial Norm DIN 8310 is an equivalent standard.

However, whether they bear an additional indication of overpressure or not, they are not intended for submarine diving. The ISO 2281 standard specifies a detailed testing procedure for each mark that defines not only pressures but also test duration, water temperature, and other parameters. Besides this ISO 2859-2 Sampling plans indexed by limiting quality (LQ) for isolated lot inspection and ISO 2859-3 Sampling procedures for inspection by attributes – Part 3: Skip-lot sampling procedures concerning procedures regarding lot sampling testing come into play, since not every single watch has to be tested for ISO 2281 approval.

- Resistance when immersed in water at a depth of 10 cm. Immersion of the watch in 10 cm of water for 1 hour.
- Resistance to different temperatures. Immersion of the watch in 10 cm of water at the following temperatures for 5 minutes each, 40 °C, 20 °C and 40 °C again, with the transition between temperatures not to exceed 1 minute. No evidence of water intrusion or condensation is allowed.
- Resistance to water overpressure. Immersion of the watch in a suitable pressure vessel and subjecting it within 1 minute to the rated pressure for 10 minutes, or to 2 bar in case where no additional indication is given. Then the overpressure is reduced to the ambient pressure within 1 minute. No evidence of water intrusion or condensation is allowed.

- Condensation test. The watch shall be placed on a heated plate at a temperature between 40 °C and 45 °C until the watch has reached the temperature of the heated plate (in practice, a heating time of 10 minutes to 20 minutes, depending on the type of watch, will be sufficient). A drop of water, at a temperature between 18 °C and 25 °C shall be placed on the glass of the watch. After about 1 minute, the glass shall be wiped with a dry rag. Any watch which has condensation on the interior surface of the glass shall be eliminated.
- Resistance of operative parts. Immersion of the watch in 10 cm of water with a force of 5 N perpendicular to the crown and pusher buttons (if any) for 10 minutes.
- Resistance to air overpressure. Exposing the watch to an overpressure of 2 bar. The watch shall show no air-flow exceeding 50 µg/min.

- No magnetic or shock resistance properties are required.
- No negative pressure test is required.
- No corrosion test is required.

ISO 6425

The standards and features for diving watches are regulated by the ISO 6425 – Divers' watches international standard. This standard was introduced in 1996. ISO 6425 defines such watches as: A watch designed to withstand diving in water at depths of at least 100 m and possessing a system to control the time. Diving watches are tested in static or still water under 125% of the rated (water) pressure, thus a watch with a 200-metre rating will be water resistant if it is stationary and under 250 metres of static water. ISO 6425 testing of the water resistance or water-tightness and resistance at a water overpressure as it is officially defined is fundamentally different from non-dive watches, because every single watch has to be tested. Testing diving watches for ISO 6425 compliance is voluntary and involves costs, so not every manufacturer present their watches for certification according to this standard.

- Reliability under water. The watches under test shall be immersed in water to a depth of 30±2 cm for 50 hours at 18 to 25 °C and all the mechanisms shall still function correctly. The condensation test shall be carried out before and after this test to ensure that the result is related to the above test.
- Resistance to thermal shock. Immersion of the watch in 30±2 cm of water at the following temperatures for 10 minutes each, 40 °C, 5 °C and 40 °C again. The time of transition from one immersion to the other shall not exceed 1 minute. No evidence of water intrusion or condensation is allowed.
- Water-tightness and resistance at a water overpressure. The watches under test shall be immersed in water contained in a suitable vessel. Then an overpressure of 125% of the rated pressure shall be applied within 1 minute and maintained for 2 hours. Subsequently, the overpressure shall be reduced to 0.3 bar within 1 minute and maintained at this pressure for 1 hour. The watches shall then be removed from the water and dried with a rag. No evidence of water intrusion or condensation is allowed.

- Resistance of crowns and other setting devices to an external force. The watches under test shall be subjected to an overpressure in water of 125% of the rated pressure for 10 minutes and to an external force of 5 N perpendicular to the crown and pusher buttons (if any). The condensation test shall be carried out before and after this test to ensure that the result is related to the above test.
- An optional test originating from the ISO 2281 tests (but not required for obtaining ISO 6425 approval) is exposing the watch to an overpressure of 200 kPa. The watch shall show no air-flow exceeding 50 µg/min.
- Condensation test. The watch shall be placed on a heated plate at a temperature between 40 and 45 °C until the watch has reached the temperature of the heated plate (in practice, a heating time of 10 minutes to 20 minutes, depending on the type of watch, will be sufficient). A drop of water, at a temperature of 18 to 25 °C shall be placed on the glass of the watch. After about 1 minute, the glass shall be wiped with a dry rag. Any watch which has condensation on the interior surface of the glass shall be eliminated.

Diver's Watches

Diving at a great depth and for a long period is done in a diving chamber, with the (saturation) diver spending time alternately in the water and in a pressurized environment, breathing a gas mixture. In this case, the watch is subjected to the pressure of the gas mixture and its functioning can be disturbed. Consequently, it is recommended to subject the watch to a special extra test. ISO 6425 defines a diver's watch for mixed-gas diving as: A watch required to be resistant during diving in water to a depth of at least 100 m and to be unaffected by the overpressure of the mixed gas used for breathing.

- Test of operation at a gas overpressure. The watch is subject to the overpressure of gas which will actually be used, i.e. 125% of the rated pressure, for 15 days. Then a rapid reduction in pressure to the atmospheric pressure shall be carried out in a time not exceeding 3 minutes. After this test, the watch shall function correctly. An electronic watch shall function normally during and after the test. A mechanical watch shall function normally after the test (the power reserve normally being less than 15 days).
- Test by internal pressure (simulation of decompression). Remove the crown together with the winding and/or setting stem. In its place, fit a crown of the same type with a hole. Through this hole, introduce the gas mixture which will actually be used and create an overpressure of the rated pressure/20 bar in the watch for a period of 10 hours. Then carry out the test at the rated water overpressure. In this case, the original crown with the stem shall be refitted beforehand. After this test, the watch shall function correctly.
- Marking. Watches used for mix-gas diving which satisfy the test requirements are marked with the words "DIVER'S WATCH xxx M FOR MIXED-GAS DIVING". The letters xxx are replaced by the diving depth, in metres, guaranteed by the manufacturer. The composition of the gas mixture used for the test shall be given in the operating instructions accompanying the watch.

Waterproofing

Information on how to waterproof anything from electronics to tents.

8 Water Flow

This section details the ways water moves and how it moves, such as in the form of waves, currents, rips and tides.

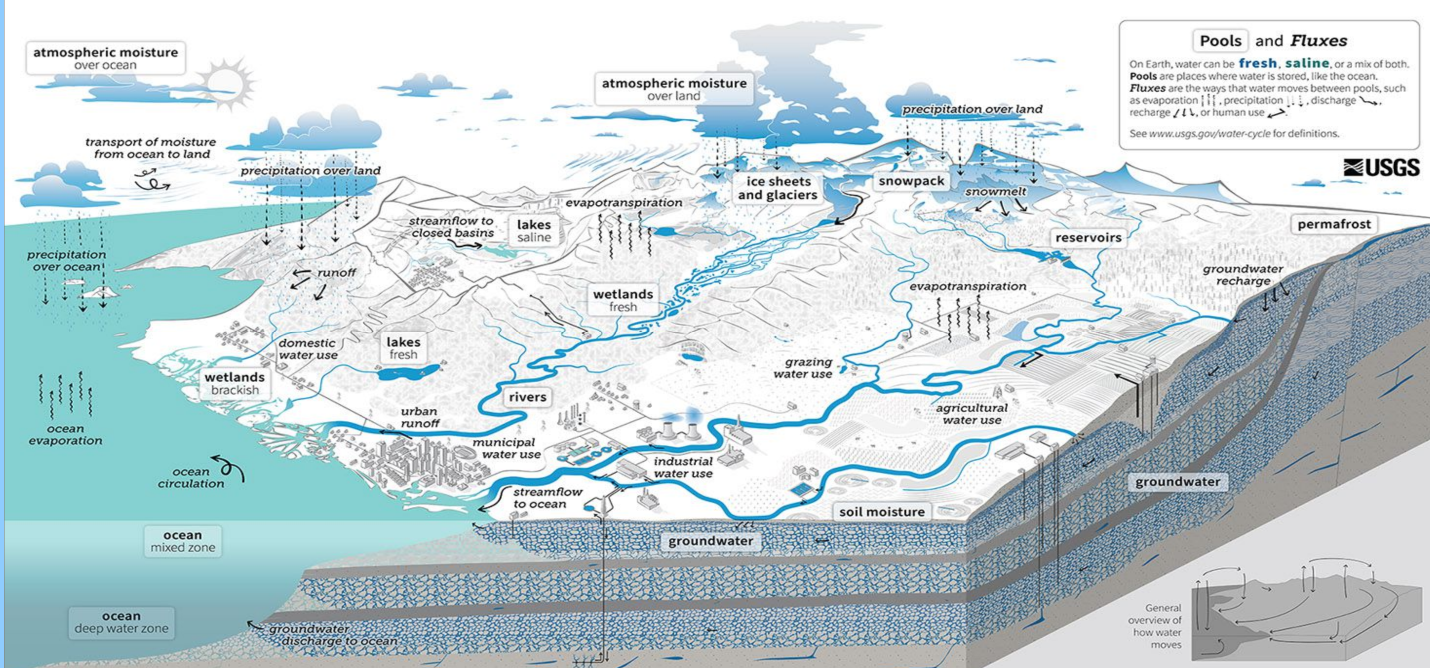
The Water Cycle

The water cycle (or hydrologic cycle or hydrological cycle), is a biogeochemical cycle that involves the continuous movement of water on, above and below the surface of the Earth. The mass of water on Earth remains fairly constant over time. However, the partitioning of the water into the major reservoirs of ice, fresh water, salt water and atmospheric water is variable and depends on climatic variables. The water moves from one reservoir to another, such as from river to ocean, or from the ocean to the atmosphere. The processes that drive these movements are evaporation, transpiration, condensation, precipitation, sublimation, infiltration, surface runoff, and subsurface flow. In doing so, the water goes through different forms: liquid, solid (ice) and vapor. The ocean plays a key role in the water cycle as it is the source of 86% of global evaporation.

The water cycle involves the exchange of energy, which leads to temperature changes. When water evaporates, it takes up energy from its surroundings and cools the environment. When it condenses, it releases energy and warms the environment. These heat exchanges influence the climate system.

The evaporative phase of the cycle purifies water because it causes salts and other solids picked up during the cycle to be left behind. The condensation phase in the atmosphere replenishes the land with freshwater. The flow of liquid water and ice transports minerals across the globe. It also reshapes the geological features of the Earth, through processes including erosion and sedimentation. The water cycle is also essential for the maintenance of most life and ecosystems on the planet.

Human actions are greatly affecting the water cycle. Activities such as deforestation, urbanization, and the extraction of groundwater are altering natural landscapes (land use changes) all have an effect on the water cycle. On top of this, climate change is leading to an intensification of the water cycle. Research has shown that global warming is causing shifts in precipitation patterns, increased frequency of extreme weather events, and changes in the timing and intensity of rainfall. These water cycle changes affect ecosystems, water availability, agriculture, and human societies.



A detailed diagram depicting the global water cycle. The direction of movement of water between reservoirs tends towards upwards movement through evapotranspiration and downward movement through gravity. The diagram also shows how human water use impacts where water is stored and how it moves.

Overall process

Further information: Water distribution on Earth

The water cycle is powered from the energy emitted by the sun. This energy heats water in the ocean and seas. Water evaporates as water vapor into the air. Some ice and snow sublimates directly into water vapor. Evapotranspiration is water transpired from plants and evaporated from the soil. The water molecule H_2O has smaller molecular mass than the major components of the atmosphere, nitrogen (N_2) and oxygen (O_2) and hence is less dense. Due to the significant difference in density, buoyancy drives humid air higher. As altitude increases, air pressure decreases and the temperature drops (see Gas laws). The lower temperature causes water vapor to condense into tiny liquid water droplets which are heavier than the air, and which fall unless supported by an updraft. A huge concentration of these droplets over a large area in the atmosphere becomes visible as cloud, while condensation near ground level is referred to as fog.

Atmospheric circulation moves water vapor around the globe; cloud particles collide, grow, and fall out of the upper atmospheric layers as precipitation. Some precipitation falls as snow, hail, or sleet, and can accumulate in ice caps and glaciers, which can store frozen water for thousands of years. Most water falls as rain back into the ocean or onto land, where the water flows over the ground as surface runoff. A portion of this runoff enters rivers, with streamflow moving water towards the oceans. Runoff and water emerging from the ground (groundwater) may be stored as freshwater in lakes. Not all runoff flows into rivers; much of it soaks into the ground as infiltration.

Some water infiltrates deep into the ground and replenishes aquifers, which can store freshwater for long periods of time. Some infiltration stays close to the land surface and can seep back into surface-water bodies (and the ocean) as groundwater discharge or be taken up by plants and transferred back to the atmosphere as water vapor by transpiration. Some groundwater finds openings in the land surface and emerges as freshwater springs. In river valleys and floodplains, there is often continuous water exchange between surface water and ground water in the hyporheic zone. Over time, the water returns to the ocean, to continue the water cycle.

The ocean plays a key role in the water cycle. The ocean holds "97% of the total water on the planet; 78% of global precipitation occurs over the ocean, and it is the source of 86% of global evaporation". Important physical processes within the water cycle include (in alphabetical order):

Advection	The movement of water through the atmosphere. Without advection, water that evaporated over the oceans could not precipitate over land. Atmospheric rivers that move large volumes of water vapor over long distances are an example of advection.
Condensation	The transformation of water vapor to liquid water droplets in the air, creating clouds and fog.
Evaporation	The transformation of water from liquid to gas phases as it moves from the ground or bodies of water into the overlying atmosphere. The source of energy for evaporation is primarily solar radiation. Evaporation often implicitly includes transpiration from plants, though together they are specifically referred to as evapotranspiration. Total annual evapotranspiration amounts to approximately 505,000 km3 (121,000 cu mi) of water, 434,000 km3 (104,000 cu mi) of which evaporates from the oceans. 86% of global evaporation occurs over the ocean.
Infiltration	The flow of water from the ground surface into the ground. Once infiltrated, the water becomes soil moisture or groundwater. A recent global study using water stable isotopes, however, shows that not all soil moisture is equally available for groundwater recharge or for plant transpiration.
Percolation	Water flows vertically through the soil and rocks under the influence of gravity.
Precipitation	Condensed water vapor that falls to the Earth's surface. Most precipitation occurs as rain, but also includes snow, hail, fog drip, graupel, and sleet. Approximately 505,000 km3 (121,000 cu mi) of water falls as precipitation each year, 398,000 km3 (95,000 cu mi) of it over the oceans. The rain on land contains 107,000 km3 (26,000 cu mi) of water per year and a snowing only 1,000 km3 (240 cu mi). 78% of global precipitation occurs over the ocean.
Runoff	The variety of ways by which water moves across the land. This includes both surface runoff and channel runoff. As it flows, the water may seep into the ground, evaporate into the air, become stored in lakes or reservoirs, or be extracted for agricultural or other human uses.
Subsurface Flow	The flow of water underground, in the vadose zone and aquifers. Subsurface water may return to the surface (e.g. as a spring or by being pumped) or eventually seep into the oceans. Water returns to the land surface at lower elevation than where it infiltrated, under the force of gravity or gravity induced pressures. Groundwater tends to move slowly and is replenished slowly, so it can remain in aquifers for thousands of years.
Transpiration	The release of water vapor from plants and soil into the air.

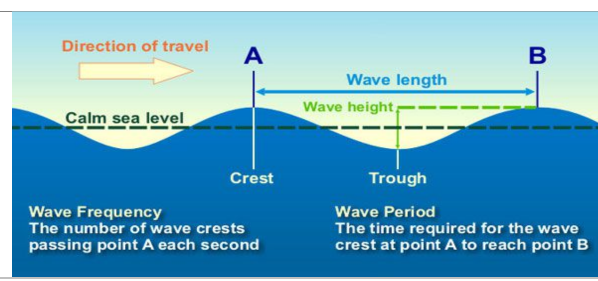
Waves

In fluid dynamics, a wind wave, or wind-generated water wave, is a surface wave that occurs on the free surface of bodies of water as a result of the wind blowing over the water's surface. The contact distance in the direction of the wind is known as the fetch. Waves in the oceans can travel thousands of kilometers before reaching land. Wind waves on Earth range in size from small ripples to waves over 30 m (100 ft) high, being limited by wind speed, duration, fetch, and water depth. When directly generated and affected by local wind, a wind wave system is called a wind sea. Wind waves will travel in a great circle route after being generated – curving slightly left in the southern hemisphere and slightly right in the northern hemisphere. After moving out of the area of fetch and no longer being affected by the local wind, wind waves are called swells and can travel thousands of kilometers. A noteworthy example of this is waves generated south of Tasmania during heavy winds that will travel across the Pacific to southern California, producing desirable surfing conditions. Wind waves in the ocean are also called ocean surface waves and are mainly gravity waves, where gravity is the main equilibrium force.

Wind waves have a certain amount of randomness: subsequent waves differ in height, duration, and shape with limited predictability. They can be described as a stochastic process, in combination with the physics governing their generation, growth, propagation, and decay – as well as governing the interdependence between flow quantities such as the water surface movements, flow velocities, and water pressure. The key statistics of wind waves (both seas and swells) in evolving sea states can be predicted with wind wave models.

Although waves are usually considered in the water seas of Earth, the hydrocarbon seas of Titan may also have wind-driven waves. Waves in bodies of water may also be generated by other causes, both at the surface and underwater (such as watercraft, animals, waterfalls, landslides, earthquakes, bubbles, and impact events).

Formation
The great majority of large breakers seen at a beach result from distant winds. Five factors influence the formation of the flow structures in wind waves:
1. Wind speed or strength relative to wave speed – the wind must be moving faster than the wave crest for energy transfer to the wave.
2. The uninterrupted distance of open water over which the wind blows without significant change in direction (called the fetch)
3. Width of the area affected by fetch (at a right angle to the distance)
4. Wind duration – the time for which the wind has blown over the water.
5. Water depth
All of these factors work together to determine the size of the water waves and the structure of the flow within them.



The main dimensions associated with wave propagation are:
- Wave height (vertical distance from trough to crest)
- Wave length (distance from crest to crest in the direction of propagation)
- Wave period (time interval between arrival of consecutive crests at a stationary point)
- Wave direction or azimuth (predominantly driven by wind direction)

Types
Three different types of wind waves develop over time:

- Capillary waves, or ripples, dominated by surface tension effects.
- Gravity waves, dominated by gravitational and inertial forces.
    - Seas, raised locally by the wind.
- Swells, which have traveled away from where they were raised by the wind, and have to a greater or lesser extent dispersed.

Ripples appear on smooth water when the wind blows, but will die quickly if the wind stops. The restoring force that allows them to propagate is surface tension. Sea waves are larger-scale, often irregular motions that form under sustained winds. These waves tend to last much longer, even after the wind has died, and the restoring force that allows them to propagate is gravity. As waves propagate away from their area of origin, they naturally separate into groups of common direction and wavelength. The sets of waves formed in this manner are known as swells. The Pacific Ocean is 19,800 km from Indonesia to the coast of Colombia and, based on an average wavelength of 76.5m, would have ~258,824 swells over that width. It is sometimes alleged that out of a set of waves, the seventh wave in a set is always the largest; while this isn't the case, the waves in the middle of a given set tend to be larger than those before and after them.

Individual "rogue waves" (also called "freak waves", "monster waves", "killer waves", and "king waves") much higher than the other waves in the sea state can occur. In the case of the Draupner wave, its 25 m (82 ft) height was 2.2 times the significant wave height. Such waves are distinct from tides, caused by the Moon and Sun's gravitational pull, tsunamis that are caused by underwater earthquakes or landslides, and waves generated by underwater explosions or the fall of meteorites—all having far longer wavelengths than wind waves.

The largest ever recorded wind waves are not rogue waves, but standard waves in extreme sea states. For example, 29.1 m (95 ft) high waves were recorded on the RRS Discovery in a sea with 18.5 m (61 ft) significant wave height, so the highest wave was only 1.6 times the significant wave height. The biggest recorded by a buoy (as of 2011) was 32.3 m (106 ft) high during the 2007 typhoon Krosa near Taiwan.

Tides

Tides are the rise and fall of sea levels caused by the combined effects of the gravitational forces exerted by the Moon and the Sun, and the rotation of the Earth. Tide tables can be used for any given locale to find the predicted times and amplitude (or "tidal range"). The predictions are influenced by many factors including the alignment of the Sun and Moon, the phase and amplitude of the tide (pattern of tides in the deep ocean), the amphidromic systems of the oceans, and the shape of the coastline and near-shore bathymetry.

They are however only predictions, the actual time and height of the tide is affected by wind and atmospheric pressure. Many shorelines experience semi-diurnal tides – two nearly equal high and low tides each day. Other locations have a diurnal tide – one high and low tide each day. A "mixed tide" – two uneven magnitude tides a day – is a third regular category.

Tides vary on timescales ranging from hours to years due to a number of factors, which determine the lunitidal interval. To make accurate records, tide gauges at fixed stations measure water level over time. Gauges ignore variations caused by waves with periods shorter than minutes. These data are compared to the reference (or datum) level usually called mean sea level.

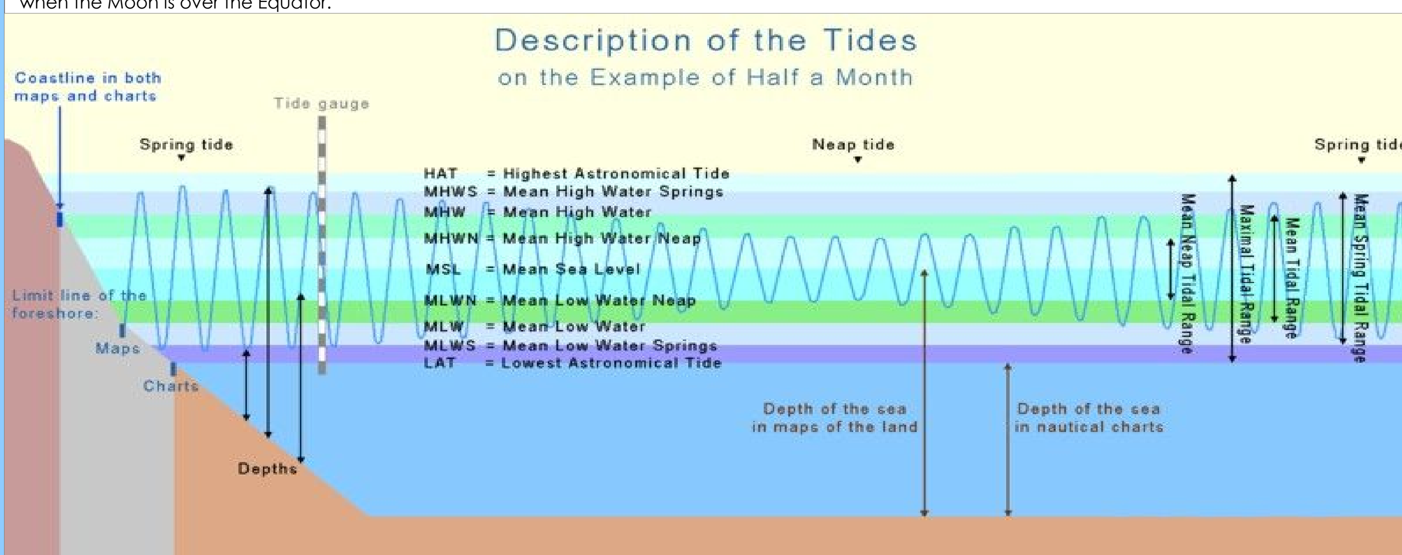
While tides are usually the largest source of short-term sea-level fluctuations, sea levels are also subject to forces such as wind and barometric pressure changes, resulting in storm surges, especially in shallow seas and near coasts. Tidal phenomena are not limited to the oceans, but can occur in other systems whenever a gravitational field that varies in time and space is present. For example, the shape of the solid part of the Earth is affected slightly by Earth tide, though this is not as easily seen as the water tidal movements.

Characteristics

Tide changes proceed via the following stages:
- Sea level rises over several hours, covering the intertidal zone; flood tide.
- The water rises to its highest level, reaching high tide.
- Sea level falls over several hours, revealing the intertidal zone; ebb tide.

The water stops falling, reaching low tide.

Oscillating currents produced by tides are known as tidal streams. The moment that the tidal current ceases is called slack water or slack tide. The tide then reverses direction and is said to be turning. Slack water usually occurs near high water and low water. But there are locations where the moments of slack tide differ significantly from those of high and low water. Tides are commonly semi-diurnal (two high waters and two low waters each day), or diurnal (one tidal cycle per day). The two high waters on a given day are typically not the same height (the daily inequality); these are the higher high water and the lower high water in tide tables. Similarly, the two low waters each day are the higher low water and the lower low water. The daily inequality is not consistent and is generally small when the Moon is over the Equator.



- Highest astronomical tide (HAT) – The highest tide which can be predicted to occur. Note that meteorological conditions may add extra height to the HAT.
- Mean high water springs (MHWS) – The average of the two high tides on the days of spring tides.
- Mean high water neaps (MHWN) – The average of the two high tides on the days of neap tides.
- Mean high water neaps (MHWN) – The average of the two high tides on the days of neap tides.
- Mean sea level (MSL) – This is the average sea level. The MSL is constant for any location over a long period.
- Mean low water neaps (MLWN) – The average of the two low tides on the days of neap tides.
- Mean low water springs (MLWS) – The average of the two low tides on the days of spring tides.
- Lowest astronomical tide (LAT) and Chart Datum (CD) – The lowest tide which can be predicted to occur.

Head of Tide
Head of tide or tidal limit is the farthest point upstream where a river is affected by tidal fluctuations, or where the fluctuations are less than a certain amount. This applies to rivers which flow into tidal bodies such as oceans, bays and deltas. Though this point may vary due to storms, spring tides, and seasonal or annual differences in water flows, there is generally an average point which is accepted as the head of tide. A river's tidal data are recorded at various locations downstream of this point.

A river's head of tide may be considered the upper boundary of its estuary. The head of tide is important in surveying, navigation, and fisheries management, and thus many jurisdictions establish a legal head of tide. As the head of tide is useful for navigation, separate maps can be made of the tidal zones up to the head of tide, such as was done in New Jersey. The head of tide may be many miles upstream from the river's mouth. For example, on the Hudson River, it is located 140 miles (225 km) upstream, near Albany, New York. On the Saint Lawrence River, tides affect shipping upstream past Quebec City, which is located several hundred miles inland from the Gulf of Saint Lawrence and the Atlantic Ocean.

Storm Surge

A storm surge, storm flood, tidal surge or storm tide is a coastal flood or tsunami-like phenomenon of rising water commonly associated with low pressure weather systems (such as tropical cyclones and strong extratropical cyclones), the severity of which is affected by the shallowness and orientation of the water body relative to storm path, as well as the timing of tides. Most casualties during tropical cyclones occur as the result of storm surges. It is a measure of the rise of water beyond what would be expected by the normal movement related to tides. The two main meteorological factors contributing to a storm surge are a long fetch of winds spiralling inward toward the storm, and a low-pressure-induced dome of water drawn up under and trailing the storm's centre.

Mechanics

At least five processes can be involved in altering tide levels during storms:	• The atmospheric pressure effect • The direct wind effect • The rainfall effect. • The effect of the Earth's rotation • The effect of waves near the shore

The pressure effects of a tropical cyclone will cause the water level in the open ocean to rise in regions of low atmospheric pressure and fall in regions of high atmospheric pressure. The rising water level will counteract the low atmospheric pressure such that the total pressure at some plane beneath the water surface remains constant. This effect is estimated at a 10 mm (0.39 in) increase in sea level for every millibar (hPa) drop in atmospheric pressure. Strong surface winds cause surface currents at a 45° angle to the wind direction, by an effect known as the Ekman Spiral.

Wind stresses cause a phenomenon referred to as "wind set-up", which is the tendency for water levels to increase at the downwind shore and to decrease at the upwind shore. Intuitively, this is caused by the storm blowing the water toward one side of the basin in the direction of its winds. Because the Ekman Spiral effects spread vertically through the water, the effect is proportional to depth. The pressure effect and the wind set-up on an open coast will be driven into bays in the same way as the astronomical tide. The Earth's rotation causes the Coriolis effect, which bends currents to the right in the Northern Hemisphere and to the left in the Southern Hemisphere. When this bend brings the currents into more perpendicular contact with the shore, it can amplify the surge, and when it bends the current away from the shore it has the effect of lessening the surge.

The effect of waves, while directly powered by the wind, is distinct from a storm's wind-powered currents. Powerful wind whips up large, strong waves in the direction of its movement. Although these surface waves are responsible for very little water transport in open water, they may be responsible for significant transport near the shore. When waves are breaking on a line more or less parallel to the beach, they carry considerable water shoreward. As they break, the water particles moving toward the shore have considerable momentum and may run up a sloping beach to an elevation above the mean water line, which may exceed twice the wave height before breaking.

The rainfall effect is experienced predominantly in estuaries. Hurricanes may dump as much as 12 in (300 mm) of rainfall in 24 hours over large areas and higher rainfall densities in localized areas. As a result, surface runoff can quickly flood Streams and rivers. This can increase the water level near the head of tidal estuaries as storm-driven waters surging in from the ocean meet rainfall flowing downstream into the estuary.

Extratropical Storms
Similar to tropical cyclones, extratropical cyclones cause an offshore rise of water. However, unlike most tropical cyclone storm surges, extratropical cyclones can cause higher water levels across a large area for longer periods of time, depending on the system. In North America, extratropical storm surges may occur on the Pacific and Alaska coasts, and north of 31°N on the Atlantic Coast. Coasts with sea ice may experience an "ice tsunami" causing significant damage inland. Extratropical storm surges may be possible further south for the Gulf coast mostly during the wintertime, when extratropical cyclones affect the coast, such as in the 1993 Storm of the Century.

Reverse Storm Surge
Water can also be sucked away from shore prior to a storm surge. This was the case on the western Florida coast in 2017, just before Hurricane Irma made landfall, uncovering land usually underwater. This phenomenon is known as a reverse storm surge, or a negative storm surge.

Rips

A rip current, often simply called a rip, or by the misnomer rip tide, is a specific kind of water current which can occur near beaches with breaking waves. A rip is a strong, localized, and narrow current of water which moves directly away from the shore, cutting through the lines of breaking waves like a river running out to sea, and is strongest near the surface of the water. Rip currents can be hazardous to people in the water. Swimmers who are caught in a rip current and who do not understand what is going on, and who may not have the necessary water skills, may panic, or exhaust themselves by trying to swim directly against the flow of water.

Because of these factors, rips are the leading cause of rescues by lifeguards at beaches, and rips are the cause of an average of 46 deaths by drowning per year in the United States. A rip current is not the same thing as undertow, although some people use the term incorrectly when they often mean a rip current. Contrary to popular belief, neither rip nor undertow can pull a person down and hold them under the water. A rip simply carries floating objects, including people, out beyond the zone of the breaking waves.

Cause

A rip current forms because wind and breaking waves push surface water towards the land, and this causes a slight rise in the water level along the shore. This excess water will tend to flow back to the open water via the route of least resistance. When there is a local area which is slightly deeper, or a break in an offshore sand bar or reef, this can allow water to flow offshore more easily, and this will initiate a rip current through that gap.

Water that has been pushed up near the beach flows along the shore towards the outgoing rip as "feeder currents", and then the excess water flows out at a right angle to the beach, in a tight current called the "neck" of the rip. The "neck" is where the flow is most rapid. When the water in the rip current reaches outside of the lines of breaking waves, the flow disperses sideways, loses power, and dissipates in what is known as the "head" of the rip.

Rip currents can often occur on a gradually shelving shore where breaking waves approach the shore parallel to it, or where underwater topography encourages outflow at a specific area. Rip currents can form at the coasts of oceans, seas, and large lakes, whenever there are waves of sufficient energy. The location of rip currents can be difficult to predict; whereas some tend to recur always in the same places, others can appear and disappear suddenly at various locations along the beach.

The appearance and disappearance of rip currents is dependent on the bottom topography and the exact direction that the surf and swells are coming in from. Rip currents can potentially occur wherever there is strong longshore variability in wave breaking. This variability may be caused by such features as sandbars, by piers and jetties, and even by crossing wave trains, and are often located in places such as where there is a gap in a reef or low area on a sandbar. Rip currents may deepen the channel through a sandbar once they have formed.

Rip currents are usually quite narrow, but tend to be more common, wider, and faster, when and where breaking waves are large and powerful. Local underwater topography makes some beaches more likely to have rip currents; a few beaches are notorious in this respect. Although rip tide is a misnomer, in areas of significant tidal range, rip currents may only occur at certain stages of the tide, when the water is shallow enough to cause the waves to break over a sand bar, but deep enough for the broken wave to flow over the bar. (In parts of the world with a big difference between high tide and low tide, and where the shoreline shelves gently, the distance between a bar and the shoreline may vary from a few meters to a kilometre or more, depending whether it is high tide or low tide.)

A fairly common misconception is that rip currents can pull a swimmer down, under the surface of the water. This is not true, and in reality a rip current is strongest close to the surface, as the flow near the bottom is slowed by friction. The surface of a rip current may appear to be a relatively smooth area of water, without any breaking waves, and this deceptive appearance may cause some beach goers to believe it is a suitable place to enter the water.

Visible Signs

Rip currents have a characteristic appearance, and, with some experience, they can be visually identified from the shore before entering the water. This is useful to lifeguards, swimmers, surfers, boaters, divers and other water users, who may need to avoid a rip, or in some cases make use of the current flow. Rip currents often look a bit like a road or a river running straight out to sea, and are easiest to notice and identify when the zone of breaking waves is viewed from a high vantage point. The following are some characteristics that can be used to visually identify a rip:

- A noticeable break in the pattern of the waves — the water often looks flat at the rip, in contrast to the lines of breaking waves on either side of the rip.
- A "river" of foam — the surface of the rip sometimes looks foamy, because the current is carrying foam from the surf out to open water.
- Different colour — the rip may differ in colour from the surrounding water; it is often more opaque, cloudier, or muddier, and so, depending on the angle of the sun, the rip may show as darker or lighter than the surrounding water.
- It is sometimes possible to see that foam or floating debris on the surface of the rip is moving out, away from the shore. In contrast, in the surrounding areas of breaking waves, floating objects are being pushed towards the shore.

These characteristics are helpful in learning to recognize and understand the nature of rip currents so that a person can recognize the presence of rips before entering the water. In the United States, some beaches have signs created by the National Oceanic and Atmospheric Administration (NOAA) and United States Lifesaving Association, explaining what a rip current is and how to escape one. These signs are titled, "Rip Currents; Break the Grip of the Rip". Beachgoers can get information from lifeguards, who are always watching for rip currents, and who will move their safety flags so that swimmers can avoid rips.

Dangers

Rip currents are a potential source of danger for people in shallow water with breaking waves in seas, oceans and lakes. Rip currents are the proximate cause of 80% of rescues carried out by beach lifeguards. Rip currents typically flow at about 0.5 m/s (1.6 ft/s), but they can be as fast as 2.5 m/s (8.2 ft/s), which is faster than any human can swim. However, most rip currents are fairly narrow, and even the widest rip currents are not very wide; usually swimmers can exit the rip easily by swimming at a right angle to the flow, parallel to the beach. Swimmers who are unaware of this fact may exhaust themselves trying unsuccessfully to swim against the flow. The flow of the current also fades out completely at the head of the rip, outside the zone of the breaking waves, so there is a definite limit to how far the swimmer will be taken out to sea by the flow of a rip current.

In a rip current, death by drowning occurs when a person has limited water skills and panics, or when a swimmer persists in trying to swim to shore against a strong rip current, thus eventually becoming exhausted and unable to stay afloat. According to NOAA, over a 10-year average, rip currents cause 46 deaths annually in the United States, and 64 people died in rip currents in 2013. However, the United States Lifesaving Association "estimates that the annual number of deaths due to rip currents on our nation's beaches exceeds 100." A study published in 2013 in Australia revealed that rips killed more people on Australian territory than bushfires, floods, cyclones and shark attacks combined.

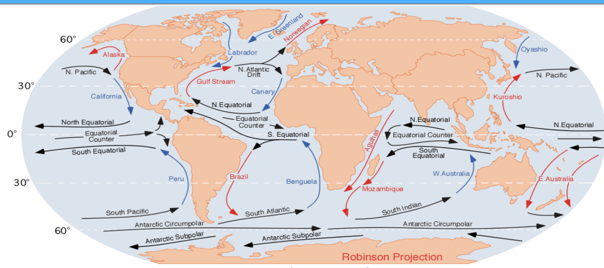
People caught in a rip current may notice that they are moving away from the shore quite rapidly. It is often not possible to swim directly back to shore against a rip current, so this is not recommended. Contrary to popular misunderstanding, a rip does not pull a swimmer under the water, it simply carries the swimmer away from the shore in a narrow band of moving water. The rip is like a moving treadmill, which the swimmer can get out of by swimming across the current, parallel to the shore, in either direction, until out of the rip current, which is usually not very wide. Once out of the rip, swimming back to shore is relatively easy in areas where waves are breaking and where floating objects and swimmers are being pushed towards the shore.

As an alternative, swimmers who are caught in a strong rip can relax and go with the flow (either floating or treading water) until the current dissipates beyond the surf line, and then they can signal for help, or swim back through the surf diagonally away from the rip and towards the shore. It is necessary for coastal swimmers to understand the danger of rip currents, to learn how to recognize them and how to deal with them, and if possible to swim in only those areas where lifeguards are on duty. Experienced and knowledgeable water users, including surfers, body boarders, divers, surf lifesavers and kayakers, will sometimes use rip currents as a rapid and effortless means of transportation when they wish to get out beyond the breaking waves.

Currents

An ocean current is a continuous, directed movement of seawater generated by a number of forces acting upon the water, including wind, the Coriolis effect, breaking waves, cabbeling, and temperature and salinity differences. Depth contours, shoreline configurations, and interactions with other currents influence a current's direction and strength.

Ocean currents move both horizontally, on scales that can span entire oceans, as well as vertically, with vertical currents (upwelling and downwelling) playing an important role in the movement of nutrients and gases, such as carbon dioxide, between the surface and the deep ocean.



Ocean currents flow for great distances and together they create the global conveyor belt, which plays a dominant role in determining the climate of many of Earth's regions. More specifically, ocean currents influence the temperature of the regions through which they travel. For example, warm currents traveling along more temperate coasts increase the temperature of the area by warming the sea breezes that blow over them.

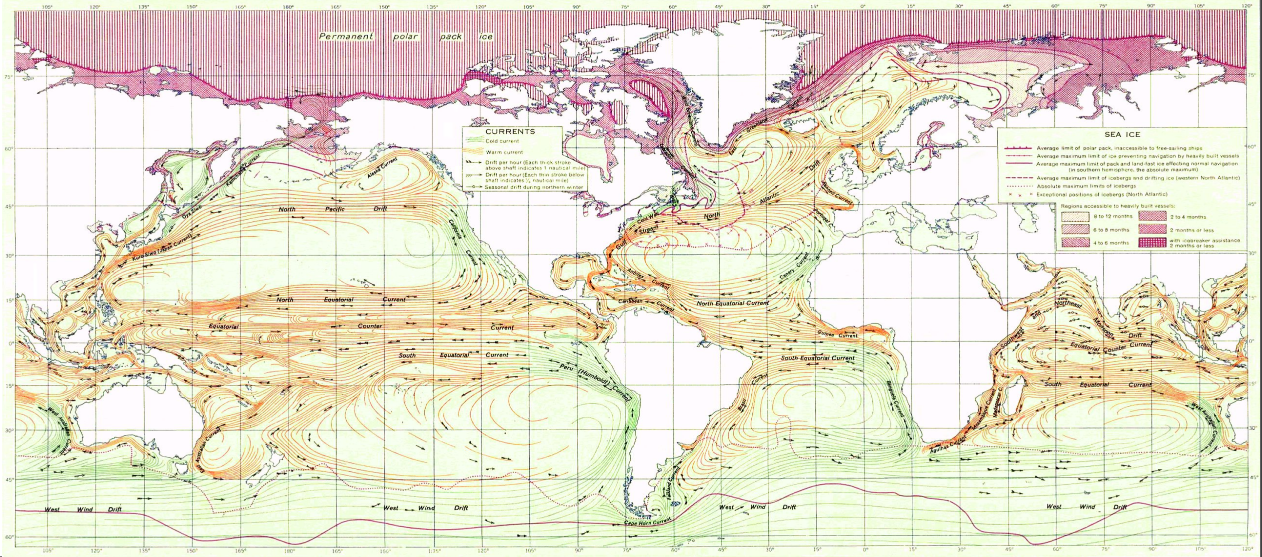
Perhaps the most striking example is the Gulf Stream, which, together with its extension the North Atlantic Drift, makes northwest Europe much more temperate for its high latitude than other areas at the same latitude. Another example is Lima, Peru, whose cooler subtropical climate contrasts with that of its surrounding tropical latitudes because of the Humboldt Current.

Causes

Ocean currents are driven by the wind, by the gravitational pull of the moon in the form of tides, and by the effects of variations in water density. Ocean dynamics define and describe the motion of water within the oceans.

Ocean temperature and motion fields can be separated into three distinct layers: mixed (surface) layer, upper ocean (above the thermocline), and deep ocean. Ocean currents are measured in units of sverdrup (Sv), where 1 Sv is equivalent to a volume flow rate of 1,000,000 m3 (35,000,000 cu ft) per second. There are two main types of currents, surface currents and deep water currents. Generally surface currents are driven by wind systems and deep water currents are driven by differences in water density due to variations in water temperature and salinity.

A 1943 map of the world's ocean currents



Food

Types and the shelf life of foods, and the best foods to stock

"Food is our common ground, a universal experience."
James Beard

Introduction

This category is an overview of foods including the properties of foods, calories, types of foods and shelf life. It should give you an idea of what foods are best to store long term, how to store them and which foods are better for your BOB.

Purpose	The aim of FOOD is to explain the different terms of food, discusses the most common long-life prepper foods, lists the shelf life of a range of different foods and how to prolong the life of food.
Lost?	● If you want a list of recipes, see the RECIPES section. ● For the cooking of food, see the COOKING section. ● If you're looking for food preservation, see the COOKING > Preservation section. ● For growing your own food, see the GARDENING section. ● If you're looking for eating all kinds of wild and foraged foods as well as the wild food edibility test, see the PLANTS section. ● If you're looking for the food groups, see the HEALTH section. ● If you want to know how to properly prepare wild game for consumption, see the FIELD DRESSING section.

Contents

1 Food

Food is any substance consumed to provide nutritional support for an organism. Food is usually of plant or animal origin, and contains essential nutrients, such as carbohydrates, fats, proteins, vitamins, or minerals. The substance is ingested by an organism and assimilated by the organism's cells to provide energy, maintain life, or stimulate growth.

Historically, humans secured food through two methods: hunting and gathering and agriculture, which gave modern humans a mainly omnivorous diet. Worldwide, humanity has created numerous cuisines and culinary arts, including a wide array of ingredients, herbs, spices, techniques, and dishes.

Today, the majority of the food energy required by the ever-increasing population of the world is supplied by the food industry. Food safety and food security are monitored by agencies like the International Association for Food Protection, World Resources Institute, World Food Programme, Food and Agriculture Organization, and International Food Information Council. They address issues such as sustainability, biological diversity, climate change, nutritional economics, population growth, water supply, and access to food.

Food Terms

These are the terms used in food manfacturing which specify the edibility of all food products.

Date of Manufacture	The date the food becomes the product as described.

Date of Packaging	The date the food is placed in the immediate container.
Best Before Date (Date of Minimum Durability)	The date which signifies the end of the period which the product will remain fully marketable and will retain the quality of the contents.
Use-By-Date	Date which signifies the end of the estimated period of storage conditions.
Shelf Life	The length of time that a commodity may be stored without becoming unfit for use, consumption, or sale.
Freshness Date	A freshness date is the date used in the brewing industry to indicate either the date the beer was bottled or the date before which the beer should be consumed.
Shelf-Stable Food (Ambient Food)	Food of a type that can be safely stored at room temperature in a sealed container. This includes foods that would normally be stored refrigerated but which have been processed so that they can be safely stored at room or ambient temperature for a usefully long shelf life.

Lack of Food

This section discusses what you can do when you don't have food.

Limited Pantry Food

If you only have remnants of ingredients left in your pantry you may not be able to make any meals out of them but you can still ration them and eat them slowly to at least give you some sustenance.

Absolutely No Food

If you absolutely don't have ANY food to eat but you have a lot of water to drink, you can gorge yourself on water so you feel full. You can also head outside and look for plants to forage or use the edibility test to see if some berries or leaves are edible.

2 Pantry

These are foods commonly stockpiled or consumed by preppers which are either very nutritious, give a boost of energy or have a long shelf life.

Common Pantry Food

A list of foods generally found in the home and are moderately easy to obtain. These foods should form the basics of a pantry and can create a large variety of dishes.

Almond Extract For adding a little extra flavour to desserts, pie crusts, vegetables and other dishes.	**Apples** For long storage, eating out of hand and making desserts.	**Applesauce** For snacking, cooking, baking and an easy dessert.	**Balsamic Vinegar** For flavouring dishes and making salad dressings.	**Baking soda** For baking and cleaning.	**Baking Powder** For baking.
Barbecue Sauce For cooking and flavouring.	**Bay Leaves** For seasoning soups, stocks, roasts, sauces and poaching liquids.	**Beans (Dried and Canned)** For soups, stews and other dishes.	**Bouillon (Beef, Chicken, and Vegetable)** For soups, seasoning, casseroles and marinades.	**Breadcrumbs** For toppings, stuffing's and other dishes.	**Brown Rice** For casseroles, soups, stuffing's and side dishes.
Brown Sugar For cooking, baking and seasoning.	**Canned Cream Soup** For a quick lunch, or to add to side dishes, soups, casseroles and other dishes.	**Canned Tomatoes** For sauces, salads, soups, stews, casseroles and other dishes.	**Canned Tuna Fish** For quick sandwiches and casseroles.	**Carrots** For long storage, snacking, soups, side dishes, roasting meats, casseroles, stews and more.	**Cocoa Powder** For baking and making hot cocoa.
Cold Cereal For baking, topping casseroles, snacking and breakfast.	**Cooking Sprays** For greasing pans for baking or frying.	**Cornmeal** For cornbread, breading proteins and for baking white bread.	**Cornstarch** For thickening puddings, sauces, stews and gravies.	**Crackers** For snacking, appetizers and topping casseroles.	**Cream of Tartar** For whipping egg whites.
Dried Fruit For desserts, sauces, roasting meat and poultry and snacking.	**Dried Herbs** For seasoning sweet and savoury dishes (good ones to have on hand: basil, oregano, thyme, rosemary, dill, cilantro, tarragon, chives)	**Dried spices** For seasoning sweet and savoury dishes (good ones to have on hand: cinnamon, nutmeg, cumin, paprika, mustard, ginger, allspice, cayenne pepper)	**Garlic** For flavouring or garlic bread.	**Ginger** Fresh for mincing or grating and adding to dishes for a spark.	**Honey** For seasoning, cooking, or eating on biscuits or cereal.
Hot Sauce For adding a touch of spice to dishes.	**Jams or Jellies** For making sandwiches, desserts or sauces.	**Ketchup** For flavouring sandwiches or other dishes.	**Salt** For seasoning	**Lemons and Limes** For squeezing into fresh juice or using the zest in cooking.	**Lentils** For soups, stews and other dishes.

Maple Syrup For breakfasts and baking	**Mayonnaise** For salads, sandwiches, salad dressings and many other dishes; low-fat or fat-free are also good choices.	**Nutmeg** For sweet and savoury dishes and sauces.	**Nuts** A selection of your favourite nuts for breads, muffins, desserts, casseroles and side dishes.	**Oatmeal** For baking, cooking and as a breakfast cereal.	**Olive Oil** For cooking, greasing pans or making salad dressings.
Onions For seasoning meats, soups, stews, casseroles and many other dishes.	**Pasta** For eating plain, with butter, or a sauce; also great for using in soups, stews, casseroles, or as a side dish.	**Peanut Butter** For cooking, baking and snacking.	**Peppercorns** For including whole in soups, stocks, marinades and roasts and for grinding for cooking and table use.	**Powdered Sugar** For making frosting, cooking, baking and decorating.	**Prepared Mustard** For sandwiches, mayonnaise-based salads, salad dressings and marinade.
Potatoes For baking, boiling, roasting and mashing.	**Red Wine Vinegar** For cooking and seasoning.	**Semisweet Chocolate Chips** For desserts and snacking.	**Solid Shortening** For baking and greasing pans.	**Soy Sauce** For flavouring and quick stir-frying.	**Tomato Paste** For making pasta sauces, stews, soups and casseroles.
Unbleached White Flour For cooking, baking, thickening.	**Unsweetened Chocolate** For baking and cooking.	**Vanilla** For flavouring many dishes, especially desserts; only use the real flavouring or vanilla beans.	**Vegetable Oil** For frying, cooking, salad dressings and greasing pans.	**White Sugar** For cooking and seasoning.	**White Wine Vinegar** For salads, flavouring and cleaning coffee pots.
Worcestershire Sauce For seasoning and adding colour.	**Yeast** For baking.				

Energy Food

Any food which gives the consumer a boost of energy to help get through the day.

Bars

Clif Bars	
Chocolate Bars	

Nutritional Foods

Cricket Protein
Besides being far easier to farm and far more ecologically friendly, they are a whole food and highly nutritious. Its easy and light to carry with no liquid and can be added to other foods to boost their nutrition.

- Double the protein of beef
- More calcium than milk
- More Omegas and B12 than wild salmon
- More Iron than Spinach

EnergyBits (Spirulina)
EnergyBits are a nutritionally dense source of mental and physical energy made from the world's purest algae. Spirulina is a cultivated algae that has been consumed for thousands of years by the indigenous peoples in Mexico and Africa. It has the highest concentration of protein on earth - triple that of steak - as well as the second highest concentration of an Essential Fatty Acid called GLA (second only to mother's milk). According to energybits, research done by NASA showed that that 1 kg of spirulina had the nutritional equivalent of 1,000 kg of fruits and vegetables… consider that many International Health Organizations including the United Nations have hailed spirulina as one of the "Greatest Superfoods on Earth.

- Rich vegetable protein (60~ 63 %, 3~4 times higher than fish or beef)
- Multi Vitamins (Vitamin B 12 is 3~4 times higher than animal liver)
- A wide range of minerals (including Iron, Potassium, Magnesium Sodium, Phosphorus, Calcium etc.)
- A high volume of Beta- carotene which protects cells (5 time more than carrots, 40 time more than spinach)
- High volumes of gamma-Linolein acid (which can reduce cholesterol and prevent heart disease).

EnergyBits (Chlorella)
Bits Are A Nutritionally Dense Source Of Mental And Physical Energy Made From The World's Purest Algae. Chlorella algae is harvested in fresh water tanks and has been used for over fifty years in Asia. It has a remarkable ability to help remove toxins and help build the immune system. All naturally. Chlorella contains over 40 nutrients including all the B vitamins, iron, zinc and many minerals. It offers so many benefits we would never have enough room here to list them all. The Japanese were the first to discover the detoxifying properties of Chlorella to remove poisonous substances from the body such as radiation. After atomic weapons were dropped on Hiroshima and Nagasaki, Chlorella was used to remove radiation from the bodies of those who had become contaminated. Chlorella soaks up radiation like a sponge.

Common Prepper Foods

These foods are commonly stored by preppers due to their long life span, their nutrition and their light weight.

- Maize (Corn)
- Pasta
- Rice
- Sorghum
- Wheat
- Beans
- Lentils
- Peas

- Ghee
- Vegetable Oils
- Fish Canned
- Corned Beef
- Chicken Canned
- Pork Canned
- Ready Meal Canned
- Tomato Paste Canned

- Canned Cheese
- Baby Food
- Coffee
- Seasoning Cube
- Iodized Salt
- Sugar
- Black Tea
- Yeast

- Dry Skimmed Milk DSM
- Dry Whole Milk DWM
- Energy Food Bar
- Biscuit
- Multivitamin
- Peanut Butter
- MRE

Food Degredation

Below is a list of processes, reactions and contaminants which causes food to spoil faster.

Oxygen	Oxygen oxidises the food it comes into contact with, reducing its shelf life the more it is exposed.
Pests	Pests, either rodents or microscopic bugs such as botulism or bacteria can get into your food and cause contamination.
Humidity & Moisture	Humidity deteriorates food and causes it to spoil much faster.
Heat	Heat causes food to spoil faster by speeding up the oxidation process.
Light	Exposure to light can degrade food faster than darkness.
Gas Transmission	The transmission of gases through the walls of containers can cause additional degredation.
Mechanical Stress	Bumps, bangs and dents can also reduce the shelf life and quality of food.

Canned Food

Check for dents and rust that may compromise the can. Bulging cans could mean a hydrogen build up in acidic foods such as tomatoes or citrus fruit. It's due to the acids attacking the metal lining of the can with a by-product of hydrogen. Bulging cans could also mean that the food has been spoiled by bacteria which release carbon dioxide gas, this food could kill you if eaten. Throw away any cans with an incorrect/almond smell. Rust: Iron, water and oxygen together causes rust, therefore try to minimize their impact when storing food.

Dented Cans

Dented cans shouldn't be any different to regular cans, however watch out for holes at the crease points in severely dented cans. You may need to take the label off to thoroughly check for pinprick holes before consuming them.

Bulging Cans

Bulging cans could mean that the food has been spoiled by bacteria which release carbon dioxide gas. This food could kill you if eaten and any non acidic bulging food cans should be thrown out. Bulging cans could also mean a hydrogen build up in acidic foods such as tomatoes or citrus fruit. It's due to the acids attacking the metal lining of the can with a by-product of hydrogen. High acidic foods in a bulging can could mean they are safe to eat but have simply reacted with the can. Make certain before you eat any bulging can as it could contain both a high acid food and bacteria. Bulging cans will spray food quite a distance if opened so be sure to open them away from all other food sources just in case they contain bacteria.

High Acid Foods

High acid foods have a pH of less than 4.6. The environment contains concentrated hydrogen ions which prevents the growth of most bacteria, fungi and yeast. Acidity stops germination of clostridium botulinum preventing the release of it's deadly neurotoxin therefore mitigating the need to kill the spores. Combinations of varying pH foods can raise or lower the pH level above the threshold. Tomatoes which are considered high pH could be raised above 4.6pH in a bolognese mix.

High Acid Foods
- Tomatoes
- Fruits
- Juices
- Picked Foods
- Fermented Foods

Low Acid Foods

Low acid foods have a pH of more than 4.6. Botulinum spores are a perfect environment for germination and producing its toxin.

Low Acid Foods
- Meat
- Fish
- Vegetables

Food Rarity

This section will go into what foods will be common and easily found during a disaster, to the ones that will go off quickly and will be impossible to find.

Canned Food	Generally one of the first types of food to disappear from the shelves during any kind of disaster.

3 Consumption

This section details how food can and should be consumed and tips on making food go further in a survival situation.

Consuming Food

Food should never be eaten when you don't have a supply of clean water to drink because it takes quite a lot of water to break down food in your stomach. Doing so will cause you to become dehydrated much quicker and as you may know, you will die in 3 days without water and about 3 weeks without food. You can however eat foods high in liquid content to be able to satisfy both needs at the same time. An example of a food rich in liquid are most fruits and canned soups.

Eating Order

This is the order you should consume food in during a disaster, assuming you have lost power but you can keep the fridge and freezers running a few more days. All food has a shelf life and you could waste a lot of it if you begin eating the canned food before the fresh food. Be sure to check that the food hasn't spoiled before you eat it, as you may only get through half the food in the fridge before it becomes risky to eat.

1	**Refrigerated Foods (Eat within 24H of power loss)** Any foods in the fridge which have a few days shelf life. You may need to eat these before the fresh foods depending on how cold the fridge is. Eat these within a day, or within 2 hours of the temperature becoming 'too high'. Some refrigerated foods will last well at room temperature such as fruits, veges and most sauces. The fridge is your top priority as it consumes the most power and you want to disconnect your power supply from it as soon as possible - assuming it's limited.
2	**Frozen Foods** A full freezer without power will safely keep food edible for 48 hours. A half-full freezer will keep it edible up to 24 hours. In both cases, you can safely re-freeze the food if you can still see ice crystals anywhere on the product. After these timeframes, you should eat the food as soon as you can - as long as it feels as if it's been refrigerated.
3	**Fresh Foods (Eat within a week)** Fruit, vegetables, bread and other unrefrigerated food which will spoil within a week or two. This includes any food you grow.
4	**Pantry Foods** The next food to go should be the pantry foods such as flour, cereal, rice etc. If you need to find a meal, combine some pantry foods with your canned foods.
5	**Snack Foods** Individually packaged mid-life foods such as potato chips, dried fruit, chocolate, lollies, muesli bars etc which often last between 6 months to a year.
6	**Ration Bars** If you have ration bars you should eat these next.
7	**MREs (Eat within a few years)** The next thing to go as these will last 10 years on average, but may already be well into this expiry date.
8	**Freeze Dried Food** Lasts between 10-35 years so this should be eaten close to last.
9	**Canned Food** Most canned foods will last indefinitely if stored correctly so these should be eaten last.

Prolonging Food

Below are a few things you can do before or after you've lost power to prolong the cold air in your fridge and freezer and thus extending the life of the food inside.

- Move the fridge/freezer to the coldest room in the house
- Wrap the fridge/freezer in insulating material such as blankets, sheets and foam, but avoid covering the sides which generate heat.
- Limit the opening of the fridge/freezer. On your first open you should take a picture of the contents inside and use that as a guide to tell you what food is remaining and where it is so you can quickly grab it without losing too much cold air. 1 second of an open door reduces the duration the food will stay cold by 6 minutes.
- A full fridge/freezer keeps colder far longer than an empty one - but only if it's full (and cold) before you lose power.
- When the power goes off, bottles of water in the fridge and freezer act as "cold batteries" which release their stored energy over a long period of time. So you should have a couple pre-frozen just in case. The same works for those cold bricks you can buy.

4 Shelf Life

Various food preservation and packaging techniques are used to extend a food's shelf life. Decreasing the amount of available water in a product, increasing its acidity, or irradiating or otherwise sterilizing the food and then sealing it in an air-tight container are all ways of depriving bacteria of suitable conditions in which to thrive. Commercial Canning involves cooking food and sealing it in sterilized tin cans. Home canning usually involves mason jars and boiling the containers to kill or weaken any remaining bacteria as a form of sterilization. Retort pouches involve heat processing the food in sterilized heat-stable flexible packages. This is used for camping food and military field rations. The first shelf-stable formulation of ranch dressing, created in 1983, had a shelf life of 150 days. Pasteurized milk in aseptically processed cartons (Tetra Brik, etc)) is shelf stable without refrigeration. Fruit juice can be processed with proper pasteurization to allow shelf stable options.

Extending Shelf Life
Elimination of oxygen and preventing oxygen to get in touch with the product. Potentially hazardous foods should be stored below 5°C (41°F) throughout their storage life.

Canned Food
Non acidic canned foods can last hundreds of years if properly stored. Foods which contain acidic content will slowly break down the lining of the can and cause it to bulge. Discard any bulging cans, heavily rusted cans or cans when don't smell right upon opening.

SOME OF THE FOOD LISTED BELOW HAS BEEN REPACKAGED INTO MYLAR BAGS FOR THE BEST SHELF LIFE. READ EACH COMMENT CAREFULLY.

Short Life Foods (1-3 Years)

These foods will last a couple of years. If a disaster looks like it'll last over 3 years it would be best to grow your own fresh foods.

Meat, Dehydrated	**Shelf Life** 2 Years	(Mylar Packaged)
Pet Biscuits, Dry	**Shelf Life** 0.5 Years	(Mylar Packaged)
Rice, Brown	**Shelf Life** 0.5 Years	

Medium Life Foods (3-5 Years)

These foods will last up to half a decade.

Baby Formula	**Shelf Life** 3-5 Years	(Mylar Packaged)
Coffee Beans, Roasted	**Shelf Life** 3-5 Years	(Mylar Packaged)
Crackers/Biscuits	**Shelf Life** 4 Years	(Mylar Packaged)

Dehydrated Fruit Slices	**Shelf Life** 5 Years	
Granola	**Shelf Life** 4-5 Years	(Mylar Packaged)
Lentils / Peas	**Shelf Life** 3-5 Years	(No Packaging)
Pearled Barley	**Shelf Life** 5 Years	(Mylar Packaged)
Popcorn	**Shelf Life** 5 Years	(Mylar Packaged)

Long Life Foods (5-10 Years)

These foods will last between 5 years to a decade.

Almond Meal	**Shelf Life** 5-8 Years	(Mylar Packaged)
Barley Grain	**Shelf Life** 10 Years	(Mylar Packaged)
Buckwheat	**Shelf Life** 10 Years	(Mylar Packaged)
Bullion Stock Powder	**Shelf Life** 5-10 Years	(Mylar Packaged)
Cereals	**Shelf Life** 10 Years	(Mylar Packaged)
Coffee, Grounded	**Shelf Life** 10+ Years	(Mylar Packaged)
Cornflour	**Shelf Life** 5-10 Years	(Mylar Packaged)
Eggs, Powdered	**Shelf Life** 5-10 Years	(Mylar Packaged)
Flax/Linseed	**Shelf Life** 8-12 Years	(Mylar Packaged)
Herbs	**Shelf Life** 5-7 Years	(Mylar Packaged)
Milk, Powdered (Full Fat)	**Shelf Life** 5-7 Years	(Mylar Packaged)
Millet	**Shelf Life** 8-12 Years	(Mylar Packaged)
MREs	**Shelf Life** 5-10 Years	MRE's have a written shelf life of 5 years, but they can often be safely consumed after that time. Use your best judgement whether to eat it or not.
Pepper, Whole	**Shelf Life** 7-10 Years	(Mylar Packaged)
Polenta/Cornmeal	**Shelf Life** 5-8 Years	(Mylar Packaged)
Quinoa	**Shelf Life** 7-9 Years	(Mylar Packaged)
Rye	**Shelf Life** 8+ Years	(Mylar Packaged)
Seeds, Edible	**Shelf Life** 5-10 Years	(Mylar Packaged)
Seeds, Sprouting	**Shelf Life** 4-7 Years	(Mylar Packaged)
Spices	**Shelf Life** 2-10 Years	(Mylar Packaged)

Extra Long Life Foods (10-50 Years)

These staples will last an extremely long time if stored correctly.

Amaranth Grain	**Shelf Life** 10 Years	(Mylar Packaged)
Arrowroot Powder	**Shelf Life** 10+ Years	(Mylar Packaged)
Baking Powder	**Shelf Life** 30+ Years	(Mylar Packaged)
Beans, Dried	**Shelf Life** 20-30 Years	(Mylar Packaged) Most beans will last between 20 and 30 years if packaged correctly.
Butter Powder	**Shelf Life** 15 Years	(Mylar Packaged)
Cheese Powder	**Shelf Life** 10-15 Years	(Mylar Packaged)
Cocoa Powder	**Shelf Life** 15 Years	(Mylar Packaged)
Corn, Dried	**Shelf Life** 10+ Years	(Mylar Packaged)
Corn, Dry (Maize)	**Shelf Life** 10-15 Years	(Mylar Packaged)
Couscous	**Shelf Life** 10+ Years	(Mylar Packaged)
Coffee (Instant)	**Shelf Life** 25+ Years	(Mylar Packaged) Instant coffee is freeze-dried, therefore it will last as long as regular freeze-dried foods.
Coffee Beans, Green	**Shelf Life** 20+ Years	(Mylar Packaged)
Dried/Dehydrated Food	**Shelf Life** 10-20 Years	

FOOD Shelf Life Extra Long Life Foods

Freekeh	**Shelf Life** 10+ Years	(Mylar Packaged)
Freeze Dried Fruit	**Shelf Life** 25+ Years	(Mylar Packaged)
Freeze Dried Veges	**Shelf Life** 25+ Years	(Mylar Packaged)
Lentils	**Shelf Life** 25+ Years	(Mylar Packaged)
Milk, Powdered (Skim)	**Shelf Life** 15-25 Years	(Mylar Packaged) This only applies to powdered skim milk in mylar bags. If it's full fat powdered milk, it will only last around 5 years in mylar bags.
Mountain House Meals	**Shelf Life** 30 Years	Mountain house products have a 30 year guarantee and are likely to taste just as good.
Oats, Hulled	**Shelf Life** 30 Years	(Mylar Packaged)
Oats, Rolled	**Shelf Life** 30 Years	(Mylar Packaged)
Oats, Steel-Cut	**Shelf Life** 15 Years	(Mylar Packaged)
Onion, Dehydrated	**Shelf Life** 10-15 Years	(Mylar Packaged)
Pasta	**Shelf Life** 25-30 Years	(Mylar Packaged)
Peanut Butter Powder	**Shelf Life** 10-15 Years	(Mylar Packaged)
Peas, Black Eyed	**Shelf Life** 15-20 Years	(Mylar Packaged)
Peas, Dehydrated	**Shelf Life** 15 Years	(Mylar Packaged)
Peas, Split	**Shelf Life** 25+ Years	(Mylar Packaged)
Pet Biscuits, Freeze Dried	**Shelf Life** 25+ Years	(Mylar Packaged)
Potatoes	**Shelf Life** 30 Years	(Mylar Packaged)
Potatoes, Instant	**Shelf Life** 15-20 Years	(Mylar Packaged)
Rice, White	**Shelf Life** 20-30 Years	(Mylar Packaged)
Spelt Grain	**Shelf Life** 10-12 Years	(Mylar Packaged)
Sorghum	**Shelf Life** 10+ Years	(Mylar Packaged)
Tea Bags	**Shelf Life** 30+ Years	(Mylar Packaged)

Indefinite Life Foods (50+ Years)

These foods will last around the span of a human life. It's extremely unlikely that any disaster will last more than 50 years. If it does then it would be easier to just grow your own food.

Baking Soda	**Shelf Life** Indefinite	(Mylar Packaged)
Canned Foods	**Shelf Life** Indefinitely	Excluding canned acids such as tomatoes which bulge over time and may leak out. Cans last between 25 years to forever. Heated cans won't affect the food inside but may cause them to rust or go off faster. Every 5.556°C (10°F) rise in temperature, the shelf life generally halves.
Honey	**Shelf Life** Indefinite	Honey may crystallize the older it gets. If this happens, put it in some hot water and give it a stir slowly.
Sugar	**Shelf Life** Indefinite	Sugar may turn into a brick over time. Hit it with something hard in a flexible bag to break it up again.
Salt	**Shelf Life** Indefinite	Salt may turn into a brick over time. Hit it with something hard in a flexible bag to break it up again.

Prolonging Food

Below are a few things you can do before or after you've lost power to prolong the cold air in your fridge and freezer and thus extending the life of the food inside.

- Move the fridge/freezer to the coldest room in the house
- Wrap the fridge/freezer in insulating material such as blankets, sheets and foam
- Limit the opening of the fridge/freezer. On your first open you should take a picture of the contents inside and use that as a guide to tell you what food is remaining and where it is so you can quickly grab it without losing too much cold air.
- A full fridge/freezer keeps colder far longer than an empty one - but only if it's full (and cold) before you lose power.
- When the power goes off, bottles of water in the fridge and freezer act as "cold batteries" which release their stored energy over a long period of time. So you should have a couple pre-frozen just in case. The same works for those cold bricks you can buy.

5 Food Shelf Life

These is the shelf life of most common nuts and grains, both pre-packaged and raw. The Pantry, Refrigerator and Freezer columns show how long the product will last when stored in each of those environments. A blank cell means it shouldn't be stored this way.

Subheadings

1. Nuts & Grains Shelf Life	**2. Vegetables Shelf Life**	**3. Fruits Shelf Life**	**4. Meat Shelf Life**

1 Nuts & Grains Shelf Life

These is the shelf life of most common nuts and grains, both pre-packaged and raw.

	Pantry	Refrigerator	Freezer	Food Tips
Almonds, Commercially Bagged Or Purchased In Bulk - In The Shell	2-4 Weeks	12 Months	2 Years	How long do almonds last in the shell? The exact answer depends to a large extent on storage conditions -because of their high oil content, almonds must be stored properly to avoid becoming rancid. To maximize the shelf life of unshelled almonds, store in cool, dry area; after opening the package, place the almonds in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. How long do unshelled almonds last at room temperature? Properly stored, unshelled almonds will generally stay at best quality for 2 to 4 weeks at room temperature. To further extend the shelf life of unshelled almonds, the almonds may be stored in the fridge or freezer; place almonds in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. How long do unshelled almonds last in the refrigerator? Properly stored, unshelled almonds will generally stay at best quality for about 12 months in the refrigerator. How long do unshelled almonds last when stored in the freezer? Unshelled almonds will generally stay at best quality for about 2 years in the freezer; the freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. Unshelled almonds can be thawed and refrozen repeatedly during the freezer time shown without any significant loss of flavour or texture. How to tell if unshelled almonds are bad? Rancid almonds will often develop a bitter, unpleasant taste; if almonds develop an off odor or taste, or if mould appears, they should be discarded.
Almonds, Commercially Bagged Or Purchased In Bulk - Out Of The Shell	2-4 Weeks	9 Months	1 Year	The precise answer to the question "How long do shelled almonds last?" depends to a large extent on storage conditions -because of their high oil content, almonds must be stored properly to avoid becoming rancid. To maximize the shelf life of shelled almonds, store in cool, dry area; after opening the package, place the almonds in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. To further extend the shelf life of shelled almonds, the almonds may be stored in the fridge or freezer; place almonds in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. Almonds can be thawed and refrozen repeatedly during the freezer time shown without any significant loss of flavour or texture. How long do almonds last when stored in the freezer? The freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if almonds are bad? Rancid almonds will often develop a bitter, unpleasant taste; if almonds develops an off odor, flavour or appearance, they should be discarded.
Angel Hair Pasta, Dry, Uncooked, Commercially Packaged, Sold Unrefrigerated—Unopened Or Opened	3 Years			How long does a package of dry angel hair pasta last? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of dry angel hair pasta store in a cool, dry area. How long does a package of dry angel hair pasta last once opened? Properly stored, a package of dry angel hair pasta will generally stay at best quality for about 3 years at room temperature. To maximize the shelf life of dry angel hair pasta, keep the package tightly closed at all times. To further maximize the shelf life of dry angel hair pasta once the package is opened, transfer dry angel hair pasta to a covered airtight container or place the dry angel hair pasta package in a resealable plastic freezer bag. Is dry angel hair pasta safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged dry angel hair pasta will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the dry angel hair pasta will remain at peak quality. Storage time shown is for best quality only - after that, the dry angel hair pasta's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly, the package is undamaged, and there are no signs of spoilage. How can you tell if dry angel hair pasta is bad or spoiled? The best way is to smell and look at the dry angel hair pasta: if the dry angel hair pasta develops an off odor, flavour or appearance, or if mould or insects appear, it should be discarded.
Baked Beans, In Sauce, Commercially Canned Or Bottled - Opened	3-5 Years (Best Quality) (Unopened)	3-4 Days	1-2 Months	How long does a can of baked beans last once opened? The precise answer depends to a large extent on storage conditions - keep opened baked beans refrigerated and tightly covered. To maximize the shelf life of canned baked beans after opening, refrigerate in covered glass or plastic container. How long do opened canned baked beans last in the refrigerator? Canned baked beans that have been continuously refrigerated will keep for about 3 to 4 days. Are canned baked beans safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned baked beans will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the baked beans will remain at peak quality. To further extend the shelf life of opened canned baked beans, freeze them: to freeze canned baked beans, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned baked beans will be softer after freezing and thawing; the thawed baked beans will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned baked beans last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - baked beans that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do canned baked beans last after being frozen and thawed? Baked beans that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; baked beans that were thawed in the microwave or in cold water should be used immediately.
Barley, Commercially Bagged Or Purchased In Bulk - Cooked	1 Year (Uncooked)	3-5 Days	1 Month	Refrigerate within two hours of cooking; store in covered container. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Bean Soup, Commercially Canned Or Bottled — Opened	3-5 Years (Best Quality) (Unopened)	3-4 Days	4-6 Months	How long does bean soup last once opened? The precise answer depends to a large extent on storage conditions - keep opened bean soup refrigerated and tightly covered. To maximize the shelf life of canned or packaged bean soup after opening, refrigerate in covered glass or plastic container. How long does opened bean soup last in the refrigerator? Bean soup that has been continuously refrigerated will keep for about 3 to 4 days. Is bean soup safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged bean soup will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the bean soup will remain at peak quality. To further extend the shelf life of opened bean soup, freeze it: to freeze bean soup, place inside covered airtight containers or heavy-duty freezer bags. How long does bean soup last in the freezer? Properly stored, it will maintain best quality for about 6 months, but will remain safe beyond that time. The freezer time shown is for best quality only - bean soup that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does bean soup last after being frozen and thawed? Bean soup that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; bean soup that was thawed in the microwave or in cold water should be used immediately. How can you tell if opened bean soup is bad or spoiled? The best way is to smell and look at the bean soup: if the bean soup develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Black Beans, Commercially Canned Or Bottled — Opened	3-5 Years (Best Quality) (Unopened)	3-4 Days	1-2 Months	How long does a can of black beans last once opened? The precise answer depends to a large extent on storage conditions - keep opened black beans refrigerated and tightly covered. To maximize the shelf life of canned black beans after opening, refrigerate in covered glass or plastic container. How long do opened canned black beans last in the refrigerator? Canned black beans that have been continuously refrigerated will keep for about 3 to 4 days. Are canned black beans safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned black beans will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the black beans will remain at peak quality. To further extend the shelf life of opened canned black beans, freeze them: to freeze canned black beans, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned black beans will be softer after freezing and thawing; the thawed black beans will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned black beans last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - black beans that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. Discard all black beans from cans or packages that are leaking, rusting, bulging or severely dented. How long do canned black beans last after being frozen and thawed? Black beans that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; black beans that were thawed in the microwave or in cold water should be used immediately. How can you tell if opened canned black beans are bad or spoiled? The best way is to smell and look at the black beans: if the black beans develop an off odor, flavour or appearance, or if mould appears, they should be discarded.
Black-Eyed Peas, Commercially Canned Or Bottled — Opened	3-5 Years (Best Quality) (Unopened)	3-4 Days	1-2 Months	How long does a can of black-eyed peas last once opened? The precise answer depends to a large extent on storage conditions - keep opened black-eyed peas refrigerated and tightly covered. To maximize the shelf life of canned black-eyed peas after opening, refrigerate in covered glass or plastic container. How long do opened canned black-eyed peas last in the refrigerator? Canned black-eyed peas that have been continuously refrigerated will keep for about 3 to 4 days. Are canned black-eyed peas safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned black-eyed peas will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the black-eyed peas will remain at peak quality. To further extend the shelf life of opened canned black-eyed peas, freeze them: to freeze canned black-eyed peas, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned black-eyed peas will be softer after freezing and thawing; the thawed black-eyed peas will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned black-eyed peas last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - black-eyed peas that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do canned black-eyed peas last after being frozen and thawed? Black-eyed peas that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; black-eyed peas that were thawed in the microwave or in cold water should be used immediately. How can you tell if opened canned black-eyed peas are bad or spoiled? The best way is to smell and look at the black-eyed peas: if the black-eyed peas develop an off odor, flavour or appearance, or if mould appears, they should be discarded. Discard all black-eyed peas from cans or packages that are leaking, rusting, bulging or severely dented.
Brazil Nuts, Commercially Bagged Or Purchased In Bulk - In The Shell	2-4 Weeks	12 Months	12-18 Months	The exact answer to the question ? How long do Brazil nuts last in the shell? depends to a large extent on storage conditions -because of their high oil content, Brazil nuts must be stored properly to avoid becoming rancid. To maximize the shelf life of unshelled Brazil nuts, store in cool, dry area; after opening the package, place the Brazil nuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. To further extend the shelf life of unshelled Brazil nuts, the Brazil nuts may be stored in the fridge or freezer; place Brazil nuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. Unshelled Brazil nuts can be thawed and refrozen repeatedly during the freezer time shown without any significant loss of flavour or texture. How long do unshelled Brazil nuts last when stored in the freezer? The freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if unshelled Brazil nuts are bad? Rancid Brazil nuts will often develop a bitter, unpleasant taste; if Brazil nuts develop an off odor or taste, or if mould appears, they should be discarded.
Brazil Nuts, Commercially Bagged Or Purchased In Bulk - Out Of The Shell	2-4 Weeks	9 Months	1 Year	The precise answer to the question ? How long do Brazil nuts last once shelled? depends to a large extent on storage conditions -because of their high oil content, Brazil nuts must be stored properly to avoid becoming rancid. To maximize the shelf life of shelled Brazil nuts, store in cool, dry area; after opening the package, place the Brazil nuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. Shelled Brazil nuts can be thawed and refrozen repeatedly during the freezer time shown without any significant loss of flavour or texture. How long do shelled Brazil nuts last when stored in the freezer? The freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if shelled Brazil nuts are bad? Rancid Brazil nuts will often develop a bitter, unpleasant taste; if Brazil nuts develop an off odor or taste, or if mould appears, they should be discarded.
Cereal, Ready-To-Eat, Commercially Packaged - Opened	2-3 Months (Best Quality) (Unopened)			How long does an opened package of cereal last? The precise answer depends to a large extent on storage conditions -to maximize the shelf life of opened cereal (including corn and bran flakes, toasted oats, rice puffs, corn puffs, granola, wheat squares) store in a cool, dry area. How long does opened cereal last at room temperature? Properly stored, an opened package of cereal will generally stay at best quality for about 2 to 3 months at room temperature. To maximize the shelf life of opened cereal, keep package tightly closed. Is opened cereal safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged cereal will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the cereal will remain at peak quality. Storage time shown is for best quality only - after that, the cereal's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly, the package is undamaged, and there are no signs of spoilage. How can you tell if cereal is bad or spoiled? The best way is to smell and look at the cereal: if cereal develops an off odor, flavour or appearance, or if mould appears, it should be discarded.

FOOD | Food Shelf Life | Nuts & Grains Shelf Life

Cereal, Ready-To-Eat, Commercially Packaged - Unopened	1 Year (Best Quality)			How long does an unopened package of cereal last? The precise answer depends to a large extent on storage conditions -to maximize the shelf life of unopened cereal (including corn and bran flakes, toasted oats, rice puffs, corn puffs, granola, wheat squares) store in a cool, dry area. Properly stored, an unopened package of cereal will generally stay at best quality for about one year. Is unopened cereal safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged cereal will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the cereal will remain at peak quality. Storage time shown is for best quality only - after that, the cereal's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly, the package is undamaged, and there are no signs of spoilage. How can you tell if cereal is bad or spoiled? The best way is to smell and look at the cereal: if cereal develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Coconuts, Fresh — In The Shell	1 Week	1 Month		Store in cool, dry area. Refrigerate for longer storage.
Coconuts, Fresh — Milk Or Water Only		2 Days	1-2 Months	Refrigerate in covered airtight container. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Coconuts, Fresh — Shelled		4-5 Days	6 Months	Refrigerate in covered airtight container. To freeze, shred coconut meat and place in airtight plastic container or heavy-duty freezer bag. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Cornstarch — Unopened Or Opened Package	Keeps Indefinitely			How long does cornstarch last? The precise answer depends to a large extent on storage conditions — to maximize the shelf life of cornstarch, store in a cool, dark cupboard, away from direct heat or sunlight. To maximize the shelf life of cornstarch, keep the package tightly sealed after opening. Properly stored, cornstarch will stay safe indefinitely without a loss of quality. Is cornstarch safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged — commercially packaged cornstarch may carry a "Best By," "Best if Used By," "Best Before," or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the cornstarch will remain at peak quality. Does cornstarch ever spoil? No, commercially packaged cornstarch does not spoil and will remain safe provided it has been stored properly.
Hazelnuts / Filberts, Commercially Bagged Or Purchased In Bulk - In The Shell	3 Months	9 Months	12 Months	The precise answer to the question? How long do hazelnuts last in the shell? depends to a large extent on storage conditions -because of their high oil content, hazelnuts (filberts) must be stored properly to avoid becoming rancid. To maximize the shelf life of unshelled hazelnuts, store in cool, dry area; after opening the package, place the hazelnuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. To further extend the shelf life of unshelled hazelnuts, the hazelnuts may be stored in the fridge or freezer; place hazelnuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. Unshelled hazelnuts can be thawed and refrozen repeatedly during the freezer time shown without any significant loss of flavour or texture. How long do unshelled hazelnuts last when stored in the freezer? The freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if unshelled hazelnuts are bad? Rancid hazelnuts will often develop a bitter, unpleasant taste; if hazelnuts develop an off odor or taste, or if mould appears, they should be discarded.
Kidney Beans, Commercially Canned Or Bottled — Opened	3-5 Years (Best Quality) (Unopened)	3-4 Days	1-2 Months	How long does a can of kidney beans last once opened? The precise answer depends to a large extent on storage conditions - keep opened kidney beans refrigerated and tightly covered. To maximize the shelf life of canned kidney beans after opening, refrigerate in covered glass or plastic container. How long do opened canned kidney beans last in the refrigerator? Canned kidney beans that have been continuously refrigerated will keep for about 3 to 4 days. Are canned kidney beans safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned kidney beans will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the kidney beans will remain at peak quality. To further extend the shelf life of opened canned kidney beans, freeze them: to freeze canned kidney beans, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned kidney beans will be softer after freezing and thawing; the thawed kidney beans will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned kidney beans last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - kidney beans that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do canned kidney beans last after being frozen and thawed? Kidney beans that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; kidney beans that were thawed in the microwave or in cold water should be used immediately. How can you tell if opened canned kidney beans are bad or spoiled? The best way is to smell and look at the kidney beans: if the kidney beans develop an off odor, flavour or appearance, or if mould appears, they should be discarded.
Lasagne - Purchased Commercially Frozen			18 months (best quality)	How long does frozen lasagne last? The precise answer to that question depends to a large extent on storage conditions - keep lasagne frozen at all times. Properly stored, frozen lasagne will maintain best quality for about 18 months in the freezer, although it will usually remain safe to eat after that. Is frozen lasagne safe to eat after the expiration date on the package? Yes, if properly stored - commercially frozen lasagne will typically carry a Best By," "Best if Used By," Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the lasagne will remain at peak quality. How long will frozen lasagne remain safe to eat? Frozen lasagne that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as it has been stored properly and the package is not damaged. How long can you safely leave frozen lasagne at room temperature? Frozen lasagne should be discarded if left for more than 2 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). How long does frozen lasagne last in the fridge after being cooked? Frozen lasagne that has been cooked can be kept for 3 to 5 days in the fridge; refrigerate the lasagne in airtight containers or wrap tightly in aluminium foil or plastic wrap. How to tell if frozen lasagne is no longer good? If dry spots or discoloration have developed on the frozen lasagne, freezer burn has begun to set in - this will not make the lasagne unsafe to eat, but it will harm the texture and taste.
Macadamia Nuts, Commercially Bagged Or Purchased In Bulk - Out Of The Shell	2-4 Weeks	6 Months	9-12 Months	The precise answer to the question ? How long do macadamia nuts last once shelled? depends to a large extent on storage conditions -because of their high oil content, macadamia nuts must be stored properly to avoid becoming rancid. To maximize the shelf life of shelled macadamia nuts, store in cool, dry area; after opening the package, place the macadamia nuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. To further extend the shelf life of shelled macadamia nuts, the macadamia nuts may be stored in the fridge or freezer; place macadamia nuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. Shelled macadamia nuts can be thawed and refrozen repeatedly during the freezer time shown without any significant loss of flavour or texture. How long do shelled macadamia nuts last when stored in the freezer? The freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if shelled macadamia nuts are bad? Rancid macadamia nuts will often develop a bitter, unpleasant taste; if macadamia nuts develop an off odor or taste, or if mould appears, they should be discarded.
Mixed Nuts, Commercially Canned Or Bottled - Opened	1 Month	4-6 Months	9-12 Months	Keep container tightly sealed after opening. Refrigerate to extend shelf life. To freeze, place nuts in airtight container or heavy-duty freezer bag. If nuts develop an off odor or taste they should be discarded.
Noodles And Sauce, Dry Mix, Commercially Packaged - Unopened Or Opened	2 Years (Best Quality)			How long does a package of noodles and sauce mix last? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of noodles and sauce mix store in a cool, dry area. How long does noodles and sauce mix last at room temperature? Properly stored, a package of noodles and sauce mix will generally stay at best quality for about 2 years at room temperature. To maximize the shelf life of noodles and sauce mix, keep the package tightly closed at all times. Is noodles and sauce mix safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged noodles and sauce mix will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the noodles and sauce mix will remain at peak quality. 'Storage time shown is for best quality only - after that, the noodles and sauce mix's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly, the package is undamaged, and there are no signs of spoilage. How can you tell if noodles and sauce mix is bad or spoiled? The best way is to smell and look at the noodles and sauce mix: if the noodles and sauce mix develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Oatmeal, Cooked		4-6 Days	6 Months	How long does cooked oatmeal last in the fridge or freezer? The precise answer to that question depends to a large extent on storage conditions - refrigerate oatmeal within two hours of cooking. To maximize the shelf life of cooked oatmeal, refrigerate in covered airtight containers or resealable plastic bags. Properly stored, cooked oatmeal will last for 4 to 6 days in the refrigerator. How long can cooked oatmeal be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); oatmeal should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked oatmeal, freeze it; freeze oatmeal in covered airtight containers or heavy-duty freezer bags. How long does cooked oatmeal last in the freezer? Properly stored, it will maintain best quality for 6 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked oatmeal that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cooked oatmeal is bad? The best way is to smell and look at the oatmeal; discard any oatmeal with an off smell or appearance, do not taste the cooked oatmeal first.
Oatmeal, Regular Or Instant, Uncooked — Unopened Or Opened Package	18-24 months (best quality)			How long does oatmeal last? The precise answer depends to a large extent on storage conditions -to maximize the shelf life of oatmeal store in a cool, dry area. How long does oatmeal last at room temperature? Properly stored, a package of oatmeal will generally stay at best quality for about 18 to 24 months at room temperature. To maximize the shelf life of oatmeal once the package is opened, transfer to a covered airtight container or place original oatmeal package in a resealable plastic freezer bag. Is oatmeal safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged oatmeal will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the oatmeal will remain at peak quality. Storage time shown is for best quality only - after that, the oatmeal's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly, the package is undamaged, and there are no signs of spoilage. How can you tell if oatmeal is bad or spoiled? The best way is to smell and look at the oatmeal: if oatmeal develops an off odor, flavour or appearance, or if insects appear, it should be discarded.
Oats, Commercially Packaged (Including Steel-Cut, Rolled, Instant Types) — Cooked	18-24 months (best quality)	4-6 Days	6 Months (Best Quality)	How long do cooked rolled oats last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate rolled oats within two hours of cooking. To maximize the shelf life of cooked rolled oats, refrigerate in covered airtight containers or resealable plastic bags. Properly stored, cooked rolled oats will last for 4 to 6 days in the refrigerator. How long can cooked rolled oats be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); rolled oats should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked rolled oats, freeze them; freeze cooked rolled oats in covered airtight containers or heavy-duty freezer bags. How long do cooked rolled oats last in the freezer? Properly stored, they will maintain best quality for 6 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked rolled oats that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cooked rolled oats are bad? The best way is to smell and look at the rolled oats; discard any rolled oats with an off smell or appearance, do not taste the cooked rolled oats first.
Pasta - Cooked Leftovers		3-5 Days	1-2 Months	How long does cooked pasta last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate pasta within two hours of cooking. To maximize the shelf life of cooked pasta for safety and quality, refrigerate the pasta in shallow airtight containers or resealable plastic bags. Properly stored, cooked pasta will last for 3 to 5 days in the refrigerator. How long can cooked pasta be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked pasta should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked pasta, freeze it; freeze in covered airtight containers or heavy-duty freezer bags. Cooked pasta dishes containing sauce freeze best; cooked dry pasta may become overly mushy when thawed. How long does cooked pasta last in the freezer? Properly stored, it will maintain best quality for about 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked pasta that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked pasta last after being frozen and thawed? Cooked pasta that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; pasta that was thawed in the microwave or in cold water should be eaten immediately. How to tell if cooked pasta is bad? If cooked pasta develops an off odor, flavour or appearance, or if mould appears, it should be discarded; do not taste first.
Peanut Butter, Commercially Manufactured And Processed (Containing Hydrogenated Fat Or Other Stabilizers) - Opened Jar	3 Months	3-4 months after pantry storage		How long does peanut butter last once opened? The precise answer depends to a large extent on storage conditions - keep opened peanut butter tightly covered at all times and store in a cool, dark area. Pantry storage will allow opened peanut butter to spread more easily; about 3 months after opening, refrigeration is recommended to help retain the peanut butter's flavour and prevent oil separation. Storage time shown is for best quality only - after that, the opened peanut butter's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been kept continuously refrigerated. "Best By," "Best if Used By," and "Use By" dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the opened peanut butter will still be safe to consume after that date, as long as it has been stored properly and kept continuously refrigerated after opening. How can you tell if peanut butter has gone bad? If peanut butter develops an off odor, flavour or appearance, it should be discarded for quality purposes; if mould appears, discard the entire product.
Peanut Butter, Commercially Manufactured And Processed (Containing Hydrogenated Fat Or Other Stabilizers) - Unopened Jar	2 Years (Best Quality)			How long does an unopened jar of peanut butter last? The precise answer depends to a large extent on storage conditions - to maximize shelf life, store in a cool, dry area. How long does an unopened jar of peanut butter last at room temperature? Properly stored, an unopened jar of peanut butter will generally stay at best quality for about 2 years. Is unopened peanut butter safe to use after the expiration date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged peanut butter will typically carry a Best By," "Best if Used By," Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the peanut butter will remain at peak quality. Storage time shown is for best quality only - after that, the peanut butter's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly, the package is undamaged, and there are no signs of spoilage. How can you tell if peanut butter is bad or spoiled? The best way is to smell and look at the peanut butter: if the peanut butter develops an off odor, flavour or appearance, or if mould appears, it should be discarded.

FOOD | Shelf Food Life | Nuts & Grains Shelf Life

Peanut Butter, Natural (Does Not Contain Hydrogenated Fat Or Other Stabilizers) - Unopened Or Opened Container		6 Months		Refrigerating natural peanut butter in a covered container will slow down the rate at which it becomes rancid. Over time, oil will separate and rise to the top of the container; this is harmless and can be resolved by simply stirring the oil back into the peanut butter.
Peanuts, Commercially Bagged Or Purchased In Bulk - In The Shell	1-2 Months	4-6 Months	9-12 Months	The exact answer to the question ? How long do peanuts last in the shell? depends to a large extent on storage conditions -because of their high oil content, peanuts must be stored properly to avoid becoming rancid. To maximize the shelf life of unshelled peanuts, store in cool, dry area; after opening the package, place the peanuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. To further extend the shelf life of unshelled peanuts, the peanuts may be stored in the fridge or freezer; place peanuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. Unshelled peanuts can be thawed and refrozen repeatedly during the freezer time shown without any significant loss of flavour or texture. How long do unshelled peanuts last when stored in the freezer? The freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if unshelled peanuts are bad? Rancid peanuts will often develop a bitter, unpleasant taste; if peanuts develop an off odor or taste, or if mould appears, they should be discarded.
Peanuts, Commercially Bagged Or Purchased In Bulk - Out Of The Shell	2-4 Weeks	4-6 Months	9-12 Months	The precise answer to the question ? How long do peanuts last once shelled? depends to a large extent on storage conditions -because of their high oil content, peanuts must be stored properly to avoid becoming rancid. To maximize the shelf life of shelled peanuts, store in cool, dry area; after opening the package, place the peanuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. To further extend the shelf life of shelled peanuts, the peanuts may be stored in the fridge or freezer; place peanuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. Shelled peanuts can be thawed and refrozen repeatedly during the freezer time shown without any significant loss of flavour or texture. How long do shelled peanuts last when stored in the freezer? The freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if shelled peanuts are bad? Rancid peanuts will often develop a bitter, unpleasant taste; if peanuts develop an off odor or taste, or if mould appears, they should be discarded.
Pecans, Commercially Bagged Or Purchased In Bulk - In The Shell	2-4 Weeks	12 Months	2 Years	The exact answer to the question ? How long do pecans last in the shell? depends to a large extent on storage conditions -because of their high oil content, pecans must be stored properly to avoid becoming rancid. To maximize the shelf life of unshelled pecans, store in cool, dry area; after opening the package, place the pecans in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. To further extend the shelf life of unshelled pecans, the pecans may be stored in the fridge or freezer; place pecans in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. Unshelled pecans can be thawed and refrozen repeatedly during the freezer time shown without any significant loss of flavour or texture. How long do unshelled pecans last when stored in the freezer? The freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if unshelled pecans are bad? Rancid pecans will often develop a bitter, unpleasant taste; if pecans develop an off odor or taste, or if mould appears, they should be discarded.
Pecans, Commercially Bagged Or Purchased In Bulk - Out Of The Shell	2-4 Weeks	9 Months	2 Years	The precise answer to the question ? How long do pecans last once shelled? depends to a large extent on storage conditions -because of their high oil content, pecans must be stored properly to avoid becoming rancid. To maximize the shelf life of shelled pecans, store in cool, dry area; after opening the package, place the pecans in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. Ravioli In Tomato Sauce, Commercially Canned Or Bottled — Opened	18-24 Months (Best Quality) (Unopened)	5-7 Days	1-2 Months	How long does a can of ravioli last once opened? The precise answer depends to a large extent on storage conditions - keep opened ravioli refrigerated and tightly covered. To maximize the shelf life of canned ravioli after opening, refrigerate in a covered glass or plastic container. How long does opened canned ravioli last in the refrigerator? Ravioli that has been continuously refrigerated will keep for about 5 to 7 days. Is canned ravioli safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged ravioli will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the ravioli will remain at peak quality. To further extend the shelf life of opened canned ravioli, freeze it: to freeze canned ravioli, place inside covered airtight containers or heavy-duty freezer bags. How long does canned ravioli last in the freezer? Properly stored, it will maintain best quality for about 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only – canned ravioli that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does canned ravioli last after being frozen and thawed? Canned ravioli that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; ravioli that was thawed in the microwave or in cold water should be used immediately. How can you tell if opened canned ravioli is bad or spoiled? The best way is to smell and look at the ravioli: if the ravioli develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Refried Beans, Commercially Canned — Opened	3-5 Years (Best Quality) (Unopened)	3-4 Days	1-2 Months	How long does a can of refried beans last once opened? The precise answer depends to a large extent on storage conditions - keep opened refried beans refrigerated and tightly covered. To maximize the shelf life of canned refried beans after opening, refrigerate in covered glass or plastic container. How long do opened canned refried beans last in the refrigerator? Canned refried beans that have been continuously refrigerated will keep for about 3 to 4 days. Are canned refried beans safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned refried beans will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the refried beans will remain at peak quality. To further extend the shelf life of opened canned refried beans, freeze them: to freeze canned refried beans, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned refried beans will be softer after freezing and thawing; the thawed refried beans will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned refried beans last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - refried beans that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do canned refried beans last after being frozen and thawed? Refried beans that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; refried beans that were thawed in the microwave or in cold water should be used immediately. How can you tell if opened canned refried beans are bad or spoiled? The best way is to smell and look at the refried beans: if the refried beans develop an off odor, flavour or appearance, or if mould appears, they should be discarded.
Rice, Brown - Cooked		4-6 Days	6 Months	How long does cooked brown rice last? The precise answer to that question depends to a large extent on storage conditions - refrigerate rice within two hours of cooking. To maximize the shelf life of cooked brown rice, refrigerate in covered airtight containers or resealable plastic bags. How long does cooked brown rice last in the refrigerator? Properly stored, cooked brown rice will last for 4 to 6 days in the refrigerator. How long can cooked brown rice be left out at room temperature? Cooked brown rice should be discarded if left out for more than 2 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). To further extend the shelf life of cooked brown rice, freeze it; freeze rice in covered airtight containers or heavy-duty freezer bags. How long does cooked brown rice last in the freezer? Properly stored, it will maintain best quality for 6 months, but will remain safe beyond that time. The freezer time shown is for best quality only – cooked brown rice that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cooked brown rice is bad? The best way is to smell and look at the rice; discard any rice with an off smell or appearance, do not taste the cooked rice first.
Rice, Brown - Uncooked, Unopened Or Opened Package	3-6 Months	6-12 Months	12-18 Months	How long does brown rice last? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of uncooked brown rice, store in a cool, dry area. How long does brown rice last at room temperature? Properly stored, a package of brown rice will generally stay at best quality for about 3-6 months at room temperature. Due to the high oil content of brown rice, pantry storage will cause it to spoil relatively quickly compared to white rice. To maximize the shelf life of brown rice once the package is opened, transfer brown rice to a covered airtight container or place original brown rice bag in a resealable plastic freezer bag. Can you keep brown rice in the fridge or freezer? Yes, to further extend the shelf life of brown rice, refrigerate or freeze it; place the brown rice inside covered airtight containers or heavy-duty freezer bags. How long does brown rice last in the fridge? Brown rice will maintain best quality for about 6-12 months in the refrigerator. The freezer time shown is for best quality only — brown rice that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does brown rice last in the freezer? Properly stored, brown rice will maintain best quality for about 12-18 months in the freezer, but will remain safe beyond that time. Is brown rice safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged brown rice will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the brown rice will remain at peak quality. Storage time shown is for best quality only - after that, the brown rice's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly, the package is undamaged, and there are no signs of spoilage. How can you tell if brown rice is bad or spoiled? The best way is to smell and look at the brown rice: if the brown rice develops an off odor, flavour or appearance, or if insects appear, it should be discarded.
Rice, White - Cooked		4-6 Days	6 Months	How long does cooked white rice last? The precise answer to that question depends to a large extent on storage conditions - refrigerate rice within two hours of cooking. To maximize the shelf life of cooked white rice, refrigerate in covered airtight containers or resealable plastic bags. How long does cooked white rice last in the refrigerator? Properly stored, cooked white rice will last for 4 to 6 days in the refrigerator. How long can cooked white rice be left out at room temperature? Cooked white rice should be discarded if left out for more than 2 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). To further extend the shelf life of cooked white rice, freeze it; freeze rice in covered airtight containers or heavy-duty freezer bags. How long does cooked white rice last in the freezer? Properly stored, it will maintain best quality for 6 months, but will remain safe beyond that time. The freezer time shown is for best quality only – cooked white rice that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cooked white rice is bad? The best way is to smell and look at the rice; discard any rice with an off smell or appearance, do not taste the cooked rice first.
Rice, White - Uncooked (Including Regular, Converted, Instant) Unopened Or Opened Package	Keeps indefinitely	Keeps indefinitely	Keeps indefinitely	The precise answer to the question "How long does white rice last?" depends to a large extent on storage conditions - when properly stored and kept free from contaminants, uncooked white rice has an indefinite shelf life. To maximize the shelf life of white rice, store in a cool dry area; after opening the package, place the uncooked white rice in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. Can you keep white rice in the fridge or freezer? Yes, for added protection against bugs, dust or other contaminants, uncooked white rice may also be stored in the fridge or freezer - place white rice in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. How long does white rice last once cooked? Cooked white rice will generally stay good for 4-6 days in the refrigerator and 6 months in the freezer. How long does uncooked brown rice last? Thanks to its higher oil content, brown rice will only keep for 3 to 6 months at room temperature. How to tell if white rice is bad? If the white rice develops an off odor, flavour or appearance, or if insects or other contaminants appear, it should be discarded.
Soybeans, Dried, Commercially Bagged Or Purchased In Bulk — Cooked At Home	1 Year (Uncooked)	5-7 Days	6 Months	Refrigerate within two hours of cooking. Refrigerate in covered container. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Spaghetti In Tomato Sauce / Spaghetti And Meatballs, Commercially Canned Or Packaged — Opened	18-24 Months (Best Quality) (Unopened)	5-7 Days	1-2 Months	How long does a can of spaghetti last once opened? The precise answer depends to a large extent on storage conditions - keep opened spaghetti refrigerated and tightly covered. To maximize the shelf life of canned spaghetti after opening, refrigerate in a covered glass or plastic container. How long does opened canned spaghetti last in the refrigerator? Spaghetti that has been continuously refrigerated will keep for about 5 to 7 days. Is canned spaghetti safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged spaghetti will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the spaghetti will remain at peak quality. To further extend the shelf life of opened canned spaghetti, freeze it: to freeze canned spaghetti, place inside covered airtight containers or heavy-duty freezer bags. How long does canned spaghetti last in the freezer? Properly stored, it will maintain best quality for about 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only – canned spaghetti that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does canned spaghetti last after being frozen and thawed? Canned spaghetti that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; spaghetti that was thawed in the microwave or in cold water should be used immediately. How can you tell if opened canned spaghetti is bad or spoiled? The best way is to smell and look at the spaghetti: if the spaghetti develops an off odor, flavour or appearance, or if mould appears, it should be discarded. Discard all spaghetti from cans or packages that are leaking, rusting, bulging or severely dented.
Spaghetti - Cooked, Leftovers		3-5 Days	1-2 Months	How long does cooked spaghetti last in the fridge or freezer? The precise answer to that question depends to a large extent on storage conditions - refrigerate spaghetti within two hours of cooking. To maximize the shelf life of cooked spaghetti for safety and quality, refrigerate the spaghetti in shallow airtight containers or resealable plastic bags. Properly stored, cooked spaghetti will last for 3 to 5 days in the refrigerator. How long can cooked spaghetti be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked spaghetti should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked spaghetti, freeze it; freeze in covered airtight containers or heavy-duty freezer bags. Cooked spaghetti dishes containing sauce freeze best; cooked dry macaroni noodles by themselves may become overly mushy when thawed. How long does cooked spaghetti last in the freezer? Properly stored, it will maintain best quality for about 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked spaghetti that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked spaghetti last after being frozen and thawed? Cooked spaghetti that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; spaghetti that was thawed in the microwave or in cold water should be eaten immediately. How to tell if cooked spaghetti is bad? If cooked spaghetti develops an off odor, flavour or appearance, or if mould appears, it should be discarded; do not taste first.

Split Peas, Commercially Canned Or Bottled — Opened	2-5 Years (Unopened)	3-4 Days	1-2 Months	How long does a can of split peas last once opened? The precise answer depends to a large extent on storage conditions - keep opened split peas refrigerated and tightly covered. To maximize the shelf life of canned split peas after opening, refrigerate in covered glass or plastic container. How long do opened canned split peas last in the refrigerator? Canned split peas that have been continuously refrigerated will keep for about 3 to 4 days. Are canned split peas safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned split peas will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the split peas will remain at peak quality. To further extend the shelf life of opened canned split peas, freeze them: to freeze canned split peas, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned split peas will be softer after freezing and thawing; the thawed split peas will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned split peas last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - split peas that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do canned split peas last after being frozen and thawed? split peas that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; split peas that were thawed in the microwave or in cold water should be used immediately. How can you tell if opened canned split peas are bad or spoiled? The best way is to smell and look at the split peas: if the split peas develop an off odor, flavour or appearance, or if mould appears, they should be discarded.
Walnuts, Commercially Bagged Or Purchased In Bulk - In The Shell	2-4 Weeks	9-12 Months	12 Months	How long do walnuts last in the shell? depends to a large extent on storage conditions -because of their high oil content, walnuts must be stored properly to avoid becoming rancid. To maximize the shelf life of unshelled walnuts, store in cool, dry area; after opening the package, place the walnuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. To further extend the shelf life of unshelled walnuts, the walnuts may be stored in the fridge or freezer; place walnuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. Unshelled walnuts can be thawed and refrozen repeatedly during the freezer time shown without any significant loss of flavour or texture. How long do unshelled walnuts last when stored in the freezer? The freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if unshelled walnuts are bad? Rancid walnuts will often develop a bitter, unpleasant taste; if walnuts develop an off odor or taste, or if mould appears, they should be discarded.
Walnuts, Commercially Bagged Or Purchased In Bulk - Out Of The Shell	2-4 Weeks	9-12 Months	18-24 Months	How long do shelled walnuts last? The precise answer depends to a large extent on storage conditions - because of their high oil content, walnuts must be stored properly to avoid becoming rancid. To maximize the shelf life of shelled walnuts, store in cool, dry area; after opening the package, place the walnuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. How long do shelled walnuts last at room temperature? Properly stored, shelled walnuts will keep well for about 2 to 4 weeks at normal room temperature. To extend the shelf life of shelled walnuts, refrigerate them; place walnuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. How long do shelled walnuts last in the refrigerator? Shelled walnuts will keep well for about 1 year in the fridge when properly stored. To further extend the shelf life of shelled walnuts, freeze them: place walnuts in a sealed airtight container or place original package in a resealable heavy-duty freezer bag. How long do shelled walnuts last in the freezer? Properly stored, shelled walnuts will maintain best quality for about 18 to 24 months in the freezer, but will remain safe to consume after that time if they have been continuously frozen. The freezer time shown is for best quality only – shelled walnuts kept constantly frozen at -18°C (0°F) will keep safe indefinitely.

2 Vegetables Shelf Life

These is the shelf life of most vegetables, both pre-packaged and raw.

	Pantry	Refrigerator	Freezer	Food Tips
Arugula (Rocket) — Fresh, Raw	2-3 Days			Store in tightly sealed plastic bag. Do not wash until ready to eat. Does not freeze well.
Asparagus - Commercially Frozen			10-12 Months	Keep frozen until ready to use. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. Once prepared, refrigerate leftovers in a covered container for up to four days.
Asparagus - Fresh, Cooked	3-5 Days		10-12 Months	How long does cooked asparagus last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate asparagus within two hours of cooking. To maximize the shelf life of cooked asparagus for safety and quality, refrigerate the asparagus in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked asparagus will last for 3 to 5 days in the refrigerator. To further extend the shelf life of cooked asparagus, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long does cooked asparagus last in the freezer? Properly stored, it will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked asparagus that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked asparagus last after being frozen and thawed? Cooked asparagus that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; asparagus that was thawed in the microwave or in cold water should be eaten immediately. How long can cooked asparagus be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked asparagus should be discarded if left out for more than 2 hours at room temperature.
Asparagus - Fresh, Raw	3-4 Days		12-18 Months	How long does raw asparagus last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep asparagus refrigerated at all times. To maximize the shelf life of raw asparagus, wrap bottom of asparagus stalks in damp paper towel, then refrigerate in an unsealed plastic bag. How long does raw asparagus last in the fridge? Properly stored, raw asparagus will usually keep well for about 3 to 4 days in the refrigerator. How long does asparagus last in the fridge once it has been cooked? Cooked asparagus will usually stay good for 3 to 5 days in the refrigerator and 10 to 12 months in the freezer. Can you freeze asparagus? Yes, to freeze: (1) Wash thoroughly and trim stalks by removing scales with a sharp knife; (2) Cut asparagus into even-sized pieces; (3) Blanch (plunge into boiling water) for three minutes and chill quickly in ice cold water; (4) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. How long does asparagus last in the freezer? Properly stored, it will maintain best quality for about 12 to 18 months, but will remain safe beyond that time. The freezer time shown is for best quality only - asparagus that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if asparagus is bad or spoiled? Asparagus that is spoiling will typically become soft and discoloured and the tips will start to darken; discard any asparagus that has an off smell or appearance.
Asparagus, Commercially Canned Or Bottled — Opened	3-4 Days		1-2 Months	How long does a can of asparagus last once opened? The precise answer depends to a large extent on storage conditions - keep opened asparagus refrigerated and tightly covered. To maximize the shelf life of canned or packaged asparagus after opening, refrigerate in a covered glass or plastic container. How long does opened canned asparagus last in the refrigerator? Asparagus that has been continuously refrigerated will keep for about 3 to 4 days. Is canned asparagus safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged asparagus will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the asparagus will remain at peak quality. To further extend the shelf life of opened canned asparagus, freeze it: to freeze asparagus, place inside covered airtight containers or heavy-duty freezer bags. How long does canned asparagus last in the freezer? Properly stored, it will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - asparagus that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does canned asparagus last after being frozen and thawed? Canned asparagus that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; asparagus that was thawed in the microwave or in cold water should be used immediately.
Asparagus, Commercially Canned Or Bottled — Unopened	3-5 Years			How long does unopened canned asparagus last? The precise answer depends to a large extent on storage conditions - to maximize shelf life, store in a cool, dry area. How long does unopened canned asparagus last at room temperature? Properly stored, unopened canned asparagus will generally stay at best quality for about 3 to 5 years, although it will usually remain safe to use after that. Is unopened canned asparagus safe to use after the "expiration" date on the can or package? Yes, provided it is properly stored and the can is undamaged - commercially packaged canned asparagus will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the canned asparagus will remain at peak quality. Storage time shown is for best quality only - after that, the canned asparagus's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly, the can is undamaged, and there are no signs of spoilage. How can you tell if canned asparagus is bad or spoiled? The best way is to smell and look at the canned asparagus: if the canned asparagus develops an off odor, flavour or appearance, or if mould appears, it should be discarded. Discard all canned asparagus from cans or packages that are leaking, rusting, bulging or severely dented.
Baby Carrots - Fresh, Raw	2-3 Weeks		12-18 Months	How long do baby carrots last? The precise answer to that question depends to a large extent on storage conditions - keep baby carrots refrigerated. To maximize the shelf life of baby carrots, refrigerate in covered container or resealable plastic bag or wrap tightly in aluminium foil or plastic wrap. How long do baby carrots last in the fridge? Properly stored, baby carrots will last for 2 to 3 weeks in the refrigerator. Can you freeze baby carrots? Yes, to freeze: (1) Blanch (plunge into boiling water) baby carrots for two minutes and chill quickly in ice cold water; (2) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Frozen baby carrots will soften when thawed and are best used in cooked dishes. How long do baby carrots last in the freezer? Properly stored, they will maintain best quality for about 12 to 18 months, but will remain safe beyond that time. The freezer time shown is for best quality only - carrots that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if baby carrots are bad or spoiled? The best way is to smell and look at the baby carrots: discard any carrots that have an off smell or appearance; if mould appears, discard the baby carrots.
Beans (All Varieties) - Commercially Frozen			10-12 Months	Keep frozen until ready to use. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. Once prepared, refrigerate leftovers in a covered container for up to four days.
Beans, Snap, String Or Wax (Green Or Yellow) - Fresh, Raw		3-5 Days	12-18 Months	Refrigerate in plastic bag; do not wash until ready to use. To freeze: (1) Wash thoroughly and remove ends; (2) Leave beans whole, or cut into 1 to 1 1/2 inch pieces; (3) Blanch (plunge into boiling water) for three minutes and chill quickly in ice cold water; (4) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Beans, Snap, String Or Wax (Green Or Yellow) - Fresh, Cooked		3-5 Days	10-12 Months	How long do cooked green beans last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate green beans within two hours of cooking. To maximize the shelf life of cooked green beans for safety and quality, refrigerate the green beans in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked green beans will last for 3 to 5 days in the refrigerator. To further extend the shelf life of cooked green beans, freeze them; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long do cooked green beans last in the freezer? Properly stored, they will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked green beans that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked green beans last after being frozen and thawed? Cooked green beans that have been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; green beans that were thawed in the microwave or in cold water should be eaten immediately. How long can cooked green beans be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked green beans should be discarded if left out for more than 2 hours at room temperature.
Beans, Snap, String Or Wax (Green Or Yellow), Commercially Canned Or Bottled — Opened		3-4 Days	1-2 Months	How long does a can of green beans last once opened? The precise answer depends to a large extent on storage conditions - keep opened green beans refrigerated and tightly covered. To maximize the shelf life of canned green beans after opening, refrigerate in covered glass or plastic container. How long do opened canned green beans last in the refrigerator? Canned green beans that have been continuously refrigerated will keep for about 3 to 4 days. Are canned green beans safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned green beans will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the green beans will remain at peak quality. To further extend the shelf life of opened canned green beans, freeze them: to freeze canned green beans, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned green beans will be softer after freezing and thawing; the thawed green beans will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned green beans last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. How long do canned green beans last after being frozen and thawed? Green beans that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; green beans that were thawed in the microwave or in cold water should be used immediately.
Beans, Snap, String Or Wax (Green Or Yellow), Commercially Canned Or Bottled — Unopened	3-5 Years (Best Quality)			How long do unopened canned green beans last? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of canned green beans, store in a cool, dry area. How long does an unopened can of green beans last at room temperature? Properly stored, an unopened can of green beans will generally stay at best quality for about 3 to 5 years, although it will usually remain safe to use after that. Are unopened canned green beans safe to use after the "expiration" date on the can or package? Yes, provided they are properly stored and the can is undamaged - commercially packaged canned green beans will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the canned green beans will remain at peak quality. Discard all canned beets from cans or packages that are leaking, rusting, bulging or severely dented.
Bell Peppers / Sweet Peppers / Capsicum (Including Green, Red, Yellow, Orange) - Fresh, Raw, Whole		1-2 Weeks	10-12 Months	How long do raw bell peppers last in the fridge? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep bell peppers refrigerated at all times. To maximize the shelf life of raw bell peppers, store in a plastic bag in the vegetable crisper of refrigerator. Green bell peppers will usually last longer than orange or red bell peppers. How long do raw bell peppers last in the refrigerator? Properly stored, bell peppers will usually keep well for 1 to 2 weeks in the fridge. Do you need to wash raw bell peppers before eating them? Yes, bell peppers should be thoroughly washed in running water before eating. How long do raw bell peppers last after they have been sliced or chopped? Chopped raw bell peppers will last for about 2 to 3 days in the refrigerator. How long do bell peppers last in the fridge once they have been cooked? Cooked bell peppers will usually stay good for 3 to 5 days in the refrigerator and 10 to 12 months in the freezer. Can you freeze bell peppers? Yes, to freeze: (1) Slice or chop bell peppers (2) Spread in a single layer on cookie tray (3) Freeze, then promptly transfer frozen bell peppers from cookie tray to airtight containers or heavy-duty freezer bags and return to freezer.
Bell Peppers / Sweet Peppers / Capsicum (Including Green, Red, Yellow, Orange) - Fresh, Raw, Sliced Or Chopped		2-3 Days	10-12 Months	How long do chopped bell peppers last? The precise answer to that question depends to a large extent on storage conditions - keep chopped peppers refrigerated. To maximize the shelf life of chopped peppers, refrigerate in covered container or resealable plastic bag or wrap tightly in aluminium foil or plastic wrap. How long do chopped bell peppers last in the fridge? Properly stored, chopped peppers will last for 2 to 3 days in the refrigerator. Can you freeze chopped peppers? Yes, to freeze: Place in airtight containers or heavy-duty freezer bags, or wrap tightly in heavy-duty aluminium foil or plastic wrap. How long do chopped bell peppers last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - peppers that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if chopped peppers are bad or spoiled? The best way is to smell and look at the chopped peppers: discard any peppers that have an off smell or appearance; if mould appears, discard the chopped peppers.
Broccoli - Commercially Frozen			10-12 Months	How long does frozen broccoli last? The precise answer to that question depends to a large extent on storage conditions - keep broccoli frozen at all times. Properly stored, frozen broccoli will maintain best quality for about 12 months in the freezer, although it will usually remain safe to eat after that. Is frozen broccoli safe to eat after the expiration date on the package? Yes, if properly stored - commercially frozen broccoli will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the frozen broccoli will remain at peak quality. How long will frozen broccoli remain safe to eat? Frozen broccoli that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as it has been stored properly and the package is not damaged. How long can you safely leave frozen broccoli at room temperature? Frozen broccoli should be discarded if left for more than 6 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). How to tell if frozen broccoli is no longer good? If dry spots or discoloration have developed on the frozen broccoli, freezer burn has begun to set in - this will not make the broccoli unsafe to eat, but it will harm the texture and taste.
Broccoli - Fresh, Cooked		3-5 Days	10-12 Months	How long does cooked broccoli last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate broccoli within two hours of cooking. To maximize the shelf life of cooked broccoli for safety and quality, refrigerate the broccoli in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked broccoli will last for 3 to 5 days in the refrigerator. To further extend the shelf life of cooked broccoli, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long does cooked broccoli last in the freezer? Properly stored, it will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked broccoli that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked broccoli last after being frozen and thawed? Cooked broccoli that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; broccoli that was thawed in the microwave or in cold water should be eaten immediately. How long can cooked broccoli be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked broccoli should be discarded if left out for more than 2 hours at room temperature.
Broccoli - Fresh, Raw		3-5 Days	12-18 Months	How long does raw broccoli last in the fridge? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep broccoli refrigerated at all times. To maximize the shelf life of raw broccoli, refrigerate in a plastic bag; do not wash until ready to use. Properly stored, broccoli will usually keep well for about 3 to 5 days in the refrigerator. Do you need to wash raw broccoli before eating it? Yes, broccoli should be thoroughly washed in running water before eating. How long does raw broccoli last after it's been sliced or chopped? Chopped raw broccoli will last for 1 to 2 days in the refrigerator. How long does broccoli last in the fridge once it has been cooked? Cooked broccoli will usually stay good for 3 to 5 days in the refrigerator and 10 to 12 months in the freezer. Can you freeze broccoli? Yes, to freeze: (1) Wash thoroughly, cut off leaves and woody stems; (2) Spit flowerets and stalks into 1 to 1 1/2 inch pieces; (3) Blanch (plunge into boiling water) broccoli for three minutes and chill quickly in ice cold water; (4) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. How long does broccoli last in the freezer? Properly stored, it will maintain best quality for about 12 to 18 months, but will remain safe beyond that time.
Cabbage - Fresh, Raw		1 Week	12-18 Months	Refrigerate in plastic bag; do not wash until ready to use. To freeze: (1) Wash thoroughly and remove course outer leaves; (2) Cut cabbage into thin wedges or separate into leaves; (3) Blanch (plunge into boiling water) for 2 minutes and chill quickly in ice cold water; (4) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Cabbage - Fresh, Cooked		3-5 Days	10-12 Months	How long does cooked cabbage last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate cabbage within two hours of cooking. To maximize the shelf life of cooked cabbage for safety and quality, refrigerate the cabbage in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked cabbage will last for 3 to 5 days in the refrigerator. To further extend the shelf life of cooked cabbage, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long does cooked cabbage last in the freezer? Properly stored, it will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked cabbage that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked cabbage last after being frozen and thawed? Cooked cabbage that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; cabbage that was thawed in the microwave or in cold water should be eaten immediately. How long can cooked cabbage be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked cabbage should be discarded if left out for more than 2 hours at room temperature.
Carrots - Commercially Frozen			10-12 Months	How long do frozen carrots last? The precise answer to that question depends to a large extent on storage conditions - keep carrots frozen at all times. Properly stored, frozen carrots will maintain best quality for about 12 months in the freezer, although they will usually remain safe to eat after that. Are frozen carrots safe to eat after the "expiration" date on the package? Yes, if properly stored - commercially frozen carrots will typically carry a Best By, Best if Used By, Best Before, or Best When Used By date but this is not a safety date, it is the manufacturer's estimate of how long the frozen carrots will remain at peak quality. How long will frozen carrots remain safe to eat? Frozen carrots that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as they have been stored properly and the package is not damaged. How long can you safely leave frozen carrots at room temperature? Frozen carrots should be discarded if left for more than 6 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). How to tell if frozen carrots are no longer good? If dry spots or discolorations have developed on the frozen carrots, freezer burn has begun to set in - this will not make the frozen carrots unsafe to eat, but it will harm the texture and taste.
Carrots - Fresh, Cooked		3-5 Days	10-12 Months	How long do cooked carrots last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate carrots within two hours of cooking. To maximize the shelf life of cooked carrots for safety and quality, refrigerate the carrots in shallow airtight containers or resealable plastic bags. Properly stored, cooked carrots will last for 3 to 5 days in the refrigerator. How long can cooked carrots be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked carrots should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked carrots, freeze them; freeze in covered airtight containers or heavy-duty freezer bags. How long do cooked carrots last in the freezer? Properly stored, they will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked carrots that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked carrots last after being frozen and thawed? Cooked carrots that have been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; carrots that were thawed in the microwave or in cold water should be eaten immediately.
Carrots - Fresh, Raw, Chopped, Carrot Sticks		2-3 Weeks	12-18 Months	How long do chopped carrots or carrot sticks last? The precise answer to that question depends to a large extent on storage conditions - keep chopped carrots refrigerated. To maximize the shelf life of chopped carrots, refrigerate in covered container or resealable plastic bag or wrap tightly in aluminium foil or plastic wrap. How long do chopped carrots last in the fridge? Properly stored, chopped carrots will last for 2 to 3 weeks in the refrigerator. Can you freeze chopped carrots? Yes, to freeze: (1) Blanch (plunge into boiling water) chopped carrots for two minutes and chill quickly in ice cold water; (2) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Frozen chopped carrots will soften when thawed and are best used in cooked dishes. How long do chopped carrots last in the freezer? Properly stored, they will maintain best quality for about 12 to 18 months, but will remain safe beyond that time. The freezer time shown is for best quality only - carrots that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if chopped carrots are bad or spoiled? The best way is to smell and look at the chopped carrots: discard any carrots that have an off smell or appearance; if mould appears, discard the chopped carrots.
Carrots - Fresh, Raw, Unpeeled		3-4 Weeks	10-12 Months	How long do raw carrots last in the fridge? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep carrots refrigerated at all times. To maximize the shelf life of raw carrots, refrigerate in a plastic bag. How long do raw carrots last in the refrigerator? Properly stored, carrots will usually keep well for about 3 to 4 weeks in the fridge. Do you need to wash raw carrots before eating them? Yes, carrots should be thoroughly washed in running water before eating. How long do raw carrots last after they have been sliced or chopped? Chopped raw carrots will last for about 2 to 3 weeks in the refrigerator. How long do carrots last in the fridge once they have been cooked? Cooked carrots will usually stay good for 3 to 5 days in the refrigerator and 10 to 12 months in the freezer. Can you freeze carrots? Yes, to freeze: (1) Wash, peel and cut into 1/2 inch slices, cubes or strips; (2) Blanch (plunge into boiling water) for two minutes and chill quickly in ice cold water; (3) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. How long do carrots last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time.
Carrots, Commercially Canned Or Bottled — Opened		3-4 Days	1-2 Months	How long does a can of carrots last once opened? The precise answer depends to a large extent on storage conditions - keep opened carrots refrigerated and tightly covered. To maximize the shelf life of canned carrots after opening, refrigerate in covered glass or plastic container. How long do opened canned carrots last in the refrigerator? Canned carrots that have been continuously refrigerated will keep for about 3 to 4 days. Are canned carrots safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned carrots will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the carrots will remain at peak quality. To further extend the shelf life of opened canned carrots, freeze them: to freeze canned carrots, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned carrots will be softer after freezing and thawing; the thawed carrots will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned carrots last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - carrots that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.

Carrots, Commercially Canned Or Bottled — Unopened	3-5 Years (Best Quality)			How long do unopened canned carrots last? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of canned carrots, store in a cool, dry area. How long does an unopened can of carrots last at room temperature? Properly stored, an unopened can of carrots will generally stay at best quality for about 3 to 5 years, although it will usually remain safe to use after that. Are unopened canned carrots safe to use after the "expiration" date on the can or package? Yes, provided they are properly stored and the can is undamaged - commercially packaged canned carrots will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the canned carrots will remain at peak quality. Storage time shown is for best quality only - after that, the canned carrots' texture, colour or flavour may change, but in most cases, they will still be safe to consume if they have been stored properly, the can is undamaged, and there are no signs of spoilage. How can you tell if canned carrots are bad or spoiled? The best way is to smell and look at the canned carrots: if the canned carrots develop an off odor, flavour or appearance, or if mould appears, they should be discarded. Discard all canned carrots from cans or packages that are leaking, rusting, bulging or severely dented.
Cauliflower - Fresh, Cooked		3-5 Days	10-12 Months	How long does cooked cauliflower last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate cauliflower within two hours of cooking. To maximize the shelf life of cooked cauliflower for safety and quality, refrigerate the cauliflower in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked cauliflower will last for 3 to 5 days in the refrigerator. To further extend the shelf life of cooked cauliflower, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long does cooked cauliflower last in the freezer? Properly stored, it will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked cauliflower that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked cauliflower last after being frozen and thawed? Cooked cauliflower that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; cauliflower that was thawed in the microwave or in cold water should be eaten immediately. How long can cooked cauliflower be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked cauliflower should be discarded if left out for more than 2 hours at room temperature.
Cauliflower - Commercially Frozen			10-12 Months	How long does frozen cauliflower last? The precise answer to that question depends to a large extent on storage conditions - keep cauliflower frozen at all times. Properly stored, frozen cauliflower will maintain best quality for about 12 months in the freezer, although it will usually remain safe to eat after that. Is frozen cauliflower safe to eat after the expiration date on the package? Yes, if properly stored - commercially frozen cauliflower will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the frozen cauliflower will remain at peak quality. How long will frozen cauliflower remain safe to eat? Frozen cauliflower that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as it has been stored properly and the package is not damaged. How long can you safely leave frozen cauliflower at room temperature? Frozen cauliflower should be discarded if left for more than 6 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). How to tell if frozen cauliflower is no longer good? If dry spots or discoloration have developed on the frozen cauliflower, freezer burn has begun to set in - this will not make the cauliflower unsafe to eat, but it will harm the texture and taste.
Cauliflower - Fresh, Raw		1 Week	12-18 Months	How long does raw cauliflower last in the fridge? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep cauliflower refrigerated at all times. To maximize the shelf life of raw cauliflower, refrigerate in a plastic bag; do not wash until ready to use. Properly stored, cauliflower will usually keep well for about 1 week in the refrigerator. Do you need to wash raw cauliflower before eating it? Yes, cauliflower should be thoroughly washed in running water before eating. How long does cauliflower last in the fridge once it has been cooked? Cooked cauliflower will usually stay good for 3 to 5 days in the refrigerator and 10 to 12 months in the freezer. Can you freeze cauliflower? Yes, to freeze: (1) Wash thoroughly, cut off leaves; (2) Split cauliflower into 1 to 1 1/2 inch pieces; (3) Blanch (plunge into boiling water) for three minutes and chill quickly in ice cold water; (4) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. How long does cauliflower last in the freezer? Properly stored, it will maintain best quality for about 12 to 18 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cauliflower that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Chopped Onions - Commercially Frozen			10-12 Months	How long do frozen chopped onions last? The precise answer to that question depends to a large extent on storage conditions - keep chopped onions frozen at all times. Properly stored, frozen chopped onions will maintain best quality for about 12 months in the freezer, although they will usually remain safe to eat after that. Are frozen chopped onions safe to eat after the "expiration" date on the package? Yes, if properly stored - commercially frozen chopped onions will typically carry a Best By, Best if Used By, Best Before, or Best When Used By date but this is not a safety date, it is the manufacturer's estimate of how long the frozen chopped onions will remain at peak quality. How long will frozen chopped onions remain safe to eat? Frozen chopped onions that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as they have been stored properly and the package is not damaged. How long can you safely leave frozen chopped onions at room temperature? Frozen chopped onions should be discarded if left for more than 6 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). How to tell if frozen chopped onions are no longer good? If dry spots or discolorations have developed on the frozen chopped onions, freezer burn has begun to set in - this will not make the frozen chopped onions unsafe to eat, but it will harm the texture and taste.
Corn — Commercially Frozen			10-12 Months	How long does frozen corn last? The precise answer to that question depends to a large extent on storage conditions - keep corn frozen at all times. Properly stored, frozen corn will maintain best quality for about 12 months in the freezer, although it will usually remain safe to eat after that. Is frozen corn safe to eat after the expiration date on the package? Yes, if properly stored - commercially frozen corn will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the frozen corn will remain at peak quality. How long will frozen corn remain safe to eat? Frozen corn that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as it has been stored properly and the package is not damaged. How long can you safely leave frozen corn at room temperature? Frozen corn should be discarded if left for more than 6 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). How to tell if frozen corn is no longer good? If dry spots or discoloration have developed on the frozen corn, freezer burn has begun to set in - this will not make the corn unsafe to eat, but it will harm the texture and taste.
Corn On The Cob - Fresh, Cooked		3-5 Days	10-12 Months	How long does cooked corn on the cob last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate corn on the cob within two hours of cooking. To maximize the shelf life of cooked corn on the cob for safety and quality, refrigerate the corn on the cob in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked corn on the cob will last for 3 to 5 days in the refrigerator. To further extend the shelf life of cooked corn on the cob, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Before freezing, cut kernels off the cobs and place in an airtight plastic container or heavy-duty freezer bag. How long does cooked corn on the cob last in the freezer? Properly stored, it will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked corn on the cob that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked corn on the cob last after being frozen and thawed? Cooked corn on the cob that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; corn on the cob that was thawed in the microwave or in cold water should be eaten immediately.
Corn On The Cob - Fresh, Raw		1-3 Days	8 Months	How long does raw corn on the cob last in the fridge? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep corn on the cob refrigerated at all times. To maximize the shelf life of raw corn on the cob and to ensure best quality, keep the husks on until ready to use. If the husks have already been removed from the raw corn on the cob, wrap the corn in plastic or foil before refrigerating. Properly stored, raw corn on the cob will usually keep well for about 1 to 3 days in the refrigerator. How long does corn on the cob last in the fridge once it has been cooked? Cooked corn on the cob will usually stay good for 3 to 5 days in the refrigerator and 10 to 12 months in the freezer. Can you freeze corn on the cob? Yes, to freeze whole corn on the cob: (1) Husk corn, remove silk and wash; (2) Blanch (plunge into boiling water) corn for 7 minutes (for small ears) to 11 minutes (for large ears) and chill quickly in ice cold water; (3) Drain off excess moisture, and package in airtight containers or freezer bags. To freeze whole kernel corn: (1) Husk corn, remove silk and wash; (2) Blanch (plunge into boiling water) corn for 4 minutes and chill quickly in ice cold water; (3) Drain, cut kernels from the cob and package in airtight containers or freezer bags. How long does corn on the cob last in the freezer? Properly stored, it will maintain best quality for about 8 months, but will remain safe beyond that time.
Corn, Commercially Canned Or Bottled (All Varieties) — Opened	3-5 Years (Best Quality) (Unopened)	3-4 Days	1-2 Months	How long does a can of corn last once opened? The precise answer depends to a large extent on storage conditions - keep opened corn refrigerated and tightly covered. To maximize the shelf life of canned or packaged corn after opening, refrigerate in a covered glass or plastic container. How long does opened canned corn last in the refrigerator? Corn that has been continuously refrigerated will keep for about 3 to 4 days. Is canned corn safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged corn will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the corn will remain at peak quality. To further extend the shelf life of opened canned corn, freeze it: to freeze corn, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned corm will be softer after freezing and thawing; the thawed canned corn will be best suited to cooked dishes, such as sauces, soups and casseroles. How long does canned corn last in the freezer? Properly stored, it will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - corn that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Commercially Canned Soups — Opened	3-5 Years (Best Quality) (Unopened)	3-4 Days	4-6 Months	How long does canned soup last once opened? The precise answer depends to a large extent on storage conditions - keep opened cream of asparagus soup refrigerated and tightly covered. To maximize the shelf life of canned soup after opening, refrigerate in covered glass or plastic container. How long does soup last in the refrigerator? Continuously refrigerated, it will keep for about 3 to 4 days. Is soup safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged cream of asparagus soup will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the cream of asparagus soup will remain at peak quality. To further extend the shelf life of opened soup, freeze it: to soup, place inside covered airtight containers or heavy-duty freezer bags. How long does soup last in the freezer? Properly stored, it will maintain best quality for about 6 months, but will remain safe beyond that time. The freezer time shown is for best quality only - soup that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does soup last after being frozen and thawed? Soup that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; soup that was thawed in the microwave or in cold water should be used immediately.
Cucumber - Fresh, Raw, Sliced Or Chopped		1-2 Days		Refrigerate in covered container or wrap tightly with heavy-duty aluminium foil or plastic wrap. Cucumber does not freeze well.
Cucumber - Fresh, Raw, Whole		1 Week		How long do cucumbers last in the fridge? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep cucumbers refrigerated at all times. To maximize the shelf life of cucumbers, store in a plastic bag in the vegetable crisper of refrigerator; do not wash until ready to use. Properly stored, cucumbers will usually keep well for 1 week in the fridge. Do you need to wash cucumbers before eating them? Yes, cucumbers should be thoroughly washed in running water before eating. How long do cucumbers last after they have been sliced or chopped? Chopped cucumbers will last for about 1 to 2 days in the refrigerator. Can you freeze cucumbers? Cucumbers do not freeze well and freezing is not recommended: cucumbers are high in moisture, which turns to ice when frozen, causing a mushy, wilted texture when thawed. How to tell if cucumbers are bad or spoiled? Cucumbers that are spoiling will typically become soft and discoloured; discard any cucumbers that have an off smell or appearance.
Dandelion Greens — Fresh, Cooked		3-5 Days	10-12 Months	Refrigerate within two hours of cooking. Refrigerate in covered container or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Dandelion Greens — Fresh, Raw		1-2 Days	10-12 Months	Refrigerate in plastic bag; do not wash until ready to use. To freeze: (1) Wash greens thoroughly and cut off woody stems; (2) Blanch (plunge into boiling water) for two minutes and chill quickly in ice cold water; (3) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Dried Vegetables, Commercially Packaged (Including Vegetable Soup Blends) — Unopened Or Opened	1 Year			Store in airtight container.
French Fries (French Fried Potatoes) - Commercially Frozen			10-12 Months	How long do frozen French fries last? The precise answer to that question depends to a large extent on storage conditions - keep French fries frozen at all times. Properly stored, frozen French fries will maintain best quality for about 12 months in the freezer, although they will usually remain safe to eat after that. Are frozen French fries safe to eat after the "expiration" date on the package? Yes, if properly stored - commercially frozen French fries will typically carry a Best By, Best if Used By, Best Before, or Best When Used By date but this is not a safety date, it is the manufacturer's estimate of how long the frozen French fries will remain at peak quality. How long will frozen French fries remain safe to eat? Frozen French fries that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as they have been stored properly and the package is not damaged. How long can you safely leave frozen French fries at room temperature? Frozen French fries should be discarded if left for more than 6 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). How to tell if frozen French fries are no longer good? If dry spots or discolorations have developed on the frozen French fries, freezer burn has begun to set in - this will not make the frozen French fries unsafe to eat, but it will harm the texture and taste.
Garlic - Fresh, Raw, Chopped		5-7 Days	10-12 Months	Refrigerate in airtight container or wrap tightly in plastic wrap and use as soon as possible. To freeze, wrap chopped garlic tightly in plastic freezer wrap or aluminium foil, or place in airtight container or heavy-duty freezer bag. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.

Garlic - Fresh, Raw, Whole Bulb / Head	3-5 Months		10-12 Months	How long does garlic last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep fresh whole garlic in a cool, dry, area. How long does fresh garlic last at room temperature? Properly stored, whole raw garlic will last for about 3 to 5 months at normal room temperature. To maximize the shelf life of garlic, store it in a moderately warm 12.7°C-15.5°C (55°-60°F) area; at higher room temperatures, the shelf life of garlic will be shorter. To further maximize the shelf life of garlic, store it a container that allows for air circulation, such as a wire-mesh basket, a paper bag, or a garlic keeper with holes. Should you refrigerate raw garlic? Whole, raw garlic should ideally not be refrigerated; doing so can cause it to sprout quickly. Once the whole garlic bulb is broken, individual cloves will last unpeeled for about 7-10 days at room temperature. How long does raw garlic last after it's been peeled and chopped? Chopped garlic will usually stay good for about 5 to 7 days in the refrigerator and 10 to 12 months in the freezer. Can you freeze raw garlic? Yes, to freeze garlic: (1) Wrap whole, unpeeled bulbs in plastic freezer wrap or aluminium foil, or place in airtight container or freezer bag and remove individual cloves from freezer as needed; or (2) Peel then chop or crush garlic and wrap tightly in plastic freezer wrap or aluminium foil, or place in airtight container or freezer bag.
Garlic, Commercially Bottled And Chopped, Sold Unrefrigerated - Opened	2 Years (Unopened)	2 years or date on package		Refrigerate after opening to maintain quality. After time shown, most commercially bottled products will still be safe to consume, but the quality may suffer - taste, appearance and consistency can change after prolonged storage.
Ginger Root - Fresh, Raw		2-3 Weeks	1 Month	Refrigerate in plastic bag. To freeze, place in covered airtight container or heavy-duty freezer bag. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Green Onions (Scallions) - Fresh, Raw		7-10 Days	10-12 Months	Wrap in plastic and refrigerate in vegetable crisper. To freeze: (1) Wash green onions and dry thoroughly; (2) Chop or leave whole and place in airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Kale — Fresh, Cooked		3-5 Days	10-12 Months	Refrigerate within two hours of cooking. Refrigerate in covered container or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Kale - Commercially Frozen			10-12 Months	How long does frozen kale last? The precise answer to that question depends to a large extent on storage conditions - keep kale frozen at all times. Properly stored, frozen kale will maintain best quality for about 12 months in the freezer, although it will usually remain safe to eat after that. Is frozen kale safe to eat after the expiration date on the package? Yes, if properly stored - commercially frozen kale will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the frozen kale will remain at peak quality. How long will frozen kale remain safe to eat? Frozen kale that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as it has been stored properly and the package is not damaged. How long can you safely leave frozen kale at room temperature? Frozen kale should be discarded if left for more than 6 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). How to tell if frozen kale is no longer good? If dry spots or discoloration have developed on the frozen kale, freezer burn has begun to set in - this will not make the kale unsafe to eat, but it will harm the texture and taste.
Kale - Fresh, Raw, Loose		5-7 Days	10-12 Months	How long does raw kale last in the fridge? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep kale refrigerated at all times. To maximize the shelf life of raw kale, refrigerate in a plastic bag; do not wash until ready to use. Properly stored, raw kale will usually keep well for about 5 to 7 days in the refrigerator. Do you need to wash raw kale before eating it? Yes, kale should be thoroughly washed in running water before eating. How long does kale last in the fridge once it has been cooked? Cooked kale will usually stay good for 3 to 5 days in the refrigerator and 10 to 12 months in the freezer. Can you freeze raw kale? Yes, to freeze: (1) Wash kale thoroughly and cut off woody stems; (2) Blanch (plunge into boiling water) for two minutes and chill quickly in ice cold water; (3) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. How long does kale last in the freezer? Properly stored, it will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - kale that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Kale, Fresh, Commercially Bagged And Prewashed - Opened Bag		3-5 Days	10-12 Months	How long does an opened bag of prewashed kale last in the fridge? The precise answer to that question depends to a large extent on storage conditions -keep an opened bag of prewashed kale refrigerated at all times. How long can an opened bag of prewashed kale be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); an opened bag of prewashed kale should be discarded if left out for more than 2 hours at room temperature. To maximize the shelf life of an opened bag of prewashed kale, place package upright in the refrigerator and keep closed. How long does an opened bag of prewashed kale last in the refrigerator? Properly stored, an opened bag of prewashed kale will usually keep well for about 3 to 5 days in the fridge. Do you need to wash an opened bag of prewashed kale before eating it? No, it is not necessary to re-wash a prewashed kale; if you choose to re-wash the salad, be sure that it does not come in contact with unclean surfaces or utensils, in order to help to avoid cross contamination. How to tell if an opened bag of prewashed kale is bad or spoiled? An opened bag of prewashed kale that is spoiling will typically become slimy and mushy and its colour will deteriorate; discard an opened bag of prewashed kale if it has an off smell or appearance.
Kale, Fresh, Commercially Bagged And Prewashed - Unopened Bag		7-10 days or date on bag	10-12 Months	How long does an unopened bag of prewashed kale last in the fridge? The precise answer to that question depends to a large extent on storage conditions -keep an unopened bag of prewashed kale refrigerated at all times. How long can an unopened bag of prewashed kale be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); an unopened bag of prewashed kale should be discarded if left out for more than 2 hours at room temperature. To maximize the shelf life of an unopened bag of prewashed kale, place package upright in the refrigerator and keep closed. How long does an unopened bag of prewashed kale last in the refrigerator? Properly stored, an unopened bag of prewashed kale will usually keep well for about 7 to 10 days in the fridge (or the date on the package, if earlier). Do you need to wash an opened bag of prewashed kale before eating it? No, it is not necessary to re-wash a prewashed kale; if you choose to re-wash the salad, be sure that it does not come in contact with unclean surfaces or utensils, in order to help to avoid cross contamination. How to tell if an unopened bag of prewashed kale is bad or spoiled? An unopened bag of prewashed kale that is spoiling will typically become slimy and mushy and its colour will deteriorate; discard an unopened bag of prewashed kale if it has an off smell or appearance.
Leeks — Fresh, Cooked		3-5 Days	10-12 Months	Refrigerate within two hours of cooking. Refrigerate in covered container or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Leeks — Fresh, Raw		7-14 Days	10-12 Months	Refrigerate in plastic bag; do not wash until ready to use. To freeze: (1) Wash leeks thoroughly and slice; (2) Blanch (plunge into boiling water) for two minutes and chill quickly in ice cold water; (3) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Lettuce, Bibb, Boston, Butter - Fresh, Raw		3-4 Days		How long does lettuce last in the fridge? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep bibb lettuce refrigerated at all times. How long can lettuce be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); lettuce should be discarded if left out for more than 2 hours at room temperature. To maximize the shelf life of lettuce, refrigerate in a loosely closed plastic bag and do not wash the lettuce until ready to eat. How long does lettuce last in the refrigerator? Properly stored, lettuce will usually keep well for about 3 to 4 days in the fridge. Do you need to wash a head of lettuce before eating it? Yes, lettuce should be thoroughly washed in running water before eating. Can you freeze lettuce? Bibb lettuce does not freeze well and freezing is not recommended: lettuce is high in moisture, which turns to ice when frozen, causing a mushy, wilted texture when thawed. How to tell if lettuce is bad or spoiled? Lettuce that is spoiling will typically become slimy and mushy and its colour will deteriorate; discard bibb lettuce if it has an off smell or appearance.
Lettuce, Iceberg, Romaine Or Cos - Fresh, Raw		7-10 Days		How long does iceberg lettuce last in the fridge? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep iceberg lettuce refrigerated at all times. How long can iceberg lettuce be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); iceberg lettuce should be discarded if left out for more than 2 hours at room temperature. To maximize the shelf life of iceberg lettuce, refrigerate in a loosely closed plastic bag and do not wash the iceberg lettuce until ready to eat. How long does iceberg lettuce last in the refrigerator? Properly stored, iceberg lettuce will usually keep well for about 7-10 days in the fridge. Do you need to wash a head of iceberg lettuce before eating it? Yes, iceberg lettuce should be thoroughly washed in running water before eating. Can you freeze iceberg lettuce? Iceberg lettuce does not freeze well and freezing is not recommended: iceberg lettuce is high in moisture, which turns to ice when frozen, causing a mushy, wilted texture when thawed. How to tell if iceberg lettuce is bad or spoiled? Iceberg lettuce that is spoiling will typically become slimy and mushy and its colour will deteriorate; discard iceberg lettuce if it has an off smell or appearance.
Lettuce, Leaf (Red Or Green) - Fresh, Raw		1 Week		How long does leaf lettuce last in the fridge? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep leaf lettuce refrigerated at all times. How long can leaf lettuce be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); leaf lettuce should be discarded if left out for more than 2 hours at room temperature. To maximize the shelf life of leaf lettuce, refrigerate in a loosely closed plastic bag and do not wash the leaf lettuce until ready to eat. How long does leaf lettuce last in the refrigerator? Properly stored, leaf lettuce will usually keep well for about 1 week in the fridge. Do you need to wash a head of leaf lettuce before eating it? Yes, leaf lettuce should be thoroughly washed in running water before eating. Can you freeze leaf lettuce? Leaf lettuce does not freeze well and freezing is not recommended: leaf lettuce is high in moisture, which turns to ice when frozen, causing a mushy, wilted texture when thawed. How to tell if leaf lettuce is bad or spoiled? Leaf lettuce that is spoiling will typically become slimy and mushy and its colour will deteriorate; discard leaf lettuce if it has an off smell or appearance.
Lettuce, Lollo Rosso - Fresh, Raw		2-3 Days		Store in a loosely closed plastic bag. Do not wash lettuce until ready to eat. Lettuce does not freeze well.
Lima Beans — Fresh, Cooked		3-5 Days	10-12 Months	Refrigerate within two hours of cooking. Refrigerate in covered container or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Mixed Vegetables - Commercially Frozen			10-12 Months	How long do frozen mixed vegetables last? The precise answer to that question depends to a large extent on storage conditions - keep mixed vegetables frozen at all times. Properly stored, frozen mixed vegetables will maintain best quality for about 12 months in the freezer, although they will usually remain safe to eat after that. Are frozen mixed vegetables safe to eat after the "expiration" date on the package? Yes, if properly stored - commercially frozen mixed vegetables will typically carry a Best By, Best if Used By, Best Before, or Best When Used By date but this is not a safety date, it is the manufacturer's estimate of how long the frozen mixed vegetables will remain at peak quality. How long will frozen mixed vegetables remain safe to eat? Frozen mixed vegetables that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as they have been stored properly and the package is not damaged. How long can you safely leave frozen mixed vegetables at room temperature? Frozen mixed vegetables should be discarded if left for more than 6 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). How to tell if frozen mixed vegetables are no longer good? If dry spots or discolorations have developed on the frozen mixed vegetables, freezer burn has begun to set in - this will not make the frozen mixed vegetables unsafe to eat, but it will harm the texture and taste.
Mixed Vegetables, Commercially Canned Or Bottled — Opened	3-5 Years (Unopened) (Best Quality)	3-4 Days	1-2 Months	How long does a can of mixed vegetables last once opened? The precise answer depends to a large extent on storage conditions - keep opened mixed vegetables refrigerated and tightly covered. To maximize the shelf life of canned mixed vegetables after opening, refrigerate in covered glass or plastic container. How long do opened canned mixed vegetables last in the refrigerator? Canned mixed vegetables that have been continuously refrigerated will keep for about 3 to 4 days. Are canned mixed vegetables safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned mixed vegetables will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the mixed vegetables will remain at peak quality. To further extend the shelf life of opened canned mixed vegetables, freeze them: to freeze canned mixed vegetables, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned mixed vegetables will be softer after freezing and thawing; the thawed mixed vegetables will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned mixed vegetables last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. How long do canned mixed vegetables last after being frozen and thawed? Mixed vegetables that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; mixed vegetables that were thawed in the microwave or in cold water should be used immediately.
Mung Bean Sprouts - Fresh, Raw		3-5 Days	10-12 Months	Refrigerate in plastic bag; do not wash until ready to use. To freeze: (1) Wash sprouts thoroughly; (2) Blanch (plunge into boiling water) for three minutes and chill quickly in ice cold water; (3) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Mushrooms (Including White, Button, Portabella, Shiitake, Oyster, Enoki Varieties) - Fresh, Raw, Sliced Or Chopped		1-2 Days	10-12 Months	Refrigerate sliced mushrooms in covered container or wrap in aluminium foil or plastic wrap. To freeze: (1) Steam sliced mushrooms for three minutes or sauté mushrooms in butter or margarine until almost done; (2) Let cool, then package in airtight containers or freezer bags and freeze immediately. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.

Mushrooms (Including White, Button, Portabella, Shiitake, Oyster, Enoki Varieties) - Fresh, Cooked		3-5 Days	10-12 Months	How long do cooked mushrooms last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate mushrooms within two hours of cooking. To maximize the shelf life of cooked mushrooms for safety and quality, refrigerate the mushrooms in shallow airtight containers or resealable plastic bags. Properly stored, cooked mushrooms will last for 3 to 5 days in the refrigerator. How long can cooked mushrooms be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked mushrooms should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked mushrooms, freeze them; freeze in covered airtight containers or heavy-duty freezer bags. How long do cooked mushrooms last in the freezer? Properly stored, they will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked mushrooms that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked mushrooms last after being frozen and thawed? Cooked mushrooms that have been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; mushrooms that were thawed in the microwave or in cold water should be eaten immediately.
Mushrooms (Including White, Button, Portabella, Shiitake, Oyster, Enoki Varieties) - Fresh, Raw, Whole		4-7 Days	10-12 Months	How long do raw mushrooms last in the fridge? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep raw whole mushrooms refrigerated at all times. To maximize the shelf life of raw mushrooms, refrigerate the mushrooms in a paper bag; do not wrap in plastic or store in airtight container, as this will speed spoilage. How long do raw mushrooms last in the refrigerator? Properly stored, raw whole mushrooms will usually keep well for 4 to 7 days in the fridge. Do you need to wash raw mushrooms before eating them? Yes, mushrooms should be thoroughly washed in running water before eating. How long do raw mushrooms last after they have been sliced or chopped? Chopped raw mushrooms will last for about 1 to 2 days in the refrigerator. How long do mushrooms last in the fridge once they have been cooked? Cooked mushrooms will usually stay good for 3 to 5 days in the refrigerator and 10 to 12 months in the freezer. Can you freeze mushrooms? Yes, to freeze: (1) Wash mushrooms thoroughly and slice; (2) Steam mushrooms for three minutes or sauté in butter or margarine until almost done; (3) Let cool, then package in airtight containers or freezer bags and freeze immediately. How long do mushrooms last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time.
Mushrooms, Commercially Canned Or Bottled (Including Whole, Pieces And Stems) — Opened	3-5 Years (Unopened) (Best Quality)	3-4 Days	1-2 Months	How long does a can or bottle of mushrooms last once opened? The precise answer depends to a large extent on storage conditions - keep opened mushrooms refrigerated and tightly covered. To maximize the shelf life of canned mushrooms after opening, refrigerate in covered glass or plastic container. How long do opened canned mushrooms last in the refrigerator? Canned mushrooms that have been continuously refrigerated will keep for about 3 to 4 days. Are canned mushrooms safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned mushrooms will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the mushrooms will remain at peak quality. To further extend the shelf life of opened canned mushrooms, freeze them: to freeze canned mushrooms, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned mushrooms will be softer after freezing and thawing; the thawed mushrooms will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned mushrooms last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - mushrooms that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Mushrooms, Dried (Including Porcini, Morel) — Opened Or Unopened Package	1 Year			Store in airtight container.
Onions (Including Yellow, White, Red, Spanish, Pearl, Vidalia Varieties) - Fresh, Cooked		3-5 Days	10-12 Months	How long do cooked onions last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate onions within two hours of cooking. To maximize the shelf life of cooked onions for safety and quality, refrigerate the onions in shallow airtight containers or resealable plastic bags. Properly stored, cooked onions will last for 3 to 5 days in the refrigerator. How long can cooked onions be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked onions should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked onions, freeze them; freeze in covered airtight containers or heavy-duty freezer bags. How long do cooked onions last in the freezer? Properly stored, they will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked onions that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked onions last after being frozen and thawed? Cooked onions that have been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; onions that were thawed in the microwave or in cold water should be eaten immediately.
Onions (Including Yellow, White, Red, Spanish, Pearl, Vidalia Varieties) - Fresh, Raw, Sliced Or Chopped		7-10 Days	6-8 Months	How long do chopped onions last? The precise answer to that question depends to a large extent on storage conditions - keep chopped onions refrigerated. To maximize the shelf life of chopped onions, refrigerate in covered container or resealable plastic bag or wrap tightly in aluminium foil or plastic wrap. How long do chopped onions last in the fridge? Properly stored, chopped onions will last for 7 to 10 days in the refrigerator. Can you freeze chopped onions? Yes, to freeze: Place in airtight containers or heavy-duty freezer bags, or wrap tightly in heavy-duty aluminium foil or plastic wrap. Frozen chopped onions will have a softer texture once thawed and are best used in cooked dishes. How long do chopped onions last in the freezer? Properly stored, they will maintain best quality for about 6 to 8 months, but will remain safe beyond that time. The freezer time shown is for best quality only - onions that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if chopped onions are bad or spoiled? The best way is to smell and look at the chopped onions: discard any onions that have an off smell or appearance; if mould appears, discard the chopped onions.
Onions, All Varieties Except Sweet (Including Yellow, White, Pearl) - Fresh, Raw, Whole	2-3 Months	2-3 Months	6-8 Months	How long do onions last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep whole raw onions in a dry, dark area. Whole raw onions will last for 2 to 3 months in a cool (7.2°C-12.7°C, 45-55°F; warmer than the refrigerator, but colder than normal room temperature) dark area. If a cool, dark area is not available, then onions should be refrigerated to ensure maximum shelf life. Properly stored, whole raw onions will last for 2 to 3 months in the refrigerator. To extend the shelf life of onions, store onions in a loosely covered paper or mesh bag or basket to allow for air circulation; do not store onions in plastic bags, as the lack of air movement will reduce their shelf life. To further extend the shelf life of onions, do not store onions near potatoes, as the chemical reaction will speed the spoilage of both. How long do raw onions last after they've been sliced or chopped? Chopped raw onions will last 7 to 10 days in the refrigerator; store in covered airtight containers. Can you freeze raw onions? Yes, to freeze: (1) Peel, then slice or chop onions; (2) Place in airtight containers or heavy-duty freezer bags, or wrap tightly in heavy-duty aluminium foil or plastic wrap.
Onions, Commercially Canned Or Bottled — Opened	2-5 Years (Unopened)	3-4 Days	1-2 Months	Do not store in opened metal can — refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Texture will be softer after freezing and thawing; the thawed food will be best suited to cooked dishes, such as sauces, soups and casseroles. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Onions, Sweet (Including Vidalia, Maui Varieties) - Fresh, Raw, Whole	1-2 Months	1-2 Months	10-12 Months	Pantry time shown is for storage in cool 7.2°C-12.7°C (45°-55°F) dry area with good air circulation; if such an area is not available, refrigerate. Do not store onions near potatoes, as the chemical reaction will speed the spoilage of both. To freeze: (1) Peel, then slice or chop onions; (2) Place in airtight containers or heavy-duty freezer bags, or wrap tightly in heavy-duty aluminium foil or plastic wrap. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Parsnips — Fresh, Cooked		3-5 Days	10-12 Months	Refrigerate within two hours of cooking. Refrigerate in covered container or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Parsnips - Fresh, Raw		3-4 Weeks	10-12 Months	Refrigerate in plastic bag. To freeze: (1) Wash, peel and cut into 1/2-inch cubes; (2) Blanch (plunge into boiling water) for two minutes and chill quickly in ice cold water; (3) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Peas And Carrots / Onions, Commercially Canned Or Bottled — Opened	2-5 Years (Unopened)	3-4 Days	1-2 Months	Do not store in opened metal can — refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Texture will be softer after freezing and thawing; the thawed food will be best suited to cooked dishes, such as sauces, soups and casseroles. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Peas, Green — Fresh, Raw, Still In The Pod		3-5 Days	12-18 Months	Refrigerate in plastic bag; do not shell peas until ready to use. To freeze: (1) Shell and wash peas; (2) Blanch (plunge into boiling water) for 1 1/2 minutes and chill quickly in ice cold water; (3) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Peas, Green - Commercially Frozen			10-12 Months	How long do frozen peas last? The precise answer to that question depends to a large extent on storage conditions - keep peas frozen at all times. Properly stored, frozen peas will maintain best quality for about 12 months in the freezer, although they will usually remain safe to eat after that. Are frozen peas safe to eat after the "expiration" date on the package? Yes, if properly stored - commercially frozen peas will typically carry a Best By, Best if Used By, Best Before, or Best When Used By date but this is not a safety date, it is the manufacturer's estimate of how long the frozen peas will remain at peak quality. How long will frozen peas remain safe to eat? Frozen peas that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as they have been stored properly and the package is not damaged. How long can you safely leave frozen peas at room temperature? Frozen peas should be discarded if left for more than 6 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). How to tell if frozen peas are no longer good? If dry spots or discolorations have developed on the frozen peas, freezer burn has begun to set in - this will not make the frozen peas unsafe to eat, but it will harm the texture and taste.
Peas, Green - Fresh, Cooked		3-5 Days	10-12 Months	How long do cooked peas last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate peas within two hours of cooking. To maximize the shelf life of cooked peas for safety and quality, refrigerate the peas in shallow airtight containers or resealable plastic bags. Properly stored, cooked peas will last for 3 to 5 days in the refrigerator. How long can cooked peas be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked peas should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked peas, freeze them; freeze in covered airtight containers or heavy-duty freezer bags. How long do cooked peas last in the freezer? Properly stored, they will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked peas that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked peas last after being frozen and thawed? Cooked peas that have been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; peas that were thawed in the microwave or in cold water should be eaten immediately.
Peas, Green, Commercially Canned Or Bottled — Opened	3-5 Years (Unopened) (Best Quality)	3-4 Days	1-2 Months	How long does a can of green peas last once opened? The precise answer depends to a large extent on storage conditions - keep opened green peas refrigerated and tightly covered. To maximize the shelf life of canned green peas after opening, refrigerate in covered glass or plastic container. How long do opened canned green peas last in the refrigerator? Canned green peas that have been continuously refrigerated will keep for about 3 to 4 days. Are canned green peas safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned green peas will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the green peas will remain at peak quality. To further extend the shelf life of opened canned green peas, freeze them: to freeze canned green peas, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned green peas will be softer after freezing and thawing; the thawed green peas will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned green peas last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. How long do canned green peas last after being frozen and thawed? Green peas that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; green peas that were thawed in the microwave or in cold water should be used immediately.
Peas, Sugar Snap — Fresh, Cooked		3-5 Days	10-12 Months	Refrigerate within two hours of cooking. Refrigerate in covered container or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Peas, Sugar Snap — Fresh, Raw		3-5 Days	10-12 Months	Refrigerate in plastic bag; do not wash until ready to use. To freeze: (1) Wash thoroughly, remove stems and leave peas whole; (2) Blanch (plunge into boiling water) for 1 1/2 minutes and chill quickly in ice cold water; (3) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Peppers, All Varieties (Including Bell Peppers) - Fresh, Cooked		3-5 Days	10-12 Months	How long do cooked peppers last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate peppers within two hours of cooking. To maximize the shelf life of cooked peppers for safety and quality, refrigerate the peppers in shallow airtight containers or resealable plastic bags. Properly stored, cooked peppers will last for 3 to 5 days in the refrigerator. How long can cooked peppers be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked peppers should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked peppers, freeze them; freeze in covered airtight containers or heavy-duty freezer bags. How long do cooked peppers last in the freezer? Properly stored, they will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked peppers that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked peppers last after being frozen and thawed? Cooked peppers that have been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; peppers that were thawed in the microwave or in cold water should be eaten immediately.

Peppers, Roasted, Commercially Canned Or Bottled - Opened	2-5 Years (Unopened)	1-2 Months	4-6 Months	How long does a can of roasted peppers last once opened? The precise answer depends to a large extent on storage conditions - keep opened roasted peppers refrigerated and tightly covered. To maximize the shelf life of canned roasted peppers after opening, refrigerate in covered glass or plastic container. How long do opened canned roasted peppers last in the refrigerator? Canned roasted peppers that have been continuously refrigerated will keep for about 1 to 2 months. Are canned roasted peppers safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned roasted peppers will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the roasted peppers will remain at peak quality. To further extend the shelf life of opened canned roasted peppers, freeze them: to freeze canned roasted peppers, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned roasted peppers will be softer after freezing and thawing; the thawed roasted peppers will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned roasted peppers last in the freezer? Properly stored, they will maintain best quality for about 6 months, but will remain safe beyond that time.
Pickled Beets, Commercially Jarred Or Canned, Sold Unrefrigerated - Opened	12-18 Months	1-3 Months (Best Quality)		How long do pickled beets last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened pickled beets keep them refrigerated and tightly covered. How long do opened pickled beets last in the refrigerator? Pickled beets that have been continuously refrigerated will generally stay at best quality for about 1 to 3 months. Are opened pickled beets safe to use after the expiration date on the jar or can? Yes, provided they have been stored properly, the jar or can is undamaged, and there are no signs of spoilage - commercially packaged pickled beets will typically carry a Best By," "Best if Used By," Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the pickled beets will remain at peak quality. The storage time shown for opened pickled beets is for best quality only - after that, the pickled beets' texture, colour or flavour may change, but in most cases, they will still be safe to consume if they have been kept continuously refrigerated, the jar or can is undamaged, and there are no signs of spoilage. How can you tell if opened pickled beets are bad or spoiled? The best way is to smell and look at the pickled beets: if the pickled beets develop an off odor, flavour or appearance, or if mould appears, they should be discarded. Discard all pickled beets from jars or cans that are leaking, rusting, bulging or severely dented.
Pickled Peppers, Commercially Jarred, Sold Unrefrigerated - Opened	2 Years (Unopened) (Best Quality)	1 Year (Best Quality)		How long do pickled peppers last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened pickled peppers keep them refrigerated and tightly covered. How long do opened pickled peppers last in the refrigerator? Pickled peppers that have been continuously refrigerated will generally stay at best quality for about 1 year. Are opened pickled peppers safe to use after the expiration date on the jar? Yes, provided they have been stored properly, the jar is undamaged, and there are no signs of spoilage - commercially packaged pickled peppers will typically carry a Best By," "Best if Used By," Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the pickled peppers will remain at peak quality. The storage time shown for opened pickled peppers is for best quality only - after that, the pickled peppers' texture, colour or flavour may change, but in most cases, they will still be safe to consume if they have been kept continuously refrigerated, the jar is undamaged, and there are no signs of spoilage. How can you tell if opened pickled peppers are bad or spoiled? The best way is to smell and look at the pickled peppers: if the pickled peppers develop an off odor, flavour or appearance, or if mould appears, they should be discarded.
Potatoes (All Varieties Except Sweet Potatoes And Yams) - Fresh, Cooked (Including Baked, Mashed, Scalloped, Roasted)		3-5 Days	10-12 Months	How long do cooked potatoes last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate all cooked potatoes (including baked, scalloped, roasted and mashed potatoes) within two hours of cooking. To maximize the shelf life of cooked potatoes for safety and quality, refrigerate the potatoes in shallow airtight containers or resealable plastic bags. Properly stored, cooked potatoes will last for 3 to 5 days in the refrigerator. How long can cooked potatoes be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked potatoes should be discarded if left out for more than 2 hours at room temperature. Can you freeze whole baked potatoes or boiled potatoes? Whole cooked potatoes will be watery when thawed, and freezing is not recommended. Can you freeze mashed, roasted or scalloped potatoes? Yes, these types of cooked potatoes freeze well; freeze in covered airtight containers or heavy-duty freezer bags. How long do cooked potatoes last in the freezer? Properly stored, they will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked potatoes that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Potatoes (All Varieties Except Sweet Potatoes And Yams) - Fresh, Raw	1-2 weeks (at normal room temperature)	3-4 Weeks* *If you must refrigerate raw potatoes (eg, due to a lack of pantry storage space or hot, humid room conditions), the potatoes will last for about 3 to 4 weeks in the fridge, but will likely develop a sweet taste and darken when cooked; this effect can sometimes be offset by storing the potatoes at room temperature for a few days after removing them from the	10-12 Months	How long do potatoes last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep potatoes in a dry, dark area. Properly stored, raw potatoes will last for 1 to 2 weeks at normal room temperature. To maximize the shelf life of potatoes, store in a cool (45-55° F; warmer than the refrigerator, but colder than normal room temperature) dark area; under those storage conditions, potatoes will last about 2 to 3 months. To further extend shelf life of potatoes, do not store potatoes near onions, as the chemical reaction will speed the spoilage of both; store potatoes in a loosely covered bag or basket to allow for air circulation. Should you refrigerate raw potatoes? Whole, raw potatoes should ideally not be refrigerated; doing so can give them a sweet taste and cause them to darken when cooked. How long do raw potatoes last after they've been cut? Cover the cut, raw potatoes completely with cold water and refrigerate; use the cut potatoes within 24 hours. How long do potatoes last in the fridge once they have been cooked? Cooked potatoes will usually stay good for 3 to 5 days in the refrigerator and 10 to 12 months in the freezer. To freeze cooked potatoes: (1) Wash, peel and boil potatoes until tender; (2) Mash potatoes and allow to cool; (3) Place in covered airtight containers or heavy-duty freezer bags.
Potatoes, Commercially Canned Or Bottled — Opened	3-5 Years (Unopened) (Best Quality)	3-4 Days	1-2 Months	How long does a can of potatoes last once opened? The precise answer depends to a large extent on storage conditions - keep opened potatoes refrigerated and tightly covered. To maximize the shelf life of canned potatoes after opening, refrigerate in covered glass or plastic container. How long do opened canned potatoes last in the refrigerator? Canned potatoes that have been continuously refrigerated will keep for about 3 to 4 days. Are canned potatoes safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned potatoes will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the potatoes will remain at peak quality. To further extend the shelf life of opened canned potatoes, freeze them: to freeze canned potatoes, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned potatoes will be softer after freezing and thawing; the thawed potatoes will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned potatoes last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. How long do canned potatoes last after being frozen and thawed? Potatoes that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; potatoes that were thawed in the microwave or in cold water should be used immediately.
Pumpkin — Fresh, Cooked		3-5 Days	10-12 Months	Refrigerate within two hours of cooking. Refrigerate in covered container or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Pumpkin — Fresh, Raw, Cut Up		2-4 Days	10-12 Months	Refrigerate in covered container or wrap in aluminium foil or plastic wrap. To freeze: (1) Cut pumpkin into sections and remove seeds; (2) Cook pumpkin until soft; (3) Remove pumpkin pulp from rind and mash; (4) Let cool and then place in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Pumpkin - Fresh, Raw, Whole	1-2 Months		10-12 Months	Pantry time shown is for storage in a cool (50Â° - 60°F) dry area; if kept at normal room temperature, storage times will be shorter. Refrigeration is not recommended, as it will harm the texture and flavour. To freeze: (1) Cut pumpkin into sections and remove seeds; (2) Cook pumpkin until soft; (3) Remove pumpkin pulp from rind and mash; (4) Let cool and then place in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Pumpkin, Commercially Canned Or Bottled — Opened	3-5 Years (Unopened) (Best Quality)	5-6 Days	2-3 Months	How long does a can of pumpkin last once opened? The precise answer depends to a large extent on storage conditions - keep opened pumpkin refrigerated and tightly covered. To maximize the shelf life of canned or packaged pumpkin after opening, refrigerate in a covered glass or plastic container. How long does opened canned pumpkin last in the refrigerator? Pumpkin that has been continuously refrigerated will keep for about 5 to 7 days. Is canned pumpkin safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged pumpkin will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the pumpkin will remain at peak quality. To further extend the shelf life of opened canned pumpkin, freeze it: to freeze pumpkin, place inside covered airtight containers or heavy-duty freezer bags. The freezer time shown is for best quality only - pumpkin that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does canned pumpkin last after being frozen and thawed? Canned pumpkin that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; pumpkin that was thawed in the microwave or in cold water should be used immediately. How can you tell if opened canned pumpkin is bad or spoiled? The best way is to smell and look at the pumpkin: if the pumpkin develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Shallots — Fresh, Raw, Sliced Or Chopped		2-3 Days	10-12 Months	Refrigerate in covered container or wrap tightly with heavy-duty aluminium foil or plastic wrap or plastic wrap. Freeze in covered airtight containers or freezer bags or wrap tightly in heavy-duty aluminium foil. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Shallots - Fresh, Cooked		3-5 Days	10-12 Months	How long do cooked shallots last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate shallots within two hours of cooking. To maximize the shelf life of cooked shallots for safety and quality, refrigerate the shallots in shallow airtight containers or resealable plastic bags. Properly stored, cooked shallots will last for 3 to 5 days in the refrigerator. How long can cooked shallots be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked shallots should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked shallots, freeze them; freeze in covered airtight containers or heavy-duty freezer bags. How long do cooked shallots last in the freezer? Properly stored, they will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked shallots that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked shallots last after being frozen and thawed? Cooked shallots that have been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; shallots that were thawed in the microwave or in cold water should be eaten immediately.
Shallots - Fresh, Raw, Whole	1 Month	1 Month	10-12 Months	Pantry time shown is for storage in cool (45Â° - 55Â° F) dry area with good air circulation; if such an area is not available, refrigerate. To freeze: Peel and chop first, then place in covered airtight containers or freezer bags, or wrap tightly in heavy-duty aluminium foil or plastic wrap. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Snow Peas — Fresh, Raw		3-4 Days	10-12 Months	Refrigerate in plastic bag; do not wash until ready to use. To freeze: (1) Wash thoroughly, remove stems and leave peas whole; (2) Blanch (plunge into boiling water) for 1 1/2 minutes and chill quickly in ice cold water; (3) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Snow Peas - Fresh, Cooked		3-5 Days	10-12 Months	How long do cooked snow peas last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate snow peas within two hours of cooking. To maximize the shelf life of cooked snow peas for safety and quality, refrigerate the snow peas in shallow airtight containers or resealable plastic bags. Properly stored, cooked snow peas will last for 3 to 5 days in the refrigerator. How long can cooked snow peas be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked snow peas should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked snow peas, freeze them; freeze in covered airtight containers or heavy-duty freezer bags. How long do cooked snow peas last in the freezer? Properly stored, they will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked snow peas that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked snow peas last after being frozen and thawed? Cooked snow peas that have been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; snow peas that were thawed in the microwave or in cold water should be eaten immediately.
Sorrel — Fresh, Raw		1-2 Days	10-12 Months	Refrigerate in plastic bag; do not wash until ready to use. To freeze: (1) Wash thoroughly and cut off woody stems; (2) Blanch (plunge into boiling water) for two minutes and chill quickly in ice cold water; (3) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Soybeans — Fresh, Cooked		3-5 Days	10-12 Months	Refrigerate within two hours of cooking. Refrigerate in covered container or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Soybeans — Fresh, Raw		3-5 Days	8 Months	Refrigerate in plastic bag. To freeze: (1) Wash beans; (2) Blanch (plunge into boiling water) for five minutes and chill quickly in ice cold water; (3) Squeeze soybeans out of pods, drain off excess moisture and package in airtight containers or freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.

FOOD Food Shelf Life Vegetables Shelf Life

Spinach - Fresh, Cooked		3-5 Days	10-12 Months	How long does cooked spinach last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate spinach within two hours of cooking. To maximize the shelf life of cooked spinach for safety and quality, refrigerate the spinach in airtight containers or resealable plastic bags. Properly stored, cooked spinach will last for 3 to 5 days in the refrigerator. How long can cooked spinach be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked spinach should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked spinach, freeze it; freeze in covered airtight containers or heavy-duty freezer bags. How long does cooked spinach last in the freezer? Properly stored, it will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked spinach that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked spinach last after being frozen and thawed? Cooked spinach that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; spinach that was thawed in the microwave or in cold water should be eaten immediately.
Spinach - Fresh, Raw, Loose		5-7 Days	10-12 Months	How long does raw spinach last in the fridge? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep spinach refrigerated at all times. To maximize the shelf life of raw spinach, refrigerate in a plastic bag; do not wash until ready to use. Properly stored, raw spinach will usually keep well for about 5 to 7 days in the refrigerator. Do you need to wash raw spinach before eating it? Yes, spinach should be thoroughly washed in running water before eating. How long does spinach last in the fridge once it has been cooked? Cooked spinach will usually stay good for 3 to 5 days in the refrigerator and 10 to 12 months in the freezer. Can you freeze raw spinach? Yes, to freeze: (1) Wash spinach thoroughly and cut off woody stems; (2) Blanch (plunge into boiling water) for two minutes and chill quickly in ice cold water; (3) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. How long does spinach last in the freezer? Properly stored, it will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - spinach that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Spinach, Commercially Canned Or Bottled — Opened	2-5 Years (Unopened)	3-4 Days	1-2 Months	Do not store in opened metal can — refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Texture will be softer after freezing and thawing; the thawed food will be best suited to cooked dishes, such as sauces, soups and casseroles. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Squash - Commercially Frozen			10-12 Months	How long does frozen squash last? The precise answer to that question depends to a large extent on storage conditions - keep squash frozen at all times. Properly stored, frozen squash will maintain best quality for about 12 months in the freezer, although it will usually remain safe to eat after that. Is frozen squash safe to eat after the expiration date on the package? Yes, if properly stored - commercially frozen squash will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the frozen squash will remain at peak quality. How long will frozen squash remain safe to eat? Frozen squash that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as it has been stored properly and the package is not damaged. How long can you safely leave frozen squash at room temperature? Frozen squash should be discarded if left for more than 6 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). How to tell if frozen squash is no longer good? If dry spots or discoloration have developed on the frozen squash, freezer burn has begun to set in - this will not make the squash unsafe to eat, but it will harm the texture and taste.
Squash, Summer (Including Zucchini, Crookneck, Scallop, Patty Pan) — Fresh, Raw, Sliced Or Chopped		2-3 Days	10-12 Months	Refrigerate in covered container or wrap tightly with heavy-duty aluminium foil or plastic wrap. To freeze: (1) Wash and cut into 1/2 inch slices (zucchini may also be grated); (2) Blanch (plunge into boiling water) for three minutes (steam grated zucchini for 2 minutes) and chill quickly in ice cold water; (3) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Squash, Summer (Including Zucchini, Crookneck, Scallop, Patty Pan) — Fresh, Raw, Whole		4-5 Days	10-12 Months	Refrigerate in plastic bag; do not wash until ready to eat. To freeze: (1) Wash and cut into 1/2 inch slices (zucchini may also be grated); (2) Blanch (plunge into boiling water) for three minutes (steam grated zucchini for 2 minutes) and chill quickly in ice cold water; (3) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Squash, Summer (Including Zucchini, Crookneck, Scallop, Patty Pan) - Fresh, Cooked		3-5 Days	10-12 Months	How long does cooked summer squash last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate summer squash within two hours of cooking. To maximize the shelf life of cooked summer squash for safety and quality, refrigerate the summer squash in airtight containers or resealable plastic bags. Properly stored, cooked summer squash will last for 3 to 5 days in the refrigerator. How long can cooked summer squash be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked summer squash should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked summer squash, freeze it; freeze in covered airtight containers or heavy-duty freezer bags. How long does cooked summer squash last in the freezer? Properly stored, it will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked summer squash that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked summer squash last after being frozen and thawed? Cooked summer squash that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; summer squash that was thawed in the microwave or in cold water should be eaten immediately.
Squash, Summer, Commercially Canned Or Bottled (Including Zucchini, Crookneck, Scallop, Patty Pan) — Opened	2-5 Years (Unopened)	3-4 Days	1-2 Months	Do not store in opened metal can — refrigerate in covered glass or plastic container after opening. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Squash, Winter (Including Acorn, Hubbard, Butternut, Spaghetti) — Fresh, Raw, Sliced Or Chopped		2-4 Days	10-12 Months	Refrigerate in covered container or wrap tightly with heavy-duty aluminium foil or plastic wrap. Raw squash does not freeze well; cook before freezing. To freeze: (1) Cook squash until soft; (2) Remove pulp from rind and mash; (3) Let cool and place in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Squash, Winter (Including Acorn, Hubbard, Butternut, Spaghetti) - Fresh, Raw, Whole	1-2 Months		10-12 Months	Pantry time shown is for storage in a cool (50Â° - 60°F) dry area; if kept at normal room temperature, storage times will be shorter. Refrigeration is not recommended, as it will harm the texture and flavour. Raw squash does not freeze well; cook before freezing. To freeze: (1) Wash squash, then cook until soft; (2) Remove pulp from rind and mash; (3) Let cool and place in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Squash, Winter (Including Acorn, Hubbard, Butternut, Spaghetti) - Fresh, Cooked		3-5 Days	10-12 Months	How long does cooked winter squash last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate winter squash within two hours of cooking. To maximize the shelf life of cooked winter squash for safety and quality, refrigerate the winter squash in airtight containers or resealable plastic bags. Properly stored, cooked winter squash will last for 3 to 5 days in the refrigerator. How long can cooked winter squash be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked winter squash should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked winter squash, freeze it; freeze in covered airtight containers or heavy-duty freezer bags. How long does cooked winter squash last in the freezer? Properly stored, it will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked winter squash that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked winter squash last after being frozen and thawed? Cooked winter squash that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; winter squash that was thawed in the microwave or in cold water should be eaten immediately.
Sweet Potatoes - Fresh, Cooked (Including Baked, Mashed, Casseroles)		3-5 Days	10-12 Months	How long do cooked sweet potatoes last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate sweet potatoes (including mashed and baked sweet potatoes) within two hours of cooking. To maximize the shelf life of cooked sweet potatoes for safety and quality, refrigerate the sweet potatoes in shallow airtight containers or resealable plastic bags. Properly stored, cooked sweet potatoes will last for 3 to 5 days in the refrigerator. How long can cooked sweet potatoes be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked sweet potatoes should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked sweet potatoes, freeze them. To freeze whole baked sweet potatoes: Wrap potatoes individually in foil and then place together in heavy-duty freezer bags or airtight containers. To freeze boiled and sliced or mashed sweet potatoes: sprinkle first with a small amount of lemon juice to prevent discoloration and then place in covered airtight containers or heavy-duty freezer bags. How long do cooked sweet potatoes last after being frozen and thawed? Cooked sweet potatoes that have been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; sweet potatoes that were thawed in the microwave or in cold water should be eaten immediately.
Sweet Potatoes - Fresh, Raw	1-2 weeks (at normal room temperature)		10-12 Months	How long do sweet potatoes last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep sweet potatoes in a dry, dark area. Properly stored, raw sweet potatoes will last for 1 to 2 weeks at normal room temperature. To maximize the shelf life of sweet potatoes, store in a cool (45-55Â° F; warmer than the refrigerator, but colder than normal room temperature) dark area; under those storage conditions, sweet potatoes will last about 1 month. To further extend shelf life of sweet potatoes, store in a loosely covered bag or basket to allow for air circulation. Should you refrigerate raw sweet potatoes? Whole, raw sweet potatoes should ideally not be refrigerated; doing so can give them a hard centre and unpleasant taste. How long do raw sweet potatoes last after they've been cut? Cover the cut, raw sweet potatoes completely with cold water and refrigerate; use the cut sweet potatoes within 24 hours. How long do sweet potatoes last in the fridge once they have been cooked? Cooked sweet potatoes will usually stay good for 3 to 5 days in the refrigerator and 10 to 12 months in the freezer. To freeze cooked sweet potatoes (1) Wash, peel and boil sweet potatoes until tender; (2) Slice or mash potatoes and sprinkle with a small amount of lemon juice to prevent discoloration; (3) Let cool and place in covered airtight containers or heavy-duty freezer bags.
Sweet Potatoes, Commercially Canned Or Bottled — Opened	3-5 Years (Unopened) (Best Quality)	3-4 Days	1-2 Months	How long does a can of sweet potatoes last once opened? The precise answer depends to a large extent on storage conditions - keep opened sweet potatoes refrigerated and tightly covered. To maximize the shelf life of canned sweet potatoes after opening, refrigerate in covered glass or plastic container. How long do opened canned sweet potatoes last in the refrigerator? Canned sweet potatoes that have been continuously refrigerated will keep for about 3 to 4 days. Are canned sweet potatoes safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned sweet potatoes will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the sweet potatoes will remain at peak quality. To further extend the shelf life of opened canned sweet potatoes, freeze them: to freeze canned sweet potatoes, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned sweet potatoes will be softer after freezing and thawing; the thawed sweet potatoes will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned sweet potatoes last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. How long do canned sweet potatoes last after being frozen and thawed? Sweet potatoes that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; sweet potatoes that were thawed in the microwave or in cold water should be used immediately.
Tomato Paste, Sold In Tube — Unopened	2-3 Years			Store in cool, dry area. Storage time shown is for best quality only— after that, the product's taste, texture and nutritional value may change, but in most cases, the unopened paste will still be safe to consume if it has been stored properly and the package is not damaged. "Best By," "Best if Used By," and "Use By" dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality — in most cases, the unopened product will still be safe to consume after that date, as long as it has been stored properly and the package is not damaged.
Tomato Paste, Commercially Canned Or Bottled - Opened	18-24 Months (Best Quality) (Unopened)	5-7 Days	3-4 Months	Do not store tomato paste in opened metal can - refrigerate in covered glass or plastic container after opening. Freeze tomato paste in airtight plastic containers or heavy-duty freezer bags, or spoon tomato paste into ice cube trays - once paste is frozen, transfer cubes to a heavy-duty freezer bag. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Tomato Sauce, Commercially Canned Or Bottled - Opened	18-24 Months (Best Quality) (Unopened)	5-7 Days	2-3 Months	How long does a can of tomato sauce last once opened? The precise answer depends to a large extent on storage conditions - keep opened tomato sauce refrigerated and tightly covered. To maximize the shelf life of canned or packaged tomato sauce after opening, refrigerate in covered glass or plastic container. How long does opened canned tomato sauce last in the refrigerator? Tomato sauce that has been continuously refrigerated will keep for about 5 to 7 days. Is canned tomato sauce safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged tomato sauce will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the tomato sauce will remain at peak quality. To further extend the shelf life of opened canned tomato sauce, freeze it: to freeze tomato sauce, place inside covered airtight containers or heavy-duty freezer bags. How long does canned tomato sauce last in the freezer? Properly stored, it will maintain best quality for about 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - tomato sauce that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does tomato sauce last after being frozen and thawed? Tomato sauce that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; tomato sauce that was thawed in the microwave or in cold water should be used immediately.
Tomato Soup, Commercially Canned Or Packaged, Sold Unrefrigerated — Opened	18-24 Months (Best Quality) (Unopened)	3-4 Days	4-6 Months	How long does tomato soup last once opened? The precise answer depends to a large extent on storage conditions - keep opened tomato soup refrigerated and tightly covered. To maximize the shelf life of canned or packaged tomato soup after opening, refrigerate in covered glass or plastic container. How long does opened tomato soup last in the refrigerator? Tomato soup that has been continuously refrigerated will keep for about 3 to 4 days. Is tomato soup safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged tomato soup will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the tomato soup will remain at peak quality. To further extend the shelf life of opened tomato soup, freeze it: to freeze tomato soup, place inside covered airtight containers or heavy-duty freezer bags. How long does tomato soup last in the freezer? Properly stored, it will maintain best quality for about 6 months, but will remain safe beyond that time. The freezer time shown is for best quality only - tomato soup that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does tomato soup last after being frozen and thawed? Tomato soup that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; tomato soup that was thawed in the microwave or in cold water should be used immediately.

Tomatoes (Including Red, Yellow, Green, Cherry, Plum, Roma) - Fresh, Cooked		3-5 Days	10-12 Months	How long do cooked tomatoes last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate tomatoes within two hours of cooking. To maximize the shelf life of cooked tomatoes for safety and quality, refrigerate the tomatoes in shallow airtight containers or resealable plastic bags. Properly stored, cooked tomatoes will last for 3 to 5 days in the refrigerator. How long can cooked tomatoes be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked tomatoes should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked tomatoes, freeze them; freeze in covered airtight containers or heavy-duty freezer bags. How long do cooked tomatoes last in the freezer? Properly stored, they will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked tomatoes that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked tomatoes last after being frozen and thawed? Cooked tomatoes that have been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; tomatoes that were thawed in the microwave or in cold water should be eaten immediately.
Tomatoes (Including Red, Yellow, Green, Cherry, Plum, Roma) - Fresh, Raw, Sliced Or Chopped		3-4 Days	2 Months	How long do chopped fresh tomatoes last? The precise answer to that question depends to a large extent on storage conditions - keep chopped tomatoes refrigerated. To maximize the shelf life of chopped tomatoes, refrigerate in covered container or resealable plastic bag or wrap tightly in aluminium foil or plastic wrap. How long do chopped tomatoes last in the fridge? Properly stored, chopped fresh tomatoes will last for 3 to 4 days in the refrigerator. Can you freeze chopped tomatoes? Yes, to freeze: Place in airtight containers or heavy-duty freezer bags, or wrap tightly in heavy-duty aluminium foil or plastic wrap. Frozen chopped tomatoes will become mushy when thawed and are best used in cooked dishes. How long do chopped tomatoes last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - tomatoes that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if chopped tomatoes are bad or spoiled? The best way is to smell and look at the chopped tomatoes: discard any tomatoes that have an off smell or appearance; if mould appears, discard the chopped tomatoes.
Tomatoes (Including Red, Yellow, Green, Cherry, Plum, Roma) - Fresh, Raw, Whole	1-5 days or until ripe	5-7 days once ripe	2-3 Months	How long do tomatoes last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep tomatoes in a dry area. Properly stored, tomatoes will become fully ripe in about 1 to 5 days at normal room temperature. How can you make tomatoes ripen faster? To hasten ripening, put tomatoes in a brown paper bag, close it and leave on the counter. Do not refrigerate tomatoes until they are fully ripe - allowing to ripen at room temperature will result in more flavourful, juicy tomatoes. To extend the shelf life of fully ripe tomatoes, place in a plastic bag and refrigerate; bring the tomatoes back to room temperature before using. How long do tomatoes last in the refrigerator? Fully ripe tomatoes will last for about 5 to 7 days in the fridge. Remove tomatoes from the refrigerator about 30 minutes prior to serving for best flavour. Can you freeze raw tomatoes? Yes: (1) Wash tomatoes and pat dry; (2) Leave skins on, or if desired, peel tomatoes by dipping in boiling water for 30 seconds to loosen skins; (3) Leave tomatoes whole or cut into pieces; (4) Place tomatoes in a single layer on cookie tray in freezer; (5) Once tomatoes are frozen, transfer to airtight containers or heavy-duty freezer bags and return to freezer.
Tomatoes, Commercially Canned Or Packaged (Including Crushed, Stewed, Whole, Or Diced) - Opened	18-24 Months (Best Quality) (Unopened)	5-7 Days	2-3 Months	How long does a can of tomatoes last once opened? The precise answer depends to a large extent on storage conditions - keep opened tomatoes (including crushed, stewed, whole, or diced tomatoes) refrigerated and tightly covered. To maximize the shelf life of canned or packaged tomatoes after opening, refrigerate in covered glass or plastic container. How long do opened canned tomatoes last in the refrigerator? Tomatoes that have been continuously refrigerated will keep for about 5 to 7 days. Are canned tomatoes safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned tomatoes will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the tomatoes will remain at peak quality. To further extend the shelf life of opened canned tomatoes, freeze them: to freeze tomatoes, place inside covered airtight containers or heavy-duty freezer bags. How long do canned tomatoes last in the freezer? Properly stored, they will maintain best quality for about 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - tomatoes that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do canned tomatoes last after being frozen and thawed? Tomatoes that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; tomatoes that were thawed in the microwave or in cold water should be used immediately.
Tomatoes, Sun-Dried, Packed In Oil — Opened	12 Months (Unopened)	6-12 Months		Refrigerate in covered container. Store in cool, dark area.
Turnip Greens — Commercially Frozen			10-12 Months	Keep frozen until ready to use. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. Once prepared, refrigerate leftovers in a covered container for up to two days.
Turnip Greens — Fresh, Cooked		3-5 Days	10-12 Months	Refrigerate within two hours of cooking. Refrigerate in covered container or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Turnip Greens — Fresh, Raw		1-2 Days	10-12 Months	Refrigerate in plastic bag; do not wash until ready to use. To freeze: (1) Wash greens thoroughly and cut off woody stems; (2) Blanch (plunge into boiling water) for two minutes and chill quickly in ice cold water; (3) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Turnip Greens, Commercially Canned Or Bottled — Opened	2-5 Years (Unopened) (Best Quality)	3-4 Days	1-2 Months	Do not store in opened metal can — refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Texture will be softer after freezing and thawing; the thawed food will be best suited to cooked dishes, such as sauces, soups and casseroles. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Turnips - Fresh, Raw		2-3 Weeks	8-10 Months	Refrigerate in plastic bag. To freeze: (1) Wash, peel and cut into 1/2-inch cubes; (2) Blanch (plunge into boiling water) for two minutes and chill quickly in ice cold water; (3) Drain off excess moisture, package in airtight containers or freezer bags and freeze immediately. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Turnips - Commercially Frozen			10-12 Months	Keep frozen until ready to use. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. Once prepared, refrigerate leftovers in a covered container for up to four days.
Turnips - Fresh, Cooked		3-5 Days	8-10 Months	How long do cooked turnips last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - refrigerate turnips within two hours of cooking. To maximize the shelf life of cooked turnips for safety and quality, refrigerate the turnips in shallow airtight containers or resealable plastic bags. Properly stored, cooked turnips will last for 3 to 5 days in the refrigerator. How long can cooked turnips be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked turnips should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cooked turnips, freeze them; freeze in covered airtight containers or heavy-duty freezer bags. How long do cooked turnips last in the freezer? Properly stored, they will maintain best quality for 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked turnips that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked turnips last after being frozen and thawed? Cooked turnips that have been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; turnips that were thawed in the microwave or in cold water should be eaten immediately.
Vegetable Broth Or Stock, Commercially Canned Or Packaged, Sold Unrefrigerated - Opened	18-24 Months (Best Quality) (Unopened)	4-5 Days	4-6 Months	How long does a can or package of vegetable broth last once opened? The precise answer depends to a large extent on storage conditions - keep opened vegetable broth refrigerated and tightly covered. To maximize the shelf life of canned or packaged vegetable broth after opening, refrigerate in covered glass or plastic container. How long does opened vegetable broth last in the refrigerator? Vegetable broth that has been continuously refrigerated will keep for about 4 to 5 days. Is vegetable broth safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged vegetable broth will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the vegetable broth will remain at peak quality. To further extend the shelf life of opened vegetable broth, freeze it: to freeze vegetable broth, place inside covered airtight containers or heavy-duty freezer bags. How long does vegetable broth last in the freezer? Properly stored, it will maintain best quality for about 6 months, but will remain safe beyond that time. The freezer time shown is for best quality only - vegetable broth that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does vegetable broth last after being frozen and thawed? Vegetable broth that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; vegetable broth that was thawed in the microwave or in cold water should be used immediately.
Vegetable Soup, Commercially Canned Or Packaged, Sold Unrefrigerated— Opened	3-5 Years (Best Quality) (Unopened)	3-4 Days	4-6 Months	How long does vegetable soup last once opened? The precise answer depends to a large extent on storage conditions - keep opened vegetable soup refrigerated and tightly covered. To maximize the shelf life of canned or packaged vegetable soup after opening, refrigerate in covered glass or plastic container. How long does opened vegetable soup last in the refrigerator? Vegetable soup that has been continuously refrigerated will keep for about 3 to 4 days. Is vegetable soup safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged vegetable soup will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the vegetable soup will remain at peak quality. To further extend the shelf life of opened vegetable soup, freeze it: to freeze vegetable soup, place inside covered airtight containers or heavy-duty freezer bags. How long does vegetable soup last in the freezer? Properly stored, it will maintain best quality for about 6 months, but will remain safe beyond that time. The freezer time shown is for best quality only - vegetable soup that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does vegetable soup last after being frozen and thawed? Vegetable soup that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; vegetable soup that was thawed in the microwave or in cold water should be used immediately.

3 Fruits Shelf Life

These is the shelf life of most fruit, both pre-packaged and raw.

	Pantry	Refrigerator	Freezer	Food Tips
Apples - Commercially Frozen			1 Year	Freeze in original packaging. Freezer time shown is for best quality - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Apples - Fresh, Raw, Cut Up		3-4 Days	10-12 Months	How long do cut apples last? The exact answer to that question depends to a large extent on storage conditions - keep cut-up apples refrigerated. Apples discolour quickly when cut - to prevent browning, sprinkle the cut apples with a little lemon juice before refrigerating. To maximize the shelf life of cut apples, wrap tightly with plastic wrap or aluminium foil, or place in covered container or resealable plastic bag and refrigerate. How long do cut apples last in the fridge? Properly stored, cut apples will last for 3 to 4 days in the refrigerator. Can you freeze cut apples? Yes, to freeze apples: (1) Wash, peel, core and slice apples; (2) Coat apples with a solution made of 1 teaspoon of ascorbic acid for each 6 tablespoons of cold water to prevent darkening; (3) Place in covered airtight containers or heavy-duty freezer bags. How long do cut apples last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cut-up apples that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cut apples are bad or spoiled? The best way is to smell and look at the cut apples: discard any apples that have an off smell or appearance; if mould appears, discard the cut apples.
Apples - Fresh, Raw, Whole	5-7 Days	1-2 Months	10-12 Months	How long do apples last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep apples in a dry area. How long do apples last at room temperature? Apples will generally keep well at room temperature for about 5 to 7 days; longer storage at room temperature can cause the apples to shrivel and lose flavour and crispness. To extend the shelf life of apples, refrigerate in a plastic bag. How long do apples last in the refrigerator? Properly stored, apples will usually keep well for 1 to 2 months in the fridge. The shelf life of apples can be extended to 6 months or more if the apples are stored in an area where the temperature is between 30°F and 40°F with high humidity (difficult to find in most households). Can you freeze apples? Yes: (1) Wash, peel, core and slice apples; (2) Coat apples with a solution made of 1 teaspoon of ascorbic acid for each 6 tablespoons of cold water to prevent darkening; (3) Place in covered airtight containers or heavy-duty freezer bags. How long do apples last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - apples that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Apples, Commercially Canned Or Bottled - Opened	12-18 Months (Unopened)	5-7 Days	1-2 Months	Do not store in opened metal can - refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.

Apples, Dried - Unopened Or Opened Package	6-12 Months	6-12 Months	12-18 Months	Store in cool, dry area; after opening, place in tightly sealed airtight container or heavy-duty plastic bag. Refrigeration is recommended in hot, humid environments. Freeze in airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Apricots — Fresh, Raw, Cut Up		3-4 Days	10-12 Months	Wrap cut fruit tightly with plastic wrap or aluminium foil before refrigerating, or store in airtight container. To freeze apricots: (1) Wash, pit and halve or slice apricots; (2) Coat apricots with a solution made of 1/2 teaspoon of ascorbic acid for each 6 tablespoons of cold water to prevent darkening; (3) Mix 1/2 cup sugar into each quart of fruit and stir until sugar is dissolved; (4) Place in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Apricots - Fresh, Raw, Whole	1-3 days or until ripe	4-5 days once ripe	10-12 Months	Once ripe, refrigerate in plastic bag. To freeze apricots: (1) Wash, pit and halve or slice apricots; (2) Coat apricots with a solution made of 1/2 teaspoon of ascorbic acid for each 6 tablespoons of cold water to prevent darkening; (3) Add 1/2 cup sugar to each quart of fruit and stir until sugar is dissolved; (4) Place in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Apricots, Commercially Canned Or Bottled — Opened	12-18 Months (Unopened)	5-7 Days	1-2 Months	Do not store in opened metal can — refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Apricots, Dried - Unopened Or Opened Package	6-12 Months	6-12 Months	12-18 Months	Store in cool, dry area; after opening, place in tightly sealed airtight container or heavy-duty plastic bag. Refrigeration is recommended in hot, humid environments. Freeze in airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Avocados - Fresh, Raw, Cut Up		3-4 Days	3-6 Months	How long do cut avocados last? The exact answer to that question depends to a large extent on storage conditions - keep cut-up avocados refrigerated. Avocados discolour quickly when cut - to keep sliced avocado from turning brown, wrap tightly in plastic; sprinkling a small amount of lemon or lime juice onto the exposed avocado flesh will also help prevent discoloration To maximize the shelf life of cut avocados, wrap tightly with plastic wrap or aluminium foil, or place in covered container or resealable plastic bag and refrigerate. How long do cut avocados last in the fridge? Properly stored, cut avocados will last for 3 to 4 days in the refrigerator. Can you freeze cut avocados? Yes, to freeze avocados: (1) Peel and puree avocados; (2) Add to the puree 1/2 tablespoon of lemon juice for every avocado used to prevent browning; (3) Place in covered airtight containers or heavy-duty freezer bags. How long do cut avocados last in the freezer? Properly stored, they will maintain best quality for about 3 to 6 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cut-up avocados that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cut avocados are bad or spoiled? The best way is to smell and look at the cut avocados: discard any avocados that have an off smell or appearance; if mould appears, discard the cut avocados.
Avocados - Fresh, Raw, Whole	4-7 days or until ripe	3-5 days once ripe	3-6 Months	How long do avocados last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep avocados in a dry area. Properly stored, avocados will become fully ripe in about 4 to 7 days at normal room temperature. How can you make avocados ripen faster? To hasten ripening, put avocados in a brown paper bag, close it and leave on the counter; to ripen them even faster, add an apple to the bag. Do not refrigerate avocados until they are fully ripe - allowing to ripen at room temperature will result in more flavourful avocados. To extend the shelf life of fully ripe avocados, place in a plastic bag and refrigerate; for best results, bring the avocados back to room temperature before using. How long do avocados last in the refrigerator? Fully ripe avocados will last for about 3 to 5 days in the fridge. Can you freeze avocados? Yes: (1) Peel and puree avocados; (2) Add to the puree 1/2 tablespoon of lemon juice for every avocado used to prevent browning; (3) Place in covered airtight containers or heavy-duty freezer bags. How long do avocados last in the freezer? Properly stored, they will maintain best quality for about 3 to 6 months, but will remain safe beyond that time.
Bananas - Fresh, Raw, Cut Up		3-4 Days	2-3 Months	How long do cut bananas last? The exact answer to that question depends to a large extent on storage conditions - keep cut-up bananas refrigerated. Bananas discolour quickly when cut - to prevent browning, sprinkle the cut bananas with a little lemon juice before refrigerating. To maximize the shelf life of cut bananas, wrap tightly with plastic wrap or aluminium foil, or place in covered container or resealable plastic bag and refrigerate. How long do cut bananas last in the fridge? Properly stored, cut bananas will last for 3 to 4 days in the refrigerator. Can you freeze cut bananas? Yes, to freeze bananas: (1) Peel and mash; (2) Add one tablespoon of lemon juice or 1/2 teaspoon ascorbic acid for each cup of mashed banana to prevent browning; (3) Place in covered airtight containers or heavy-duty freezer bags. How long do cut bananas last in the freezer? Properly stored, they will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cut-up bananas that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cut bananas are bad or spoiled? The best way is to smell and look at the cut bananas: discard any bananas that have an off smell or appearance; if mould appears, discard the cut bananas.
Bananas - Fresh, Raw, Whole	2-5 days or until ripe	5-7 days once ripe	2-3 Months	How long do bananas last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep bananas in a dry area. Properly stored, bananas will become fully ripe in about 2 to 5 days at normal room temperature. How can you make bananas ripen faster? To hasten ripening, put bananas in a brown paper bag on the counter; to ripen bananas even faster, add an apple to the bag. Should you refrigerate raw bananas? Yes: Store bananas at room temperature until they are fully ripe, then refrigerate to extend shelf life. How long do bananas last in the refrigerator? Fully ripe bananas will last for about 5 to 7 days in the fridge. Refrigeration will turn banana skins black, but will not harm the fruit. Can you freeze raw bananas? Yes- to freeze bananas: (1) Peel and mash; (2) Add one tablespoon of lemon juice or 1/2 teaspoon ascorbic acid for each cup of mashed banana to prevent browning; (3) Place in covered airtight containers or heavy-duty freezer bags. How long do bananas last in the freezer? Properly stored, they will maintain best quality for 2 to 3 months, but will remain safe beyond that time.
Bananas, Dried - Unopened Or Opened Package	6-12 Months	6-12 Months	12-18 Months	Store in cool, dry area; after opening, place in tightly sealed airtight container or heavy-duty plastic bag. Refrigeration is recommended in hot, humid environments. Freeze in airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Blackberries - Fresh, Raw		2-3 Days	10-12 Months	How long do blackberries last? The precise answer to that question depends to a large extent on storage conditions and how ripe the berries were when purchased or picked - for maximum shelf life, keep blackberries refrigerated at all times. How long do blackberries last at room temperature? Blackberries should only be left out at room temperature if being consumed within the same day, as blackberries are highly perishable and do not ripen after being picked. Refrigerate blackberries in their closed plastic clamshell container (if purchased in one) or place berries loosely in a shallow container and cover with plastic wrap. Discard any bruised or mouldy blackberries before refrigerating. To extend the shelf life of blackberries, do not wash the berries until ready to eat or use. How long do blackberries last in the refrigerator? Properly stored, blackberries will usually keep for about 2 to 3 days in the fridge. Can you freeze whole blackberries? Yes, to freeze: (1) Wash berries carefully in cold water, pat dry and place in a single layer on cookie tray in freezer; (2) Once berries are frozen, transfer to airtight containers or heavy-duty freezer bags and return to freezer. How long do whole blackberries last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time.
Blackberries, Commercially Canned Or Bottled — Opened	12-18 Months (Unopened)	5-7 Days	1-2 Months	Do not store in opened metal can — refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Blueberries - Fresh, Raw		1-2 Weeks	10-12 Months	How long do blueberries last? The precise answer to that question depends to a large extent on storage conditions and how ripe the berries were when purchased or picked - for maximum shelf life, keep blueberries refrigerated at all times. How long do blueberries last at room temperature? Blueberries should only be left out at room temperature if being consumed within the same day, as blueberries are highly perishable and do not ripen after being picked. Refrigerate blueberries in their closed plastic clamshell container (if purchased in one) or place berries loosely in a shallow container and cover with plastic wrap. Discard any bruised or mouldy blueberries before refrigerating. To extend the shelf life of blueberries, do not wash the berries until ready to eat or use. How long do blueberries last in the refrigerator? Properly stored, blueberries will usually keep for about 1 to 2 weeks in the fridge. Can you freeze whole blueberries? Yes, to freeze:(1) Wash berries carefully in cold water, pat dry and place in a single layer on cookie tray in freezer; (2) Once berries are frozen, transfer to airtight containers or heavy-duty freezer bags and return to freezer. How long do whole blueberries last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time.
Blueberries, Commercially Canned Or Bottled — Opened	12-18 Months (Unopened)	5-7 Days	1-2 Months	Do not store in opened metal can — refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Blueberries, Dried - Unopened Or Opened Package	6-12 Months	6-12 Months	12-18 Months	Store in cool, dry area; after opening, place in tightly sealed airtight container or heavy-duty plastic bag. Refrigeration is recommended in hot, humid environments. Freeze in airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Cherries - Fresh, Raw		4-10 Days	10-12 Months	How long do cherries last? The precise answer to that question depends to a large extent on storage conditions - for maximum shelf life, keep cherries refrigerated at all times. How long do cherries last at room temperature? Cherries should only be left out at room temperature if being consumed within the same day, as cherries are highly perishable and do not ripen after being picked. Refrigerate cherries in a plastic bag; discard any bruised or mouldy cherries before refrigerating. To extend the shelf life of cherries, do not wash the cherries until ready to eat or use. How long do cherries last in the refrigerator? Properly stored, cherries will usually keep for about 4 to 10 days in the fridge. Can you freeze whole cherries? Yes, to freeze: (1) Wash, stem and pit cherries; (2) Add 3/4 cup sugar to each quart of cherries and stir until sugar is dissolved; (3) Place in covered airtight containers or heavy-duty freezer bags. How long do whole cherries last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cherries that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Cherries, Commercially Canned Or Bottled (Except Maraschino) — Opened	18-24 Months (Best Quality) (Unopened)	5-7 Days	1-2 Months	How long does a can of cherries last once opened? The precise answer depends to a large extent on storage conditions - keep opened canned cherries refrigerated and tightly covered. To maximize the shelf life of canned cherries after opening, refrigerate in covered glass or plastic container. How long do opened canned cherries last in the refrigerator? Canned cherries that have been continuously refrigerated will keep for about 5 to 7 days. Are canned cherries safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned cherries will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the cherries will remain at peak quality. To further extend the shelf life of opened canned cherries, freeze them: to freeze canned cherries, place inside covered airtight containers or heavy-duty freezer bags. How long do canned cherries last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cherries that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do canned cherries last after being frozen and thawed? Cherries that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; cherries that were thawed in the microwave or in cold water should be used immediately.
Cherries, Dried - Unopened Or Opened Package	6-12 Months	6-12 Months	12-18 Months	Store in cool, dry area; after opening, place in tightly sealed airtight container or heavy-duty plastic bag. Refrigeration is recommended in hot, humid environments. Freeze in airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Dates - Opened Or Unopened Package	1-2 Months	1 Year	1-2 Years	Store in tightly sealed container or plastic bag. Freeze in airtight containers or heavy-duty freezer bags. Hard dates will generally keep longer when frozen than softer varieties. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Elderberries — Fresh, Raw		2-3 Days	10-12 Months	Place elderberries loosely in a shallow container, cover with plastic wrap and refrigerate. Do not wash elderberries until ready to eat, as excess moisture during storage will hasten decay. To freeze: (1) Wash berries carefully in cold water, pat dry and place in a single layer on cookie tray in freezer; (2) Once berries are frozen, transfer to airtight containers or heavy-duty freezer bags and return to freezer. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Feijoa - Fresh, Raw	2-3 days or until ripe	1-2 days once ripe	10-12 Months	Store at room temperature until ripe, then refrigerate. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Figs — Fresh, Raw		1-2 Days	10-12 Months	Refrigerate in plastic bag. To freeze figs: (1) Wash and peel if desired; (2) Coat figs with a solution made of 1 1/2 teaspoons of ascorbic acid for each 6 tablespoons of cold water to prevent darkening; (3) Place in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Figs — Stewed		2-4 Days		Refrigerate in covered container.

Figs, Commercially Canned Or Bottled — Opened	12-18 Months (Unopened)	5-7 Days	1-2 Months	Do not store in opened metal can — refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Figs, Dried - Unopened Or Opened Package	6-12 Months	6-12 Months	12-18 Months	Store in cool, dry area; after opening, place in tightly sealed airtight container or heavy-duty plastic bag. Refrigeration is recommended in hot, humid environments. Freeze in airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Fruit Cocktail /Salad /Mixed Fruit, Commercially Canned Or Bottled — Opened	18-24 Months (Best Quality) (Unopened)	5-7 Days	1-2 Months	How long does a can of fruit cocktail last once opened? The precise answer depends to a large extent on storage conditions - keep opened fruit cocktail refrigerated and tightly covered. To maximize the shelf life of canned or packaged fruit cocktail after opening, refrigerate in covered glass or plastic container. How long does opened canned fruit cocktail last in the refrigerator? Fruit cocktail that has been continuously refrigerated will keep for about 5 to 7 days. Is canned fruit cocktail safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned fruit cocktail will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the fruit cocktail will remain at peak quality. To further extend the shelf life of opened canned fruit cocktail, freeze: to freeze canned fruit cocktail, place inside covered airtight containers or heavy-duty freezer bags. How long does canned fruit cocktail last in the freezer? Properly stored, it will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - fruit cocktail that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does canned fruit cocktail last after being frozen and thawed? Canned fruit cocktail that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; fruit cocktail that was thawed in the microwave or in cold water should be used immediately.
Fruit Salad - Fresh, Raw		3-5 Days		How long does fresh fruit salad last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate fruit salad within two hours of preparing or purchasing. To maximize the shelf life of fresh fruit salad for safety and quality, refrigerate the fruit salad in airtight containers. Properly stored, fresh fruit salad will last for about 3 to 5 days in the refrigerator. How long can fruit salad be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); fruit salad should be discarded if left out for more than 2 hours at room temperature. How to tell if fruit salad is bad? If fruit salad develops an off odor, flavour or appearance, or if mould appears, it should be discarded; do not taste first.
Grapefruit Sections, Commercially Canned Or Bottled - Opened	12-18 Months (Unopened)	5-7 Days	1-2 Months	Do not store in opened metal can - refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Grapefruit - Fresh, Raw, Cut Up		3-4 Days	10-12 Months	How long does cut grapefruit last? The exact answer to that question depends to a large extent on storage conditions - keep cut-up grapefruit refrigerated. To maximize the shelf life of cut grapefruit, wrap tightly with plastic wrap or aluminium foil, or place in covered container or resealable plastic bag and refrigerate. How long does cut grapefruit last in the fridge? Properly stored, cut grapefruit will last for 3 to 4 days in the refrigerator. Can you freeze cut grapefruit? Yes, to freeze grapefruit: (1) Divide fruit into sections, removing all membranes and seeds; (2) In a saucepan, combine 2 3/4 cups sugar and 4 cups water, mix until the solution is clear, and bring to a boil; (3) Cool the syrup and pour over grapefruit; (4) Place grapefruit and syrup in covered airtight containers or heavy-duty freezer bags. How long does cut grapefruit last in the freezer? Properly stored, it will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cut-up grapefruit that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cut grapefruit is bad or spoiled? The best way is to smell and look at the cut grapefruit: discard any grapefruit that has an off smell or appearance; if mould appears, discard the cut grapefruit.
Grapefruit - Fresh, Raw, Whole	1 Week	3-4 Weeks	10-12 Months	How long does grapefruit last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep grapefruit in a cool, dry area. How long does grapefruit last at room temperature? Grapefruit will generally keep well at room temperature for about one week; longer storage at room temperature can cause the grapefruit to shrivel and lose flavour. To extend the shelf life of grapefruit, refrigerate in a plastic bag. How long does grapefruit last in the refrigerator? Properly stored, grapefruit will usually keep well for about 3 to 4 weeks in the fridge. Can you freeze grapefruit? Yes: (1) Wash and peel, then divide fruit into sections, removing all membranes and seeds; (2) In a saucepan, combine 2 3/4 cups sugar and 4 cups water, mix until the solution is clear, and bring to a boil; (3) Cool the syrup and pour over grapefruit; (4) Place grapefruit and syrup in covered airtight containers or heavy-duty freezer bags. How long does grapefruit last in the freezer? Properly stored, it will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - grapefruit that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if grapefruit is bad or spoiled? The best way is to smell and look at the grapefruit: discard any grapefruit if mould appears or if the grapefruit has an off smell or appearance.
Grapes - Fresh, Raw		7-14 Days	10-12 Months	How long do grapes last? The precise answer to that question depends to a large extent on storage conditions - for maximum shelf life, keep grapes refrigerated at all times. How long do grapes last at room temperature? Grapes should only be left out at room temperature if being consumed within the same day, as grapes are highly perishable and do not ripen after being picked. Refrigerate grapes in perforated plastic bag; discard any bruised or mouldy grapes before refrigerating. To extend the shelf life of grapes, do not wash the grapes until ready to eat or use. How long do grapes last in the refrigerator? Properly stored, grapes will usually keep for about 7 to 14 days in the fridge. Can you freeze whole grapes? Yes, to freeze:(1) Take off the stems, wash grapes carefully in cold water, pat dry and place in a single layer on cookie tray in freezer; (2) Once grapes are frozen, transfer to airtight containers or heavy-duty freezer bags and return to freezer. How long do whole grapes last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - grapes that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Grapes, Commercially Canned Or Bottled — Opened	12-18 Months (Unopened)	5-7 Days	1-2 Months	Do not store in opened metal can — refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Guava — Fresh, Raw, Cut Up		3-4 Days	10-12 Months	Wrap cut fruit tightly with plastic wrap or aluminium foil before refrigerating, or store in airtight container. To freeze guavas: (1) Wash, peel, and cut in half; (2) In a saucepan, combine 1 3/4 cups sugar and 4 cups water, mix until the solution is clear, and bring to a boil; (3) Cool the syrup and pour over guavas; (4) Place guavas and syrup in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Guava - Fresh, Raw, Whole	2-5 days or until ripe	3-4 days once ripe	10-12 Months	Store at room temperature until ripe, then refrigerate in plastic bag. To freeze guavas: (1) Wash, peel, and cut in half; (2) In a saucepan, combine 1 3/4 cups sugar and 4 cups water, mix until the solution is clear, and bring to a boil; (3) Cool the syrup and pour over guavas; (4) Place guavas and syrup in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Honeydew Melons - Fresh, Raw, Cut Up		3-5 Days	10-12 Months	How long does cut honeydew melon last? The exact answer to that question depends to a large extent on storage conditions - keep cut-up honeydew melon refrigerated. To maximize the shelf life of cut honeydew melon, wrap tightly with plastic wrap or aluminium foil, or place in covered container or resealable plastic bag and refrigerate. How long does cut honeydew melon last in the fridge? Properly stored, cut honeydew melon will last for 3 to 5 days in the refrigerator. Can you freeze cut honeydew melon? Yes, to freeze: Place in airtight containers or heavy-duty freezer bags. How long does cut honeydew melon last in the freezer? Properly stored, it will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cut-up honeydew melon that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cut honeydew melon is bad or spoiled? The best way is to smell and look at the cut honeydew melon: discard any honeydew melon that has an off smell or appearance; if mould appears, discard the cut honeydew melon.
Honeydew Melons - Fresh, Raw, Whole	2-4 Days	5-7 Days	10-12 Months	How long does honeydew melon last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep honeydew melon in a cool, dry area. How long does honeydew melon last at room temperature? Honeydew melon will generally keep well at room temperature for about 2 to 4 days. To extend the shelf life of honeydew melon, refrigerate. How long does honeydew melon last in the fridge? Properly stored, honeydew melon will usually keep well for about 5 to 7 days in the refrigerator. Can you freeze honeydew melon? Yes, to freeze: (1) Cut honeydew melon in half and remove seeds and rind; (2) Slice or cube melon, or cut into balls; (3) Place in covered airtight containers or heavy-duty freezer bags. How long does honeydew melon last in the freezer? Properly stored, it will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - honeydew melon that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if honeydew melon is bad or spoiled? The best way is to smell and look at the honeydew melon: if honeydew melon develops an off odor, flavour or appearance, it should be discarded; if mould appears, discard all of the honeydew melon.
Lemons - Fresh, Raw, Cut Up		3-4 Days	3-4 Months	How long do cut lemons last? The exact answer to that question depends to a large extent on storage conditions - keep cut-up lemons refrigerated. To maximize the shelf life of cut lemons, wrap tightly with plastic wrap or aluminium foil, or place in covered container or resealable plastic bag and refrigerate. How long do cut lemons last in the fridge? Properly stored, cut lemons will last for 3 to 4 days in the refrigerator. Can you freeze cut lemons? Yes, cut up lemons may be frozen "as is" in plastic bags; they will be mushy when thawed, but can be used for juice. Freeze fresh lemon juice in ice cube trays and then transfer to heavy-duty freezer bags. How long do cut lemons last in the freezer? Properly stored, they will maintain best quality for about 3 to 4 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cut-up lemons that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cut lemons are bad or spoiled? The best way is to smell and look at the cut lemons: discard any lemons that have an off smell or appearance; if mould appears, discard the cut lemons.
Lemons - Fresh, Raw, Whole	1 Week	3-4 Weeks	3-4 Months	How long do lemons last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep lemons in a cool, dry area. How long do lemons last at room temperature? Lemons will generally keep well at room temperature for about one week; longer storage at room temperature can cause the lemons to shrivel and lose flavour. To extend the shelf life of lemons, refrigerate in a plastic bag. How long do lemons last in the refrigerator? Properly stored, lemons will usually keep well for about 3 to 4 weeks in the fridge. Can you freeze whole lemons? Yes: Whole lemons may be frozen "as is" in plastic bags; they will be mushy when thawed, but can be used for juice. Defrost frozen lemons in the microwave for a few seconds (or submerge in cold water for about 15 minutes). How long do whole lemons last in the freezer? Properly stored, they will maintain best quality for about 3 to 4 months, but will remain safe beyond that time. The freezer time shown is for best quality only - lemons that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Limes - Fresh, Raw, Cut Up		3-4 Days	3-4 Months	How long do cut limes last? The exact answer to that question depends to a large extent on storage conditions - keep cut-up limes refrigerated. To maximize the shelf life of cut limes, wrap tightly with plastic wrap or aluminium foil, or place in covered container or resealable plastic bag and refrigerate. How long do cut limes last in the fridge? Properly stored, cut limes will last for 3 to 4 days in the refrigerator. Can you freeze cut limes? Yes, cut up limes may be frozen "as is" in plastic bags; they will be mushy when thawed, but can be used for juice. Freeze fresh lemon juice in ice cube trays and then transfer to heavy-duty freezer bags. How long do cut limes last in the freezer? Properly stored, they will maintain best quality for about 3 to 4 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cut-up limes that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cut limes are bad or spoiled? The best way is to smell and look at the cut limes: discard any limes that have an off smell or appearance; if mould appears, discard the cut limes.
Limes - Fresh, Raw, Whole	1 Week	3-4 Weeks	3-4 Months	How long do limes last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep limes in a cool, dry area. How long do limes last at room temperature? Limes will generally keep well at room temperature for about one week; longer storage at room temperature can cause the limes to shrivel and lose flavour. To extend the shelf life of limes, refrigerate in a plastic bag. How long do limes last in the refrigerator? Properly stored, limes will usually keep well for about 3 to 4 weeks in the fridge. Can you freeze whole limes? Yes: Whole limes may be frozen "as is" in plastic bags; they will be mushy when thawed, but can be used for juice. Defrost frozen limes in the microwave for a few seconds (or submerge in cold water for about 15 minutes). How long do whole limes last in the freezer? Properly stored, they will maintain best quality for about 3 to 4 months, but will remain safe beyond that time. The freezer time shown is for best quality only - limes that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Litchis (Lychees) — Fresh, Raw		5-7 Days	10-12 Months	Store unpeeled in the refrigerator. Freezer time shown is for best quality — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Litchis (Lychees), Commercially Canned Or Bottled — Opened	12-18 Months (Unopened)	5-7 Days	1-2 Months	Do not store in opened metal can — refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Mango, Dried - Unopened Or Opened Package	6-12 Months	6-12 Months	12-18 Months	Store in cool, dry area; after opening, place in tightly sealed airtight container or heavy-duty plastic bag. Refrigeration is recommended in hot, humid environments. Freeze in airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Mangos (Mangoes) — Fresh, Raw, Cut Up		3-4 Days	10-12 Months	Wrap cut fruit tightly with plastic wrap or aluminium foil before refrigerating, or store in airtight container. To freeze: (1) Wash, peel and slice mangoes; (2) Place mango slices in a single layer on cookie tray in freezer; (3) Once slices are frozen, transfer to airtight containers or heavy-duty freezer bags and return to freezer. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Mangos (Mangoes) - Fresh, Raw, Whole	2-5 days or until ripe	5-7 days once ripe	10-12 Months	Store at room temperature until ripe, then refrigerate in plastic bag. To freeze: (1) Wash, peel and slice mangoes; (2) Place mango slices in a single layer on cookie tray in freezer; (3) Once slices are frozen, transfer to airtight containers or heavy-duty freezer bags and return to freezer. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.

Maraschino Cherries, Commercially Canned Or Bottled — Opened	1-2 Months	6-12 Months		How long do maraschino cherries last once opened? The precise answer depends to a large extent on storage conditions - keep opened maraschino cherries tightly covered. To maximize the shelf life of maraschino cherries after opening, keep in a cool, dark area. How long do opened maraschino cherries last at room temperature? Maraschino cherries that have stored properly will stay at best quality for about 1 to 2 months at room temperature. How long do opened maraschino cherries last in the refrigerator? Maraschino cherries that have been continuously refrigerated will keep for about 6 to 12 months. Are maraschino cherries safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the package is undamaged, and there are no signs of spoilage - commercially maraschino cherries will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the cherries will remain at peak quality. How can you tell if opened maraschino cherries are bad or spoiled? The best way is to smell and look at the cherries: if the cherries develop an off odor, flavour or appearance, or if mould appears, they should be discarded. Discard all cherries from cans or bottles that are leaking, rusting, bulging or severely dented.
Maraschino Cherries, Commercially Canned Or Bottled — Unopened	3 Years (Best Quality)			How long do unopened maraschino cherries last? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of maraschino cherries, store in a cool, dry area. How long do unopened maraschino cherries last at room temperature? Properly stored, an unopened bottle of maraschino cherries will generally stay at best quality for about 3 years, although it will usually remain safe to use after that. Are unopened maraschino cherries safe to use after the "expiration" date on the can or package? Yes, provided they are properly stored and the can is undamaged - commercially packaged maraschino cherries will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the maraschino cherries will remain at peak quality. Storage time shown is for best quality only - after that, the maraschino cherries' texture, colour or flavour may change, but in most cases, they will still be safe to consume if they have been stored properly, the bottle is undamaged, and there are no signs of spoilage. How can you tell if maraschino cherries are bad or spoiled? The best way is to smell and look at the maraschino cherries: if the maraschino cherries develop an off odor, flavour or appearance, or if mould appears, they should be discarded. Discard all maraschino cherries from bottles or cans that are leaking, rusting, bulging or severely dented.
Mixed Berries - Commercially Frozen			1 Year	How long do frozen mixed berries last? The precise answer to that question depends to a large extent on storage conditions - keep mixed berries frozen at all times. Properly stored, frozen mixed berries will maintain best quality for about 12 months in the freezer, although they will usually remain safe to eat after that. Are frozen mixed berries safe to eat after the "expiration" date on the package? Yes, if properly stored - commercially frozen mixed berries will typically carry a Best By, Best if Used By, Best Before, or Best When Used By date but this is not a safety date, it is the manufacturer's estimate of how long the frozen mixed berries will remain at peak quality. How long will frozen mixed berries remain safe to eat? Frozen mixed berries that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as they have been stored properly and the package is not damaged. How to tell if frozen mixed berries are no longer good? If dry spots or discolorations have developed on the frozen mixed berries, freezer burn has begun to set in - this will not make the frozen mixed berries unsafe to eat, but it will harm the texture and taste.
Mixed Fruit- Fresh, Raw, Cut Up		3-5 Days	10-12 Months	How long does cut mixed fruit last? The exact answer to that question depends to a large extent on storage conditions - keep cut-up mixed fruit refrigerated. To maximize the shelf life of cut mixed fruit, refrigerate in covered container or resealable plastic bag. How long does cut mixed fruit last in the fridge? Properly stored, cut mixed fruit will last for about 3 to 5 days in the refrigerator. Can you freeze cut mixed fruit? Yes, to freeze: Place in airtight containers or heavy-duty freezer bags. How long does cut mixed fruit last in the freezer? Properly stored, it will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cut-up mixed fruit that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cut mixed fruit is bad or spoiled? The best way is to smell and look at the cut mixed fruit: discard any mixed fruit that has an off smell or appearance; if mould appears, discard the cut mixed fruit.
Nectarines — Fresh, Raw, Cut Up		3-4 Days	10-12 Months	Wrap cut fruit tightly with plastic wrap or aluminium foil before refrigerating, or store in airtight container. To freeze nectarines: (1) Wash, pit and halve or slice nectarines; (2) Coat nectarines with a solution made of 1/2 teaspoon of ascorbic acid for each 6 tablespoons of cold water to prevent darkening; (3) Add 2/3 cup sugar to each quart of fruit and stir until sugar is dissolved; (4) Place in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Nectarines - Fresh, Raw, Whole	2-3 days or until ripe	3-5 days once ripe	10-12 Months	How long do nectarines last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep nectarines in a dry area. Properly stored, nectarines will become fully ripe in about 2 to 3 days at normal room temperature. How can you make nectarines ripen faster? To hasten ripening, put nectarines in a brown paper bag, close it and leave on the counter. Do not refrigerate nectarines until they are fully ripe - allowing to ripen at room temperature will result in more flavourful, juicy nectarines. To extend the shelf life of fully ripe nectarines, place in a plastic bag and refrigerate; for best results, bring the nectarines back to room temperature before using. How long do nectarines last in the refrigerator? Fully ripe nectarines will last for about 3 to 5 days in the fridge. Can you freeze raw nectarines? Yes: (1) Wash, pit and halve or slice nectarines; (2) Coat nectarines with a solution made of 1/2 teaspoon of ascorbic acid for each 6 tablespoons of cold water to prevent darkening; (3) Add 2/3 cup sugar to each quart of fruit and stir until sugar is dissolved; (4) Place in covered airtight containers or heavy-duty freezer bags. How long do nectarines last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time.
Olives, Green Or Black (All Types, Including Pimiento-Stuffed, Kalamata, Pitted, Manzanilla), Commercially Canned Or Bottled - Opened	2-3 Years (Unopened) (Best Quality)	4-6 Months (Best Quality)		How long do olives last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened olives keep them refrigerated and tightly covered. How long do opened olives last in the refrigerator? Olives that have been continuously refrigerated will generally stay at best quality for about 4 to 6 months. Are opened olives safe to use after the "expiration date" on the jar or can? Yes, provided they have been stored properly, the jar or can is undamaged, and there are no signs of spoilage - commercially packaged olives will typically carry a " Best By," "Best if Used By," "Best Before" or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the olives will remain at peak quality. The storage time shown for opened olives is for best quality only - after that, the olives' texture, colour or flavour may change, but in most cases, they will still be safe to consume if they have been kept continuously refrigerated, the jar or can is undamaged, and there are no signs of spoilage. How can you tell if opened olives are bad or spoiled? The best way is to smell and look at the olives: if the olives develop an off odor, flavour or appearance, or if mould appears, they should be discarded. Discard all olives from cans or bottles that are leaking, rusting, bulging or severely dented.
Olives, Loose, In Oil		1-2 Months (Best Quality)		How long do loose olives (or deli olives) last? The precise answer depends to a large extent on storage conditions - keep olives them refrigerated and tightly covered. To maximize the shelf life of loose olives, refrigerate in covered glass or plastic container and keep olives submerged in liquid when storing. How long do loose olives last in the refrigerator? Loose olives that have been continuously refrigerated will generally stay at best quality for about 1 to 2 months. How can you tell if loose olives are bad or spoiled? The best way is to smell and look at the loose olives: if the olives develop an off odor, flavour or appearance, or if mould appears, they should be discarded.
Oranges - Fresh, Raw, Cut Up		3-4 Days	10-12 Months	How long do cut oranges last? The exact answer to that question depends to a large extent on storage conditions - keep cut-up oranges refrigerated. To maximize the shelf life of cut oranges, wrap tightly with plastic wrap or aluminium foil, or place in covered container or resealable plastic bag and refrigerate. How long do cut oranges last in the fridge? Properly stored, cut oranges will last for 3 to 4 days in the refrigerator. Can you freeze cut oranges? Yes, to freeze oranges: (1) Wash and peel, then divide fruit into sections, removing all membranes and seeds; (2) In a saucepan, combine 2 3/4 cups sugar and 4 cups water, mix until the solution is clear, and bring to a boil; (3) Cool the syrup and pour over oranges; (4) Place oranges and syrup in covered airtight containers or heavy-duty freezer bags. How long do cut oranges last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cut-up oranges that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cut oranges are bad or spoiled? The best way is to smell and look at the cut oranges: discard any oranges that have an off smell or appearance; if mould appears, discard the cut oranges.
Oranges - Fresh, Raw, Whole	5-7 Days	3-4 Weeks	10-12 Months	How long do oranges last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep oranges in a cool, dry area. How long do oranges last at room temperature? Oranges will generally keep well at room temperature for about one week; longer storage at room temperature can cause the oranges to shrivel and lose flavour. To extend the shelf life of oranges, refrigerate in a plastic bag. How long do oranges last in the refrigerator? Properly stored, oranges will usually keep well for about 3 to 4 weeks in the fridge. Can you freeze oranges? Yes: (1) Wash and peel, then divide fruit into sections, removing all membranes and seeds; (2) In a saucepan, combine 2 3/4 cups sugar and 4 cups water, mix until the solution is clear, and bring to a boil; (3) Cool the syrup and pour over oranges; (4) Place oranges and syrup in covered airtight containers or heavy-duty freezer bags. How long do oranges last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - oranges that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if oranges are bad or spoiled? The best way is to smell and look at the oranges: discard any oranges if mould appears or if the oranges have an off smell or appearance.
Passion Fruit (Granadilla) - Fresh, Raw	2-5 days or until ripe	5-7 days once ripe	6-8 Months	Leave at room temperature to ripen, then refrigerate. To freeze: (1) Scoop out flesh and place in ice cube trays; (2) Once frozen, transfer cubes to airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Peaches - Fresh, Raw, Cut Up		3-4 Days	10-12 Months	How long do cut peaches last? The exact answer to that question depends to a large extent on storage conditions - keep cut-up peaches refrigerated. Peaches discolour quickly when cut - to prevent browning, sprinkle the cut peaches with a little lemon juice before refrigerating. To maximize the shelf life of cut peaches, wrap tightly with plastic wrap or aluminium foil, or place in covered container or resealable plastic bag and refrigerate. How long do cut peaches last in the fridge? Properly stored, cut peaches will last for 3 to 4 days in the refrigerator. Can you freeze cut peaches? Yes, to freeze peaches: (1) Wash, pit and halve or slice peaches; (2) Coat peaches with a solution made of 1/2 teaspoon of ascorbic acid for each 6 tablespoons of cold water to prevent darkening; (3) Add 2/3 cup sugar to each quart of fruit and stir until sugar is dissolved; (4) Place in covered airtight containers or heavy-duty freezer bags. How long do cut peaches last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cut-up peaches that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cut peaches are bad or spoiled? The best way is to smell and look at the cut peaches: discard any peaches that have an off smell or appearance; if mould appears, discard the cut peaches.
Peaches - Fresh, Raw, Whole	1-3 days or until ripe	3-5 days once ripe	10-12 Months	How long do peaches last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep peaches in a dry area. Properly stored, peaches will become fully ripe in about 1 to 3 days at normal room temperature. How can you make peaches ripen faster? To hasten ripening, put peaches in a brown paper bag, close it and leave on the counter. Do not refrigerate peaches until they are fully ripe - allowing to ripen at room temperature will result in more flavourful, juicy peaches. To extend the shelf life of fully ripe peaches, place in a plastic bag and refrigerate; for best results, bring the peaches back to room temperature before using. How long do peaches last in the refrigerator? Fully ripe peaches will last for about 3 to 5 days in the fridge. Can you freeze raw peaches? Yes: (1) Wash, pit and halve or slice peaches; (2) Coat peaches with a solution made of 1/2 teaspoon of ascorbic acid for each 6 tablespoons of cold water to prevent darkening; (3) Add 2/3 cup sugar to each quart of fruit and stir until sugar is dissolved; (4) Place in covered airtight containers or heavy-duty freezer bags. How long do peaches last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time.
Peaches, Commercially Canned Or Bottled — Opened	18-24 Months (Best Quality) (Unopened)	5-7 Days	1-2 Months	How long does a can of peaches last once opened? The precise answer depends to a large extent on storage conditions - keep opened canned peaches refrigerated and tightly covered. To maximize the shelf life of canned or packaged peaches after opening, refrigerate in covered glass or plastic container. How long do opened canned peaches last in the refrigerator? Peaches that have been continuously refrigerated will keep for about 5 to 7 days. Are canned peaches safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned peaches will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the peaches will remain at peak quality. To further extend the shelf life of opened canned peaches, freeze them: to freeze peaches, place inside covered airtight containers or heavy-duty freezer bags. How long do canned peaches last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - peaches that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do canned peaches last after being frozen and thawed? Peaches that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; peaches that were thawed in the microwave or in cold water should be used immediately.
Peaches, Dried - Unopened Or Opened Package	6-12 Months	6-12 Months	12-18 Months	Store in cool, dry area; after opening, place in tightly sealed airtight container or heavy-duty plastic bag. Refrigeration is recommended in hot, humid environments. Freeze in airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Pears - Fresh, Raw, Cut Up		3-4 Days	10-12 Months	How long do cut pears last? The exact answer to that question depends to a large extent on storage conditions - keep cut-up pears refrigerated. Pears discolour quickly when cut - to prevent browning, sprinkle the cut pears with a little lemon juice before refrigerating. To maximize the shelf life of cut pears, wrap tightly with plastic wrap or aluminium foil, or place in covered container or resealable plastic bag and refrigerate. How long do cut pears last in the fridge? Properly stored, cut pears will last for 3 to 4 days in the refrigerator. Can you freeze cut pears? Yes, to freeze pears: (1) Wash, core and slice pears; (2) In a saucepan, combine 2 3/4 cups sugar and 4 cups water, mix until the solution is clear, and bring to a boil; (3) Heat pears in the boiling syrup for 1 to 2 minutes, depending on the size of the slices; (4) Drain and cool; (5) Place pears and syrup in covered airtight containers or heavy-duty freezer bags. How long do cut pears last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cut-up pears that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cut pears are bad or spoiled? The best way is to smell and look at the cut pears: discard any pears that have an off smell or appearance; if mould appears, discard the cut pears.
Pears - Fresh, Raw, Whole	1-4 days or until ripe	5-7 days once ripe	10-12 Months	How long do pears last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep pears in a dry area. Properly stored, pears will become fully ripe in about 1 to 4 days at normal room temperature. How can you make pears ripen faster? To hasten ripening, put pears in a brown paper bag, close it and leave on the counter. Do not refrigerate pears until they are fully ripe - allowing to ripen at room temperature will result in more flavourful, juicy pears. To extend the shelf life of fully ripe pears, place in a plastic bag and refrigerate; for best results, bring the pears back to room temperature before using. How long do pears last in the refrigerator? Fully ripe pears will last for about 5 to 7 days in the fridge. Can you freeze raw pears? Yes: (1) Wash, core and slice pears; (2) In a saucepan, combine 2 3/4 cups sugar and 4 cups water, mix until the solution is clear, and bring to a boil; (3) Heat pears in the boiling syrup for 1 to 2 minutes, depending on the size of the slices; (4) Drain and cool; (5) Place pears and syrup in covered airtight containers or heavy-duty freezer bags. How long do pears last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time.

Pears, Commercially Canned Or Bottled — Opened	18-24 Months (Best Quality) (Unopened)	5-7 Days	1-2 Months	How long does a can of pears last once opened? The precise answer depends to a large extent on storage conditions - keep opened canned pears refrigerated and tightly covered. To maximize the shelf life of canned or packaged pears after opening, refrigerate in covered glass or plastic container. How long do opened canned pears last in the refrigerator? Pears that have been continuously refrigerated will keep for about 5 to 7 days. Are canned pears safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned pears will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the pears will remain at peak quality. To further extend the shelf life of opened canned pears, freeze them: to freeze pears, place inside covered airtight containers or heavy-duty freezer bags. How long do canned pears last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - pears that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do canned pears last after being frozen and thawed? Pears that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; pears that were thawed in the microwave or in cold water should be used immediately.
Pears, Dried - Unopened Or Opened Package	6-12 Months	6-12 Months	12-18 Months	Store in cool, dry area; after opening, place in tightly sealed airtight container or heavy-duty plastic bag. Refrigeration is recommended in hot, humid environments. Freeze in airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Pineapple (Chunks, Sliced, Crushed, Tidbits), Commercially Canned Or Bottled — Opened	18-24 Months (Best Quality) (Unopened)	5-7 Days	1-2 Months	How long does a can of pineapple last once opened? The precise answer depends to a large extent on storage conditions - keep opened pineapple (including chunks, sliced, crushed, tidbits) refrigerated and tightly covered. To maximize the shelf life of canned or packaged pineapple after opening, refrigerate in covered glass or plastic container. How long does opened canned pineapple last in the refrigerator? Pineapple that has been continuously refrigerated will keep for about 5 to 7 days. Is canned pineapple safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned pineapple will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the pineapple will remain at peak quality. To further extend the shelf life of opened canned pineapple, freeze: to freeze canned pineapple, place inside covered airtight containers or heavy-duty freezer bags. How long does canned pineapple last in the freezer? Properly stored, it will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - pineapple that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does canned pineapple last after being frozen and thawed? Canned pineapple that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; pineapple that was thawed in the microwave or in cold water should be used immediately.
Pineapple - Commercially Frozen			1 Year	How long does frozen pineapple last? The precise answer to that question depends to a large extent on storage conditions - keep pineapple frozen at all times. Properly stored, frozen pineapple will maintain best quality for about 12 months in the freezer, although it will usually remain safe to eat after that. Is frozen pineapple safe to eat after the expiration date on the package? Yes, if properly stored - commercially frozen pineapple will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the frozen pineapple will remain at peak quality. How long will frozen pineapple remain safe to eat? Frozen pineapple that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as it has been stored properly and the package is not damaged. How to tell if frozen pineapple is no longer good? If dry spots or discoloration have developed on the frozen pineapple, freezer burn has begun to set in - this will not make the pineapple unsafe to eat, but it will harm the texture and taste.
Pineapple - Fresh, Raw, Cut Up		3-4 Days	10-12 Months	How long does cut pineapple last? The exact answer to that question depends to a large extent on storage conditions - keep cut-up pineapple refrigerated. To maximize the shelf life of cut pineapple, wrap tightly with plastic wrap or aluminium foil, or place in covered container or resealable plastic bag and refrigerate. How long does cut pineapple last in the fridge? Properly stored, cut pineapple will last for 3 to 4 days in the refrigerator. Can you freeze cut pineapple? Yes, to freeze: Place in airtight containers or heavy-duty freezer bags. How long does cut pineapple last in the freezer? Properly stored, it will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cut-up pineapple that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cut pineapple is bad or spoiled? The best way is to smell and look at the cut pineapple: discard any pineapple that has an off smell or appearance; if mould appears, discard the cut pineapple.
Pineapples - Fresh, Raw, Whole	1-2 Days	3-5 Days	10-12 Months	How long do pineapples last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep whole pineapples in a cool, dry area. How long do pineapples last at room temperature? Whole pineapples will generally keep well at room temperature for about 1 to 2 days. To extend the shelf life of fresh pineapples, refrigerate. How long do pineapples last in the fridge? Properly stored, whole pineapples will usually keep well for about 3 to 5 days in the refrigerator. Can you freeze pineapples? Yes, to freeze: (1) Pare pineapples and remove core and eyes; (2) Slice or dice the pineapples, or cut into wedges or sticks; (3) Place in covered airtight containers or heavy-duty freezer bags. How long do pineapples last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - pineapples that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if pineapples are bad or spoiled? The best way is to smell and look at the pineapples: if pineapples develop an off odor, flavour or appearance, they should be discarded; if mould appears, discard all of the pineapple.
Pineapples, Dried - Unopened Or Opened Package	6-12 Months	6-12 Months	12-18 Months	Store in cool, dry area; after opening, place in tightly sealed airtight container or heavy-duty plastic bag. Refrigeration is recommended in hot, humid environments. Freeze in airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Plums - Fresh, Raw, Whole	2-3 days or until ripe	3-5 days once ripe	10-12 Months	How long do plums last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, keep plums in a dry area. Properly stored, plums will become fully ripe in about 2 to 3 days at normal room temperature. How can you make plums ripen faster? To hasten ripening, put plums in a brown paper bag, close it and leave on the counter. Do not refrigerate plums until they are fully ripe - allowing to ripen at room temperature will result in more flavourful, juicy plums. To extend the shelf life of fully ripe plums, place in a plastic bag and refrigerate; for best results, bring the plums back to room temperature before using. How long do plums last in the refrigerator? Fully ripe plums will last for about 3 to 5 days in the fridge. Can you freeze raw plums? Yes: (1) Wash and leave whole or cut in halves or quarters and remove pit; (2) In a saucepan, combine 2 3/4 cups sugar and 4 cups water, mix until the solution is clear, and bring to a boil; (3) Cool the syrup and pour over plums; (4) Place plums and syrup in covered airtight containers or heavy-duty freezer bags. How long do plums last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time.
Plums, Commercially Canned Or Bottled — Opened	12-18 Months (Best Quality) (Unopened)	5-7 Days	1-2 Months	Do not store in opened metal can — refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Pomegranates - Fresh, Raw	1-2 Weeks	1-2 Months	10-12 Months	Pomegranates may be stored at room temperature; to extend shelf life, refrigerate. To freeze: (1) Scoop out pomegranate seeds and place in a single layer on cookie tray in freezer; (2) Once seeds are frozen, transfer to airtight containers or heavy-duty freezer bags and return to freezer. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Prickly Pears — Fresh, Raw, Cut Up		3-4 Days	10-12 Months	Wrap cut fruit tightly with plastic wrap or aluminium foil before refrigerating, or store in airtight container. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Prickly Pears - Fresh, Raw, Whole	2-5 days or until ripe	1-3 days once ripe	10-12 Months	Store at room temperature until ripe, then refrigerate. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Prunes (Dried Plums) - Cooked At Home		2-4 Days	1-2 Months	Refrigerate within two hours of cooking. Store in covered glass or plastic container. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Prunes (Dried Plums) - Unopened Or Opened Bag	6-12 Months	6-12 Months	12-18 Months	Store in cool, dry area; after opening, place in tightly sealed airtight container or heavy-duty plastic bag. Refrigeration is recommended in hot, humid environments. Freeze in airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Prunes (Dried Plums), Commercially Canned Or Bottled - Opened	12-18 Months (Best Quality) (Unopened)	5-7 Days	1-2 Months	Do not store in opened metal can - refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Raisins, Commercially Packaged - Unopened Or Opened	6-12 Months	6-12 Months	12-18 Months	Store in cool, dry area; after opening, place in tightly sealed airtight container or heavy-duty plastic bag. Refrigeration will extend shelf life after opening and is recommended in hot, humid environments. Freeze in airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Raspberries - Fresh, Raw		2-3 Days	10-12 Months	How long do raspberries last? The precise answer to that question depends to a large extent on storage conditions and how ripe the berries were when purchased or picked - for maximum shelf life, keep raspberries refrigerated at all times. How long do raspberries last at room temperature? Raspberries should only be left out at room temperature if being consumed within the same day, as raspberries are highly perishable and do not ripen after being picked. Refrigerate raspberries in their closed plastic clamshell container (if purchased in one) or place berries loosely in a shallow container and cover with plastic wrap. Discard any bruised or mouldy raspberries before refrigerating. To extend the shelf life of raspberries, do not wash the berries until ready to eat or use. How long do raspberries last in the refrigerator? Properly stored, raspberries will usually keep for about 2 to 3 days in the fridge. Can you freeze whole raspberries? Yes, to freeze: (1) Wash berries carefully in cold water, pat dry and place in a single layer on cookie tray in freezer; (2) Once berries are frozen, transfer to airtight containers or heavy-duty freezer bags and return to freezer.
Raspberries, Commercially Canned Or Bottled — Opened	12-18 Months (Unopened)	5-7 Days	1-2 Months	Do not store in opened metal can — refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Strawberries - Fresh, Raw		3-7 Days	10-12 Months	How long do strawberries last? The precise answer to that question depends to a large extent on storage conditions and how ripe the berries were when purchased or picked - for maximum shelf life, keep strawberries refrigerated at all times. How long do strawberries last at room temperature? Strawberries should only be left out at room temperature if being consumed within the same day, as strawberries are highly perishable and do not ripen after being picked. Refrigerate strawberries in their closed plastic clamshell container (if purchased in one) or place berries loosely in a shallow container and cover with plastic wrap. Discard any bruised or mouldy strawberries before refrigerating. To extend the shelf life of strawberries, do not wash the berries until ready to eat or use. How long do strawberries last in the refrigerator? Properly stored, strawberries will usually keep for about 3 to 7 days in the fridge. Can you freeze whole strawberries? Yes, to freeze: (1) Rinse berries and blot dry (2) Slice stems off at top of berry (3) Place strawberries, cut side down, on a cookie sheet lined with waxed paper (4) Place uncovered cookie sheet in the freezer for several hours, until frozen (5)Transfer frozen strawberries to covered airtight containers or heavy-duty freezer bags. How long do whole strawberries last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time.
Strawberries, Commercially Canned Or Bottled — Opened		5-7 Days	1-2 Months	Do not store in opened metal can — refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Tangerines (Mandarin Oranges) - Fresh, Raw	1 Week	1-2 Weeks	10-12 Months	Tangerines may be stored at room temperature; to extend shelf life, refrigerate. To freeze tangerines: (1) Wash and peel, then divide fruit into sections, removing all membranes and seeds; (2) In a saucepan, combine 2 3/4 cups sugar and 4 cups water, mix until the solution is clear, and bring to a boil; (3) Cool the syrup and pour over tangerines; (4) Place tangerines and syrup in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Tangerines (Mandarin Oranges), Commercially Canned Or Bottled — Opened	12-18 Months (Best Quality) (Unopened)	5-7 Days	1-2 Months	How long does a can of mandarin oranges last once opened? The precise answer depends to a large extent on storage conditions - keep opened canned mandarin oranges refrigerated and tightly covered. To maximize the shelf life of canned or packaged mandarin oranges after opening, refrigerate in covered glass or plastic container. How long do opened canned mandarin oranges last in the refrigerator? Mandarin oranges that have been continuously refrigerated will keep for about 5 to 7 days. Are canned mandarin oranges safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned mandarin oranges will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the mandarin oranges will remain at peak quality. To further extend the shelf life of opened canned mandarin oranges, freeze them: to freeze mandarin oranges, place inside covered airtight containers or heavy-duty freezer bags. How long do canned mandarin oranges last in the freezer? Properly stored, they will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - mandarin oranges that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do canned mandarin oranges last after being frozen and thawed? Mandarin oranges that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; mandarin oranges that were thawed in the microwave or in cold water should be used immediately.

Watermelon - Fresh, Raw, Cut Up		3-5 Days	10-12 Months	How long does cut watermelon last? The exact answer to that question depends to a large extent on storage conditions - keep cut-up watermelon refrigerated. To maximize the shelf life of cut watermelon, wrap tightly with plastic wrap or aluminium foil, or place in covered container or resealable plastic bag and refrigerate. How long does cut watermelon last in the fridge? Properly stored, cut watermelon will last for 3 to 5 days in the refrigerator. Can you freeze cut watermelon? Yes, to freeze: Place in airtight containers or heavy-duty freezer bags. How long does cut watermelon last in the freezer? Properly stored, it will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cut-up watermelon that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cut watermelon is bad or spoiled? The best way is to smell and look at the cut watermelon: discard any watermelon that has an off smell or appearance; if mould appears, discard the cut watermelon.
Watermelon - Fresh, Raw, Whole	7-10 Days	2 Weeks	10-12 Months	

4 Meat Shelf Life

These is the shelf life of most meat, both pre-packaged and raw.

	Pantry	Refrigerator	Freezer	Food Tips
Bacon - Cooked, Leftovers		4-5 Days	2-3 Months	How long does cooked bacon last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate bacon within two hours of cooking. To maximize the shelf life of cooked bacon for safety and quality, refrigerate the bacon in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked bacon will last for 4 to 5 days in the refrigerator. To further extend the shelf life of cooked bacon, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long does cooked bacon last in the freezer? Properly stored, it will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked bacon that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked bacon last after being frozen and thawed? Cooked bacon that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; bacon that was thawed in the microwave or in cold water should be eaten immediately. How long does cooked bacon last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked bacon should be discarded if left for more than 2 hours at room temperature.
Bacon, Raw, Commercially Vacuum Packaged - Opened Package		7-10 Days	1-2 Months	How long does an opened package of bacon last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - keep bacon refrigerated at all times. How long does bacon last after the sell-by date? After bacon is opened, it may be refrigerated for about 7 to 10 days - the "sell-by" date on the package may expire during that storage period, but the bacon will remain safe to use after the sell by date if it has been properly stored. Opened bacon may be kept in its original store packaging when refrigerating; to maximize the shelf life of opened bacon, place the opened package inside a resealable plastic bag or wrap tightly with aluminium foil or plastic wrap. How long can bacon be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); bacon should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of bacon, freeze; when freezing, place bacon in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of bacon in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does bacon last in the freezer? Properly stored, it will maintain best quality for about 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - bacon that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Bacon, Raw, Commercially Vacuum Packaged - Unopened Package		1 week after "sell by" date on package	1-2 Months	How long does an unopened package of bacon last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - keep bacon refrigerated at all times. How long does an unopened packaged of bacon last after the sell-by date? After bacon is purchased, it may be kept refrigerated for about 1 week after the "sell-by" date on the package if it has been properly stored. Unopened bacon may be kept in its original store packaging when refrigerating; to maximize the shelf life of bacon, do not open the package until ready to use. How long can bacon be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); bacon should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of bacon, freeze; when freezing, place bacon in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of bacon in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does an unopened package of bacon last in the freezer? Properly stored, it will maintain best quality for about 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - bacon that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Beef Brisket - Cooked		3-4 Days	2-3 Months	How long does cooked beef brisket last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate beef brisket within two hours of cooking. To maximize the shelf life of cooked beef brisket for safety and quality, refrigerate the beef brisket in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked beef brisket will last for 3 to 4 days in the refrigerator. To further extend the shelf life of cooked beef brisket, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long does cooked beef brisket last in the freezer? Properly stored, it will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked beef brisket that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked beef brisket last after being frozen and thawed? Cooked beef brisket that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; beef brisket that was thawed in the microwave or in cold water should be eaten immediately. How long does cooked beef brisket last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked beef brisket should be discarded if left for more than 2 hours at room temperature.
Beef Brisket - Fresh, Raw		3-5 Days	6-12 Months	How long does raw beef brisket last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - keep beef brisket refrigerated at all times. How long does raw beef brisket last after the sell-by date? After beef brisket is purchased, it may be refrigerated for 3 to 5 days - the "sell-by" date on the package may expire during that storage period, but the beef brisket will remain safe to use after the sell by date if it has been properly stored. Unopened beef brisket may be kept in its original store packaging when refrigerating; to maximize the shelf life of beef brisket, do not open the package until ready to use. How long can raw beef brisket be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); beef brisket should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of beef brisket, freeze; when freezing, place beef brisket in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of beef brisket in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does raw beef brisket last in the freezer? Properly stored, it will maintain best quality for about 6 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - beef that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely How long does raw beef brisket last after being frozen and thawed? Beef brisket that has been defrosted in the fridge can be kept for an additional 3 to 5 days in the refrigerator before cooking; beef brisket that was thawed in the microwave or in cold water should be cooked immediately.
Beef Burgers, Cooked - Purchased Commercially Frozen			6 Months (Best Quality)	How long do frozen cooked beef burgers last? The precise answer to that question depends to a large extent on storage conditions - keep cooked beef burgers frozen at all times. Properly stored, frozen cooked beef burgers will maintain best quality for about 6 months in the freezer, although they will usually remain safe to eat after that. Are frozen cooked beef burgers safe to eat after the expiration date on the package? Yes, if properly stored - commercially frozen cooked beef burgers will typically carry a Best By," "Best if Used By," Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the cooked beef burgers will remain at peak quality. How long will frozen cooked beef burgers remain safe to eat? Frozen cooked beef burgers that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as they have been stored properly and the package is not damaged. How long can you safely leave frozen cooked beef burgers at room temperature? Frozen cooked beef burgers should be discarded if left for more than 2 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). How to tell if frozen cooked beef burgers are no longer good? If dry spots or discoloration have developed on the frozen cooked beef burgers, freezer burn has begun to set in - this will not make the cooked beef burgers unsafe to eat, but it will harm the texture and taste.
Beef Burgers, Raw — Purchased Commercially Frozen			6 Months	How long do frozen raw beef burgers last? The precise answer to that question depends to a large extent on storage conditions - keep raw beef burgers frozen at all times. Properly stored, frozen raw beef burgers will maintain best quality for about 6 months in the freezer, although they will usually remain safe to eat after that. Are frozen raw beef burgers safe to eat after the expiration date on the package? Yes, if properly stored - commercially frozen raw beef burgers will typically carry a Best By," "Best if Used By," Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the raw beef burgers will remain at peak quality. How long will frozen raw beef burgers remain safe to eat? Frozen raw beef burgers that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as they have been stored properly and the package is not damaged. How long can you safely leave frozen raw beef burgers at room temperature? Frozen raw beef burgers should be discarded if left for more than 2 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). How to tell if frozen raw beef burgers are no longer good? If dry spots or discoloration have developed on the frozen raw beef burgers, freezer burn has begun to set in - this will not make the beef burgers unsafe to eat, but it will harm the texture and taste.
Beef Entrees / Dinners — Commercially Frozen			3-4 Months	Keep frozen until ready to use. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Beef Jerky — Homemade		1-2 Months		Keep refrigerated and wrapped tightly in plastic wrap or aluminium foil. Does not freeze well.
Beef Jerky, Commercially Vacuum Packaged - Opened	1 Year (Unopened)	2-3 Months		Refrigerate after opening. Does not freeze well.
Beef Ribs, All Cuts (Including Back Ribs, Short Ribs) - Cooked		3-4 Days	2-3 Months	How long do cooked beef ribs last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate beef ribs within two hours of cooking. To maximize the shelf life of cooked beef ribs for safety and quality, refrigerate the beef ribs in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked beef ribs will last for 3 to 4 days in the refrigerator. To further extend the shelf life of cooked beef ribs, freeze them; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long do cooked beef ribs last in the freezer? Properly stored, they will maintain best quality for about 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked beef ribs that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked beef ribs last after being frozen and thawed? Cooked beef ribs that have been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; beef ribs that were thawed in the microwave or in cold water should be eaten immediately. How long do cooked beef ribs last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked beef ribs should be discarded if left for more than 2 hours at room temperature.
Beef Ribs, All Cuts (Including Back Ribs, Short Ribs) - Fresh, Raw		3-5 Days	6-12 Months	How long do raw beef ribs last in the fridge or freezer? Bologna Deli Meat / Cold Cuts, Commercially Pre-Packaged - Opened Package		5-7 Days	1-2 Months	How long does an opened package of bologna deli meat last in the fridge? The exact answer to that question depends to a large extent on storage conditions - keep bologna deli meat (also known as lunch meat, luncheon meat or cold cuts) refrigerated at all times. To maximize the shelf life of bologna deli meat after opening, keep refrigerated in airtight containers or wrapped tightly in plastic wrap or aluminium foil. Properly stored, an opened package of bologna deli meat will last for 5 to 7 days in the refrigerator. How long can bologna deli meat be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); bologna deli meat should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of opened bologna deli meat, freeze it; when freezing, place bologna deli meat in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of bologna deli meat in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does bologna deli meat last in the freezer? Properly stored, it will maintain best quality for 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - bologna deli meat that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Bologna Deli Meat / Cold Cuts, Commercially Pre-Packaged - Unopened Package		1 week after "use by" date on package	1-2 Months	How long does an unopened package of bologna deli meat last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - keep packaged bologna deli meat (also known as lunch meat, luncheon meat or cold cuts) refrigerated at all times. How long does an unopened package of bologna deli meat last after the ? sell-by date or ? best before date on the package? After bologna deli meat is purchased, it may be kept refrigerated for about 1 week after the ? sell by or ? best before date on the package if it has been properly stored. Unopened bologna deli meat may be kept in its original store packaging when refrigerating; to maximize the shelf life of bologna deli meat, do not open the package until ready to use. How long can an unopened package of bologna deli meat be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); bologna deli meat should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of packaged bologna deli meat, freeze; when freezing, place bologna deli meat in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of unopened bologna deli meat in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does pre-packaged bologna deli meat last in the freezer? Properly stored, it will maintain best quality for about 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - bologna deli meat that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Breakfast Sausages - Cooked, Leftovers		3-4 Days	1-2 Months	Refrigerate within two hours of cooking. Refrigerate cooked meat in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Breakfast Sausages - Fresh, Raw (Not Smoked)		1-2 Days	1-2 Months	Unopened meat may be kept in its original store packaging when refrigerating - do not open package until ready to use. If freezing, place in freezer before the number of days shown for refrigerator storage has elapsed. If freezing for longer than 2 months, overwrap original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Breakfast Sausages, Smoked, Links Or Patties — Opened Package		7 Days	1-2 Months	Keep refrigerated and wrapped tightly in plastic wrap or aluminium foil. To freeze, wrap tightly with heavy-duty aluminium foil or freezer wrap or place in heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Breakfast Sausages, Smoked, Links Or Patties — Unopened Package		1 week after "use by" date on package	1-2 Months	Keep refrigerated. Unopened meat may be kept in its original packaging when freezing — if freezing for longer than 2 months, overwrap packaging with airtight heavy-duty aluminium foil or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Canadian Bacon — Purchased As Chunk		1 Week	1-2 Months	Keep refrigerated and wrapped tightly in plastic wrap or aluminium foil. To freeze, wrap tightly with heavy-duty aluminium foil or freezer wrap or place in heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Canadian Bacon — Purchased Sliced		3-4 Days	1-2 Months	Keep refrigerated and wrapped tightly in plastic wrap or aluminium foil. To freeze, wrap tightly with heavy-duty aluminium foil or freezer wrap or place in heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Chicken Pieces, Including Chicken Breasts / Thighs / Wings - Cooked		3-4 Days	4 Months	How long does cooked chicken last in the fridge or freezer? The precise answer to that question depends to a large extent on storage conditions - refrigerate chicken within two hours of cooking. To maximize the shelf life of cooked chicken for safety and quality, refrigerate the chicken in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked chicken will last for 3 to 4 days in the refrigerator. To further extend the shelf life of cooked chicken, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long does cooked chicken last in the freezer? Properly stored, it will maintain best quality for about 4 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked chicken that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked chicken last after being frozen and thawed? Cooked chicken that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; chicken that was thawed in the microwave or in cold water should be eaten immediately. How long does cooked chicken last at room temperature? Bacteria grow rapidly at temperatures between 40°F and 140°F; cooked chicken should be discarded if left for more than 2 hours at room temperature.
Chicken Pieces, Including Chicken Breasts / Thighs / Wings - Fresh, Raw		1-2 Days	9-12 Months	How long does raw chicken last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - keep chicken refrigerated at all times. How long does raw chicken last after the sell-by date? After chicken is purchased, it may be refrigerated for 1 to 2 days - the "sell-by" date on the package may expire during that storage period, but the chicken will remain safe to use after the sell by date if it has been properly stored. Unopened raw chicken may be kept in its original store packaging when refrigerating; to maximize the shelf life of chicken, do not open the package until ready to use. How long does raw chicken last at room temperature? Bacteria grow rapidly at temperatures between 40° F and 140° F; chicken should be discarded if left for more than 2 hours at room temperature. To further extend the shelf life of raw chicken, freeze; when freezing, place chicken in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of chicken in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn.

Chicken Deli Meat / Cold Cuts, Commercially Pre-Packaged		5-7 Days	1-2 Months	How long does an opened package of chicken deli meat last in the fridge? The exact answer to that question depends to a large extent on storage conditions - keep chicken deli meat (also known as lunch meat, luncheon meat or cold cuts) refrigerated at all times. To maximize the shelf life of chicken deli meat after opening, keep refrigerated in airtight containers or wrapped tightly in plastic wrap or aluminium foil. Properly stored, an opened package of chicken deli meat will last for 5 to 7 days in the refrigerator. How long can chicken deli meat be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); chicken deli meat should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of opened chicken deli meat, freeze it; when freezing, place chicken deli meat in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of chicken deli meat in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does chicken deli meat last in the freezer? Properly stored, it will maintain best quality for 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - chicken deli meat that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Chicken Strips, Commercially Packaged, Fully Cooked And Sold Refrigerated - Opened Package		5 Days	6 Months	Keep refrigerated and tightly sealed. Freeze in heavy-duty freezer bag or airtight container. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Chicken Strips, Commercially Packaged, Fully Cooked And Sold Refrigerated — Unopened Package		Date on Package	6 Months	Keep refrigerated. If freezing, place in freezer before the time shown for refrigerator storage has elapsed. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Chicken Tenderloins, Commercially Packaged, Fully Cooked And Sold Refrigerated - Opened Package		5 Days	6 Months	Keep refrigerated and tightly sealed. Freeze in heavy-duty freezer bag or airtight container. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Chicken Tenderloins, Commercially Packaged, Fully Cooked And Sold Refrigerated — Unopened Package		Date on Package	6 Months	Keep refrigerated. If freezing, place in freezer before the time shown for refrigerator storage has elapsed. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Chicken, Commercially Canned Or In Vacuum Pouch - Opened	3-5 Years (Best Quality)	3-4 Days	1-2 Months	How long does a can of chicken last once opened? The precise answer depends to a large extent on storage conditions - keep opened chicken refrigerated and tightly covered. To maximize the shelf life of canned chicken (or chicken sold in a vacuum-sealed pouch) after opening, refrigerate in a covered glass or plastic container. How long does opened canned chicken last in the refrigerator? Chicken that has been continuously refrigerated will keep for about 3 to 4 days. Is canned chicken safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged chicken will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the chicken will remain at peak quality. To further extend the shelf life of opened canned chicken, freeze it: to freeze canned chicken, place inside covered airtight containers or heavy-duty freezer bags. How long does canned chicken last in the freezer? Properly stored, it will maintain best quality for about 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only – canned chicken that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does canned chicken last after being frozen and thawed? Canned chicken that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; chicken that was thawed in the microwave or in cold water should be used immediately.
Chicken, Whole — Purchased Commercially Frozen, Raw			1 Year	Keep frozen until ready to use. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Chicken, Whole - Cooked (Including Roasted, Rotisserie, Barbecued)		3-4 Days	4 Months	How long does cooked rotisserie chicken last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate rotisserie chicken within two hours of cooking. To maximize the shelf life of cooked rotisserie chicken for safety and quality, refrigerate the rotisserie chicken in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked rotisserie chicken will last for 3 to 4 days in the refrigerator. To further extend the shelf life of cooked rotisserie chicken, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long does cooked rotisserie chicken last in the freezer? Properly stored, it will maintain best quality for about 4 months, but will remain safe beyond that time. How long does rotisserie chicken last after being frozen and thawed? Rotisserie chicken that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; chicken that was thawed in the microwave or in cold water should be eaten immediately.
Chorizo Sausage, Spanish, Dry		2-3 Weeks	1-2 Months	Keep refrigerated and wrapped tightly in plastic wrap or aluminium foil. To freeze, wrap tightly with heavy-duty aluminium foil or freezer wrap or place in heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Corned Beef - Cooked		3-4 Days	2-3 Months	How long does cooked corned beef last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate corned beef within two hours of cooking. To maximize the shelf life of cooked corned beef for safety and quality, refrigerate the corned beef in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked corned beef will last for 3 to 4 days in the refrigerator. To further extend the shelf life of cooked corned beef, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long does cooked corned beef last in the freezer? Properly stored, it will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked corned beef that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked corned beef last after being frozen and thawed? Cooked corned beef that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; corned beef that was thawed in the microwave or in cold water should be eaten immediately. How long does cooked corned beef last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked corned beef should be discarded if left for more than 2 hours at room temperature.
Corned Beef Hash, Commercially Canned — Opened	3-5 Years (Unopened) (Best Quality)	3-4 Days	2-3 Months	How long does a can of corned beef hash last once opened? The precise answer depends to a large extent on storage conditions - keep opened corned beef hash refrigerated and tightly covered. To maximize the shelf life of canned corned beef hash after opening, refrigerate in a covered glass or plastic container. How long does opened canned corned beef hash last in the refrigerator? Corned beef hash that has been continuously refrigerated will keep for about 3 to 4 days. Is canned corned beef hash safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged corned beef hash will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the corned beef hash will remain at peak quality. To further extend the shelf life of opened canned corned beef hash, freeze it: to freeze canned corned beef hash, place inside covered airtight containers or heavy-duty freezer bags. How long does canned corned beef hash last in the freezer? Properly stored, it will maintain best quality for about 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only – canned corned beef hash that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does canned corned beef hash last after being frozen and thawed? Canned corned beef hash that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; corned beef hash that was thawed in the microwave or in cold water should be used immediately.
Country Ham - Cooked At Home, Leftovers		7 Days	1 Month	Refrigerate within two hours of cooking. Refrigerate cooked meat in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Deer — Cooked		3-4 Days	2-3 Months	Refrigerate within two hours of cooking. Refrigerate cooked meat in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Deer - Fresh, Raw		3-5 Days	6-9 Months	Unopened meat may be kept in its original store packaging when refrigerating - do not open package until ready to use. If freezing, place in freezer before the number of days shown for refrigerator storage has elapsed. If freezing for longer than 2 months, overwrap original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Dried Beef / Chipped Beef, Commercially Canned Or Bottled — Opened	2-5 Years (Unopened)	1 Month	1-2 Months	Keep refrigerated in covered container. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Fried Chicken - Homemade Or Takeout		3-4 Days	4 Months	How long does fried chicken last in the fridge or freezer? The precise answer to that question depends to a large extent on storage conditions - refrigerate chicken within two hours of cooking or purchasing. To maximize the shelf life of fried chicken for safety and quality, refrigerate the chicken in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, fried chicken will last for 3 to 4 days in the refrigerator. To further extend the shelf life of fried chicken, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long does fried chicken last in the freezer? Properly stored, it will maintain best quality for about 4 months, but will remain safe beyond that time. The freezer time shown is for best quality only - fried chicken that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does fried chicken last after being frozen and thawed? Fried chicken that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; chicken that was thawed in the microwave or in cold water should be eaten immediately. How long does fried chicken last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); fried chicken should be discarded if left for more than 2 hours at room temperature.
Ham Deli Meat / Cold Cuts - Sliced At Grocery Deli Counter		3-5 Days	1-2 Months	How long does sliced ham deli meat last in the fridge? The exact answer to that question depends to a large extent on storage conditions - keep ham deli meat (also known as lunch meat, luncheon meat or cold cuts) refrigerated at all times. To maximize the shelf life of ham deli meat after opening, keep refrigerated in airtight containers or wrapped tightly in plastic wrap or aluminium foil. Properly stored, sliced ham deli meat will last for 3 to 5 days in the refrigerator. How long can ham deli meat be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); ham deli meat should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of ham deli meat, freeze it; when freezing, place ham deli meat in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of ham deli meat in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does ham deli meat last in the freezer? Properly stored, it will maintain best quality for 1 to 2 months, but will remain safe beyond that time. How long does ham deli meat last after being frozen and thawed? Sliced ham deli meat that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; sliced ham deli meat that was thawed in the microwave or in cold water should be used immediately.
Ham Deli Meat / Cold Cuts, Commercially Pre-Packaged - Unopened		1 week after "use by" date on package	1-2 Months	How long does an unopened package of ham deli meat last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - keep packaged ham deli meat (also known as lunch meat, luncheon meat or cold cuts) refrigerated at all times. How long does an unopened package of ham deli meat last after the ? sell-by date or ? best before date on the package? After ham deli meat is purchased, it may be kept refrigerated for about 1 week after the ? sell by or ? best before date on the package if it has been properly stored. Unopened ham deli meat may be kept in its original store packaging when refrigerating; to maximize the shelf life of ham deli meat, do not open the package until ready to use. How long can an unopened package of ham deli meat be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); ham deli meat should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of packaged ham deli meat, freeze; when freezing, place ham deli meat in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of unopened ham deli meat in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does pre-packaged ham deli meat last in the freezer? Properly stored, it will maintain best quality for about 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - ham deli meat that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Ham, Commercially Canned, Sold Unrefrigerated — Opened	2 Years (Unopened)	3-4 Days	2-3 Months	How long does a can of shelf-stable ham last once opened? The precise answer depends to a large extent on storage conditions - keep opened ham refrigerated and tightly covered. To maximize the shelf life of canned ham after opening, refrigerate in a covered glass or plastic container. How long does opened canned ham last in the refrigerator? Ham that has been continuously refrigerated will keep for about 3 to 4 days. Is canned ham safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged ham will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the ham will remain at peak quality. To further extend the shelf life of opened canned ham, freeze it: to freeze canned ham, place inside covered airtight containers or heavy-duty freezer bags. How long does canned ham last in the freezer? Properly stored, it will maintain best quality for about 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only – canned ham that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does canned ham last after being frozen and thawed? Canned ham that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; ham that was thawed in the microwave or in cold water should be used immediately.

Hot Dogs (Hotdogs) / Frankfurters / Wieners - Cooked, Leftovers		3-4 Days	1-2 Months	How long do cooked hot dogs last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate hot dogs (hotdogs) within two hours of cooking. To maximize the shelf life of cooked hot dogs for safety and quality, refrigerate the hot dogs in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked hot dogs will last for 3 to 4 days in the refrigerator. To further extend the shelf life of cooked hot dogs, freeze them; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long do cooked hot dogs last in the freezer? Properly stored, they will maintain best quality for about 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked hot dogs that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked hot dogs last after being frozen and thawed? Cooked hot dogs that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; hot dogs that were thawed in the microwave or in cold water should be eaten immediately. How long do cooked hot dogs last at room temperature? Bacteria grow rapidly at temperatures between 40°F and 140°F; cooked hot dogs should be discarded if left for more than 2 hours at room temperature.
Italian Sausages - Cooked, Leftovers		3-4 Days	1-2 Months	How long do cooked Italian sausages last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate Italian sausages within two hours of cooking. To maximize the shelf life of cooked Italian sausages for safety and quality, refrigerate the Italian sausages in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked Italian sausages will last for 3 to 4 days in the refrigerator. To further extend the shelf life of cooked Italian sausages, freeze them; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long do cooked Italian sausages last in the freezer? Properly stored, they will maintain best quality for about 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked Italian sausages that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked Italian sausages last after being frozen and thawed? Cooked Italian sausages that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; Italian sausages that were thawed in the microwave or in cold water should be eaten immediately. How long do cooked Italian sausages last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked Italian sausages should be discarded if left for more than 2 hours at room temperature.
Italian Sausages - Fresh, Raw		1-2 Days	1-2 Months	How long do raw Italian sausages last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - keep Italian sausages refrigerated at all times. How long do raw Italian sausages last after the sell-by date? After Italian sausages are purchased, they may be refrigerated for 1 to 2 days - the "sell-by" date on the package may expire during that storage period, but the Italian sausages will remain safe to use after the sell by date if they has been properly stored. Unopened raw Italian sausages may be kept in its original store packaging when refrigerating; to maximize the shelf life of Italian sausages, do not open the package until ready to use. How long can raw Italian sausages be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); Italian sausages should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of raw Italian sausages, freeze; when freezing, place Italian sausages in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of Italian sausages in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long do raw Italian sausages last in the freezer? Properly stored, they will maintain best quality for about 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - Italian sausages that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Lamb Chops, All Cuts (Including Shoulder, Loin, Rib) - Cooked		3-4 Days	2-3 Months	How long do cooked lamb chops last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate lamb chops within two hours of cooking. To maximize the shelf life of cooked lamb chops for safety and quality, refrigerate the lamb chops in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked lamb chops will last for 3 to 4 days in the refrigerator. To further extend the shelf life of cooked lamb chops, freeze them; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long do cooked lamb chops last in the freezer? Properly stored, they will maintain best quality for 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked lamb chops that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked lamb chops last after being frozen and thawed? Cooked lamb chops that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; lamb chops that were thawed in the microwave or in cold water should be eaten immediately. How long do cooked lamb chops last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked lamb chops should be discarded if left for more than 2 hours at room temperature.
Lamb Chops, All Cuts (Including Shoulder, Loin, Rib) - Fresh, Raw		3-5 Days	6-9 Months	How long do raw lamb chops last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - keep lamb chops refrigerated at all times. How long do raw lamb chops last after the sell-by date? After lamb chops are purchased, they may be refrigerated for 3 to 5 days - the "sell-by" date on the package may expire during that storage period, but the lamb chops will remain safe to use after the sell by date if they has been properly stored. Unopened raw lamb chops may be kept in its original store packaging when refrigerating; to maximize the shelf life of lamb chops, do not open the package until ready to use. How long can raw lamb chops be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); lamb chops should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of raw lamb chops, freeze; when freezing, place lamb chops in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of lamb chops in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long do raw lamb chops last in the freezer? Properly stored, they will maintain best quality for about 6 to 9 months, but will remain safe beyond that time. The freezer time shown is for best quality only - lamb chops that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Luncheon Meat, Commercially Canned — Opened	3-5 Years (Best Quality) (Unopened)	3-4 Days	2-3 Months	How long does a can of luncheon meat last once opened? The precise answer depends to a large extent on storage conditions - keep opened luncheon meat refrigerated and tightly covered. To maximize the shelf life of canned luncheon meat after opening, refrigerate in a covered glass or plastic container. How long does opened canned luncheon meat last in the refrigerator? Luncheon meat that has been continuously refrigerated will keep for about 3 to 4 days. Is canned luncheon meat safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged luncheon meat will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the luncheon meat will remain at peak quality. To further extend the shelf life of opened canned luncheon meat, freeze it: to freeze canned luncheon meat, place inside covered airtight containers or heavy-duty freezer bags. How long does canned luncheon meat last in the freezer? Properly stored, it will maintain best quality for about 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only – canned luncheon meat that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does canned luncheon meat last after being frozen and thawed? Canned luncheon meat that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; luncheon meat that was thawed in the microwave or in cold water should be used immediately.
Meat Pie, Freshly Baked (Including Steak And Kidney Pie, Tourtiere)		3-5 Days	1-2 Months	How long does meat pie last? The precise answer to that question depends to a large extent on storage conditions - keep freshly baked meat pie (including steak and kidney pie, tourtiere) refrigerated. How long can meat pie be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); meat pie should be discarded if left out for more than 2 hours at room temperature. How long does meat pie last in the fridge? Freshly baked meat pie will keep for about 3 to 5 days in the fridge; refrigerate covered with aluminium foil or plastic wrap. Can you freeze meat pie? Yes, to freeze: wrap meat pie tightly with aluminium foil or plastic freezer wrap, or place in heavy-duty freezer bag. How long does meat pie last in the freezer? Properly stored, it will maintain best quality for about 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - meat pie that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if meat pie is bad or spoiled? The best way is to smell and look at the meat pie: discard any that has an off smell or appearance; if mould appears, discard the meat pie.
Meatballs, Cooked - Homemade Or Take-Out		3-4 Days	3-4 Months	How long do cooked meatballs last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate meatballs within two hours of cooking. To maximize the shelf life of cooked meatballs for safety and quality, refrigerate the meatballs in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked meatballs will last for 3 to 4 days in the refrigerator. To further extend the shelf life of cooked meatballs, freeze them; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long do cooked meatballs last in the freezer? Properly stored, they will maintain best quality for 3 to 4 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked meatballs that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked meatballs last after being frozen and thawed? Cooked meatballs that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; meatballs that were thawed in the microwave or in cold water should be eaten immediately. How long do cooked meatballs last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked meatballs should be discarded if left for more than 2 hours at room temperature.
Meatloaf - Homemade, Leftovers		3-4 Days	3-4 Months	How long does cooked meatloaf last in the fridge or freezer? The precise answer to that question depends to a large extent on storage conditions - refrigerate meatloaf within two hours of cooking. To maximize the shelf life of cooked meatloaf for safety and quality, refrigerate the meatloaf in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked meatloaf will last for 3 to 4 days in the refrigerator. To further extend the shelf life of cooked meatloaf, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Cooked meatloaf dishes containing sauce freeze best; cooked dry meatloaf may become overly mushy when thawed. How long does cooked meatloaf last in the freezer? Properly stored, it will maintain best quality for about 3 to 4 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked meatloaf that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked meatloaf last after being frozen and thawed? Cooked meatloaf that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; meatloaf that was thawed in the microwave or in cold water should be eaten immediately.
Pepperoni, Dry — Opened Package		2-3 Weeks	1-2 Months	Refrigerate after opening. To freeze, wrap tightly with heavy-duty aluminium foil or freezer wrap or place in heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Pepperoni, Dry - Unopened Package	4-6 Weeks	6 Months	2-3 months (after refrigeration)	Refrigerate to extend storage life. If freezing, place in freezer before time shown for refrigerator storage has elapsed. If freezing for longer than 2 months, overwrap original store packaging with airtight heavy-duty aluminium foil or freezer wrap or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Pork, All Cuts (Including Loin, Centre-Cut, Rib) - Cooked		3-4 Days	2-3 Months	How long do cooked pork chops last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate pork chops within two hours of cooking. To maximize the shelf life of cooked pork chops for safety and quality, refrigerate the pork chops in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked pork chops will last for 3 to 4 days in the refrigerator. To further extend the shelf life of cooked pork chops, freeze them; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long do cooked pork chops last in the freezer? Properly stored, they will maintain best quality for 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked pork chops that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked pork chops last after being frozen and thawed? Cooked pork chops that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; pork chops that were thawed in the microwave or in cold water should be eaten immediately. How long do cooked pork chops last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked pork chops should be discarded if left for more than 2 hours at room temperature.
Pork, All Cuts (Including Loin, Centre-Cut, Rib) - Fresh, Raw		3-5 Days	4-6 Months	How long do raw pork chops last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - keep pork chops refrigerated at all times. How long do raw pork chops last after the sell-by date? After pork chops are purchased, they may be refrigerated for 3 to 5 days - the "sell-by" date on the package may expire during that storage period, but the pork chops will remain safe to use after the sell by date if they has been properly stored. Unopened raw pork chops may be kept in its original store packaging when refrigerating; to maximize the shelf life of pork chops, do not open the package until ready to use. How long can raw pork chops be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); pork chops should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of raw pork chops, freeze; when freezing, place pork chops in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of pork chops in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long do raw pork chops last in the freezer? Properly stored, they will maintain best quality for about 4 to 6 months, but will remain safe beyond that time. The freezer time shown is for best quality only - pork chops that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Prosciutto, Parma Or Serrano Ham (Dry Cured) - Purchased As Chunk		2-3 Months	1-2 months (after refrigeration)	Keep refrigerated and wrapped tightly in plastic wrap or aluminium foil. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Rabbit — Cooked		3-4 Days	4-6 Months	Refrigerate within two hours of cooking. Refrigerate cooked meat in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Rabbit, Whole - Fresh, Raw		1-2 Days	1 Year	Unopened meat may be kept in its original store packaging when refrigerating - do not open package until ready to use. If freezing, place in freezer before the number of days shown for refrigerator storage has elapsed. If freezing for longer than 2 months, overwrap original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.

Roast Beef Deli Meat / Cold Cuts - Sliced At Grocery Deli Counter		3-5 Days	1-2 Months	How long does sliced roast beef deli meat last in the fridge? The exact answer to that question depends to a large extent on storage conditions - keep roast beef deli meat (also known as lunch meat, luncheon meat or cold cuts) refrigerated at all times. To maximize the shelf life of roast beef deli meat after opening, keep refrigerated in airtight containers or wrapped tightly in plastic wrap or aluminium foil. Properly stored, sliced roast beef deli meat will last for 3 to 5 days in the refrigerator. How long can roast beef deli meat be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); roast beef deli meat should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of roast beef deli meat, freeze it; when freezing, place roast beef deli meat in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of roast beef deli meat in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does roast beef deli meat last in the freezer? Properly stored, it will maintain best quality for 1 to 2 months, but will remain safe beyond that time. How long does roast beef deli meat last after being frozen and thawed? Sliced roast beef deli meat that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; sliced roast beef deli meat that was thawed in the microwave or in cold water should be used immediately.
Salami Deli Meat / Cold Cuts - Sliced At Grocery Deli Counter		3-5 Days	1-2 Months	How long does sliced salami deli meat last in the fridge? The exact answer to that question depends to a large extent on storage conditions - keep salami deli meat (also known as lunch meat, luncheon meat or cold cuts) refrigerated at all times. To maximize the shelf life of salami deli meat after opening, keep refrigerated in airtight containers or wrapped tightly in plastic wrap or aluminium foil. Properly stored, sliced salami deli meat will last for 3 to 5 days in the refrigerator. How long can salami deli meat be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); salami deli meat should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of salami deli meat, freeze it; when freezing, place salami deli meat in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of salami deli meat in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does salami deli meat last in the freezer? Properly stored, it will maintain best quality for 1 to 2 months, but will remain safe beyond that time. How long does salami deli meat last after being frozen and thawed? Sliced salami deli meat that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; sliced salami deli meat that was thawed in the microwave or in cold water should be used immediately.
Sausage Patties - Purchased Commercially Frozen			6 Months (Best Quality)	How long do frozen sausage patties last? The precise answer to that question depends to a large extent on storage conditions - keep sausage patties frozen at all times. Properly stored, frozen sausage patties will maintain best quality for about 6 months in the freezer, although they will usually remain safe to eat after that. Are frozen sausage patties safe to eat after the expiration date on the package? Yes, if properly stored - commercially frozen sausage patties will typically carry a Best By," "Best if Used By," Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the sausage patties will remain at peak quality. How long will frozen sausage patties remain safe to eat? Frozen sausage patties that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as they have been stored properly and the package is not damaged. How long can you safely leave frozen sausage patties at room temperature? Frozen sausage patties should be discarded if left for more than 2 hours at room temperature, as bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F). How to tell if frozen sausage patties are no longer good? If dry spots or discoloration have developed on the frozen sausage patties, freezer burn has begun to set in - this will not make the sausage patties unsafe to eat, but it will harm the texture and taste.
Sausages - Cooked		3-4 Days	1-2 Months	How long do cooked sausages last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate sausages within two hours of cooking. To maximize the shelf life of cooked sausages for safety and quality, refrigerate the sausages in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked sausages will last for 3 to 4 days in the refrigerator. To further extend the shelf life of cooked sausages, freeze them; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long do cooked sausages last in the freezer? Properly stored, they will maintain best quality for about 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked sausages that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do cooked sausages last after being frozen and thawed? Cooked sausages that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; sausages that were thawed in the microwave or in cold water should be eaten immediately. How long do cooked sausages last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked sausages should be discarded if left for more than 2 hours at room temperature.
Sausages, Fresh, Raw		1-2 Days	1-2 Months	How long do raw sausages last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - keep sausages refrigerated at all times. How long do raw sausages last after the sell-by date? After sausages are purchased, they may be refrigerated for 1 to 2 days - the "sell-by" date on the package may expire during that storage period, but the sausages will remain safe to use after the sell by date if they has been properly stored. Unopened raw sausages may be kept in its original store packaging when refrigerating; to maximize the shelf life of sausages, do not open the package until ready to use. How long can raw sausages be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); sausages should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of raw sausages, freeze; when freezing, place sausages in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of sausages in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. The freezer time shown is for best quality only - sausages that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do raw sausages last after being frozen and thawed? Sausages that have been defrosted in the fridge can be kept for an additional 1 to 2 days in the refrigerator before cooking; sausages that were thawed in the microwave or in cold water should be cooked immediately.
Shepherd's Pie, Freshly Baked		3-5 Days	4-6 Months	How long does shepherd's pie last? The precise answer to that question depends to a large extent on storage conditions - keep freshly baked shepherd's pie refrigerated. How long can shepherd's pie be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); shepherd's pie should be discarded if left out for more than 2 hours at room temperature. How long does shepherd's pie last in the fridge? Freshly baked shepherd's pie will keep for about 3 to 5 days in the fridge; refrigerate covered with aluminium foil or plastic wrap. Can you freeze shepherd's pie? Yes, to freeze: wrap shepherd's pie tightly with aluminium foil or plastic freezer wrap, or place in heavy-duty freezer bag. How long does shepherd's pie last in the freezer? Properly stored, it will maintain best quality for about 4 to 6 months, but will remain safe beyond that time. The freezer time shown is for best quality only - shepherd's pie that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if shepherd's pie is bad or spoiled? The best way is to smell and look at the shepherd's pie: discard any that has an off smell or appearance; if mould appears, discard the shepherd's pie.
Turkey Deli Meat / Cold Cuts - Sliced At Grocery Deli Counter		3-5 Days	1-2 Months	How long does sliced turkey deli meat last in the fridge? The exact answer to that question depends to a large extent on storage conditions - keep turkey deli meat (also known as lunch meat, luncheon meat or cold cuts) refrigerated at all times. To maximize the shelf life of turkey deli meat after opening, keep refrigerated in airtight containers or wrapped tightly in plastic wrap or aluminium foil. Properly stored, sliced turkey deli meat will last for 3 to 5 days in the refrigerator. How long can turkey deli meat be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); turkey deli meat should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of turkey deli meat, freeze it; when freezing, place turkey deli meat in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of turkey deli meat in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does turkey deli meat last in the freezer? Properly stored, it will maintain best quality for 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - turkey deli meat that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Turkey Pieces — Cooked		3-5 Days	2-3 Months	Refrigerate within two hours of cooking. Refrigerate cooked poultry in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Turkey Pieces - Fresh, Raw		1-2 Days	9 Months	Unopened poultry may be kept in its original store packaging when refrigerating - do not open package until ready to use. If freezing, place in freezer before the number of days shown for refrigerator storage has elapsed. If freezing for longer than 2 months, overwrap original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Turkey, Commercially Canned - Opened	2-5 Years (Unopened)	3-4 Days	1-2 Months	Do not store in opened metal can - refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Turkey, Whole - Cooked		3-4 Days	2-3 Months	The precise answer to the question ? How long does cooked turkey last? depends to a large extent on storage conditions - refrigerate within two hours of cooking; if turkey is stuffed, remove stuffing to a separate container before refrigerating or freezing leftovers. To maximize the shelf life of cooked turkey, refrigerate cooked poultry in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. To further extend the shelf life of cooked turkey, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long does cooked turkey last in the freezer for safety purposes? The freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked turkey last after being frozen and thawed? Cooked turkey that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; turkey that was thawed in the microwave or in cold water should be eaten immediately. How long does Thanksgiving turkey last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); turkey should be discarded if left for more than 2 hours at room temperature. How to tell if cooked turkey is bad? The best way is to smell and look at the turkey: signs of bad turkey are a sour smell and a slimy texture to the cooked turkey; discard any turkey with an off smell or appearance, do not taste the turkey first.
Turkey, Whole - Fresh, Raw		1-2 Days	1 Year	Fresh turkey may be kept in its original store packaging when refrigerating - do not open package until ready to use. If freezing fresh turkey, place in freezer before the number of days shown for refrigerator storage has elapsed. If freezing fresh, uncooked turkey for longer than 2 months, overwrap original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. Freezer time shown for fresh turkey is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Veal Steak - Fresh, Raw		3-5 Days	6-12 Months	Unopened meat may be kept in its original store packaging when refrigerating - do not open package until ready to use. If freezing, place in freezer before the number of days shown for refrigerator storage has elapsed. If freezing for longer than 2 months, overwrap original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Veal Steak — Cooked		3-4 Days	2-3 Months	Refrigerate within two hours of cooking. Refrigerate cooked meat in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Venison — Cooked		3-5 Days	6-9 Months	Refrigerate within two hours of cooking. Refrigerate cooked meat in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Venison - Fresh, Raw		3-5 Days	6-9 Months	Unopened meat may be kept in its original store packaging when refrigerating - do not open package until ready to use. If freezing, place in freezer before the number of days shown for refrigerator storage has elapsed. If freezing for longer than 2 months, overwrap original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Vienna Sausages, Commercially Canned - Opened	2-5 Years (Unopened)	3-4 Days	1-2 Months	Do not store in opened metal can — refrigerate in covered glass or plastic container after opening. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.

5 Seafood Shelf Life

These is the shelf life of most seafood, both pre-packaged and raw.

	Pantry	Refrigerator	Freezer	Food Tips

Anchovies, Commercially Canned Or Bottled — Opened	18 Months (Unopened)	1-2 Months	3 Months	Keep refrigerated and tightly covered. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Caviar, Fresh, Commercially Jarred Or Tinned, Sold Refrigerated — Opened		2-3 Days 2-4 Weeks (Unopened)		Keep refrigerated and tightly covered. Caviar does not freeze well.
Clams — Fresh, Cooked		3-4 Days	3 Months	Refrigerate within two hours of cooking. Refrigerate cooked clams in covered airtight containers. To freeze, place clams in airtight plastic containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Clams — Fresh, Raw, Shucked		1-2 Days	3-4 Months	Keep refrigerated in covered container. To freeze, place clams in airtight plastic containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Clams - Fresh, Live		1-2 Days	2-3 Months	How long do raw clams last in the fridge or freezer? The exact answer to that question depends to a large extent on storage conditions - keep clams refrigerated at all times. Store live, raw clams in the refrigerator in an open container and cover with damp cloths or paper towels. How long do raw clams last in the fridge? After clams are purchased, they may be refrigerated for 1 to 2 days. Raw clams must be kept alive before cooking. How long can raw clams be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); clams should be discarded if left out for more than 2 hours at room temperature and always discard if clams are no longer alive. To further extend the shelf life of raw clams, freeze; when freezing, place clams in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of clams in the freezer by placing the clams inside a heavy-duty freezer bag in order to prevent freezer burn. How long do raw clams last in the freezer? Properly stored, they will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - clams that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do raw clams last after being frozen and thawed? Clams that have been defrosted in the fridge can be kept for an additional 1 to 2 days in the refrigerator before cooking; clams that were thawed in the microwave or in cold water should be cooked immediately. How long do clams last in the fridge once they are cooked? Cooked clams will usually stay good for 3 to 4 days in the fridge and 4 months in the freezer.
Clams, Commercially Canned — Opened	3-5 Years (Best Quality) (Unopened)	3-4 Days	3 Months	How long does a can of clams last once opened? The precise answer depends to a large extent on storage conditions - keep opened clams refrigerated and tightly covered. To maximize the shelf life of canned clams after opening, refrigerate in covered glass or plastic container. How long do opened canned clams last in the refrigerator? Canned clams that have been continuously refrigerated will keep for about 3 to 4 days. Are canned clams safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned clams will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the clams will remain at peak quality. To further extend the shelf life of opened canned clams, freeze them: to freeze canned clams, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned clams will be softer after freezing and thawing; the thawed clams will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned clams last in the freezer? Properly stored, they will maintain best quality for about 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - clams that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do canned clams last after being frozen and thawed? Clams that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; clams that were thawed in the microwave or in cold water should be used immediately. How can you tell if opened canned clams are bad or spoiled? The best way is to smell and look at the clams: if the clams develop an off odor, flavour or appearance, or if mould appears, they should be discarded. Discard all clams from cans or packages that are leaking, rusting, bulging or severely dented.
Cod - Fresh, Cooked		3-4 Days	2-3 Months	How long does cooked cod last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate cod within two hours of cooking. To maximize the shelf life of cooked cod for safety and quality, refrigerate the cod in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked cod will last for 3 to 4 days in the refrigerator. To further extend the shelf life of cooked cod, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long does cooked cod last in the freezer? Properly stored, it will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked cod that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked cod last after being frozen and thawed? Cooked cod that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; cod that was thawed in the microwave or in cold water should be eaten immediately. How long does cooked cod last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked cod should be discarded if left for more than 2 hours at room temperature. How to tell if cooked cod is bad? The best way is to smell and look at the cod: signs of bad cod are a sour smell and a slimy texture; discard any cod with an off smell or appearance, do not taste first.
Cod - Fresh, Raw		1-2 Days	6-8 Months	How long does raw cod last in the fridge or freezer? The precise answer depends to a large extent on storage conditions - keep cod refrigerated at all times. How long does raw cod last after the sell-by date? After cod is purchased, it may be refrigerated for 1 to 2 days - the "sell-by" date on the package may expire during that storage period, but the cod will remain safe to use after the sell by date if it has been properly stored. Unopened raw cod may be kept in its original store packaging when refrigerating; to maximize the shelf life of cod, do not open the package until ready to use. How long can raw cod be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cod should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of raw cod, freeze; when freezing, place cod in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of cod in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does raw cod last in the freezer? Properly stored, it will maintain best quality for about 6 to 8 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cod that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does raw cod last after being frozen and thawed? Cod that has been defrosted in the fridge can be kept for an additional 1 to 2 days in the refrigerator before cooking; cod that was thawed in the microwave or in cold water should be cooked immediately. How long does cod last in the fridge once it is cooked? Cooked cod will usually stay good for 3 to 4 days in the fridge and 4 months in the freezer. How to tell if raw cod is bad? The best way is to smell and look at the cod: signs of bad cod are a sour smell, dull colour and slimy texture; discard any cod with an off smell or appearance.
Crab — Fresh, Cooked, Still In The Shell		3-5 Days	3 Months	Refrigerate within two hours of cooking. Refrigerate cooked crab in covered airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. To freeze, place whole cooked crabs in heavy-duty freezer bags or place in airtight plastic containers. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Crab - Fresh, Raw, Live		1-2 Days		Store live crabs in the refrigerator in an open container and cover with damp cloths, paper towels or newspaper. Crabs must be kept alive before cooking.
Crab Meat - Fresh, Cooked, Out Of The Shell		3-5 Days	3 Months	How long does cooked crab meat last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate crab meat within two hours of cooking. To maximize the shelf life of cooked crab meat for safety and quality, refrigerate the crab meat in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, cooked crab meat will last for 3 to 5 days in the refrigerator. To further extend the shelf life of cooked crab meat, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long does cooked crab meat last in the freezer? Properly stored, it will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked crab meat that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked crab meat last after being frozen and thawed? Cooked crab meat that has been thawed in the fridge can be kept for an additional 3 to 5 days in the refrigerator before cooking; crab meat that was thawed in the microwave or in cold water should be eaten immediately. How long does cooked crab meat last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked crab meat should be discarded if left for more than 2 hours at room temperature. How to tell if cooked crab meat is bad? The best way is to smell and look at the crab meat: signs of bad crab meat are a sour smell and a slimy texture; discard any crab meat with an off smell or appearance, do not taste first.
Frozen Seafood Dinners/ Entrees — Purchased Commercially Frozen			6-8 Months	Keep frozen until ready to use. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Halibut - Fresh, Cooked		3-4 Days	2-3 Months	How long does cooked halibut last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate halibut within two hours of cooking. To maximize the shelf life of cooked halibut for safety and quality, refrigerate the halibut in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. To further extend the shelf life of cooked halibut, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long does cooked halibut last in the freezer? Properly stored, it will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. Properly stored, cooked halibut will last for 3 to 4 days in the refrigerator. The freezer time shown is for best quality only - cooked halibut that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked halibut last after being frozen and thawed? Cooked halibut that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; halibut that was thawed in the microwave or in cold water should be eaten immediately. How long does cooked halibut last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked halibut should be discarded if left for more than 2 hours at room temperature. How to tell if cooked halibut is bad? The best way is to smell and look at the halibut: signs of bad halibut are a sour smell and a slimy texture; discard any halibut with an off smell or appearance, do not taste first.
Halibut - Fresh, Raw		1-2 Days	6-8 Months	How long does raw halibut last in the fridge or freezer? The precise answer depends to a large extent on storage conditions - keep halibut refrigerated at all times. How long does raw halibut last after the sell-by date? After halibut is purchased, it may be refrigerated for 1 to 2 days - the "sell-by" date on the package may expire during that storage period, but the halibut will remain safe to use after the sell by date if it has been properly stored. How long can raw halibut be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); halibut should be discarded if left out for more than 2 hours at room temperature. Unopened raw halibut may be kept in its original store packaging when refrigerating; to maximize the shelf life of halibut, do not open the package until ready to use. To further extend the shelf life of raw halibut, freeze; when freezing, place halibut in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of halibut in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does raw halibut last in the freezer? Properly stored, it will maintain best quality for about 6 to 8 months, but will remain safe beyond that time. The freezer time shown is for best quality only - halibut that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does raw halibut last after being frozen and thawed? Halibut that has been defrosted in the fridge can be kept for an additional 1 to 2 days in the refrigerator before cooking; halibut that was thawed in the microwave or in cold water should be cooked immediately. How long does halibut last in the fridge once it is cooked? Cooked halibut will usually stay good for 3 to 4 days in the fridge and 4 months in the freezer. How to tell if raw halibut is bad? The best way is to smell and look at the halibut: signs of bad halibut are a sour smell, dull colour and slimy texture; discard any halibut with an off smell or appearance.
Lobster - Fresh, Live		1-2 Days		Store live lobster in the refrigerator in a large bowl or baking tray and cover with damp cloths or newspaper. Lobster must be kept alive before cooking.
Lobster - Fresh, Cooked, Shell Removed		3-4 Days	3 Months	How long does cooked lobster last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate lobster within two hours of cooking. To maximize the shelf life of cooked lobster for safety and quality, refrigerate the lobster in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. To further extend the shelf life of cooked lobster, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Properly stored, cooked lobster will last for 3 to 4 days in the refrigerator. How long does cooked lobster last in the freezer? Properly stored, it will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked lobster that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked lobster last after being frozen and thawed? Cooked lobster that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; lobster that was thawed in the microwave or in cold water should be eaten immediately. How long does cooked lobster last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked lobster should be discarded if left for more than 2 hours at room temperature. How to tell if cooked lobster is bad? The best way is to smell and look at the lobster: signs of bad lobster are a sour smell and a slimy texture; discard any lobster with an off smell or appearance, do not taste first.
Mackerel — Fresh, Cooked		3-4 Days	2-3 Months	Refrigerate within two hours of cooking. Refrigerate cooked fish in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.

Mackerel - Fresh, Raw		1-2 Days	2-3 Months	How long does raw mackerel last in the fridge or freezer? The precise answer depends to a large extent on storage conditions - keep mackerel refrigerated at all times. How long does raw mackerel last after the sell-by date? After mackerel is purchased, it may be refrigerated for 1 to 2 days - the "sell-by" date on the package may expire during that storage period, but the mackerel will remain safe to use after the sell by date if it has been properly stored. Unopened raw mackerel may be kept in its original store packaging when refrigerating; to maximize the shelf life of mackerel, do not open the package until ready to use. How long can raw mackerel be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); mackerel should be discarded if left out for more than 2 hours at room temperature. You can maximize the shelf life of mackerel in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. To further extend the shelf life of raw mackerel, freeze; when freezing, place mackerel in the freezer before the number of days shown for refrigerator storage has elapsed. How long does raw mackerel last in the freezer? Properly stored, it will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. How long does raw mackerel last after being frozen and thawed? Mackerel that has been defrosted in the fridge can be kept for an additional 1 to 2 days in the refrigerator before cooking; mackerel that was thawed in the microwave or in cold water should be cooked immediately. The freezer time shown is for best quality only - mackerel that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does mackerel last in the fridge once it is cooked? Cooked mackerel will usually stay good for 3 to 4 days in the fridge and 4 months in the freezer.
Mullet — Fresh, Cooked		3-4 Days	2-3 Months	Refrigerate within two hours of cooking. Refrigerate cooked fish in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Mullet - Fresh, Raw		1-2 Days	2-3 Months	Unopened fish may be kept in its original store packaging when refrigerating - do not open package until ready to use. If freezing, place in freezer before the number of days shown for refrigerator storage has elapsed. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Octopus — Fresh, Cooked		2-3 Days	2-3 Months	Refrigerate within two hours of cooking. Refrigerate cooked fish in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Octopus - Fresh, Raw		1-2 Days	2-3 Months	Unopened fish may be kept in its original store packaging when refrigerating - do not open package until ready to use. If freezing, place in freezer before the number of days shown for refrigerator storage has elapsed. If freezing for longer than 2 months, overwrap original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Oysters — Fresh, Cooked		3-4 Days	3 Months	Refrigerate within two hours of cooking. Refrigerate cooked oysters in covered airtight containers. To freeze, place oysters in airtight plastic containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Oysters - Fresh, Live		1-2 Days	2-3 Months	Store live oysters in the refrigerator in an open container and cover with damp cloths or paper towels. Oysters must be kept alive before cooking. To freeze, place whole oysters in heavy-duty freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Perch — Fresh, Cooked		3-4 Days	2-3 Months	Refrigerate within two hours of cooking. Refrigerate cooked fish in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Perch - Fresh, Raw		1-2 Days	4 Months	Unopened fish may be kept in its original store packaging when refrigerating - do not open package until ready to use. If freezing, place in freezer before the number of days shown for refrigerator storage has elapsed. If freezing for longer than 2 months, overwrap original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Salmon - Fresh, Cooked		3-4 Days	2-3 Months	How long does cooked salmon last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate salmon within two hours of cooking. To maximize the shelf life of cooked salmon for safety and quality, refrigerate the salmon in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. To further extend the shelf life of cooked salmon, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Properly stored, cooked salmon will last for 3 to 4 days in the refrigerator. How long does cooked salmon last in the freezer? Properly stored, it will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cooked salmon that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cooked salmon last after being frozen and thawed? Cooked salmon that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; salmon that was thawed in the microwave or in cold water should be eaten immediately. How long does cooked salmon last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked salmon should be discarded if left for more than 2 hours at room temperature. How to tell if cooked salmon is bad? The best way is to smell and look at the salmon: signs of bad salmon are a sour smell and a slimy texture; discard any salmon with an off smell or appearance, do not taste first.
Salmon - Fresh, Raw		1-2 Days	2-3 Months	How long does raw salmon last in the fridge or freezer? The precise answer depends to a large extent on storage conditions - keep salmon refrigerated at all times. Unopened raw salmon may be kept in its original store packaging when refrigerating; to maximize the shelf life of salmon, do not open the package until ready to use. How long does raw salmon last after the sell-by date? After salmon is purchased, it may be refrigerated for 1 to 2 days - the "sell-by" date on the package may expire during that storage period, but the salmon will remain safe to use after the sell by date if it has been properly stored. How long can raw salmon be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); salmon should be discarded if left out for more than 2 hours at room temperature. You can maximize the shelf life of salmon in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. To further extend the shelf life of raw salmon, freeze; when freezing, place salmon in the freezer before the number of days shown for refrigerator storage has elapsed. How long does raw salmon last in the freezer? Properly stored, it will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. How long does raw salmon last after being frozen and thawed? Salmon that has been defrosted in the fridge can be kept for an additional 1 to 2 days in the refrigerator before cooking; salmon that was thawed in the microwave or in cold water should be cooked immediately. The freezer time shown is for best quality only - salmon that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does salmon last in the fridge once it is cooked? Cooked salmon will usually stay good for 3 to 4 days in the fridge and 4 months in the freezer. How to tell if raw salmon is bad? The best way is to smell and look at the salmon: signs of bad salmon are a sour smell, dull colour and slimy texture; discard any salmon with an off smell or appearance.
Sardines, Commercially Canned In Oil Or Sauce — Opened	3-5 Years (Unopened)	3-4 Days	3 Months	How long does a can of sardines last once opened? The precise answer depends to a large extent on storage conditions - keep opened sardines refrigerated and tightly covered. To maximize the shelf life of canned sardines after opening, refrigerate in covered glass or plastic container. How long do opened canned sardines last in the refrigerator? Canned sardines that have been continuously refrigerated will keep for about 3 to 4 days. Are canned sardines safe to use after the "expiration" date on the package? Yes, provided they have been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned sardines will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the sardines will remain at peak quality. To further extend the shelf life of opened canned sardines, freeze them; to freeze canned sardines, place inside covered airtight containers or heavy-duty freezer bags. The texture of canned sardines will be softer after freezing and thawing; the thawed sardines will be best suited to cooked dishes, such as sauces, soups and casseroles. How long do canned sardines last in the freezer? Properly stored, they will maintain best quality for about 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - sardines that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do canned sardines last after being frozen and thawed? Sardines that have been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; sardines that were thawed in the microwave or in cold water should be used immediately. How can you tell if opened canned sardines are bad or spoiled? The best way is to smell and look at the sardines: if the sardines develop an off odor, flavour or appearance, or if mould appears, they should be discarded. Discard all sardines from cans or packages that are leaking, rusting, bulging or severely dented.
Sea Bass — Fresh, Cooked		3-4 Days	2-3 Months	Refrigerate within two hours of cooking. Refrigerate cooked fish in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Sea Bass - Fresh, Raw		1-2 Days	2-3 Months	How long does raw sea bass last in the fridge or freezer? The precise answer depends to a large extent on storage conditions - keep sea bass refrigerated at all times. How long does raw sea bass last after the sell-by date? After sea bass is purchased, it may be refrigerated for 1 to 2 days - the "sell-by" date on the package may expire during that storage period, but the sea bass will remain safe to use after the sell by date if it has been properly stored. Unopened raw sea bass may be kept in its original store packaging when refrigerating; to maximize the shelf life of sea bass, do not open the package until ready to use. To further extend the shelf life of raw sea bass, freeze; when freezing, place sea bass in the freezer before the number of days shown for refrigerator storage has elapsed. How long can raw sea bass be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); sea bass should be discarded if left out for more than 2 hours at room temperature. You can maximize the shelf life of sea bass in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does raw sea bass last in the freezer? Properly stored, it will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - sea bass that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does raw sea bass last after being frozen and thawed? Sea bass that has been defrosted in the fridge can be kept for an additional 1 to 2 days in the refrigerator before cooking; sea bass that was thawed in the microwave or in cold water should be cooked immediately. How long does sea bass last in the fridge once it is cooked? Cooked sea bass will usually stay good for 3 to 4 days in the fridge and 4 months in the freezer. How to tell if raw sea bass is bad? The best way is to smell and look at the sea bass: signs of bad sea bass are a sour smell, dull colour and slimy texture; discard any sea bass with an off smell or appearance.
Sea Trout — Fresh, Cooked		3-4 Days	2-3 Months	Refrigerate within two hours of cooking. Refrigerate cooked fish in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Sea Trout - Fresh, Raw		1-2 Days	4 Months	Unopened fish may be kept in its original store packaging when refrigerating - do not open package until ready to use. If freezing, place in freezer before the number of days shown for refrigerator storage has elapsed. If freezing for longer than 2 months, overwrap original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Shrimp, Commercially Canned — Opened	3-5 Years (Best Quality) (Unopened)	3-4 Days	3 Months	How long does a can of shrimp last once opened? The precise answer depends to a large extent on storage conditions - keep opened shrimp refrigerated and tightly covered. To maximize the shelf life of canned shrimp after opening, refrigerate in a covered glass or plastic container. How long does opened canned shrimp last in the refrigerator? Shrimp that has been continuously refrigerated will keep for about 3 to 4 days. Is canned shrimp safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged shrimp will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the shrimp will remain at peak quality. To further extend the shelf life of opened canned shrimp, freeze it; to freeze canned shrimp, place inside covered airtight containers or heavy-duty freezer bags. How long does canned shrimp last in the freezer? Properly stored, it will maintain best quality for about 3 months, but will remain safe beyond that time. How long does canned shrimp last after being frozen and thawed? Canned shrimp that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; shrimp that was thawed in the microwave or in cold water should be used immediately. How can you tell if opened canned shrimp is bad or spoiled? The best way is to smell and look at the shrimp: if the shrimp develops an off odor, flavour or appearance, or if mould appears, it should be discarded. The freezer time shown is for best quality only – canned shrimp that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. Discard all shrimp from cans or packages that are leaking, rusting, bulging or severely dented.
Snapper — Fresh, Cooked		3-4 Days	2-3 Months	Refrigerate within two hours of cooking. Refrigerate cooked fish in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Snapper - Fresh, Raw		1-2 Days	6-8 Months	How long does raw snapper last in the fridge or freezer? The precise answer depends to a large extent on storage conditions - keep snapper refrigerated at all times. How long does raw snapper last after the sell-by date? After snapper is purchased, it may be refrigerated for 1 to 2 days - the "sell-by" date on the package may expire during that storage period, but the snapper will remain safe to use after the sell by date if it has been properly stored. Unopened raw snapper may be kept in its original store packaging when refrigerating; to maximize the shelf life of snapper, do not open the package until ready to use. How long can raw snapper be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); snapper should be discarded if left out for more than 2 hours at room temperature. You can maximize the shelf life of snapper in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. To further extend the shelf life of raw snapper, freeze; when freezing, place snapper in the freezer before the number of days shown for refrigerator storage has elapsed. How long does raw snapper last in the freezer? Properly stored, it will maintain best quality for about 6 to 8 months, but will remain safe beyond that time. How long does raw snapper last after being frozen and thawed? Snapper that has been defrosted in the fridge can be kept for an additional 1 to 2 days in the refrigerator before cooking; snapper that was thawed in the microwave or in cold water should be cooked immediately. The freezer time shown is for best quality only - snapper that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does snapper last in the fridge once it is cooked? Cooked snapper will usually stay good for 3 to 4 days in the fridge and 4 months in the freezer.

Squid / Calamari — Fresh, Cooked		3-4 Days	3 Months	Refrigerate within two hours of cooking. Refrigerate cooked fish in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Squid / Calamari - Fresh, Raw		1-2 Days	3-6 Months	Unopened fish may be kept in its original store packaging when refrigerating - do not open package until ready to use. If freezing, place in freezer before the number of days shown for refrigerator storage has elapsed. If freezing for longer than 2 months, overwrap original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Sushi — Fresh, Raw		1 Day		Keep refrigerated in covered container. Does not freeze well.
Tilapia - Fresh, Cooked		3-4 Days	2-3 Months	How long does cooked tilapia last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate tilapia within two hours of cooking. To maximize the shelf life of cooked tilapia for safety and quality, refrigerate the tilapia in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. To further extend the shelf life of cooked tilapia, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Properly stored, cooked tilapia will last for 3 to 4 days in the refrigerator. How long does cooked tilapia last in the freezer? Properly stored, it will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. How long does cooked tilapia last after being frozen and thawed? Cooked tilapia that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; tilapia that was thawed in the microwave or in cold water should be eaten immediately. How long does cooked tilapia last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked tilapia should be discarded if left for more than 2 hours at room temperature. How to tell if cooked tilapia is bad? The best way is to smell and look at the tilapia: signs of bad tilapia are a sour smell and a slimy texture; discard any tilapia with an off smell or appearance, do not taste first. The freezer time shown is for best quality only - cooked tilapia that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Tilapia - Fresh, Raw		1-2 Days	6-8 Months	How long does raw tilapia last in the fridge or freezer? The precise answer depends to a large extent on storage conditions - keep tilapia refrigerated at all times. Unopened raw tilapia may be kept in its original store packaging when refrigerating; to maximize the shelf life of tilapia, do not open the package until ready to use. How long does raw tilapia last after the sell-by date? After tilapia is purchased, it may be refrigerated for 1 to 2 days - the "sell-by" date on the package may expire during that storage period, but the tilapia will remain safe to use after the sell by date if it has been properly stored. How long can raw tilapia be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); tilapia should be discarded if left out for more than 2 hours at room temperature. You can maximize the shelf life of tilapia in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does raw tilapia last in the freezer? Properly stored, it will maintain best quality for about 6 to 8 months, but will remain safe beyond that time. To further extend the shelf life of raw tilapia, freeze; when freezing, place tilapia in the freezer before the number of days shown for refrigerator storage has elapsed. How long does raw tilapia last after being frozen and thawed? Tilapia that has been defrosted in the fridge can be kept for an additional 1 to 2 days in the refrigerator before cooking; tilapia that was thawed in the microwave or in cold water should be cooked immediately. The freezer time shown is for best quality only - tilapia that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does tilapia last in the fridge once it is cooked? Cooked tilapia will usually stay good for 3 to 4 days in the fridge and 4 months in the freezer. How to tell if raw tilapia is bad? The best way is to smell and look at the tilapia: signs of bad tilapia are a sour smell, dull colour and slimy texture; discard any tilapia with an off smell or appearance.
Trout, Lake Or Rainbow — Fresh, Cooked		3-4 Days	2-3 Months	Refrigerate within two hours of cooking. Refrigerate cooked fish in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Trout, Lake Or Rainbow - Fresh, Raw		1-2 Days	2-3 Months	Unopened fish may be kept in its original store packaging when refrigerating - do not open package until ready to use. If freezing, place in freezer before the number of days shown for refrigerator storage has elapsed. If freezing for longer than 2 months, overwrap original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Trout, Smoked — Whole Fish Or Large Pieces		5-8 Days	2 Months	Keep refrigerated and tightly wrapped in plastic or aluminium wrap. To freeze, wrap tightly with heavy-duty aluminium foil or freezer wrap or place in heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Tuna (Including Yellowfin) - Fresh, Cooked		3-4 Days	2-3 Months	How long does cooked tuna last in the fridge? The precise answer to that question depends to a large extent on storage conditions - refrigerate tuna within two hours of cooking. To maximize the shelf life of cooked tuna for safety and quality, refrigerate the tuna in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. To further extend the shelf life of cooked tuna, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Properly stored, cooked tuna will last for 3 to 4 days in the refrigerator. How long does cooked tuna last in the freezer? Properly stored, it will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. How long does cooked tuna last after being frozen and thawed? Cooked tuna that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; tuna that was thawed in the microwave or in cold water should be eaten immediately. How long does cooked tuna last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cooked tuna should be discarded if left for more than 2 hours at room temperature. The freezer time shown is for best quality only - cooked tuna that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cooked tuna is bad? The best way is to smell and look at the tuna: signs of bad tuna are a sour smell and a slimy texture; discard any tuna with an off smell or appearance, do not taste first.
Tuna (Including Yellowfin) - Fresh, Raw		1-2 Days	2-3 Months	How long does raw tuna last in the fridge or freezer? The precise answer depends to a large extent on storage conditions - keep tuna refrigerated at all times. How long does raw tuna last after the sell-by date? After tuna is purchased, it may be refrigerated for 1 to 2 days - the "sell-by" date on the package may expire during that storage period, but the tuna will remain safe to use after the sell by date if it has been properly stored. How long can raw tuna be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); tuna should be discarded if left out for more than 2 hours at room temperature. Unopened raw tuna may be kept in its original store packaging when refrigerating; to maximize the shelf life of tuna, do not open the package until ready to use. Unopened raw tuna may be kept in its original store packaging when refrigerating; to maximize the shelf life of tuna, do not open the package until ready to use. To further extend the shelf life of raw tuna, freeze; when freezing, place tuna in the freezer before the number of days shown for refrigerator storage has elapsed. How long does raw tuna last in the freezer? Properly stored, it will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. You can maximize the shelf life of tuna in the freezer by overwrapping the original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does raw tuna last after being frozen and thawed? Tuna that has been defrosted in the fridge can be kept for an additional 1 to 2 days in the refrigerator before cooking; tuna that was thawed in the microwave or in cold water should be cooked immediately. The freezer time shown is for best quality only - tuna that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does tuna last in the fridge once it is cooked? Cooked tuna will usually stay good for 3 to 4 days in the fridge and 4 months in the freezer.
Tuna, Commercially Canned Or Vacuum-Sealed Pouch (In Oil Or Water) — Opened	3-5 Years (Best Quality) (Unopened)	3-4 Days	3 Months	How long does a can of tuna last once opened? The precise answer depends to a large extent on storage conditions - keep opened tuna refrigerated and tightly covered. To maximize the shelf life of canned tuna (or tuna sold in a vacuum-sealed pouch) after opening, refrigerate in a covered glass or plastic container. How long does opened canned tuna last in the refrigerator? Tuna that has been continuously refrigerated will keep for about 3 to 4 days. Is canned tuna safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the package is undamaged, and there are no signs of spoilage - commercially packaged tuna will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the tuna will remain at peak quality. To further extend the shelf life of opened canned tuna, freeze it: to freeze canned tuna, place inside covered airtight containers or heavy-duty freezer bags. How long does canned tuna last in the freezer? Properly stored, it will maintain best quality for about 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only – canned tuna that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does canned tuna last after being frozen and thawed? Canned tuna that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; tuna that was thawed in the microwave or in cold water should be used immediately. How can you tell if opened canned tuna is bad or spoiled? The best way is to smell and look at the tuna: if the tuna develops an off odor, flavour or appearance, or if mould appears, it should be discarded. Discard all tuna from cans or pouches that are leaking, rusting, bulging or severely dented.
Whitefish — Fresh, Cooked		3-4 Days	2-3 Months	Refrigerate within two hours of cooking. Refrigerate cooked fish in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Whitefish - Fresh, Raw		1-2 Days	2-3 Months	Unopened fish may be kept in its original store packaging when refrigerating - do not open package until ready to use. If freezing, place in freezer before the number of days shown for refrigerator storage has elapsed. If freezing for longer than 2 months, overwrap original store packaging with airtight heavy-duty aluminium foil, plastic wrap, or freezer paper or place the package inside a heavy-duty freezer bag in order to prevent freezer burn. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.

6 Dairy Shelf Life

These is the shelf life of most dairy, both pre-packaged and raw.

	Pantry	Refrigerator	Freezer	Food Tips
American Cheese, Pasteurized Processed Slices (Individually Wrapped) - Opened Package		1-2 Months	3 Months	Keep refrigerated and tightly covered. If cheese slices develop an off odor, flavour or appearance, they should be discarded for quality purposes. To freeze: wrap cheese slices tightly in heavy-duty aluminium foil or plastic freezer wrap or place in heavy-duty freezer bags. Frozen cheese may become crumbly and lose some of its flavour; the thawed cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Brick Cheese, Shredded Or Sliced, Commercially Packaged — Unopened Package		1 week after date on package	3 months	Keep refrigerated; do not open package until ready to use. If cheese develops an off odor, flavour or appearance, it should be discarded; if mould appears, discard the entire package. To freeze, place original packaging in freezer; if freezing for longer than 2 months, place package inside a heavy-duty freezer bag in order to prevent freezer burn. Frozen cheese may lose some of its texture and flavour; the thawed cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Brick Cheese, Shredded Or Sliced, Commercially Packaged - Opened Package		5-7 Days	3 months	How long does an opened package of shredded brick cheese last in the fridge? The exact answer to that question depends to a large extent on storage conditions - keep shredded brick cheese refrigerated at all times. To maximize the shelf life of shredded brick cheese after opening, tightly seal original packaging or place the cheese in resealable plastic bags or airtight containers. Properly stored, an opened package of shredded brick cheese will last for about 5 to 7 days in the refrigerator. Once the package is opened, consume or freeze the shredded brick cheese within the time shown for refrigeration, even if the "Best By," "Best if Used By," or "Use By" date has not yet been reached. How long can shredded brick cheese be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); shredded brick cheese should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of opened shredded brick cheese, freeze it; when freezing, place shredded brick cheese in the freezer before the number of days shown for refrigerator storage has elapsed. To freeze shredded brick cheese, tightly seal original packaging and place in freezer; if freezing for longer than 2 months, place package inside a heavy-duty freezer bag in order to prevent freezer burn. The freezer time shown is for best quality only - shredded brick cheese that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely.

Brick Cheese, Sold In Wrapped Block - Unopened Or Opened		2-3 Weeks	2 Months	How long does a chunk of brick cheese last? The exact answer to that question depends to a large extent on storage conditions - keep the cheese refrigerated at all times. To maximize the shelf life of a chunk of brick cheese after opening, wrap the original packaging tightly in plastic wrap or aluminium foil; for even better results, wrap the cheese first in wax or parchment paper and then cover with plastic wrap before refrigerating. Properly stored, a chunk of brick cheese will last for 2 to 3 weeks in the refrigerator. Is a chunk of brick cheese still safe after the ? sell by date or "best by date" on the package? Yes - assuming it is properly stored, it will typically remain safe to use for 2 to 3 weeks, even if the "sell-by" or "best by date on the package expires. If a chunk or block of brick cheese has mould on it, is it still safe to eat? Yes - cut away at least 1 inch around and below the mouldy area (do not touch mould with the knife) and re-cover the cheese in fresh wrap. Note: if mould appears in a package of shredded, sliced or crumbled brick cheese, the entire package should be discarded. To further extend the shelf life of brick cheese, freeze it; when freezing, place the cheese in the freezer before the number of days shown for refrigerator storage has elapsed. To freeze a chunk or block of brick cheese: Cut the cheese into portions no larger than 1/2 pound each, and wrap tightly in heavy-duty aluminium foil or plastic freezer wrap, or place inside a heavy-duty freezer bag. How long does a chunk of brick cheese last after being frozen and thawed? A chunk of brick cheese that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; a chunk of brick cheese that was thawed in the microwave or in cold water should be used immediately. Frozen cheese may become crumbly and lose some of its flavour; the thawed chunk of brick cheese will be best suited to cooked dishes, such as sauces, soups and casseroles.
Brie Cheese, Sold In Wrapped Wedge - Unopened Or Opened		1-2 Weeks	3 months	How long does a wedge of Brie cheese last? The exact answer to that question depends to a large extent on storage conditions - keep the cheese refrigerated at all times. To maximize the shelf life of a wedge of Brie cheese after opening, wrap the original packaging tightly in plastic wrap or aluminium foil; for even better results, wrap the cheese first in wax or parchment paper and then cover with plastic wrap before refrigerating. Properly stored, a wedge of Brie cheese will last about 1 to 2 weeks in the refrigerator. If a wedge of Brie cheese has mould on it, is it still safe to eat? If mould that was not a normal part of the manufacturing process appears on the Brie cheese, discard it entirely. To further extend the shelf life of Brie cheese, freeze it; when freezing, place the cheese in the freezer before the number of days shown for refrigerator storage has elapsed. Frozen cheese may become crumbly and lose some of its flavour; the thawed Brie cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. To freeze a wedge or block of Brie cheese: Cut the cheese into portions no larger than 1/2 pound each, and wrap tightly in heavy-duty aluminium foil or plastic freezer wrap, or place inside a heavy-duty freezer bag. How long does a wedge of Brie cheese last after being frozen and thawed? A wedge of Brie cheese that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; a wedge of Brie cheese that was thawed in the microwave or in cold water should be used immediately.
Butter - Unopened Or Opened Package		1 month after "sell by" date on package	6-12 Months	How long does butter last? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of butter, keep it refrigerated at all times. To maximize the shelf life of butter, keep refrigerated in airtight containers or wrapped tightly in plastic wrap or aluminium foil. To further maximize the shelf of butter, do not store butter in the moulded butter compartment of the refrigerator door, where the temperature is warmer - butter will keep much longer when stored in the main body of the refrigerator. How long does butter last in the refrigerator? Butter will generally last for about one month after the "sell-by" date on the package, assuming it has been continuously refrigerated. How long can butter be left out at room temperature? Butter may be kept at room temperature for 1 to 2 days, but it will begin to spoil rapidly if not refrigerated after that. To further extend the shelf life of butter, freeze it: to freeze butter, wrap tightly in heavy-duty aluminium foil or plastic freezer wrap, or place inside a heavy-duty freezer bag. How long does butter last in the freezer? Frozen salted butter will generally maintain best quality for about 12 months, while unsalted butter will stay at peak quality for about 6 months; in both cases, the butter will remain safe beyond those times. The freezer time shown is for best quality only - butter that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if butter is bad or spoiled? The best way is to smell and look at the butter: If butter develops an off odor, flavour or appearance, it should be discarded.
Cheddar Cheese, Shredded Or Sliced, Commercially Packaged — Unopened Package		1 week after date on package	3 months	Keep refrigerated; do not open package until ready to use. If cheese develops an off odor, flavour or appearance, it should be discarded; if mould appears, discard the entire package. To freeze, place original packaging in freezer; if freezing for longer than 2 months, place package inside a heavy-duty freezer bag in order to prevent freezer burn. Frozen cheese may lose some of its texture and flavour; the thawed cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Cheddar Cheese, Shredded Or Sliced, Commercially Packaged - Opened Package		5-7 Days	3 months	How long does an opened package of shredded cheddar cheese last in the fridge? The exact answer to that question depends to a large extent on storage conditions - keep shredded cheddar cheese refrigerated at all times. To maximize the shelf life of shredded cheddar cheese after opening, tightly seal original packaging or place the cheese in resealable plastic bags or airtight containers. Properly stored, an opened package of shredded cheddar cheese will last for about 5 to 7 days in the refrigerator. Once the package is opened, consume or freeze the shredded cheddar cheese within the time shown for refrigeration, even if the "Best By," "Best if Used By," or "Use By" date has not yet been reached. How long can shredded cheddar cheese be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); shredded cheddar cheese should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of opened shredded cheddar cheese, freeze it; when freezing, place shredded cheddar cheese in the freezer before the number of days shown for refrigerator storage has elapsed. Frozen cheddar cheese may lose some of its texture and flavour; the thawed cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. To freeze shredded cheddar cheese, tightly seal original packaging and place in freezer; if freezing for longer than 2 months, place package inside a heavy-duty freezer bag in order to prevent freezer burn.
Cheddar Cheese, Sold In Wrapped Chunk Or Block - Opened		3-4 Weeks	6 Months	How long does a chunk of cheddar cheese last once opened? The exact answer to that question depends to a large extent on storage conditions - keep the cheese refrigerated at all times. To maximize the shelf life of a chunk of cheddar cheese after opening, wrap the original packaging tightly in plastic wrap or aluminium foil; for even better results, wrap the cheese first in wax or parchment paper and then cover with plastic wrap before refrigerating. Properly stored, an opened chunk of cheddar cheese will last for 3 to 4 weeks in the refrigerator. How long does a chunk of cheddar cheese last in the freezer? Properly stored, it will maintain best quality for about 6 months, but will remain safe beyond that time. Is an opened chunk of cheddar cheese still safe after the "sell by" date or "best by date" on the package? Yes - after the cheese is opened, it will typically remain safe to use for 3 to 4 weeks, even if the "sell-by" or "best by" date on the package expires. If a chunk or block of cheddar cheese has mould on it, is it still safe to eat? Yes - cut away at least 1 inch around and below the mouldy area (do not touch mould with the knife) and re-cover the cheese in fresh wrap. Note: if mould appears in a package of shredded, sliced or crumbled cheddar cheese, the entire package should be discarded. To further extend the shelf life of cheddar cheese, freeze it; when freezing, place the cheese in the freezer before the number of days shown for refrigerator storage has elapsed. To freeze a chunk or block of cheddar cheese: Cut the cheese into portions no larger than 1/2 pound each, and wrap tightly in heavy-duty aluminium foil or plastic freezer wrap, or place inside a heavy-duty freezer bag. How long does a chunk of cheddar cheese last after being frozen and thawed? A chunk of cheddar cheese that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; a chunk of cheddar cheese that was thawed in the microwave or in cold water should be used immediately.
Chocolate Milk / Flavoured Milk, Pasteurized (Including Whole, 2% Varieties), Sold Refrigerated - Unopened Or Opened		1 week after "sell by" date on package	3 months	How long does chocolate milk last? The precise answer to that question depends to a large extent on storage conditions - to maximize the shelf life of chocolate milk, keep it refrigerated at all times. How long does chocolate milk last after the sell-by date? Chocolate milk will generally remain drinkable for about one week after the "sell-by" date on the package, assuming it has been continuously refrigerated; be sure to keep the temperature of your refrigerator at or below 40° F at all times. To maximize the shelf of chocolate milk, do not store it on the fridge door, as the temperature is too warm - the chocolate milk will last longer when they stored in the main body of the refrigerator, in its original package. How long can chocolate milk be left at room temperature? If kept at temperatures above 40 °F, chocolate milk will rapidly develop signs of spoilage; chocolate milk should be discarded if left out for more than 4 hours at room temperature. To further extend the shelf life of chocolate milk, freeze it; frozen chocolate milk will often become separated and the texture may become somewhat grainy, but it is usually acceptable for cooking and baking purposes. Freeze chocolate milk in an airtight container and leave at least 1/2 inch headspace at the top, as chocolate milk will expand when frozen; thaw in refrigerator. How long does chocolate milk last in the freezer? Properly stored, it will maintain best quality for about 4 months, but will remain safe beyond that time. The freezer time shown is for best quality only - chocolate milk that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if chocolate milk is bad? The best way is to smell and look at the chocolate milk: signs of bad chocolate milk are a sour smell, off colour and a thick or clumpy texture.
Cream Cheese, Sold In Foil-Wrapped Block - Opened Package		1-2 Weeks	2 Months	How long does cream cheese last once opened? The exact answer to that question depends to a large extent on storage conditions - to maximize the shelf life of cream cheese, keep it refrigerated at all times. How long does cream cheese last after the sell-by date? An opened package of cream cheese will generally last for about one to two weeks after the "sell-by" date on the package, assuming it has been continuously refrigerated. How long can cream cheese be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cream cheese should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of cream cheese, freeze it: to freeze cream cheese, wrap tightly in heavy-duty aluminium foil or plastic freezer wrap, or place inside a heavy-duty freezer bag. Frozen cream cheese may become crumbly and lose some of its flavour; the thawed cream cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. How long does cream cheese last in the freezer? Properly stored, it will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cream cheese that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cream cheese last after being frozen and thawed? Cream cheese that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; cream cheese that was thawed in the microwave or in cold water should be used immediately.
Cream Cheese, Sold In Foil-Wrapped Block - Unopened Package		1 month after date on package	2 Months	How long does an unopened package of cream cheese last? The exact answer depends to a large extent on storage conditions - to maximize the shelf life of cream cheese, keep it refrigerated at all times. How long does unopened cream cheese last after the "sell by" date or "best before" date? Cream cheese will generally keep for about 1 month after the "sell by" or " best before" date on the package, assuming it has been continuously refrigerated. How long does cream cheese last at room temperature? If kept at temperatures above 40 °F, cream cheese will rapidly develop signs of spoilage; cream cheese should be discarded if left for more than 2 hours at room temperature. To further extend the shelf life of opened cream cheese, freeze it: Unopened cream cheese sold in a foil-wrapped block may be frozen in its original packaging. Frozen cream cheese may become crumbly and lose some of its flavour; the thawed cream cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. How long does cream cheese last in the freezer? Properly stored, it will maintain best quality for about 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cream cheese that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does cream cheese last after being frozen and thawed? Cream cheese that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; cream cheese that was thawed in the microwave or in cold water should be used immediately.
Cream, Whipped - Homemade Using Fluid Cream		1 Day	1-2 Months	Keep refrigerated. To freeze, spoon mounds of whipped cream onto cookie sheet and place in freezer; when frozen, transfer to airtight container. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Custard, Made With Milk — Homemade		5-6 Days		Keep refrigerated in covered container. Does not freeze well.
Eggs - Cooked, Hard Boiled		1 Week		How long do hard boiled eggs last in the fridge? The exact answer to that question depends to a large extent on storage conditions - refrigerate hard boiled eggs within two hours of cooking. To maximize the shelf life of hard boiled eggs for safety and quality, refrigerate the hard boiled eggs in shallow airtight containers or resealable plastic bags or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, hard boiled eggs will last one week in the refrigerator. How long can hard boiled eggs be left at room temperature? Bacteria grow rapidly at temperatures between 40°F and 140°F; hard boiled eggs should be discarded if left out for more than 2 hours at room temperature. Can you freeze hard boiled eggs? Whole, hard boiled eggs do not freeze well; the whites will become tough and rubbery. You can freeze the cooked egg yolks of hard boiled eggs successfully as follows: (1) Place cooked yolks in covered airtight container or heavy-duty freezer bag; (2) Freeze yolks up to for 3 months for best quality. How to tell if hard boiled eggs are bad? The best way is to smell and look at the eggs; discard any discoloured eggs or eggs with an off smell or appearance, do not taste the eggs first. The easiest way to peel hard boiled eggs: Buy eggs at least 7 to 10 days before using them and peel eggs right after they've been cooked and cooled.
Eggs - Fresh, Raw, In The Shell		4-5 Weeks	10-12 Months	How long do raw eggs last in the fridge or freezer? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of eggs, keep refrigerated at all times. How long do raw eggs last after the expiration date or sell-by date? After eggs are purchased, they will maintain their best quality for about 3 weeks after the "sell by", "use by", "best by", or "expiration" date on the carton, assuming continuous refrigeration. To maximize the shelf life of eggs, do not store them in the moulded egg rack of the refrigerator door, as the temperature is too warm - the eggs will last much longer when they are stored in the main body of the refrigerator, in their purchased carton. How long can raw eggs be left at room temperature? Bacteria grow rapidly at temperatures between 40°F and 140 °F; raw eggs should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of eggs, freeze them; do not freeze eggs in their shells. To freeze whole eggs: (1) Remove eggs from their shells; (2) Pierce yolks and gently mix in 1/2 teaspoon of salt for every one cup of raw eggs (if using eggs for main dishes) or 1 tablespoon of sugar (if using for baking or desserts); (3) Place in covered airtight containers or heavy-duty freezer bags and freeze. How long do raw eggs last in the freezer? Properly stored, they will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - eggs that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long do eggs last in the fridge if they are hard boiled? Hard boiled eggs will generally stay good for one week in the refrigerator; freezing hard boiled eggs is not recommended. How to tell if eggs are bad? The best way is to crack open the egg and examine it: a fresh egg will have a round, high bright yellow yolk and the white will be thick and cloudy; a bad egg will have a very flat yolk and the white will be runny and watery.
Farmer Cheese — Opened Package		5-7 Days	6 Months	Keep refrigerated and tightly covered. If cheese develops an off odor, flavour or appearance, it should be discarded for quality purposes; if mould appears, discard the entire package. To freeze, tightly seal original package and place inside a heavy-duty freezer bag in order to prevent freezer burn. Frozen farmer cheese may lose some of its texture and flavour; the thawed cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Farmer Cheese — Unopened Package		1 week after date on container	6 Months	Keep refrigerated and tightly covered. If cheese develops an off odor, flavour or appearance, it should be discarded for quality purposes; if mould appears, discard the entire package. To freeze, tightly seal original package and place in freezer; if freezing for longer than 2 months, place package inside a heavy-duty freezer bag in order to prevent freezer burn. Frozen farmer cheese may lose some of its texture and flavour; the thawed cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.

Feta Cheese, Packaged In Brine		3 Months	3 Months	Keep refrigerated and covered in brine contained in package. If additional brine is needed, mix one pound of salt (preferably kosher) with one gallon of water — milk may also be used instead of brine. If mould appears on the feta cheese, discard it entirely. To freeze, drain feta and wrap tightly in plastic freezer wrap or place in heavy-duty freezer bag. Frozen feta may lose some of its texture and flavour; the thawed cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Goat Cheese/ Chevre, Fresh — Unopened Or Opened		2-3 Weeks	3 Months	Keep refrigerated and tightly covered. If cheese develops an off odor, flavour or appearance, it should be discarded for quality purposes; if mould appears on goat cheese, discard the cheese entirely. To freeze, wrap tightly in plastic freezer wrap or place in heavy-duty freezer bag. Frozen goat cheese may lose some of its texture and flavour; the thawed cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Heavy Cream, Plain Pasteurized - Opened Package		5-7 Days	4 Months	How long does heavy cream last once opened? The precise answer depends to a large extent on storage conditions — keep opened heavy cream refrigerated and tightly closed. To maximize the shelf of opened heavy cream, do not store it on the fridge door, as the temperature is too warm - the opened heavy cream will last longer when stored in the main body of the refrigerator, in its original package. How long does opened heavy cream last in the refrigerator? Heavy cream that has been continuously refrigerated will keep for about 5 to 7 days after opening. To further extend the shelf life of heavy cream, freeze it: frozen heavy cream will not whip well when thawed, will often become separated and the texture may become somewhat grainy, but it is usually acceptable for cooking and baking purposes. Freeze heavy cream in an airtight container and leave at least 1/2 inch headspace at the top, as heavy cream will expand when frozen; thaw in refrigerator. How long does heavy cream last in the freezer? Properly stored, it will maintain best quality for about 4 months, but will remain safe beyond that time. The freezer time shown is for best quality only - heavy cream that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if heavy cream is bad? The best way is to smell and look at the heavy cream: signs of bad heavy cream are an off smell, off colour and a thick or clumpy texture.
Light Cream, Plain Pasteurized - Opened Package		5-7 Days	4 Months	How long does light cream last once opened? The precise answer depends to a large extent on storage conditions — keep opened light cream refrigerated and tightly closed. To maximize the shelf of opened light cream, do not store it on the fridge door, as the temperature is too warm - the opened light cream will last longer when stored in the main body of the refrigerator, in its original package. How long does opened light cream last in the refrigerator? Light cream that has been continuously refrigerated will keep for about 5 to 7 days after opening. To further extend the shelf life of light cream, freeze it: frozen light cream will not whip well when thawed, will often become separated and the texture may become somewhat grainy, but it is usually acceptable for cooking and baking purposes. Freeze light cream in an airtight container and leave at least 1/2 inch headspace at the top, as light cream will expand when frozen; thaw in refrigerator. How long does light cream last in the freezer? Properly stored, it will maintain best quality for about 4 months, but will remain safe beyond that time. The freezer time shown is for best quality only - light cream that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if light cream is bad? The best way is to smell and look at the light cream: signs of bad light cream are an off smell, off colour and a thick or clumpy texture.
Light Cream, Plain Pasteurized - Unopened Package		1-2 weeks after date on package	4 Months	How long does unopened light cream last? The precise answer to that question depends to a large extent on storage conditions - to maximize the shelf life of unopened light cream, keep it refrigerated at all times. How long does unopened light cream last in the fridge? Unopened light cream will generally stay at best quality for about 1 to 2 weeks after the date on the package, assuming it has been continuously refrigerated. To maximize the shelf of unopened light cream, do not store it on the fridge door, as the temperature is too warm - the unopened light cream will last longer when stored in the main body of the refrigerator, in its original package. To further extend the shelf life of light cream, freeze it: frozen light cream will not whip well when thawed, will often become separated and the texture may become somewhat grainy, but it is usually acceptable for cooking and baking purposes. Freeze light cream in an airtight container and leave at least 1/2 inch headspace at the top, as light cream will expand when frozen; thaw in refrigerator. How long does light cream last in the freezer? Properly stored, it will maintain best quality for about 4 months, but will remain safe beyond that time. The freezer time shown is for best quality only - light cream that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if light cream is bad? The best way is to smell and look at the light cream: signs of bad light cream are an off smell, off colour and a thick or clumpy texture.
Milk, Evaporated, Commercially Canned - Opened	18-24 Months (Best Quality) (Unopened)	4-6 Days		How long does a can of evaporated milk last once opened? The precise answer depends to a large extent on storage conditions - keep opened evaporated milk refrigerated and tightly covered. To maximize the shelf life of canned evaporated milk after opening, covered opened can tightly with a plastic wrap or lid, or with aluminium foil. How long does opened canned evaporated milk last in the refrigerator? Evaporated milk that has been continuously refrigerated will keep for about 4 to 6 days. Is canned evaporated milk safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned evaporated milk will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the evaporated milk will remain at peak quality. Can you freeze evaporated milk? Freezing is not recommended, as the evaporated milk will separate and become watery when thawed. How can you tell if canned evaporated milk is bad or spoiled? The best way is to smell and look at the canned evaporated milk: if the canned evaporated milk develops an off odor, flavour or appearance, it should be discarded. Discard all canned evaporated milk from cans that are leaking, rusting, bulging or severely dented.
Milk, Powdered, Dry — Reconstituted Into Liquid Milk		5-7 Days	3 Months	Keep refrigerated. Freeze in airtight container and leave at least 1/2 inch headspace at the top, as milk will expand when frozen; thaw in refrigerator. Freezer time shown is for best quality only— foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Milk, Regular, Pasteurized (Including Whole, Skim, 2%, 1% Varieties), Sold Refrigerated - Unopened Or Opened		5-7 days after "sell by" date on package	3-4 Months	How long does milk last? The precise answer to that question depends to a large extent on storage conditions - to maximize the shelf life of milk, keep it refrigerated at all times. How long does milk last after the sell-by date? Milk will generally remain drinkable for about one week after the "sell-by" date on the package, assuming it has been continuously refrigerated; be sure to keep the temperature of your refrigerator at or below 40° F at all times. To maximize the shelf of milk, do not store it on the fridge door, as the temperature is too warm - the milk will last longer when they stored in the main body of the refrigerator, in its original package. How long can milk be left at room temperature? If kept at temperatures above 40 °F, milk will rapidly develop signs of spoilage; milk should be discarded if left out for more than 4 hours at room temperature. To further extend the shelf life of milk, freeze it; frozen milk will often become separated and the texture may become somewhat grainy, but it is usually acceptable for cooking and baking purposes. Freeze milk in an airtight container and leave at least 1/2 inch headspace at the top, as milk will expand when frozen; thaw in refrigerator. How long does milk last in the freezer? Properly stored, it will maintain best quality for about 4 months, but will remain safe beyond that time. The freezer time shown is for best quality only - milk that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if milk is bad? The best way is to smell and look at the milk: signs of bad milk are a sour smell, an off-white or yellowish tinge to the colour and a thick or clumpy texture.
Milk, Sweetened, Condensed, Commercially Canned - Opened	1 Year (Unopened)	4-6 Days		How long does a can of sweetened condensed milk last once opened? The precise answer depends to a large extent on storage conditions - keep opened sweetened condensed milk refrigerated and tightly covered. To maximize the shelf life of canned sweetened condensed milk after opening, covered opened can tightly with a plastic wrap or lid, or with aluminium foil. How long does opened canned sweetened condensed milk last in the refrigerator? Sweetened condensed milk that has been continuously refrigerated will keep for about 4 to 6 days. Is canned sweetened condensed milk safe to use after the "expiration" date on the package? Yes, provided it has been stored properly, the can or package is undamaged, and there are no signs of spoilage - commercially canned sweetened condensed milk will typically carry a "Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the sweetened condensed milk will remain at peak quality. Can you freeze sweetened condensed milk? Freezing is not recommended, as the sweetened condensed milk will separate and become watery when thawed. How can you tell if canned sweetened condensed milk is bad or spoiled? The best way is to smell and look at the canned sweetened condensed milk: if the canned sweetened condensed milk develops an off odor, flavour or appearance, it should be discarded. Discard all canned sweetened condensed milk from cans that are leaking, rusting, bulging or severely dented.
Milk, Ultra-High-Temperature (UHT), Sold Unrefrigerated — Opened	2-4 weeks after date on package (Unopened)	7-10 Days		How long does shelf-stable, ultra-high temperature (UHT) milk last once opened? The precise answer depends to a large extent on storage conditions — keep opened shelf-stable UHT milk (UHT milk that has been sold unrefrigerated) refrigerated and tightly closed. To maximize the shelf of opened shelf-stable UHT milk, do not store it on the fridge door, as the temperature is too warm - the opened shelf-stable UHT milk will last longer when stored in the main body of the refrigerator, in its original package. How long does opened shelf-stable UHT milk last in the refrigerator? Shelf-stable UHT milk that has been continuously refrigerated will keep for about 7 to 10 days after opening. How can you tell if opened shelf-stable UHT milk is bad or spoiled? The best way is to smell and look at the shelf-stable UHT milk: if the shelf-stable UHT milk develops an off odor, flavour or appearance it should be discarded.
Mozzarella Cheese, Fresh, High Moisture (Including Buffalo/Buffalo Varieties) — Unopened Or Opened		1-2 Weeks	3 Months	Keep refrigerated and covered in liquid contained in package. If cheese develops an off odor, flavour or appearance, it should be discarded; if mould appears, discard the cheese entirely. To freeze, drain cheese and wrap tightly in plastic freezer wrap or aluminium foil or place in heavy-duty freezer bag. Frozen cheese may lose some of its texture and flavour; the thawed cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Mozzarella Cheese, Low Moisture Variety - Sliced At Grocery Deli Counter		2-3 Weeks	2 Months	How long does sliced Mozzarella deli cheese last? The exact answer to that question depends to a large extent on storage conditions - after purchasing from the deli, keep sliced Mozzarella deli cheese refrigerated at all times. How long does sliced Mozzarella deli cheese last after the sell-by date? After sliced Mozzarella deli cheese is purchased from the deli, it may be refrigerated for 2 to 3 weeks. Unopened sliced Mozzarella deli cheese may be kept in its original store deli packaging when refrigerating; to maximize the shelf life of the cheese, do not open the package until ready to use. To further extend the shelf life of sliced Mozzarella deli cheese, freeze; when freezing, place the cheese in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of sliced Mozzarella deli cheese in the freezer by wrapping the sliced cheese tightly in heavy-duty aluminium foil or plastic freezer wrap or place in heavy-duty freezer bags. How long does sliced Mozzarella deli cheese last in the freezer? Properly stored, it will maintain best quality for 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - Mozzarella deli cheese that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does sliced Mozzarella deli cheese last after being frozen and thawed? Sliced Mozzarella deli cheese that has been defrosted can be kept for an additional 3 to 4 days in the refrigerator before using; for best results, thaw cheese in the refrigerator. Frozen cheese may become crumbly and lose some of its flavour; the thawed slice Mozzarella deli cheese will be best suited to cooked dishes, such as sauces, soups and casseroles.
Mozzarella Cheese, Shredded Or Sliced, Commercially Packaged — Unopened Package		1 week after date on package	3 Months	Keep refrigerated; do not open package until ready to use. If cheese develops an off odor, flavour or appearance, it should be discarded; if mould appears, discard the entire package. To freeze, place original packaging in freezer; if freezing for longer than 2 months, place package inside a heavy-duty freezer bag in order to prevent freezer burn. Frozen cheese may lose some of its texture and flavour; the thawed cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Mozzarella Cheese, Shredded Or Sliced, Commercially Packaged - Opened Package		5-7 Days	3 Months	How long does an opened package of shredded mozzarella cheese last in the fridge? The exact answer to that question depends to a large extent on storage conditions - keep shredded mozzarella cheese refrigerated at all times. To maximize the shelf life of shredded mozzarella cheese after opening, tightly seal original packaging or place the cheese in resealable plastic bags or airtight containers. Properly stored, an opened package of shredded mozzarella cheese will last for about 5 to 7 days in the refrigerator. Once the package is opened, consume or freeze the shredded mozzarella cheese within the time shown for refrigeration, even if the "Best By," "Best if Used By," or "Use By" date has not yet been reached. How long can shredded mozzarella cheese be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); shredded mozzarella cheese should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of opened shredded mozzarella cheese, freeze it; when freezing, place shredded mozzarella cheese in the freezer before the number of days shown for refrigerator storage has elapsed. Frozen mozzarella cheese may lose some of its texture and flavour; the thawed cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. How long does shredded mozzarella cheese last in the freezer? Properly stored, it will maintain best quality for about 3 months, but will remain safe beyond that time. To freeze shredded mozzarella cheese, tightly seal original packaging and place in freezer; if freezing for longer than 2 months, place package inside a heavy-duty freezer bag in order to prevent freezer burn. How can you tell if shredded mozzarella cheese is bad or spoiled? The best way is to smell and look at the cheese: if cheese develops an off odor, flavour or appearance, it should be discarded; if mould appears, discard all of the shredded mozzarella cheese.
Parmesan Cheese, Grated, Sold Unrefrigerated, Commercially Packaged - Opened		9-12 Months	9-12 Months	How long does opened grated Parmesan cheese last? The precise answer to that question depends to a large extent on storage conditions - to maximize the shelf life of opened grated Parmesan cheese, keep it tightly covered and store it in a cool, dry area. To further maximize the shelf life of opened grated Parmesan cheese, keep it in the refrigerator. How long does opened grated Parmesan cheese last in the fridge? Opened grated Parmesan cheese will generally stay at best quality for about 9-12 months in the refrigerator. To further extend the shelf life of opened grated Parmesan cheese, freeze it: to freeze, place grated Parmesan cheese in covered airtight containers or heavy-duty freezer bags. Frozen Parmesan cheese may lose some of its texture and flavour; the thawed cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. How long does grated Parmesan cheese last in the freezer? Properly stored, it will maintain best quality for about 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - grated Parmesan cheese that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How can you tell if grated Parmesan cheese is bad or spoiled? The best way is to smell and look at the cheese: if cheese develops an off odor, flavour or appearance, it should be discarded; if mould appears, discard all of the grated Parmesan cheese.

Parmesan Cheese, Grated, Sold Unrefrigerated, Commercially Packaged - Unopened	9-12 Months	9-12 Months	9-12 Months	How long does unopened grated Parmesan cheese last? The precise answer to that question depends to a large extent on storage conditions - to maximize the shelf life of unopened grated Parmesan cheese, keep it in a cool, dry area. How long does unopened grated Parmesan cheese last at room temperature? Unopened grated Parmesan cheese that has been sold unrefrigerated will generally stay at best quality for about 9-12 months at room temperature. How long does unopened grated Parmesan cheese last in the fridge? Unopened grated Parmesan cheese will generally stay at best quality for about 9-12 months in the refrigerator. To further extend the shelf life of unopened grated Parmesan cheese, freeze it: to freeze, place grated Parmesan cheese in covered airtight containers or heavy-duty freezer bags. Frozen Parmesan cheese may lose some of its texture and flavour; the thawed cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. How long does grated Parmesan cheese last in the freezer? Properly stored, it will maintain best quality for about 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - grated Parmesan cheese that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How can you tell if grated Parmesan cheese is bad or spoiled? The best way is to smell and look at the cheese: if cheese develops an off odor, flavour or appearance, it should be discarded; if mould appears, discard all of the grated Parmesan cheese.
Parmesan Cheese, Sold In Wrapped Chunk Or Block - Unopened Or Opened		1 Year	10-12 Months	How long does a chunk of Parmesan cheese last? The exact answer to that question depends to a large extent on storage conditions - keep the cheese refrigerated at all times. To maximize the shelf life of a chunk of Parmesan cheese after opening, wrap the original packaging tightly in plastic wrap or aluminium foil; for even better results, wrap the cheese first in wax or parchment paper and then cover with plastic wrap before refrigerating. Properly stored, a chunk of Parmesan cheese will last for 1 year in the refrigerator. Is a chunk of Parmesan cheese still safe after the ? sell by date or "best by date" on the package? Yes - provided it is properly stored, it will typically remain safe to use for 1 year, even if the "sell-by" or "best by date on the package expires. Note: if mould appears in a package of shredded, sliced or crumbled Parmesan cheese, the entire package should be discarded. To further extend the shelf life of Parmesan cheese, freeze it; when freezing, place the cheese in the freezer before the number of days shown for refrigerator storage has elapsed. To freeze a chunk or block of Parmesan cheese: Cut the cheese into portions no larger than 1/2 pound each, and wrap tightly in heavy-duty aluminium foil or plastic freezer wrap, or place inside a heavy-duty freezer bag. How long does a chunk of Parmesan cheese last in the freezer? Properly stored, it will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only - Parmesan cheese that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does a chunk of Parmesan cheese last after being frozen and thawed? A chunk of Parmesan cheese that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; a chunk of Parmesan cheese that was thawed in the microwave or in cold water should be used immediately.
Pasteurized Processed Cheese Spread, Dip, Or Sauce, Commercially Packaged —		3-4 Weeks	3 Months	Keep refrigerated and tightly covered. If processed cheese product develops an off odor, flavour or appearance, it should be discarded for quality purposes. Freeze in airtight containers or place in heavy-duty freezer bags. Frozen cheese product may lose some of its texture and flavour; the thawed cheese product will be best suited to cooked dishes, such as sauces, soups and casseroles. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Pasteurized Processed Cheese Spread, Dip, Or Sauce, Commercially Packaged — Unopened	5-6 months or date on package		3 Months	Store in cool, dry area — if package was sold refrigerated, store in refrigerator for best results. If cheese product develops an off odor, flavour or appearance, it should be discarded for quality purposes. Freeze in airtight containers or place in heavy-duty freezer bags. Frozen cheese product may lose some of its texture and flavour; the thawed cheese product will be best suited to cooked dishes, such as sauces, soups and casseroles. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Powdered Milk, Dry, Nonfat - Opened Package	3 Months		3 Years	How long does a package of opened powdered milk last? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened powdered milk store in a cool, dry area and keep tightly closed. How long does opened powdered milk last at room temperature? Properly stored, a package of opened powdered milk will generally stay at best quality for about 3 months at room temperature. Is powdered milk safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged powdered milk will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the powdered milk will remain at peak quality. Can you keep opened powdered milk in the freezer? Yes, to further extend the shelf life of opened powdered milk, freeze it; place the opened powdered milk inside covered airtight containers or heavy-duty freezer bags. How long does opened powdered milk last in the freezer? Properly stored, it will maintain best quality for about 3 years, but will remain safe beyond that time. The freezer time shown is for best quality only — powdered milk that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How can you tell if powdered milk is bad or spoiled? The best way is to smell and look at the opened powdered milk: if the opened powdered milk develops an off odor, flavour or appearance, or if mould or insects appear, it should be discarded.
Powdered Milk, Dry, Nonfat - Unopened Package	12-18 months (best quality)		3 Years	How long does a package of unopened powdered milk last? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of unopened powdered milk store in a cool, dry area. How long does unopened powdered milk last at room temperature? Properly stored, a package of unopened powdered milk will generally stay at best quality for about 12 to 18 months at room temperature. Is unopened powdered milk safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged powdered milk will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the powdered milk will remain at peak quality. Storage time shown is for best quality only - after that, the powdered milk's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly, the package is undamaged, and there are no signs of spoilage. Can you keep powdered milk in the freezer? Yes, to further extend the shelf life of powdered milk, freeze it; place the unopened powdered milk inside heavy-duty freezer bags. How long does powdered milk last in the freezer? Properly stored, it will maintain best quality for about 3 years, but will remain safe beyond that time. The freezer time shown is for best quality only — powdered milk that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How can you tell if powdered milk is bad or spoiled? The best way is to smell and look at the powdered milk: if the powdered milk develops an off odor, flavour or appearance, or if mould or insects appear, it should be discarded.
Provolone Cheese - Sliced At Grocery Deli Counter		2-3 Weeks	2 Months	How long does sliced Provolone deli cheese last? The exact answer to that question depends to a large extent on storage conditions - after purchasing from the deli, keep sliced Provolone deli cheese refrigerated at all times. How long does sliced Provolone deli cheese last after the sell-by date? After sliced Provolone deli cheese is purchased from the deli, it may be refrigerated for 2 to 3 weeks - the "sell-by" date on the package may expire during that storage period, but the cheese will remain safe to use after the sell by date if it has been properly stored. Unopened sliced Provolone deli cheese may be kept in its original store deli packaging when refrigerating; to maximize the shelf life of the cheese, do not open the package until ready to use. To further extend the shelf life of sliced Provolone deli cheese, freeze; when freezing, place the cheese in the freezer before the number of days shown for refrigerator storage has elapsed. You can maximize the shelf life of sliced Provolone deli cheese in the freezer by wrapping the sliced cheese tightly in heavy-duty aluminium foil or plastic freezer wrap or place in heavy-duty freezer bags. How long does sliced Provolone deli cheese last in the freezer? Properly stored, it will maintain best quality for 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - Provolone deli cheese that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does sliced Provolone deli cheese last after being frozen and thawed? Sliced Provolone deli cheese that has been defrosted can be kept for an additional 3 to 4 days in the refrigerator before using; for best results, thaw cheese in the refrigerator. Frozen cheese may become crumbly and lose some of its flavour; the thawed slice Provolone deli cheese will be best suited to cooked dishes, such as sauces, soups and casseroles.
Sour Cream - Opened Package		2 Weeks		How long does sour cream last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened sour cream, keep it refrigerated at all times. To maximize the shelf life of sour cream after opening, keep refrigerated and tightly covered, either in the original packaging or in an airtight container. Properly stored, an opened package of sour cream will generally last for about two weeks after opening, assuming it has been continuously refrigerated. How long can sour cream be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); sour cream should be discarded if left out for more than 2 hours at room temperature. Can you freeze sour cream? Freezing is not recommended, as the texture of sour cream once thawed will be watery and clumpy. How can you tell if sour cream is bad or spoiled? The best way is to smell and look at the sour cream: discard any sour cream with an off smell or appearance or if mould appears; do not taste the sour cream first.
Sour Cream - Unopened Package		10-14 days after date on package		How long does an unopened package of sour cream last? The exact answer depends to a large extent on storage conditions - to maximize the shelf life of sour cream, keep it refrigerated at all times. How long does unopened sour cream last after the sell-by date? Sour cream will generally keep for one to two weeks after the "sell-by" date on the package, assuming it has been continuously refrigerated; be sure that the temperature of your refrigerator remains at or below 40 ? at all times. How long does sour cream last at room temperature? If kept at temperatures above 40 °F, sour cream will rapidly develop signs of spoilage; sour cream should be discarded if left for more than 2 hours at room temperature. Can you freeze sour cream? Freezing is not recommended, as the texture of sour cream once thawed will be watery and clumpy. How long does sour cream last once opened? Sour cream will generally last for about 2 weeks after opening, assuming it has been continuously refrigerated. How can you tell if sour cream is bad or spoiled? The best way is to smell and look at the sour cream: discard any sour cream with an off smell or appearance or if mould appears; do not taste the sour cream first.
Swiss Cheese, Shredded Or Sliced, Commercially Packaged - Opened Package		5-7 Days	3 months	How long does an opened package of shredded Swiss cheese last in the fridge? The exact answer to that question depends to a large extent on storage conditions - keep shredded Swiss cheese refrigerated at all times. To maximize the shelf life of shredded Swiss cheese after opening, tightly seal original packaging or place the cheese in resealable plastic bags or airtight containers. Properly stored, an opened package of shredded Swiss cheese will last for about 5 to 7 days in the refrigerator. Once the package is opened, consume or freeze the shredded Swiss cheese within the time shown for refrigeration, even if the "Best By," "Best if Used By," or "Use By" date has not yet been reached. How long can shredded Swiss cheese be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); shredded Swiss cheese should be discarded if left out for more than 2 hours at room temperature. To further extend the shelf life of opened shredded Swiss cheese, freeze it; when freezing, place shredded Swiss cheese in the freezer before the number of days shown for refrigerator storage has elapsed. Frozen Swiss cheese may lose some of its texture and flavour; the thawed cheese will be best suited to cooked dishes, such as sauces, soups and casseroles. To freeze shredded Swiss cheese, tightly seal original packaging and place in freezer; if freezing for longer than 2 months, place package inside a heavy-duty freezer bag in order to prevent freezer burn. How long does shredded Swiss cheese last in the freezer? Properly stored, it will maintain best quality for about 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - shredded Swiss cheese that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How can you tell if shredded Swiss cheese is bad or spoiled? The best way is to smell and look at the cheese: if cheese develops an off odor, flavour or appearance, it should be discarded; if mould appears, discard all of the shredded Swiss cheese.
Swiss Cheese, Sold In Wrapped Block - Unopened		6 Months	6-8 Months	How long does an unopened chunk of Swiss cheese last? The exact answer to that question depends to a large extent on storage conditions - keep the unopened chunk of cheese refrigerated at all times. An unopened chunk of Swiss cheese may be kept in its original packaging when refrigerating; to maximize the shelf life, do not open the package until ready to use. Properly stored, an unopened chunk of Swiss cheese will last for about 6 months in the refrigerator. Is an unopened chunk of Swiss cheese still safe after the ? sell by date or "best by date" on the package? Yes -the unopened Swiss cheese will typically remain safe to use for about 6 months, even if the "sell-by" or "best by date on the package expires. If an unopened chunk or block of Swiss cheese has mould on it, is it still safe to eat? Yes - cut away at least 1 inch around and below the mouldy area (do not touch mould with the knife) and re-cover the cheese in fresh wrap. Note: if mould appears in a package of shredded, sliced or crumbled Swiss cheese, the entire package should be discarded. To further extend the shelf life of Swiss cheese, freeze it; when freezing, place the cheese in the freezer before the number of days shown for refrigerator storage has elapsed. To freeze an unopened chunk or block of Swiss cheese: Cut the cheese into portions no larger than 1/2 pound each, and wrap tightly in heavy-duty aluminium foil or plastic freezer wrap, or place inside a heavy-duty freezer bag. How long does an unopened chunk of Swiss cheese last in the freezer? Properly stored, it will maintain best quality for about 6 to 8 months, but will remain safe beyond that time. The freezer time shown is for best quality only - Swiss cheese that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does an unopened chunk of Swiss cheese last after being frozen and thawed? An unopened chunk of Swiss cheese that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; an unopened chunk of Swiss cheese that was thawed in the microwave or in cold water should be used immediately. Frozen cheese may become crumbly and lose some of its flavour; the thawed chunk of Swiss cheese will be best suited to cooked dishes, such as sauces, soups and casseroles.
Whipped Cream (Real), Sold In Aerosol Can - Unopened Or Opened		3-4 Weeks		Keep refrigerated. Does not freeze well.
Yogurt (Yoghurt), Commercially Frozen — Unopened			2-4 Months	Store in original container and keep frozen at all times. If frozen yogurt thaws completely, discard it— do not refreeze, as harmful bacteria may develop. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Yogurt (Yoghurt), Commercially Frozen - Opened			1-2 Months	Keep frozen at all times. After opening, place plastic wrap over the surface of exposed yogurt before re-closing the package; this will minimize the formation of ice crystals and prevent the loss of texture. If frozen yogurt thaws completely, discard it- do not refreeze, as harmful bacteria may develop. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Yogurt (Yoghurt), Commercially Packaged, Sold Refrigerated - Unopened Or Opened Package		1-2 weeks after "sell by" date on package	1-2 Months	How long does yogurt last in the fridge? The precise answer to that question depends to a large extent on storage conditions - keep yogurt refrigerated and tightly covered at all times. How long does yogurt last after the sell-by date? Yogurt that has been continuously refrigerated will usually keep for at least 1 to 2 weeks after the "sell by" date on the package. How long does yogurt remain at peak quality after opening? Opened yogurt will typically stay at peak quality for 5 to 7 days after opening, but will generally remain safe to consume for at least 1 to 2 weeks after the "sell by" date on the package, provided it has been properly stored- discard entire package if any sign of mould appears. How long can yogurt be left at room temperature? Bacteria grow rapidly at temperatures between 40°F and 140°F; yogurt should be discarded if left out for more than 2 hours at room temperature. Can you freeze yogurt? Yes - to further extend the shelf life of yogurt, freeze it in a covered airtight container or heavy-duty freezer bag. How long does yogurt last in the freezer? Properly stored, it will maintain best quality for 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - yogurt that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does yogurt last after being frozen and thawed? Yogurt that has been defrosted in the fridge can be kept for an additional 3 to 4 days in the refrigerator before using; yogurt that was thawed in the microwave or in cold water should be used immediately. How to tell if yogurt is bad? The best way is to smell and look at the yogurt: signs of spoilage include a highly runny and watery consistency, a clumpy texture and a sour smell; if any sign of mould appears, discard the entire package, do not taste the yogurt first.

7 Snacks Shelf Life

These is the shelf life of most snacks, both pre-packaged and raw.

	Pantry	Refrigerator	Freezer	Food Tips
Baking Powder - Opened Package	6 Months 18 Months (Unopened)			How long does baking powder last once opened? The precise answer to the question depends to a large extent on storage conditions; store in cool, dry area. To maximize the shelf life of opened baking powder, keep the package tightly sealed after opening. How long does opened baking powder last at room temperature? Properly stored, opened baking powder will generally stay at best quality for about 6 months. Is baking powder safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged — commercially packaged baking powder will typically carry a "Best By," "Best if Used By," "Best Before," or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the baking powder will remain at peak quality. How can you tell whether opened baking powder is still good to use? To test whether opened baking powder is still potent enough to be effective: add one teaspoon of baking powder to one-third cup of hot water - if mixture bubbles, the baking powder is still potent enough to use.
Baking Soda - Opened Package	6 Months 2 Years (Unopened)			How long does baking soda last once opened? The precise answer to the question depends to a large extent on storage conditions; store in cool, dry area. To maximize the shelf life of opened baking soda, keep the package tightly sealed after opening. How long does opened baking soda last at room temperature? Properly stored, opened baking soda will generally stay at best quality for about 6 months. Is baking soda safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged — commercially packaged baking soda will typically carry a "Best By," "Best if Used By," "Best Before," or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the baking soda will remain at peak quality. How can you tell whether opened baking soda is still good to use? To test whether opened baking soda is still potent enough to be effective: add one teaspoon of baking soda to 3 tablespoons of vinegar - if mixture bubbles, the baking soda is still potent enough to use.
Biscuits, Freshly Baked - Homemade Or Bakery	1-2 Days	1 Week	2-3 Months	How long do biscuits last? The precise answer to that question depends to a large extent on storage conditions - keep freshly baked biscuits in a dry area. To maximize the shelf life of biscuits, cover with foil or plastic wrap or place in plastic bag to prevent drying out. Properly stored, freshly baked biscuits will last for about 1 to 2 days at normal room temperature. How long do biscuits last in the fridge? Freshly baked biscuits will keep well for about 1 week in the fridge when properly stored. Can you freeze biscuits? Yes, to freeze: wrap biscuits tightly with aluminium foil or plastic freezer wrap, or place in heavy-duty freezer bag. How long do biscuits last in the freezer? Properly stored, they will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - biscuits that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if biscuits are bad or spoiled? The best way is to smell and look at the biscuits: discard any that have an off smell or appearance; if mould appears, discard the biscuits.
Blackberry Jam, Commercially Jarred - Opened	2 years (best quality) (Unopened)	1 year (best quality)		How long does blackberry jam last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened blackberry jam, keep it refrigerated and tightly covered. How long does opened blackberry jam last in the refrigerator? Blackberry jam that has been continuously refrigerated will generally stay at best quality for about 1 year. Is opened blackberry jam safe to use after the expiration date on the jar? Yes, provided it has been stored properly, the jar is undamaged, and there are no signs of spoilage - commercially jarred blackberry jam will typically carry a Best By," "Best if Used By," Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the blackberry jam will remain at peak quality. The storage time shown for opened blackberry jam is for best quality only - after that, the jam's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been kept continuously refrigerated, the jar is undamaged, and there are no signs of spoilage. How can you tell if opened blackberry jam is bad or spoiled? The best way is to smell and look at the blackberry jam: if the jam develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Bread Crumbs, Dried, Commercially Packaged — Unopened Or Opened Package	1 Year		1 Year	Store in cool, dry area; keep tightly covered after opening. Freezing is recommended in hot, humid environments. Storage time shown is for best quality only — after that, the bread crumbs' texture, colour or flavour may change, but in most cases, they will still be safe to consume if they have been stored properly. If bread crumbs develop an off odor, flavour or appearance, they should be discarded for quality purposes; if mould appears, discard entire product. "Best By," "Best if Used By," and "Use By" dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality — in most cases, the unopened bread crumbs will still be safe to consume after that date, as long as they have been stored properly and the package is not damaged. Freeze in covered airtight containers or heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Cheesecake, Freshly Baked - Homemade Or Bakery		1 Week	2-3 Months	How long does cheesecake last? The precise answer to that question depends to a large extent on storage conditions - keep freshly baked cheesecake refrigerated. How long can cheesecake be left at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); cheesecake should be discarded if left out for more than 2 hours at room temperature. How long does cheesecake last in the fridge? Freshly baked cheesecake will keep for about 1 week in the fridge; refrigerate covered loosely with aluminium foil or plastic wrap. Can you freeze cheesecake? Yes, to freeze: wrap cheesecake tightly with aluminium foil or plastic freezer wrap, or place in heavy-duty freezer bag. How long does cheesecake last in the freezer? Properly stored, it will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cheesecake that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cheesecake is bad or spoiled? The best way is to smell and look at the cheesecake: discard any that has an off smell or appearance; if mould appears, discard the cheesecake.
Cherry Pie, Freshly Baked - Homemade Or Bakery	2 Days	4-5 Days	6-8 Months	How long does cherry pie last? The precise answer to that question depends to a large extent on storage conditions - keep freshly baked cherry pie in a dry area. To maximize the shelf life of cherry pie, cover loosely with foil or plastic wrap. How long does cherry pie last at room temperature? Properly stored, freshly baked cherry pie will last for about 2 days at normal room temperature. How long does cherry pie last in the fridge? Freshly baked cherry pie will keep well for about 4 to 5 days in the refrigerator; cover loosely with foil or plastic wrap. Can you freeze cherry pie? Yes, to freeze: wrap cherry pie tightly with aluminium foil or plastic freezer wrap, or place in heavy-duty freezer bag. How long does cherry pie last in the freezer? Properly stored, it will maintain best quality for about 6 to 8 months, but will remain safe beyond that time. The freezer time shown is for best quality only - cherry pie that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if cherry pie is bad or spoiled? The best way is to smell and look at the cherry pie: discard any that has an off smell or appearance; if mould appears, discard the cherry pie.
Chocolate - Milk Chocolate	1 year (best quality)		1 year (best quality)	How long does milk chocolate last? The precise answer depends to a large extent on storage conditions - store milk chocolate in a cool, dry area. To maximize the shelf life of milk chocolate, store at a room temperature between 60°F -75°F and keep milk chocolate tightly wrapped after opening. How long does milk chocolate last at room temperature? Properly stored, milk chocolate will generally stay at best quality for about 1 year at normal room temperature. Is milk chocolate safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged milk chocolate will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the milk chocolate will remain at peak quality. Storage time shown is for best quality only - after that, the milk chocolate's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly, the package is undamaged, and there are no signs of spoilage. If milk chocolate has white spots or white film on the surface, it is still safe to eat? Yes when milk chocolate is exposed to overly warm or humid conditions, whiteness can develop on the surface --this affects appearance only and the milk chocolate will still be safe to eat. Should you refrigerate milk chocolate? Milk chocolate should ideally not be refrigerated, as doing so may cause the milk chocolate to absorb odours from other foods and it may also develop a moist surface when brought back to room temperature. In very hot, humid environments (consistently above 75°F), milk chocolate can be refrigerated; keep the milk chocolate tightly wrapped or place in a covered airtight container or plastic freezer bag. Can you keep milk chocolate in the freezer? Yes, it is fine to store milk chocolate in the freezer, although doing so will not significantly change the shelf life; to freeze, place the milk chocolate inside covered airtight containers or heavy-duty freezer bags.
Chocolate - Dark, Baking, Bittersweet, Semi-Sweet	2 years (best quality)		2 years (best quality)	How long does chocolate last? The precise answer depends to a large extent on storage conditions - store chocolate in a cool, dry area. To maximize the shelf life of chocolate, store at a room temperature between 60°F -75°F and keep chocolate tightly wrapped after opening. How long does chocolate last at room temperature? Properly stored, dark, baking, bittersweet and semi-sweet chocolate will generally stay at best quality for about 2 years at normal room temperature. How long does milk chocolate last? Properly stored, milk chocolate will generally stay at best quality for about 1 year at normal room temperature. Dark chocolate will keep well for about 5 years if it is constantly stored at temperatures ranging between 60°F - 65°F. Is chocolate safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged chocolate will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the chocolate will remain at peak quality. Storage time shown is for best quality only - after that, the chocolate's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly, the package is undamaged, and there are no signs of spoilage. If chocolate has white spots or white film on the surface, it is still safe to eat? Yes when chocolate is exposed to overly warm or humid conditions, whiteness can develop on the surface --this affects appearance only and the chocolate will still be safe to eat. Should you refrigerate chocolate? Chocolate should ideally not be refrigerated, as doing so may cause the chocolate to absorb odours from other foods and it may also develop a moist surface when brought back to room temperature. In very hot, humid environments (consistently above 75°F), chocolate can be refrigerated; keep the chocolate tightly wrapped or place in a covered airtight container or plastic freezer bag. Can you keep chocolate in the freezer? Yes, it is fine to store chocolate in the freezer, although doing so will not significantly change the shelf life; to freeze, place the chocolate inside covered airtight containers or heavy-duty freezer bags.
Chocolates, Boxed, Regular, Assorted Pieces - Unopened Or Opened Package	6-9 months (Best Quality)	9-12 months (Best Quality)	12-18 months (Best Quality)	Store in cool, dry area and keep covered. For pantry storage, room temperature should not exceed 70°F; if this is not possible, refrigeration or freezing is recommended. When exposed to overly warm or humid temperatures, chocolate may develop a white film - this affects appearance only; the chocolate will still be safe to eat. To refrigerate or freeze, place original box or package in heavy-duty freezer bag. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Cocoa Powder, Unsweetened, Commercially Packaged — Opened	3 years (Best Quality) Keeps Indefinitely (Unopened)			How long does an opened package of cocoa powder last? The precise answer depends to a large extent on storage conditions -to maximize the shelf life of opened unsweetened cocoa powder store in a cool, dry area. How long does opened cocoa powder last at room temperature? Properly stored, an opened package of unsweetened cocoa powder will generally stay at best quality for about 3 years at room temperature. To maximize the shelf life of opened cocoa powder, keep package tightly closed. Is opened cocoa powder safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged unsweetened cocoa powder will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the cocoa powder will remain at peak quality. Storage time shown is for best quality only - after that, the unsweetened cocoa powder's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly, the package is undamaged, and there are no signs of spoilage. How can you tell if unsweetened cocoa powder is bad or spoiled? The best way is to smell and look at the unsweetened cocoa powder: if unsweetened cocoa powder develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Crackers, Commercially Packaged (All Types, Including Saltines, Water Crackers) — Opened	1-2 months 6-9 months (Best Quality) (Unopened)			How long does an opened package of crackers last? The precise answer depends to a large extent on storage conditions -to maximize the shelf life of crackers (including saltines, water crackers, rice crackers, oyster crackers and animal crackers) store in a cool, dry area. How long do opened crackers last at room temperature? Properly stored, an opened package of crackers will generally stay at best quality for about 1 to 2 months at room temperature. To maximize the shelf life of opened crackers, keep package tightly closed. Are opened crackers safe to use after the "expiration" date on the package? Yes, provided they are properly stored and the package is undamaged - commercially packaged crackers will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the crackers will remain at peak quality. Storage time shown is for best quality only - after that, the crackers' texture, colour or flavour may change, but in most cases, they will still be safe to consume if they have been stored properly, the package is undamaged, and there are no signs of spoilage. How can you tell if crackers are bad or spoiled? The best way is to smell and look at the crackers: if crackers develop an off odor, flavour or appearance, or if mould appears, they should be discarded.
Crusty White Bread, Freshly Baked, Homemade Or Bakery	2-3 Days		3 Months	How long does crusty white bread last? The precise answer to that question depends to a large extent on storage conditions - keep crusty white bread in a cool, dry area. To maximize the shelf life of bakery-bought crusty white bread, keep in original packaging and store at room temperature. Properly stored, crusty white bread will last for about 2 to 3 days at normal room temperature. To maximize the shelf life of homemade crusty white bread, cool thoroughly before storing and place in plastic storage bag or breadbox, or wrap in foil and store at room temperature. How long does crusty white bread last in the fridge? crusty white bread should ideally not be refrigerated, as the bread will dry out and become stale faster than at room temperature. If you must refrigerate crusty white bread (eg, due to a lack of pantry storage space or very hot, humid room conditions), the bread will typically last for only about a day before getting stale. Can you freeze crusty white bread? Yes, to freeze: (1) Slice bread or leave loaf whole; (2) Wrap tightly with aluminium foil or plastic freezer wrap, or place in heavy-duty freezer bag and freeze. How long does a loaf of crusty white bread last in the freezer? Properly stored, it will maintain best quality for about 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - crusty white bread that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if crusty white bread is bad or spoiled? The best way is to smell and look at the bread: discard any bread that has an off smell or appearance; if mould appears, discard the entire loaf.

Flour, White, All-Purpose - Unopened Or Opened Package	1 Year	2 Years	2 Years	How long does a package of white flour last? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of white flour (all-purpose white flour) store in a cool, dry area. How long does white flour last at room temperature? Properly stored, a package of white flour will generally stay at best quality for about 1 year at room temperature. To maximize the shelf life of white flour once the package is opened, transfer flour to a covered airtight container or place original flour bag in a resealable plastic freezer bag. Is white flour safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged white flour will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the white flour will remain at peak quality. Storage time shown is for best quality only - after that, the white flour's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly, the package is undamaged, and there are no signs of spoilage. Can you keep white flour in the fridge or freezer? Yes, to further extend the shelf life of white flour, refrigerate or freeze it; place the white flour inside covered airtight containers or heavy-duty freezer bags. How long does white flour last in the fridge? White flour will maintain best quality for about 2 years in the refrigerator. How long does white flour last in the freezer? Properly stored, it will maintain best quality for about 2 years, but will remain safe beyond that time. The freezer time shown is for best quality only — white flour that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How can you tell if white flour is bad or spoiled? The best way is to smell and look at the white flour: if the white flour develops an off odor, flavour or appearance, or if insects appear, it should be discarded.
Flour, Whole Wheat - Unopened Or Opened Package	1-3 Months	6-8 Months	1 Year	How long does a package of whole wheat flour last? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of whole wheat flour store in a cool, dry area. How long does whole wheat flour last at room temperature? Properly stored, a package of whole wheat flour will generally stay at best quality for about 1 to 3 months at room temperature. To maximize the shelf life of whole wheat flour once the package is opened, transfer flour to a covered airtight container or place original flour bag in a resealable plastic freezer bag. Is whole wheat flour safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged whole wheat flour will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the whole wheat flour will remain at peak quality. Storage time shown is for best quality only - after that, the whole wheat flour's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly, the package is undamaged, and there are no signs of spoilage. Can you keep whole wheat flour in the fridge or freezer? Yes, to further extend the shelf life of whole wheat flour, refrigerate or freeze it; place the whole wheat flour inside covered airtight containers or heavy-duty freezer bags. How long does whole wheat flour last in the fridge? Whole wheat flour will maintain best quality for about 6 to 8 months in the refrigerator. How long does whole wheat flour last in the freezer? Properly stored, it will maintain best quality for about 1 year, but will remain safe beyond that time. The freezer time shown is for best quality only — whole wheat flour that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How can you tell if whole wheat flour is bad or spoiled? The best way is to smell and look at the whole wheat flour: if the whole wheat flour develops an off odor, flavour or appearance, or if insects appear, it should be discarded.
Graham Crackers, Commercially Packaged — Opened	1-2 Months 6-9 Months (Unopened)			How long does an opened package of graham crackers last? The precise answer depends to a large extent on storage conditions -to maximize the shelf life of graham crackers, store in a cool, dry area. How long do opened graham crackers last at room temperature? Properly stored, an opened package of graham crackers will generally stay at best quality for about 1 to 2 months at room temperature. To maximize the shelf life of opened graham crackers, keep package tightly closed. Are opened graham crackers safe to use after the "expiration" date on the package? Yes, provided they are properly stored and the package is undamaged - commercially packaged graham crackers will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the graham crackers will remain at peak quality. Storage time shown is for best quality only - after that, the graham crackers' texture, colour or flavour may change, but in most cases, they will still be safe to consume if they have been stored properly, the package is undamaged, and there are no signs of spoilage. How can you tell if graham crackers are bad or spoiled? The best way is to smell and look at the graham crackers: if graham crackers develop an off odor, flavour or appearance, or if mould appears, they should be discarded.
Granola Bars, Commercially Packaged - Unopened Or Opened Package	6-9 Months (Best Quality)			How long does a package of granola bars last? The precise answer depends to a large extent on storage conditions -to maximize the shelf life of granola bars, store in a cool, dry area. Properly stored, a package of granola bars will generally stay at best quality for about 6 to 8 months. Are granola bars safe to use after the "expiration" date on the package? Yes, provided they have been properly stored and the package is undamaged - commercially packaged granola bars will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the granola bars will remain at peak quality. Storage time shown is for best quality only - after that, the granola bars' texture, colour or flavour may change, but in most cases, they will still be safe to consume if they have been stored properly, the package is undamaged, and there are no signs of spoilage. How can you tell if granola bars are bad or spoiled? The best way is to smell and look at the granola bars: if granola bars develop an off odor, flavour or appearance, or if mould appears, the package should be discarded.
Hard Candies, Commercially Packaged Or Purchased In Bulk - Unopened Or Opened Package	1 Year	1 Year	1 Year	Store in cool, dry area. Refrigeration or freezing is recommended in very hot, humid environments (over 80°F). Freeze in covered airtight containers or heavy-duty freezer bags. Storage time shown is for best quality only - after that, the candy's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly. If candy develops an off odor, flavour or appearance, it should be discarded for quality purposes. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the candy will still be safe to consume after that date, as long as it has been stored properly and the package is not damaged.
Honey, Pure, Liquid, Commercially Bottled - Unopened Or Opened	Keeps Indefinitely	Keeps Indefinitely	Keeps Indefinitely	How long does honey last? The answer depends to a large extent on storage conditions - store honey in a cool, dry area and keep tightly covered at all times. Properly stored, honey will remain safe to consume indefinitely. Is honey still safe after the "Best Before" or "Best By" date? Yes- honey will remain safe to use indefinitely if it has been stored properly. After prolonged storage, honey may darken in colour and lose some of its flavour, but it will still be safe to consume if it has been stored properly. Over time, the honey may become cloudy and crystallize - this is not harmful; the honey will still be safe to consume if it has been stored properly. If honey crystallizes, place the honey jar in warm water and stir until the crystals dissolve. Should you refrigerate honey? Refrigeration of honey is not recommended, as it accelerates the crystallization process. Should you freeze honey? While not necessary, freezing honey will help prevent crystallization; to freeze honey, store in an airtight container and leave at least 1/2 inch headspace at the top.
Ice Cream, Commercially Frozen (All Flavours) — Opened Package			2-4 Months (Best Quality) 8-12 Months (Unopened) (Best Quality)	How long does opened ice cream last? The precise answer to that question depends to a large extent on storage conditions — keep ice cream frozen at all times. How long does opened ice cream last in the freezer? Opened ice cream that has been kept constantly frozen at 0°F will maintain best quality for about 2 to 4 months in the freezer. To maximize the shelf life of ice cream after opening, place plastic wrap over the surface of the exposed ice cream before re-closing the package; this will minimize the formation of ice crystals and prevent the loss of texture. Is opened ice cream safe to eat after the "expiration" date on the package? Yes, if properly stored - commercially packaged ice cream will typically carry a "Best By," "Best if Used By," Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the ice cream will remain at peak quality. How long will opened ice cream remain safe to eat? Opened ice cream that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely, as long as it has been stored properly and the package is not damaged. How long does opened ice cream last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); opened ice cream should be discarded if left for more than 2 hours at room temperature. Can you re-freeze ice cream that has melted or thawed out? If opened ice cream thaws completely, discard it — do not refreeze, as harmful bacteria may develop. How to tell if ice cream is bad? Ice cream that has been stored too long will typically develop ice crystals on the surface and the ice cream will lose its creamy texture; ice cream that develops an off odor or flavour should be discarded.
Lollipops, Commercially Packaged Or Purchased In Bulk	1 Year	1 Year	1 Year	Store in cool, dry area. Refrigeration or freezing is recommended in very hot, humid environments (over 80°F). Freeze in covered airtight containers or heavy-duty freezer bags. Storage time shown is for best quality only — after that, the candy's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly. If candy develops an off odor, flavour or appearance, it should be discarded for quality purposes. "Best By," "Best if Used By," and "Use By" dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality — in most cases, the candy will still be safe to consume after that date, as long as it has been stored properly and the package is not damaged.
Maple Syrup, 100% Pure — Opened Container	1 Year (Unopened)	1 Year	Keeps Indefinitely	Refrigerate after opening - for longer-term storage, freeze. If syrup was purchased in a tin container, transfer the syrup to an airtight plastic or glass jar when refrigerating. To freeze, pour syrup into airtight plastic containers.
Marshmallows, Commercially Packaged Or Purchased In Bulk — Opened Package	2-4 Months (Unopened)	1 Month		Store in cool, dry area and keep tightly covered. Storage time shown is for best quality only — after that, the marshmallows' texture, colour or flavour may change, but in most cases, they will still be safe to consume if they have been stored properly. If marshmallows develop an off odor, flavour or appearance, they should be discarded for quality purposes. "Best By," "Best if Used By," and "Use By" dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality — in most cases, the unopened marshmallows will still be safe to consume after that date, as long as they have been stored properly and the package is not damaged.
Molasses, Commercially Packaged Or Purchased In Bulk — Unopened Or Opened	2 Years			Store in cool, dry area and keep tightly covered. Storage time shown is for best quality only — after that, the molasses' texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly. If molasses develops an off odor, flavour or appearance, it should be discarded for quality purposes; if mould appears, discard the entire product. "Best By," "Best if Used By," and "Use By" dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality — in most cases, the molasses will still be safe to consume after that date, as long as it has been stored properly and the package is not damaged. If mould appears, discard the entire product.
Muffins (Including Bran, Blueberry, Banana, Corn, Chocolate Chip) - Freshly Baked	1-2 Days	1 Week	2-3 Months	How long do muffins last? The precise answer to that question depends to a large extent on storage conditions - keep freshly baked muffins (including bran, blueberry, banana, corn, chocolate chip) in a dry area. To maximize the shelf life of muffins, cover with foil or plastic wrap or place in plastic bag to prevent drying out. Properly stored, freshly baked muffins will last for about 1 to 2 days at normal room temperature. How long do muffins last in the fridge? Freshly baked muffins will keep well for about 1 week in the fridge when properly stored. Can you freeze muffins? Yes, to freeze: wrap muffins tightly with aluminium foil or plastic freezer wrap, or place in heavy-duty freezer bag. How long do muffins last in the freezer? Properly stored, they will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - muffins that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if muffins are bad or spoiled? The best way is to smell and look at the muffins: discard any that have an off smell or appearance; if mould appears, discard the muffins.
Multi-Grain Bread, Freshly Baked, Homemade Or Bakery	4-5 Days		3 Months	How long does multi-grain bread last? The precise answer to that question depends to a large extent on storage conditions - keep multi-grain bread in a cool, dry area. To maximize the shelf life of bakery-bought multi-grain bread, keep in original packaging and store at room temperature. To maximize the shelf life of homemade multi-grain bread, cool thoroughly before storing and place in plastic storage bag or breadbox, or wrap in foil and store at room temperature. Properly stored, multi-grain bread will last for about 4 to 5 days at normal room temperature. How long does a loaf of multi-grain bread last in the freezer? Properly stored, it will maintain best quality for about 3 months, but will remain safe beyond that time. How long does multi-grain bread last in the fridge? Multi-grain bread should ideally not be refrigerated, as the bread will dry out and become stale faster than at room temperature. If you must refrigerate multi-grain bread (eg, due to a lack of pantry storage space or very hot, humid room conditions), the bread will typically last for only about 2-3 days before getting stale. Can you freeze multi-grain bread? Yes, to freeze: (1) Slice bread or leave loaf whole; (2) Wrap tightly with aluminium foil or plastic freezer wrap, or place in heavy-duty freezer bag and freeze. The freezer time shown is for best quality only - multi-grain bread that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if multi-grain bread is bad or spoiled? The best way is to smell and look at the bread: discard any bread that has an off smell or appearance; if mould appears, discard the entire loaf.
Pancake / Breakfast Syrup, Commercially Bottled, Artificial Maple Or Butter Flavour — Unopened Or Opened	1 Year			Store in cool, dry area. Storage time shown is for best quality only — after that, the syrup's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been stored properly. If product develops an off odor, flavour or appearance, it should be discarded for quality purposes; if mould appears, discard the entire product. "Best By," "Best if Used By," and "Use By" dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality — in most cases, the syrup will still be safe to consume after that date, as long as it has been stored properly and the package is not damaged.
Pastries (Including Danish Pastry) — Filled With Cream, Custard Or Cheese		3-4 Days	2-3 Months	Keep refrigerated; cover pastries with foil or plastic wrap or place in plastic bag when refrigerating to prevent drying out. To freeze, wrap pastries tightly with aluminium foil or plastic freezer wrap, or place in heavy-duty freezer bags. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Pizza, Cooked, Leftovers		3-4 Days	1-2 Months	How long does leftover pizza last in the fridge or freezer? The precise answer to that question depends to a large extent on storage conditions - refrigerate pizza within two hours of cooking or purchasing. To maximize the shelf life of leftover pizza for safety and quality, refrigerate the pizza in shallow airtight containers or wrap tightly with heavy-duty aluminium foil or plastic wrap. Properly stored, leftover pizza will last for 3 to 4 days in the refrigerator. To further extend the shelf life of leftover pizza, freeze it; freeze in covered airtight containers or heavy-duty freezer bags, or wrap tightly with heavy-duty aluminium foil or freezer wrap. How long does leftover pizza last in the freezer? Properly stored, it will maintain best quality for about 1 to 2 months, but will remain safe beyond that time. The freezer time shown is for best quality only - leftover pizza that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How long does leftover pizza last after being frozen and thawed? Leftover pizza that has been thawed in the fridge can be kept for an additional 3 to 4 days in the refrigerator before cooking; pizza that was thawed in the microwave or in cold water should be eaten immediately. How long does leftover pizza last at room temperature? Bacteria grow rapidly at temperatures between 4.4°C and 60°C (40°F and 140°F); leftover pizza should be discarded if left for more than 2 hours at room temperature. How to tell if leftover pizza is bad? If leftover pizza develops an off odor, flavour or appearance, or if mould appears, it should be discarded.

Potato Chips, Commercially Packaged - Opened	1-2 Weeks 2-3 months after date on package (best quality)			How long does an opened package of potato chips last? The precise answer depends to a large extent on storage conditions - store in cool, dry area. How long do opened potato chips last at room temperature? Properly stored, an opened package of potato chips will generally stay at best quality for about 1 to 2 weeks at room temperature. To maximize the shelf life of opened potato chips, keep package tightly closed. Are opened potato chips safe to use after the "expiration" date on the package? Yes, provided they are properly stored and the package is undamaged - commercially packaged potato chips will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the potato chips will remain at peak quality. Storage time shown is for best quality only - after that, the potato chips' texture, colour or flavour may change, but in most cases, they will still be safe to consume if they have been stored properly, the package is undamaged, and there are no signs of spoilage. How can you tell if potato chips are bad or spoiled? The best way is to smell and look at the potato chips: if potato chips develop an off odor, flavour or appearance, or if mould appears, they should be discarded.
Protein Bars, Commercially Packaged Or Purchased In Bulk	1 month after date on package			Store in cool, dry area; after opening box, leave individually wrapped bars sealed.
Raspberry Jam, Commercially Jarred - Opened	2 Years (Best Quality) (Unopened)	1 Year (Best Quality)		How long does raspberry jam last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened raspberry jam, keep it refrigerated and tightly covered. How long does opened raspberry jam last in the refrigerator? Raspberry jam that has been continuously refrigerated will generally stay at best quality for about 1 year. Is opened raspberry jam safe to use after the expiration date on the jar? Yes, provided it has been stored properly, the jar is undamaged, and there are no signs of spoilage - commercially jarred raspberry jam will typically carry a Best By," "Best if Used By," Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the raspberry jam will remain at peak quality. The storage time shown for opened raspberry jam is for best quality only - after that, the jam's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been kept continuously refrigerated, the jar is undamaged, and there are no signs of spoilage. How can you tell if opened raspberry jam is bad or spoiled? The best way is to smell and look at the raspberry jam: if the jam develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Raspberry Jelly, Commercially Jarred - Opened	2 Years (Best Quality) (Unopened)	1 Year (Best Quality)		How long does raspberry jelly last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened raspberry jelly, keep it refrigerated and tightly covered. How long does opened raspberry jelly last in the refrigerator? Raspberry jelly that has been continuously refrigerated will generally stay at best quality for about 1 year. Is opened raspberry jelly safe to use after the expiration date on the jar? Yes, provided it has been stored properly, the jar is undamaged, and there are no signs of spoilage - commercially jarred raspberry jelly will typically carry a Best By," "Best if Used By," Best Before, or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the raspberry jelly will remain at peak quality. The storage time shown for opened raspberry jelly is for best quality only - after that, the jelly's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been kept continuously refrigerated, the jar is undamaged, and there are no signs of spoilage. How can you tell if opened raspberry jelly is bad or spoiled? The best way is to smell and look at the raspberry jelly: if the jelly develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Sandwiches, Homemade Or Store-Prepared		2-3 Days	1 Month	Keep refrigerated; wrap sandwiches tightly with aluminium foil or plastic wrap or place in plastic bag or airtight sandwich container. For best results when freezing, coat bread completely with a layer of butter or margarine before adding filling; this will help prevent soggy bread when thawed. Lettuce and tomatoes do not freeze well and should not be used in sandwiches that will be frozen.
Scones, Freshly Baked - Homemade Or Bakery	1-2 Days	1 Week	2-3 Months	How long do scones last? The precise answer to that question depends to a large extent on storage conditions - keep freshly baked scones in a dry area. To maximize the shelf life of scones, cover with foil or plastic wrap or place in plastic bag to prevent drying out. Properly stored, freshly baked scones will last for about 1 to 2 days at normal room temperature. How long do scones last in the fridge? Freshly baked scones will keep well for about 1 week in the fridge when properly stored. Can you freeze scones? Yes, to freeze: wrap scones tightly with aluminium foil or plastic freezer wrap, or place in heavy-duty freezer bag. How long do scones last in the freezer? Properly stored, they will maintain best quality for about 2 to 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - scones that have been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if scones are bad or spoiled? The best way is to smell and look at the scones: discard any that have an off smell or appearance; if mould appears, discard the scones.
Snack Bars, Fruit-Flavoured, Commercially Packaged Or Purchased In Bulk	6-8 Months			Store in cool, dry area; after opening box, leave individually wrapped bars sealed. Storage time shown is for best quality only — after that, the product's texture, colour or flavour may change, but in most cases, the unopened snack bars will still be safe to consume if they have been stored properly and each foil packet is still sealed. If bars develop an off odor, flavour or appearance, they should be discarded for quality purposes. "Best By," "Best if Used By," and "Use By" dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality — in most cases, the unopened snack bars will still be safe to consume after that date, as long as they have been stored properly and the package is not damaged.
Strawberry Jam, Commercially Jarred - Opened	2 Years (Best Quality) (Unopened)	1 Year (Best Quality)		How long does strawberry jam last once opened? The precise answer depends to a large extent on storage conditions - to maximize the shelf life of opened strawberry jam, keep it refrigerated and tightly covered. How long does opened strawberry jam last in the refrigerator? Strawberry jam that has been continuously refrigerated will generally stay at best quality for about 1 year. Is opened strawberry jam safe to use after the "expiration date" on the jar? Yes, provided it has been stored properly, the jar is undamaged, and there are no signs of spoilage - commercially jarred strawberry jam will typically carry a Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the strawberry jam will remain at peak quality. The storage time shown for opened strawberry jam is for best quality only - after that, the jam's texture, colour or flavour may change, but in most cases, it will still be safe to consume if it has been kept continuously refrigerated, the jar is undamaged, and there are no signs of spoilage. How can you tell if opened strawberry jam is bad or spoiled? The best way is to smell and look at the strawberry jam: if the jam develops an off odor, flavour or appearance, or if mould appears, it should be discarded.
Sugar, Brown - Unopened Or Opened Package	Keeps Indefinitely			How long does brown sugar last? The precise answer depends to a large extent on storage conditions - store brown sugar in a cool, dry area. To maximize the shelf life of brown sugar, keep the package tightly sealed after opening. To further extend the shelf life of brown sugar and to prevent it from hardening once opened, place sugar in a covered airtight container or cover original package with a heavy-duty plastic bag and seal. How long does brown sugar last at room temperature? When properly stored and kept free from contaminants, brown sugar has an indefinite shelf life. To moisten brown sugar that has hardened, place a cut piece of apple in the package with the sugar, reseal and leave overnight. If hardened brown sugar is needed immediately, wrap the sugar with foil or plastic wrap and pound with a hammer.
Sugar, Granulated (White) - Unopened Or Opened Package	Keeps Indefinitely			How long does granulated white sugar last? The precise answer depends to a large extent on storage conditions - store granulated sugar in a cool, dry area. To maximize the shelf life of granulated white sugar, keep tightly sealed after opening. How long does granulated white sugar last at room temperature? When properly stored and kept free from contaminants, granulated white sugar has an indefinite shelf life. To further extend the shelf life of granulated white sugar and to prevent it from hardening once opened, place sugar in a covered airtight container or cover original package with a heavy-duty plastic bag and seal.
Taco Shells, Commercially Packaged — Opened	1 Month 1 Year (Unopened)			Store in covered airtight container. Storage time shown is for best quality only — after that, the shells' texture, colour or flavour may change, but in most cases, they will still be safe to consume if they have been stored properly. If shells develop an off odor, flavour or appearance, they should be discarded for quality purposes; if mould appears, discard entire package. "Best By," "Best if Used By," and "Use By" dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality — in most cases, the shells will still be safe to consume after that date, as long as they have been stored properly and the package is not damaged.
Tortillas, Commercially Packaged, Sold Unrefrigerated — Unopened Or Opened Package	2-4 weeks or date on package		3 Months	Keep tortillas tightly closed in original packaging and store at room temperature. To freeze, overwrap original packaging with aluminium foil or place in a heavy-duty freezer bag. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
White Bread, Freshly Baked (Soft-Crusted), Homemade Or Bakery	4-5 Days		3 Months	How long does white bread last? The precise answer to that question depends to a large extent on storage conditions - keep white bread in a cool, dry area. To maximize the shelf life of bakery-bought white bread, keep in original packaging and store at room temperature. To maximize the shelf life of homemade white bread, cool thoroughly before storing and place in plastic storage bag or breadbox, or wrap in foil and store at room temperature. Properly stored, white bread will last for about 4 to 5 days at normal room temperature. How long does white bread last in the fridge? White bread should ideally not be refrigerated, as the bread will dry out and become stale faster than at room temperature. If you must refrigerate white bread (eg, due to a lack of pantry storage space or very hot, humid room conditions), the bread will typically last for only about 2-3 days before getting stale. Can you freeze white bread? Yes, to freeze: (1) Slice bread or leave loaf whole; (2) Wrap tightly with aluminium foil or plastic freezer wrap, or place in heavy-duty freezer bag and freeze. How long does a loaf of white bread last in the freezer? Properly stored, it will maintain best quality for about 3 months, but will remain safe beyond that time. The freezer time shown is for best quality only - white bread that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if white bread is bad or spoiled? The best way is to smell and look at the bread: discard any bread that has an off smell or appearance; if mould appears, discard the entire loaf.
White Rolls Or Buns — Homemade	4-5 Days		3 Months	Cool home-baked rolls thoroughly before storing. Place rolls in plastic storage bag, or wrap in foil and store at room temperature. Refrigerator storage is not recommended, as rolls will quickly dry out and become stale — for longer-term storage, freeze rolls instead. To freeze, wrap tightly with aluminium foil or place in a heavy-duty freezer bag. Freezer time shown is for best quality only — foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Whole Wheat Bread, Freshly Baked, Homemade Or Bakery	4-5 Days		3 Months	How long does whole wheat bread last? The precise answer to that question depends to a large extent on storage conditions - keep whole wheat bread in a cool, dry area. To maximize the shelf life of bakery-bought whole wheat bread, keep in original packaging and store at room temperature. To maximize the shelf life of homemade whole wheat bread, cool thoroughly before storing and place in plastic storage bag or breadbox, or wrap in foil and store at room temperature. Properly stored, whole wheat bread will last for about 4 to 5 days at normal room temperature. How long does a loaf of whole wheat bread last in the freezer? Properly stored, it will maintain best quality for about 3 months, but will remain safe beyond that time. How long does whole wheat bread last in the fridge? Whole wheat bread should ideally not be refrigerated, as the bread will dry out and become stale faster than at room temperature. If you must refrigerate whole wheat bread (eg, due to a lack of pantry storage space or very hot, humid room conditions), the bread will typically last for only about 2-3 days before getting stale. Can you freeze whole wheat bread? Yes, to freeze: (1) Slice bread or leave loaf whole; (2) Wrap tightly with aluminium foil or plastic freezer wrap, or place in heavy-duty freezer bag and freeze. The freezer time shown is for best quality only - whole wheat bread that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if whole wheat bread is bad or spoiled? The best way is to smell and look at the bread: discard any bread that has an off smell or appearance; if mould appears, discard the entire loaf.
Yeast, Dry, Commercially Packaged — Opened	12-18 months or expiration date on package	4-6 Months (Best Quality)	10-12 Months (Best Quality)	How long does an opened package of active dry yeast last? The precise answer depends to a large extent on storage conditions - store opened dry yeast in the refrigerator or freezer. To maximize the shelf life of active dry yeast once the package is opened, transfer yeast to a covered airtight container or place original yeast package in a resealable plastic freezer bag. Is active dry yeast safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged - commercially packaged active dry yeast will typically carry a " Best By," "Best if Used By," "Best Before", or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the active dry yeast will remain at peak quality. How long does active dry yeast last in the fridge? Active dry yeast will maintain best quality for about 4 to 6 months in the refrigerator. How long does active dry yeast last in the freezer? Properly stored, it will maintain best quality for about 10 to 12 months, but will remain safe beyond that time. The freezer time shown is for best quality only — active dry yeast that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How can you tell if active dry yeast is still good to use? To test whether yeast is still potent enough to be effective: Add 1 teaspoon sugar to 1/4 cup warm water and stir in 1 envelope (or 2 1/4 teaspoons) of yeast; let stand 10 minutes — if the yeast foams up to the 1/2 cup mark, it will still be effective.

8 Herbs & Spices Shelf Life

These is the shelf life of most herbs and spics, both pre-packaged and raw.

	Pantry	Refrigerator	Freezer	Food Tips
Allspice, Ground, Dried, Commercially Bottled Or Purchased In Bulk - Unopened Or Opened	3-4 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.

Basil - Fresh, Raw	7-10 Days		4-6 Months	How long does fresh basil last? The precise answer to that question depends to a large extent on storage conditions - after purchasing, store fresh basil in a dry area and keep loosely covered. Should you refrigerate fresh basil? No, refrigerating fresh basil is not recommended, as it can cause the leaves to turn black. How should fresh basil be stored? To maximize the shelf life of fresh basil: (1)Trim the ends and place basil in a glass containing about one inch of water; (2) Cover with a loose-fitting plastic bag and leave at room temperature; (3) Replace water when it gets cloudy. How long does fresh basil last at room temperature? Properly stored, fresh basil will usually keep well for about 7 to 10 days at room temperature. Can you freeze fresh basil? Yes, to freeze fresh basil: (1) Wash, trim and chop the basil; (2) Allow to dry thoroughly; (3) Once dry, place in heavy-duty freezer bags or freeze in ice cube trays with a small amount of water, then transfer to freezer bags. How long does fresh basil last in the freezer? Properly stored, fresh basil will maintain best quality for about 4 to 6 months in the freezer, but will remain safe beyond that time. The freezer time shown is for best quality only - basil that has been kept constantly frozen at -18°C (0°F) will keep safe indefinitely. How to tell if basil is bad or spoiled? Basil that is spoiling will typically become soft and discoloured and the leaves will start to darken; discard any basil that has an off smell or appearance.
Basil Leaves, Dried, Commercially Bottled Or Purchased In Bulk — Unopened Or Opened	1-3 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only — commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it — if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. "Best By," "Best if Used By," and "Use By" dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality — in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Bay Leaves, Dried, Commercially Bottled Or Purchased In Bulk — Unopened Or Opened	1-3 Years (Best Quality)			How long do dried bay leaves last? The precise answer depends to a large extent on storage conditions —to maximize the shelf life of dried bay leaves store in a cool, dark cupboard, away from direct heat or sunlight. How long do dried bay leaves last at room temperature? Properly stored, dried bay leaves will generally stay at best quality for about 1 to 3 years. To maximize the shelf life of dried bay leaves purchased in bulk, and to better retain flavour and potency, store in containers with tight-fitting lids. Are dried bay leaves safe to use after the "expiration" date on the package? Yes, provided they are properly stored and the package is undamaged — commercially packaged dried bay leaves will typically carry a "Best By," "Best if Used By," "Best Before," or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the dried bay leaves will remain at peak quality. Do dried bay leaves ever spoil? No, commercially packaged dried bay leaves do not spoil, but they will start to lose potency over time and not flavour food as intended - the storage time shown is for best quality only. How can you tell if dried bay leaves are still good? To test whether dried bay leaves are still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell them - if the aroma is weak and the flavour is not obvious, the dried bay leaves should be replaced.
Black Pepper, Cracked, Dried, Commercially Bottled Or Purchased In Bulk — Unopened Or Opened	3-4 Years (Best Quality)			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only — commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it — if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. "Best By," "Best if Used By," and "Use By" dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality — in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Black Pepper, Ground, Dried, Commercially Bottled Or Purchased In Bulk - Unopened Or Opened	3-4 Years (Best Quality)			How long does ground black pepper last? The precise answer depends to a large extent on storage conditions —to maximize the shelf life of ground black pepper store in a cool, dark cupboard, away from direct heat or sunlight. How long does ground black pepper last at room temperature? Properly stored, ground black pepper will generally stay at best quality for about 3 to 4 years. To maximize the shelf life of ground black pepper purchased in bulk, and to better retain flavour and potency, store in containers with tight-fitting lids. Is ground black pepper safe to use after the "expiration" date on the package? Yes, provided it is properly stored and the package is undamaged — commercially packaged ground black pepper will typically carry a "Best By," "Best if Used By," "Best Before," or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the ground black pepper will remain at peak quality. Does ground black pepper ever spoil? No, commercially packaged ground black pepper does not spoil, but it will start to lose potency over time and not flavour food as intended - the storage time shown is for best quality only. How can you tell if ground black pepper is still good? To test whether ground black pepper is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the ground black pepper should be replaced.
Chilli Pepper, Ground, Commercially Bottled Or Purchased In Bulk - Unopened Or Opened	3-4 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Chilli Powder, Dried, Commercially Bottled Or Purchased In Bulk - Unopened Or Opened	3-4 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Chives - Fresh, Raw		10-14 Days	4-6 Months	To store fresh chives: Wrap in a damp paper towel and place in a plastic bag in the refrigerator. To freeze fresh chives: (1) Wash, trim and chop the chives; (2) Allow to dry thoroughly; (3) Once dry, place in heavy-duty freezer bags or freeze in ice cube trays with a small amount of water, then transfer to freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Chives, Dried, Commercially Bottled Or Purchased In Bulk - Unopened Or Opened	1-3 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Cilantro (Coriander) - Fresh, Raw		7-10 Days	4-6 Months	To store fresh cilantro: (1) Trim the ends and place in a glass containing about one inch of water; (2) Cover with a loose-fitting plastic bag and refrigerate; (3) Replace water when it gets cloudy. To freeze fresh cilantro: (1) Wash, trim and chop the cilantro; (2) Allow to dry thoroughly; (3) Once dry, place in heavy-duty freezer bags or freeze in ice cube trays with a small amount of water, then transfer to freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.
Cinnamon Sticks, Dried, Commercially Bottled Or Purchased In Bulk - Unopened Or Opened	4 Years (Best Quality)			How long do cinnamon sticks last? The precise answer depends to a large extent on storage conditions —to maximize the shelf life of cinnamon sticks store in a cool, dark cupboard, away from direct heat or sunlight. How long do cinnamon sticks last at room temperature? Properly stored, cinnamon sticks will generally stay at best quality for about 4 years. To maximize the shelf life of cinnamon sticks purchased in bulk, and to better retain flavour and potency, store in containers with tight-fitting lids. Are cinnamon sticks safe to use after the "expiration" date on the package? Yes, provided they are properly stored and the package is undamaged — commercially packaged cinnamon sticks will typically carry a "Best By," "Best if Used By," "Best Before," or "Best When Used By" date but this is not a safety date, it is the manufacturer's estimate of how long the cinnamon sticks will remain at peak quality. Do cinnamon sticks ever spoil? No, commercially packaged cinnamon sticks do not spoil, but they will start to lose potency over time and not flavour food as intended - the storage time shown is for best quality only. How can you tell if cinnamon sticks are still good? To test whether cinnamon sticks are still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell them - if the aroma is weak and the flavour is not obvious, the cinnamon sticks should be replaced.
Cinnamon, Ground, Commercially Bottled Or Purchased In Bulk - Unopened Or Opened	3-4 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Cloves, Ground, Dried, Commercially Bottled Or Purchased In Bulk - Unopened Or Opened	3-4 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Cloves, Whole, Dried, Commercially Bottled Or Purchased In Bulk - Unopened Or Opened	4 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Coriander, Ground, Dried, Commercially Bottled Or Purchased In Bulk - Unopened Or Opened	3-4 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Cumin, Ground, Dried, Commercially Bottled Or Purchased In Bulk - Unopened Or Opened	3-4 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Curry Powder, Dried, Commercially Bottled Or Purchased In Bulk - Unopened Or Opened	3-4 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Dehydrated Garlic, Commercially Bottled Or Purchased In Bulk — Unopened Or Opened	2 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Dill - Fresh, Raw		10-14 Days	4-6 Months	To store fresh dill: Wrap in a damp paper towel and place in a plastic bag in the refrigerator. To freeze fresh dill: (1) Wash, trim and chop the dill; (2) Allow to dry thoroughly; (3) Once dry, place in heavy-duty freezer bags or freeze in ice cube trays with a small amount of water, then transfer to freezer bags. Freezer time shown is for best quality only - foods kept constantly frozen at -18°C (0°F) will keep safe indefinitely.

Fennel Seed, Dried, Commercially Bottled Or Purchased In Bulk — Unopened Or Opened	3-4 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Garlic Powder, Dried, Commercially Bottled Or Purchased In Bulk - Unopened Or Opened	3-4 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Garlic Salt, Commercially Bottled Or Purchased In Bulk — Unopened Or Opened	1-2 Years			Store in cool, dark cupboard, away from direct heat or sunlight. Time shown is for best quality only — commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it — if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. "Best By," "Best if Used By," and "Use By" dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality — in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Garlic, Minced, Dried, Commercially Bottled Or Purchased In Bulk — Unopened Or Opened	2-3 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Ginger, Ground, Dried, Commercially Bottled Or Purchased In Bulk - Unopened Or Opened	3-4 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids. Storage time shown is for best quality only - commercially dried spices and herbs do not spoil, but they will lose their potency over time and not flavour food as intended. To test whether a spice or herb is still potent enough to be effective: Rub or crush a small amount in your hand, then taste and smell it - if the aroma is weak and the flavour is not obvious, the herb or spice should be replaced. Best By, Best if Used By, and Use By dates on commercially packaged foods sold in the United States represent the manufacturer's estimate of how long the product will remain at peak quality - in most cases, the dried spice or herb will still be safe to consume after that date, although it will lose potency over time. Freezing is not recommended.
Italian Seasoning, Dried, Commercially Bottled Or Purchased In Bulk — Unopened Or Opened	1-3 Years			Store in cool, dark cupboard, away from direct heat or sunlight; keep tightly closed when not in use. Spices and herbs bought in bulk will better retain flavour and potency if stored in containers with tight-fitting lids.
